ABSTRACT

Remediation of areas contaminated by potentially toxic elements (PTE) requires the appropriate assessment of the environmental mobility of contaminants. The fractionation techniques developed for agrochemical and environmental purposes model the pathways of environmental mobilization mainly by sequential extraction procedures. In Europe mostly the simplified extraction scheme proposed by Community Bureau of Reference (BCR) in 1993 is widely used, why only to this certified sediment sample (BCR 701) is available, certified for fractionation of six elements (Cu, Cd, Cr, Ni, Pb, Zn). In the BCR extracts the reagentsolvents applied in leaching steps cause strong matrix interferences when for determination the PTE-contents of these solutions the multielemental capacity of inductively coupled plasma optical emission spectrometry (ICP-OES) should be utilized. Due to the different source of contamination the flexible multi-elemental ICP-OES method should be applied for analysis of the different BCR-extractant-solvent media which makes possible the reliable detection of all occurring PTE in the area. For this purpose as the most adequate solution the application of ICP-OES spectrometer with charge-coupled device (CCD)-detection was selected which is able to record the entire spectral range between 120-800 nm. On the basis of detailed study of BCR-solvent-matrix- and expected-analite-line interferences it was established that the sensitivities of the prominent lines of pollutant elements strongly depend on the type of extractants. For improving the accuracy of analytical results obtained for soils and environmental sediments, matrix matched calibration, internal standardization and robust plasma conditions were recommended and optimized. The successful application of this methodology is presented for a PTE-contamited lake sediment sample and for selected typical Hungarian soil samples stored in sample bank of Hungarian Soil Protection Information and Monitoring System.

Keywords: potentially toxic element; sequential extraction; fractionation; ICP-OES; multielemental determination; sediments and soils.

1. INTRODUCTION

Mobility and biological impact of potentially toxic elements (PTE) is determined by the chemical speciation of these elements in the environmental systems. According to recommendation of IUPAC Committees [1] speciation means the quantitative distribution of a given element among its chemical species identifiable in the system. Total biological risk assessment in PTE-contaminated areas should be based on complete speciation of detectable

contaminant elements, however complete speciation is an impracticable analytical task, As a compromise, fractionation techniques were developed in which the solvents (reagents) modeling the pathways of environmental mobilization are applied sequentially for the extraction of PTE content of solid environmental samples as proposed by Tessier [2]. In Europe it is the simplified extraction scheme issued by Community Bureau of Reference (BCR) in 1993 and modified in 2001 that is most widely used [3, 4]. Up to now this has been only a fractionation procedure, to which certified sediment samples (BCR 601 and 701) were issued [4, 5, 6, 7, 8, 9, 10], therefore was it selected for present quality assessment studies.

In the 1st, 2nd and 3rd steps of the BCR procedure batch leaching technique is applied, the solid sediment or soil sample is shaken by the reagent-solvents for 16 hours and the extracts are separated by centrifugation respectively. By this way the chemical structures of the sediment or soil samples are gradually decomposed and the following mobility fractions of PTE can be distinguished:

1ststep: Water-soluble and carbonate-bound fraction, dissoluble in diluted acetic acid;

2ndstep: Associated with reducible Fe- and Mn-oxides, dissoluble in hydroxilamine hydrochloride;

 3^{rd} step: Organic complexed and sulphides, dissoluble after oxidation by H_2O_2 in ammonium-acetate;

(+1) step: Residual fraction, soluble by digestion in oxidative acids (HNO_3/H_2O_2) , or aqua regia).

The certification is given only for the 1^{st} , 2^{nd} and 3^{rd} fractions, for determination of the (+1) residual fraction and for direct analysis of PTE content of original BCR 701 CRM sample only indicative values are given for aqua regia extraction according to ISO Norm 11466 [11].

