10 Abstract

11 Natural amino acids have been introduced as potential additives for gas hydrate inhibition,
12 natural gas storage, and CO₂ capture and sequestration. Herein, almost all amino acids hydrate-
13 based additives are critically reviewed. The hydrate inhibition/promotion effect of each amino
14 acid and factors that affect their performance on gas hydrate formation are discussed.
15 Furthermore, amino acids hydrate inhibition/promotional mechanism and modelling studies are
16 reviewed. Detailed comparison between amino acids and convention hydrate additives alongside
17 future directions towards amino acids hydrate-based technology commercialization are also
18 discussed. The findings presented in this work are relevant for future amino acids breakthrough
19 research in hydrate-based technologies.

39 1. Introduction

40 Gas hydrates are ice-like crystalline compounds formed by the trapping of gas molecules in
 41 hydrogen bonded water molecules at high-pressure and low temperature conditions. The gas
 42 molecules are trapped in the water molecules through van der Waals forces (Koh et al., 2011;
 43 Sloan and Koh, 2007). Depending on the type, shape and size of the gas molecules, three basic
 44 gas hydrate structures occur: cubic structure I, cubic structure II and hexagonal structure H.
 45 Figure 1 shows the available gas hydrate structures (Sloan and Koh, 2007). Gas hydrate has
 46 applications such as future energy source (Englezos, 1993), CO₂ capture and gas separation
 47 (Babu et al., 2015; Park et al., 2013), storage and transportation of gases (such as natural gas,
 48 hydrogen, carbon dioxide and etc.) (Lang et al., 2010; Najibi et al., 2009; Strobel et al., 2006).

49
50

Figure 1. Common gas hydrate crystal structures (Tariq et al., 2014).

51 On the contrary, gas hydrate causes major flow assurance problems in the oil and gas industry.

52 During hydrocarbons drilling, production and processing operations, gas hydrate forms in

53 pipelines and facilities which results in pipeline blockage, huge cost of prevention/removal,
54 environmental hazards and sometimes loss of lives (Koh et al., 2011). Heating, water removal,
55 depressurization and chemical injection are the techniques used to prevent or remove gas hydrate
56 plugs in pipelines. However, chemical injection is widely used due to economic and current
57 technological feasibility (Koh et al., 2011; Tariq et al., 2014). Generally, depending on the area
58 of application, two major types of gas hydrate chemical additives (inhibitors/ promoters) are
59 usually used to influence the formation of gas hydrate thermodynamically, by changing the
60 hydrate phase equilibrium boundary conditions, and/or kinetically, by enhancing/delaying the
61 hydrate formation nucleation and crystal growth rate.

62 Thermodynamic hydrate inhibitors (THIs) and low dosage hydrate inhibitors (LDHIs) are the
63 available chemical inhibitors. THIs (Glycols and methanol) inhibit gas hydrates
64 thermodynamically by reducing the activity of water in hydrate formation by the formation of
65 hydrogen bonds with water molecules. Hence, they increase the non-hydrate formation region of
66 the hydrate formation phase boundary by shifting the equilibrium hydrate formation curve to
67 high pressures and/or low temperatures. The use of THIs require high concentration, which
68 results in high operational cost. At high subcooling temperatures, over 40 wt% is required to
69 guarantee inhibition in most cases. Also, they are highly volatile, and thus environmentally
70 prohibited (Bavoh et al., 2018b; Broni-Bediako et al., 2017). Alternatively, LDHIs comprises of
71 kinetic hydrate inhibitors (KHIs) and anti-agglomerates. KHIs are generally polymers
72 (polyvinylpyrrolidone and poly-N-VinylCaprolactam), and they prevent the formation of gas
73 hydrates by sticking on the hydrate crystals to prolong or delay hydrate nucleation time
74 (induction time) and growth rate. KHIs are used at low concentrations (< 2 wt%), however, they
75 are ineffective at high subcooling and shutdown conditions, hence, it's encouraging to introduce

76 new chemical inhibitors which are environmentally friendly, less expensive, and highly effective
77 to combat the above mentioned problems (Carroll, 2014; Kamal et al., 2016).

