## RIEMANNIAN VECTOR BUNDLES HAVE NO CANONICAL LINEAR CONNECTIONS

**Abstract.** We prove that Riemannian vector bundles have no canonical linear connections.

### Introduction

Given a vector bundle  $E \rightarrow M$ , a Riemannian structure on  $E \rightarrow M$  is a map  $G : E \times_M E \rightarrow \mathbf{R}$  such that for any  $x \in M$  the restriction  $G_x : E_x \times E_x \rightarrow \mathbf{R}$  of  $G$  is an inner product on the fiber  $E_x$  of  $E \rightarrow M$  over  $x$  (i.e. it is symmetric bilinear and positive definite). For example, if  $E = TM \rightarrow M$  is a tangent bundle of a manifold  $M$ , then a Riemannian structure on  $TM \rightarrow M$  is called a Riemannian structure on  $M$ .

Given a vector bundle  $E \rightarrow M$ , by a linear connection  $D$  on  $E \rightarrow M$  we mean an  $\mathbf{R}$ -bilinear map  $D : \mathcal{X}(M) \times \Gamma(E) \rightarrow \Gamma(E)$  such that

- (i)  $D_{fX}\sigma = fD_X\sigma$  and
- (ii)  $D_Xf\sigma = Xf\sigma + fD_X\sigma$

for any vector field  $X \in \mathcal{X}(M)$  on  $M$ , any map  $f : M \rightarrow \mathbf{R}$  and any section  $\sigma \in \Gamma(E)$  of  $E \rightarrow M$ . For example, if  $E = TM \rightarrow M$  is the tangent bundle of a manifold  $M$ , then a linear connection on  $TM \rightarrow M$  is called a classical linear connection on  $M$ .

**EXAMPLE 1.** Let  $g$  be a Riemannian structure on a manifold  $M$ . It is well-known that there exist many classical linear connections  $\nabla$  on  $M$  such that

$$(1) \quad Zg(X, Y) = g(\nabla_Z X, Y) + g(X, \nabla_Z Y)$$

---

*Key words and phrases:* vector bundle, Riemannian vector bundle, classical linear connection, linear connection.

1991 *Mathematics Subject Classification:* 58A20, 58A32.

for any vector fields  $X, Y, Z$  on  $M$ . However, if  $\nabla$  satisfying the above property (1) satisfies also an additional condition (depending canonically on  $\nabla$  and  $g$ ) saying that

$$(2) \quad \nabla_X Y - \nabla_Y X - [X, Y] = 0$$

for any vector fields  $X, Y$  on  $M$ , then such connection  $\nabla$  is unique. This is the well-known Levi-Civita connection of  $g$ .

**EXAMPLE 2.** Let  $G$  be a Riemannian structure on a vector bundle  $E \rightarrow M$ . Similarly as in the Riemannian manifold case, there exist many linear connections  $D$  on a  $E \rightarrow M$  such that

$$(3) \quad XG(\sigma, \eta) = G(D_X \sigma, \eta) + G(\sigma, D_X \eta)$$

for any vector field  $X \in \mathcal{X}(M)$  and any sections  $\sigma, \eta \in \Gamma(E)$ , see [4].

So, we have the following natural question.

**QUESTION 1.** Whether there exists a condition

$$(4) \quad C(G, D)$$

(canonically determined by  $G$  and  $D$ ) such that  $D$  satisfying (3) and this additional condition (4) is uniquely determined? In other words, whether do Riemannian structures  $G$  on a vector bundle have (induce canonically) linear connections (like Levi-Civita one)?

In this note we prove that the answer to the above question is negative. In fact, we prove a more general result that there is no canonical condition

$$(5) \quad C(G, D, \nabla)$$

determined by  $G, D$  and an additional classical linear connection  $\nabla$  on  $M$  such that  $D$  satisfying (3) and condition (5) is uniquely determined.

All manifolds and maps are assumed to be smooth (of class  $C^\infty$ ).

### 1. The main result

To present a mathematical formulation of the main result of the paper we need the following definition being a particular case of a definition of natural operators from [3].

Let  $\mathcal{VB}_{m,n}$  be the category of vector bundles with  $m$ -dimensional bases and  $n$ -dimensional fibres and their (local) vector bundle isomorphisms.

**DEFINITION 1.** A  $\mathcal{VB}_{m,n}$ -gauge natural operator  $A : C \times \text{Riem} \rightsquigarrow Q$  is a  $\mathcal{VB}_{m,n}$ -invariant family

$$A : \text{Con}_{\text{clas}}(M) \times \text{Riem}(E) \rightarrow \text{Con}(E)$$

of operators for any  $\mathcal{VB}_{m,n}$ -object  $E \rightarrow M$ , where  $\text{Con}_{\text{clas}}(M)$  is the set of all classical linear connections on  $M$ ,  $\text{Riem}(E)$  is the set of all Riemannian

structures on  $E \rightarrow M$  and  $Con(E)$  is the set of all linear connections on  $E \rightarrow M$ . The invariance means that if  $(\nabla_1, G_1) \in Con_{clas}(M_1) \times Riem(E_1)$  and  $(\nabla_2, G_2) \in Con_{clas}(M_2) \times Riem(E_2)$  are  $\Phi$ -related by an  $\mathcal{VB}_{m,n}$ -map  $\Phi : E_1 \rightarrow E_2$  then so are  $A(\nabla_1, G_1)$  and  $A(\nabla_2, G_2)$ .