Standardization of the BCR procedure, however, has up to now been hindered by methodological problems:

- The solvents applied in the BCR system do not model natural mobilization processes and do not preserve intact species forms for further speciation analysis.
- The time demands of the batch leaching extraction steps is too long (4-5 days).
- Certified reference material (CRM) sample which is certified for the fractionation of six elements (Cu, Cd, Cr, Ni, Pb, Zn) is available only for freshwater sediments, therefore the extension of validation for other environmental matrices (soils, rocks, ores, solid wastes) and for further PTE is limited.
- The results of completion the BCR sequential extraction procedure is four solutions with the excess concentration of reagents applied in leaching steps. When for determination the PTE-contents of these solutions the multi-elemental capacity of spectrochemical analytical techniques like inductively coupled plasma optical emission spectrometry (ICP-OES) or inductively coupled plasma mass spectrometry (ICP-MS) should be utilized, we have to calculate with significant solvent-matrix interferences, which may strongly influence the reliability of analytical results.

Up to now methodological developments to improve the BCR system have been mainly focused on extraction procedures: continuous flow systems were developed [12, 13, 14, 15, 16,17], alternative reagents were applied [18, 19, 20, 21,22] and acceleration of batch leaching by sonication [23] or microwave treatment [24] was applied. A review of the methodological development of the BCR sequential extraction procedure was given in our previous papers [25a,b].

When the elaboration and the modification of BCR procedure was performed in 1993 and in 2001 the matrix interferences caused by the reagent content of BCR extractant-solvents during spectrochemical element detection were not systematically assessed. In those interlaboratory analytical campaigns all participating laboratories have applied their own

methodology and quality assurance individually for element analysis, and the results of different methods as applied in different laboratories were compared statistically to detect sources of methodological errors of analytical procedures [3, 4, 5, 6, 7, 8, 9, 10]. For the determination of Cu, Cd, Cr, Ni, Pb, Zn concentrations in BCR extracts flame atomic absorption spectrometry (FAAS), electrothermal atomization atomic absorption spectrometry (ETA-AAS), ICP-OES and ICP-MS methods were applied in the different laboratories and the solvent matrix interferences were mainly reduced by solvent-matrix-matched calibration and in several cases by standard addition. The calibrations were optimized for the above six elements individually and only in a few cases ICP-OES or ICP-MS multi-elemental calibration was applied.

In spite of the above methodological problems the application of BCR procedure in risk assessment of PTE-contaminations is exponentially growing. Most of the applications were elaborated for PTE contaminated sediments. Soils and other environmental matrices were less often considered, because CRM is available only for sediments to the BCR procedure. Demand for the extension of application and validation to more PTE in other matrices (soils, rocks, sewage sluids, red mud, gravitation dust, compost, biofilm, etc.), however, is continuously growing, and for this purpose the application of robust simultaneous multielemental spectrochemical methods with flexible selection of analite elements seems to be the optimal choice [26-49]. Considering this trend the main goal of our recent study was to support the extension of BCR-fractionation to different solid matrices and to more PTE by means of elaboration a robust and flexible multielemental ICP-OES methodology. For this purpose the HORIBA Jobin Yvon ACTIVA-M ICP-OES spectrometer was selected which is equipped with rapid scanning charge-coupled device (CCD)-detection system and is able to record and acquisite the entire spectral range between 120-800 nm and supplied with a data base of single-element spectra with spectroscopic data under standard ICP operating conditions for 75 elements [50,51]. This data base, the instrument arrengement and operation mode provides appropriate information for multi-line selection adopted to the analytical task [52]. The program suggests more lines for each analyte that are adequate for the defined concentration range and that are not interfered by the concomitant elements when they are present at their highest expected concentration. The number of lines to be suggested, as well as sensitivity and interference filtering criteria, are user-defined. The analyte spectrum can be displayed along with those of concomitant elements and the blank spectrum. This helps in the acceptance or rejection of a line, and to determine the correct background correction positions [52]. In the users manual there are several proposal for optimal conditions for multi-elemental analysis of different type of samples (aequeos, oil, organic, salt), however such a complex task as the sequential extraction when four different ageous solvent-matrix is applied requires additional study of matrix effects caused by BCR-extractants during multi-elemental ICP-OES determination, and a careful survey of spectral line coincidences of proposed analite lines [53, 54].

