Abstract

A critical capability required in the operation of cyberspace is the ability to maintain situational awareness of the status of the infrastructure elements that comprise cyberspace. Event logs from cyber devices can yield significant information, and when properly utilized can provide timely situational awareness about the state of the cyber infrastructure. In addition, proper Information Assurance requires the validation and verification of the integrity of results generated by a commercial log analysis tool. Event log analysis can be performed using relational databases. To enhance database query performance, previous literatures affirm denormalization of databases; yet, database normalization can also increase query performance. Database normalization improved majority of the queries performed using very large data sets of router events; however, performance is also dependent on the type of query executed. Queries performed faster on normalized table if all the necessary data are contained in the normalized tables. Furthermore, database normalization improves table organization and maintains better data consistency than non-normalized. Nonetheless, there are some tradeoffs when normalizing a database such as additional preprocessing time and extra storage requirements though minimal in this experiment. Overall, normalization improved query performance and must be considered as an option when analyzing event logs using relational databases.

Acknowledgments

I would like to say many thanks to my thesis advisor, Dr. Michael Grimaila, for his unwavering support, mentorship, and patience throughout many months school and research effort. I would also like to thank Dr. Robert Mills and LtCol Brent Langhals for their guidance and support. I would also like to send my appreciation to the Information Resource Management program faculty and staff. Additionally, I want to acknowledge my fellow students and classmates for their fellowship and camaraderie.

Thanks for the support from my friends and family. Most importantly, I would like to say thank you to my wife for her love, support, and understanding all throughout this process. She gave me all the strength and encouragement to successfully graduate while taking care of our newborn son. It has been an awesome and unforgettable experience.

ANALYSIS OF THE IMPACT OF DATA NORMALIZATION ON CYBER EVENT CORRELATION QUERY PERFORMANCE

I. Introduction

1.1 Research Motivation

Virtually all modern organizations depend on Information and Communication technologies (ICT), collectively called "cyberspace", to accomplish their core mission processes. The United States (US) Department of Defense (DoD) uses cyberspace to conduct all aspects of military operations. The United States Air Force (USAF) is tasked to support the DoD cyberspace effort and provides a wide variety of cyber capabilities to the Joint Force Commander (JFC) (Donley & Schwartz, 2009). A critical capability required in the operation of cyberspace is the ability to maintain situational awareness of the status of the infrastructure elements (e.g., routers, intrusion detection systems, intrusion prevention systems, firewalls, VPNs, switches, desktop systems, servers) that comprise cyberspace. Event logs from cyber devices can yield significant information, and when properly stored, processed, and analyzed can provide timely situational awareness about the state of the cyber infrastructure. In addition, the ability to monitor cyber devices across multiple locations provides the ability to identify distributed attacks that may be missed when only viewing event logs from a single geographic location (Grimaila et al., 2011).

In cyberspace, situational awareness requires the ability to sense, understand the sensed data, and use it to determine future actions (Okolica et al., 2009). Cyberspace is an attractive unconventional domain for many nation states, terrorists, and hackers; as such, mission assurance in cyberspace is vital. For this reason, data gathered from event logs supports Information Assurance and Mission Assurance. Mission Assurance is critical to military strategies because it links several risk management programs including Information Assurance to

assure mission success (DoDD, 2010, p.19). Recent empirical studies have shown organizations are beginning to realize the importance of event logs to diagnose error and identify malicious activities (Shenk, 2009; Shenk, 2010). While the number of organizations with network event log database servers has steadily grown in the past few years, the top two reported challenges in exploiting the value of event logs are "Searching through Data" and "Analysis and Reports" (Shenk, 2010, p. 5). Difficulties in the implementation and maintenance of an event log analysis capability cause many organizations to under utilize their existing event logs (Baker et al., 2011). The USAF is not impervious to these log management challenges. Each day, millions of events are generated in USAF networks and are transported to centralized log servers where they are stored, processed, and analyzed to extract actionable information. Analysis methods must be carefully chosen as the number of stored events continues to grow monotonically. To exacerbate the situation, there is no standard for the storage of event logs, which explicitly enumerates all of the data elements present in event log that makes storage and analysis less efficient.

1.2 Problem Statement

In order to maintain situational awareness of the network, everyday USAF organizations must collect, transport, store, process, and analyze millions of events generated by cyber devices with limited resources. Analyzing millions of event logs can be cumbersome, inefficient, and resource intensive (Myers, 2010). For historical and intensive analysis, event logs are captured and stored in relational databases. Log analysts can then use database queries to conduct event correlation and search for actionable information. The logs must be analyzed in a timely manner and archived accordingly to save disk space. The efficient creation, storage, processing, and dissemination of log events are essential. Currently, the USAF employs commercial log analysis tools, which require large yearly licensing fees. However, proper Information Assurance

requires the validation and verification of the integrity of results generated by a commercial log analysis tool. To this end, organizations can use a relational database to collect and analyze event log data to provide the ability to validate results generated by commercial tools without paying additional licensing fees.

1.3 Research Goals

The primary goal of this research is to determine the impact of database normalization on database query performance in the context of analyzing events logs generated by routers in USAF networks. A study will be conducted to compare query performance between a non-normalized database and a normalized database containing the same data for a set of representative simple and complex queries that would typically be conducted by network security personnel. The secondary objective of this research is to provide recommendations on when normalization should be used based upon tradeoffs in time, storage space, and query performance.

1.4 Research Questions

There are three primary research questions addressed in this thesis:

1) What standards exist for the generation, transport, storage, and analysis of event log data for security analysis?
2) How does database normalization impact query performance when using very large data sets (over 30 million) of router events?
3) What are the tradeoffs between using a normalized versus non-normalized database in terms of preprocessing time, query performance, storage requirements, and database consistency?

1.5 Scope, Assumptions, and Limitations

The scope of this research is limited to the analysis of router event logs provided collected in the Integrated Network Operations and Security Center West (INOSC-W) network from October 2010 to March 2011. A limitation of this work is that it deals only with router event logs, which is just one of many types of cyber event logs. Another limitation of the study is that it uses to a fixed number of events during the analysis. This resulted from a delay in developing and implementing the normalized database and queries. It is believed that increasing or decreasing the number of events in the database could yield dramatically different results.

1.6 Thesis Overview

This chapter describes the goals of this research and motivates the need for understanding how query performance is impacted by database normalization. Chapter 2 reviews background literature in the areas of event log management, event correlation, and the technologies being used to conduct the research. Chapter 3 presents the experimental design and the methodology used for conducting analysis of that design. Chapter 4 describes the results of the experiment and provides an analysis of those results. Finally, Chapter 5 presents the conclusions of the research, recommendation for action, and recommendations on future research.

II. Literature Review

2.1 Chapter Overview

In this chapter, the literature relevant to the research objective will be reviewed. Specifically, the subject of event logs and event correlation will be explored, and a review of database performance will be covered.

2.2 Event Logs

Event logs also known as audit trails, log files, audit logs, data logs are text streams recorded from information systems that contain a combination of the following data: timestamp, event number, type, source, destination, user identification, and message of the event that occurred (MITRE, 2010a; MITRE, 2010b). Initially, event logs were used as an industrial tool for monitoring, troubleshooting, and maintenance of machines. It was a source of information to diagnose internal technical issues without much added benefit for the enterprise network and organization as a whole (Sah, 2002). In 1973, the DoD issued an Automatic Data Processing (ADP) Security Manual specifically for protecting classified systems which required maintenance of audit log or file that records the historical use of ADP systems; this allowed administrators to regularly inspect system activities (Department of Defense, 1973). A 1980 technical report began to considered computer logs as a tool to monitor and audit security incidents (Anderson, 1980). During the same period, event correlations in combination with other techniques were used in artificial intelligence. Today, organizations value event logs for more than just a passive diagnostic tool; it is a security and an operational asset (Shenk, 2010). The advances in computer technology, techniques, and the amount of computer logs that can be collected presents a prime opportunity to analyze and learn from multiple event logs with millions of data using an effective and efficient methodology.

Essentially, there is no agreed upon format or industry standard for event logs as seen on the examples below, which makes it more difficult to analyze (MITRE, 2010). There are some similarities in the type of data however, for the most part each device or manufacturer has its own format and type of fields in their event logs.

Example of Cisco of event log (Cisco Understanding, 2011)

```
*May  1 22:12:13.243: %SEC-6-IPACCESSLOGP: list ACL-IPv4-E0/0-IN permitted
   tcp 192.168.1.3(1024) -> 192.168.2.1(22), 1 packet
*May  1 22:17:16.647: %SEC-6-IPACCESSLOGP: list ACL-IPv4-E0/0-IN permitted
   tcp 192.168.1.3(1024) -> 192.168.2.1(22), 9 packets

*May  3 19:08:23.027: %IPV6-6-ACCESSLOGP: list ACL-IPv6-E0/0-IN/10 permitted
   tcp 2001:DB8::3(1028) (Ethernet0/0 000e.9b5a.9839) -> 2001:DB8:1000::1(22), 1 packet
*May  3 19:13:32.619: %IPV6-6-ACCESSLOGP: list ACL-IPv6-E0/0-IN/10 permitted
   tcp 2001:DB8::3(1028) (Ethernet0/0 000e.9b5a.9839) -> 2001:DB8:1000::1(22), 9 packets
```

Example of Microsoft Windows Firewall (Microsoft, 2011)

```
2005-04-11 08:05:57 DROP UDP 123.45.678.90 123.456.78.255 137 137 78 - - - - - - - RECEIVE
2005-04-11 08:05:57 DROP UDP 123.45.678.90 255.255.255.255 1631 2234 37 - - - - - - - RECEIVE
2005-04-11 08:05:58 OPEN UDP 123.45.678.90 123.456.78.90 500 500 - - - - - - - - -
2005-04-11 08:05:58 DROP UDP 123.45.678.90 123.456.78.255 138 138 299 - - - - - - - RECEIVE
2005-04-11 08:06:02 CLOSE UDP 123.45.678.90 123.456.78.90 1027 53 - - - - - - - - -
2005-04-11 08:06:02 CLOSE UDP 123.45.678.90 123.456.78.90 137 137 - - - - - - - - -
2005-04-11 08:06:05 DROP UDP 0.0.0.0 255.255.255.255 68 67 328 - - - - - - - RECEIVE
```

Example of Blue Coat Firewall event log (Blue Coat, 2011)

```
2011-01-18 02:32:22+07:00ICT  "Access Log (main): Unable to connect to remote server for log
uploading"  0 E0008:1   ../alog_facility_impl.cpp:2726
2011-01-18 02:33:21+07:00ICT  "Access Log FTP (main): Connecting to primary 192.168.4.66 server
192.168.4.66:21."  0 E0000:96   ../alog_ftp_client.cpp:110
2011-01-18 02:33:39+07:00ICT  "Snapshot sysinfo_stats_2min has fetched /sysinfo-stats"  0
2D0006:96   ../snapshot_worker.cpp:214
2011-01-18 02:33:39+07:00ICT  "Snapshot CPU_Monitor has fetched

2011-01-18 02:34:36+07:00ICT  "Access Log FTP (main): Couldn't connect control socket to primary
server 192.168.4.66"  3C E000A:1   ../alog_ftp_client.cpp:155
```

2.2.1 Types of Event Logs and Event Entries

There are several types of cyber event logs including, computers, servers, routers, firewalls, and intrusion detection systems. Each device can potentially capture and record events

into a file or log. Table 1 lists the different types of event logs, examples, and types of log entries and functions.

Table 1. Types of Event Logs (MITRE, 2010; Hucaby, 2005; Microsoft Types, 2011)

Common Types of Event Logs	Examples	Log Entry Types/Functions
Computer	Personal computers, portable devices	Application, Security, System
Servers	Web servers, Email, Database, Domain	Application, Security, System, Directory Service, DNS Server, File Service
Network Layer Devices	Routers, Switches	Alert, Warning, Error, Information
Network Security Devices	Firewalls, Intrusion Detection Systems	Allow and Deny Audit, Protocol usage, Traffic Log

2.3 Current Standardization Effort

2.3.1 Syslog Protocol

The creation of the syslog daemon and protocol is largely credited to Eric Allman of Sendmail and originally described in Request for Comments (RFC) 3164 The Berkley Software Distribution (BSD) syslog Protocol by the Internet Engineering Task Force (IETF) (Lonvick, 2001). RFC 3164 was categorized for informational purposes but has become the de-facto standard (Lonvick, 2001). The protocol allowed the transmission of event logs across IP networks to syslog servers. The simplicity of the protocol allowed programmers to write codes independently with no strict requirements on the type of source or format of the message. Simplicity is one of the reasons for its wide acceptance among industry leaders (Lonvick, 2001). Cisco Systems is one of the companies that have leniently adopted the syslog protocol.

However, the flexibility of the protocol resulted in divergent formats that make correlation and analysis challenging for administrators.

The Syslog Protocol RFC 5424, which superseded RFC 3164, is a document in a Proposed Standard status of the IETF as opposed to informational (Gerhards, 2009). Although the BSD syslog protocol became a de-facto standard, it was never formalized. Actual industry implementations have many different variations for every platform (Gerhards, 2009). RFC 5424 provides a foundation for standard syslog format and transport methods using layered architecture. The three syslog conceptual layers are content, application, and transport. This research is primarily concerned with the content layer and to some extent the application layer. The syslog content layer deals with the "information contained in the syslog message" (Gerhards, 2009, p. 4) while the syslog application layer "handles generation, interpretation, routing, and storage of syslog message" (Gerhards, 2009, p. 4). Furthermore, the transport layer in RFC 3164 recommended utilizing user datagram protocol (UDP) port 514 could now use any transport protocol and port number as long as it does not alter the content. Another addition in RFC 5424 is a mechanism for structured-data that enable "easily parseable and interpretable data format" (Gerhards, 2009, p. 15). Some of the challenges when storing, sorting, and querying event logs are being able to efficiently and accurately parse the different data elements. Structured-data provides a standard format with vital meta-information in the log message such as IP addresses or event ID for efficient parsing. In addition to structured information format, it also permits vendor specific extensions and free-form text. RFC 5424 also provides flexibility to reformat contents for backwards compatibility with RFC 3164. In general, log messages compliant to RFC 5424 should be consistent and contain distinct field separations that are easily parseable.

2.3.2 Common Event Expression (CEE)

Other organizations such as MITRE, a non-profit entity that receives sponsorships from government agencies and private enterprises, had also initiated log standardization effort known as CEE. The goal of CEE's architecture is to provide a foundation for "standardizing the creation and interpretation" of event logs particularly from computers and sensors (MITRE, 2010c, p. 4). A similar goal between RFC 5424 and CEE is to make parsing of event logs simple. Figure 1 shows the CEE architecture and components; the bidirectional arrows represent the ability not only to generate event logs but also to recreate the events based on the logs.

