BOUNDARY LIMIT THEORY FOR FUNCTIONAL LOCAL TO UNITY REGRESSION

ANNA BYKHOVSKAYA AND PETER C. B. PHILLIPS

ABSTRACT. This paper studies functional local unit root models (FLURs) in which the autoregressive coefficient may vary with time in the vicinity of unity. We extend conventional local to unity (LUR) models by allowing the localizing coefficient to be a function which characterizes departures from unity that may occur within the sample in both stationary and explosive directions. Such models enhance the flexibility of the LUR framework by including break point, trending, and multi-directional departures from unit autoregressive coefficients. We study the behavior of this model as the localizing function diverges, thereby determining the impact on the time series and on inference from the time series as the limits of the domain of definition of the autoregressive coefficient are approached. This boundary limit theory enables us to characterize the asymptotic form of power functions for associated unit root tests against functional alternatives. Both sequential and simultaneous limits (as the sample size and localizing coefficient diverge) are developed. We find that asymptotics for the process, the autoregressive estimate, and its t statistic have boundary limit behavior that differs from standard limit theory in both explosive and stationary cases. Some novel features of the boundary limit theory are the presence of a segmented limit process for the time series in the stationary direction and a degenerate process in the explosive direction. These features have material implications for autoregressive estimation and inference which are examined in the paper.

Keywords and phrases: Boundary asymptotics, Functional local unit root; Local to unity; Sequential limits; Simultaneous limits; Unit root model

1. INTRODUCTION

Time varying coefficient models have been extensively used in applied econometric work and provide a natural mechanism for a model to evolve over time. Various approaches have been studied in the literature, including early work originally published in 1971 by Swamy (2012) on random coefficients, explicit parametric time series formulations (Harvey (1990)), time varying probability measures that are implied in Bayesian autoregressions

(Phillips and Ploberger (1994)) and recent non-parametric work using kernel regression methods (Gao et al. (2008), Kristensen (2012), Giraitis et al. (2014)). The latter developments have emphasized the flexibility of nonparametric formulations and smooth transition approaches of capturing temporal coefficient evolution. Both these ideas have been used in practical econometric work. They also provide a mechanism for modeling nonstationarity through the vehicle of nearly integrated time series without insisting on a fixed local unit root structure, thereby accommodating departures from unity in both stationary and explosive directions that can evolve over time (Phillips and Yu (2011); Greenaway-McGrevy and Phillips (2016)). Such models are called functional local unit root models (FLURs). They were recently studied in Bykhovskaya and Phillips (2017) in the context of point optimal unit root tests, showing how different the power envelope can be when the departures from a unit root are time varying.

The advantage of FLUR models compared to the standard local unit root (LUR) model (Phillips (1987), Chan and Wei (1987)) is that they explicitly allow the autoregression coefficient θ to vary with time, while retaining proximity to a unit root. This proximity is achieved through the specification $\theta_{tn} = 1 + \frac{c(t/n)}{n}$ which involves a localizing time varying coefficient function $c(\frac{t}{n})$ dependent on the position of observation t within the sample of size n . With this FLUR mechanism we can model economic and financial data that are well described in parts of the sample as unit root processes and yet subject to episodes of booms, busts, and recoveries at other times during the same sample period. Bykhovskaya and Phillips (2017) developed a limit theory for the FLUR process and analyzed some of the properties of functional point optimal unit root tests in comparison with standard (scalar) point optimal tests, showing that the latter delivers power that is often well below the optimal (functional) power envelope. This power deficiency of the standard point optimal test reflects the limitation of specifications that involve constant unidirectional departures from unity throughout the sample period when the data involves more complex forms of behavior, such as periods of intermittent departures from a unit root or periods of financial exuberance and collapse.

The present paper studies the same FLUR model as Bykhovskaya and Phillips (2017) and examines behavior as the localizing function $c(\frac{t}{n})$ diverges, thereby determining the impact on the properties of the time series as the limits of the domain of definition of the autoregressive coefficient are approached. This boundary limit theory enables us to characterize the asymptotic form of power functions for associated unit root tests when the alternatives involve time varying functional forms of differing types. The results therefore extend the original work on boundary limit behavior of LUR models as a scalar localizing coefficient c approaches the limits of its domain of definition. In contrast to this earlier work, the asymptotics for the process itself, the autoregressive estimate, and its associated t statistic are all found to have boundary limit behavior that differs from standard limit

theory in the explosive and stationary directions. Novel features of this boundary limit theory in the functional case are the presence of a segmented limit process for the time series in the stationary direction, a degenerate process in the explosive direction, and more complex function-dependent centering and standardization in the limit theory for the autoregressive coefficient estimator. These results differ markedly from the boundary limit theory that applies as the scalar localizing coefficient $c \rightarrow \pm\infty$ in the standard LUR model developed in Phillips (1987).

The paper is organized as follows. Some preliminary limit theory is given in the following section. Section 3 develops the boundary limit theory as the localized coefficient function $c(\cdot) \rightarrow \pm\infty$, which enables us to explore properties of the process at the limits of its domain of definition. Section 4 considers some mildly integrated (Phillips and Magdalinos (2007)) FLUR cases and the corresponding limit behavior at the boundary. This framework is of particular interest because it enables the analysis of asymptotics as $c(\cdot) \rightarrow \infty$ and $n \rightarrow \infty$ jointly, which has proved to be particularly useful in the study of uniform inference (Giraitis and Phillips (2006), Mikusheva (2007)). Implications of the findings are discussed in Section 5. Proofs are given in the Appendix.

2. PRELIMINARIES

To fix ideas, we consider a time series generated by the model

$$(1) \quad X_t = \theta_{tn} X_{t-1} + u_t, \quad t = 0, 1, \dots, n,$$

where the autoregressive coefficient $\theta_{tn} = \exp\left(\frac{c(t/n)}{n}\right) \approx 1 + \frac{c(t/n)}{n}$, the process X_t is initialized at $X_{-1} = o_p(\sqrt{n})$ and the disturbances u_t are zero mean stationary with variance σ^2 and partial sums that satisfy the functional law $\sum_{t=1}^{\lfloor nr \rfloor} u_t \xrightarrow[n \rightarrow \infty]{d} B(r)$, a Brownian motion with variance $\omega^2 = \mathbb{E}u_0^2 + 2 \sum_{h=1}^{\infty} \mathbb{E}u_0 u_h$, primitive conditions for which are widely available (e.g., Phillips and Solo (1992)).

Time series generated by (1) are near integrated arrays with a localizing coefficient function $c\left(\frac{t}{n}\right)$ that allows for variation in the autoregressive coefficient according to the position in the sample while retaining proximity to unity. The model is therefore a time varying coefficient model in the vicinity of unity. It is a particularly useful framework for studying the effects of departures from simple unit root and LUR models to more complex time series behavior.

Bykhovskaya and Phillips (2017) show that upon standardization the process X_t satisfies the mentioned below functional law with a Gaussian limit process which extends the limit theory for LUR time series. In what follows, we confine attention to finite variance

processes, Gaussian limit processes and functionals of them. Certain extensions to infinite variance processes and stable limit processes are also possible but will not be pursued here.

Lemma 1.

$$(2) \quad n^{-\frac{1}{2}} X_{\lfloor nr \rfloor} \xrightarrow[n \rightarrow \infty]{} F_c(r) := \omega K_c(r) = \omega \int_0^r e^{\int_s^r c(a) da} dW(s),$$

where W is standard Brownian motion and $K_c(r)$ satisfies the following nonlinear diffusion equation $dK_c(r) = c(r)K_c(r)dr + dW(r)$.

When $c(r) = c$ is constant throughout the sample, the limit process $K_c(r)$ reduces to the linear diffusion $\int_0^r e^{c(r-s)dk} dW(s)$ studied in Phillips (1987) and Chan and Wei (1987). In this LUR case, locally stationary and locally explosive time series occur according to the sign of c . Moreover, as $c \rightarrow \pm\infty$, LUR asymptotics of the centred least squares estimate of θ and its t ratio transition to the asymptotics for stationary and explosive time series. This transition provides a linkage between the limit theory for unit root, local unit root, stationary, and explosive models.

The following sections explore the behavior of certain functionals of $K_c(r)$ as $c(\cdot)$ approaches the limits of its domain of definition. This limit behavior is of interest because it describes the links between near-integrated time series of the FLUR class (1) and time series that transition between unit root, stationary, and explosive processes. Correspondingly, this limit theory captures the limiting forms of the power functions of unit root tests at the limits of the domain of definition of $c(r)$. In particular, when $c(\cdot) \rightarrow \pm\infty$, the limit theory determines whether unit root tests are consistent against certain functional alternatives to a unit root in both stationary and explosive directions and the role of functional shape in determining power.

The fixed coefficient autoregression can be viewed as a special case of the FLUR model with $c(r) = n \times const$ and $const \neq 0$. Thus, taking limits as $c(\cdot) \rightarrow \pm\infty$ may be viewed as delivering an approximate route to standard autoregression at least when $c(r) \neq 0$ for all r . Our primary interest in the present paper, however, concerns cases in which $c(r) = 0$ and $c(r) \neq 0$ occur over complementary subperiods, thereby allowing for finite sample episodes of unit root and FLUR behavior within the same sample of observations. Boundary limit theory as $c(\cdot) \rightarrow \pm\infty$ then reveals the asymptotic impact of these subperiod extremes of stationarity and explosiveness. As usual in multidimensional asymptotics (Phillips and Moon, 1999), there are two possibilities: sequential and simultaneous limit theory. The following section considers sequential limits, when first n goes to infinity and then $c(\cdot)$ goes to either plus or minus infinity. This limit theory extends to the FLUR environment the sequential asymptotics for LUR models (Phillips (1987)). Later we develop pathwise joint limit theory that provides simultaneous asymptotics under the condition that $k_n =$

$n/c \rightarrow \pm\infty$. These pathwise joint limits implement in the FLUR setting the concept of mild integration/mild explosiveness that was developed in Phillips and Magdalinos (2007).

Our discussion concentrates on the use of ordinary least squares (OLS) regression on (1). This focus is useful because the limit theory (both as $n \rightarrow \infty$ and the boundary limit theory where $c(\cdot) \rightarrow \pm\infty$) shows the impact on the standard OLS estimator and associated tests of episodes of near integration that take a general functional form of departure from unity. The theory also provides asymptotic power function behavior of unit root tests against such general alternatives in which there may still exist periods of unit root behavior. The presence of near integration in the generating process of X_t is unknown and, in practice, unknowable given that the localizing coefficient is not consistently estimable. It is therefore of wide interest to understand the properties of standard OLS regression under general functional departures from unity. Issues of confidence interval construction and the potential for uniform inference in the presence of such function departures are considered in other ongoing work (Phillips (2017)).

3. LIMIT DISTRIBUTIONS AS $c(\cdot) \rightarrow \pm\infty$

One advantage of the FLUR specification is that use of a localizing function $c(\cdot)$ rather than a constant c in characterizing departures from unity accommodates subsample unit root behavior whenever the localizing function is zero. As might therefore be expected, asymptotic behavior can vary considerably depending on the specific form and properties of $c(\cdot)$. Regions of zero and non-zero values of $c(\cdot)$ turn out to be particularly important in the limit theory as they switch unit root behavior on and off during the sample. The impact of such switches are naturally magnified as $c(\cdot)$ approaches the limits of its domain of definition.

This section investigates the impact of switching behavior on the limit theory by considering localizing functions $c(\cdot)$ that switch from zero over some interval $[0, r_1]$ to non-zero values over $(r_1, r_2]$ and switch back to zero on $(r_2, 1]$ for $0 < r_1 < r_2 < 1$. This specification enables us to study rather general forms of subperiod near integration and near explosiveness in the data on the asymptotic behavior of FLUR autoregressions.

To capture boundary behavior we model passage to the limit $c(\cdot) \rightarrow \pm\infty$ via the specification $c(t) = c \cdot f(t)$, where c is a scalar that passes to $\pm\infty$, and $f(\cdot)$ is a given integrable function of constant sign, designating the direction of the departure from unity. The model therefore has the form (1) with time varying coefficient

$$(3) \quad \theta_{tn} = \begin{cases} 1, & t \leq \tau_1 = \lfloor nr_1 \rfloor, \\ 1 + \frac{cf(t/n)}{n}, & t \in (\tau_1, \tau_2], \tau_2 = \lfloor nr_2 \rfloor \\ 1, & t > \tau_2, \end{cases}$$

where the function $f(\cdot)$ is zero outside $[r_1, r_2]$, integrable on $[r_1, r_2]$, and strictly positive on (r_1, r_2) . Simple examples include level partial departures from unity such as $f(x) = \mathbf{1}\{x \in [r_1, r_2]\}$, triangular departures such as $f(x) = (x - r_1)\mathbf{1}\{x \in [r_1, \bar{r}]\} + \frac{\bar{r} - r_1}{\bar{r} - r_2}(x - r_2)\mathbf{1}\{x \in (\bar{r}, r_2]\}$ or various smooth variants of such functions.

Using (3) and iterative back-substitution for X_t in (1) we have the solution

$$X_t = \left\{ X_{-1} + \sum_{s=0}^t u_s \right\} \mathbf{1}\{t \leq \tau_1\} + \left\{ \sum_{j=0}^{t-\tau_1-1} u_{t-j} \prod_{l=0}^{j-1} \theta_{t-l,n} + X_{\tau_1} \prod_{l=0}^{t-\tau_1-1} \theta_{t-l,n} \right\} \mathbf{1}\{t \in (\tau_1, \tau_2]\} \\ + \left\{ \sum_{s=\tau_2+1}^t u_s + X_{\tau_2} \right\} \mathbf{1}\{t > \tau_2\},$$

showing the presence of two periods of unit root behavior that occur at the start and at the end of the sample. Intermediate between these periods is an episode in which the process evolves with a time varying parameter in the vicinity of unity.

The following subsections examine limit behavior in two boundary cases corresponding to stationary ($c < 0$) and explosive ($c > 0$) departures from unity as the extent of the departure $|c| \rightarrow \infty$ while retaining the same functional form for the localizing coefficient function $f(\cdot)$. Sequential limits are used in the following three theorems and these limits employ the notation $(-c, n)_{seq} \rightarrow \infty$ for limits in which $n \rightarrow \infty$ followed by $c \rightarrow -\infty$, and similarly $(c, n)_{seq} \rightarrow \infty$ denotes limits in which $n \rightarrow \infty$ followed by $c \rightarrow \infty$. We look first at the stationary boundary.

3.1. Sequential limits when $c(\cdot) \rightarrow -\infty$.

Theorem 1. *The standardized process $\frac{X_{\lfloor nr \rfloor}}{\sqrt{n}}$, the least squares estimate $\hat{\theta}_{OLS}$ of θ_{tn} , and the associated t -ratio centered on unity have the following limit behavior under sequential limits in which $n \rightarrow \infty$ followed by $c \rightarrow -\infty$:*

$$(4) \quad \frac{X_{\lfloor nr \rfloor}}{\sqrt{n}} \xrightarrow[(-c, n)_{seq} \rightarrow \infty]{d} B^a(r) \times \mathbf{1}\{0 \leq r \leq r_1\} + B^b(r) \times \mathbf{1}\{r_2 < r \leq 1\},$$

$$(5) \quad n \left(\hat{\theta}_{OLS} - 1 - \frac{\int_0^1 cf(r)F_c^2(r)dr}{n \int_0^1 F_c^2(r)dr} \right) \\ \xrightarrow[(-c, n)_{seq} \rightarrow \infty]{d} \frac{\int_0^{r_1} B^a(r)dB^a(r) + \int_{r_2}^1 B^b(r)dB^b(r) + \lambda}{\int_0^{r_1} B^a(r)^2dr + \int_{r_2}^1 B^b(r)^2dr},$$

$$(6) \quad n \left(\hat{\theta}_{OLS} - 1 \right) \\ \xrightarrow[(-c, n)_{seq} \rightarrow \infty]{d} \frac{\int_{r_2}^1 B^b(r)dB^b(r) + \lambda - \frac{1}{2}\omega^2 r_2}{\int_0^{r_1} B^a(r)^2dr + \int_{r_2}^1 B^b(r)^2dr},$$

$$(7) \quad t_{\hat{\theta}_{OLS}} \xrightarrow[(-c,n)_{seq} \rightarrow \infty]{d} \frac{\int_{r_2}^1 B^b(r) dB^b(r) + \lambda - \frac{1}{2}\omega^2 r_2}{\sigma \left(\int_0^{r_1} B^a(r)^2 dr + \int_{r_2}^1 B^b(r)^2 dr \right)^{1/2}},$$

where B^a and B^b are independent Brownian motions with variance ω^2 , and $\lambda = \frac{1}{2}(\omega^2 - \sigma^2)$.

The limit (4) is a segmented Brownian motion process which vanishes on the interval where $f(r) > 0$ and has independent Brownian motion segments on the intervals $[0, r_1]$ and $(r_2, 1]$ where the localizing function $f(r) = 0$. When the one-sided long run covariance $\lambda = 0$, the limit distribution of the random-centred least squares estimate $\hat{\theta}_{OLS}$ given by (5) has the simpler form

$$n \left(\hat{\theta}_{OLS} - 1 - \frac{\int_0^1 cf(r)F_c^2(r)dr}{n \int_0^1 F_c^2(r)dr} \right) \xrightarrow[(-c,n)_{seq} \rightarrow \infty]{d} \frac{\int_0^{r_1} B^a(r)dB^a(r) + \int_{r_2}^1 B^b(r)dB^b(r)}{\int_0^{r_1} B^a(r)^2 dr + \int_{r_2}^1 B^b(r)^2 dr},$$

which we call a segmented unit root limit distribution because of the excision of the subperiod $[r_1, r_2]$ in the numerator and denominator integrals. When $r_1 = 1$ or $r_2 = 0$ there is no episode of near integration and this distribution corresponds to the standard unit root distribution. As is apparent from the form of (5), the OLS estimate $\hat{\theta}_{OLS}$ has random centering that involves the component $\int_0^1 cf(r)F_c^2(r)dr / \int_0^1 F_c^2(r)dr$. As shown in the proof, when $c \rightarrow -\infty$, this centering can be replaced by unit centering, but with an impact on the limit distribution as evident in the form of the limit density for the (non-random) unit-centred density given in (6).