In a preliminary study BCR-solvent matrix matched multi-elemental ICP-OES calibration was applied for ten elements (Cd, Cr, Cu, Ni, Pb, Zn, Co, Fe, Mn, V) and the ICP-OES operating conditions were applied according to producer's manual proposal to aeqeous matrices [54] and accuracy of BCR procedure was controlled by fractionation of element content of BCR-701 sediment CRM sample. It was established that the sensitivity of ICP-OES determinations is strongly influenced by calibration solvent matrix, and the summarized recoveries of certified concentrations of the three certificated extraction steps are acceptable for all certified elements. However in the individual extraction steps for several elements are significantly outlying from the acceptable limits [25b]. For reliable application therefore this simple matrix matched calibration was not proved satisfactory and further improvement was necessary

based on study of the extractant-solvent matrix interferences [55] and controlling the interelement analite interferences. Utilizing the possibility of whole analytical spectral range acquisition the BCR solvent blank spectra, single elemental analite element spectra in each BCR solvent and finally the multi-elemental analite spectra in each BCR solvent were recorded with expected highest concentrations. All these spectra were stored in an electronic library and then the best interference-free spectral lines were selected on the basis of a detailed comparison of these spectra for all extractant media and for all analytical lines proposed by the instrument producer. After this the multi-elemental matrix matched calibration was repeated at elevated RF-power for reduction the solvent matrix effects [49, 55] with more robust plasma conditions, and internal standardization was applied to improve the reliability. Main goal of this methodological studies was the elaboration of such multielemental ICP-OES method which is flexibly and reliably applicable for evaluation of PTE-mobility in soils and in sediments by BCR-fractionation. The successful application of this optimalized method is presented on real lake-sediment and soil samples.

2. EXPERIMENTAL

2.1. BCR Sequential Extraction Procedure and its Quality Assessment

Quality assessment of BCR procedure with the CRM 701 sediment, reference sample was performed. The fractionation of its element content was performed according to the modified BCR protocol in triplicates, as described in Table 1 [10]. The 1st, 2nd and 3rd batch leaching steps were performed for 16 hours using a mechanical end-over-end shaker, at a speed of 240 ± 10 rpm, followed by centrifugation at 3000 g for 20 minutes.

Extraction	Extractant solvent	Element fraction
step		
1 st	0.11 M acetic acid (HOAc)	Exchangeable, water soluble, carbonate bound fraction
	0.5 M NH ₂ -OH·HCl (adjusted to	Reducible fraction (joint to Fe/Mn
2^{nd}	pH = 1.5	oxides, oxyhydroxides)
	by adding 25 mL 2 M HNO ₃)	
	(preliminary oxydization by	Oxidizable element fraction
3 rd	8.8 M H ₂ O ₂)	(bound to organic matter or
	then 1 M NH ₄ OAc ($pH = 2$)	sulphides)
(+1)	cc. HNO ₃ /H ₂ O ₂ microwave supported	Residual fraction (soluble in
(1)	digestion	oxydative acids)

 Table 1. The BCR sequential extraction scheme

For the extraction of residual fraction in the (+1) step microwave supported cc. HNO₃/H₂O₂ digestion was applied according to the former Hungarian Standard [56].

Total soluble element content of the CRM 701 sample was determined also by microwave supported cc. HNO_3/H_2O_2 digestion of the original sample.

The results of microwave supported cc. HNO_3/H_2O_2 digestion-extraction were compared with aqua regia digestion-extraction according to ISO Norm 11466 [11] and with microwave supported aqua regia digestion-extraction.

2.2. Element Analytical Instrument [54]

HORIBA Jobin Yvon ACTIVA-M ICP-OES spectrometer was employed, which is able to record the entire UV-VIS spectrum range by rapid scanning CCD detection.

Generator: radio frequency, solid-state, 40.68 MHz, water cooled, 800-1550 W.