78 The application of hydrate-based technology for carbon capture and sequestration (CCS) and
79 natural gas storage involves the use of chemicals to enhance hydrate formation instead of hydrate
80 prevention in the case of flow assurance systems. Gas hydrate-based CCS initially involves CO₂
81 separation process via formation of CO₂ hydrates in a CO₂ mixed gas system (e.g flue gas and
82 natural gas). Since CO₂ is very prone to hydrate formation at low pressures, its able to form
83 hydrates faster with high gas (CO₂) to hydrate conversion ratio than other gases. The residual gas
84 can be transferred to a vessel as demonstrated in Figure 2. The rich CO₂ hydrates are then
85 dissociated to remove the CO₂ for further sequestration process similar to hydrate based natural
86 gas storage process. The separated CO₂ can then be sequestered or stored in reservoirs in
87 hydrate form. Also, the CO₂ hydrates can be deposited as hydrate pellets on sea bed conditions
88 as long as they are stable.

89 Thermodynamic hydrate promoters (THPs) and kinetic hydrate promoters (KHPs) are the
90 available gas hydrate chemical promoters. THPs are basically used to shift the hydrate phase
91 boundary conditions to higher temperatures and low-pressure regions. KHPs are also employed
92 to increase the hydrate induction time, formation rate, and the gas/water uptake during hydrate
93 formation.

94

95

Figure 2. Hydrate-based gas separation process (CO₂ capture process) (Zheng et al., 2017)

96 Commonly used THPs are tetrahydrofuran (THF) (Rong et al., 2015) and acetone, while nano
 97 particles (Nashed et al., 2018b), Sodium dodecyl sulfate (SDS) (Pan et al., 2018; Zhiming Liu et
 98 al., 2018) and some other surfactants are KHPs. THPs and KHPs are applied in CO₂ capture and
 99 sequestration (Li et al., 2010; Park et al., 2013), and gas storage and transportation (Hao et al.,
 100 2008; Veluswamy et al., 2018). These conventional promoters just like conventional inhibitors
 101 are environmentally prohibitive and less effective.

102 Base on the general knowledge that compounds that exhibit strong electrostatic charges and/or
 103 strong hydrogen bond forming affinity can inhibit gas hydrates formation (Kim and Kang, 2011),
 104 some novel gas hydrate inhibitors have been introduced as potential inhibitors which may
 105 replace the commercially existing inhibitors. One of such classes of inhibitors are ionic liquids
 106 (Khan et al., 2017a, 2017b; Nashed et al., 2018a; Tariq et al., 2014; Xiao and Adidharma, 2009).
 107 Ionic liquids have attracted much attention due to their zero volatility and dual functionality in
 108 hydrate inhibition (Xiao and Adidharma, 2009) (i.e. they function as both THIs and KHIs). More
 109 details on ionic liquids (ILs) as gas hydrate inhibitors is presented in reference (Khan et al.,
 110 2019, 2018; Tariq et al., 2014; Yaqub et al., 2018). However, an IL review (Pham et al., 2010)
 111 shows that most commonly used ILs for gas hydrate inhibition are toxic in nature. In addition,

112 ILs are relatively expensive and might not be cost effective to be used in the oil and gas industry
113 (Zare et al., 2013). This led to the introduction of amino acids as new gas hydrate inhibitors in
114 2011 by Sa et al., (2011). They reported that amino acids exhibit strong electric
115 charges/electrostatic interactions with water as zwitterions and interact with water molecules
116 through strong hydrogen bonding due to their hydrophilic nature which qualifies them as good
117 inhibitors. This electrostatic interaction between amino acids and water molecules reduces the
118 ice-like crystalline structure of the hydrogen bonded water molecules, thus, causing a negative
119 affinity amongst them (Hecht et al., 1993; Nigam and Srihari, 2013; Pertsemlidis et al., 1996).

