Developing and validating a multi-dimensional scale for operationalizing industrial service offering

1. Introduction

Manufacturing firms are increasingly shifting the focus of their businesses from tangible products to intangible services (Antioco et al. 2008; Fang, Palmatier, and Steenkamp 2008; Gebauer, Gustafsson, and Witell 2011; Jacob and Ulaga 2008). The reasoning behind such strategic shift encompasses the need to achieve competitive advantage (Anderson and Narus 1997; Heskett, Sasser, and Schlesinger 1997) by locking in customers and by locking out competitors (Neely 2008) as well as to generate new and more stable sources of revenues (Quinn, Doorley, and Paquette 1990; Wise and Baumgartner 1999) and higher profit margins (Mathe and Shapiro 1993). This implies that industrial companies are moving away from simply selling industrial goods as traditional manufacturing companies to strategically reposition themselves by offering 'integrated solutions' (Tuli, Kohli, and Bharadwaj 2007; Helander and Möller, 2008) or 'hybrid offerings' (Ulaga and Reinartz 2011).

The literature acknowledges that such repositioning labeled as e.g., servitization (Kastalli and Van Looy 2013) or service infusion (Ostrom et al. 2010) requires various changes in a firm's corporate culture and human resource management (Homburg, Fassnacht, and Guenther 2003); organizational structures (Sheth and Sharma, 2008; Neu and Brown 2005); pricing methods (Steiner et al. 2016); and internal capabilities (Ulaga and Loveland, 2014). While these studies unquestionably generate valuable knowledge on this topical phenomenon, the essential question of how to measure the scope of industrial service business - that is, the breadth and depth of the service offering of an industrial firm - has received limited attention in the academic literature (Parasuraman, 1998).

Prior studies acknowledge this shortcoming, related with a need for a multi-dimensional scale for measuring industrial services. According to Gebauer (2008, p. 281), “the literature offers little conceptualization of service offerings as a key dimension in the service strategy [of manufacturing firms].” Indeed, several studies in the field emphasize the need to investigate the impact of service business and service strategy on performance (Gebauer et al. 2010; Kastalli and Van Looy 2013). Yet, sophisticated operationalization of industrial service business for conducting such studies does not seem to exist. Ostrom et al. (2010, p. 26), for example, highlight that the topic of “creating and enhancing service standards and metrics that link to financial outcomes of the firm’ is one of the key areas of future research.” Gebauer et al. (2012, p. 130), in turn, state that “there is still confusion about what is the appropriate explanatory variable to describe service provision” and that “future research could discuss how to conceptualize and operationalize the main construct of the research field of service provision.” Finally, prior studies have measured industrial service business as an aggregate, firm-level phenomenon. This level of analysis, however, theoretically contradicts the service literature, which states that the value of service business is co-created in interaction between the firm and its customers (Grönroos 2008; Payne, Storbacka, and Frow 2008; Tuli, Kohli, and Bharadwaj 2007; Vargo and Lusch 2008). Moreover, a manufacturing B2B firm typically has different kinds of customer relationships (Gebauer, Gustafsson, and Witell 2011) and several customer segments (Powers and Reagan 2007), and as consequence, different product-service offerings (Cannon and Perreault 1999). Therefore, one aggregate firm-level measurement is not always the most appropriate level of analysis to deduce theoretically relevant implications.

Motivated by these studies, we argue that a clear need exists for a rigorous, comprehensive, relationship-level, and statistical measure to operationalize and analyze the scope of industrial service business. As such, our study contributes to the service literature by

1
2
3 developing and validating a new measurement, which captures the service offering of an
4
5 industrial firm. More specifically, this measure provides possibilities to undertake empirical
6
7 examinations of several conceptual propositions and hypotheses related to antecedents,
8
9 mediators and moderators that influence industrial services-performance relationship.
10
11

12 13 14 **2. Theoretical background**

15 16 2.1 Defining and classifying industrial services

17
18 Prior literature offers numerous definitions of industrial services (Mathe and Shapiro 1993;
19
20 Morris and Davis 1992; Oliva and Kallenberg 2003). We build on the view of LaLonde and
21
22 Zinszer (1976, p. 344), who define industrial service as “those activities that occur at the
23
24 interface between the customer and the corporation, which enhance or facilitate the sale and
25
26 use of the corporation’s products and services”, but extend it with the fairly simple statement
27
28 from Berry (1980: 24), who posits that “services are consumed but not possessed.” In other
29
30 words, the key distinguishing factor between products and services is the aspect of ownership
31
32 (Edvardsson, Gustafsson, and Roos 2005; Lovelock and Gummesson 2004). Thus, we define
33
34 industrial services as all value-adding activities that are consumed, but not possessed, by the
35
36 industrial customer.
37
38
39

40
41 The scope of the industrial service business resonates closely with how such services are
42
43 classified. Prior studies offer several service typologies, which are summarized in Table 1.
44
45

46
47
48 Insert Table 1 here
49

50
51 As Table 1 demonstrates, the moment of transaction forms the traditional basis for
52
53 classifying industrial services (e.g., LaLonde and Zinszer 1976; Morris and Davis 1992;
54
55 Samli, Jacobs, and Wills 1992). However, this classification has a certain limitation. More
56
57 specifically, service marketing scholars emphasize that the service business does not sequence
58
59
60

1
2
3 itself on the basis of transactional moments (e.g., the sale of industrial equipment), but is an
4
5 ongoing (Grönroos and Helle 2010) and interactive (Wynstra, Axelsson, and Van der Valk
6
7 2006) or 'co-creative' (Payne, Storbacka, and Frow 2008) process that is typically established
8
9 and maintained by relationship management (Barry and Terry, 2008; Edvardsson, Holmlund,
10
11 and Strandvik 2008; Tuli, Kohli, and Bharadwaj 2007; Vargo and Lusch 2008).