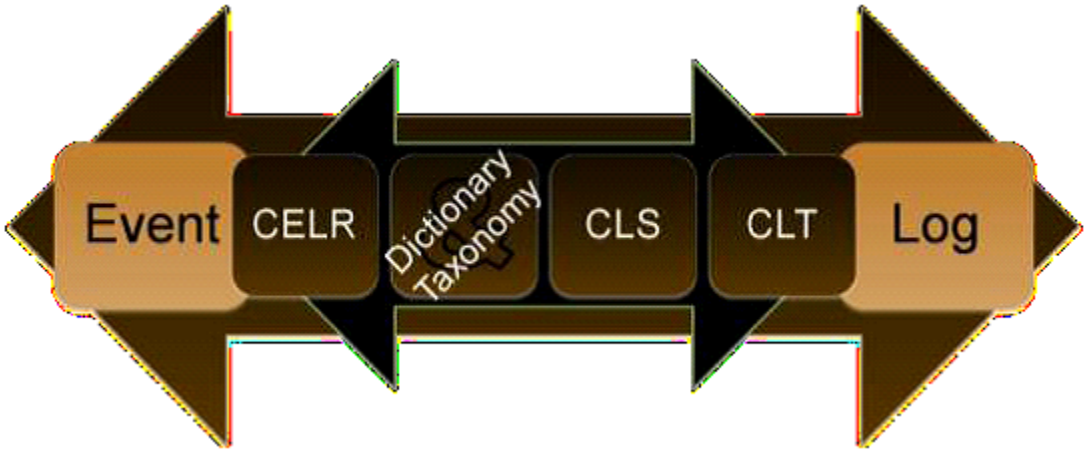

Figure 1. CEE Architecture and Components (MITRE, 2010c)

Four major components transform an event into a log and vice versa. Common Event Log Recommendations (CELR) provides recommendations on which events should be recorded and the type of situations it should be recorded. CEE Dictionary and Taxonomy (CDET) defines the event terminology such as field names and value types in the dictionary while taxonomy contains a collection of categories of events that provide common vocabulary and similarity of events. Common Log Syntax (CLS) describes the representation of the event and event data when it is produced by the source and processed by the event consumer. Finally, the Common Log

Transport (CLT) provides specific guidance for reliable and secure transport of the log. CEE has identified six core fields, shown in Table 2, that are common to most logs; these are pre-defined fields to make processing simpler. Each CEE compliant event log must have all the fields specified. However, there could be cases where one or more fields do not have a value; in such cases, the field should represent a null value (Heinbockel, 2011). In Cisco logs, the ID, time, action, status, and p_sys_id fields are most common while the p_prod_id field is less common. RFC 5424 and CEE are possible standards that future event logs should comply with to make generation, transmission, storage, and analysis more efficient.

Table 2. Core Fields (Heinbockel, 2011; Heinbockel & Graves, 2011)

Field	Field Type	Description
id	string	Event ID
time	timestamp	Event start time
action	tag	Primary action of the event
status	tag	Result of the event action
p_sys_id	string	ID of the producing system
p_prod_id	string	ID of the producing product

2.4 Purpose of Event Logs

The National Institute of Standards and Technology (NIST), underscore the importance of event logs when investigating security incidents, fraud, policy breach, and auditing just to name a few (Kent & Souppaya, 2006). Federal law and regulations such as the Federal Information Security Management Act of 2002 (FISMA), the Health Insurance Portability and Accountability Act of 1996 (HIPAA), the Sarbanes-Oxley Act of 2002 (SOX), the Gramm-Leach-Bliley Act (GLBA), and the Payment Card Industry Data Security Standard (PCI DSS) require organizations to "store and analyze certain logs" few (Kent & Souppaya, 2006, p. 2-11). Furthermore, in the private sector, a 2006 report from a key organization in information security underlines five essential log reports: failed attempts to gain access through existing accounts, failed file access attempts, unauthorized changes, systems that are most vulnerable to attack, and suspicious or unauthorized network traffic patterns (Brenton, Bird, & Ranum, 2006). In a 2010 survey shown in Figure 2 of over 500 organizations of different sizes and information technology budgets, showed that 63% would like to use logs to "Detect/prevent unauthorized access and insider abuse" as their top priority. The second highest objectives which are all statistically tied at 40% include, "Meet regulatory requirements", "Forensic analysis and correlation", and "Ensure Regulatory Compliance" (Shenk, 2010, p. 4). These reports show that network security and compliance are top priorities for most organizations and they believe that event logs can be a very useful tool for this. In fact, an overwhelming number of the respondents (91%) suggest that logs were "useful or very useful for tracking suspicious behavior". Regardless of this optimistic view of event logs' usefulness, many still believe that searching and analyzing logs can be better. Thirty-six percent believe that "Searching through data" is cumbersome and 32% view "Analysis

and reports (and ability to interpret results)" as very challenging, both ranking as the top obstacles (Shenk, 2010, p. 4).

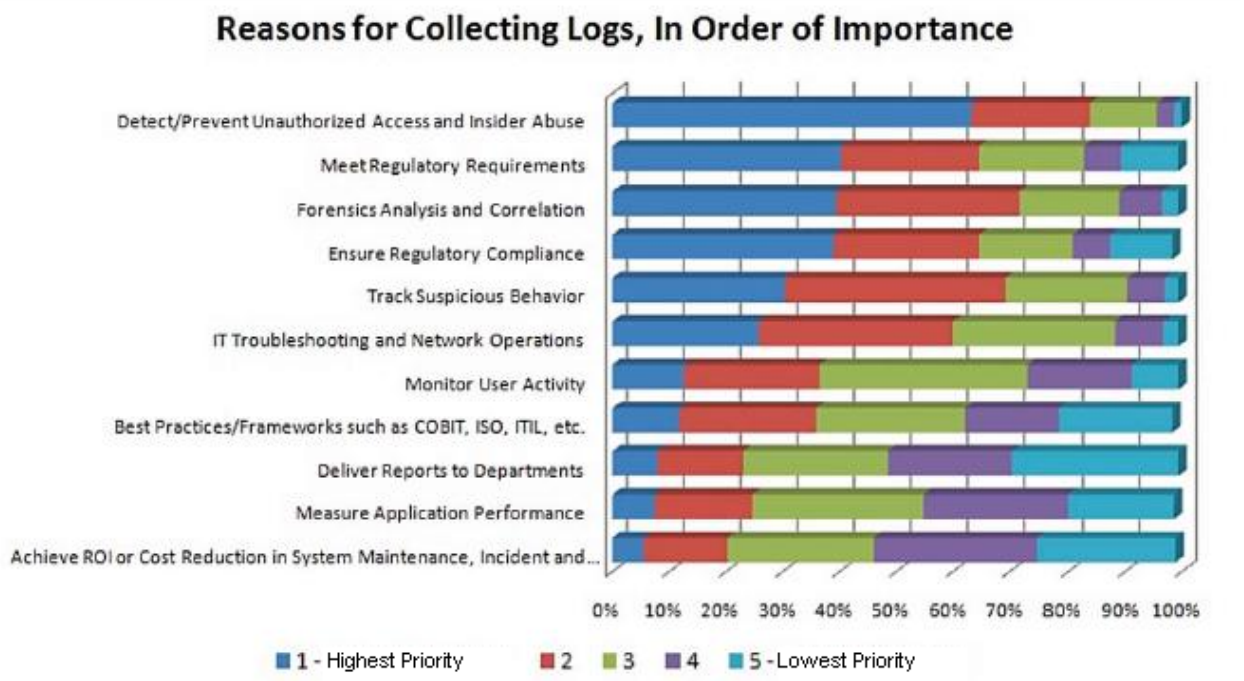

Figure 2. Priority for Collecting Logs (Shenk, 2010, p. 4)

There are several propriety solutions and services for event log management and analysis being offered presently. According to a review, leading hardware and software solutions for log management are NitroSecurity NitroView, ArcSight Logger, and LogRhythm, which varies in prices starting from $20,000 up to $40,000 for an initial price (Grimes, 2010). The pros and cons vary and it depends on the organization's goal and structure, which one fits them better. The USAF is currently using ArcSight as its log management tool and the licensing price could cost millions of dollars. There should be alternatives that are less expensive yet simple tools for analyzing event logs.

2.5 Log Analysis of Security Incidents and Complexity

In a 2010 joint study by the U.S. Secret Service (USSS) and Verizon involving 761 investigated reports of network security breaches, found that 3.8 million known records were compromised (Baker et al., 2011). The study showed an exponential increase on the number of breaches based on previous years although there was a significant drop in the number of compromised data. The study could not conclusively pinpoint the reasons for this phenomenon. Figure 3 suggest that external threat had steadily increased according to the Verizon data and it significantly increased according to the USSS data from 2007 to 2010. Organized criminals mostly perpetrated the external threats based on the report. Additionally, investigators found that the number of unknown external attacks decreased, mostly in part, because larger organizations who managed their event logs adequately allowed the authorities to identify and prosecute the perpetrators. On the other hand, smaller companies who did not or could not keep sufficient log data were unsuccessful in identifying the attackers (Baker et al., 2011). Events logs added another tool that standard forensic methods would have missed. This report highlighted the importance of external security threats, why event logs are important in mitigating these risks, and potentially learning new information from the logs.

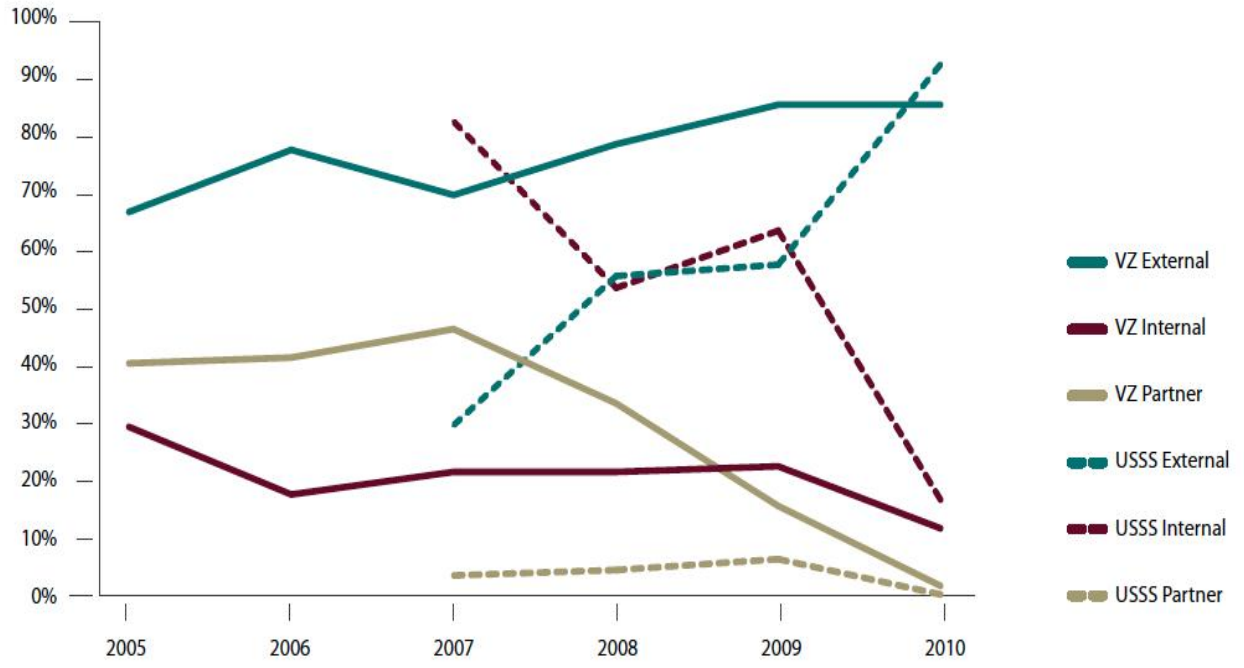

Figure 3. Threat Agents Yearly Trend by Percentage (Baker et al., 2011)

Each device on the network can produce hundreds of thousands of audit logs a day. A large organization with several firewalls, routers, and servers can easily generate hundreds of gigabytes a day. Sifting through this enormous amount of data can be a daunting task this is why an earlier study found that over 60% of the respondents consider either "Searching through data" or "Analysis and Reports" as the first or second most challenging tasks for them (Shenk, 2010, p. 4). The NIST Guide to Computer Security Log Management enumerated many of the challenges in log management; the three main categories are log generation and storage, log protection, and log analysis (Kent, & Souppaya, 2006). This research focuses on log analysis; however, the techniques also address some aspects of the other two categories. One of the main challenges in log analysis for administrators is that they do not have the proper tools to efficiently analyze security incidents and threats. Moreover, this additional task is not the most glamorous job, and administrators would rather perform other maintenance and troubleshooting duties (Kent, &

Souppaya, 2006). A simple and efficient process should make log analysis quick and easy. Additionally, when more logs are accumulated the more complicated analysis becomes, thus necessitating better methods (Kent, & Souppaya, 2006). Many of the current log analysis techniques are insufficient such as using predefined algorithms, frequent patterns, and algorithms that ignore patterns other than event types (Vaarandi, 2002). Based on the studies and surveys discussed previously, organizations have ample reasons to invest in event logs to improve information security, decision-making, and more importantly mission accomplishment.

2.6 Enhancing Situational Awareness, Information Assurance, and Mission Assurance

2.6.1 Situational Awareness

Situational awareness is "the perception of elements in the environment within a volume of time and space, the comprehension of their meaning, and the projection of their status in the near future" according to Endsley (1995, p. 1; Okolica et al., 2009, p. 47). A cyber situational awareness system must be able to sense the situation, interpret the sense data, and predict future outcome (Okolica et al., 2009, p. 47). To understand the sense data, the system depends on several types of event logs to construct a known "insider threat" profile, for example (Okolica et al,. 2009, p. 47). Moreover, in Information Assurance, a process called System Security Engineering and Assurance (SSEA) involves managing complex interrelations between engineering, situational awareness, and maintenance (Capitan, 2008). SSEA combines mission assurance, information assurance, and security through systems engineering concepts (Capitan, 2008, p. 7). Using the systems engineering approach, event logs will provide better situational awareness hence improving both mission and information assurance. Archiving event logs in data warehouses could provide long-term use throughout the system's development life cycle. There could be several situations where more information is needed in the future, management

may come up with new questions, and network security personnel will have to retrieve archived event logs. In each case, proactively searching for valuable knowledge in a stack of logs remains challenging. Information systems personnel in general, could use built-in reporting templates or the Top 10 list of well-known security profiles to create an executive summary for upper management and later build on this report based on management and user feedback (Babbin, 2006, p. 16). There are tools and methods available to create standard and management-level reports that show the effectiveness of the security policies using event logs (Babbin, 2006, pg. 32). Management normally would require metrics and statistical data when new network security investments are needed or immediately after a new installation. Event logs can significantly contribute to management's cyber situational awareness through information system reports and feedback. Information Assurance personnel can provide reports to management on the effectiveness of the organization's security investment and policies by utilizing event logs. Event logs when properly utilized contributes to better situational awareness for the operators, leadership, and upper management.