Figure 1 shows the asymptotic density of the unit-centred (6) OLS estimate $n(\hat{\theta}_{OLS} - 1)$ for $\lambda = 0$, $\omega = 1$, $r_1 = 1/3$, $r_2 = 2/3$ along with the densities of the corresponding segmented (5) and standard unit root densities for comparison. All these densities are skewed and have a typical unit root distributional shape with a long left tail. The standard unit root density has the largest skewness and most dispersion, the segmented unit root has the least skewness and dispersion, and the unit-centred OLS density is the most left shifted, showing how miscentering accentuates the downward bias in the limit distribution. These shapes become more distinct as $r_1 \rightarrow 0$ and $r_2 \rightarrow 1$.

These results reveal the substantial impact that FLUR specifications have on near unit root limit theory. In the standard LUR model as the localizing scalar parameter $c \rightarrow -\infty$, the correctly centred and scaled OLS estimate has a boundary limit normal distribution that correctly reproduces the standard stationary case limit theory. This uniformity in the limit theory plays an important role in the construction of uniform inference procedures (Mikusheva (2007); Mikusheva (2012); Phillips (2014)). In the FLUR model, the boundary limit theory has greater complexity that reflects features of the

FIGURE 1. Densities of the OLS estimate, unit root, and segmented unit root for $\lambda = 0$, $\omega = 1$, $r_1 = 1/3$, $r_2 = 2/3$.

localizing coefficient function even in the limit as $c \rightarrow -\infty$ and this no longer generally reproduces the stationary limit theory. In particular, the form of the localizing coefficient function plays a role in correct centering of the distribution, when this centering is random. When there are episodes of unit root behavior in the process, these episodes continue to impact the limit theory at the boundary.

The boundary limits (6) and (7) show that both the coefficient-based and t-ratio unit root tests are inconsistent against the alternative of breaks that involve subperiods of stationarity. When there are subperiods of unit root behavior in the data, the tests do not diverge and therefore fail to detect the existence of stationary episodes in the sample with probability one as $c \rightarrow -\infty$.

3.2. Sequential limits when $c(\cdot) \rightarrow \infty$.

Theorem 2. *Upon appropriate standardization, the process $\frac{X_{\lfloor nr \rfloor}}{\sqrt{n}}$, the least squares estimate $\hat{\theta}_{OLS}$ of θ_{tn} , and the associated t-ratio centered on unity have the following limit behavior under sequential limits in which $n \rightarrow \infty$ followed by $c \rightarrow \infty$:*

$$(8) \quad \left(e^{-c \int_{r_1}^{r_2} f(a) da} \right) \frac{X_{\lfloor nr \rfloor}}{\sqrt{n}} \xrightarrow[(c,n)_{seq \rightarrow \infty}]{d} B^a(r_1) \times \mathbf{1}\{r_2 \leq r \leq 1\},$$

$$(9) \quad e^{c \int_{r_1}^{r_2} f(a) da} n \left(\hat{\theta}_{OLS} - 1 - \frac{\int_0^1 c f(r) F_c^2(r) dr}{n \int_0^1 F_c^2(r) dr} \right) \xrightarrow[(c,n)_{seq \rightarrow \infty}]{d} \frac{1}{\sqrt{r_1(1-r_2)}} \mathcal{C},$$

$$(10) \quad n \left(\hat{\theta}_{OLS} - 1 \right) \xrightarrow[(c,n)_{seq \rightarrow \infty}]{d} \frac{1}{2(1-r_2)},$$

$$(11) \quad e^{-c \int_{r_1}^{r_2} f(a) da} t_{\hat{\theta}_{OLS}} \xrightarrow[(c,n)_{seq} \rightarrow \infty]{d} \frac{\omega \sqrt{r_1}}{2\sigma \sqrt{1-r_2}} |\mathcal{N}(0, 1)|,$$

where B^a is a Brownian motion with variance ω^2 , and \mathcal{C} is standard Cauchy.

As shown in the proof of the theorem in (44), the limit behavior of $X_{[nr]}$ as $n \rightarrow \infty$ has the form

$$\frac{X_{[nr]}}{\sqrt{n}} \rightarrow F_c(r) = \begin{cases} B^a(r), & r \leq r_1, \\ J_c(r; r_1), & r_1 < r \leq r_2, \\ B^b(r) + J_c(r_2; r_1), & r_2 < r \leq 1; \end{cases}$$

with independent Brownian motion components $B^a \perp B^b$ and nonlinear diffusion component

$$J_c(r; r_1) = \int_0^r e^{c \int_s^r f(a) da} dB(s) = e^{c \int_{r_1}^r f(a) da} B^a(r_1) + \int_{r_1}^r e^{c \int_s^r f(a) da} dB(s).$$

As $c \rightarrow \infty$ the FLUR period of explosive behavior dominates through the presence of $J_c(r; r_1)$. In particular, we have $X_{[nr]} \sim \sqrt{n} e^{c \int_{r_1}^r f(a) da} B^a(r_1) \times \mathbf{1}\{r_1 \leq r \leq r_2\}$ and, as in (8), $X_{[nr]} \sim \sqrt{n} e^{c \int_{r_1}^{r_2} f(a) da} B^a(r_1) \times \mathbf{1}\{r_2 \leq r \leq 1\}$, showing that the process diverges exponentially from the level $\sqrt{n} B^a(r_1)$ when $r > r_1$. Thus, over the period $[0, r_1]$ the standardized process $n^{-1/2} X_{[nr]}$ evolves as a unit root process and reaches the limit value $B^a(r_1)$ at $r = r_1$, at which point a break occurs in the generating mechanism and the process evolves in an explosive FLUR way that inflates the initial condition reached at $r = r_1$. This behavior continues until $r = r_2$ when unit root behavior re-commences but from an explosive initial condition given by $J_c(r_2; r_1)$.

Correspondingly from (9), an appropriately centred OLS estimate $\hat{\theta}_{OLS}$ has an explosive rate of convergence with rate $e^{c \int_{r_1}^{r_2} f(a) da} \times n$. In this case, the centering is the random quantity $1 + \int_0^1 c f(r) F_c^2(r) dr / n \int_0^1 F_c^2(r) dr$, which depends on the scale coefficient c , the function $f(\cdot)$ and the stochastic process $F_c(r)$. When $c \rightarrow \infty$, as shown in the proof of the theorem, the random component of this centering element approaches a constant, satisfying

$$(12) \quad \frac{\int_0^1 c f(r) F_c^2(r) dr}{\int_0^1 F_c^2(r) dr} \xrightarrow[c \rightarrow \infty]{d} \frac{1}{2(1-r_2)},$$

which leads to (10). Thus, the coefficient-based unit root test $n(\hat{\theta}_{OLS} - 1) = O_p(1)$ as $(c, n)_{seq} \rightarrow \infty$ and therefore the test fails to diverge in the presence of an internal subperiod $(r_1, r_2]$ of explosive behavior in the FLUR model even at the boundary as $c \rightarrow \infty$. However, because the limit $\frac{1}{2(1-r_2)} > 0$, the test does have non-trivial power at the boundary limit $c \rightarrow \infty$ and test power continues to increase as $r_2 \rightarrow 1$ and the period of explosive behavior expands in the sample. This result provides analytic confirmation of the simulation results in Evans (1991) that showed how full sample period unit root tests performed poorly in

the detection of periodically collapsing bubbles within sample. On the other hand, as shown in Phillips, Wu and Yu (2011), recursive unit root tests are consistent against such subperiod explosive alternatives. Recursive mechanisms of detection therefore have considerable advantage in this context, particularly in the presence of multiple bubbles (Phillips et al. (2015a), Phillips et al. (2015b)).

Note that the limit theory (9) for the centred OLS estimate is a scaled Cauchy distribution. Importantly, the scale coefficient $\{r_1(1-r_2)\}^{-1/2}$ diverges when either $r_1 \rightarrow 0$ or $r_2 \rightarrow 1$. This is explained by the fact that the convergence rate changes as the limits of the region of explosive behavior are reached. Such cases involve different asymptotics and different rates of convergence that account for the shape behavior of the functional coefficient $f(\cdot)$ at the limits of the domain of definition. They are reported in detail in ongoing work (Phillips (2017)) and one such result is given in Theorem 5 in the following section.

Interestingly, the asymptotic distribution of $\hat{\theta}_{OLS}$ is degenerate when centered on unity, as evident in the limit of the coefficient-based unit root test (10). Moreover, it is insufficient to simply recenter again using the constant $\frac{1}{2(1-r_2)}$. In fact, in the spirit of the proof of Theorem 2, we can show that when $f(r_2) > 0$,

$$cn \left(\hat{\theta}_{OLS} - 1 - \frac{1}{2(1-r_2)n} \right) \xrightarrow[(c,n)_{seq} \rightarrow \infty]{d} \frac{-1}{4(1-r_2)^2 f(r_2)},$$

leading to a further degenerate distribution. The limit theory requires more precise approximation than (12) of the random centering that is present in (9). Our next theorem gives the correct non-degenerate asymptotics with deterministic centering.

Theorem 3. *If $f(r) \geq C > 0$ for all $r \in [r_1, r_2]$, the OLS estimate $\hat{\theta}_{OLS}$ has the following limiting Cauchy distribution after appropriate deterministic centering and scaling*

$$(13) \quad e^{c \int_{r_1}^{r_2} f(a) da} n \left(\hat{\theta}_{OLS} - 1 - \frac{1 - e^{-2c \int_{r_1}^{r_2} f(a) da}}{2n \left(1 - r_2 + \int_{r_1}^{r_2} e^{-2c \int_r^{r_2} f(a) da} dr \right)} \right) \xrightarrow[(c,n)_{seq} \rightarrow \infty]{d} \frac{C}{\sqrt{3r_1(1-r_2)}}.$$

Intriguingly, Theorems 2 and 3 both lead to very similar Cauchy limit distributions. The only difference besides the recentering is the numerical coefficient $\frac{1}{\sqrt{3}}$ in Theorem 3. The explanation for this simple scalar difference in the limits lies in the replacement of a random centering in (9) with accurate non-random centering in (13). The intuition is as follows: in Theorem 2 the centered statistic (9) has additional variability because of the random centering, which leads to larger dispersion in the Cauchy limit theory than in Theorem 3 where the centering is constant and dispersion decreases.

As is apparent in the proof of Theorem 3, the reason for the specific numerical constant $\frac{1}{\sqrt{3}}$ is that adjustment of the centering produces a demeaned Brownian motion in the limit theory rather than a Brownian motion, with a corresponding reduction in the variance of the numerator. In particular, in Theorem 2 the limit distribution is governed by the ratio $\frac{B^b(1) - B^b(r_2)}{(1-r_2)B^a(r_1)}$, whereas in Theorem 3 the governing ratio is

$$(14) \quad \frac{B^b(1) - B^b(r_2) - \frac{1}{1-r_2} \int_{r_2}^1 B^b(r) dr}{(1-r_2)B^a(r_1)}.$$

The numerator in (14) is the demeaned form of the Brownian motion differential $B^b(1) - B^b(r_2)$ and, correspondingly, the numerator variance reduces by the scale factor $\frac{1}{3}$, thereby leading to the numerical coefficient $1/\sqrt{3}$ which appears in (13).

4. MILD FLUR MODELS AND SIMULTANEOUS ASYMPTOTICS

The models considered so far in the paper all follow (1) with a time varying coefficient in the local vicinity of unity that has the generalized LUR form $\theta_{tn} = 1 + \frac{c(t/n)}{n}$. In order to widen the vicinity of unity under analysis, this section considers coefficients θ_{tn} that pass to unity at a slower rate $O(k_n^{-1})$ than $O(n^{-1})$ where $k_n \rightarrow \infty$ and $\frac{k_n}{n} \rightarrow 0$. The autoregressive coefficients have the form

$$(15) \quad \theta_{tn} = 1 + \frac{c(t/n)}{k_n},$$

for some fixed function $c(\cdot)$. The formulation (15) falls in the class of mildly integrated/mildly explosive processes considered by Phillips and Magdalinos (2007). With this specification, wider departures from unity may be considered and it is possible to develop simultaneous asymptotics where the parameters $(|c(\cdot)|, n)$ may jointly pass to infinity. In this passage to infinity what matters is the ratio $k_n = \frac{n}{|c(\cdot)|}$ and, as above, we assume that $\frac{1}{k_n} + \frac{k_n}{n} \rightarrow 0$. For example, we may have $k_n = n^\alpha$ with $\alpha \in (0, 1)$ or $k_n = n/\log n$.

Since the parameter setting (15) leads to autoregressive coefficients that are ‘closer’ asymptotically to the stationary zone than those of the FLUR model when $c(\cdot) < 0$, it is convenient to develop the limit theory under stationary martingale difference errors $\{u_t\}$, a setting that is better suited to that context (Phillips and Magdalinos (2007); Giraitis and Phillips (2006)). Further, the functions $c(\cdot)$ permitted in this section correspond to some of those used in Phillips (2017). Specifically, we assume the function $c(\cdot) \neq 0$ on $[0, 1]$. More precisely, in the explosive case where $c(\cdot) > 0$ we assume $c(\cdot)$ is non-zero in some fixed regions of the origin and unity, so that the FLUR process is active in those regions. As will become clear in the following analysis, behavior in those regions is particularly important in the explosive case because they play a significant role in the behavior of the time series and, in consequence, the limit theory also. Finally, it is convenient to set the initial condition in (1) at $t = 0$ and assume that $X_0 = o_p(\sqrt{k_n})$, which rules out initial

condition effects, although this condition may be relaxed as in Phillips and Magdalinos (2009) with some attendant differences in the asymptotics.

Models such as (1) with time varying autoregressive coefficients of the form (15) are mildly integrated/explosive functional local unit root (MIFLUR, MEFLUR) models. As will become clear, MEFLUR specifications lead to asymptotics where there are dependencies on specific function values, such as the origination and end point values $c(0), c(1)$ as well as the function $c(\cdot)$ over its full domain $[0, 1]$.

For the MEFLUR case we also consider a second specification for the coefficient function in place of (15), viz.,

$$(16) \quad \theta_{tn} = 1 + \frac{c(t/k_n)}{k_n},$$

where θ_{tn} converges to unity at the slower rate $O(k_n^{-1})$ and the time varying coefficient function $c(\cdot)$ is now scaled consonantly in $1/k_n$ units rather than $1/n$ units. In this case, the limit theory depends on the coefficient function $c(\cdot)$ over its entire domain, which is now $[0, \infty)$, and $c(\cdot)$ is accordingly assumed to be integrable over this domain.

4.1. Mildly Explosive FLUR. We start from the first specification (15) of θ_{tn} with $c(\cdot) > 0$. Solving the system yields

$$(17) \quad X_t = \theta_{tn} X_{t-1} + u_t = \sum_{j=1}^t e^{\frac{1}{k_n} \sum_{l=1}^{t-j} c(\frac{t-l+1}{n})} u_j + e^{\frac{1}{k_n} \sum_{j=1}^t c(\frac{j}{n})} X_0.$$

It is convenient to construct the two standardized processes (without employing array notation)

$$(18) \quad \tilde{X}_t = \frac{X_t}{e^{\frac{1}{k_n} \sum_{j=1}^t c(\frac{j}{n})}} = \sum_{j=1}^t \frac{u_j}{e^{\frac{1}{k_n} \sum_{l=t-j+1}^t c(\frac{t-l+1}{n})}} + X_0,$$

and $\tilde{Y}_t = \sum_{j=1}^t u_j e^{-\frac{1}{k_n} \sum_{l=j}^t c(\frac{l}{n})}$.

The time series \tilde{X}_t upweights early innovations $\{u_j : j = 1, 2, \dots\}$ because of the smaller number of components that enter the summation $\sum_{l=t-j+1}^t c(\frac{t-l+1}{n})$ in the exponent when the index j is small. In a similar way, the time series \tilde{Y}_t downweights early innovations $\{u_j : j = 1, 2, \dots\}$ because of the larger number of components that enter the summation $\sum_{l=j}^t c(\frac{l}{n})$ in the exponent. The process \tilde{X}_t is therefore weighted in favor of the origination point of the observations, and \tilde{Y}_t , as a mirror image, is weighted in favor of the terminal point t of the observations in the sum. The limit theory when $t \geq k_n \rightarrow \infty$ as $n \rightarrow \infty$ for these two standardized processes is given in the following theorem which reveals the importance of the endpoint conditions.

Theorem 4. *If there exists $\varepsilon > 0$ such that for all $r \in [0, \varepsilon] \cup [1 - \varepsilon, 1]$, $c(r) \geq C > 0$, then for all $r \in (0, 1]$ as $\frac{1}{k_n} + \frac{k_n}{n} \rightarrow 0$*

$$(19) \quad \frac{1}{\sqrt{k_n}} \tilde{X}_{[nr]} \xrightarrow[n \rightarrow \infty]{d} X_{c(0)} =_d \mathcal{N} \left(0, \frac{\sigma^2}{2c(0)} \right),$$

$$(20) \quad \frac{1}{\sqrt{k_n}} \tilde{Y}_{[nr]} \xrightarrow[n \rightarrow \infty]{d} Y_{c(1)} =_d N \left(0, \frac{\sigma^2}{2c(1)} \right),$$

and the limit variates $X_{c(0)}$ and $Y_{c(1)}$ are independent.

Thus, the standardized process $\tilde{X}_{[nr]}/\sqrt{k_n}$ tends for all $r \in (0, 1]$ to the same random variable $X_{c(0)}$ whose distribution depends on $c(0)$ and no other value of the function $c(\cdot)$. The explanation is that since $c(\cdot) > 0$ the time series X_t is explosive, which means that initial shocks and initial conditions are magnified, as is apparent in the solution (17). More particularly, the coefficient $\exp \left\{ \frac{1}{k_n} \sum_{l=1}^{t-j} c \left(\frac{t-l+1}{n} \right) \right\}$ is positive and increasing as j decreases, so that in (17), the early shocks $\{u_1, u_2, \dots\}$ have the largest coefficients and the greatest impact on X_t comes from the early part of the series. Correspondingly, the standardized process \tilde{X}_t in (18) is dominated by the early k_n elements of the series, which leads to the common central limit theorem given in Theorem 4 for $\frac{1}{\sqrt{k_n}} \tilde{X}_{[nr]}$, whose variance involves only $c(0)$ rather than the full function $c(\cdot)$. Analogous mirror-image intuition applies to the standardized process $\tilde{Y}_{[nr]}/\sqrt{k_n}$ where the terminal k_n elements of the series lead to a common limit theory that depends on the end point $c(1)$ rather than the full function $c(\cdot)$.