12
13
14 More recent studies, in turn, recognize the role of relational dimension of service business
15
16 and establish their typologies on such dichotomies of product vs. process-based services
17
18 (Mathieu 2001; Oliva and Kallenberg 2003) and input vs. performance-based services (Ulaga
19
20 and Reinartz 2011). Such typologies are obviously valuable in advancing theoretical
21
22 development. Yet, they tend to be based on conceptual arguments or in-depth case studies,
23
24 thus lacking the statistical support of empirical data. To our knowledge, only two of the recent
25
26 classifications are based on quantitative evidence. Gebauer (2008) examines the fit between
27
28 the external environment and the strategy of manufacturing firms and yields four service
29
30 offering typologies, namely after sales services, process-oriented services, research and
31
32 development services, and operational services. Raddats and Kowalkowski (2014), in turn,
33
34 base their classification on two dimensions (single vs. multi-vendor orientation; product vs.
35
36 customer orientation) and identify three service typologies: product-attached services,
37
38 operations services on own products, and vendor independent operations services. While
39
40 being pioneering studies in the field, both of them leave room for more fine-grained, service-
41
42 specific measures. Overall, the variety of classifications reflects the heterogeneity and
43
44 complexity of industrial service offerings.

50

51 52 2.2 Measuring the scope of industrial service business

53
54 Prior studies operationalize the scope of industrial service business in several ways. Martinez-
55
56 Tur, Peiró, and Ramós (2001) conceptualize the structural complexity of services by
57
58
59
60

1
2
3 measuring the number of services a firm offers customers. Homburg, Fassnacht, and Guenther
4
5 (2003), in turn, examine the role of corporate culture and human resource management in
6
7 implementing a service-oriented business strategy in industrial companies. They
8
9 conceptualize the service-orientated business strategy with two measurements. The first
10
11 measurement, number of services, features five categories of services with a total of 30
12
13 services. Respondents rate these services on a dichotomous scale (0 = *offered*; 1 = *not offered*;
14
15 cf. Gebauer 2008). The second measurement is the emphasis respondents place on services;
16
17 that is, how strongly a respondent's firm emphasizes various service categories when selling
18
19 the services to customers (1 = *not at all*; 5 = *very actively*). Gebauer et al. (2010) investigate
20
21 the service strategies of manufacturing companies. By building on prior studies, they form
22
23 five service categories and assess them on three dimensions: (1) the number of services
24
25 offered (0 = *offered*; 1 = *not offered*); (2) the number of customers the services are offered to
26
27 (1 = *few customers*; 5 = *many customers*); and (3) how strongly these services are emphasized
28
29 (1 = *not strongly*; 5 = *very strongly*). Finally, Raddats and Kowalkowski (2014) develop a list
30
31 of 11 items corresponding to their framework of multi vs. single vendor orientation and
32
33 product vs. customer orientation (e.g., "My company has taken over some of our customers'
34
35 business processes") and analyze them on a 7-point Likert-scale (1=strongly disagree;
36
37 7=strongly agree). All of these measurements tend to focus on a broader service category
38
39 level, thus neglecting the relative importance of each specific service. In such, these
40
41 measurements offer an opportunity for developing comprehensive, service-specific measures.
42
43
44
45
46

47
48 Regarding more straightforward measurements, some recent studies calculate the extent of
49
50 the service business by investigating the volume of the firms' revenues generated by services.
51
52 Antioco et al. (2008), for example, ask "What percentage of your company's revenues is
53
54 generated by services?" and provide eight categories from which the respondents could
55
56 choose. Neely (2008), in turn, measures different services offered by manufacturing firms and
57
58
59
60

1
2
3 relates them to the extent of their level service development. Fang, Palmatier, and Steenkamp
4
5 (2008) assess service ratio by using a database that provides firms' sales revenue for different
6
7 business segments, dividing these segments into categories of services and non-services.
8
9 Suarez, Cusumano, and Kahl (2013) and Cusumano (2008) operationalize service provision
10
11 by equating it with the share of service revenues. These convenient measuring approaches
12
13 have one major limitation related to the various pricing policies found among industrial
14
15 companies; indeed, prior studies have suggested that negotiated (Indounas, 2009) and
16
17 reference pricing (Bruno, Che, and Dutta 2012), as well as price bundling (Steiner et al. 2016;
18
19 Stremersch and Tellis 2002; Stremersch, Wuyts, and Frambach 2001) are used widely in
20
21 industrial markets. Yet, these common pricing policies make it difficult to distinguish
22
23 (Desiraju and Shugan 1999; Noble and Gruca 1999) and report (Gebauer et al. 2012; Kastalli,
24
25 Van Looy, and Neely 2013) product revenues from service revenues at an aggregate level.
26
27 Hence, these measurements do not fully capture the complexity and heterogeneity of the
28
29 industrial service business; or, as Gebauer et al. (2012, p. 129) state, "Simplifying the
30
31 measurement of service provision may lead to erroneous conclusions."
32
33
34
35

36 Given these various measurement approaches, we concur with Gebauer et al. (2012, p.
37
38 129), who state that "there is great variance in the way service provision has been
39
40 operationalized" and argue that development of multi-dimensional scale for measuring
41
42 industrial service offering represents an important step towards an advanced understanding of
43
44 manufacturing companies' service business.
45
46
47
48

49 **3. Methodology**

50 3.1 Development of measurements

51
52 Building on the work of Antioco et al. (2008), Boyt and Harvey (1997), Gebauer et al. (2010),
53
54 Homburg, Fassnacht, and Guenther (2003), Morris and Davis (1992), Oliva and Kallenberg
55
56
57
58
59
60