2.6.2 Information Assurance

Information Assurance and information security are similarly defined in the Committee on National Security Systems (CNSS) National Information Assurance Glossary (2010) and include the three tenets of information namely confidentiality, integrity, and availability (CIA). Information Assurance is defined as "measures that protect and defend information and information systems by ensuring their availability, integrity, authentication, confidentiality, and non-repudiation. These measures include providing for restoration of information systems by incorporating protection, detection, and reaction capabilities." (CNSS, 2010, p. 35) Information security, likewise, is defined as "the protection of information and information systems from

unauthorized access, use, disclosure, disruption, modification, or destruction in order to provide confidentiality, integrity, and availability." (CNSS, 2010, p. 37) Both definitions highlight three tenets of information. In most cases, the value of information as an asset depends upon maintaining its CIA (Pipkin, 2000, p. 14). Specifically, confidentiality is an Information Assurance attribute that limits access to those individuals or organizations on a need to know basis; integrity or accuracy of information guarantees that it is correct and has not been tampered with; and availability is access to information when and where it is needed (Pipkin, 2000, p. 14).

The value of event logs evolved from being just a passive diagnostic tool to a more valuable network security and operational asset (Shenk, 2010). Event logs today, can play a major role in the quality on each of the CIA attributes if manage properly. Confidentiality requires limiting access to information; event logs can record important information and track timestamps, usernames, IP addresses, port numbers, protocols, and whether access was permitted or denied. This information, if properly managed, can provide investigators valuable clues if someone tried to access a resource without proper authority. The integrity of information depends on two major components: known good source and accuracy of data (Pipkin, 2000, p. 14). Event logs support the first component of integrity by identifying the source such as the username, IP address, process, and product that produced the information. This is not a foolproof process; however, it can still provide valuable knowledge. The accuracy of the information, similarly, can be verified using event logs by recording modifications, transmissions, and storage of files. Accuracy can also be protected using the "tripwire" technique by creating and securely storing hash values of critical files. The hash value of each file is unique; hence, it can then be calculated and compared to the original value in a consistent manner to detect any unauthorized modifications. The tripwire methodology also produces logs

that records important events that can be analyzed for additional information (Tripwire, 2011). Availability is another attribute of Information Assurance which is arguably the most difficult to ensure because it involves wide range of resources and most of them may not be under the control of a single organization (Pipkin, 2000, p. 149). Availability means providing accessibility and usability of information to authorized personnel wherever and whenever requested. To maintain a high level of availability, an organization must prevent outages especially unscheduled interruptions such as long-lasting equipment failures. Network devices normally produce event logs that warn the administrator of an impending failure. For example, error messages could be generated stating if a fan is malfunctioning on a critical router. Total outage and lengthy downtime could be avoided if the hardware is repaired on time. Proper monitoring of event logs will avoid lengthy downtime. Another concern for information systems availability is Denial of Service (DOS) attack, which could be both intentional and unintentional. In a DOS attack, event logs can record the source of attack and assist investigators in finding and possibly prosecuting the perpetrators. Unintentional DOS attack can also be monitored and detected in different ways depending on its source.

2.6.3 Mission Assurance

The heavy dependence of the United States military on information systems in accomplishing its goals and objectives makes it vulnerable to attacks from cyberspace. In today's modern warfare, cyberspace is an attractive unconventional domain for many nation states, terrorists, and hackers; as such, mission assurance in cyber domain is vital. Some authors described cyberspace as the "center of gravity" because of the reliance of mission essential functions on its capabilities (Jabbour & Mucio, 2011, pg. 62). Mission assurance is critical to military strategies because it links several risk management programs including Information

Assurance (DoDD, 2010, p.19). As discussed previously, proper event log management can lead to effective Information Assurance and therefore enhance mission assurance.

There are several definitions for mission assurance, which varies upon on the individual or organization's perspective. One definition by Alberts and Dorofee (2005, pg. 23) from a Carnegie Mellon University, defines mission assurance as "establishing a reasonable degree of confidence in mission success." According to the authors, it is not an on/off binary aspect, but rather, a continuous attribute that range from guaranteed failure to guaranteed success. The DoD defines Mission Assurance as "a process to ensure that assigned tasks or duties can be performed in accordance with the intended purpose or plan. It is a summation of the activities and measures taken to ensure that required capabilities and all supporting infrastructures are available to the Department of Defense to carry out the National Military Strategy." (DoDD, 2010, p.19)

Some authors suggest that traditional engineering focuses more on building complex systems that perform in a tolerant cyber environment; however, these systems fail when operating in a hostile environment (Jabbour & Mucio, 2011, pg. 63). Yet, this is the type of cyber warfare domain where the military is expected to operate. A reliable system does not equal a secure system especially in a hostile environment (Jabbour & Mucio, 2011, pg. 64). Risk is considered the loss of any of the three attributes of Information Assurance, namely, confidentiality, integrity, and availability of information (CNSS, 2010, p. 61); it is also the intersection of threat, vulnerability, and resource. Jabbour and Mucio (2011, p. 64) suggest that threat and vulnerability are dependent variables hence "there is no threat without vulnerability." Cyber security should therefore focus more on the vulnerabilities rather than the threat (Jabbour & Mucio, 2011, pg. 64). This may sound like a noble idea, however, vulnerabilities in software with millions of codes and hardware from thousands of manufacturers are difficult to avoid.

Nevertheless, developers have more control over limiting vulnerabilities on their products than the threats coming from hackers, terrorists, nation states, and criminals. Moreover, event logs can be useful both in limiting vulnerabilities and in detecting threats.

It is important to record and document events throughout the life cycle of information systems in order to maintain mission assurance. In today's military operations, most missions depend on cyberspace to attain a level of confidence for a successful mission. Jabbour and Mucio (2011) proposed 13 rules for building and designing future secure systems and a four-step methodology for already existing systems. In the 13 rules they proposed, event logs could be very useful for generation, processing, storage, communication, consumption, and destruction. Each stage could produce substantial amount of logs for documentation and analysis that could enhance system design, operation, and maintenance. The four-step stopgap methodology for existing systems includes prioritization, mission mapping, vulnerability assessment, mitigation, and an optional red teaming. Likewise, all these steps would benefit from proper use of event logs particularly in mission mapping, vulnerability assessment, and threat mitigation. Mission mapping identifies the military missions dependent on the functionality of cyber processes as well as their internal and external interactions with other processes (Jabbour & Mucio, 2011, pg 69). More specifically, event logs can be valuable in two particular steps, identifying "all data communication among cyber processes" and documenting "the data format, speed, and protocol for each data communication". In vulnerability assessment, event logs perform a major role during identification, documentation, and estimation of vulnerabilities. Additionally, event logs are also valuable in threat mitigation during threat identification and intrusion detection.

Event logs can be very instrumental tools to enhancing situational awareness, Information Assurance, and mission assurance. However, one must realize that raw event logs are simply

data generated by information systems. At present, system managers still need to collect, correlate, and analyze these logs to get meaningful information from them and possibly gain knowledge. Understanding how raw log data can turn into actionable information and useful knowledge is essential to analyzing event logs.

2.7 Learning from Event Log Data

Computer systems use event logs to communicate to the users. Presently however, raw log data are still difficult to comprehend. Computers are still far from communicating system events in non-technical human understandable form. Event logs currently produced by most computers are nothing more than data. Davenport and Prusak (2000) defined data as "a set of discrete, objective facts about events" (p. 2). It is raw numbers, facts, and "a structured records of transactions" (Davenport & Prusak, 2000, p. 2; Alavi & Leidner, 2001). Computer logs by itself do not mean anything unless someone adds context to it. When context and structure is combined with facts, it turns into information (Tuomi, 2000). Information gathered from a single event log or even a collection of logs may still be insufficient to form a broader situational awareness of an organization's network. When a person or an analyst personally processes the information in his or her mind using concepts, procedures, understandings, experiences, judgments and given meaning then it becomes knowledge (Alavi & Leidner, 2001; Davenport & Prusak, 2000; Tuomi, 2000). Therefore, to effectively analyze these event logs and form actionable knowledge one should be mindful of these elements and their distinctions. Consequently, organizations should realize that current log analysis tools and technologies could only achieve so much. At some point personalized human knowledge and analysis of data that is beyond any computer or analytical technique becomes critical. Analyst must understand the organization's mission in order to gain a better understanding of the log data. Organizations who

over emphasize and set excessive expectations from these tools often leads disappointment (Davenport & Prusak, 2000; Feld & Stoddard, 2004; Van den Hoven, 2001). This could a reason why majority of organizations in the surveys, who after millions of dollars and years of investing in log management systems, still find analyzing data very challenging. Despite these challenges, information technology systems are still critical enablers in managing data and information to most organizations (Alavi & Leidner, 2001).

2.8 Event Correlation

Event correlation is the process of discovering the relationship between events for the purpose of finding the source of a fault and sorting out unnecessary information (Grimaila, et al., 2011; Hasan, Sugla, & Viswanathan, 1999). It is dependent on event-based management model were the system translate relevant information into form of events (Lee, 1995). Event correlators had become popular tools for managing complex enterprise network (Jakobson, Weissman, Brenner, Lafond, & Matheus, 2000). In the past, the main function of audit logs data communications network was for investigating faults and outages (Jakobson et al., 2000). A large organization would normally have several hundreds if not thousands of network devices that generates event logs. Event correlation can potentially make it simpler to digest all the different information. At present, log correlation can be used in tracing and discovering network security incidents. This technique in addition to case-based reasoning had also been proposed to assist in battlefield management, specifically in military planning and operations where situations are often fluid (Lee, 1995). In large networks were faulty equipments can produce large amount of logs in a short amount of time flooding the network, in these conditions event correlations can filter the data (Vaarandi, 2002). Obviously, event correlation provides

administrator with better knowledge of the status of an organization's network (Grimaila, et al., 2011).

2.9 Database Normalization

One of the fundamental first steps in learning and mining for information in databases is data normalization (Ogasawara, 2010). It is a process of refining the raw data sequentially into well-structured relations devoid of all the anomalies (Hoffer et al., 2009; Sanders, & Shin, 2001). According to Hoffer et al. (2009), these are the main reasons for normalization:

> 1. Minimize data redundancy, thereby avoiding anomalies and conserving storage space.
> 2. Simplify the enforcement of referential integrity constraints
> 3. Make it easier to maintain data
> 4. Provide a better design that is an improved representation of the real world and a stronger basis for future growth. (p. 226)

Event logs are collected non-normalized without any well-defined structures, therefore redundancy and anomalies exist making analysis less efficient and more complex. This also adds to the difficulty of maintaining data. The lack of structure and standardization make mining and correlating data more challenging (MITRE, 2010c). Normalization takes several steps when filtering all the dependencies until all the anomalies are gone (see Figure 4).

Nonetheless, there are some drawbacks to normalization. Firstly, writing the queries will be more complex thus reducing the ease of use (Sanders, & Shin, 2001). Typically, whenever the number of tables increases, so as the number of joins and possibly the number of sub-queries, this makes queries more complicated. Secondly, normalization reduces system performance because of added query processing (Hoffer et al., 2009; Lee, 1995; Sanders, & Shin, 2001; Westland, 1992). This could be particularly true when the amount of data stored and being retrieved is relatively small (Westland, 1992). Hoffer et al., (2009) cited a report by William H. Inmon, which showed that fully normalized tables performed slower. However, the highest

number of rows contained in each of the eight normalized tables in the study was only 50,000. If the amount of data being queried is rather large, it could be that query performance of normalized table will outperform non-normalized. Smaller normalized tables can be queried using SQL joins. According to Plivna (2008) databases are designed to handle joins very efficiently. Relational databases are also known for its power when processing multiple tables (Hoffer et al., 2009) such as in SQL queries.

Some database administrators may prefer the denormalized form. Denormalization is defined as "the process of transforming normalized relations into unnormalized physical record specifications" (Hoffer et al., 2009, p. 266). The idea is to reduce the number of tables and consequently the number of joins when writing queries. This research does not consider denormalization because it can only optimize certain queries but sacrifices the performance of others (Hoffer et al., 2009). Additionally, if for some reason the most frequently used query changes, then the tables will have to be denormalized again or the performance advantage will no longer apply. Further, developing or finding the most frequently used queries for event logs now can be short sighted as this list can change whenever new demands or threats come up which will make database maintenance complex and time consuming.

2.9.1 Steps in Normalization

There are seven identified forms of normalization: first normal form (1NF), second normal form (2NF), third normal form (3NF), Boyce-Codd normal form (BCNF), and fourth normal form (4NF) as shown in Figure 4. The fifth normal form (5NF) and Domain-Key Normal Form (DKNF) are mentioned but not discussed in this paper. The goal in each step is to remove anomalies and dependencies. The first step is to remove multivalued attributes in a table in order to be considered in 1NF. Each cell in the table should only have one value and there are

no duplicate rows. To move into the 2NF, a table must not have any partial dependencies. Partial functional dependency is "a functional dependency in which one or more nonkey attributes are functionally dependent on part (but not all) of the primary key" (Hoffer et al., 2009, p. 233). Each nonkey attribute must be fully dependent on one primary key. The next step is 3NF; where in all transitive dependencies must be removed. A transitive dependency is a functional dependency of attributes to another attribute that is not the primary key. A quicker way to achieve 3NF is to create tables based on functional dependencies of determinants (Hoffer et al., 2009). After a table is in 3NF anomalies can still exist when there is more than one candidate key. The BCNF proposed by R. F. Boyce and E. F. Codd, makes certain that every determinant in the table is a candidate key. A determinant is an attribute that other attributes are functionally dependent on. For example, a person's name, address, and birthdate are functionally dependent on the Social Security Number. A candidate key is an attribute that is unique and nonredundant (Hoffer et al., 2009). The final normalization step discussed in this paper is the 4NF. This phase ensures that there are no multivalued dependencies in a table (Wyllys, 2010). To comply with this step, the attributes with multivalued dependencies should be stored in separate tables; otherwise, the table will contain redundant information that can cause anomalies and confusion. Some authors consider tables in 3NF to be satisfactory for databases used in most practical applications (Hoffer et al., 2009, p. 651) while Wyllys (2010) consider 4NF sufficient in practice. The last two normalization steps, 5NF and DKNF, are not discussed, mainly because the 5NF is difficult to define and has little practical value (Hoffer et al., 2009; Wyllys, 2010) while DKNF has a simple definition but minimal practical significance (Hoffer et al., 2009). In summary, when creating tables "strive for single-theme" to achieve normalization and avoid anomalies (Wyllys, 2010).