Now, a negative answer of Question 1 follows (obviously) from the following theorem (which is the main result of the present note).

**THEOREM 1.** *There is no  $\mathcal{VB}_{m,n}$ -gauge natural operator  $A : C \times Riem \rightsquigarrow Q$  transforming Riemannian structures  $G : E \times_M E \rightarrow \mathbf{R}$  on vector bundles  $E \rightarrow M$  and classical linear connections  $\nabla$  on  $M$  into linear connections  $A(\nabla, G)$  on  $E \rightarrow M$ .*

### 2. Preparations to the proof of Theorem 1

In the proof of Theorem 2 we will use the following well-known facts.

**PROPOSITION 1.** ([2]) *Let  $\nabla$  be a classical linear connection on a connected manifold  $N$ . Then the group  $Aff(\nabla)$  of all  $\nabla$ -affine isomorphisms is a Lie group.*

**PROPOSITION 2.** ([4; Proposition 2.116]) *Let  $\nabla$  be a classical linear connection on a connected manifold  $N$ . Let  $f, g : N \rightarrow N$  be  $\nabla$ -affine maps. If  $j_x^1 f = j_x^1 g$  at some point  $x \in N$  then  $f = g$ .*

We will also use the following fact.

**PROPOSITION 3.** ([1], [3]) *Let  $D$  be a linear connection on a vector bundle  $E \rightarrow M$  and  $\nabla$  be a classical linear connection on  $M$ . Then there exists a unique classical linear connection  $\Gamma = \Gamma(D, \nabla)$  on the total space  $E$  with the following property*

$$\begin{aligned} \Gamma_{XD} Y^D &= (\nabla_X Y)^D, \quad \Gamma_{XD} s^V = (D_X s)^V, \\ \Gamma_{s^V} X^D &= 0, \quad \Gamma_{s^V} \sigma^V = 0, \end{aligned}$$

for all vector fields  $X, Y$  on  $M$  and all sections  $s, \sigma$  of  $E \rightarrow M$ . Here  $X^D \in \mathcal{X}(E)$  denotes the  $D$ -horizontal lift of  $X$  and  $s^V \in \mathcal{X}(E)$  means the vertical lift of  $s$ ,  $s^V(e) = [e + ts(x)]$ ,  $e \in E_x$ ,  $x \in M$ .

### 3. Proof of Theorem 1

Suppose that  $A : C \times Riem \rightsquigarrow Q$  is such a  $\mathcal{VB}_{m,n}$ -gauge natural operator. Let  $E = \mathbf{R}^m \times \mathbf{R}^n \rightarrow \mathbf{R}^m$  be the trivial vector bundle. Let  $G^o \in Riem(E)$  be the trivial Riemannian structure, i.e.  $G_x^o = \langle, \rangle : \mathbf{R}^n \times \mathbf{R}^n \rightarrow \mathbf{R}$  for any  $x \in \mathbf{R}^m$ , where  $\langle, \rangle$  is the standard scalar multiple on  $\mathbf{R}^n$ . Let  $\nabla^o$  be the usual flat classical linear connection on  $\mathbf{R}^m$ . Then on  $E$  we can define a classical linear connection

$$\Theta = \Gamma(A(\nabla^o, G^o), \nabla^o),$$

where operator  $\Gamma$  is defined in Proposition 3. We have a group monomorphism (injection)  $I : C^\infty(\mathbf{R}^m, O(n)) \rightarrow \text{Aut}(\mathbf{R}^m \times \mathbf{R}^n)$ ,  $I(B) : \mathbf{R}^m \times \mathbf{R}^n \rightarrow \mathbf{R}^m \times \mathbf{R}^n$ ,

$$I(B)(x, y) = (x, B(x)y) ,$$

$(x, y) \in \mathbf{R}^m \times \mathbf{R}^n$ . Given  $B \in C^\infty(\mathbf{R}^m, O(n))$ ,  $I(B)$  preserves  $\nabla^o$  and  $B^o$ . Then  $I(B)$  preserves  $A(\nabla^o, G^o)$  (because of the invariance of  $A$ ) and consequently  $I(B)$  preserves  $\Theta$  (because of the invariance of the construction  $\Gamma$ ). Then (in fact)  $I : C^\infty(\mathbf{R}^m, O(n)) \rightarrow \text{Aff}(\Theta)$  is a group inclusion. This is a contradiction because  $\text{Aff}(\Theta)$  is a Lie group (see Proposition 1) and  $C^\infty(\mathbf{R}^m, O(n))$  is not finite dimensional.

#### 4. Another proof of Theorem 1

Suppose that such operator  $A$  exists. We use the notations of Section 3. In particular,  $\Theta$  and  $I$  be as in Section 3. Consider  $B, C \in C^\infty(\mathbf{R}^m, O(n))$  such that  $B(0) = C(0)$  and  $B \neq C$ . Then  $I(B)$  and  $I(C)$  are  $\Theta$ -affine maps such that  $j_{(0,0)}^1(I(B)) = j_{(0,0)}^1(I(C))$  and  $I(B) \neq I(C)$ . Contradiction because of Proposition 2. ■