(2003), and Samli, Jacobs, and Wills (1992), we created an initial list of 29 industrial services. To complement the key literature, we relied on two corresponding sources of in-depth knowledge. First, we had explorative discussions with five academics in the field of industrial and service marketing, who provided additional insights into prior studies on industrial services, and assisted in developing or brainstorming previously missed or ignored industrial service items and measurement scales. Second, our research project had an advisory board, which included four practitioners (three CEOs and one R&D manager) operating in four different manufacturing firms. During the research project (2008–2010), the advisory board met several times with the authors, who presented initial drafts of the new measurement and collected feedback via discussions. The role of the advisory board was vital as it provided practitioner-oriented viewpoint and validation on our scale development. This iterative and reflective process between theory and practice generated a list of 36 industrial services in four initial categories based on prior theory (Gebauer et al. 2010; Oliva and Kallenberg 2003; Homburg, Fassnacht, and Guenther 2003): (1) technical and optimization services (e.g., installation, just-in-time systems, spare parts); (2) R&D services (e.g., prototyping, feasibility studies, analyzing potential for manufacturing a product); (3) business services (e.g., procurement services, performance services); and (4) product information sharing services (product demonstrations, customer seminars, technical documentation). The categories were synthesized to build a basis for measurement development. Moreover, these initial categories were needed for guiding the development and recognition of service items. At this point, categories were kept broad so that they would not limit identification of service items, but would provide initial structure.

Before collecting data, we pre-tested the constructs for content validity by following the guidelines of Hardesty and Bearden (2004) and Polit, Beck, and Owen (2007). The validation process involved nine scholars in the field of industrial and service marketing research to

1
2
3 assess whether each item fitted the definition of the construct. We developed and sent out a
4
5 web-based questionnaire for the scholars to use in assessing the item-construct fit, with a
6
7 scale ranging from one to four (1 = *not relevant*, 2 = *somewhat relevant*, 3 = *quite relevant*, 4
8
9 = *highly relevant*). In total, the validation process required three validation rounds before the
10
11 measurement was considered methodologically rigorous.
12

13
14 During these validation rounds, three services were discarded due to low content validity:
15
16 namely, sales personnel visits to customer organizations, just-in-time delivery service, and
17
18 providing a customer magazine. After the evaluations, we calculated the content validity
19
20 index (Average I-CVI) and compared the Average I-CVI (I-CVI/AVE) value to the threshold
21
22 value of .8 (Davis 1992; Polit, Beck, and Owen 2007). All constructs, except for “business
23
24 services,” exceeded the threshold, which returned an I-CVI/AVE value of .78 that is slightly
25
26 below the threshold. The final pre-validated questionnaire includes 33 industrial services
27
28 divided into four service categories (Table 2).
29
30
31
32

33
34 Insert Table 2 here
35
36

37
38 After the pre-validation of the construct, a questionnaire was developed. Before collecting
39
40 the data, we sent the questionnaire to the managers of the advisory board for additional
41
42 comments, which resulted in a final survey. Finally, we translated the measure (i.e., the list of
43
44 industrial services and the Likert scale statements) from English into Finnish and asked an
45
46 expert academic to back-translate from Finnish into English to ensure translation equivalence
47
48 (Brislin 1970).
49
50

51 52 53 3.2 Measurement models 54

55 The final questionnaire asked the respondents to identify a single customer relationship with
56
57 the most extensive (i.e., greatest share of revenue) and diverse (i.e., breadth) service business.
58

Thereafter, the questionnaire guided the respondents to evaluate each service on two dimensions. On the first dimension, respondents evaluated how actively each service was offered in the customer relationship (Likert scale: 0 = *not offered*; 1 = *not active at all*; 7 = *very actively*). This evaluation builds on recent studies in the field (Gebauer et al. 2010; Homburg, Fassnacht, and Guenther 2003; Homburg, Hoyer, and Fassnacht 2002), and is in line with Bitner's (1995: 247) 'making service promises'. On the second dimension, the respondents evaluated the significance each service has for the overall revenues in the customer relationship (Likert scale: 0 = *not offered*; 1 = *not significant at all*; 7 = *very significant*). This dimension, too, builds on the recent studies by investigating the revenue generation of services (Antioco et al. 2008; Suarez, Cusumano, and Kahl 2013), and thus resonates well with Bitner's (1995: 247) 'enabling and keeping service promises'.

For measurement, we used both of these dimensions for improved knowledge about the scope of industrial services. Of each service item, the two measurements (offering and revenue generation) were summed together to capture both perspectives of one service item (e.g., how actively installation service is offered, and what is the revenue contribution of the installation service). This was done for each of the 33 different service items, which were then used as items in the measurement model. This approach was applied because activeness in offering captures the firm's internal emphasis or "push" to offer each service (Homburg, Fassnacht, and Guenther 2003); whereas, the revenue contribution captures the customer demand (Adner and Zemsky 2006) or "pull" for such services (Kastalli, Van Looy, and Neely 2013).

In addition, we needed to decide whether to apply the formative or reflective measurement model (Diamantopoulos and Siguaw 2006). A reflective measurement model is appropriate when the latent variable captures the shared variance between the items and thus reflects the latent phenomenon (Borsboom, Mellenbergh, and van Heerden 2004; Law, Wong, and

1
2
3 Mobley 1998; Rossiter 2002). Consequently, our scale applies a reflective measurement
4
5 model because the items reflect the overall latent scope of industrial services (e.g., shared
6
7 variance between items measuring R&D services) (Law, Wong, and Mobley 1998).
8

9
10 Moreover, a reflective measurement model is appropriate as our scale can be considered a
11
12 reflection, and not a sum, of the state of a firm's service strategy. In the alternative case of a
13
14 formative measurement model, the dimensions would need to cover all of the firm's potential
15
16 service dimensions and services, and thus, provide summation for the scope of industrial
17
18 services (MacCallum and Browne 1993: 533). However, this is very challenging due to
19
20 diversity in the empirical world. Thus, we adopted a reflective measurement model, where the
21
22 measurement functions as a reflection of a firm's scope of industrial services, measured as a
23
24 shared variance between items and dimensions.
25
26
27