120 Generally, amino acids comprise of carboxylic acid, amine groups and a side chain (which
121 ranges from apolar alkyl chain (hydrophobic) to a positive or negative charge moiety
122 (hydrophilic)) with their chemical and physical properties strongly dependent on the particular
123 side chain (Madeira et al., 2014; Vaitheeswaran and Thirumalai, 2008). Some key advantages of
124 amino acids are their biological friendliness in nature and biodegradability. More so, amino acids
125 are less expensive and can be purchased at a relatively cheaper cost in bulk quantities. Amino
126 acids are also reported (Badawy et al., 2005; Barouni et al., 2008) to act as corrosion inhibitors
127 for metals in various chemical systems (such as sulphuric acid, aqueous chloride solutions in
128 molar nitric mediums) which makes their use in the field application ease corrosion concerns.
129 Based on these properties, amino acids have wide applications in areas such as biological science
130 and biotechnology, pharmaceutical industry for protein purification (Arakawa et al., 2007). Most
131 importantly, these properties make them potential candidates for gas hydrate inhibition in
132 pipelines. In addition, not only has amino acids been reported as gas hydrate inhibitors, they are
133 also reported as good gas hydrate promoters in both stirring and non-stirring conditions, thus

134 making them good candidate for future gas hydrate-based applications in CO₂ capture, gas
135 separation, storage and transportation.

136 The kinetics and thermodynamics data of gas hydrates in the presence of amino acids are critical
137 for the developing effect of amino acids based hydrate inhibitors and promoters. Since gas
138 hydrate-based research in the presence of amino acids (as gas hydrate inhibitors/promoters) is
139 still at the early stages with several number of different studies been performed on its
140 thermodynamics and kinetics, a critical review of the available data is therefore needed.
141 Currently, no review article is reported in open literature on the use of amino acids as gas hydrate
142 promoters/ inhibitors. Hence, a review of reported articles in open literature on gas hydrate-based
143 applications using amino acids is presented herein. It will present up-to-date findings on amino
144 acids as hydrate promoters and inhibitors and will be relevant for future potential research for the
145 development and application of amino acids in hydrate based related technologies.

146 **2. Role of amino acids in hydrate inhibition/CO₂ Capture/Natural gas storage**

147 Review of literature shows that; thermodynamics and kinetics of gas hydrate studies have been
148 studied in the presence of amino acids. However, most of the reported studies focused on the
149 formation kinetics of gas hydrate which deals with CO₂ capture/separation and gas storage. The
150 normal isochoric method with step heating is employed by researchers for thermodynamic
151 studies while isothermal, constant cooling and isochoric method are employed for kinetic studies.
152 For proper data analysis, data on amino acids as gas hydrate additives were gathered from open
153 literature and analyzed separately for their thermodynamic effect and kinetic effect. All gas
154 hydrate studied systems in the presence of amino acids with their respective tested
155 concentrations and physicochemical properties are presented in Table 1.

Table 1. List of various studied amino acids + studied gas systems, concentrations used and physicochemical properties.