Next we turn to the limit behavior of the autoregressive coefficient estimate $\hat{\theta}_{OLS}$. After suitable centering and scaling we obtain the following result.

Theorem 5. *Suppose $c(r)$ is integrable over $[0, 1]$ and $c(r) \geq C > 0$ for all $r \in [0, \varepsilon] \cup [1 - \varepsilon, 1]$ for some $\varepsilon > 0$. Then, as $\frac{1}{k_n} + \frac{k_n}{n} \rightarrow 0$, the least squares estimate $\hat{\theta}_{OLS}$ has the following common limit theory with random and deterministic centering*

$$(21) \quad k_n e^{\frac{n}{k_n} \int_0^1 c(a) da} \left(\hat{\theta}_{OLS} - 1 - \frac{\sum_{t=1}^n \frac{c(t/n)}{k_n} X_{t-1}^2}{\sum_{t=1}^n X_{t-1}^2} \right) \xrightarrow[n \rightarrow \infty]{d} 2\sqrt{c(0)c(1)}\mathcal{C},$$

$$(22) \quad k_n e^{\frac{n}{k_n} \int_0^1 c(a) da} \left(\hat{\theta}_{OLS} - 1 - \frac{\sum_{t=1}^n c(t/n) e^{-\frac{2}{k_n} \sum_{j=t}^n c(j/n)}}{k_n \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c(j/n)}} \right) \xrightarrow[n \rightarrow \infty]{d} 2\sqrt{c(0)c(1)}\mathcal{C},$$

where \mathcal{C} is a standard Cauchy variate.

The proof of Theorem 5 is lengthy and involves complex calculations which are given in full in the proof in the Appendix. Importantly, although (21) and (22) differ in terms of their respective centering, the limit distribution behavior remains the same. As shown in the proof, the random centering quantity $\frac{\sum_{t=1}^n c(t/n)X_{t-1}^2}{k_n \sum_{t=1}^n X_{t-1}^2}$ that appears in (21) equals $\frac{\sum_{t=1}^n c(t/n)e^{-\frac{2}{k_n} \sum_{j=t}^n c(j/n)}}{k_n \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c(j/n)}}$ plus a random component of smaller order that is too small to affect centering but which, as shown in the proof, still comes into play in calculating the limit behavior of the rescaled and recentered estimator. As the result shows, the random centering can be replaced by a deterministic centering that is still dependent on the sample size but without affecting the Cauchy limit distribution or the scale of this distribution.

Further, as $\frac{1}{k_n} + \frac{k_n}{n} \rightarrow 0$ we find that

$$(23) \quad \frac{\sum_{t=1}^n c(t/n)e^{-\frac{2}{k_n} \sum_{j=t}^n c(j/n)}}{\sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c(j/n)}} = \frac{\frac{1}{n} \sum_{t=1}^n c(t/n)e^{-\frac{2n}{k_n} \frac{1}{n} \sum_{j=t}^n c(j/n)}}{\frac{1}{n} \sum_{t=1}^n e^{-\frac{2n}{k_n} \frac{1}{n} \sum_{j=t}^n c(j/n)}} \rightarrow c(1),$$

giving a simple limiting form of the re-centering element (23). This simple form cannot, however, be used directly in the limit theory (22) because the exponential rate of convergence $k_n e^{\frac{n}{k_n} \int_0^1 c(a) da}$ plays a key role in defining those components that drive the asymptotics, as explained in the proof of Theorem 5 .

Observing that $\theta_{nn}^2 - 1 = \frac{2c(1)}{k_n} \{1 + o(1)\}$, $\theta_{1n}^2 - 1 = \frac{2c(0)}{k_n} \{1 + o(1)\}$ and $\prod_{t=1}^n \theta_{tn} \sim e^{k_n^{-1} \sum_{t=1}^n c(\frac{t}{n})} \sim e^{\frac{n}{k_n} \int_0^1 c(a) da}$, we may write (22) in the equivalent form

$$(24) \quad \frac{\prod_{t=1}^n \theta_{tn}}{[(\theta_{nn}^2 - 1)(\theta_{1n}^2 - 1)]^{\frac{1}{2}}} \left(\hat{\theta}_{OLS} - 1 - \frac{\sum_{t=1}^n c(t/n)e^{-\frac{2}{k_n} \sum_{j=t}^n c(j/n)}}{k_n \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c(j/n)}} \right) \xrightarrow[n \rightarrow \infty]{d} \mathcal{C},$$

which is suggestive of earlier work in simpler cases of explosive process autoregression. In particular, (24) shows that, upon suitable standardization which in this cases relies on the time varying autoregressive coefficient, central limit theory holds for autoregressive estimation in the functional LUR with the same Cauchy limit theory as holds in (i) the fixed coefficient explosive case under Gaussian innovations with no invariance principle, and (ii) in the mildly explosive case under central limit theory (Phillips and Magdalinos (2007)). Importantly, both the convergence rate and the centering depend on the functional coefficient $c(\cdot)$ throughout the $[0, 1]$ interval.

In the special case where $c(\cdot) = c > 0$ is constant and $\theta_{tn} = 1 + \frac{c}{k_n} =: \theta_n$ for all $t = 1, \dots, n$, (24) reduces to the form

$$(25) \quad \frac{\theta_n^n}{\theta_n^2 - 1} \left(\hat{\theta}_{OLS} - 1 - \frac{c}{k_n} \right) \xrightarrow[n \rightarrow \infty]{d} \mathcal{C},$$

the result obtained originally in Phillips and Magdalinos (2007) for a constant mildly explosive process X_t with autoregressive coefficient $\theta = 1 + \frac{c}{k_n}$ for which $\theta_n^{2n} \sim e^{\frac{2n}{k_n}c}$. In that case the convergence rate of (25) is $\frac{\theta_n^n}{\theta_n^2 - 1} \sim \frac{k_n}{2c} e^{\frac{n}{k_n}c}$. The limit theory given in (24) then specializes to this earlier theory as $\frac{1}{k_n} + \frac{k_n}{n} \rightarrow 0$.

In the present case, the primary implication of a functional localizing coefficient is to adjust the rate of convergence in (22) to embody the aggregate impact of the function $c(\cdot)$ over its full domain via the integral $\int_0^1 c(a) da$, so that the standardization factor is $k_n e^{\frac{2n}{k_n} \int_0^1 c(a) da}$ rather than $k_n e^{\frac{2n}{k_n}c}$. It is then the accumulative (mild FLUR) departure from unity that determines the convergence rate of the estimator $\hat{\theta}$. Interestingly, a secondary implication of the new limit theory in (22) is that the limit random variable $2\sqrt{c(0)c(1)}\mathcal{C}$ depends explicitly on the behavior of the localizing function at the origination and termination dates via the pair $(c(0), c(1))$. This dependence is a consequence of the magnification of early and late shocks that takes place in the limiting process described above for a mildly explosive time series. The re-standardization by $[(\theta_{nn}^2 - 1)(\theta_{1n}^2 - 1)]^{\frac{1}{2}}$ in (24) adjusts for these initial and terminal effects and the dependence is eliminated.

Next consider the second specification (16) with $c(\cdot) > 0$. In this case, time is measured in $1/k_n$ units rather than $1/n$ units in the localizing coefficient function $c(\cdot)$ and since $\frac{n}{k_n} \rightarrow \infty$ the domain of the function is $[0, \infty)$, leading to the following limit theory for the standardized process when $c(\cdot) > 0$ is integrable over $[0, \infty)$

$$(26) \quad \frac{1}{\sqrt{k_n}} \tilde{X}_{[nr]} \xrightarrow[n \rightarrow \infty]{d} X_{c,\infty} =_d \mathcal{N} \left(0, \sigma^2 \int_0^\infty e^{-2 \int_0^a c(p) dp} da \right).$$

The limit in (26) remains the same random variable for all values of r , just as in Theorem 4 above. But in the present case, as is clear from (26), the limit variance depends on function values $c(\cdot) > 0$ over the full domain $[0, \infty)$ rather than the single function value $c(0)$ at the origin.

We may also consider the case where the standardized time series is measured in segments of length $O(k_n)$ rather than length $O(n)$. The framework then matches the usual FLUR model of Bykhovskaya and Phillips (2017) but over a much wider (infinite) domain. More specifically, when we focus on the process X_t with $t = [k_n r]$ instead of $t = [nr]$, we have the following limit theory for the standardized process $\frac{1}{\sqrt{k_n}} \tilde{X}_{[k_n r]}$.

$$(27) \quad \frac{1}{\sqrt{k_n}} \tilde{X}_{[k_n r]} \xrightarrow[n \rightarrow \infty]{d} X_{c,r} =_d \sigma \int_0^r e^{-\int_0^a c(p) dp} dW(a).$$

Importantly, in (27) the domain of r is the half line $[0, \infty)$, thereby accommodating limit behavior of the process X_t for $t \geq k_n$. Thus, the limit $X_{c,\infty}$ in (26) may be interpreted as the limit of the stochastic process $X_{c,r}$ as $r \rightarrow \infty$. The covariance kernel of $X_{c,r}$ is $\gamma(r, s) = \sigma^2 \int_0^{\min(r,s)} e^{-2 \int_0^a c(p) dp} da$, which reduces to the usual expression for the covariance

kernel of a linear diffusion when $c(\cdot)$ is constant or to that of a Brownian motion when $c(\cdot) = 0$.

4.2. Mildly stationary FLUR. We focus on the first specification (15). As shown below, this formulation leads to a limit process for a standardized version of $X_{t=\lfloor nr \rfloor}$ where there is explicit dependence on the localizing function value $c(r)$ at the sample fraction r corresponding to the sample point t . This outcome differs from (19) and (20) in the mildly explosive case where there is dependence on the end point values $c(0)$ and $c(1)$.

Suppose that $c(\cdot) \leq -C < 0$. By (17) we have the representation

$$X_t = \sum_{j=1}^t e^{\frac{1}{k_n} \sum_{l=1}^{t-j} c\left(\frac{t-l+1}{n}\right)} u_j + e^{\frac{1}{k_n} \sum_{j=1}^t c(j/n)} X_0.$$

and the following limit theory then holds for X_t after suitable standardization.

Theorem 6. *Given any fixed $r \in (0, 1]$ for which $c(r) \leq -C < 0$, then as $n \rightarrow \infty$*

$$(28) \quad \frac{1}{\sqrt{k_n}} X_{\lfloor nr \rfloor} \xrightarrow[n \rightarrow \infty]{fdd} X_c(r) =_d \mathcal{N}\left(0, \frac{\sigma^2}{-2c(r)}\right), \quad r \in (0, 1].$$

Different values of r lead to independent random variables.

Importantly, (28) gives a finite dimensional limit distribution for each fixed r , not a functional law. This is signified in (28) by the affix ‘fdd’ in place of weak convergence over $[0, 1]$. As the theorem indicates, the limit variates X_r and X_s are independent for all $r \neq s$. While the limit random variable X_r exists for each fixed r , the limiting stochastic process X_r on $r \in (0, 1]$ has pathological path properties because the independence of arbitrarily adjacent components X_r and X_s implies a degree of local variability that is unrealizable.

5. SOME IMPLICATIONS OF BOUNDARY LIMIT THEORY

Local unit root limit theory enabled analysis of the power properties of unit root tests and helped explore the passage to stationary and explosive behavior by examining boundary behavior in the asymptotics. The LUR methodology has since been used extensively in the econometric analysis of tests in unit root models, cointegrated systems, and predictive regression. In FLUR models, departures from unity allow for functional, time dependent forms that vary over the sample period. Correspondingly, in FLUR specifications both the limit theory and the asymptotic power properties involve richer possibilities that accommodate realistic empirical situations where unit root behavior may be interrupted by episodes of near-stationary or near-explosive behavior in the data. The passages to stationary and explosive behavior at the boundary of functional specifications become

similarly more complex and have implications for practical work with inference for time series data.

This paper has explored these implications in autoregressions when no allowance is made for time variation in the parameters in estimation and inference, as happens in practice when an investigator proceeds with parametric autoregression and standard testing procedures in ignorance of the greater complexity of the generating mechanism. In moving to the stationary boundary as might be expected in a time varying environment, the dominating component of the limit theory is any remaining nonstationary episode in the data. For the process itself, for the autoregressive estimate, and for unit root test statistics, the boundary asymptotics depend on the interval that defines this episode, leading to a form of segmented unit root limit theory. These results differ significantly from those of LUR boundary asymptotics which are well known to lead to standard normal asymptotics at the stationary boundary (Phillips (1987); Giraitis and Phillips (2006); Mikusheva (2007)). The implication is that functional departures from unity can have a major effect on limit theory and test performance.

Likewise, moving to the explosive boundary produces material changes in the asymptotics. In this case, the dominating component of the limit theory comes from the explosive episode in the data. Again, the boundary limit theory depends on the region that defines the episode. In the explosive direction, the boundary limit theory is centred in the explosive region. But while unit root tests have non-trivial power at the boundary they are not consistent, which partly explains the poor performance of right-sided unit root tests in the detection of periodic episodes of bubbles and the need for recursive regression methods of detection which have greater sensitivity to local departures from unity.

Functional local alternatives such as those considered here in the unit root context obviously have wider applications in statistical limit theory and power function analysis beyond those of unit root models, although there seems to have been little use or mention of them in the literature to date. They are also useful in the construction of functional point-optimal test procedures, where there are potential gains from the consideration of explicit functional alternatives rather than fixed alternatives. For instance, Bykhovskaya and Phillips (2017) examine some of the implications of functional departures for unit root testing with a focus on the properties of point optimal procedures. A further application of these boundary asymptotics that is relevant to empirical work is the impact of local time variation of the type considered here on uniform inference in autoregression. That subject is investigated in other ongoing work (Phillips (2017)).

6. APPENDIX

Proof of Theorem 1.

Proof. From (2) and with long run variance $\omega^2 = \sum_{h=-\infty}^{\infty} \mathbb{E}u_o u_h$, we deduce that the limit process for X_t as $n \rightarrow \infty$ has the following segmented form

$$\frac{X_{[nr]}}{\sqrt{n}} \xrightarrow[n \rightarrow \infty]{d} \omega K_c(r) = F_c(r) = \begin{cases} B^a(r), & r \leq r_1, \\ J_c(r; r_1), & r_1 < r \leq r_2, \\ B^b(r) + J_c(r_2; r_1), & r_2 < r \leq 1; \end{cases}$$

with $B^a, B^b = BM(\omega)$, $B^a \perp B^b$ and

$$\begin{aligned} J_c(r; r_1) &= \int_0^r e^{\int_s^r cf(a)da} dB(s) = \int_0^{r_1} e^{\int_s^r cf(a)da} dB(s) + \int_{r_1}^r e^{\int_s^r cf(a)da} dB(s) \\ &= e^{c \int_{r_1}^r f(a)da} B^a(r_1) + \int_{r_1}^r e^{c \int_s^r f(a)da} dB(s). \end{aligned}$$

Because $f(\cdot)$ is strictly positive on (r_1, r_2) , we know that $\int_s^r f(a)da > 0$ for all $s > r_1$, $r > s$. Thus, $e^{c \int_s^r f(a)da} \rightarrow 0$ monotonically in s as $c \rightarrow -\infty$, so that $J_c(r; r_1) \rightarrow 0$ as $c \rightarrow -\infty$ for $r \in (r_1, r_2]$. Therefore, the limit process $F_c(r)$ in (2) converges to $F_-(r) = B^a(r) \times \mathbf{1}\{0 \leq r \leq r_1\} + B^b(r) \times \mathbf{1}\{r_2 < r \leq 1\}$.