28 29 30 3.3 Empirical study

31 32 3.3.1 Data collection, response pattern, and respondents

33
34 Firms for the present study were drawn from a sample database that contains information
35
36 about all Finnish businesses liable to pay value-added taxes. The sample dataset includes
37
38 firms operating in the machine and equipment manufacturing industry (SIC 28) in Finland
39
40 that employ 20 or more persons. We decided to include small firms in the sample, as their
41
42 perspective has not been widely captured within existing studies and we wanted our scale to
43
44 measure industrial service offering across large variation of firm size (cf. Raddats and
45
46 Kowalkowski, 2014). This results in an original sample size of 404 firms.
47
48

49
50 Prior to sending out the web-based questionnaire, the research team contacted all the
51
52 potential respondent companies and discussed identifying a respondent in a relevant
53
54 managerial position to evaluate the comprehensive nature of the service business in a single
55
56 customer relationship. From the 404 companies, 262 persons promised to answer the
57
58
59
60

questionnaire, 37 persons declined, and 105 remained unreachable. In total, the research team conducted 989 answered phone calls, an average of two calls per company. Persons who were unreachable were called several times. Ultimately, the survey yielded 91 successfully completed questionnaires, accounting for a satisfactory response rate of 23% (Baruch 1999) after accounting for the refusals (25%). Furthermore, the respondents received two email reminders during the data collection period. In line with the key-respondent approach, 4% of the respondents were chief executive officers, 57% were key account/sales managers, 15% were production managers, 12% were R&D managers, 4% were business developers, and 8% remained unclassified. Ninety-three percent of the respondents were male.

3.3.2 *Nonresponse bias and data profile*

The data were tested for nonresponse bias. We compared the actual respondent companies to the nonrespondents on three variables—revenues, profits, and balance sheet values—to determine that those who did not respond did not significantly differ statistically from the respondents. In addition, we compared the first third of the respondents to the last third on the key study variables (Armstrong and Overton 1977; Werner, Praxedes, and Kim 2007). Again, the groups do not significantly differ statistically; thus, the data is free from nonresponse bias.

To describe the respondent companies and relationships, we use median values as they allow for a more accurate description of the data than averages allow. A typical respondent firm in the sample generates an annual turnover of approximately €13.6 million, has a return on investment of 19.4%, employs a staff of 100, and serves 120 customers. In a typical customer relationship, product business generates 63% of the turnover, while the service business generates 20%; and subcontracting (i.e., manufacturing industrial components by application of customers' product specifications, when the customer owns the product rights; Nellore and Söderquist 2000) generates 17% of the turnover. The companies produce 90% of

1
2
3 the services they sell by themselves, whereas only 10% outsource their service operations. In
4
5 terms of pricing services, in 58% of the transactions, the service prices are embedded in the
6
7 product prices. In 35% of transactions, pricing is based on consumption; in 16%, pricing is
8
9 based on fixed invoicing (€ / month); and in 6%, pricing is based on the value created for the
10
11 customer (e.g., productivity or decrease in costs). Finally, the suppliers' factories and service
12
13 units are located nearby their customers (factories \approx 130 km, service units \approx 120 km).
14
15

16 17 18 **4. Results** 19

20 21 4.1 Explorative factor analysis

22
23 To determine the dimensional structure of the measurement method, we conducted an
24
25 explorative factor analysis using SPSS 22.0 (Anderson and Gerbing 1988; Jöreskog and
26
27 Sörbom 1989). We applied the maximum likelihood extraction with an oblique rotation
28
29 method (Promax). As an exclusion criteria, items with low communalities (< 0.3) and
30
31 substantial loadings on two or more factors, as well as items that did not have factor loadings
32
33 on any factor (< 0.4), were removed (Stevens 1992; Tabachnick and Fidell 2007). Final
34
35 decisions on removing items were based on these criteria and by examining the
36
37 representativeness of each item identified as a candidate for deletion.
38
39

40
41 The analysis began with the original 33 items. As a result of the explorative factor
42
43 analysis, 12 items were excluded one by one, rerunning the analysis each time. Excluded
44
45 items include delivery service, electronic ordering system for the customer, recycling service,
46
47 product upgrading service, problem analyses, procurement service, warehousing service for
48
49 other manufacturers' products, mediation of personnel, consulting service, mediation of
50
51 products, financing services, and insurance services.
52
53

54
55 A parsimonious and interpretable solution, which displays a simple structure and
56
57 comprises a respectable 21 of the original 33 items, is presented in Table 3. All items have
58
59
60

1
2
3 significant loadings on five factors, each with eigenvalues greater than 1 (Tabachnick and
4
5 Fidell 2007). The five-factor solution coincided with the scree plot image, corresponding with
6
7 those identified in the literature and explaining 67% of the variance in the data. The factor
8
9 solution demonstrated a statistically significant Bartlett test of sphericity ($\chi^2 = 1056$, $df = 210$,
10
11 $p < .000$) (Bartlett 1950), while the KMO value (.85) was above the typical threshold of .5
12
13 (Kaiser, 1970). The resulting items also illustrated acceptable communalities above the
14
15 threshold of .3, except the item 'technical support for similar products of other
16
17 manufacturers,' which we kept in the analysis due to satisfactory factor loading (Tabachnick
18
19 and Fidell, 2007). In the final factor solution, the first factor accounted for 40% of the
20
21 variance, while all the factors with eigenvalues above 1 accounted for 67% of the total
22
23 variance. The fact that all items load onto their main factors and most of the items show no
24
25 significant side-loadings suggests satisfactory discriminant validity. Despite high side-
26
27 loadings of installation, maintenance and documentation services, they were kept in the
28
29 analysis due to their acceptable main loadings.