No	Amino Acid	Gas	Side chain Polarity	Side chain	Hydropathy index ^d	Test type	Conc. ^{a,b,c}	Remarks	Ref.
1	Glycine	CO ₂	Nonpolar	-H	-0.4	THI	0.1 ^a – 3.0 ^a	Shows good thermodynamic hydrate inhibition impact.	(Sa et al., 2011)
2	L-Alanine	CO ₂	Nonpolar	-CH ₃	1.8	THI	0.1 ^a – 2.2 ^a	Thermodynamically inhibit CO ₂ hydrates	
3	L-Valine	CO ₂	Nonpolar	-CH(CH ₃) ₂	4.2	THI	0.1 ^a – 0.5 ^a	Shows thermodynamic CO ₂ hydrate inhibition	
4	Glycine	CO ₂	Nonpolar	-H	-0.4	KHI	0.01 ^a – 1.0 ^a	Shows effective KHI impact by increasing the subcooling temperature and can eliminate the memory effect.	(Sa et al., 2013)
5	L-Alanine	CO ₂	Nonpolar	-CH ₃	1.8	KHI	0.1 ^a	Demonstrates kinetic hydrate inhibition impact but less efficient than glycine.	
6	L-Valine	CO ₂	Nonpolar	-CH(CH ₃) ₂	4.2	KHI	0.1 ^a	Shows very less significant hydrate inhibition impact. Longer chains which are more hydrophobic do not inhibit hydrate. This is contrary to the understanding that hydrophobic compounds turns to be good KHIs (especially in ionic liquids (Tariq et al., 2014))	
7	Leucine	CO ₂	nonpolar	-CH ₂ CH(CH ₃) ₂	3.8	KHI	0.1 ^a	Shows very less significant hydrate inhibition impact.	
8	Isoleucine	CO ₂	nonpolar	-CH(CH ₃)C ₂ H ₅	4.5	KHI	0.1 ^a	Shows very less significant hydrate inhibition impact.	
9	Glycine	CO ₂	nonpolar	-H	-0.4	Crystal structure	0.1 ^a – 0.5 ^a	Amino acids inclusion expands the hydrate crystal lattice, causing hydrate inhibition effect. At 2.2 mol% glycine's lattice expansion ability saturation is reached.	(Sa et al., 2014)
10	L-Alanine	CO ₂	nonpolar	-CH ₃	1.8	Crystal structure	0.1 ^a – 0.5 ^a	A structure I hydrate was formed with hydrate inhibition crystallization phenomenon. The lattice expansion magnitude was saturated at 0.5 mol%	
11	L-Valine	CO ₂	nonpolar	-CH(CH ₃) ₂	4.2	Crystal structure	0.1 ^a – 0.5 ^a	All amino acids have a distinct crystal structure. However, the inhibition strength of amino acids depends on whether they act individually or agglomerate during hydrate crystallization.	
12	L-Alanine	CO ₂	nonpolar	-CH ₃	1.8	KHI + spectroscopy	0.01 ^a – 0.1 ^a	Delays hydrate nucleation and growth rate via disruption of the water structure in hydrate formation.	(Sa et al., 2015)
13	Aspartic acid	CO ₂	acidic polar	-CH ₂ COOH	-3.5	KHI + spectroscopy	0.01 ^a	Delays hydrate nucleation and growth rate better than alanine but similar to asparagine via disruption of the water structure in hydrate formation.	