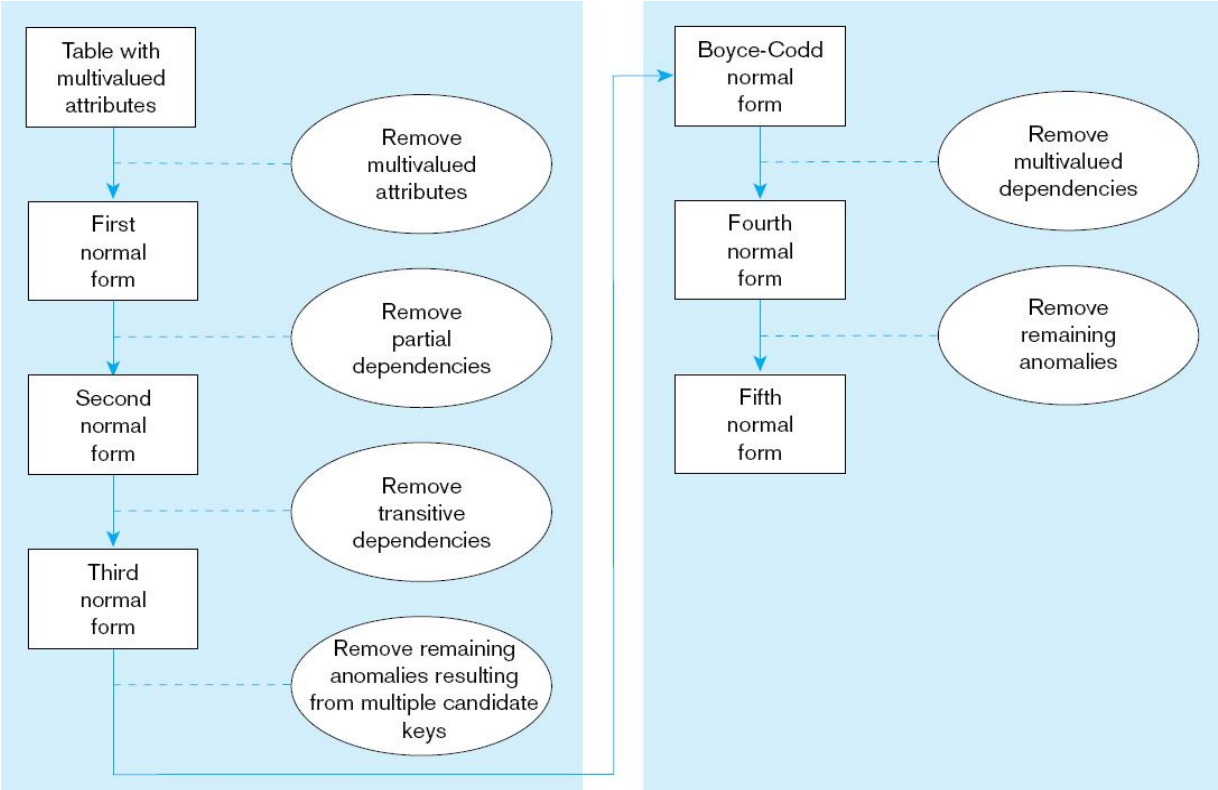

Figure 4. Six Steps in Normalization (Hoffer et al., 2009, p. 227)

2.9.2 Linking Normalized Tables

Normalized tables may need to be linked together to identify applicable associations and reduce the complexity of queries. One way of doing this is to create an additional table or an associative entity. This entity is also known as an associative relation (Hoffer et al., 2009). Often times, an associative entity is used when the relationship between two entities are many-to-many (M:N) (see Figure 5a). After the associative table is created, the database designer needs to decide if an identifier needs to be assigned. The identifier has to uniquely identify the each instance in the table. If an identifier is not assigned, then the foreign keys, which are the primary keys from the two tables, become the identifier (see Figure 5b) (Hoffer et al., 2009).

(a) Two entities with M:N relationship

(b) Three resulting tables from the two entities with M:N relationship

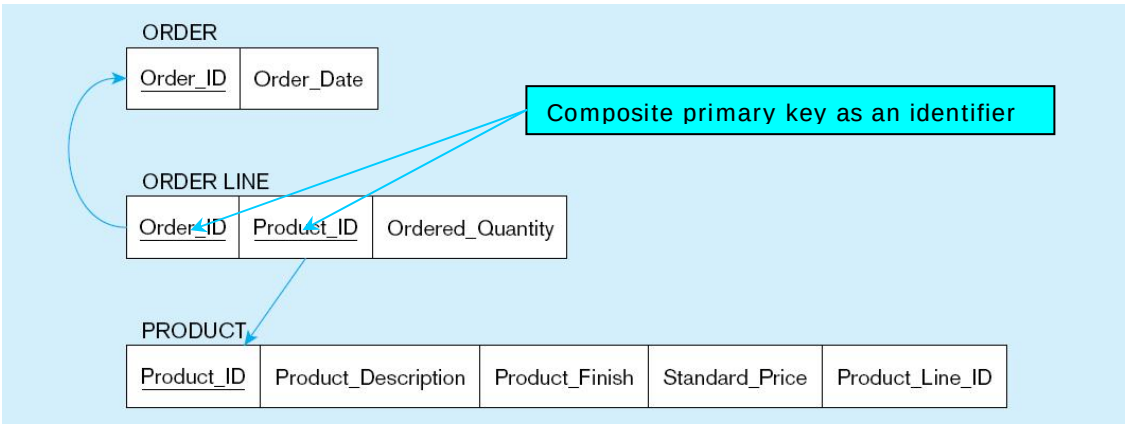

Figure 5. Example of Mapping Tables with an Associative Entity (Hoffer et al., 2009).

2.10 Data Warehousing

Normalization and denormalization strategies are normally found in data warehousing depending on the design chosen. Data warehouse is a subject-oriented, integrated, time-variant, non-updatable collection of data used in support of management decision-making processes (Hoffer et al., 2009). It contains informational data, derived from operational data, which can then support planning and forecasting (Dunham, 2003). The main driver for data warehousing development was the discovery of the difference between operational systems and informational systems (Hoffer et al., 2009). Organizations extract meaning and information to enhance

decision-making and performance from informational assets (Hoffer et al., 2009). Since the early 1990s, data warehousing techniques have been used to find and learn new information from a collection of data. Data warehouse has become significant because it is a vital tool in integrated management of decision support data in organizations (Shin, 2003). Organizations use it in planning, target marketing, decision-making, data analysis, and customer services (Shin, 2003). Organizations that use this tool appropriately will have a critical knowledge-based competitive advantage over competitors (Shin, 2003). One of the challenges in data warehousing is its complexity because it pulls data from different sources like transactional and operational databases, external data, and others. Improving system throughput and response are major challenges developers should address (Shin, 2003). Databases designed for data warehousing should be less concerned with update consistency compared to operational real-time databases (Inmon, 2000).

Data mining tools and techniques have been used in data warehousing to improve decision-making and develop solutions for specific problems. Analysts have constructed predictive models using warehouse data to forecast the outcomes of different decision alternatives (Apte, Pednault, & Smyth, 2002). Data mining is knowledge discovery using a sophisticated blend of techniques from traditional statistics, artificial intelligence, and computer graphics (Westland, 1992). Data mining is the process of finding hidden information in a database; it is an exploratory data analysis, data driven discovery, and deductive learning (Dunham, 2003). The three goals of data mining are explanatory, to explain some observed event or condition; confirmatory, to confirm a hypothesis; and exploratory, to analyze data for new or unexpected relationships (Hoffer et al., 2009).

2.11 Summary

The two prevailing event log standards today are, MITRE's CEE and the Syslog protocol (RFC 5424). Regulatory compliance and network security issues have increased the importance of event logs to many organizations. Log analysis still remain complex due to lack of industry standards, lack of simple and efficient analysis methods to process numerous amount of logs generated daily. Event logs can provide cyber situational awareness to management and other network users in the organization. Proper event log utilization through information systems monitoring and threat detection enhances mission assurance and information assurance. Database analysis of event logs is only one of the tools in the information system security toolbox that is still limited and dependent on the human operator's understanding and knowledge of the entire situation. One way to increase understanding of a situation is to correlate different events wherein logs contribute critical data for analysis. A relational database can be used as a tool for log analysis; a proper methodology for this process will be discussed in the next chapter.

III. Methodology

3.1 Overview

This research utilized an experimental methodology, which consists of two major parts. The first part involves loading the router event logs into the database and normalizing the database into single-themed tables. The database was normalized based on functional themes or relevance of the data such as the Basename, ReportIP, DestinationPort, and others. Once normalized, the second part consists of measuring the query runtimes on both normalized and non-normalized configuration. Two sets of similar queries were developed one for normalized and the other for non-normalized. The differences in runtimes were recorded and statistically measured. The main goal is to measure if there are any differences in query runtimes between normalized and non-normalized router log data. The differences between the performances were calculated using a t-test of independent samples. The chosen methodology was designed to specifically fulfill the research goals and answer the research question described in Chapter 1, which are briefly revisited in the next section. Additionally, the database used for this experiment is not for operational real-time transactions that need to be consistently updated although it can be for data mining and warehousing purposes. The experiment's focus is on the structuring of data for efficient query processing. Therefore, ensuring well-structured relations and complete normalization were not the main concerns.

3.2 Hardware and Database Configuration

The computer setup consists of database server running on a Hewlett-Packard Compaq 8710w with Intel Pentium III Xenon 2.6 gigahertz processor, 150 gigabytes of hard drive space, and 4 gigabytes of random access memory. The operating system is Windows XP Professional

Service Pack 3. The database platform is Oracle Database 10g Enterprise Edition Release 10.2.0.1 using only the default settings with no additional performance tuning involved.

3.3 Overview of Steps in Normalization and Query Performance Analysis

This research used approximately 30 million records of actual unprocessed USAF-network router event logs. In order to load the logs into a database and query their contents several steps were taken. This process was not based on any known standard approach for event log normalization; rather, the steps were developed using systematic experimental process as well as trial and error. The steps are briefly described here.

1. Parse the unprocessed network event logs in text format into comma-separated values (CSV) format.
2. Parsed event logs were exported into a flat non-normalized table.
3. Eight normalized tables were created based on the log data context ensuring that each table only has a single theme.
4. The eight normalized tables were populated using the data from the non-normalized table.
5. Eight associative tables that link the normalized tables together as well as to the flat non-normalized table were created.
6. The associative link tables were populated using the primary keys of the flat non-normalized table and the respective normalized table creating a composite primary key.
7. A set of 15 queries were developed based on Information Assurance principles, network security best practices, and general statistical information about the event logs.

8. The queries' runtime performance on both normalized and non-normalized sets of tables were recorded.
9. The differences in runtime performance where analyzed using a t-test of independent samples.

3.4 Loading Event Logs and Table Normalization

The original text format of event logs can be unreadable to most network analyst; therefore, the logs must be partitioned into separate logical classifications according to their purpose. As described in the previous steps, the logs must be parsed, loaded into the database, and then finally normalized. The first attempt to normalize the flat table took much longer than expected and was ultimately unsuccessful. The database table of event logs was consequently normalized based on functional theme or relevance of the data into eight tables. There are several reasons for normalizing the table, namely, to remove unnecessary duplication of data, maintain consistency, and to create well-structured relations (Hoffer et al., 2009).

3.4.1 Parsing Event Logs

The Cisco router event logs have two separate portions, structured and unstructured, as shown in Figure 6; RFC 5424, which is the most recent version of the syslog protocol, refers to a similar format (Gerhards, R., 2009). The structured portion has a format that remains constant through all the event logs regardless of the Cisco router device. In contrast, the unstructured segment contains the free text form of the message. In the structured portion, the first set of date and time records when the event took place in the log server. The subsequent IP address belongs to the reporting router. Following this IP address is a router message sequence number. This is a globally unique number for each router terminal and can range from 000,000,001 to 999,999,999 (Cisco, 2011). Then, the second set of date, time, and time zone are recorded from the reporting

router. The words preceded by a % sign is the event message type, which in this example, has a format of "%<facility>-<severity>-<mnemonic>:" (Cisco System Log). Facility codes as well as mnemonic codes could vary in meaning depending on the device. The severity codes are described in a table in Appendix A. Finally, the parser also appended the Basename for every event where the logs came from.

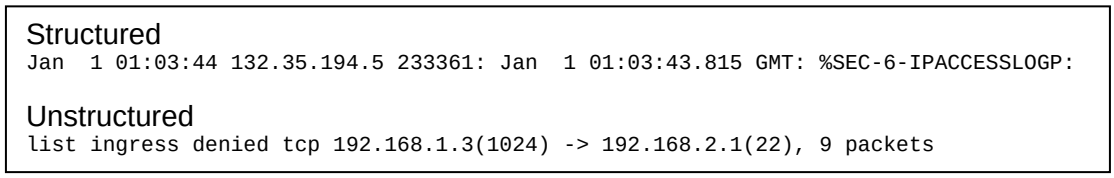

Figure 6. Structured and Unstructured Segments of a Cisco Router Log

The unstructured part of the event log contains free text message. The format can vary because of the different designs of hardware and software as well as the various types of network traffic (Cisco IPhelp, Understanding, 2011). In Figure 6, it starts with the type of Access Control List (ACL) followed by the ACL name or list name, which on this example is ingress. In some cases, the ACL name can be a number instead. Next, it states that this specific event was denied. This value can be either permitted or denied based on the ACL policy outcome. TCP identifies that the ACL is applied to Transmission Control Protocol (TCP) ports; in this example, the TCP port number is 22. The first IP address, 192.168.1.3(1024), identifies the source with the ephemeral port number inside the parenthesis. This IP address is extracted by the parser and placed in the SourceIP attribute of the LogMessage table along with its decimal or long IP notation. The purpose of having the decimal equivalent of the IP address is to readily calculate, compare, and query the IP addresses and ranges if necessary. The second IP address after the

right-arrow represents the destination of the network packet with the port number inside the parenthesis. Lastly, the number indicates the number of packets that was recorded for the event.

This categorization allowed the logs to be exported into a database and given some context. The first step in normalizing the router event logs was to parse them into CSV files that can be entered in Microsoft Excel. The attributes assigned to the logs are listed and described in Appendix B. The program used to parse the logs is a Perl script named, Parselog.pl, shown in Appendix C. Oracle's Structured Query Language (SQL) files and Microsoft Disk Operating System (MS-DOS) batch files are used to create the tables, parsed the log files into CSV files, and loaded the CSV files into the Oracle database tables. The CreateLogMessage.SQL shown in Appendix D creates the Oracle database tables named LogMessage and IPToCountry. The LogMessage table structure is shown in Appendix E. The IPToCountry table contains a range of IP addresses and the known countries they belong. The IPToCountry table structure is shown in Appendix F. The MS-DOS batch file called Doit.bat in Appendix G, invokes the PERL parser for the log files from a particular USAF base, and invokes the CTL file that loads the resultant CSV file into the LogMessage table. An overall control batch file called Redoit.BAT (see Appendix H) invokes CreateLogMessage.SQL, LoadIPCountry.CTL and Doit.BAT. This file displays the start time and end time. It also logs-in to Oracle using sqlplus with username and password and calls the CreateLogMessage.SQL file. Then the LoadIPCountry.CTL (see Appendix I) is invoked using sqlldr with the same username and password. A loadipcountry.log is generated. After all the doit batch files for each base are executed the finished time is displayed and a redoit.log file is generated. The Load*Basename*.CTL (see Appendix J) loads the tokens in the CSV file into the "LogMessage" table. Each base has its own load<basename>.CTL file, specific to the path name for each base. A brief description of each

of the files is in Table 3. Figure 7 describes the diagram of the sequence in which the files were executed.