39

40 4.2 Confirmatory factor analysis 41

42 To further analyze the dimensionality of service scope, we conducted a confirmatory factor
43
44 analysis using AMOS Version 4.0. The maximum likelihood estimation was applied, as
45
46 suggested by the methodology literature (Anderson and Gerbing 1988; Jöreskog and Sörbom
47
48 1989). The model was tested and improved by leaving out items one by one and comparing
49
50 the fit statistics, theoretical framework, and modification indices (Byrne 2001).

59
60

4.2.1 Assessing the overall fit and parameter estimates

The confirmatory factor analysis, low item loadings, poor model fit, and modification indices led to removing 6 items from the remaining 21 items. Deleted items include technical support for similar products of other manufacturers, product tailoring service, analyses of product's manufacturability, documentation service, written information material, and cost-benefit calculation. The final measurement model resulted in the respective 15 items loading to five latent factors.

Several statistics assisted in evaluating the model fit. As Table 4 summarizes, fit indices for the final model suggest an adequate model, as the chi-squared to degrees of freedom ratio is less than 2.00 and the p value is satisfactorily above the threshold of .05 ($\chi^2 = 76.57$, $df = 59$, $p = .588$) (Brooke, Russell, and Price 1988; Carmines and McIver 1981). Furthermore, the root mean squared error of approximation (.000) is at excellent level (threshold of .06) (Hu and Bentler 1999). In addition, the model provides a good fit, as the normed fit index remains at .89, which is only slightly below the threshold of .90. Yet, prior studies have suggested that the normed fit index underestimates models with small sample sizes (Byrne 2001). So, to interpret the model fit, we used the comparative fit index and incremental fit index, which take the sample size into account (Bollen 1989). The comparative fit index (1.00) and incremental fit index (1.01) both demonstrated satisfactory values significantly above the threshold (.90) suggesting an excellent model fit. In sum, the final resulting research model fits well with the data.

The first-order 5-factor model provides the best fit with the data compared to the other model, as Table 4 illustrates. In addition, the second-order factor model performs worse than the first factor model, as expected. It still provides an excellent model fit and shows that the model applies as a first- and second-order factor model.

4.2.2 *The final measurement model*

The resulting measurement method includes 15 items categorized into five factors. The model fits satisfactory with the data, while the construct, dimensions, and measurements provide satisfactory reliability and validity. Figure 1 illustrates the resulting dimensions of the industrial service scope, together with the items, item loadings, Cronbach's alpha (CA), composite reliability (CR) and average variance extracted (AVE) values for each dimension. The correlation matrix for the final items is reported in Appendix A.

All in all, the findings suggest that the scope of service business consists of five dimensions, or "bundles," of services. The first dimension includes two services, i.e., product demonstrations and customer seminars, which are typically used for attracting new customers for the industrial product business. Hence, we label them as 'pre-sales services.' The second dimension includes services such as warranty, technical user training, and customer consulting and support by phone. We classify them as 'product support services.' The third dimension includes such services as installation, repair services, spare parts, and maintenance. As this dimension covers services that are needed to install, repair, and maintain industrial products, we label it as 'product life-cycle services.' The fourth dimension incorporates research services, prototype design and development services, and feasibility studies, and is thus labeled as 'R&D services.' The services of the fifth dimension do not focus on the industrial product, but on the customer's processes. Such services include project management service, service for operating the product sold for the customer, and service for operating a customer's process, and are thus defined as 'operational services'.

Insert Figure 1 here

4.2.3 Reliability of the measurements

In terms of reliability, the constructs resulted in adequate Cronbach's alpha and composite reliability values, suggesting satisfactory reliability of the constructs. Cronbach's alpha values for each construct exceed the threshold of .7, being .87 for pre-sales services; .79 for product support services; .81 for product life-cycle services; .78 for R&D services; and .79 for operational services. Similarly, the constructs achieve satisfactory composite reliability values (threshold of .7), being .87 for pre-sales services, .84 for product support services, .92 for product life-cycle services, .85 for R&D services and .78 for operational services. In conclusion, the constructs demonstrate satisfactory reliability.

4.2.4 Convergent and discriminant validity

The items satisfactorily measure the latent construct they attempted to measure, as the loadings in the structural analysis were above .60 and statistically significant ($p < .001$). Similarly, the dimensions demonstrated satisfactory values for the average variance extracted (AVE) values, as all the AVE values exceeded the threshold of .5, being .88 for pre-sales services, .77 for product support services, .84 for product life-cycle services, .79 for R&D services and .72 for operational services. Thus, the model suggests high convergent validity. As for the discriminant validity, the final measurement model demonstrated an excellent model fit. It is also notable that the fit of the 5-factor model was much better than the fit of other models, thereby demonstrating validity of the structure of the measurement model. Satisfactory model fit of the measurement model also provides evidence for a satisfactory discriminant validity of the constructs and items.

5. Discussion

5.1 Theoretical contribution

The distinct contribution of the present study is the development of a new tool to measure and operationalize the scope of industrial service business. This measurement combines and builds on the key features from the prior literature, and on the insight gained through interviews with practitioners. More specifically, our scale is novel as it captures the breadth (i.e., the extensiveness of the offered services) and depth (i.e., internal emphasis and revenue generation of each service) of industrial service offering. In addition, this study applies this new scale on the level of the supplier-customer relationship, as well as validates it through quantitative empirical data analysis. By doing so, we address a research gap which has been highlighted by several researches (Eggert et al., 2014). As Ostrom et al. (2010, p. 27) state, the “service value measurement and optimization is truly a [research] priority in its infancy.”