Plasma: fully demountable torch (3 mm i.d., alumina injector) with software controlled gas flow system. The gas-flows can be set by switching between valves of fix nominal cross-flow capacity:

Plasma gas flow:	P1: 12 L/min,	P2: 16 L/min.	
Sheath gas flow:	G1: 0.3 L/min,	G2: 0.5 L/min,	G3: 0.7 L/min.
Auxiliary gas flow:	OFF: 0 L/min,	ON: 0.6 L/min.	
Nebulizer gas pressur	e:	2.86 bar.	

Sample introduction: concentric glass nebulizer, cyclonic glass spray chamber, 3 channels peristaltic pump. Aerosol transport by the sheath device (patented HORIBA Jobin Yvon system).

Optical system: thermo-regulated, 0.64 meter focal length, dual back-to-back gratings, 4343 g/mm and 2400 g/mm used in the 1^{st} order with optical resolution <10 pm for 120-430 nm and <18 pm for 430-800 nm.

Wavelength range: 120-800 nm, reference line set by the user (C 193.026 nm, or the Ar 404.442 nm).

Detection: back thinned illuminated CCD, 2048x512 pixels (13.5x13.5 µm), Peltier cooled.

2.3. ICP-OES Operational Parameters, Optimalization of Calibration

In the first stage of this study BCR-solvent matrix matched multi-elemental calibration was applied for ten elements (Cd, Cr, Cu, Ni, Pb, Zn, Co, Fe, Mn, V) applying operational analytical parameters and lines according to producer's manual proposed for multi-elemental analysis of environmental water samples (1st settings) [25b, 54]. Study of solvent matrix effects and spectral interferences was performed applying this 1st settings. Study of spectral interferences in the different calibration solutions is described in APPENDIX 1.

After that the matrix matched calibration was repeated at elevated RF-power and for all elements at least two analytical lines were selected (2nd settings) with gas flows proposed by producer to the applied RF-power. In 3rd settings the same RF-power was applied as in the 2nd settings but sheet gas flow was reduced and the Yttrium internal standard was applied, and interference-free analytical lines were selected for all elements (Table 2 and Table S2).

OPERATION PARAMETERS	1 st settings	2 nd settings	3 rd settings
Incident RF-power	1000 W	1200 W	1200 W
Outer gas flow (Argon)	13.14 L/min	15.94 L/min	15.94 L/min
Sheet gas flow (Argon)	0.32 L/min	0.62 L/min	0.32 L/min
Auxiliary gas flow (Argon)	OFF	0.604 L/min	0.604 L/min
Nebulizer gas pressure (Argon)	2.86 bar	2.86 bar	2.86 bar
Nebulizer solution uptake (Meinhardt-cyclonic spray chamber)	0.85 mL/min	0.85 mL/min	0.85 mL/min
Internal standard	-	-	1 mg/L Yttrium

Table 2. ICP-OES operational parameters during optimalization of calibration

2.4. Preparation of Matrix Matched Calibration Solutions

For preparing the calibration solutions MERCK CertiPUR ICP multi-element 1.11355.0100 standard solution was used, containing elements Ag, Al, B, Ba, Bi, Ca, Cd, Co, Cr, Cu, Fe, Ga, In, K, Li, Mg, Mn, Na, Ni, Pb, Sr, Tl, Zn in 1000 mg/L concentration. Volumes corresponding to 0, 5 and 20 mg/L concentrations were pipetted into a 50 ml volumetric flask and then diluted by solvents applied in the steps of BCR sequential extraction procedure:

1st step: 0.11 M acetic acid 2nd step: 0.5 M hydroxylamine-hydrochloride 3rd step: 1 M ammonium-acetate (+1) step: 13 (m/m)% nitric acid

3. RESULTS

3.1. Fractionation Results Obtained with BCR-solvent Matrix Matched Multi-elemental Calibration for the Three Different Operational Settings

At producer proposed analytical line wavelengths several spectral overlapping was occurred as described in APPENDIX 1. On Figure S1, S2, S3, S4 characteristic interelemental line coincidences are presented for Cd, Co, Pb and Zn lines proposed to application. As a result of interelemental line coincidence study it was estabilished that primary producer proposed analytical lines can be used for Cr, Cu, Fe, Mn, Pb, and Zn, but low level spectral interferences occur for Zn and Pb. For Cd, Co, Ni the primary proposed lines could not be used. As an example for result of rejection of primary proposed analytical line the analytical calibration lines obtained for Cd at three different operational settings in case of different solvents are presented on Figure S5(a). For comparison on Figure S5(b) the analytical calibration lines obtained for Zn using the primary proposed lines at three different operational settings in case of different solvents are presented.