We may now calculate the limit distribution of the OLS estimate $\hat{\theta}_{OLS} = \frac{\sum_{t=0}^n X_t X_{t-1}}{\sum_{t=0}^n X_{t-1}^2}$ in sequential asymptotics as n passes to infinity followed by c passing to minus infinity, which we write as $(-c, n)_{seq.} \rightarrow \infty$. Write

$$(29) \quad n \left(\hat{\theta}_{OLS} - 1 \right) = \frac{\frac{1}{n} \sum_{t=0}^n X_{t-1} \Delta X_t}{\frac{1}{n^2} \sum_{t=0}^n X_{t-1}^2} = \frac{\frac{1}{n} \sum_{t=0}^n X_{t-1} u_t}{\frac{1}{n^2} \sum_{t=0}^n X_{t-1}^2} + \frac{\frac{1}{n} \sum_{t=0}^n \frac{cf(t/n)}{n} X_{t-1}^2}{\frac{1}{n^2} \sum_{t=0}^n X_{t-1}^2},$$

and note from Lemma 1 that we may deduce the joint weak convergence

$$\begin{aligned} \frac{1}{n^2} \sum_{t=0}^n X_{t-1}^2 &\xrightarrow[n \rightarrow \infty]{d} \int_0^1 F_c^2(r) dr, \\ \frac{1}{n^2} \sum_{t=0}^n cf(t/n) X_{t-1}^2 &\xrightarrow[n \rightarrow \infty]{d} \int_0^1 cf(r) F_c^2(r) dr = \omega^2 \int_{r_1}^{r_2} cf(r) K_c^2(r) dr. \end{aligned}$$

To calculate the limit of $\frac{1}{n} \sum_{t=0}^n X_{t-1} u_t$ in the numerator of the first member of 29, square (1), sum over t , and scale by n , giving

$$n^{-1} X_n^2 = n^{-1} \sum_t u_t + 2n^{-1} \sum_t X_{t-1} u_t + 2n^{-1} \sum_t \frac{cf(t/n)}{n} X_{t-1}^2 + O_p(n^{-0.5}),$$

so that

$$n^{-1} \sum_{t=0}^n X_{t-1} u_t \xrightarrow[n \rightarrow \infty]{d} \omega^2 K_c^2(1)/2 - \sigma^2/2 - \omega^2 \int_0^1 c f(r) K_c^2(r) dr.$$

Stochastic differentiation of $K_c^2(r)$ gives $K_c^2(r) = r + 2 \int_0^r c f(r) K_c^2(r) dr + 2 \int_0^r K_c(r) dW(r)$, from which we deduce that $n^{-1} \sum_{t=0}^n X_{t-1} u_t \xrightarrow[n \rightarrow \infty]{d} \omega^2 \int_0^1 K_c(r) dW(r) + \lambda$, where $\lambda = \sum_{h=1}^{\infty} \mathbf{E} u_o u_h = \frac{1}{2}(\omega^2 - \sigma^2)$, $B(r) = B^a(r) \times \mathbf{1}\{0 \leq r \leq r_1\} + B(r) \times \mathbf{1}\{r_1 < r \leq r_2\} + B^b(r) \times \mathbf{1}\{r_2 < r \leq 1\}$. Thus, as $n \rightarrow \infty$ we find that

$$(30) \quad n \left(\hat{\theta}_{OLS} - 1 - \frac{\int_{r_1}^{r_2} c f(r) F_c^2(r) dr}{n \int_0^1 F_c(r)^2 dr} \right) \xrightarrow[n \rightarrow \infty]{} \frac{\int_0^1 F_c(r) dB(r) + \lambda}{\int_0^1 F_c(r)^2 dr},$$

$$n \left(\hat{\theta}_{OLS} - 1 \right) \xrightarrow[n \rightarrow \infty]{} \frac{\int_0^1 F_c(r) dB(r) + \lambda + \int_{r_1}^{r_2} c f(r) F_c^2(r) dr}{\int_0^1 F_c(r)^2 dr}.$$

The limits of $\int_0^1 F_c(r) dB(r) + \lambda$ and $\int_0^1 F_c(r)^2 dr$ as $c \rightarrow -\infty$ are straightforward and we find the following centered limit theory in the boundary asymptotics

$$(31) \quad n \left(\hat{\theta}_{OLS} - 1 - \frac{\int_{r_1}^{r_2} c f(r) F_c^2(r) dr}{n \int_0^1 F_c(r)^2 dr} \right) \xrightarrow[(-c, n)_{seq.} \rightarrow \infty]{} \frac{\int_0^{r_1} B^a(r) dB^a(r) + \int_{r_2}^1 B^b(r) dB^b(r) + \lambda}{\int_0^{r_1} B^a(r)^2 dr + \int_{r_2}^1 B^b(r)^2 dr}.$$

Note that the centering of the limit theory for $\hat{\theta}$ in (31) is stochastic and involves the weighted quantity $\int_{r_1}^{r_2} c f(r) F_c^2(r) dr$ whose limit behavior is complicated. We proceed to calculate this limit to develop a non random centering in place of (31).

$$(32) \quad c \int_{r_1}^{r_2} f(r) F_c^2(r) dr = \omega^2 c \int_{r_1}^{r_2} f(r) \left(e^{c \int_{r_1}^r f(a) da} W^a(r_1) + \int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) \right)^2 dr$$

$$= \omega^2 c W^a(r_1)^2 \int_{r_1}^{r_2} f(r) e^{2c \int_{r_1}^r f(a) da} dr$$

$$+ 2\omega^2 c W^a(r_1) \int_{r_1}^{r_2} f(r) e^{c \int_{r_1}^r f(a) da} \int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) dr$$

$$+ \omega^2 c \int_{r_1}^{r_2} f(r) \left(\int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) \right)^2 dr.$$

We evaluate the limit of each of the three terms in Eq. (32). First, denoting $\partial_r := \frac{\partial}{\partial r}$,

$$\begin{aligned}
(33) \quad & \omega^2 c W^a(r_1)^2 \int_{r_1}^{r_2} f(r) e^{2c \int_{r_1}^r f(a) da} dr = \omega^2 c W^a(r_1)^2 \int_{r_1}^{r_2} \partial_r \left(\frac{1}{2c} e^{2c \int_{r_1}^r f(a) da} \right) dr \\
& = \omega^2 W^a(r_1)^2 \frac{1}{2} \left(e^{2c \int_{r_1}^{r_2} f(a) da} - 1 \right) \xrightarrow{c \rightarrow -\infty} -\frac{1}{2} B^a(r_1)^2.
\end{aligned}$$

The second term has mean

$$\mathbb{E} \left[2c W^a(r_1) \int_{r_1}^{r_2} f(r) e^{c \int_{r_1}^r f(a) da} \int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) dr \right] = 0,$$

as W^a and W are independent. We now show that the variance of this term converges to zero as $c \rightarrow -\infty$, so that the term tends in probability to zero. We have

$$\begin{aligned}
(34) \quad & \mathbb{E} \left[2c W^a(r_1) \int_{r_1}^{r_2} f(r) e^{c \int_{r_1}^r f(a) da} \int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) dr \right]^2 \\
& = 4r_1 c^2 \mathbb{E} \left[\int_{r_1}^{r_2} f(r) e^{c \int_{r_1}^r f(a) da} \int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) dr \right]^2 \\
& = 4r_1 c^2 \mathbb{E} \left[\int_{r_1}^{r_2} \int_s^{r_2} f(r) e^{c \int_{r_1}^r f(a) da} e^{c \int_s^r f(a) da} dr dW(s) \right]^2 \\
& = 4r_1 c^2 \int_{r_1}^{r_2} \left(\int_s^{r_2} f(r) e^{c \int_{r_1}^r f(a) da} e^{c \int_s^r f(a) da} dr \right)^2 ds \\
& = 4r_1 c^2 \int_{r_1}^{r_2} \left(\frac{1}{2c} \left(e^{c \int_{r_1}^{r_2} f(a) da + c \int_s^{r_2} f(a) da} - e^{c \int_{r_1}^s f(a) da} \right) \right)^2 ds \\
& = r_1 \int_{r_1}^{r_2} \left(e^{2c \int_{r_1}^{r_2} f(a) da + 2c \int_s^{r_2} f(a) da} + e^{2c \int_{r_1}^s f(a) da} - 2e^{2c \int_{r_1}^{r_2} f(a) da} \right) dr \xrightarrow{c \rightarrow -\infty} 0,
\end{aligned}$$

and hence

$$(35) \quad 2\omega^2 c W^a(r_1) \int_{r_1}^{r_2} f(r) e^{c \int_{r_1}^r f(a) da} \int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) dr \xrightarrow{c \rightarrow -\infty} 0.$$

We are left with the third term. As with the second term, we show that the variance converges to zero, and thus the whole term converges to the limit of its expectation. We

first calculate this limit as follows

$$\begin{aligned}
(36) \quad & \mathbb{E} \left[\omega^2 c \int_{r_1}^{r_2} f(r) \left(\int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) \right)^2 dr \right] \\
&= \omega^2 c \int_{r_1}^{r_2} f(r) \mathbb{E} \left[\int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) \right]^2 dr = \omega^2 c \int_{r_1}^{r_2} f(r) \int_{r_1}^r e^{2c \int_s^r f(a) da} ds dr \\
&= \omega^2 c \int_{r_1}^{r_2} \int_{r_1}^{r_2} f(r) e^{2c \int_s^r f(a) da} dr ds = \frac{\omega^2}{2} \int_{r_1}^{r_2} \left(e^{2c \int_s^{r_2} f(a) da} - 1 \right) ds \\
&= \frac{\omega^2}{2} \int_{r_1}^{r_2} e^{2c \int_s^{r_2} f(a) da} ds - \frac{\omega^2}{2} (r_2 - r_1) \xrightarrow{c \rightarrow -\infty} -\frac{\omega^2}{2} (r_2 - r_1).
\end{aligned}$$

We proceed to show that the variance of the third term goes to zero. We use the fact that for a stochastic process ξ_t with finite second moments we have

$$\begin{aligned}
\mathbb{V} \int_{r_1}^{r_2} \xi_t dt &= \mathbb{E} \left(\int_{r_1}^{r_2} \xi_t dt \right)^2 - \left(\mathbb{E} \int_{r_1}^{r_2} \xi_t dt \right)^2 \\
&= \mathbb{E} \left(\int_{r_1}^{r_2} \xi_t dt \int_{r_1}^{r_2} \xi_s ds \right) - \mathbb{E} \int_{r_1}^{r_2} \xi_t dt \mathbb{E} \int_{r_1}^{r_2} \xi_s ds \\
&= \int_{r_1}^{r_2} \int_{r_1}^{r_2} \mathbb{E} (\xi_t \xi_s) ds dt - \int_{r_1}^{r_2} \int_{r_1}^{r_2} (\mathbb{E} \xi_t) (\mathbb{E} \xi_s) ds dt = \int_{r_1}^{r_2} \int_{r_1}^{r_2} cov(\xi_t, \xi_s) ds dt.
\end{aligned}$$

Therefore,

$$\begin{aligned}
(37) \quad & \mathbb{V} \left[c \int_{r_1}^{r_2} f(r) \left(\int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) \right)^2 dr \right] \\
&= c^2 \int_{r_1}^{r_2} \int_{r_1}^{r_2} f(r) f(r') cov \left\{ \left(\int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) \right)^2, \left(\int_{r_1}^{r'} e^{c \int_s^{r'} f(a) da} dW(s) \right)^2 \right\} dr' dr.
\end{aligned}$$

For this calculation, we need the covariance between two squared normal variables with zero mean. By Isselis's theorem, if $\xi_r, \xi_{r'}$ are normally distributed (possibly dependent) with zero mean, then

$$cov(\xi_r^2, \xi_{r'}^2) \equiv \mathbb{E} \xi_r^2 \xi_{r'}^2 - \mathbb{E} \xi_r^2 \mathbb{E} \xi_{r'}^2 = 2 (\mathbb{E} \xi_r \xi_{r'})^2.$$

Thus, we can rewrite Eq. (37) as

$$\begin{aligned}
& \mathbb{V} \left[c \int_{r_1}^{r_2} f(r) \left(\int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) \right)^2 dr \right] \\
&= 2c^2 \int_{r_1}^{r_2} \int_{r_1}^{r_2} f(r) f(r') \left(\mathbb{E} \int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) \int_{r_1}^{r'} e^{c \int_s^{r'} f(a) da} dW(s) \right)^2 dr' dr \\
&= 2c^2 \int_{r_1}^{r_2} \int_{r_1}^{r_2} f(r) f(r') \left(\int_{r_1}^{\min(r, r')} e^{c \int_s^r f(a) da} e^{c \int_s^{r'} f(a) da} ds \right)^2 dr' dr \\
&= 4c^2 \int_{r_1}^{r_2} \int_{r_1}^r f(r) f(r') e^{2c \int_{r'}^r f(a) da} \left(\int_{r_1}^{r'} e^{2c \int_s^{r'} f(a) da} ds \right)^2 dr' dr
\end{aligned} \tag{38}$$

$$\begin{aligned}
&= 4c^2 \int_{r_1}^{r_2} \int_{r_1}^r \int_{r_1}^{r'} \int_{r_1}^{r'} f(r) f(r') e^{2c \int_{r'}^r f(a) da} e^{2c \int_s^{r'} f(a) da} e^{2c \int_{s'}^{r'} f(a) da} ds' ds dr' dr \\
&= 4c^2 \int_{r_1}^{r_2} \int_s^{r_2} \int_{r'}^{r_2} \left(\int_{r_1}^{r'} e^{2c \int_{s'}^{r'} f(a) da} ds' \right) f(r) e^{2c \int_{r'}^r f(a) da} dr f(r') e^{2c \int_s^{r'} f(a) da} dr' ds \\
&= 2c \int_{r_1}^{r_2} \int_s^{r_2} \left(\int_{r_1}^{r'} e^{2c \int_{s'}^{r'} f(a) da} ds' \right) \left(e^{2c \int_{r'}^{r_2} f(a) da} - 1 \right) f(r') e^{2c \int_s^{r'} f(a) da} dr' ds \\
&= 2c \int_{r_1}^{r_2} \int_{r_1}^{r_2} \int_{\max(s, s')}^{r_2} e^{2c \int_{s'}^{r'} f(a) da} \left(e^{2c \int_{r'}^{r_2} f(a) da} - 1 \right) f(r') e^{2c \int_s^{r'} f(a) da} dr' ds' ds,
\end{aligned} \tag{39}$$

with

$$\begin{aligned}
& 2c \int_{r_1}^{r_2} \int_{r_1}^{r_2} \int_{\max(s, s')}^{r_2} e^{2c \int_{s'}^{r'} f(a) da} f(r') e^{2c \int_{r'}^{r_2} f(a) da} e^{2c \int_s^{r'} f(a) da} dr' ds' ds \\
&= \int_{r_1}^{r_2} \int_{r_1}^{r_2} e^{2c \int_s^{r_2} f(a) da} \left(e^{2c \int_{s'}^{r_2} f(a) da} - e^{2c \int_{s'}^{\max(s, s')} f(a) da} \right) ds' ds \\
&= \left(\int_{r_1}^{r_2} e^{2c \int_s^{r_2} f(a) da} ds \right)^2 - \int_{r_1}^{r_2} e^{2c \int_s^{r_2} f(a) da} \left(\int_{r_1}^s e^{2c \int_{s'}^s f(a) da} ds' + \int_s^{r_2} ds' \right) ds \\
&= \left(\int_{r_1}^{r_2} e^{2c \int_s^{r_2} f(a) da} ds \right)^2 - \int_{r_1}^{r_2} \int_{r_1}^s e^{2c \int_{s'}^{r_2} f(a) da} ds' ds - \int_{r_1}^{r_2} (r_2 - s) e^{2c \int_s^{r_2} f(a) da} ds,
\end{aligned} \tag{40}$$

and

$$\begin{aligned}
& 2c \int_{r_1}^{r_2} \int_{r_1}^{r_2} \int_{\max(s,s')}^{r_2} e^{2c \int_{s'}^{r'} f(a) da} f(r') e^{2c \int_s^{r'} f(a) da} dr' ds' ds \\
(41) \quad &= \frac{1}{2} \int_{r_1}^{r_2} \int_{r_1}^{r_2} \left(e^{2c \int_{s'}^{r_2} f(a) da + 2c \int_s^{r_2} f(a) da} - e^{2c \int_{s'}^{\max(s,s')} f(a) da + 2c \int_s^{\max(s,s')} f(a) da} \right) ds' ds \\
&= \frac{1}{2} \left(\int_{r_1}^{r_2} e^{2c \int_s^{r_2} f(a) da} ds \right)^2 - \int_{r_1}^{r_2} \int_{r_1}^s e^{2c \int_{s'}^s f(a) da} ds' ds.
\end{aligned}$$

Using (40) and (41) in (39) gives

$$\begin{aligned}
& \mathbb{V} \left[c \int_{r_1}^{r_2} f(r) \left(\int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) \right)^2 dr \right] \\
(42) \quad &= \frac{1}{2} \left(\int_{r_1}^{r_2} e^{2c \int_s^{r_2} f(a) da} ds \right)^2 - \int_{r_1}^{r_2} \int_{r_1}^s e^{2c \int_{s'}^{r_2} f(a) da} ds' ds - \int_{r_1}^{r_2} (r_2 - s) e^{2c \int_s^{r_2} f(a) da} ds \\
&+ \int_{r_1}^{r_2} \int_{r_1}^s e^{2c \int_{s'}^s f(a) da} ds' ds \xrightarrow{c \rightarrow -\infty} 0,
\end{aligned}$$

as each term goes to zero. It follows that

$$(43) \quad \omega^2 c \int_{r_1}^{r_2} f(r) \left(\int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) \right)^2 dr \xrightarrow{c \rightarrow -\infty} -\frac{\omega^2}{2} (r_2 - r_1).$$

and using 33, (35), and (43) in (32), we obtain

$$\int_{r_1}^{r_2} c f(r) F_c^2(r) dr \xrightarrow{c \rightarrow -\infty} -\frac{1}{2} (\omega^2 (r_2 - r_1) + B^a(r_1)^2).$$

Finally, taking the limit as $c \rightarrow -\infty$ in (30) leads to a form of segmented unit root limit distribution as follows

$$\begin{aligned}
& \frac{\int_0^1 F_c(r) dB(r) + \lambda + \int_{r_1}^{r_2} c f(r) F_c^2(r) dr}{\int_0^1 F_c(r)^2 dr} \\
& \xrightarrow{c \rightarrow -\infty} \frac{\int_0^{r_1} B^a(r) dB^a(r) + \int_{r_2}^1 B^b(r) dB^b(r) + \lambda - \frac{1}{2} (\omega^2 (r_2 - r_1) + B^a(r_1)^2)}{\int_0^{r_1} B^a(r)^2 dr + \int_{r_2}^1 B^b(r)^2 dr} \\
& = \frac{\int_{r_2}^1 B^b(r) dB^b(r) + \lambda - \frac{\omega^2 r_2}{2}}{\int_0^{r_1} B^a(r)^2 dr + \int_{r_2}^1 B^b(r)^2 dr}.
\end{aligned}$$

Using these results and working in a similar way, we can derive the boundary limit behavior of the unit root t statistic associated with $\hat{\theta}_{OLS}$, i.e.,

$$t_{\hat{\theta}_{OLS}} = \frac{\hat{\theta}_{OLS} - 1}{\hat{s}_{\hat{\theta}_{OLS}}} := \frac{\sqrt{\sum_{t=1}^n X_{t-1}^2} (\hat{\theta}_{OLS} - 1)}{\sqrt{\frac{1}{n} \sum_{t=1}^n (X_t - \hat{\theta}_{OLS} X_{t-1})^2}}.$$

Since $\hat{\theta}_{OLS} = 1 + O_p(n^{-1}) = 1 + cf(t/n)/n + O_p(n^{-1})$, it follows that

$$n^{-1} \sum_{t=1}^n (X_t - \hat{\theta}_{OLS} X_{t-1})^2 \xrightarrow[n \rightarrow \infty]{p} \sigma^2,$$

and we have already shown that

$$\begin{aligned} n \left(\hat{\theta}_{OLS} - 1 \right) &\xrightarrow[n \rightarrow \infty]{d} \frac{\int_0^1 F_c(r) dB(r) + \lambda + \int_{r_1}^{r_2} cf(r) F_c^2(r) dr}{\int_0^1 F_c(r)^2 dr}, \\ \int_0^1 F_c(r) dB(r) + \lambda &\xrightarrow[c \rightarrow -\infty]{d} \int_0^{r_1} B^a(r) dB^a(r) + \int_{r_2}^1 B^b(r) dB^b(r) + \lambda, \\ \int_{r_1}^{r_2} cf(r) F_c^2(r) dr &\xrightarrow[c \rightarrow -\infty]{d} -\frac{1}{2} (\omega^2(r_2 - r_1) + B^a(r_1)^2), \\ \int_0^1 F_c(r)^2 dr &\xrightarrow[c \rightarrow -\infty]{d} \int_0^{r_1} B^a(r)^2 dr + \int_{r_2}^1 B^b(r)^2 dr, \end{aligned}$$

Combining these limits yields the desired result

$$\begin{aligned} &\xrightarrow[t_{\hat{\theta}_{OLS}}]{d} \frac{\int_0^{r_1} B^a(r) dB^a(r) + \int_{r_2}^1 B^b(r) dB^b(r) + \lambda - \frac{1}{2} (\omega^2(r_2 - r_1) + B^a(r_1)^2)}{\sigma \left(\int_0^{r_1} B^a(r)^2 dr + \int_{r_2}^1 B^b(r)^2 dr \right)^{1/2}} \\ &= \frac{\int_{r_2}^1 B^b(r) dB^b(r) + \lambda - \frac{\omega^2 r_2}{2}}{\sigma \left(\int_0^{r_1} B^a(r)^2 dr + \int_{r_2}^1 B^b(r)^2 dr \right)^{1/2}}. \end{aligned}$$

□

Proof of Theorem 2.