Academics can use this measurement when investigating the scope of service business as one construct in their research settings. More importantly, one of the novelties of our measurement is its relationship-specific approach which enables focused empirical studies on complex phenomena. For instance, the scale enables researchers to measure and reflect the extent and level of service strategy to facilitate testing of service-structure settings (Chandler 1962) at the relational level. Or the scale can be used to examine the performance effects of different types of service offerings, as well as the role of variety of moderating or mediating factors (e.g., relational capabilities) between service offering and performance. This first version of the measurement (labeled as e.g., Servscope 1.0) also creates a fruitful platform for further development. More specifically, scholars can apply the scale to firm-level studies to examine the financial impact of industrial services on a product oriented firm revenue and growth, which still remains an understudied relationship (Gebauer et al. 2010; Ostrom et al. 2010). For these purposes, Appendix B provides the questionnaire with original 33 items and

1
2
3 relationship-level questions as well as alternative questions for firm-level inquiries. In short,
4
5 this new measurement is a valuable tool for academics operating in the field of industrial
6
7 service business.
8

9
10 By developing a new measurement that distinguishes different service dimensions, we
11
12 also contribute to prior literature in relation to classifying industrial services, which has been
13
14 dominated by conceptual argumentation (Boyt and Harvey 1997; Homburg and Garbe 1999)
15
16 and exploratory case studies (Mathieu 2001; Oliva and Kallenberg 2003; Ulaga and Reinartz
17
18 2011). More specifically, our empirical evidence partially supports, yet partially challenges,
19
20 these classifications. Interestingly, the identified first and the second dimension (pre-sales
21
22 services and product support services) seem to partially confirm the seminal work of LaLonde
23
24 and Zinszer (1976) and Samli, Jacobs, and Wills (1992), i.e., the moment of transaction of an
25
26 industrial product forms a basis for identifying two categories of industrial services. Our
27
28 service dimension of product-life-cycle services, in turn, amplifies the work of Ulaga and
29
30 Reinartz (2011, p. 17), or challenges the models of Oliva and Kallenberg (2003) and Gebauer
31
32 (2008) by adopting service items from the categories of 'basic installed-base services' and
33
34 'maintenance services' (Oliva and Kallenberg 2003, p. 168), or from the categories of 'after-
35
36 sales services' and 'process-oriented services' (Gebauer 2008, p. 284). Finally, the
37
38 dimensions of R&D services and operational services correspond well with the prior
39
40 classifications in the field (Gebauer 2008; Gebauer et al. 2010; Mathieu 2001; Oliva and
41
42 Kallenberg 2003; Windahl and Lakemond 2010). These two dimensions are largely discussed
43
44 but have remained understudied within the existing literature, as they represent a more
45
46 complex product-service combination which demands co-creation between provider and
47
48 customer. All in all, our findings extend the current body of knowledge on industrial services
49
50 by providing a new set of service categories that are based on quantitative data and a
51
52 statistically rigorous empirical survey.
53
54
55
56
57
58
59
60

1
2
3 Finally, one specific counterintuitive finding is that the conventional industrial service of
4 delivery (Morris and Davis 1992; Oliva and Kallenberg 2003) does not have a similar
5 variance with the other services. Consequently, this service does not appear in the model. The
6 rationale behind this finding could be that for an industrial firm, delivery service may be a
7 basic ‘unprofitable necessity’ (Oliva and Kallenberg, 2003, p. 165) that their clients require
8 and are thus obligatory to stay in business.

16
17

18 5.2 Managerial implications 19

20 The present study is also valuable for strategic managers in industrial firms for several
21 reasons. First, the scale and its items can be used as a managerial navigator to assess the
22 current status of the service business. By examining the firm’s current service portfolio,
23 industrial managers can analyze the role of services in their overall business model, and more
24 importantly, set objectives to develop their service business further. Second, the new
25 classification of industrial services can help industrial managers divide their portfolio of
26 services into logical groups. This assessment is useful for deciding which services should be
27 developed and commercialized simultaneously, as well as for evaluating different possibilities
28 for service bundling. Third, the emerged service classification is a useful tool for developing
29 service packages for different industrial customer segments. Providing an extensive service
30 portfolio for the collaborative key clients while offering less comprehensive service packages
31 to other customer segments may be effective.

49 5.3 Limitations and future research opportunities 50

51 Although the research outlined here is comprehensive, there are some limitations that need to
52 be considered when interpreting the results. One limitation of the study is that the data is
53 slightly oversampled towards small- and medium-sized industrial firms from Finland.
54
55
56
57
58
59
60

1
2
3 Consequently, low fit-indices may result from the non-normality of the data, despite the fact
4
5 that the maximum likelihood estimation is not robust to violations of multivariate normality
6
7 (Williams and O'Boyle 2008). However, multivariate normality may cause lower overall fit
8
9 statistics (Williams and O'Boyle 2008). Thus, the development of the measurement in the
10
11 context of large industrial firms, or in different industries and countries, provides one fruitful
12
13 avenue for further research. Second, we have used the existing literature, interaction with
14
15 practitioners and quantitative data analysis to develop and validated the proposed scale. Still,
16
17 with further maturity of existing literature and industrial practices, there is scope for further
18
19 developing and fine-tuning the proposed scale. Nevertheless, the present study represents a
20
21 positive step towards operationalizing industrial service offering.