For detailed comparison the parameters of analytical calibration lines, the background equivalent concentrations (BEC) and the instrumental detection limits $[LOD(3\sigma)]$ obtained for different extraction matrices at three different ICP-OES operational settings are summarized in Tables S3, S4, S5 of APPENDIX 2. Data in Table S3 of APPENDIX 2 were published earlier [25b], but as a reference for comparison is given there too.

It can be observed that the calibration solvent media strongly influences the slope of the analytical calibration lines (i.e. the B sensitivity values) at the three different operational settings. The residual standard deviation values show, that the best fitting of analytical lines was achieved at 3^{rd} operational settings. The solvent matrix influence can be easier compared if the B sensitivity values are normalized to the (+1) step solvent [13 (m/m) % nitric acid] while in general nitric acid medium is used in ICP-OES calibration (Table 3).

Element		1 st setting			2 nd setting	5	3 rd setting		
	HOAc	NH ₂ OH	NH ₄ OAc	HOAc	NH ₂ OH	NH ₄ OAc	HOAc	NH ₂ OH	NH ₄ OAc

V 309.311	1.013	1.014	1.217	1.228	1.313	0.681			

Table 3. The ratio of B sensitivity values in different extractant media related to the corresponding sensitivity values obtained in 13 (m/m) % nitric acid medium at the three operational setting.

V 311.071				1.224	1.285	0.700			
Zn 213.857	0.691	0.729	0.910	1.391	1.426	0.755	0.812	0.937	0.832
Zn 280.087				0.789	0.838	0.645			
AVERAGE	0.871	0.891	1.092	1.067	1.128	0.626	0.929	0.967	0.897

It can be established that at the 1st operational settings using the acetic acid and hydroxilamin-hydrocloride containing calibrant solvents significant decrease of sensitivity was obtained which mainly can be attributed to the nebulization matrix-effects [55]. On contrary the 1 M ammonium-acetate containing calibration solvent resulted in significant, but uneven increase of sensitivities for different elements. In this case probably chemical matrix interferences have overcompensated the nebulization-matrix effects.

When the incident RF-power was increased to get more robust plasma at 2^{nd} settings the reverse situation was experienced: in the acetic acid and hydroxilamin-hydrocloride containing calibrant solvents significant, but uneven increase of sensitivities was obtained while the ammonium-acetate containing calibration solvent resulted in dramatic decrease of sensitivities for different elements. These effects probably can be attributed to change of plasma shape due to the elevated sheet gas flow, while the position of observation height is fixedly set to optimal compromise conditions by the producer.

When **3rd settings** was used the sheet gas flow was reduced at elevated RF-power and Yttrium internal standard was applied. In this case the sensitivities in all three calibrant media shows more uniform picture the ratios in all cases are less than 1.000, in the case of acetic acid and hydroxilamin-hydrocloride containing calibrant solvents these differences are not significant. At this 3rd settings the background equivalent concentrations (BEC) are minimal and change in a narrow range supporting the right selection of Yttrium internal standard. If solutions of such diverse composition should be analyzed reliably application of an internal standard is necessary.

The robustness of the three plasma operational settings was controlled by the determination of intensity ratio of magnesium ionic and atomic lines [MgII(280.271 nm)/MgI(285.213 nm)] as proposed by J.M. Mermet [57]. The results summarized in Table 4 clearly show that the robustness of plasma drastically decreased at 2^{nd} operational settings and by the 3^{rd} operational settings was improved related to the 1^{st} operational settings which is proposed by the manufacturer to multi-elemental analysis of environmental water samples.