Proof. By Eq. (2), the limit process for X_t has the segmented form

$$(44) \quad \frac{X_{\lfloor nr \rfloor}}{\sqrt{n}} \xrightarrow[n \rightarrow \infty]{d} F_c(r) = \begin{cases} B^a(r), & r \leq r_1, \\ J_c(r; r_1), & r_1 < r \leq r_2, \\ B^b(r) + J_c(r_2; r_1), & r_2 < r \leq 1; \end{cases}$$

with $B^a \perp B^b$ and

$$(45) \quad J_c(r; r_1) = \int_0^r e^{c \int_s^r f(a) da} dB(s) = e^{c \int_{r_1}^r f(a) da} B^a(r_1) + \int_{r_1}^r e^{c \int_s^r f(a) da} dB(s).$$

So

$$\begin{aligned}
(46) \quad e^{-c \int_{r_1}^r f(a) da} J_c(r; r_1) &= B^a(r_1) + \int_{r_1}^r e^{-c \int_{r_1}^r f(a) da} e^{c \int_s^r f(a) da} dB(s) \\
&= B^a(r_1) + \int_{r_1}^r e^{-c \int_{r_1}^s f(a) da} dB(s) = B^a(r_1) + o_p(1).
\end{aligned}$$

Thus, for all r ,

$$e^{-c \int_{r_1}^{r_2} f(a) da} B(r) = e^{-c \int_{r_1}^{r_2} f(a) da} \times O_p(1) \xrightarrow{c \rightarrow \infty} 0,$$

and, for all $r < r_2$

$$e^{-c \int_{r_1}^{r_2} f(a) da} J_c(r; r_1) = e^{-c \int_r^{r_2} f(a) da} (B^a(r_1) + o_p(1)) \xrightarrow{c \rightarrow \infty} 0,$$

while

$$e^{-c \int_{r_1}^{r_2} f(a) da} J_c(r_2; r_1) \xrightarrow{c \rightarrow \infty} B^a(r_1).$$

$$\text{Thus } e^{-c \int_{r_1}^{r_2} f(a) da} \frac{X_{\lfloor nr \rfloor}}{\sqrt{n}} \xrightarrow[(c, n)_{seq} \rightarrow \infty]{d} B^a(r_1) \times \mathbf{1} \{r_2 \leq r \leq 1\}.$$

By the same argument as in the proof of Theorem 1,

$$\begin{aligned}
n \left(\hat{\theta}_{OLS} - 1 \right) &= \frac{\frac{1}{n} \sum_{t=0}^n X_{t-1} u_t}{\frac{1}{n^2} \sum_{t=0}^n X_{t-1}^2} + \frac{\frac{1}{n} \sum_t \frac{cf(t/n)}{n} X_{t-1}^2}{\frac{1}{n^2} \sum_t X_{t-1}^2} \\
&\xrightarrow[n \rightarrow \infty]{d} \frac{\int_0^1 F_c(r) dB(r) + \lambda + \int_{r_1}^{r_2} cf(r) F_c(r)^2 dr}{\int_0^1 F_c(r)^2 dr},
\end{aligned}$$

so that

$$n \left(\hat{\theta}_{OLS} - 1 - \frac{\int_{r_1}^{r_2} cf(r) F_c(r)^2 dr}{n \int_0^1 F_c(r)^2 dr} \right) \xrightarrow[n \rightarrow \infty]{d} \frac{\int_0^1 F_c(r) dB(r) + \lambda}{\int_0^1 F_c(r)^2 dr}.$$

Using Eq. (46), we can calculate the limit of the denominator $\int_0^1 F_c(r)^2 dr$ as c goes to infinity. First,

$$(47) \quad \int_0^{r_1} F_c(r)^2 dr = \int_0^{r_1} (B^a(r))^2 dr = O_p(1).$$

Then,

$$\begin{aligned}
(48) \quad \int_{r_1}^{r_2} F_c(r)^2 dr &= \int_{r_1}^{r_2} J_c(r; r_1)^2 dr = \int_{r_1}^{r_2} \left[e^{c \int_{r_1}^r f(a) da} B^a(r_1) + \int_{r_1}^r e^{c \int_s^r f(a) da} dB(s) \right]^2 dr \\
&= \int_{r_1}^{r_2} e^{2c \int_{r_1}^r f(a) da} \left[B^a(r_1) + \int_{r_1}^r e^{-c \int_{r_1}^s f(a) da} dB(s) \right]^2 dr \\
&= \int_{r_1}^{r_2} e^{2c \int_{r_1}^r f(a) da} (B^a(r_1) + o_p(1))^2 dr \\
&= (B^a(r_1))^2 \int_{r_1}^{r_2} e^{2c \int_{r_1}^r f(a) da} dr + o_p(1) \int_{r_1}^{r_2} e^{2c \int_{r_1}^r f(a) da} dr.
\end{aligned}$$

Finally,

$$\begin{aligned}
\int_{r_2}^1 F_c(r)^2 dr &= \int_{r_2}^1 (B^b(r) + J_c(r_2; r_1))^2 dr \\
&= \int_{r_2}^1 B^b(r)^2 dr + 2 \int_{r_2}^1 B^b(r) J_c(r_2; r_1) dr + \int_{r_2}^1 J_c(r_2; r_1)^2 dr.
\end{aligned}$$

Hence, using Eq. (45), we have

$$\begin{aligned}
(49) \quad e^{-2c \int_{r_1}^{r_2} f(a) da} \int_{r_2}^1 F_c(r)^2 dr &= o_p(1) + 2B^a(r_1) e^{-c \int_{r_1}^{r_2} f(a) da} \int_{r_2}^1 B^b(r) dr \\
&\quad + (1 - r_2) (B^a(r_1))^2 = (1 - r_2) (B^a(r_1))^2 + o_p(1).
\end{aligned}$$

Combining Eq. 47, Eq. 48, and Eq. 49 then yields

$$\begin{aligned}
(50) \quad e^{-2c \int_{r_1}^{r_2} f(a) da} \int_0^1 F_c(r)^2 dr &= o_p(1) + (B^a(r_1))^2 \int_{r_1}^{r_2} e^{-2c \int_r^{r_2} f(a) da} dr \\
&\quad + o_p(1) \int_{r_1}^{r_2} e^{-2c \int_r^{r_2} f(a) da} dr + (1 - r_2) (B^a(r_1))^2 \\
&= (1 - r_2) (B^a(r_1))^2 + o_p(1).
\end{aligned}$$

In a similar way, we can analyze the first part of the numerator, $\int_0^1 F_c(r) dB(r) + \lambda$. Note that

$$\begin{aligned}
\int_0^1 F_c(r) dB(r) &= \int_0^{r_1} B^a(r) dB^a(r) + \int_{r_1}^{r_2} J_c(r; r_1) dB(r) \\
&\quad + \int_{r_2}^1 (B^b(r) + J_c(r_2; r_1)) dB^b(r) \\
&= \int_0^{r_1} B^a(r) dB^a(r) + \int_{r_2}^1 B^b(r) dB^b(r) \\
&\quad + \int_{r_1}^{r_2} J_c(r; r_1) dB(r) + J_c(r_2; r_1) (B^b(1) - B^b(r_2)).
\end{aligned}$$

Thus,

$$\begin{aligned}
(51) \quad & e^{-c \int_{r_1}^{r_2} f(a) da} \left[\int_0^1 F_c(r) dB(r) + \lambda \right] = o_p(1) + B^a(r_1) (B^b(1) - B^b(r_2)) \\
& + \int_{r_1}^{r_2} e^{-c \int_r^{r_2} f(a) da} (B^a(r_1) + o_p(1)) dB(r) \\
& = B^a(r_1) (B^b(1) - B^b(r_2)) + o_p(1).
\end{aligned}$$

Combining Eq. 50 and Eq. 51, we obtain

$$\begin{aligned}
& \frac{e^{-c \int_{r_1}^{r_2} f(a) da} \left[\int_0^1 F_c(r) dB(r) + \lambda \right]}{e^{-2c \int_{r_1}^{r_2} f(a) da} \int_0^1 F_c(r)^2 dr} \xrightarrow{c \rightarrow \infty} \frac{B^a(r_1) (B^b(1) - B^b(r_2))}{(1 - r_2) (B^a(r_1))^2} \\
& = \frac{B^b(1) - B^b(r_2)}{(1 - r_2) B^a(r_1)} \\
& = \frac{\mathcal{N}(0, 1 - r_2)}{(1 - r_2) \mathcal{N}(0, r_1)} = \frac{1}{\sqrt{r_1(1 - r_2)}} \mathcal{C}.
\end{aligned}$$

Thus

$$e^{c \int_{r_1}^{r_2} f(a) da} n \left(\hat{\theta} - 1 - \frac{\int_{r_1}^{r_2} c f(r) F_c(r)^2 dr}{n \int_0^1 F_c(r)^2 dr} \right) \xrightarrow{(c, n)_{seq} \rightarrow \infty} \frac{1}{\sqrt{r_1(1 - r_2)}} \mathcal{C},$$

leading to a scaled Cauchy distribution in the limit.

We are left to analyze the second part of the numerator, $\int_{r_1}^{r_2} c f(r) F_c(r)^2 dr$. The analysis is almost identical to the case $c \rightarrow -\infty$ studied in the proof of Theorem 1. By Eq. (32),

$$\begin{aligned}
c \int_{r_1}^{r_2} f(r) F_c^2(r) dr &= \omega^2 c W^a(r_1)^2 \int_{r_1}^{r_2} f(r) e^{2c \int_{r_1}^r f(a) da} dr \\
&+ 2\omega^2 c W^a(r_1) \int_{r_1}^{r_2} f(r) e^{c \int_{r_1}^r f(a) da} \int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) dr \\
&+ \omega^2 c \int_{r_1}^{r_2} f(r) \left(\int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) \right)^2 dr.
\end{aligned}$$

By Eq. 33, for the first term we have

$$\begin{aligned}
(52) \quad & e^{-2c \int_{r_1}^{r_2} f(a) da} \omega^2 c W^a(r_1)^2 \int_{r_1}^{r_2} f(r) e^{2c \int_{r_1}^r f(a) da} dr \\
&= \omega^2 W^a(r_1)^2 \frac{1}{2} \left(1 - e^{-2c \int_{r_1}^{r_2} f(a) da} \right) \xrightarrow{c \rightarrow \infty} \frac{1}{2} B^a(r_1)^2.
\end{aligned}$$

Next, for the second term,

$$\begin{aligned} & \mathbb{E} e^{-2c \int_{r_1}^{r_2} f(a) da} \left[2c W^a(r_1) \int_{r_1}^{r_2} f(r) e^{c \int_{r_1}^r f(a) da} \int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) dr \right] \\ &= 2c \mathbb{E} W^a(r_1) \mathbb{E} \int_{r_1}^{r_2} f(r) e^{-c \int_{r_1}^{r_2} f(a) da} \int_{r_1}^r e^{-c(\int_{r_1}^s + \int_r^{r_2}) f(a) da} dW(s) dr = 0, \end{aligned}$$

and by Eq 34,

$$\begin{aligned} & \mathbb{E} \left[e^{-2c \int_{r_1}^{r_2} f(a) da} 2c W^a(r_1) \int_{r_1}^{r_2} f(r) e^{c \int_{r_1}^r f(a) da} \int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) dr \right]^2 \\ &= r_1 \int_{r_1}^{r_2} \left(e^{-2c \int_{r_1}^s f(a) da} + e^{-2c \int_{r_1}^{r_2} f(a) da - 2c \int_s^{r_2} f(a) da} - 2e^{-2c \int_{r_1}^{r_2} f(a) da} \right) dr \xrightarrow{c \rightarrow \infty} 0. \end{aligned}$$

Finally, by Eq. 36 and 42,

$$\begin{aligned} & \mathbb{E} \left[e^{-2c \int_{r_1}^{r_2} f(a) da} \omega^2 c \int_{r_1}^{r_2} f(r) \left(\int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) \right)^2 dr \right] \\ &= \frac{\omega^2}{2} \int_{r_1}^{r_2} e^{-2c \int_{r_1}^s f(a) da} ds - \frac{\omega^2}{2} (r_2 - r_1) e^{-2c \int_{r_1}^{r_2} f(a) da} \xrightarrow{c \rightarrow \infty} 0, \end{aligned}$$

and

$$\begin{aligned} & \mathbb{V} \left[e^{-2c \int_{r_1}^{r_2} f(a) da} c \int_{r_1}^{r_2} f(r) \left(\int_{r_1}^r e^{c \int_s^r f(a) da} dW(s) \right)^2 dr \right] \\ &= \frac{1}{2} \left(\int_{r_1}^{r_2} e^{-2c \int_{r_1}^s f(a) da} ds \right)^2 - e^{-2c \int_{r_1}^{r_2} f(a) da} \int_{r_1}^{r_2} \int_{r_1}^s e^{-2c \int_{r_1}^{s'} f(a) da} ds' ds \\ &\quad - e^{-2c \int_{r_1}^{r_2} f(a) da} \int_{r_1}^{r_2} (r_2 - s) e^{-2c \int_{r_1}^s f(a) da} ds \\ &\quad + e^{-2c \int_{r_1}^{r_2} f(a) da} \int_{r_1}^{r_2} \int_{r_1}^s e^{-2c \left(\int_{r_1}^{s'} + \int_s^{r_2} \right) f(a) da} ds' ds \xrightarrow{c \rightarrow \infty} 0. \end{aligned}$$

Combining these three terms gives

$$(53) \quad e^{-2c \int_{r_1}^{r_2} f(a) da} \int_{r_1}^{r_2} c f(r) F_c(r)^2 dr \xrightarrow{c \rightarrow \infty} \frac{1}{2} B^a(r_1)^2.$$

Further, combining Eq. 50, Eq. 51, and Eq. 53, we get

$$\begin{aligned} & \frac{e^{-2c \int_{r_1}^{r_2} f(a) da} \left[\int_0^1 F_c(r) dB(r) + \lambda + c \int_{r_1}^{r_2} f(r) F_c(r)^2 dr \right]}{e^{-2c \int_{r_1}^{r_2} f(a) da} \int_0^1 F_c(r)^2 dr} \\ & \xrightarrow{c \rightarrow \infty} \frac{\frac{1}{2} B^a(r_1)^2}{(1 - r_2) (B^a(r_1))^2} = \frac{1}{2(1 - r_2)}, \end{aligned}$$

so that

$$n \left(\hat{\theta} - 1 \right) \xrightarrow[(c,n)_{seq} \rightarrow \infty]{p} \frac{1}{2(1-r_2)},$$

giving a constant in the limit.

The limit behavior of the t statistic for $\hat{\theta}_{OLS}$ follows as in previous results. In particular, we have

$$n \left(\hat{\theta} - 1 \right) \xrightarrow[(c,n)_{seq} \rightarrow \infty]{d} \frac{1}{2(1-r_2)},$$

$$e^{-c \int_{r_1}^{r_2} f(a) da} \left(\int_0^1 F_c(r)^2 dr \right)^{1/2} \xrightarrow[c \rightarrow \infty]{d} \sqrt{1-r_2} |B^a(r_1)|.$$

leading to

$$e^{-c \int_{r_1}^{r_2} f(a) da} t_{\hat{\theta}_{OLS}} \xrightarrow[(c,n)_{seq} \rightarrow \infty]{d} \frac{1}{2(1-r_2)} \sqrt{1-r_2} |B^a(r_1)| \frac{1}{\sigma} = \frac{\sqrt{r_1} \omega}{2\sigma \sqrt{1-r_2}} |\mathcal{N}(0, 1)|.$$

□

Proof of Theorem 3.