Table 3. Description of Files

Filename	Description
Parselog.PL	Parser that accepts Cisco log files for each base,tokenizes each log file record, and outputs the tokens into a CSV file
CreateLogMessage.SQL	Creates the Oracle tables named "LogMessage" and "IPToCountry"
Doit.BAT	Batch file that invokes the PERL parser for the log files at a particular base, and invokes the CTL file that loads the resultant CSV file into the "LogMessage" table. Each base has its own Doit.BAT file, specific to the path name for each base, and base name for parser input
Redoit.BAT	Overall control batch file. It invokes CreateLogMessage.SQL, LoadIPCountry.CTL and Doit.BAT
Load<basename>.CTL	Loads the tokens in the CSV file into the "LogMessage" table. Each base has its own Load<basename>.CTL file, specific to the path name for each base
LoadIPCountry.CTL	Loads the IP ranges of each country into the "IPToCountry" table

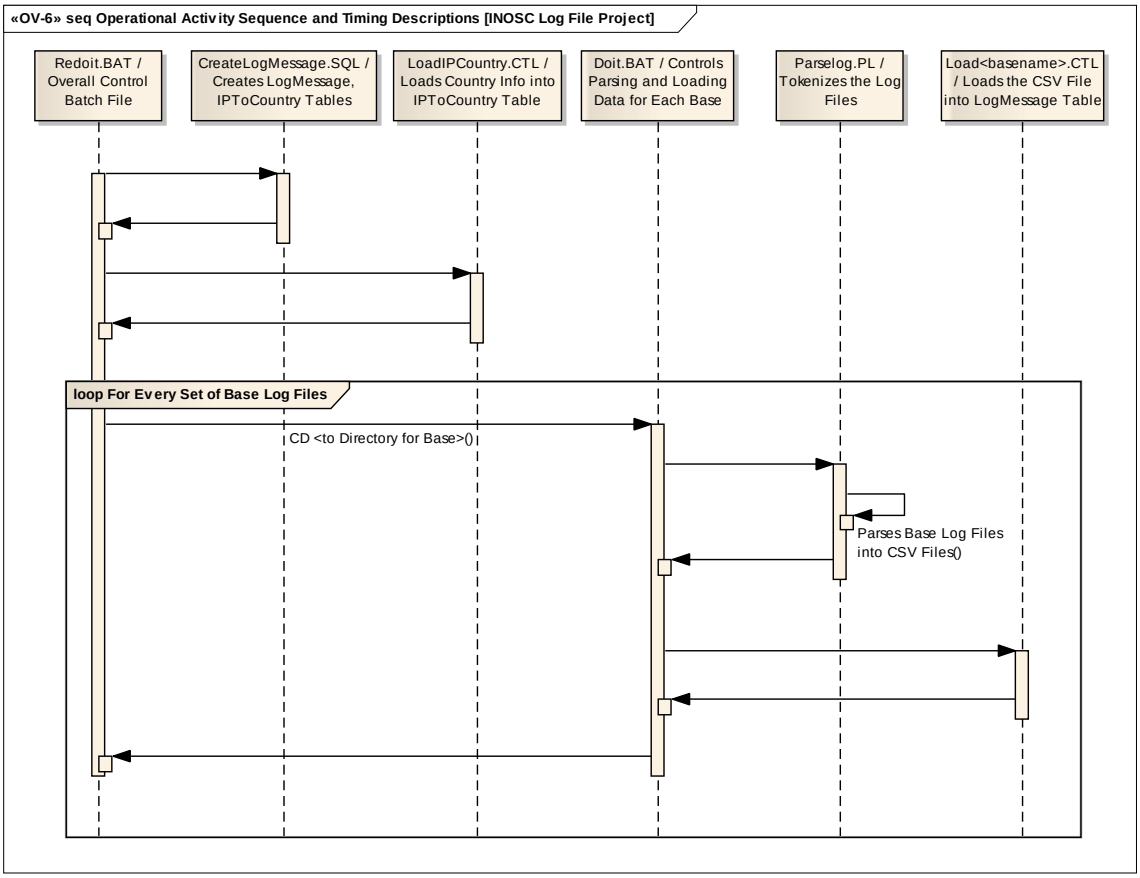

Figure 7. Sequence of File Executions

3.4.2 Table Normalization with Index Table

After the log data is parsed and loaded into the database, it is all contained in one flat non-normalized table. This table as it stands can be queried. The query performance, however, may not be efficient in some cases which normalization can improve. The first attempt to normalize the database was unsuccessful due to the complexity of the algorithm and number of attributes and records involved. The process is described briefly for informational purposes. To summarize, Figure 8 visually depicts the tables, their attributes, primary keys, and the foreign keys after normalization; for readability purposes, it is not in a standard entity-relationship diagram and not all the tables are displayed. A message ID was appended to each record to

uniquely identify it because the sequence number produced by the reporting device is not distinctive enough when combined with logs from other devices. SQL scripts were created to normalized the tables and their attributes. This pre-processing method of linking the primary keys using a MsgIndex Table (see Figure 8) took longer than expected which would not have been practical for this experiment or in real-world implementation. The methodology therefore had to be revised which is described in the next section.

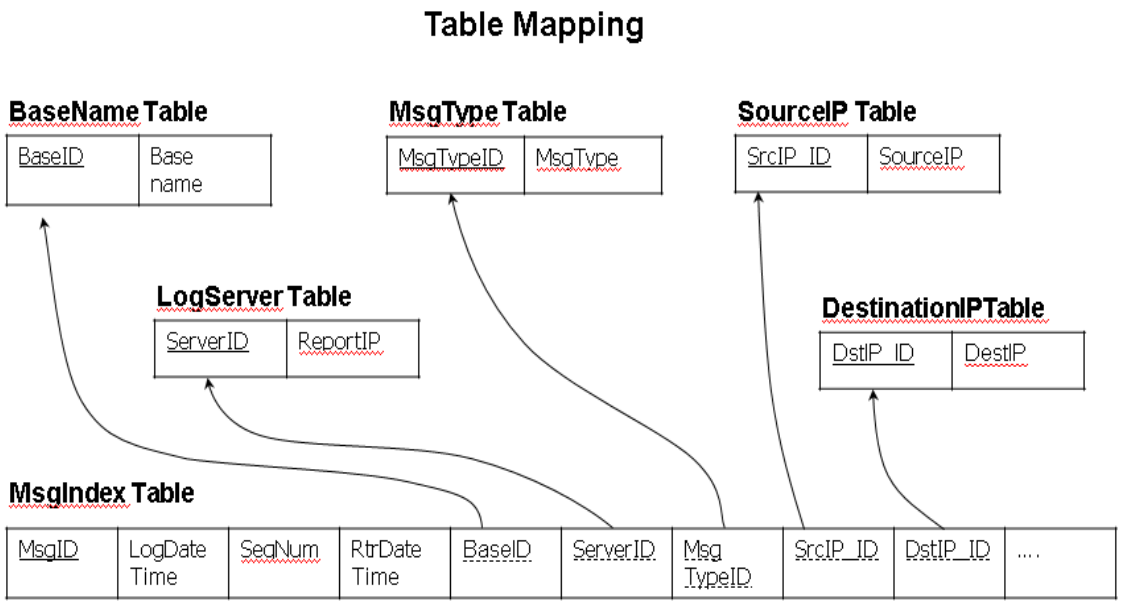

Figure 8. Visual Depiction of Normalized the Tables

3.4.3 Table Normalization with Associative Tables

For this experiment, eight normalized tables were created for performance comparison (see Figure 9). The normalized tables were created based on the purpose of the log data; the SQL script to create the tables is in Appendix K. The normalized tables created are single-themed and at least in 4NF. Then, the tables are populated using eight individual SQL scripts shown combined in Appendix L.

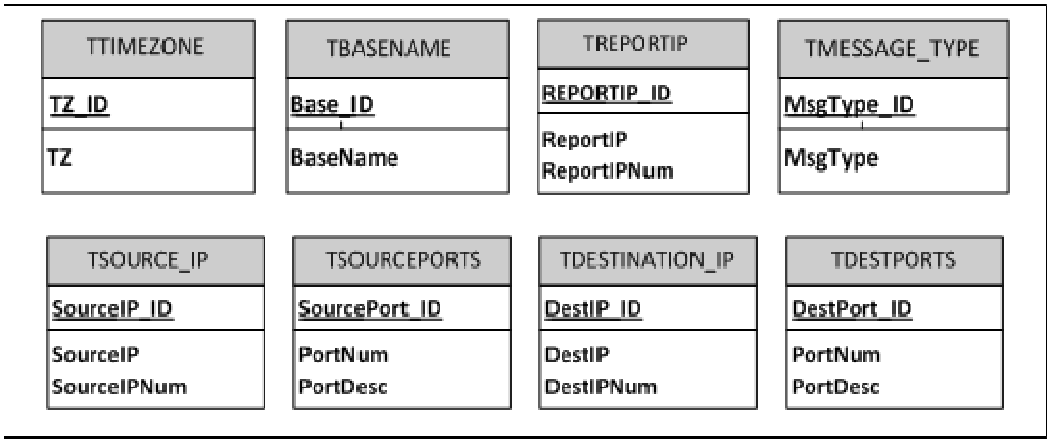

Figure 9. Table Structure of the Normalized Tables

In order to link the normalized tables to the non-normalized table, an associative entity is created for each table (see Figure 10). These associative entities also allow the network analyst to write less complex normalized queries. Each of the associative entity contains foreign keys from the non-normalized table and the normalized that are combined to form a composite primary key (see Figure 11). There are eight associative tables created using a SQL script detailed in Appendix M. After the associative entities are created, they are populated using a SQL script described in Appendix N. At this point, all the tables necessary are created and populated; queries can now be run on both non-normalized and normalized configuration.

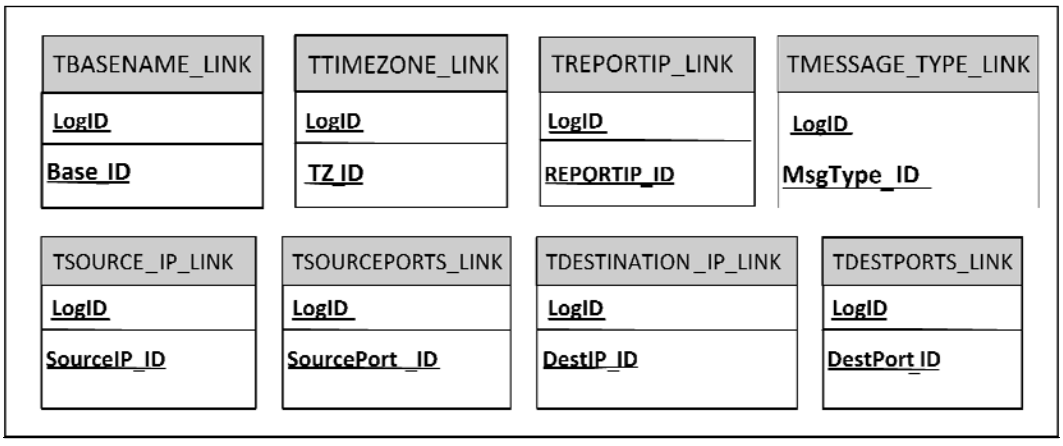

Figure 10. Table Structure of the Associative Tables

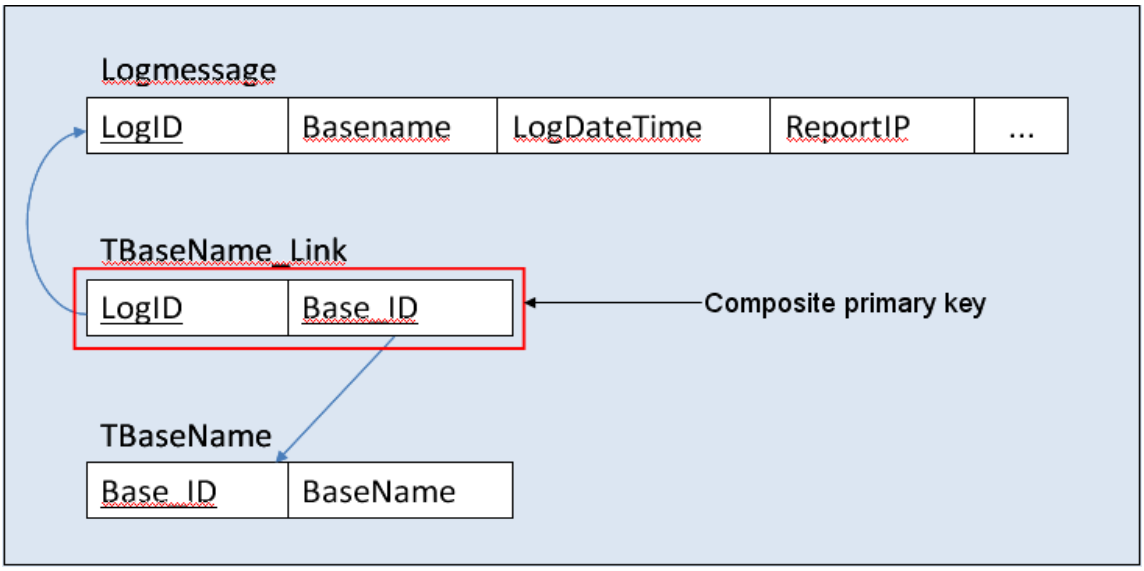

Figure 11. Example of Mapping the TBaseName_Link Associative Entity

3.5 Event Log Database Queries

Once the log data had been normalized, SQL queries can be created to search for statistical data, network security analysis, and other related information a network defender may request. Examples include the number of distinct types of messages that are found in the logs, the number of routers reporting from each location, the IP addresses associated to certain well-known protocols. These simple queries can be built upon for more complex and informative queries. To build the queries, SQL joins were used to efficiently combine tables into a single view or table. Examples of the joins used include natural joins where duplicate columns are excluded; inner join, a join where rows must have matching values in order to appear in the result table; and outer joins where rows that do not have matching values in common columns are included in the result (Hoffer et al., 2009, pg. 360-361). The results were analyzed for any trends or commonality. Based on the results of the analysis, more advanced queries, sub-queries, and joins were developed.

Two sets of 15 queries were developed for both non-normalized (see Appendix O) and normalized (see Appendix P) tables that are representative of simple and complex queries that would typically be conducted by network security personnel. These queries were customized according to the specific situation and purpose. Queries were also developed based on industry best practices and event log analysis. The queries answer specific questions described in Table 4. The actual outputs of the queries were inspected to make sure the results matched and if there are any discrepancies that they could be explained. The set of queries were specifically developed to have a combination of both simple and complex queries to measure any performance differences. In general, the complexity of the non-normalized queries does not vary significantly in terms of number of joins as seen in Table 5a. The lengths of the queries are also generally longer for normalized (see Table 5b), for more details on the queries see Appendix O and P.