14	Asparagine	CO ₂	polar	- CH ₂ CONH ₂	- 3.5	KHI + spectroscopy	0.01 ^a	Delays hydrate nucleation and growth rate via disruption of the water structure in hydrate formation.	
15	Phenylalanine	CO ₂	nonpolar	- CH ₂ C ₆ H ₅	2.8	KHI + spectroscopy	0.1 ^a	Relatively shows no effect on the nucleation kinetics of hydrate formation, especially in memory water, due to its water structure hydrogen bonding strengthening ability. However, delays growth process but less than alanine.	
16	Histidine	CO ₂	basic polar	- CH ₂ C ₃ H ₃ N ₂	- 3.2	KHI + spectroscopy	0.1 ^a	Efficient in hydrate inhibition than alanine but less than aspartic acid and asparagine via disruption of the water structure in hydrate formation.	
17	Glycine	C ₂ H ₆	nonpolar	-H	- 0.4	KHI	0.05 ^b - 3 ^b	Shows strong KHI strength due to its lower hydrophobicity	(Rad et al., 2015)
18	Leucine	C ₂ H ₆	nonpolar	-CH ₂ CH(CH ₃)	3.8	KHI	0.05 ^b - 3 ^b	Inhibits hydrate formation kinetics but less than glycine.	
19	Asparagine	CH ₄	polar	- CH ₂ CONH ₂	- 3.5	KHI + MD simulation		Efficiently suppress hydrate formation kinetics. Asparagine do not adsorb on the gas/water interface during hydrate inhibition.	(Oluwunmi et al., 2015)
20	Glycine	THF	nonpolar	-H	- 0.4	KHI	0.05 ^b - 1.5 ^b	Shows strong KHI strength due to its lower hydrophobicity	(Naeiji et al., 2014a)
21	Leucine	THF	nonpolar	-CH ₂ CH(CH ₃)	3.8	KHI	0.05 ^b - 1.5 ^b	Inhibits hydrate formation kinetics but less than glycine.	
22	L-threonine	CH ₄	polar	- CH(OH)CH ₃	- 0.7	KHI	2770 ^c - 1385 ^c	Shows no significant KHI effect in delaying hydrate nucleation in both fresh and memory system.	(Perfeldt et al., 2014)
23	L-valine	CH ₄	nonpolar	-CH(CH ₃) ₂	4.2	KHI	2770 ^c - 1385 ^c	Shows no significant KHI effect in delaying hydrate nucleation in both fresh and memory system.	
24	L-histidine	CH ₄	Basic polar	-NH-CH=N-CH=C-CH ₂	-3.2	KHI	0.1 ^b - 1 ^b	Significantly promotes hydrate formation than SDS.	(Bhattacharjee et al., 2016)
25	PVP and L-Tyrosine	NG	Polar	-HO-Ph-CH ₂	-1.3	KHI	1 ^b	The presence of tyrosine improves the hydrate inhibition impact of NaCl + PVP system.	(Kakati et al., 2016a)
26	PVP and L-Tyrosine	NG	Polar	-HO-Ph-CH ₂	-1.3	KHI	100 ^c - 275 ^c	Tyrosine is a strong inhibitor than PVP and its addition into PVP enhances hydrate nucleation time in several folds.	(Talaghat, 2014)
27	Glycine	CH ₄	nonpolar	-H	-0.4	THI	0.5 ^a - 3 ^a	Inhibits hydrate phase boundary curve with concentration.	(Sa et al., 2016)
28	Alanine	CH ₄	nonpolar	-CH ₃	1.8	THI	0.5 ^a - 2.2 ^a	Inhibits hydrate phase boundary curve with concentration.	
29	Serine	CH ₄	polar	-HO-CH ₂	-0.8	THI	1.3 ^a - 3 ^a	Inhibits hydrate phase boundary curve with concentration.	
30	Proline	CH ₄	nonpolar	-NH-(CH ₂) ₃	-1.6	THI	1.3 ^a - 9 ^a	Inhibits hydrate phase boundary curve with concentration.	