Proof. From the proof of Theorem 2, we know that $e^{c \int_{r_1}^r J_c(r; r_1)} = B^a(r_1) + o_p(1)$. Thus, $J_c(r_2; r_1)$ has the largest stochastic order among the $J_c(r; r_1)$ for $r \leq r_2$. It is convenient to rewrite $J_c(r; r_1)$ in terms of $J_c(r_2; r_1)$ as

$$(54) \quad J_c(r; r_1) = \int_0^r e^{c \int_s^r f(a) da} dB(s) = e^{-c \int_r^{r_2} f(a) da} J_c(r_2; r_1) - \int_r^{r_2} e^{-c \int_r^s f(a) da} dB(s),$$

whose first term is exponentially large and whose second term is $O_p(c^{-0.5})$, since it is Gaussian with zero mean and variance $\int_r^{r_2} e^{-2c \int_r^s f(a) da} ds \approx \int_r^{r+\varepsilon} e^{-2c \int_r^s f(r) da} ds = \frac{1}{2cf(r)} (1 - e^{-2cf(r)\varepsilon}) \approx \frac{1}{2cf(r)}$. Define $\xi_r := \int_r^{r_2} e^{-c \int_r^s f(a) da} dB(s) \sqrt{2cf(r)} \approx \mathcal{N}(0, 1)$ and re-

write both numerator and denominator of $\frac{\int_0^1 F_c(r) dB(r) + \lambda + \int_{r_1}^{r_2} cf(r) F_c^2(r) dr}{\int_0^1 F_c^2(r) dr}$ in terms of $J_c(r_2; r_1)$

as follows.

$$(55) \quad \int_0^1 F_c(r) dB(r) = \int_0^{r_1} B^a(r) dB^a(r) + \int_{r_1}^{r_2} J_c(r; r_1) dB(r) + \int_{r_2}^1 (B^b(r) + J_c(r_2; r_1)) dB^b(r)$$

$$= J_c(r_2; r_1) (B^b(1) - B^b(r_2)) + J_c(r_2; r_1) \int_{r_1}^{r_2} e^{-c \int_r^{r_2} f(a) da} dB(s) + O_p(1),$$

$$\int_{r_1}^{r_2} cf(r) F_c^2(r) dr = \int_{r_1}^{r_2} cf(r) J_c^2(r; r_1) dr = J_c^2(r_2; r_1) c \int_{r_1}^{r_2} f(r) e^{-2c \int_r^{r_2} f(a) da} dr$$

$$- \frac{2c J_c(r_2; r_1)}{\sqrt{2c}} \int_{r_1}^{r_2} \xi_r \sqrt{f(r)} e^{-c \int_r^{r_2} f(a) da} dr + \frac{1}{2} \int_{r_1}^{r_2} \xi_r^2 dr,$$

where

$$\begin{aligned} & \mathbb{E} \left(\int_{r_1}^{r_2} \xi_r \sqrt{f(r)} e^{-c \int_r^{r_2} f(a) da} dr \right)^2 = \mathbb{E} \int_{r_1}^{r_2} \int_{r_1}^{r_2} \xi_r \xi_t \sqrt{f(r)f(t)} e^{-c \int_r^{r_2} f(a) da} e^{-c \int_t^{r_2} f(a) da} dt dr \\ & \leq \int_{r_1}^{r_2} \int_{r_1}^{r_2} \sqrt{f(r)f(t)} e^{-c \int_r^{r_2} f(a) da} e^{-c \int_t^{r_2} f(a) da} dt dr = \left(\int_{r_1}^{r_2} \sqrt{f(r)} e^{-c \int_r^{r_2} f(a) da} dr \right)^2 \approx \frac{1}{(2c)^2 f(r_2)}. \end{aligned}$$

Hence, $\int_{r_1}^{r_2} \xi_r \sqrt{f(r)} e^{-c \int_r^{r_2} f(a) da} dr = O_p(1/c)$. Noting that $c \int_{r_1}^{r_2} f(r) e^{-2c \int_r^{r_2} f(a) da} dr = \frac{1}{2} \left(1 - e^{-2c \int_{r_1}^{r_2} f(a) da} \right)$, we then have

$$(56) \quad \int_{r_1}^{r_2} c f(r) F_c^2(r) dr = \frac{1}{2} \left(1 - e^{-2c \int_{r_1}^{r_2} f(a) da} \right) J_c^2(r_2; r_1) + J_c(r_2; r_1) O_p(1/\sqrt{c}),$$

and

$$\begin{aligned} & \int_0^1 F_c^2(r) dr = \int_0^{r_1} B^a(r)^2 dr + \int_{r_1}^{r_2} J_c^2(r; r_1) dr + \int_{r_2}^1 (B^b(r) + J_c(r_2; r_1))^2 dr \\ & = J_c^2(r_2; r_1) \int_{r_1}^{r_2} e^{-2c \int_r^{r_2} f(a) da} dr - \frac{2J_c(r_2; r_1)}{\sqrt{2c}} \int_{r_1}^{r_2} \frac{\xi_r}{\sqrt{f(r)}} e^{-c \int_r^{r_2} f(a) da} dr \\ (57) \quad & + \frac{1}{2c} \int_{r_1}^{r_2} \frac{\xi_r^2}{f(r)} dr + (1 - r_2) J_c^2(r_2; r_1) + 2J_c(r_2; r_1) \int_{r_2}^1 B^b(r) dr + O_p(1) \\ & = J_c^2(r_2; r_1) \left(1 - r_2 + \int_{r_1}^{r_2} e^{-2c \int_r^{r_2} f(a) da} dr \right) + 2J_c(r_2; r_1) \int_{r_2}^1 B^b(r) dr \\ & + J_c(r_2; r_1) O_p(1/c\sqrt{c}) + O_p(1), \end{aligned}$$

where $\frac{1}{2c} \int_{r_1}^{r_2} \frac{\xi_r^2}{f(r)} dr \leq \frac{1}{2C_c} \int_{r_1}^{r_2} \xi_r^2 dr = O_p(1/c)$. Combining Eq. (55), (56), and (57), we get

${}^1 \mathbb{E} \xi_r \xi_t \leq \sqrt{\mathbb{E} \xi_r^2 \mathbb{E} \xi_t^2} = \sqrt{1 \cdot 1} = 1.$

$$\begin{aligned}
& \frac{\int_0^1 F_c(r)dB(r) + \lambda + \int_{r_1}^{r_2} cf(r)F_c^2(r)dr}{\int_0^1 F_c^2(r)dr} \\
& \approx \frac{\frac{1}{2} \left(1 - e^{-2c \int_{r_1}^{r_2} f(a)da}\right) J_c^2(r_2; r_1) + J_c(r_2; r_1)(B^b(1) - B^b(r_2))}{J_c^2(r_2; r_1) \left(1 - r_2 + \int_{r_1}^{r_2} e^{-2c \int_r^{r_2} f(a)da} dr\right) + 2J_c(r_2; r_1) \int_{r_2}^1 B^b(r)dr} \\
& = \frac{\frac{1}{2} \left(1 - e^{-2c \int_{r_1}^{r_2} f(a)da}\right)}{1 - r_2 + \int_{r_1}^{r_2} e^{-2c \int_r^{r_2} f(a)da} dr} \cdot \frac{1 + \frac{(B^b(1) - B^b(r_2))}{\frac{1}{2} \left(1 - e^{-2c \int_{r_1}^{r_2} f(a)da}\right) J_c(r_2; r_1)}}{2 \int_{r_2}^1 B^b(r)dr} \\
(58) \quad & \frac{1 + \frac{(B^b(1) - B^b(r_2))}{\frac{1}{2} \left(1 - e^{-2c \int_{r_1}^{r_2} f(a)da}\right) J_c(r_2; r_1)}}{\left(1 - r_2 + \int_{r_1}^{r_2} e^{-2c \int_r^{r_2} f(a)da} dr\right) J_c(r_2; r_1)} \\
& \approx \frac{\frac{1}{2} \left(1 - e^{-2c \int_{r_1}^{r_2} f(a)da}\right)}{1 - r_2 + \int_{r_1}^{r_2} e^{-2c \int_r^{r_2} f(a)da} dr} \cdot \left(1 + \frac{(B^b(1) - B^b(r_2))}{\frac{1}{2} \left(1 - e^{-2c \int_{r_1}^{r_2} f(a)da}\right) J_c(r_2; r_1)}\right. \\
& \left. - \frac{2 \int_{r_2}^1 B^b(r)dr}{\left(1 - r_2 + \int_{r_1}^{r_2} e^{-2c \int_r^{r_2} f(a)da} dr\right) J_c(r_2; r_1)}\right).
\end{aligned}$$

Rewriting Eq. (58) and using the fact that $J_c(r_2; r_1) = e^{c \int_{r_1}^{r_2} f(a)da} B^a(r_1) + O_p(1)$, we get

$$\begin{aligned}
(59) \quad & e^{c \int_{r_1}^{r_2} f(a)da} \left(\frac{\int_0^1 F_c(r)dB(r) + \lambda + \int_{r_1}^{r_2} cf(r)F_c^2(r)dr}{\int_0^1 F_c^2(r)dr} - \frac{\frac{1}{2} \left(1 - e^{-2c \int_{r_1}^{r_2} f(a)da}\right)}{1 - r_2 + \int_{r_1}^{r_2} e^{-2c \int_r^{r_2} f(a)da} dr} \right) \\
& \approx \frac{1}{B^a(r_1)} \left(\frac{B^b(1) - B^b(r_2)}{\frac{1}{2} \left(1 - e^{-2c \int_{r_1}^{r_2} f(a)da}\right)} - \frac{2 \int_{r_2}^1 B^b(r)dr}{1 - r_2 + \int_{r_1}^{r_2} e^{-2c \int_r^{r_2} f(a)da} dr} \right) \frac{\frac{1}{2} \left(1 - e^{-2c \int_{r_1}^{r_2} f(a)da}\right)}{1 - r_2 + \int_{r_1}^{r_2} e^{-2c \int_r^{r_2} f(a)da} dr} \\
(60) \quad & \approx \frac{1}{2(1 - r_2)B^a(r_1)} \left(2(B^b(1) - B^b(r_2)) - \frac{2 \int_{r_2}^1 B^b(r)dr}{1 - r_2} \right).
\end{aligned}$$

Because $2(B^b(1) - B^b(r_2)) - \frac{2 \int_{r_2}^1 B^b(r)dr}{1 - r_2}$ is Gaussian and independent of $B^a(r_1)$ the limit variate in (60) has a Cauchy distribution. We proceed to calculate the scale coefficient of

this distribution. The component terms in the variance of the numerator are as follows:

$$\begin{aligned}\mathbb{E}\left(2(B^b(1) - B^b(r_2))\frac{2}{1-r_2}\int_{r_2}^1 B^b(r)dr\right) &= \frac{4}{1-r_2}\mathbb{E}B(1-r_2)\int_0^{1-r_2} B(r)dr \\ &= \frac{4\omega^2}{1-r_2}\int_0^{1-r_2} r dr = 2(1-r_2)\omega^2,\end{aligned}$$

$$\mathbb{E}\left(2(B^b(1) - B^b(r_2))\right)^2 = 4(1-r_2)\omega^2,$$

$$\begin{aligned}\mathbb{E}\left(\frac{2}{1-r_2}\int_{r_2}^1 B^b(r)dr\right)^2 &= \frac{4}{(1-r_2)^2}\int_0^{1-r_2}\int_0^{1-r_2}\mathbb{E}(B(s)B(r))dsdr \\ &= \frac{4\omega^2}{(1-r_2)^2}\int_0^{1-r_2}\int_0^{1-r_2}\min(s,r)dsdr \\ &= \frac{4\omega^2}{(1-r_2)^2}\frac{(1-r_2)^3}{3} = \frac{4}{3}(1-r_2)\omega^2,\end{aligned}$$

so that $2(B^b(1) - B^b(r_2)) - \frac{2\int_{r_2}^1 B^b(r)dr}{1-r_2} \sim \mathcal{N}\left(0, \frac{4}{3}(1-r_2)\omega^2\right)$ and thus

$$\begin{aligned}e^{c\int_{r_1}^{r_2} f(a)da}\left(\frac{\int_0^1 F_c(r)dB(r) + \lambda + \int_{r_1}^{r_2} cf(r)F_c^2(r)dr}{\int_0^1 F_c^2(r)dr} - \frac{1 - e^{-2c\int_{r_1}^{r_2} f(a)da}}{2\left(1-r_2 + \int_{r_1}^{r_2} e^{-2c\int_r^{r_2} f(a)da}dr\right)}\right) \\ \xrightarrow[c \rightarrow +\infty]{d} \frac{1}{2(1-r_2)}\frac{\sqrt{4/3(1-r_2)}}{\sqrt{r_1}}\mathcal{C} = \frac{1}{\sqrt{3r_1(1-r_2)}}\mathcal{C}.\end{aligned}$$

It follows that

$$e^{c\int_{r_1}^{r_2} f(a)da}n\left(\hat{\theta}_{OLS} - 1 - \frac{1 - e^{-2c\int_{r_1}^{r_2} f(a)da}}{2n\left(1-r_2 + \int_{r_1}^{r_2} e^{-2c\int_r^{r_2} f(a)da}dr\right)}\right) \xrightarrow[(n,c)_{seq} \rightarrow +\infty]{d} \frac{1}{\sqrt{3r_1(1-r_2)}}\mathcal{C}.$$

□

Proof of Theorem 4.

Proof. The proof of (19) follows by the martingale CLT for triangular arrays by establishing the stability and Lindeberg conditions. First consider the variance of $\frac{1}{\sqrt{k_n}}\tilde{X}_{[nr]}$, for

$r \in (0, 1]$. Using the martingale difference property of $\{u_t\}_t$, we have

$$\begin{aligned}
(61) \quad \left\langle \frac{1}{\sqrt{k_n}} \tilde{X}_{[nr]} \right\rangle &= \frac{\sigma^2}{k_n} \sum_{j=1}^{[nr]} e^{-\left\{ \frac{2}{k_n} \sum_{l=[nr]-j+1}^{[nr]} c\left(\frac{[nr]-l+1}{n}\right) \right\}} + o(1) \\
&\approx \sigma^2 \int_0^{\frac{[nr]}{k_n}} e^{-2 \int_0^z c\left(x \frac{k_n}{n}\right) dx} dz + o(1) \\
&\xrightarrow{n \rightarrow \infty} \sigma^2 \int_0^\infty e^{-2zc(0)} dz = \frac{\sigma^2}{2c(0)},
\end{aligned}$$

which is constant. Next suppose that $s > r$ and note the covariance

$$\begin{aligned}
&\left\langle \frac{1}{\sqrt{k_n}} \tilde{X}_{[nr]}, \frac{1}{\sqrt{k_n}} \tilde{X}_{[ns]} \right\rangle \\
&= \frac{\sigma^2}{k_n} \sum_{j=1}^{[nr]} e^{-\frac{1}{k_n} \left(\sum_{l=[nr]-j+1}^{[nr]} c\left(\frac{[nr]-l+1}{n}\right) + \sum_{l=[ns]-j+1}^{[ns]} c\left(\frac{[ns]-l+1}{n}\right) \right)} + o_p(1) \\
&\approx \sigma^2 \int_0^{\frac{[nr]}{k_n}} e^{-2 \int_0^z c\left(x \frac{k_n}{n}\right) dx} dz + o(1) \\
&\xrightarrow{n \rightarrow \infty} \sigma^2 \int_0^\infty e^{-2zc(0)} dz = \frac{\sigma^2}{2c(0)} = \left\langle \frac{1}{\sqrt{k_n}} \tilde{X}_{[nr]} \right\rangle = \left\langle \frac{1}{\sqrt{k_n}} \tilde{X}_{[ns]} \right\rangle,
\end{aligned}$$

is also constant. The Lindeberg condition is established as follows. Take $\delta > 0$, and noting that $c(a) \geq 0$ over $a \in [0, 1]$ and $c(a) \geq C > 0$ for all $a \in [0, \varepsilon] \cup [1 - \varepsilon, 1]$ for some $\varepsilon > 0$, we obtain

$$\begin{aligned}
&\sum_{j=1}^{[nr]} \mathbb{E} \left\{ \frac{e^{-\frac{2}{k_n} \sum_{l=[nr]-j+1}^{[nr]} c\left(\frac{[nr]-l+1}{n}\right)}}}{k_n} u_j^2 \mathbf{1} \left[|u_j| > \delta \sqrt{k_n} e^{\frac{1}{k_n} \sum_{l=[nr]-j+1}^{[nr]} c\left(\frac{[nr]-l+1}{n}\right)} \right] \right\} \\
&= \frac{1}{k_n} \sum_{j=1}^{[nr]} e^{-\frac{2}{k_n} \sum_{l=[nr]-j+1}^{[nr]} c\left(\frac{[nr]-l+1}{n}\right)} \mathbb{E} \left\{ u_j^2 \mathbf{1} \left[|u_j| > \delta \sqrt{k_n} e^{\frac{1}{k_n} \sum_{l=[nr]-j+1}^{[nr]} c\left(\frac{[nr]-l+1}{n}\right)} \right] \right\} \\
&\leq \frac{1}{k_n} \sum_{j=1}^{[nr]} e^{-\frac{2}{k_n} \sum_{l=[nr]-j+1}^{[nr]} c\left(\frac{[nr]-l+1}{n}\right)} \times \mathbb{E} \left\{ u_1^2 \mathbf{1} \left[|u_1| > \delta \sqrt{k_n} \right] \right\} \\
&= \frac{1}{n} \frac{n}{k_n} \sum_{j=1}^{[nr]} e^{-\frac{2n}{k_n} \sum_{l=[nr]-j+1}^{[nr]} c\left(\frac{[nr]-l+1}{n}\right) \frac{1}{n}} \times \mathbb{E} \left\{ u_1^2 \mathbf{1} \left[|u_1| > \delta \sqrt{k_n} \right] \right\} \\
&\sim \frac{n}{k_n} \int_0^r e^{-\frac{2n}{k_n} \int_0^s c(a) da} ds \times \mathbb{E} \left\{ u_1^2 \mathbf{1} \left[|u_1| > \delta \sqrt{k_n} \right] \right\} \\
&\sim \frac{1}{2c(0)} \mathbb{E} \left\{ u_1^2 \mathbf{1} \left[|u_1| > \delta \sqrt{k_n} \right] \right\} \rightarrow 0
\end{aligned}$$

since $\mathbb{E}(u_1^2) < \infty$ and

$$\int_0^r e^{-\frac{2n}{k_n} \int_0^s c(a) da} ds \approx \int_0^\varepsilon e^{-\frac{2n}{k_n} c(0)s} ds = \frac{k_n}{2nc(0)} \left(1 - e^{-\frac{2n}{k_n} c(0)\varepsilon}\right) \approx \frac{k_n}{2nc(0)}.$$

Thus, the Lindeberg condition holds and (19) holds for all $r \in (0, 1]$. Result (20) follows in a related way and the proof is omitted. \square

Proof of Theorem 5.