Table 4. Query Numbers and Purpose

Query Number	Description/Purpose
Q1	What are the different message types?
Q2	What are the different base names?
Q3	What are the report IP addresses from each base?
Q4	What are the destination ports and how many events?
Q5	What are the Top 10 destination ports for January?
Q6	What bases have port 445 as a destination port and how many events?
Q7	What bases have port 445 as destination port and how many events occurred in January?
Q8	How many events used port 23 (Telnet) as destination port?
Q9	What bases have port 23 as destination port and how many events?
Q10	What are the bases and message types with message severity of 2 (see Appendix A) and the number of events?
Q11	What are the bases, ReportIPs, message types, with message severity of 2 and the number of events during the month of January?
Q12	What bases have sourceIP from a user defined table in January and what country?
Q13	What LogID, Basename, ReportIP, SourceIP, Country, Token3, and Token4 have sourceIP from Enemy table that is on the egress list and permitted and what country?
Q14	What Basename, ReportIP, SourceIP, Country_Name, DestinationIP Egress/Ingress, Permitted/Denied did a source IP address from a user defined table show up in the log?
Q15	What are the Top 10 message types in the log?

Table 5. SQL Queries

(a) *Non-normalized Queries*

Query Number	Non-normalized Syntax
Q1	SELECT DISTINCT (Messagetype) FROM Logmessage;
Q2	SELECT DISTINCT (Basename) FROM Logmessage ORDER BY Basename;
Q3	SELECT DISTINCT BASENAME, ReportIP FROM LOGMESSAGE ORDER BY BASENAME;
Q4	SELECT Destinationport, Count(*) AS "Number of Events" FROM Logmessage WHERE Destinationport LIKE '%' GROUP BY Destinationport ORDER BY "Number of Events";
Q5	SELECT * FROM (SELECT Destinationport, "Number of Events", RANK () OVER (ORDER BY "Number of Events" DESC) Rank FROM (SELECT Destinationport, Count(*) AS "Number of Events" FROM Logmessage WHERE Destinationport LIKE '%' AND (logdatetime >= '01-jan-11' and logdatetime<= '31-jan-11') GROUP BY Destinationport ORDER BY "Number of Events")) WHERE Rank <=10;
Q6	SELECT BaseName, Destinationport, Count(*) AS "Number of Events" FROM Logmessage WHERE Destinationport = '445' GROUP BY BaseName, Destinationport ORDER BY "Number of Events";
Q7	SELECT BaseName, Destinationport, Count(*) AS "Number of Events" FROM Logmessage WHERE Destinationport = '445' AND (logdatetime >= '01-Jan-11' AND logdatetime<= '31-Jan-11') GROUP BY BaseName, Destinationport ORDER BY "Number of Events";
Q8	SELECT Destinationport, Count(*) AS "Number of Events" FROM Logmessage WHERE Destinationport = '23' GROUP BY Destinationport ORDER BY "Number of Events";
Q9	SELECT BaseName, Destinationport, Count(*) AS "Number of Events" FROM Logmessage WHERE Destinationport = '23' GROUP BY BaseName, Destinationport ORDER BY "Number of Events";
Q10	SELECT DISTINCT Basename, Messagetype, Count(*) AS "Number of Events" FROM Logmessage WHERE messagetype LIKE '%-2-%' GROUP BY Basename, Messagetype ORDER BY "Number of Events";
Q11	SELECT Basename, ReportIP, Messagetype, Count(*) AS "Number of Events" FROM Logmessage WHERE Messagetype LIKE '%-2-%' AND (Logmessage.logdatetime >= '01-jan-11' and Logmessage.logdatetime <= '31-jan-11') GROUP BY Basename, ReportIP, Messagetype ORDER BY "Number of Events";
Q12	SELECT BASENAME, ReportIP, SourceIP, COUNTRY_NAME FROM LOGMESSAGE L, ENEMY E WHERE L.SourceIPNum <= E.IP_TO AND L.SourceIPNum >= E.IP_FROM AND (L.logdatetime >= '01-jan-11' and L.logdatetime <= '31-jan-11');
Q13	SELECT LogID, Basename, ReportIP, SourceIP, COUNTRY_NAME, Token3, Token4 FROM LOGMESSAGE L, ENEMY E WHERE L.SourceIPNum <= E.IP_TO AND L.SourceIPNum >= E.IP_FROM AND TOKEN3 LIKE '%egress%' AND TOKEN4 = 'permitted';
Q14	SELECT SourceIP, LogDateTime, Basename, ReportIP, DestinationIP COUNTRY_NAME, Token3, Token4 FROM Logmessage, Enemy WHERE SourceIP = '203.171.234.174' AND (Logmessage.SourceIPNum <= Enemy.IP_TO and Logmessage.SourceIPNum >= Enemy.IP_FROM);
Q15	SELECT * FROM (SELECT MessageType, "Number of Events", RANK () OVER (ORDER BY "Number of Events" DESC) Rank FROM (SELECT MessageType, Count(*) AS "Number of Events" FROM Logmessage WHERE MessageType LIKE '%' GROUP BY MessageType ORDER BY "Number of Events")) WHERE Rank <=10;

(b) *Normalized Queries*

Query Number	Normalized Syntax
Q1	SELECT MsgType FROM TMESSAGE_TYPE ORDER BY MsgType;
Q2	SELECT BaseName FROM TBASENAME ORDER BY BaseName;
Q3	SELECT DISTINCT BaseName, ReportIP FROM TBASENAME, TBASENAME_LINK, TREPORTIP, TREPORTIP_LINK WHERE TBASENAME.Base_ID = TBASENAME_LINK.Base_ID AND TBASENAME_LINK.LOGID = TREPORTIP_LINK.LOGID AND TREPORTIP_LINK.REPORTIP_ID = TREPORTIP.REPORTIP_ID ORDER BY BaseName;
Q4	SELECT DISTINCT PortNum, Count(*) AS "Number of Events" FROM TDESTPORTS, TDESTPORT_LINK WHERE TDESTPORT_LINK.DPort_ID = TDESTPORTS.DestPort_ID GROUP BY PortNum ORDER BY "Number of Events";

Q6	SELECT DISTINCT TBASENAME.BASENAME, TDESTPORTS.PortNum, Count(*) AS "Number of Events" FROM TBASENAME, BASENAME_LINK, TDESTPORTS, TDESTPORT_LINK WHERE TBASENAME.Base_ID = TBASENAME_LINK.Base_ID AND TBASENAME_LINK.LOGID = TDESTPORT_LINK.LOGID AND TDESTPORT_LINK.DPort_ID = TDESTPORTS.DestPort_ID AND TDESTPORTS.PortNum = '445' GROUP BY TBASENAME.BASENAME, TDESTPORTS.PortNum ORDER BY "Number of Events";
Q7	SELECT BASENAME, DestinationPort, Count(*) AS "Number of Events" FROM Logmessage WHERE Logmessage.LogID IN (SELECT TDESTPORT_LINK.LOGID FROM TDESTPORTS, TDESTPORT_LINK WHERE DESTPORTS.DestPort_ID = TDESTPORT_LINK.DPort_ID AND TDESTPORTS.PortNum = '445') AND (Logmessage.logdatetime >= '01-jan-11' and Logmessage.logdatetime <= '31-jan-11') GROUP BY BASENAME, DestinationPort ORDER BY "Number of Events";
Q8	SELECT DISTINCT PortNum, Count(*) AS "Number of Events" FROM TDESTPORTS, TDESTPORT_LINK WHERE TDESTPORT_LINK.DPort_ID = TDESTPORTS.DestPort_ID AND TDESTPORTS.PortNum = '23' GROUP BY PortNum ORDER BY "Number of Events";
Q9	SELECT DISTINCT TBASENAME.BASENAME, TDESTPORTS.PortNum, Count(*) AS "Number of Events" FROM TBASENAME, TBASENAME_LINK, TDESTPORTS, TDESTPORT_LINK WHERE TBASENAME.Base_ID = TBASENAME_LINK.Base_ID AND TBASENAME_LINK.LOGID = TDESTPORT_LINK.LOGID AND TDESTPORT_LINK.DPort_ID = TDESTPORTS.DestPort_ID AND TDESTPORTS.PortNum = '23' GROUP BY TBASENAME.BASENAME, TDESTPORTS.PortNum ORDER BY "Number of Events";
Q10	SELECT DISTINCT Basename, Msgtype, Count(*) AS "Number of Events" FROM TBASENAME, TBASENAME_LINK, TMESSAGE_TYPE, TMESSAGE_TYPE_LINK WHERE TBASENAME.BASE_ID = TBASENAME_LINK.BASE_ID AND TMESSAGE_TYPE_LINK.MSGTYPE_ID = TMESSAGE_TYPE.MSGTYPE_ID AND TBASENAME_LINK.LOGID = TMESSAGE_TYPE_LINK.LOGID AND TMESSAGE_TYPE.MSGTYPE LIKE '%-2-%' GROUP BY Basename, Msgtype ORDER BY "Number of Events";
Q11	SELECT Basename, ReportIP, Messagetype, Count(*) AS "Number of Events" FROM Logmessage WHERE Logmessage.LOGID IN (SELECT TMESSAGE_TYPE_LINK.LOGID FROM TMESSAGE_TYPE, TMESSAGE_TYPE_LINK WHERE TMESSAGE_TYPE_LINK.MSGTYPE_ID = TMESSAGE_TYPE.MSGTYPE_ID AND TMESSAGE_TYPE.MSGTYPE LIKE '%-2-%') AND (Logmessage.logdatetime >= '01-jan-11' and Logmessage.logdatetime <= '31-jan-11') GROUP BY Basename, ReportIP, Messagetype ORDER BY "Number of Events";

Q12	SELECT Basename, ReportIP, SourceIP, COUNTRY_NAME FROM Logmessage, Enemy WHERE Logmessage.LOGID IN (SELECT TBASENAME_LINK.LOGID FROM TBASENAME, TBASENAME_LINK, TSOURCE_IP, TSOURCE_IP_LINK WHERE TBASENAME.BASE_ID = TBASENAME_LINK.BASE_ID AND TSOURCE_IP.SOURCEIP_ID = TSOURCE_IP_LINK.SOURCEIP_ID AND TBASENAME_LINK.LOGID = TSOURCE_IP_LINK.LOGID) AND (Logmessage.logdatetime >= '01-jan-11' and Logmessage.logdatetime <= '31-jan-11') AND (Logmessage.SourceIPNum <= Enemy.IP_TO and Logmessage.SourceIPNum >= Enemy.IP_FROM);
Q13	SELECT LogID, Basename, ReportIP, SourceIP, COUNTRY_NAME, Token3, Token4 FROM Logmessage JOIN Enemy ON Logmessage.LOGID IN (SELECT TBASENAME_LINK.LOGID FROM TBASENAME, TBASENAME_LINK, TSOURCE_IP, TSOURCE_IP_LINK WHERE TBASENAME.BASE_ID = TBASENAME_LINK.BASE_ID AND TSOURCE_IP.SOURCEIP_ID = TSOURCE_IP_LINK.SOURCEIP_ID AND TBASENAME_LINK.LOGID = TSOURCE_IP_LINK.LOGID) AND (Logmessage.SourceIPNum <= Enemy.IP_TO and Logmessage.SourceIPNum >= Enemy.IP_FROM) AND TOKEN3 LIKE '%egress%' AND TOKEN4 = 'permitted';
Q14	SELECT SourceIP, LogDateTime, Basename, ReportIP, DestinationIP, COUNTRY_NAME, Token3, Token4 FROM Logmessage, Enemy WHERE Logmessage.LogID IN (SELECT TSOURCE_IP_LINK.LogID FROM TSOURCE_IP, TSOURCE_IP_LINK WHERE TSOURCE_IP.SourceIP_ID = TSOURCE_IP_LINK.SourceIP_ID AND TSOURCE_IP.SourceIP = '203.171.234.174') AND (Logmessage.SourceIPNum <= Enemy.IP_TO and Logmessage.SourceIPNum >= Enemy.IP_FROM);
Q15	SELECT * FROM (SELECT MsgType, "Number of Events", RANK () OVER (ORDER BY "Number of Events" DESC) RANK FROM (SELECT MsgType, Count(*) AS "Number of Events" FROM TMESSAGE_TYPE, TMESSAGE_TYPE_LINK WHERE TMESSAGE_TYPE.MsgType_ID = TMESSAGE_TYPE_LINK.MsgType_ID GROUP BY MsgType ORDER BY "Number of Events"))WHERE RANK <=10;

3.6 Runtime Comparison of Normalized and Non-normalized Event Logs

A series of 32 query runs, both non-normalized and normalized, are performed and the runtime for each of the 15 queries was recorded using Oracle's timing command. According to the *central limit theorem* as the sample size grows larger (more than 30) the sampling distribution becomes normal and has a mean equal to the population mean (Fields, 2009, pg. 42). In order to collect the necessary timing and statistical data without accumulating the large output and still be able to fetch the queries, the script executes Oracle's "autotrace traceonly" command. For more details, see Appendix O and P. Two more SQL scripts where created to invoke the non-normalized and normalized queries automatically (see Appendix Q and R). Oracle's timing format is hh:mm:ss.ss. In order to have a simple numerical format for statistical analysis, the runtime unit of measurement was converted to seconds.

3.6.1 Statistical Analysis

To analyze if there are differences between the means of non-normalized and normalized queries, a Student's t-test of independent samples was employed. The null and alternative hypotheses are:

H_0 = *There are no statistical differences between the means of non-normalized and normalized queries.*

H_A = *There are statistical differences between the means of non-normalized and normalized queries.*

The program used for statistical analysis is SPSS release 16.0. Fifteen variables were created in SPSS to represent the 15 queries and a grouping variable with values of 1 and 2 for non-normalized and normalized groups respectively. Sixty-four timing data points were entered in SPSS and assigned into two groups of 32. The groupings identify whether a query is non-normalized or normalized. The complete dataset can be found in Appendix S. The results of the queries, timing, and statistical analysis are discussed in the next chapter.

3.6.2 Preprocessing and Disk Space Requirements

When comparing the runtimes between non-normalized and normalized it is necessary to consider the preprocessing time incurred to create and populate the normalized tables. This processing time overhead can be found in the SQL logs when the tables were created and populated (see Table 21). The break-even point can be determined by calculating the preprocessing time divided by the difference of the average mean time of the non-normalized (NN) and normalized (N) queries.

$$\text{NN average mean time} = \sum_{i=1}^{15} i \tag{1}$$

$$\text{N average mean time} = \sum_{i=1}^{15} i \tag{2}$$

$$\text{Difference} = \text{NN average mean time} - \text{N average mean time} \tag{3}$$

$$\text{Break - even point} = \text{Preprocessing time} / \text{Difference} \tag{4}$$

To be specific, the break-even point is the number of times the queries need to be ran to pay off for the normalization preprocessing overhead. The tables are only created once but can be updated whenever necessary. For this experiment, however, the normalized tables were populated one time using a fixed amount of 30 million event logs. In some real-world situations, the preprocessing would only occur if a new value or data does not already exist in the normalized tables.