Der extracts. (In brackets wigi 205.215 min me/background mensity ratios are given.)						
BCR extractant	Intensity ratio of MgII(280.271 nm)/MgI(285.213 nm) lines					
	1 st settings	2 nd settings	3 rd settings			
0.11 M HOAc	8 (64.7)	3 (119.3)	9 (70.9)			
0.5 M NH ₂ OH·HCl	8 (61.3)	3 (137.3)	10 (66.7)			
1 M NH ₄ OAc	9 (64.6)	3 (55.0)	11 (66.5)			
13 (m/m) % HNO ₃	8 (61.7)	3 (142.8)	9 (70.4)			

Table 4. Results of robustness control of three operational settings by determination of the MgII(280.271 nm)/MgI(285.213 nm) ionic/atomic line intensity ratio measured in different BCR extracts. (In brackets MgI 285.213 nm line/background intensity ratios are given.)

Summarizing the above it may be concluded that improving the robustness of the plasma and elimination of matrix effects caused by the calibrant solvents is not possible by increasing the incident RF-power only while in this case the MgI 285.213 nm line/background intensity ratios were changed drastically and to achieve more robust conditions the sheet gas flow must be adopted properly.

3.2. Accuracy of fractionation applying the BCR-solvent Matrix Matched Multielemental Calibration

Accuracy of the above described improvement of calibration can be justified when we compare the fractionation results of the BCR-701 CRM sample applying the 1st and 3rd settings in Table 5. The measured concentrations of three repeated fractionations were compared by Student test with certified values. With the 1st operational settings at p = 1 % level in 11 case, while at p = 0.1 % level in 4 case the measured values significantly differ from the certified values. With the 3rd operational settings were no significant differences at p = 1 % level and at p = 5 % level was in 1 case significant difference (Cr 1st step).

Table 5. Average results and standard deviations of three repeated fractionation of PTE content of BCR-701 CRM sample using the 1st and 3rd ICP-OES operational settings. Symbol * means the significant difference at p = 1 % level and symbol ** means the significant difference at p = 0.1 % level.

Pb	158 ± 3.32	108 ± 10
Zn	418± 8.73	343 ± 18

With the operational parameters of third setting the fractionation of PTE content of BCR-701 CRM sample was performed in three repeation using:

(1) aqua regia digestion-extraction according to ISO Norm 11466 [11],

(2) microwave supported aqua regia digestion-extraction,

(3) microwave supported cc. HNO_3/H_2O_2 digestion-extraction

for determination of residual (+1) fraction and pseudototal fraction. The summaries of the $\Sigma[1^{st}+2^{nd}+3^{rd}+(+1)]$ fractions were compared with the pseudototal fractions statistically, there were no significant differences in the three above cases. On Figures S6(a) and S6(b) this comparison presented graphically for Cr and Ni.

3.3. Application for real samples

PTE-contaminated lake sediment

In our previous paper [25a] was published a longterm study of transformation of potentially toxic element pollution in a lake system Gödöllő by means of BCR-fractionation procedure. In Table 6 is presented the fractionation results of one of the most polluted sediment sample (Gödöllő-Lake VII. 0-10 cm layer) and the BCR CRM 701 sample. The reliability of the optimized ICP-OES method for evaluation of environmental mobility of PTE-pollution was controlled by the simultaneously performed fractionation of the BCR CRM 701 sample [25a].