Proof. The proof is similar to the line of reasoning used in the proof of Theorem 3 but the calculations are considerably more complex. First, it is useful to re-normalize the time series X_t as \tilde{X}_t , and then rewrite everything in terms of the last observation, \tilde{X}_n . Note that

$$\begin{aligned} \tilde{X}_t &= e^{-\frac{1}{k_n} \sum_{l=1}^t c(\frac{t-l+1}{n})} X_t = e^{-\frac{1}{k_n} \sum_{j=1}^t c(\frac{j}{n})} X_t = X_0 + \sum_{j=1}^t e^{-\frac{1}{k_n} \sum_{l=1}^j c(l/n)} u_j \\ (62) \quad &= \tilde{X}_n - \sum_{j=t+1}^n e^{-\frac{1}{k_n} \sum_{l=1}^j c(l/n)} u_j. \end{aligned}$$

We start with the decomposition

$$(63) \quad k_n \left(\hat{\theta}_{OLS} - 1 \right) = \frac{\frac{1}{n} \sum_{t=1}^n X_{t-1} \Delta X_t}{\frac{1}{nk_n} \sum_{t=1}^n X_{t-1}^2} = \frac{\frac{1}{n} \sum_{t=1}^n \frac{c(\frac{t}{n})}{k_n} X_{t-1}^2}{\frac{1}{nk_n} \sum_{t=1}^n X_{t-1}^2} + \frac{\frac{1}{n} \sum_{t=1}^n X_{t-1} u_t}{\frac{1}{nk_n} \sum_{t=1}^n X_{t-1}^2},$$

and rewrite the component sums in terms of \tilde{X}_n using (62). We consider each term separately, starting with the common denominator.

(i) Denominator of (63)

Upon scaling by $e^{-\frac{2}{k_n} \sum_{j=1}^n c(\frac{j}{n})}$, we write the denominator as

$$\begin{aligned} &e^{-\frac{2}{k_n} \sum_{j=1}^n c(\frac{j}{n})} \frac{1}{n} \sum_{t=1}^n \left(\frac{X_{t-1}}{\sqrt{k_n}} \right)^2 = \frac{1}{n} \sum_{t=1}^n \left(\frac{\tilde{X}_{t-1}}{\sqrt{k_n}} \right)^2 \frac{e^{\frac{2}{k_n} \sum_{j=1}^{t-1} c(\frac{j}{n})}}{e^{\frac{2}{k_n} \sum_{j=1}^n c(\frac{j}{n})}} \\ (64) \quad &= \frac{1}{n} \sum_{t=1}^n \left(\frac{\tilde{X}_n - \sum_{j=t}^n e^{-\frac{1}{k_n} \sum_{l=1}^j c(l/n)} u_j}{\sqrt{k_n}} \right)^2 e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})} \\ &= \frac{1}{n} \left(\frac{\tilde{X}_n}{\sqrt{k_n}} \right)^2 \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})} - \frac{2}{n} \frac{\tilde{X}_n}{\sqrt{k_n}} \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})} \sum_{j=t}^n e^{-\frac{1}{k_n} \sum_{l=1}^j c(l/n)} \frac{u_j}{\sqrt{k_n}} \\ &+ \frac{1}{n} \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})} \left(\sum_{j=t}^n e^{-\frac{1}{k_n} \sum_{l=1}^j c(l/n)} \frac{u_j}{\sqrt{k_n}} \right)^2 =: D_{n,1} + D_{n,2} + D_{n,3}. \end{aligned}$$

From Theorem 4, we know that $\frac{\tilde{X}_n}{\sqrt{k_n}} = O_p(1)$. It is easy to see that in the last part of (64) the first term $D_{n,1}$ has the largest order of magnitude and the second term $D_{n,2}$ has the second largest order. More specifically, the three terms of (64) take the following forms as $\frac{1}{k_n} + \frac{k_n}{n} \rightarrow 0$

$$\begin{aligned}
(65) \quad D_{n,1} &= \frac{1}{n} \left(\frac{\tilde{X}_n}{\sqrt{k_n}} \right)^2 \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})} \approx \left(\frac{\tilde{X}_n}{\sqrt{k_n}} \right)^2 \int_0^1 e^{-\frac{2n}{k_n} \int_s^1 c(a) da} ds \\
&\approx \left(\frac{\tilde{X}_n}{\sqrt{k_n}} \right)^2 \int_{1-\varepsilon}^1 e^{-\frac{2n}{k_n} c(1)(1-s)} ds = \left(\frac{\tilde{X}_n}{\sqrt{k_n}} \right)^2 \frac{k_n}{2nc(1)} \left(1 - e^{-\frac{2n}{k_n} c(1)\varepsilon} \right) = O_p \left(\frac{k_n}{n} \right),
\end{aligned}$$

$$\begin{aligned}
(66) \quad D_{n,2} &= \frac{2}{n} \frac{\tilde{X}_n}{\sqrt{k_n}} \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})} \sum_{j=t}^n e^{-\frac{1}{k_n} \sum_{l=1}^j c(l/n)} \frac{u_j}{\sqrt{k_n}} \\
&\approx \frac{2\tilde{X}_n}{\sqrt{k_n}} \sqrt{\frac{n}{k_n}} \int_0^1 e^{-\frac{2n}{k_n} \int_z^1 c(a) da} \int_z^1 e^{-\frac{n}{k_n} \int_0^s c(a) da} dB(s) dz \\
&= \frac{2\tilde{X}_n}{\sqrt{k_n}} \sqrt{\frac{n}{k_n}} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \int_0^1 e^{-\frac{n}{k_n} \int_z^1 c(a) da} \int_z^1 e^{-\frac{n}{k_n} \int_z^s c(a) da} dB(s) dz \\
&= \frac{2\tilde{X}_n}{\sqrt{k_n}} \sqrt{\frac{n}{k_n}} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} \int_0^s e^{-\frac{2n}{k_n} \int_z^s c(a) da} dz dB(s) \\
&\approx \frac{2\tilde{X}_n}{\sqrt{k_n}} \sqrt{\frac{k_n}{n}} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} \frac{1}{2c(s)} dB(s) \\
&= \frac{2\tilde{X}_n}{\sqrt{k_n}} \frac{k_n}{n} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \sqrt{\frac{n}{k_n}} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} \frac{1}{2c(s)} dB(s), \\
&= O_p \left(\frac{k_n}{n} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \right),
\end{aligned}$$

and

$$\begin{aligned}
(67) \quad D_{n,3} &= \frac{1}{n} \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})} \left(\sum_{j=t}^n e^{-\frac{1}{k_n} \sum_{l=1}^j c(l/n)} \frac{u_j}{\sqrt{k_n}} \right)^2 \\
&\approx \frac{n}{k_n} \int_0^1 e^{-\frac{2n}{k_n} \int_z^1 c(a) da} \left(\int_z^1 e^{-\frac{n}{k_n} \int_0^s c(a) da} dB(s) \right)^2 dz \\
&= \frac{n}{k_n} e^{-\frac{2n}{k_n} \int_0^1 c(a) da} \int_0^1 \left(\int_z^1 e^{-\frac{n}{k_n} \int_z^s c(a) da} dB(s) \right)^2 dz \\
&= e^{-\frac{2n}{k_n} \int_0^1 c(a) da} \int_0^1 \left(\sqrt{\frac{n}{k_n}} \int_z^1 e^{-\frac{n}{k_n} \int_z^s c(a) da} dB(s) \right)^2 dz \\
&= O_p \left(e^{-\frac{2n}{k_n} \int_0^1 c(a) da} \right).
\end{aligned}$$

Note that the stochastic integral representation $\int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} \frac{1}{2c(s)} dB(s)$ that appears in the Eq. (66) relies as $n \rightarrow \infty$ on the function $c(s)$ only in the immediate neighborhood of the end point $s = 1$, so asymptotically the condition $c(1) > 0$ is sufficient for the asymptotics to hold.

(ii) Numerators of (63)

Start by considering the numerator in the first term on the right side of (63). Upon scaling by $e^{-\frac{2}{k_n} \sum_{j=1}^n c(\frac{j}{n})}$, as for the denominator, and by expanding the expression in terms of \tilde{X}_n , we obtain

$$\begin{aligned}
(68) \quad & e^{-\frac{2}{k_n} \sum_{j=1}^n c(\frac{j}{n})} \frac{1}{n} \sum_{t=1}^n c\left(\frac{t}{n}\right) \left(\frac{X_{t-1}}{\sqrt{k_n}}\right)^2 = \frac{1}{n} \sum_{t=1}^n c\left(\frac{t}{n}\right) \left(\frac{\tilde{X}_{t-1}}{\sqrt{k_n}}\right)^2 e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})} \\
& = \frac{1}{n} \left(\frac{\tilde{X}_n}{\sqrt{k_n}}\right)^2 \sum_{t=1}^n c\left(\frac{t}{n}\right) e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})} - \frac{2}{n} \frac{\tilde{X}_n}{\sqrt{k_n}} \sum_{t=1}^n c\left(\frac{t}{n}\right) e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})} \sum_{j=t}^n e^{-\frac{1}{k_n} \sum_{l=1}^j c(\frac{l}{n})} \frac{u_j}{\sqrt{k_n}} \\
& + \frac{1}{n} \sum_{t=1}^n c\left(\frac{t}{n}\right) e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})} \left(\sum_{j=t}^n e^{-\frac{1}{k_n} \sum_{l=1}^j c(\frac{l}{n})} \frac{u_j}{\sqrt{k_n}}\right)^2 \\
& =: N_{n,1}^A + N_{n,2}^A + N_{n,3}^A.
\end{aligned}$$

By the same logic employed with the denominator, in (68) the first term has the largest order of magnitude, and the second has the second largest order of magnitude. Note, in particular, that

$$\begin{aligned}
(69) \quad & N_{n,2}^A = \frac{2}{n} \frac{\tilde{X}_n}{\sqrt{k_n}} \sum_{t=1}^n c\left(\frac{t}{n}\right) e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})} \sum_{j=t}^n e^{-\frac{1}{k_n} \sum_{l=1}^j c(\frac{l}{n})} \frac{u_j}{\sqrt{k_n}} \\
& \approx \frac{2\tilde{X}_n}{\sqrt{k_n}} \sqrt{\frac{n}{k_n}} \int_0^1 c(z) e^{-\frac{2n}{k_n} \int_z^1 c(a) da} \int_z^1 e^{-\frac{n}{k_n} \int_0^s c(a) da} dB(s) dz \\
& = \frac{2\tilde{X}_n}{\sqrt{k_n}} \sqrt{\frac{n}{k_n}} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \int_0^1 c(z) e^{-\frac{n}{k_n} \int_z^1 c(a) da} \int_z^1 e^{-\frac{n}{k_n} \int_z^s c(a) da} dB(s) dz \\
& = \frac{2\tilde{X}_n}{\sqrt{k_n}} \sqrt{\frac{n}{k_n}} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} \int_0^s c(z) e^{-\frac{2n}{k_n} \int_z^s c(a) da} dz dB(s), \\
& \approx \frac{2\tilde{X}_n}{\sqrt{k_n}} \sqrt{\frac{k_n}{n}} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} \frac{1}{2} dB(s), \\
& = \frac{\tilde{X}_n}{\sqrt{k_n}} \frac{k_n}{n} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \sqrt{\frac{n}{k_n}} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} dB(s), \\
& = O_p\left(\frac{k_n}{n} e^{-\frac{n}{k_n} \int_0^1 c(a) da}\right),
\end{aligned}$$

which has precisely the same form and consequently the same order as (66). Similar arguments to those of the denominator apply to the other two terms in this numerator expansion.

Next consider the numerator of the second component of (63). Scaling this term by $\frac{n}{k_n} e^{-\frac{1}{k_n} \sum_{j=1}^n c(\frac{j}{n})}$, we have

$$\begin{aligned}
& e^{-\frac{1}{k_n} \sum_{j=1}^n c(\frac{j}{n})} \sum_{t=1}^n \frac{X_{t-1}}{\sqrt{k_n}} \frac{u_t}{\sqrt{k_n}} = \sum_{t=1}^n \frac{\tilde{X}_{t-1}}{\sqrt{k_n}} \frac{u_t}{\sqrt{k_n}} \frac{e^{\frac{1}{k_n} \sum_{j=1}^{t-1} c(\frac{j}{n})}}{e^{\frac{1}{k_n} \sum_{j=1}^n c(\frac{j}{n})}} \\
(70) \quad & = \sum_{t=1}^n \frac{\tilde{X}_n - \sum_{j=t}^n e^{-\frac{1}{k_n} \sum_{l=1}^j c(\frac{l}{n})} u_j}{\sqrt{k_n}} \frac{u_t}{\sqrt{k_n}} e^{-\frac{1}{k_n} \sum_{j=t}^n c(\frac{j}{n})} \\
& = \frac{\tilde{X}_n}{\sqrt{k_n}} \sum_{t=1}^n \frac{u_t}{\sqrt{k_n}} e^{-\frac{1}{k_n} \sum_{j=t}^n c(\frac{j}{n})} - \sum_{t=1}^n \frac{u_t}{\sqrt{k_n}} e^{-\frac{1}{k_n} \sum_{j=t}^n c(\frac{j}{n})} \sum_{j=t}^n e^{-\frac{1}{k_n} \sum_{l=1}^j c(\frac{l}{n})} \frac{u_j}{\sqrt{k_n}} \\
& =: N_{n,1}^B + N_{n,2}^B.
\end{aligned}$$

The first term of (70) is approximately

$$N_{n,1}^B = \frac{\tilde{X}_n}{\sqrt{k_n}} \sqrt{\frac{n}{k_n}} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} dB(s) = O_p \left(\sqrt{\frac{n}{k_n}} \right) \times \mathcal{N} \left(0, \frac{k_n \sigma^2}{2nc(1)} \right) = O_p(1),$$

since

$$\begin{aligned}
& \mathbb{V} \left(\sqrt{\frac{n}{k_n}} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} dB(s) \right) = \sigma^2 \frac{n}{k_n} \int_0^1 e^{-\frac{2n}{k_n} \int_s^1 c(a) da} ds \\
& \approx \sigma^2 \frac{n}{k_n} \int_{1-\varepsilon}^1 e^{-\frac{2n}{k_n} c(1)(1-s)} ds = \frac{\sigma^2}{2c(1)} \left(1 - e^{-\frac{2n}{k_n} c(1)\varepsilon} \right) \rightarrow \frac{\sigma^2}{2c(1)}.
\end{aligned}$$

The second term of (70) is approximately

$$\begin{aligned}
(71) \quad N_{n,2}^B & \approx -\frac{n}{k_n} \int_0^1 e^{-\frac{n}{k_n} \int_z^1 c(a) da} \int_z^1 e^{-\frac{n}{k_n} \int_0^s c(a) da} dB(s) dB(z) \\
& = -e^{-\frac{n}{k_n} \int_0^1 c(a) da} \frac{n}{k_n} \int_0^1 \int_z^1 e^{-\frac{n}{k_n} \int_z^s c(a) da} dB(s) dB(z) \\
& = O_p \left(\sqrt{\frac{n}{k_n}} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \right),
\end{aligned}$$

which is of smaller order than the term $N_{n,1}^B$. Further, upon multiplication by $\frac{k_n}{n} e^{-\frac{1}{k_n} \sum_{j=1}^n c(\frac{j}{n})}$ to match the scaling of the denominator and the first part of the numerator, both terms of (70) are evidently of smaller order than (64) and (68). It is

convenient to employ this standardization in what follows and let

$$\bar{N}_{n,1}^B = \frac{k_n}{n} e^{-\frac{1}{k_n} \sum_{j=1}^n c(\frac{j}{n})} N_{n,1}^B \quad \text{and} \quad \bar{N}_{n,2}^B = \frac{k_n}{n} e^{-\frac{1}{k_n} \sum_{j=1}^n c(\frac{j}{n})} N_{n,2}^B.$$

(iii) Bias Calculation

Combining (64), (68), and (70), we obtain the following bias expression for centering the limit behavior of $\hat{\theta}_{OLS}$

$$\begin{aligned} (72) \quad k_n(\hat{\theta}_{OLS} - 1) &= \frac{N_{n,1}^A + O_p\left(\frac{k_n}{n} e^{-\frac{n}{k_n}} \int_0^1 c(a) da\right)}{D_{n,1} + O_p\left(\frac{k_n}{n} e^{-\frac{n}{k_n}} \int_0^1 c(a) da\right)} \\ &= \frac{\frac{1}{n} \left(\frac{\tilde{X}_n}{\sqrt{k_n}}\right)^2 \sum_{t=1}^n c\left(\frac{t}{n}\right) e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})} + O_p\left(\frac{k_n}{n} e^{-\frac{n}{k_n}} \int_0^1 c(a) da\right)}{\frac{1}{n} \left(\frac{\tilde{X}_n}{\sqrt{k_n}}\right)^2 \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})} + O_p\left(\frac{k_n}{n} e^{-\frac{n}{k_n}} \int_0^1 c(a) da\right)} \\ &= \frac{\frac{1}{n} \sum_{t=1}^n c\left(\frac{t}{n}\right) e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})}}{\frac{1}{n} \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c(\frac{j}{n})}} \left(1 + O_p\left(\frac{k_n}{n} e^{-\frac{n}{k_n}} \int_0^1 c(a) da\right)\right) \xrightarrow[n \rightarrow \infty]{p} c(1). \end{aligned}$$

(iv) Combining the Components of (63)

Neglecting smaller order terms according to the earlier calculations of the respective orders of the elements of the numerator and denominator terms yields the asymptotic approximation

$$\begin{aligned} (73) \quad k_n(\hat{\theta}_{OLS} - 1) - \frac{N_{n,1}^A}{D_{n,1}} &= \frac{N_{n,1}^A + N_{n,2}^A + N_{n,3}^A + \bar{N}_{n,1}^B + \bar{N}_{n,2}^B}{D_{n,1} + D_{n,2} + D_{n,3}} - \frac{N_{n,1}^A}{D_{n,1}} \\ &= \frac{D_{n,1} (N_{n,2}^A + N_{n,3}^A + \bar{N}_{n,1}^B + \bar{N}_{n,2}^B) - N_{n,1}^A (D_{n,2} + D_{n,3})}{D_{n,1} (D_{n,1} + D_{n,2} + D_{n,3})} \\ &\approx \frac{N_{n,2}^A + \bar{N}_{n,1}^B}{D_{n,1}} - \frac{N_{n,1}^A D_{n,2}}{D_{n,1}^2}. \end{aligned}$$

Using (65), (66), (69) and (72), this recentered and scaled estimation error has the following explicit representation