Table 1
Key studies on classifying industrial services

Service categories	Basis of classification	Author(s)
<ul style="list-style-type: none"> ▪ Pre-transaction (or pre-sale) services (e.g., written customer policy) ▪ Transaction services (e.g., order cycle time) ▪ Post-transaction (or post-sale) services (e.g., replacements and repairs) 	Conceptual argumentation: The moment of transaction of an industrial good	LaLonde & Zinszer 1976; Samli et al. 1992
<ul style="list-style-type: none"> ▪ Pre-transaction services related to internal operations (e.g., formal production schedules) ▪ Transaction services related to physical appearance (e.g., employee appearance to customers) ▪ Transaction services related to order status (e.g., providing order status information) ▪ Transaction services related to order accuracy (e.g., billing and shipping accuracy) ▪ Post-transaction services related to start-up (e.g., installation, training) ▪ Post-transaction services related to problem handling (e.g., preventing stockouts, product tracing for recalls). 	Conceptual argumentation and a survey: The moment of transaction of an industrial good	Morris & Davis 1992
<ul style="list-style-type: none"> ▪ Services supporting the product (e.g., delivery, technical support) ▪ Services supporting the customer's process (e.g., training, R&D) 	Conceptual argumentation with a case study: Service supporting the supplier's product vs. supporting the client's action	Mathieu 2001
<ul style="list-style-type: none"> ▪ Basic installed base services (e.g., documentation, installation, repairs) ▪ Maintenance services (e.g., preventive maintenance, spare part management) ▪ Professional services (e.g., process-oriented engineering, research and development) ▪ Operational services (e.g., management of the operations and maintenance function) 	Case study: Transaction-based vs. relationship-based services and product-based vs. end-user's process-based services	Oliva & Kallenberg 2003
<ul style="list-style-type: none"> ▪ Information and consulting services (e.g., product demonstrations) ▪ Services for training and consulting (e.g., feasibility studies) ▪ Services in the business-related field (e.g., insurance) ▪ Services for technical security and optimization (e.g., installation) ▪ Services supporting the process of cooperation (e.g., project management) 	Conceptual argumentation and interviews	Homburg et al. 2003
<ul style="list-style-type: none"> ▪ Consumption services used by the industrial customer (e.g., office cleaning) ▪ Instrumental services that help improve the customer's core processes (e.g., consulting) ▪ Component services offered further to the customers' customers (e.g., outsourced baggage handling in airports) ▪ Semi-manufactured services that act as an input in the final customer offering or process (e.g., outsourced weather forecasts in airline route planning). 	Conceptual argumentation: The service use situation of the customer	Wynstra et al. 2006
<ul style="list-style-type: none"> ▪ After sales services (e.g., spare parts, repair, basic training, inspection/diagnosis) ▪ Customer support services (e.g., maintenance services, process optimization & consulting, advanced operator training) ▪ Outsourced services (e.g., maintenance services, process optimization & consulting, advanced operator training) ▪ Development services (e.g., design and construction services, process-oriented R&D) 	Quantitative survey on environmental-strategy fit	Gebauer 2008
<ul style="list-style-type: none"> ▪ R&D services (e.g., process design, process-oriented engineering, development services) ▪ Basic services for the installed base (e.g., product-oriented training, help desk, repair services) ▪ Maintenance services (e.g., preventive maintenance, full maintenance contracts, process optimization) ▪ Operational services (e.g., managing the whole maintenance function, managing spare parts logistics) 	Conceptual argumentation: Service strategies of manufacturing firms	Gebauer et al. 2010
<ul style="list-style-type: none"> ▪ Product attached services on own products (e.g., installation, training, support) ▪ Product attached services on own and third party products (e.g., installation, training, support) ▪ Operations services on own products (e.g., managed services, asset availability) ▪ Vendor-agnostic operations services (e.g., systems integration, technical consultancy) 	Conceptual argumentation with a qualitative analysis: single vs. multi-vendor orientation; and product vs. customer orientation	Raddats and Easingwood 2010
<ul style="list-style-type: none"> ▪ Product life-cycle services (e.g., delivery, inspection, recycling) ▪ Asset efficiency services (e.g., remote monitoring, software customization) ▪ Process support services (e.g., efficiency audit, logistics consulting) ▪ Process delegation services (e.g., fleet management, supply management) 	Conceptual argumentation with a case study: goods-based vs. process-based services; input-based vs. output-based services	Uлага & Reinartz 2011
<ul style="list-style-type: none"> ▪ Product-attached services ▪ Operations services on own products ▪ Vendor independent operations services 	Quantitative survey on two dimensions: single vs. multi-vendor orientation; and product vs. customer orientation	Raddats and Kowalkowski 2014

Table 2
Dimensions of industrial services, service items measured by a Likert scale and item source (literature/interview)