Soil samples from Hungarian Soil Protection Information and Monitoring System (four different type)

In this study the applicability of BCR-fractionation for agrochemical purposes was studied using different

physical wives soil samples. For this study four samples (Sandy soil, Sandy loam soil, Loam soil and Clay soil) were selected and the information content of BCR fractionation was compared with the information content with single step extractions applied in agrochemical practice. This project is still running and hereby only the results of BCR fractionation for 11 elements are presented (Table S6). For BCR-procedure no soil CRM is available, therefore only for the pseudototal element content certified ERM-CC141 soil sample was applied for quality assessment (Table 7). These data clearly show that the BCR-procedure with the optimized ICP-OES element detection reliably applicable for agricultural soil analysis and the number of analite elements can be increased, accordingly with the agrochemical interest (A1, Ca, Fe, K, Mg, Mn, Na)

LOAM SOIL	Measured value	Certified value		
ERM-CC141	[mg/kg]	[mg/kg]		
Cd 214.441 nm	$0,25 \pm 0,03$	$0,25 \pm 0,04$		
Cr 205.571 nm	$37,7 \pm 1,8$	31 ± 4		
Cu 324.754 nm	$9,9 \pm 0,6$	$12,4 \pm 0,9$		
Mn 257.610 nm	324 ± 16	387 ± 17		
Ni 222.296 nm	$13,9 \pm 1,7$	$21,9 \pm 1,6$		
Pb 220.353 nm	$27,0 \pm 2,11$	$32,2 \pm 1,4$		
Zn 213.857 nm	$40,3 \pm 3,6$	50 ± 4		

Table 7. Measured pseudototal PTE concentrations and certified concentrations of a soil CRM sample.

4. CONCLUSION

It can be concluded that optimalization of the flexible multielemental calibration for various solvent matrices gained by BCR-sequential extraction is necessary even when we apply it for fractionation of PTE content of freshwater-lake sediments. In this case the reliability of the fractionation results can be strictly controlled by simultaneous fractionation of BCR CRM 701 sample as it seems in Table 6. This procedure was successfully applied for controlling the remediation of PTE contaminated lakes like the Gödöllő-lake system [25a, 15, 22, 48]. For characterization of environmental mobility of PTE, and other micro- and macroelement content of soils the optimalized ICP-OES method can be applied successfully too. In these case the lack of soil CRM certified for BCR-fractionation does not make possible the strict control of accuracy of 1st, 2nd, and 3rd BCR-extraction step, only the pseudototal element content can be controlled by analysis of appropriate soil CRM samples. The reliability in this case can be evaluated on the basis of comparison of the sum of $[1^{st}+2^{nd}+3^{rd}+(+1)]$ fractions with the certificated pseudototal values. This comparison for data presented in Table S6 has shown an acceptable agreement. The application of BCR-fractionation for different type soil seems to be advantageous related to single step extraction procedures applied in agrochemical practice [56]. By this way about the biologically available PTE content can be characterized better and relationships with the soil properties can be also estimated. For example the of lime content. Fe-and Mn-oxides. and the humus influence content for mobilization/immobilization processes can be evaluated. This question is the subject of our ongoing project in this field. Recently this methodology is being applied for study of PTEand radionuclide migration in a spoil area of the abandoned Uranium mine in Hungary too.

ACKNOWLEDGEMENT

This work was supported the Hungarian Scientific Research Fund (OTKA 108558, 118101). This research was supported by the Higher Education Institutional Excellence Program (1783-3/2018/FEKUTSTRAT) awarded by the Ministry of Human Capacities within the framework of water related researches of Szent István University.

APPENDIX

1. STUDY OF SPECTRAL INTERFERENCES IN THE DIFFERENT CALIBRATION SOLUTIONS

To detect the interfering line coincidences the following spectra were recorded in the 185-400 nm range applying the 1st operational settings:

- In 0.11 M acetic acid:
 5 mg /L mono-elemental Cd, Co, Cr, Cu, Fe, Mn, Ni, Pb, V, Zn solutions;
 5 mg/L multi-elemental (Cd, Co, Cr, Cu, Fe, Mn, Ni, Pb, V, Zn) solution.
- In 0.5 M hydroxylamine-hydrochloride:
 -- 5 mg dm⁻³ mono-elemental Cd, Co, Cr, Cu, Fe, Mn, Ni, Pb, V, Zn solutions;
 -- 5 mg dm⁻³ multi-elemental (Cd, Co, Cr, Cu, Fe, Mn, Ni, Pb, V, Zn) solution.
- In 1 M ammonium-acetate:
 -- 5 mg dm⁻³ mono-elemental Cd, Co, Cr, Cu, Fe, Mn, Ni, Pb, V, Zn solutions;
 -- 5 mg dm⁻³ multi-elemental (Cd, Co, Cr, Cu, Fe, Mn, Ni, Pb, V, Zn) solution.
- In 13 (m/m)% nitric acid:
 -- 5 mg dm⁻³ mono-elemental Cd, Co, Cr, Cu, Fe, Mn, Ni, Pb, V, Zn solutions;
 -- 5 mg dm⁻³ multi-elemental (Cd, Co, Cr, Cu, Fe, Mn, Ni, Pb, V, Zn) solution.