(74)

$$\begin{aligned}
& k_n \left(\hat{\theta}_{OLS} - 1 - \frac{\sum_{t=1}^n c\left(\frac{t}{n}\right) e^{-\frac{2}{k_n} \sum_{j=t}^n c\left(\frac{j}{n}\right)}}{k_n \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c\left(\frac{j}{n}\right)}} \right) \approx \left[\frac{\frac{k_n}{n} e^{-\frac{1}{k_n} \sum_{j=1}^n c\left(\frac{j}{n}\right)} \tilde{X}_n}{\sqrt{k_n}} \sum_{t=1}^n \frac{u_t}{\sqrt{k_n}} e^{-\frac{1}{k_n} \sum_{j=t}^n c\left(\frac{j}{n}\right)} \right. \\
& \left. - \frac{2}{n} \frac{\tilde{X}_n}{\sqrt{k_n}} \sum_{t=1}^n c\left(\frac{t}{n}\right) e^{-\frac{2}{k_n} \sum_{j=t}^n c\left(\frac{j}{n}\right)} \sum_{j=t}^n e^{-\frac{1}{k_n} \sum_{l=1}^j c\left(\frac{l}{n}\right)} \frac{u_j}{\sqrt{k_n}} \right] / \left[\frac{1}{n} \left(\frac{\tilde{X}_n}{\sqrt{k_n}} \right)^2 \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c\left(\frac{j}{n}\right)} \right] \\
& + \left[\frac{1}{n} \left(\frac{\tilde{X}_n}{\sqrt{k_n}} \right)^2 \sum_{t=1}^n c\left(\frac{t}{n}\right) e^{-\frac{2}{k_n} \sum_{j=t}^n c\left(\frac{j}{n}\right)} \times \frac{2}{n} \frac{\tilde{X}_n}{\sqrt{k_n}} \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c\left(\frac{j}{n}\right)} \sum_{j=t}^n e^{-\frac{1}{k_n} \sum_{l=1}^j c\left(\frac{l}{n}\right)} \frac{u_j}{\sqrt{k_n}} \right] / \\
& \left[\frac{1}{n} \left(\frac{\tilde{X}_n}{\sqrt{k_n}} \right)^2 \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c\left(\frac{j}{n}\right)} \right]^2 \\
& \approx \left[\sqrt{\frac{k_n}{n}} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} dB(s) \right. \\
& \left. - 2 \sqrt{\frac{n}{k_n}} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} \int_0^s c(z) e^{-\frac{2n}{k_n} \int_z^s c(a) da} dz dB(s) \right] / \\
& \left[\frac{\tilde{X}_n}{\sqrt{k_n}} \int_0^1 e^{-\frac{2n}{k_n} \int_s^1 c(a) da} ds \right] \\
& + \left[2 \int_0^1 c(s) e^{-\frac{2n}{k_n} \int_s^1 c(a) da} ds \sqrt{\frac{n}{k_n}} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} \int_0^s e^{-\frac{2n}{k_n} \int_z^s c(a) da} dz dB(s) \right] \\
& / \left[\frac{\tilde{X}_n}{\sqrt{k_n}} \left(\int_0^1 e^{-\frac{2n}{k_n} \int_s^1 c(a) da} ds \right)^2 \right].
\end{aligned}$$

From Theorem 4, $\frac{\tilde{X}_n}{\sqrt{k_n}} \xrightarrow[n \rightarrow \infty]{d} X_{c(0)} =_d \mathcal{N}(0, \frac{\sigma^2}{2c(0)})$, and only early innovations with $t \approx 0$ influence the limit behavior of \tilde{X}_n and, hence, the denominator of (74). By contrast, the numerator in (74) downweights early innovations and its limit behavior is governed as $n \rightarrow \infty$ by the right side of the unit interval, i.e. for values of $t \approx n$. Thus, numerator and denominator of (74) are independent as $n \rightarrow \infty$, both being Gaussian in the limit. Thus, the limit distribution of the ratio on the right side of (74) is Cauchy (\mathcal{C}) and it remains to calculate the correct scaling factor of this distribution, which is determined by the respective variances of the Gaussian components.

Note that

$$\int_0^1 e^{-\frac{2n}{k_n} \int_s^1 c(a) da} ds \approx \int_{1-\varepsilon}^1 e^{-\frac{2n}{k_n} c(1)(1-s)} ds = \frac{k_n}{2nc(1)} \left(1 - e^{-\frac{2n}{k_n} c(1)\varepsilon} \right) \approx \frac{k_n}{2nc(1)},$$

$$\int_0^1 \frac{1}{(2c(s))^2} e^{-\frac{2n}{k_n} \int_s^1 c(a) da} ds \approx \frac{k_n}{2n} \frac{1}{(2c(1))^3},$$

and

$$\int_0^1 c(s) e^{-\frac{2n}{k_n} \int_s^1 c(a) da} ds = \frac{k_n}{2n} \left(1 - e^{-\frac{2n}{k_n} \int_0^1 c(a) da}\right) \approx \frac{k_n}{2n}.$$

Then

$$X_{c(0)} \left(\int_0^1 e^{-\frac{2n}{k_n} \int_s^1 c(a) da} ds \right)^2 \approx_d \frac{\sigma}{\sqrt{2c(0)}} \mathcal{N}(0, 1) \left(\frac{k_n}{2nc(1)} \right)^2,$$

and by direct integration

$$\begin{aligned} & 2\sqrt{\frac{n}{k_n}} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} \int_0^s c(z) e^{-\frac{2n}{k_n} \int_z^s c(a) da} dz dB(s) \\ &= \sqrt{\frac{k_n}{n}} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} \left(1 - e^{-\frac{2n}{k_n} \int_0^s c(a) da}\right) dB(s) \approx \sqrt{\frac{k_n}{n}} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} dB(s). \end{aligned}$$

We may therefore simplify the representation (74) as follows

(75)

$$\begin{aligned} & k_n \left(\hat{\theta}_{OLS} - 1 - \frac{\sum_{t=1}^n c\left(\frac{t}{n}\right) e^{-\frac{2}{k_n} \sum_{j=t}^n c\left(\frac{j}{n}\right)}}{k_n \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c\left(\frac{j}{n}\right)}} \right) \\ & \approx \left[2 \int_0^1 c(s) e^{-\frac{2n}{k_n} \int_s^1 c(a) da} ds \sqrt{\frac{n}{k_n}} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} \int_0^s e^{-\frac{2n}{k_n} \int_z^s c(a) da} dz dB(s) \right] \\ & / \left[\frac{\tilde{X}_n}{\sqrt{k_n}} \left(\int_0^1 e^{-\frac{2n}{k_n} \int_s^1 c(a) da} ds \right)^2 \right] \\ & \approx \left[\sqrt{\frac{k_n}{n}} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} \int_0^s e^{-\frac{2n}{k_n} \int_z^s c(a) da} dz dB(s) \right] / \left[\frac{\sigma}{\sqrt{2c(0)}} \mathcal{N}(0, 1) \left(\frac{k_n}{2nc(1)} \right)^2 \right] \\ & \approx \left[\sqrt{\frac{k_n}{n}} e^{-\frac{n}{k_n} \int_0^1 c(a) da} \frac{k_n}{n} \int_0^1 \frac{1}{2c(s)} e^{-\frac{n}{k_n} \int_s^1 c(a) da} dB(s) \right] / \left[\frac{\sigma}{\sqrt{2c(0)}} \mathcal{N}(0, 1) \left(\frac{k_n}{2nc(1)} \right)^2 \right] \\ & = \left[e^{-\frac{n}{k_n} \int_0^1 c(a) da} \sqrt{\frac{n}{k_n}} \int_0^1 \frac{1}{2c(s)} e^{-\frac{n}{k_n} \int_s^1 c(a) da} dB(s) \right] / \left[\frac{\sigma}{\sqrt{2c(0)}} \mathcal{N}(0, 1) \left(\frac{1}{2c(1)} \right)^2 \right] \\ & \approx_d \left[e^{-\frac{n}{k_n} \int_0^1 c(a) da} \frac{\sigma}{(2c(1))^{\frac{3}{2}}} \mathcal{N}(0, 1) \right] / \left[\frac{\sigma}{\sqrt{2c(0)}} \left(\frac{1}{2c(1)} \right)^2 \mathcal{N}(0, 1) \right] \\ & =_d e^{-\frac{n}{k_n} \int_0^1 c(a) da} \times 2\sqrt{c(0)c(1)} \times \mathcal{C}. \end{aligned}$$

As earlier, the representations involving $\int_0^1 \frac{1}{2c(s)} e^{-\frac{n}{k_n} \int_s^1 c(a) da} dB(s)$ in the above argument rely as $n \rightarrow \infty$ on the function $c(s)$ only in the immediate vicinity of $s = 1$ and $c(1) > 0$ suffices for the asymptotics to hold.

We deduce the following asymptotic form of the centered estimator

$$k_n \left(\hat{\theta}_{OLS} - 1 - \frac{\sum_{t=1}^n c\left(\frac{t}{n}\right) e^{-\frac{2}{k_n} \sum_{j=t}^n c\left(\frac{j}{n}\right)}}{k_n \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c\left(\frac{j}{n}\right)}} \right) \approx 2e^{-\frac{n}{k_n} \int_0^1 c(a) da} \sqrt{c(0)c(1)} \mathcal{C},$$

which leads to the limit theory

$$k_n e^{\frac{n}{k_n} \int_0^1 c(a) da} \left(\hat{\theta}_{OLS} - 1 - \frac{\sum_{t=1}^n c\left(\frac{t}{n}\right) e^{-\frac{2}{k_n} \sum_{j=t}^n c\left(\frac{j}{n}\right)}}{k_n \sum_{t=1}^n e^{-\frac{2}{k_n} \sum_{j=t}^n c\left(\frac{j}{n}\right)}} \right) \xrightarrow[n \rightarrow \infty]{d} 2\sqrt{c(0)c(1)} \mathcal{C},$$

as stated.

Finally, from (63) we have with random re-centering

$$k_n \left(\hat{\theta}_{OLS} - 1 - \frac{\sum_{t=1}^n \frac{c(t/n)}{k_n} X_{t-1}^2}{\sum_{t=1}^n X_{t-1}^2} \right) = \frac{\frac{1}{n} \sum_{t=1}^n X_{t-1} u_t}{\frac{1}{nk_n} \sum_{t=1}^n X_{t-1}^2}.$$

Then, using (64), (70), and the fact that

$$\mathbb{V} \left(\sqrt{\frac{n}{k_n}} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} dB(s) \right) = \sigma^2 \frac{n}{k_n} \int_0^1 e^{-\frac{2n}{k_n} \int_s^1 c(a) da} ds \rightarrow \frac{\sigma^2}{2c(1)}$$

we have

$$\begin{aligned} k_n e^{\frac{n}{k_n} \int_0^1 c(a) da} \left(\hat{\theta}_{OLS} - 1 - \frac{\sum_{t=1}^n \frac{c(t/n)}{k_n} X_{t-1}^2}{\sum_{t=1}^n X_{t-1}^2} \right) &\approx_d \frac{\frac{k_n}{n} N_{n,1}^B}{D_{n,1}} \\ &\approx_d \frac{\frac{k_n}{n} \sqrt{\frac{n}{k_n}} \int_0^1 e^{-\frac{n}{k_n} \int_s^1 c(a) da} dB(s)}{\frac{\sigma}{\sqrt{2c(0)}} \left(\frac{k_n}{2nc(1)} \right) \mathcal{N}(0, 1)} \\ &\xrightarrow[n \rightarrow \infty]{d} 2\sqrt{c(0)c(1)} \mathcal{C}, \end{aligned}$$

as required. □

Proof of Theorem 6.

Proof. We proceed in the same manner as for Theorem 4 and apply the martingale CLT. We first establish the stability condition for the variance of

$$\frac{1}{\sqrt{k_n}} X_{[nr]} = \frac{1}{\sqrt{k_n}} \sum_{j=1}^{[nr]} e^{\frac{1}{k_n} \sum_{l=1}^{[nr]-j} c\left(\frac{[nr]-l+1}{n}\right)} u_j.$$

which has the form

$$\begin{aligned}
\left\langle \frac{1}{\sqrt{k_n}} X_{[nr]} \right\rangle &= \frac{\sigma^2}{k_n} \sum_{j=1}^{[nr]} e^{\frac{2}{k_n} \sum_{l=1}^{[nr]-j} c\left(\frac{[nr]-l+1}{n}\right)} \\
(76) \qquad &= \frac{\sigma^2}{k_n} \sum_{j=1}^{[nr]-[\sqrt{k_n n}]-1} \exp \left\{ \frac{2}{k_n} \sum_{l=1}^{[nr]-j} c\left(\frac{[nr]-l+1}{n}\right) \right\} \\
&\quad + \frac{\sigma^2}{k_n} \sum_{j=[nr]-[\sqrt{k_n n}]}^{[nr]} \exp \left\{ \frac{2}{k_n} \sum_{l=1}^{[nr]-j} c\left(\frac{[nr]-l+1}{n}\right) \right\}.
\end{aligned}$$

Note that when $j \leq [nr] - [\sqrt{k_n n}]$, we get $[nr] - j \geq [\sqrt{k_n n}]$, so that

$$\exp \left\{ \frac{2}{k_n} \sum_{l=1}^{[nr]-j} c\left(\frac{[nr]-l+1}{n}\right) \right\} \leq \exp \left\{ -2\sqrt{n/k_n} C \right\},$$

and

$$\begin{aligned}
(77) \qquad &\frac{\sigma^2}{k_n} \sum_{j=1}^{[nr]-[\sqrt{k_n n}]-1} \exp \left\{ \frac{2}{k_n} \sum_{l=1}^{[nr]-j} c\left(\frac{[nr]-l+1}{n}\right) \right\} \\
&\leq \sigma^2 \frac{[nr] - \sqrt{k_n n}}{k_n} \exp \left\{ -2\sqrt{n/k_n} C \right\} \xrightarrow{n \rightarrow \infty} 0.
\end{aligned}$$

Now consider the second summation in (76). If $j \geq [nr] - \sqrt{k_n n}$, we get $\frac{j+1}{n} \geq \frac{[nr]-\sqrt{k_n n}}{n} \approx r$, so that $c\left(\frac{[nr]-l+1}{n}\right) \approx c(r)$ uniformly for $l = 1, \dots, [nr] - j$. Then

$$\begin{aligned}
(78) \qquad &\frac{\sigma^2}{k_n} \sum_{j=[nr]-[\sqrt{k_n n}]}^{[nr]} \exp \left\{ \frac{2}{k_n} \sum_{l=1}^{[nr]-j} c\left(\frac{[nr]-l+1}{n}\right) \right\} \\
&\approx \frac{\sigma^2}{k_n} \sum_{j=[nr]-[\sqrt{k_n n}]}^{[nr]} \exp \left\{ 2c(r) \frac{[nr]-j}{k_n} \right\} \\
&\approx \sigma^2 \int_0^{\frac{\sqrt{k_n n}}{k_n}} e^{2c(r)z} dz \xrightarrow{n \rightarrow \infty} \sigma^2 \int_0^\infty e^{2c(r)z} dz = \frac{\sigma^2}{-2c(r)}.
\end{aligned}$$

Using (77) and (78) in (76) gives

$$(79) \qquad \left\langle \frac{1}{\sqrt{k_n}} X_{[nr]} \right\rangle \xrightarrow{n \rightarrow \infty} \frac{\sigma^2}{-2c(r)}.$$

Next observe that for n large enough and $s > r$, $[nr] < [ns] - \sqrt{k_n n}$, as k_n goes to infinity slower than n . Hence, for $s > r$ the covariance

$$\left\langle \frac{1}{\sqrt{k_n}} X_{[nr]}, \frac{1}{\sqrt{k_n}} X_{[ns]} \right\rangle$$

$$\begin{aligned}
&= \frac{\sigma^2}{k_n} \sum_{j=1}^{\lfloor nr \rfloor} \exp \left\{ \frac{1}{k_n} \left(\sum_{l=1}^{\lfloor nr \rfloor - j} c \left(\frac{\lfloor nr \rfloor - l + 1}{n} \right) + \sum_{l=1}^{\lfloor ns \rfloor - j} c \left(\frac{\lfloor ns \rfloor - l + 1}{n} \right) \right) \right\} \\
&\leq \frac{\sigma^2}{k_n} \sum_{j=1}^{\lfloor ns \rfloor - \sqrt{k_n n}} \exp \left\{ \frac{1}{k_n} \left(\sum_{l=1}^{\lfloor nr \rfloor - j} c \left(\frac{\lfloor nr \rfloor - l + 1}{n} \right) + \sum_{l=1}^{\lfloor ns \rfloor - j} c \left(\frac{\lfloor ns \rfloor - l + 1}{n} \right) \right) \right\} \\
&\leq \frac{\sigma^2}{k_n} e^{-\sqrt{n/k_n} C} \sum_{j=1}^{\lfloor ns \rfloor - \sqrt{k_n n}} \exp \left\{ \frac{1}{k_n} \sum_{l=1}^{\lfloor nr \rfloor - j} c \left(\frac{\lfloor nr \rfloor - l + 1}{n} \right) \right\} \\
&\leq \frac{\sigma^2 (\lfloor ns \rfloor - \sqrt{k_n n})}{k_n} e^{-\sqrt{n/k_n} C} \xrightarrow{n \rightarrow \infty} 0.
\end{aligned}$$

In precisely the same way as earlier in the proof of theorem 4, it can be shown that the Lindeberg condition holds, thereby giving the finite dimensional convergence

$$\begin{aligned}
\frac{1}{\sqrt{k_n}} X_{\lfloor nr \rfloor} &= \frac{1}{\sqrt{k_n}} \sum_{j=1}^{\lfloor nr \rfloor} \exp \left\{ \frac{1}{k_n} \sum_{l=1}^{\lfloor nr \rfloor - j} c \left(\frac{\lfloor nr \rfloor - l + 1}{n} \right) \right\} u_j \\
&\quad + \frac{1}{\sqrt{k_n}} \exp \left\{ \frac{1}{k_n} \sum_{j=1}^t c(j/n) \right\} X_0 \\
&\xrightarrow[n \rightarrow \infty]{d} \mathbb{N} \left(0, \frac{\sigma^2}{-2c(r)} \right),
\end{aligned}$$

and the stated result follows. \square