Creating the normalized tables will obviously incur additional disk space to accommodate the extra tables. There are several ways to determine the table sizes. One is using Oracle's Database Control Interface. Using Oracle's web-based graphical user interface, the table sizes are located in the Administration tab, Schema, Database Objects, Tables, search for the table name, and the table size is under Statistics called Sample Size. However, there is a lack of documentation on what this parameter actually measures. The second and preferred option uses the average row length multiplied by the number of rows. According to Oracle's

documentation, AVG_ROW_LEN is the “average row length, including the row overhead, in bytes” (2005). The SQL syntax is:

```
SELECT TABLE_NAME, ROUND ((AVG_ROW_LEN * NUM_ROWS / 1024), 2) SIZE_KB FROM USER_TABLES ORDER BY TABLE_NAME;
```

3.7 Summary

This chapter explained, in detail, each step taken to perform the experiment and be able to reproduce it as accurately as possible. The main steps explained include parsing and loading the event logs, normalizing the database, running and comparing the queries, and calculating the preprocessing time and disk space. The next chapter shows and analyzes the results of the methods described in this chapter.

IV. Results

4.1 Overview

The results of the statistical analysis and query performance will be analyzed in this chapter. First, the results of the t-test from SPSS are discussed as it relates to the experiment, specifically the test statistic (*t*), degrees of freedom (*df*), and the probability value (*p*-value) of the test statistic. Information from the group or summary statistics will also be briefly discussed. The main findings of the statistical analysis are in the independent samples test. Second, the runtimes and statistical output from the actual queries will be discussed explaining the difference in performance between non-normalized and normalized configuration.

4.2 Test Statistics Results

Table 6 shows the summary statistics of the t-test. Each row represents one of the 15 queries (Q1-15). The first column indicates the results for non-normalized or normalized queries. As mentioned in Chapter 3, according to the *central limit theorem* as the sample size grows larger (more than 30) the sampling distribution becomes normal and has a mean equal to the population mean (Fields, 2009, pg. 42). Each query ran 32 times (N) and the mean runtime in seconds including the standard deviation and standard error mean are also included in the table.

Table 6. Group Statistics

	Is this query Normalized or Non-Normalized	N	Mean	Std. Deviation	Std. Error Mean
Q1	Non-Normalized	32	179.1747	3.37547	.59671
	Normalized	32	.0088	.02136	.00378
Q2	Non-Normalized	32	178.7297	3.62914	.64155
	Normalized	32	.0150	.03844	.00679

	Normalized	32	428.8850	21.87962	3.86781
Q8	Non-Normalized	32	179.0097	3.29555	.58258
	Normalized	32	5.9631	1.43762	.25414
Q9	Non-Normalized	32	178.4925	3.67427	.64953
	Normalized	32	22.9162	2.04290	.36114
Q10	Non-Normalized	32	179.7838	5.02242	.88785
	Normalized	32	32.7353	3.60482	.63725
Q11	Non-Normalized	32	178.4147	3.71542	.65680
	Normalized	32	336.3216	13.58484	2.40148
Q12	Non-Normalized	32	3835.8384	233.20236	41.22474
	Normalized	32	769.9984	15.10613	2.67041
Q13	Non-Normalized	32	179.8703	3.49814	.61839
	Normalized	32	259.1588	7.28158	1.28721
Q14	Non-Normalized	32	178.7362	3.99942	.70700
	Normalized	32	7.7987	1.37545	.24315
Q15	Non-Normalized	32	179.8806	4.23768	.74912
	Normalized	32	21.0847	.72725	.12856

The main results of the t-test are in Table 7. Again, each row represents one of the 15 queries, additionally, the first column indicates if the null hypothesis (H_0) of *"There are no statistical differences between the means of non-normalized and normalized queries"* is either Rejected or Failed to reject. SPSS also includes the Levene's test for equality of variances that is

similar to a t-test, wherein, it tests if the variances are assumed equal or are assumed different. If the *p*-value (Sig) of the Levene's test is less than 0.05 then there is a significant chance that the variances are assumed to be different. If $p > 0.05$, then the variances are assumed equal. For example, Q1 in the table has a Levene's test of $p < 0.05$, therefore, the variances are assumed to be different; however, Q3 has $p = 0.149$ that is larger than 0.05, therefore, variances are assumed equal. Other queries with $p > 0.05$ are Q5, Q6, Q10, and Q13.

The remaining columns in Table 7 show the results of the t-test for equality of means. The test statistic column shows the *t*-value used by SPSS in conjunction with the *df* to calculate probability that H_0 is true. Furthermore, the negative *t*-value denotes that non-normalized condition has smaller mean and performed faster than the normalized condition. The non-normalized queries that performed faster are Q5, Q7, Q11, and Q13. The p-values (Sig. 2-tailed) of the t-test are all exceedingly less than 0.05 ($p = 0.000$) which signify that there is enough evidence to reject the H_0. The first column shows that H_0 is rejected in all of the queries. The full SPSS table output is in Appendix T; the last column of the table shows additional information about the confidence interval for the mean difference at 95%. These boundaries suggest where the true values of the mean difference can be found. The findings, in general, suggest that most of the normalized queries performed faster than the non-normalized queries except for Q5, Q7, Q11, and Q13 and they were all significant at $p < 0.05$.

Table 7. Independent Samples Test

Reject or Accept null			Levene's Test for Equality of Variances		t-test for Equality of Means		
			F	Sig.	t	df	Sig. (2-tailed)
Reject	Q1	Equal variances assumed	91.353	0.000	300.253	62.000	0.000
		Equal variances not assumed			300.253	31.002	0.000

		Equal variances not assumed			208.922	32.824	0.000

4.3 Query Performance Statistics

As mentioned in the previous section, all of the normalized queries outperformed non-normalized queries except Q5, Q7, Q11, and Q13. Several factors could affect performance depending on each specific query. The most common issues are the maximum number of records involved, the number of joins, the number of physical hard drive reads, or a combination of any of these factors. According to Oracle's documentation, physical reads is defined as the "total number of data blocks read from disk"; it is a combination of direct, cache, and private buffer reads (2009). Each of the 15 queries both non-normalized (NN) and normalized (N) will be compared side by side using one of the query logs and discussed why one may have outperformed the other. The number of physical hard drive reads varies from run to run; however, the maximum number of records involved and the number of joins stays the same. Refer to Table 4 for the query description, Table 5a and 5b for non-normalized and normalized query syntax.

4.3.1 Q1: What are the different message types?

Table 6. Q1 Statistics

Q1	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	179.1747	30M	0	925255
N	.0088	169	0	0

Q1 results in Table 6 shows that N (M = .0088) exceedingly outperforms NN (M = 179.1747). The big difference is in number of records and physical hard drive reads. The N query only had to sort through 169 rows compared to 30 million for NN. In addition the number of physical reads for N query is virtually zero.

4.3.2 Q2: What are the different base names?

Table 7. Q2 Statistics

Q2	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	178.7297	30M	0	925434
N	.0150	44	0	0

Q2 results in Table 7 shows that N (M = . 0150) exceedingly outperforms NN (M = 178.7297). Q2 is very similar to Q1 in terms of structure. The only difference is the type of attribute involved as seen in the syntax. Similarly, the big difference is in number of records and physical hard drive reads. The N query only had to sort through 44 rows compared to 30 million for NN. In addition, the number of physical reads for N query is virtually zero.

4.3.3 Q3: What are the report IPs from each base?

Table 8. Q3 Statistics

Q3	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	179.8128	30M	0	925436
N	147.5572	30M	3	249874

Q3 results in Table 8 shows that N (M = 147.5572) outperforms NN (M = 147.5572). The difference in this query is the number of joins and physical hard drive reads, while the maximum number of rows is the same. The N query involves four tables and even if it has three times the number joins. The number of physical reads is less than one-third.

4.3.4 Q4: What are the destination ports and how many events?

Table 9. Q4 Statistics

Q4	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	178.9691	1.536M	0	925536
N	7.1028	9.294M	0	18509

Q4 results in Table 9 shows that N (M = 178.9691) outperforms NN (M = 7.1028). The difference in this query is the maximum number of rows and physical hard drive reads, while the number of joins is the same. The N query only involves two tables.

4.3.5 Q5: What are the Top 10 destination ports for January?

Table 10. Q5 Statistics

Q5	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	180.7591	3841	0	925324
N	227.1262	9.294M	1	977595

Q5 results in Table 10 shows that NN (M = 180.7591) outperforms N (M = 227.1262). The difference in this query is the maximum number of rows, number of joins, and physical hard drive reads all in favor of NN. The N query had to sort through over 9 million records while the NN query only involved 3,841 rows and a difference of 52,271 physical reads. Additionally, the N query had to go to the Logmessage table to fetch for the LogDateTime timestamp after processing a subquery. In all, the N query had to process three tables versus one for the NN query.

4.3.6 Q6: What are the bases with port 445 as destination port and how many events?

Table 11. Q6 Statistics

Q6	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	178.5216	364K	0	925989
N	22.7825	30M	3	77602

Q6 results in Table 11 shows that N (M = 22.7825) outperforms NN (M = 178.5216). The difference in this query is the maximum number of rows, number of joins, and physical hard drive reads. The N query had to sort through 30 million rows in table TBASENAME_LINK how ever it is a smaller table with only two columns. There are three times the number of joins in query N however, the physical reads is 848,387 less than NN.

4.3.7 Q7: What are the bases with port 445 as destination port and how many events in January?

Table 12. Q7 Statistics

Q7	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	179.5547	910	0	925632
N	428.8850	9.294M	1	149889

Q7 results in Table 12 shows that NN (M = 179.5547) outperforms N (M = 428.8850). The difference in this query is the maximum number of rows and number of joins both in favor of NN. However, the physical reads, although it is lower for the N query by 775,743 reads the performance remained slow. Q7 is similar to Q5 in that it has to go to the Logmessage table to

fetch for the LogDateTime timestamp after processing a subquery in a nested loop. In all, the N query had to process three tables versus one for the NN query.

4.3.8 Q8: How many events have port 23 (Telnet) as destination port?

Table 13. Q8 Statistics

Q8	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	179.0097	8293	0	925627
N	5.9631	9.294M	1	18680

Q8 results in Table 13 shows that N (M = 5.9631) outperforms NN (M = 179.0097). The difference in this query is the maximum number of rows and number of joins both in favor of NN. The physical reads is lower for the N query by 906,947. These statistics are very similar to Q7 except N outperformed NN on this case. The major difference is that the N query in this case did not have to go to the Logmessage table to fetch for the LogDateTime timestamp. The N query also had to process only two tables.

4.3.9 Q9: What bases use port 23 (Telnet) and how many?

Table 14. Q9 Statistics

Q9	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	178.4925	8293	0	925627
N	22.9162	30M	3	77615

Q9 results in Table 14 shows that N (M = 22.9162) outperforms NN (M = 178.4925). The difference in this query is the maximum number of rows and number of joins both in favor of NN. However, the physical reads is lower for the N query by 848,012. This query is similar

to Q8 in terms of the question but with additional data such as the base names. It also took longer by a few seconds.

4.3.10 Q10: What are the bases and message types with message severity of 2 and the number of events?

Table 15. Q10 Statistics

Q10	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	179.7838	1.536M	0	925638
N	32.7353	30M	3	119950

Q10 results in Table 15 shows that N (M = 32.7353) outperforms NN (M = 179.7838). The difference in this query is the maximum number of rows and number of joins both in favor of NN. However, the number of physical reads is lower for N by 805,688 reads. Further, the N query does not have to go to the Logmessage to get additional data.

4.3.11 Q11: What are the bases, ReportIP, message type, with message severity of 2 and the number of events during the month of January 2011?

Table 16. Q11 Statistics

Q11	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	178.4147	3841	0	925653
N	336.3216	30M	2	1093787

Q11 results in Table 16 shows that NN (M = 178.4147) outperforms N (M = 336.3216). The difference in this query is the maximum number of rows, number of joins, and number of physical reads all in favor of NN. This is similar to Q5 and Q7 in that it has to go to the

Logmessage table to fetch for the LogDateTime timestamp after processing a subquery in a nested loop. In all, the N query had to process three tables versus one for the NN query.

4.3.12 Q12: What bases have sourceIP from Enemy table in January 2011 and what country and reportIP?

Table 17. Q12 Statistics

Q12	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	3835.8384	196K	3	13734324
N	769.9984	30 M	5	1189702

Q12 results in Table 17 shows that N (M = 769.9984) outperforms NN (M = 3835.8384). The difference in this query is the maximum number of rows and number of joins both in favor of NN. However, the number of physical reads is lower for N by 685,738 reads. This query has the highest difference in means (3,065 seconds). This is also one of the two queries with the highest number of joins and tables for both N and NN. There are two tables involved in the NN query and six tables in the N query. The N query still outperformed NN even though the N query had to go to the Logmessage table to fetch for the LogDateTime timestamp. However, the NN query also had to use three joins and filter results using the timestamp, which could have caused the slow performance.

4.3.13 Q13: What LogID, Basename, ReportIP, SourceIP, Country, Token3, and Token4 have sourceIP from Enemy table that is on the egress list and permitted and what country?

Table 18. Q13 Statistics

Q13	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	179.8703	1023	3	926290
N	259.1588	30M	5	1066356

Q13 results in Table 18 shows that NN (M = 179.8703) outperforms N (M = 259.1588). The difference in this query is the maximum number of rows, number of joins, and number of physical reads all in favor of NN. This query is similar to Q12 but with additional data such Token 3 and 4 minus the timestamp. The physical reads in this query is lower for NN by 140,066 reads. The NN query was faster because the N query needed to fetch more data (Token 3 and 4) from the non-normalized Logmessage table.

4.3.14 Q14: What Basename, LogDateTime, ReportIP, SourceIP, COUNTRY_NAME, DestinationIP Egress/Ingress (Token3), Permitted/Denied (Token4) did a source IP address from Enemy table show up in the log?

Table 19. Q14 Statistics

Q14	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	178.7362	36493	3	925580
N	7.7987	11M	4	26592

Q14 results in Table 19 shows that N (M = 7.7987) outperforms NN (M = 178.7362). The difference in this query is the maximum number of rows and number of joins both in favor of NN. However, the number of physical reads is lower for N by 898,988 reads. This query is similar to Q13 but with additional information and it searches for a specific IP address from the Enemy table. Oracle also automatically implemented an index unique scan for the N query for this instance.

4.3.15 Q15: What are the Top 10 message types in the log?

Table 20. Q15 Statistics

Q15	Mean	Max Number of Rows	Number of Joins	Physical Reads
NN	179.8806	30M	0	925581
N	21.0847	30M	1	60841

Q15 results in Table 20 shows that N (M = 21.0847) outperforms NN (M = 179.8806). The difference in this query is the number of joins and physical hard drive reads. The NN query did not use any joins and the N query used one join. The number of physical reads is lower for N by 864,740 reads. The maximum number of rows is the same. This query is similar to Q5; however, the N query does not have to go to the Logmessage table for additional data, hence, the query was faster.

In general, the query with higher physical hard drive reads performs slower except in cases where the normalized queries have to access the non-normalized Logmessage for additional data. The mean and physical hard drive reads for NN queries remained relatively constant throughout the experiment while the N queries have values that vary from query to query. This experiment showed that query performance is faster on normalized table if all the

necessary data are contained in the normalized tables. If however, the query needs to fetch additional data from the non-normalized table, then query performance decreases.