For preparation of monoelemental solutions mono-elemental standard solution (Précis Certified Standards for ICP Spectroscopy, HORIBA Scientific, France) were used.

All these spectra were stored in an electronic library and then the best interference-free spectral lines were selected on the basis of a detailed comparison of these spectra for all calibrant media and for all analytical lines proposed by the instrument producer. The results of the detectable interferences are summarized in Table S1. These results were considered when analytical lines were selected for 3rd settings operational conditions. It can be seen that primary proposed analytical lines could be used for Cr, Cu, Fe, Mn, Pb and Zn, but in some cases one has to calculate with some low level spectral interferences (Zn, Pb). For Cd, Co, Ni and V the primary proposed lines could not be used. Some tipical overlapping are presented on Figures S1, S2, S3, S4.

Figures S1. Ni and Cd overlapping at 361 nm

Figures S2. Pb and Cu overlapping at 224 nm

Figures S3. Pb and Co overlapping at 261 nm

Figures S4. Zn and Cu overlapping at 213 nm

·· · · ·			
c: commeasurable intensity, I	: lower than 1:10 intensity	y ratio, h : higher than	10:1 intensity ratio.

Table S2. Analytical lines selected at different operational settings. In the case of 1st, 2^{nd} , and the (+1) extracts the wavelength readout was started from the C 193.026 nm reference line. In

the case of 3rd extracts, correct wavelength readout was only possible when the readout was started from the Ar 404.442 nm reference line due to the high C-content of 1 M ammonium-acetate solution.

2. PARAMETERS OF ANALYTICAL CALIBRATION LINES, THE BACKGROUND EQUIVALENT CONCENTRATIONS (BEC) AND THE INSTRUMENTAL DETECTION LIMITS [LOD(3σ)] OBTAINED FOR DIFFERENT BCR-EXTRACTION-SOLVENT MATRICES AT THREE DIFFERENT ICP-OES OPERATIONAL SETTINGS

Table S3. The parameters of calibration lines (I = A+Bc), at wavelength λ in nm, correlation R² values, the relative residual standard deviations (RSD %), the background equivalent concentrations (BEC) in μ g/L and the instrumental detection limits [C_L(3 σ)] in μ g/L obtained for 1st setting of operational parameters in case of different solvents [24].

Table S5. The parameters of calibration lines (I = A+Bc), at wavelength λ in nm, correlation R² values, the relative residual standard deviations (RSD %), the background equivalent concentrations (BEC) in μ g/L and the instrumental detection limits [C_L(3 σ)] in μ g/L obtained for 3rd setting of operational parameters in case of different solvents.

Figure S6. Comparison of the summaries of the $\Sigma[1^{st}+2^{nd}+3^{rd}+(+1)]$ fractions with the pseudototal fractions for Cr (a) and Ni (b) applying (1) aqua regia digestion-extraction according to ISO Norm 11466 [11], (2) microwave supported aqua regia digestion-extraction, (3) microwave supported cc. HNO₃/H₂O₂ digestion-extraction for determination of residual (+1) fraction and pseudototal fraction.

3. APPLICATION of BCR FRACTIONATION for DIFFERENT TEXTURE TYPE SOILS

Steps	Elements	Sandy soil (I 1904)	Sandy loam soil (1 0509)	Loam soil (I 1104)	Clay soil (I 4615)