Service category	Related services
Optimization services	<ul style="list-style-type: none"> ▪ Installation service (Gebauer et al. 2010; Oliva & Kallenberg 2003; Homburg et al. 2003; Morris & Davis 1992; Samli et al. 1992) ▪ Delivery service (Oliva & Kallenberg 2003; Homburg et al. 2003, Morris & Davis 1992; Ulaga & Reinartz 2011) ▪ Technical support for similar products offered by other manufacturers (Raddats and Easingwood 2010; Raddats and Kowalkowski 2014) ▪ Repair service (Gebauer et al. 2010; Oliva & Kallenberg 2003; Boyt & Harvey 1997) ▪ Spare parts (Gebauer et al. 2010; Oliva & Kallenberg 2003) ▪ Electronic ordering system for the customer (Homburg et al. 2003; Morris & Davis 1992; Samli et al. 1992) ▪ Recycling service (Oliva & Kallenberg 2003; Homburg et al. 2003) ▪ Product upgrade service (Homburg et al. 2003) ▪ Maintenance (Gebauer et al. 2010; Oliva & Kallenberg 2003; Boyt & Harvey 1997; Samli et al. 1992) ▪ Warranty (Morris & Davis 1992; Samli et al. 1992)
Research and development services	<ul style="list-style-type: none"> ▪ Product tailoring service (Homburg et al. 2003; Samli et al. 1992) ▪ Prototype design and development service (academic/practitioner interviews) ▪ Feasibility studies (Homburg et al. 2003) ▪ Problem analyses (Oliva & Kallenberg 2003; Homburg et al. 2003) ▪ Analyses of product's manufacturability (Oliva & Kallenberg 2003) ▪ Research services (Gebauer et al. 2010; Homburg et al. 2003)
Business services	<ul style="list-style-type: none"> ▪ Procurement service (Homburg et al. 2003) ▪ Warehousing services for other manufacturers' products (Homburg et al. 2003) ▪ Mediation of products (Homburg et al. 2003) ▪ Project management (Homburg et al. 2003) ▪ Service for operating the product sold for the customer (academic/practitioner interviews) ▪ Service for operating customer's process (Gebauer et al. 2010; Oliva & Kallenberg 2003) ▪ Consulting service (Oliva & Kallenberg 2003; Homburg et al. 2003; Boyt & Harvey 1997; Ulaga & Reinartz 2011) ▪ Mediation of personnel (Homburg et al. 2003) ▪ Financing service (Homburg et al. 2003; Samli et al. 1992) ▪ Insurance service (Homburg et al. 2003)
Product information sharing services	<ul style="list-style-type: none"> ▪ Product demonstrations (Gebauer et al. 2010; Homburg et al. 2003) ▪ Customer seminars (Homburg et al. 2003) ▪ Technical user training (Gebauer et al. 2010; Oliva & Kallenberg 2003; Homburg et al. 2003; Morris & Davis 1992; Samli et al. 1992) ▪ Documentation service (academic/practitioner interviews) ▪ Written information material (Homburg et al. 2003) ▪ Customer consulting and support by phone (Homburg et al. 2003) ▪ Cost-benefit-calculation (Homburg et al. 2003)

Table 4
Confirmatory factor analysis fit statistics for alternative models

Model	χ^2	<i>df</i>	χ^2/df	P-value	NFI	CFI	IFI	RMSEA
First-order factor models								
1-factor model ¹	232.86	90	2.59	.000	.67	.77	.77	.133
2-factor model ²	199.10	89	2.24	.000	.72	.82	.82	.117
3-factor model ³	167.86	87	1.93	.000	.77	.87	.87	.102
4-factor model ⁴	135.02	84	1.61	.000	.91	.92	.92	.082
5-factor model ⁵	76.57	59	0.96	.588	.89	1.00	1.01	.000
Second-order reflective factor models								
5-factor model ⁶	97.81	85	1.15	.162	.86	.98	.98	.041

¹ One-factor model (First-order): All items load to the first factor.

² Two-factor model (First-order): Items of maintenance, operational and R&D services load to factor 1, customer and product services to factor 2.

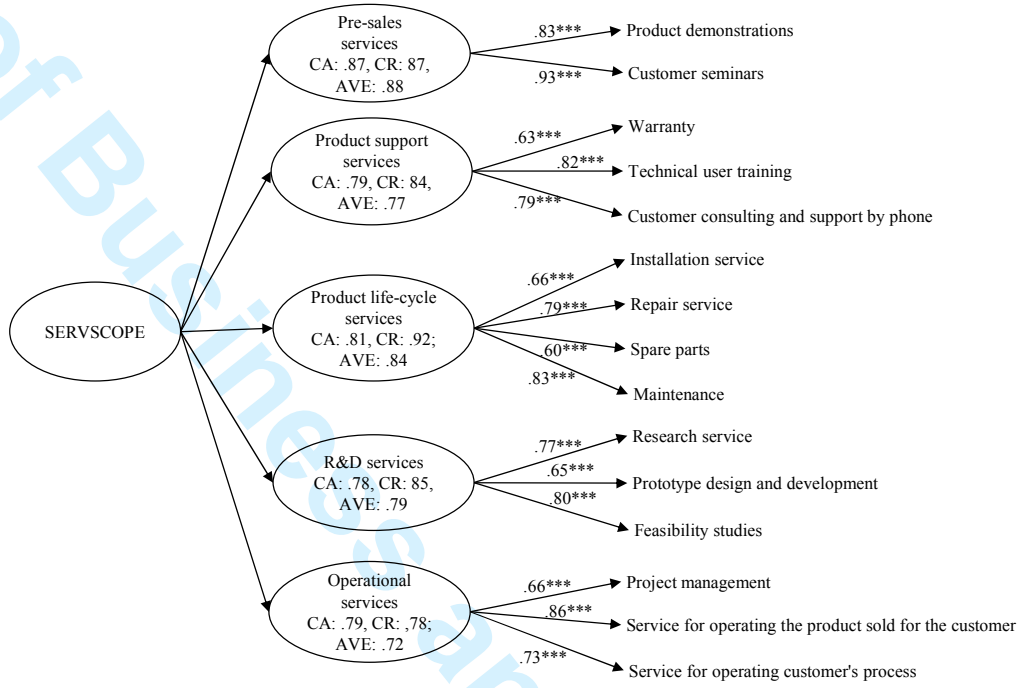

³ Three-factor model (First-order): Items of maintenance services load to factor 1, operational and R&D services to factor 2, customer and product services to factor 3.

⁴ Four-factor model (First-order): Items of maintenance services load to factor 1, operational and R&D services to factor 2, customer services to factor 3, and product services to factor 4.

⁵ Five-factor model (First-order): Items of operational services load to factor 1, R&D services to factor 2, operational services to factor 3; customer services to factor 4, and product services to factor 5.

⁶ Five-factor model (Reflective second-order): One second-order factor, under which items of maintenance services load to factor 1, R&D services to factor 2, operational services to factor 3; customer services to factor 4, and product services to factor 5.

Figure 1
Dimensions of industrial services, items, item loadings, Cronbach's alpha (CA), composite reliability (CR), and average variance extracted (AVE) values for each dimension.

Statistical significance *** P < .001