4.4 Preprocessing of Normalized Tables

4.4.1 Preprocessing Time

The query performance results showed that in some cases, it is possible to normalized the tables based on consequential queries if the queries are known ahead of time. Nevertheless, completely normalizing a large table incurs pre-processing time that can negate any query performance advantage. The pre-processing in real-world network log analysis would be to update the normalized tables only if new log data does not exist already. In other words, the normalized tables will only be updated if new data is introduced from the logs. Therefore, majority of the pre-processing time will only be incurred during the initial setup of the normalized tables. Generally, static tables such as the Basename, Timezones, and MessageTypes should not change often. The actual pre-processing time will also depend on the overall size of the log. The preprocessing times can be found in the Table 21. As discussed in section 3.6.1, below are the preprocessing parameters.

NN average mean time = 423.04 seconds

N average mean time = 152.63 seconds

Difference 423.04 - 152.63 = 270.41 seconds

Total preprocessing time = 8,655.63 seconds

Break-even point

8,655.63/270.41 = 32 times

These results show that the normalized queries need to be ran at least 32 times to pay back the preprocessing overhead for this experiment. In real-world scenario, if the queries are performed daily then the normalization will pay off in approximately one month.

Table 21. Preprocessing Time

Log Filename	**Total Preprocessing Time** (hh:mm:ss.00)
1. BuildLinkTables.log	00:00:00.83
2. BuildSummaryTables.log	00:00:00.43
3. PopLinkTables.log	01:57:38.64
4. PopTBasename.log	00:03:08.84
5. PopTDestIP.log	00:03:57.23
6. PopTDestPorts.log	00:03:10.17
7. PopTMessage_Type.log	00:03:05.28
8. PopTReportIP.log	00:03:09.07
9. PopTSourceIP.log	00:03:33.08
10. PopTSourcePorts.log	00:03:16.68
11. PopTTZ.log	00:03:15.38
	Grand Total = 02:24:15.63 or 8,655.63 seconds

4.4.2 Disk Space Requirement

The process for determining the disk space requirement was discussed in section 3.6.1. Table 22 shows the table sizes for each of the normalized tables and the corresponding

associative tables. The sizes are measured in kilobytes (KB) and the total in gigabytes (GB). The additional disk space of 1.36GB is not a substantial increase.

Table 22. Table Sizes

Table Name	Size KB
TBASENAME	.47
TBASENAME_LINK	240194.84
TDESTINATION_IP	15693.54
TDESTINATION_IP_LINK	110054.61
TDESTPORTS	544.05
TDESTPORT_LINK	81689.03
TMESSAGE_TYPE	3.47
TMESSAGE_TYPE_LINK	270435.92
TREPORTIP	4.16
TREPORTIP_LINK	269978.55
TSOURCEPORTS	568.93
TSOURCEPORT_LINK	81665.1
TSOURCE_IP	7016.52
TSOURCE_IP_LINK	113502.11
TTIMEZONE	.05
TTIMEZONE_LINK	231300.3

Total	1,422,651.65 KB or **1.36 GB**

4.5 Statistical Query Results

Actual statistical information from the event logs and some of the actual results from the queries are found in Appendix U and V.

4.6 Summary

Database normalization improved 11 of the 15 normalized queries performed using 30 million router log events; however, performance is also dependent on the type of query executed. Query performance is faster on normalized table if all the necessary data are contained in the normalized tables. If however, the query needs to fetch additional data from the non-normalized table, then query performance decreases. The tradeoff between using a non-normalized versus normalized database is additional preprocessing time that depends on data and purpose of the queries. Additionally, normalized database adds extra storage requirements although minimal in this experiment. Finally, a normalized database has better table organization and maintains better data consistency than non-normalized. The next chapter reiterates and explains the main findings of the research, recommendation for actions, and recommendation for future research.

V. Conclusion and Recommendations

Chapter Overview

This chapter discusses the conclusions of the research, its significance, recommendation for actions and future research.

Conclusions of Research

The two prevailing event log standards today are, MITRE's CEE and the Syslog protocol (RFC 5424). Regulatory compliance and network security issues have increased the importance of event logs to many organizations. Log analysis still remain complex due to lack of industry standards, lack of simple and efficient analysis methods to process numerous amount of logs generated daily.

Event logs can provide cyber situational awareness to management and other network users in the organization. Proper event log utilization through information systems monitoring and threat detection enhances mission assurance and information assurance. Database analysis of event logs is only one of the tools in the information system security toolbox that is still limited and dependent on the human operator's understanding and knowledge of the entire situation. One way to increase understanding of a situation is to correlate different events wherein logs contribute critical data for analysis.

Event log analysis can be performed using relational databases. To enhance database query performance, databases are usually denormalized. However, database normalization can also increase query performance. Database normalization improved majority of the queries performed using 30 million router log events; however, performance is also dependent on the type of query executed. Query performance is faster on normalized table if all the necessary data are contained in the normalized tables. If however, the query needs to fetch additional data from

the non-normalized table, then query performance decreases. The tradeoff between using a non-normalized versus normalized database is additional preprocessing time that depends on data and purpose of the queries. Additionally, normalized database adds extra storage requirements although minimal in this experiment. Finally, a normalized database has better table organization and maintains better data consistency than non-normalized.

Significance of Research

This research explored the different standards for event log generation, transport, storage, and analysis. It showed that database normalization does not always decrease query performance on databases. Database normalization enhanced performance for majority of the queries and will improve event log analysis for network defenders. Eleven of the 15 of the normalized queries, on average performed 2.77 times faster than non-normalized queries. There is a total of 270 seconds advantage in average mean query time for normalized queries. This experiment also established an early model for log analysis that is simple, customizable, and cost effective option to commercial log analyzers.

Recommendations for Action

One of the main findings of this research is that database query performance on event logs can be faster using normalized tables if all the data required is in the normalized tables. In most cases where the data required are not contained in the normalized tables, query performance degrades. If the queries that need to be performed on the event logs are known ahead of time, then the tables can be normalized to fit the queries in order to capture all the required data and avoid fetching them from the non-normalized table. Queries must be written to exclusively utilize the normalized tables and avoid referring back to the non-normalized table as much as possible to take advantage of faster performance. However, there are cases when the

queries and questions that an organization needs to ask are not pre-determined. If a new type of query is needed, the normalized tables can be updated and renormalized. The analyst, therefore, should consider the pre-processing time required and the frequency of the queries. For example, if a query is only required once, it may not be practical to normalize the tables for this purpose as the analyst can just directly query the non-normalized table. The decision to normalize the tables should be a balance between the pre-processing time required and the desired purpose of the query. Organizations can also implement a weighted-query approach where certain queries are assigned levels of importance and normalization can be tailored to the most important ones. Since performances vary from the type of queries, organizations may prefer a slower performance on some and faster on queries that are more important.

There is no fail-safe solution for normalizing event logs. Just like any other information systems solutions, the decision should be made based on the mission. Not every organization or base has similar missions and therefore the purpose for analyzing event logs could vary significantly. For instance, an organization that still uses Telnet to perform its mission may not be very interested in Telnet permitted connections; however, an organization that does not use Telnet should be very interested in Telnet type logs. IT personnel who understand the local mission can make better judgments of the results and take timely and decisive actions. Finally, proper Information Assurance requires the validation and verification of the integrity of results generated by a commercial log analysis tool. Network defenders can use this relational database to collect and analyze event log data to provide the ability to validate results generated by commercial tools.

Recommendations for Future Research

Despite the important and significant findings of this research, there are still several follow-up studies that can expand the results. This research was only conducted on one set of 30M records. A future study can perform further performance analysis using lower incremental amount of event logs (300K and 30K) and compare the performances. What is the query performance difference between non-normalized and normalize databases if the total size of the logs is 30M, 300K, and 30K? Does the total size of event logs affect the query performance of non-normalized and normalize databases? Moreover, can further normalization of the logs by creating additional normalized tables increase or decrease query performance? Creating additional normalized tables will minimize the need to fetch for additional data from the non-normalized logs, which can improve query performance, however it can complicate the queries and add additional joins. Another future research is to create a model to determine what variables are predictive of slowing down query performance. Does the maximum number of rows processed, number of joins, physical reads and others correlate to slow query performance? Finally, this experiment only used Cisco router and switch event logs but should be applicable to other cyber logs; a future study using other event logs can validate the results.

APPENDIX A

Severity Level	Description
0 - emergency	System is unusable
1 - alert	Immediate action required
2 - critical	Critical condition
3 - error	Error condition
4 - warning	Warning condition
5 - notification	Normal but significant condition
6 - informational	Informational message only
7 - debugging	Message that appears during debugging only

Event Logs Severity Code (Lonvick, 2001) p. 9

APPENDIX B

Attribute	Type	Description
LogID	INTEGER,	Primary key and unique identifier for each record
BaseName	VARCHAR2(20),	The name of the base/location where the log came from
LogDateTime	TIMESTAMP,	The timestamp from the log server
ReportIP	VARCHAR2(20),	The IP address of the reporting router
ReportIPNum	INTEGER,	The decimal equivalent of the report IP address
RouterNum	INTEGER,	The router sequence number assigned to each event
RouterNum2	INTEGER,	A second router sequence number assigned to each event
RouterDateTime	TIMESTAMP,	The timestamp from the router
RouterMsecs	INTEGER,	Millisecond from the timestamp from the router
TimeZone	VARCHAR2(6),	Time zones in the logs
MessageType	VARCHAR2(35),	Identifies the type of message or event
SourceIP	VARCHAR2(20),	Source IP address of the event recorded
SourceIPNum	INTEGER,	The decimal equivalent of the Source IP address
SourcePort	INTEGER,	Source port numbers in the logs
DestinationIP	VARCHAR2(20),	Destination IP address of the event recorded
DestinationIPNum	INTEGER,	The decimal equivalent of the destination IP address
DestinationPort	INTEGER,	Destination port numbers in the logs

APPENDIX C

Parselog.PL

Description

This a script to extract relevant elements from a Cisco syslog file and write it into a CSV file that can be easily imported into Oracle. This file must be present in each of the base folders.

```
#!/usr/bin/perl
use warnings;
# use strict;
#
#       parselog.pl -- a script to extract relevant elements from a cisco syslog file
#                       and write it into a CSV file that can be easily imported into oracle
#
# Version 1.0 - Initial version - 02/28/11
# Version 1.2 - Fixed error in line count - 03/01/11
# Version 1.2 - Fixed variable router message numbers - 03/02/11
# Version 1.3 - Fixed millisecond to zero when not present - 03/03/11
# Version 1.4 - Fixed status message - 03/03/11
# Version 1.5 - Fixed bug in identifying dotted decimal - 03/04/11
# Version 1.6 - Fixed bug in router time trailing colon - 03/04/11
# Version 1.7 - Rewrite - 03/06/11
# Version 1.8 - Debug - 03/07/11
# Version 1.9 - Debug - 03/09/11
# Version 2.0 - Debug - 03/10/11
# Version 2.1 - Debug - 03/16/11
# Version 2.2 - Debug - 03/17/11

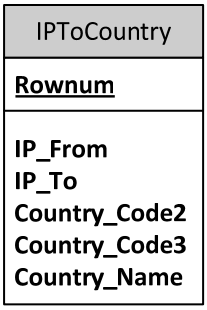
APPENDIX E

LogMessage Table Structure

APPENDIX F

IPToCountry Table Structure



APPENDIX G

Doit.BAT

Description

This file invokes the PERL parser for the log files from a particular USAF base, and invokes the CTL file that loads the resultant CSV file into the LogMessage table.

REM Edit "*pathname**basename*\parselog.pl" *basename*

```
del *.csv
for %%A in (cisco*.log) do perl "D:\INOSCWest561st\basename\parselog.pl" %%A basename
2011
copy *.csv all-basename.log.csv
sqlldr user1/pass1 loadbasename.ctl
type loadbasename.log
```

APPENDIX H

Redoit.BAT

Description

This file is the overall control batch file. It invokes CreateLogMessage.SQL, LoadIPCountry.CTL and Doit.BAT. This file displays the start time and end time. It also logs-in to Oracle using sqlplus with username and password and calls the CreateLogMessage.SQL file. Then the LoadIPCountry.CTL is invoked using sqlldr with the same username and password. A loadipcountry.log is generated. After all the doit batch files for each base are executed the finished time is displayed and a redoit.log file is generated. When executing redoit.bat, there maybe messages stating "Commit point reached - logical record count...", this is normal and not to be concerned about. This batch process can take up to several hours depending on the system. Below is the actual batch file:

```
echo Starting at %time%
sqlplus username/password @CREATELOGMESSAGE
sqlldr username/password loadipcountry.ctl
type loadipcountry.log

APPENDIX I

LoadIPCountry.CTL

Description

Loads the IP ranges of each country into the “IPToCountry” table.

REM cd to *pathname*\ip-to-country.csv'

```
load data
  infile 'D:Country IPs\ip-to-country.csv'
  into table IPTOCOUNTRY
  fields terminated by "," optionally enclosed by ""
  TRAILING NULLCOLS
  (IP_FROM, IP_TO, COUNTRY_CODE2, COUNTRY_CODE3, COUNTRY_NAME)
```

APPENDIX J

Load*Basename*.CTL

Description

Loads the tokens in the CSV file into the “LogMessage” table. Each base has its own load<basename>.CTL file, specific to the path name for each base.

REM Edit “*pathname*\all-*basename*log.csv”

```
load data
  infile 'D:\INOSCWest561st\ basename \all-basename.log.csv'
  into table LOGMESSAGE
  append
  fields terminated by "," optionally enclosed by ""
  TRAILING NULLCOLS
   (BaseName, LogDateTime DATE 'DD-MON-YYYY HH24.MI.SS', ReportIP, ReportIPNum,
    RouterNum, RouterNum2, RouterDateTime DATE 'DD-MON-YYYY HH24.MI.SS',

APPENDIX U

Statistical information about the actual event logs.

1. Number of records in the event logs:

   30,721,104

2. Number of bases in the event logs:

   43

3. Date range of the logs:

   19-OCT-10 06.00.26.00000 AM to 04-Mar-11 11.59.55.000000 AM

4. Number of message types:

   169

5. Number of events for each month:

   October

   6642

   November

   36237

   December

   4828245

   January

   13934721

   Febuary

   10347568

   March

   427357

6. Number of rows from each base:

14. ABSTRACT

A critical capability required in the operation of cyberspace is the ability to maintain situational awareness of the status of the infrastructure elements that comprise cyberspace. Event logs from cyber devices can yield significant information, and when properly utilized can provide timely situational awareness about the state of the cyber infrastructure. In addition, proper Information Assurance requires the validation and verification of the integrity of results generated by a commercial log analysis tool. Event log analysis can be performed using relational databases. To enhance database query performance, previous literatures affirm denormalization of databases; yet, database normalization can also increase query performance. Database normalization improved majority of the queries performed using very large data sets of router events; however, performance is also dependent on the type of query executed. Queries performed faster on normalized table if all the necessary data are contained in the normalized tables. Furthermore, database normalization improves table organization and maintains better data consistency than non-normalized. Nonetheless, there are some tradeoffs when normalizing a database such as additional preprocessing time and extra storage requirements though minimal in this experiment. Overall, normalization improved query performance and must be considered as an option when analyzing event logs using relational databases.