31	Glycine	CH ₄	nonpolar	-H	-0.4	KHI	0.1 ^a	Exhibits hydrate nucleation time and growth rate delay in both fresh and memory water	
32	Alanine	CH ₄	nonpolar	-CH ₃	1.8	KHI	0.1 ^a	Do not inhibit hydrate formation nucleation and growth rate	
33	Serine	CH ₄	polar	-HO-CH ₂	-0.8	KHI	0.1 ^a	Exhibits hydrate nucleation time and growth rate delay in both fresh and memory water	
34	Proline	CH ₄	nonpolar	-NH-(CH ₂) ₃	-1.6	KHI	0.1 ^a	Do not inhibit hydrate formation nucleation and growth rate	
35	Glycine	NG	nonpolar	-H	-0.4	THI	0.5 ^a – 3 ^a	Inhibits hydrate phase boundary curve with concentration.	
36	Alanine	NG	nonpolar	-CH ₃	1.8	THI	0.5 ^a – 2.2 ^a	Inhibits hydrate phase boundary curve with concentration.	
37	Serine	NG	polar	-HO-CH ₂	-0.8	THI	1.3 ^a – 3 ^a	Inhibits hydrate phase boundary curve with concentration.	
38	Proline	NG	nonpolar	-NH-(CH ₂) ₃	-1.6	THI	1.3 ^a – 9 ^a	Inhibits hydrate phase boundary curve with concentration.	
39	Glycine	NG	nonpolar	-H	-0.4	KHI	0.1 ^a	Exhibits hydrate nucleation time and growth rate inhibition effect.	
40	Alanine	NG	nonpolar	-CH ₃	1.8	KHI	0.1 ^a	Do not inhibit hydrate formation nucleation and growth rate	
41	Serine	NG	polar	-HO-CH ₂	-0.8	KHI	0.1 ^a	Could inhibit hydrate formation kinetics better than glycine	
42	Proline	NG	nonpolar	-NH-(CH ₂) ₃	-1.6	KHI	0.1 ^a	Do not inhibit hydrate formation nucleation and growth rate	
43	Glycine	CO ₂	nonpolar	-H	-0.4	KHI	0.5 ^b – 2 ^b	Inhibits hydrate formation rate with increasing concentration	
44	Proline	CO ₂	nonpolar	-NH-(CH ₂) ₃	-1.6	KHI	0.5 ^b – 2 ^b	Inhibits hydrate formation rate with inhibition strength less than glycine but similar with serine and threonine.	
45	Serine	CO ₂	polar	-HO-CH ₂	-0.8	KHI	0.5 ^b – 2 ^b	Inhibits hydrate formation rate	(Roosta et al., 2016)
46	Threonine	CO ₂	polar	CH ₃ -CH(OH)	-0.7	KHI	0.5 ^b – 2 ^b	Inhibits hydrate formation rate	
47	Glutamine	CO ₂	polar	H ₂ N-CO-(CH ₂) ₂	-3.5	KHI	0.5 ^b – 2 ^b	Inhibits hydrate formation rate with the least inhibition strength compared with other studied amino acids.	
48	Histidine	CO ₂	basic polar	NH-CH=N-CH=C-CH ₂	-3.2	KHI	0.5 ^b – 2 ^b	Shows the highest hydrate formation inhibition impact compared with other studies amino acids.	
49	Glycine	CH ₄	nonpolar	-H	-0.4	THI	5 ^b – 20 ^b	Shows the highest hydrate phase behavior conditions inhibition compared with other studied amino acids.	(Bavoh et al., 2016b)
50	Alanine	CH ₄	nonpolar	-CH ₃	1.8	THI	10 ^b	Inhibits gas hydrate thermodynamically.	

51	Serine	CH ₄	polar	-HO-CH ₂	-0.8	THI	10 ^b	Inhibits gas hydrate thermodynamically.	
52	Proline	CH ₄	nonpolar	-NH-(CH ₂) ₃	-1.6	THI	10 ^b	Inhibits gas hydrate thermodynamically.	
53	Arginine	CH ₄	basic polar	HN=C(NH ₂)-NH-(CH ₂) ₃	-4.5	THI	10 ^b	Inhibits gas hydrate thermodynamically.	
54	Glycine	CO ₂	nonpolar	-H	-0.4	THI	5 ^b – 20 ^b	Shows the highest hydrate phase behavior conditions inhibition compared with other studied amino acids.	(Bavoh et al., 2017)
55	Alanine	CO ₂	nonpolar	-CH ₃	1.8	THI	10 ^b	Inhibits gas hydrate thermodynamically.	
56	Serine	CO ₂	polar	-HO-CH ₂	-0.8	THI	10 ^b	Inhibits gas hydrate thermodynamically.	
57	Proline	CO ₂	nonpolar	-NH-(CH ₂) ₃	-1.6	THI	10 ^b	Inhibits gas hydrate thermodynamically.	
58	Arginine	CO ₂	basic polar	HN=C(NH ₂)-NH-(CH ₂) ₃	-4.5	THI	10 ^b	Inhibits gas hydrate thermodynamically.	
59	L-Leucine	CH ₄	nonpolar	-CH ₂ CH(CH ₃)	3.8	KHP/morphology	0.1 ^b – 0.5 ^b	Shows kinetic promotion with no promotion effect observed below 0.3 wt%.	(Veluswamy et al., 2016)
60	L- Methionine	CO ₂	nonpolar	CH ₃ -S-(CH ₂) ₂ -	1.9	KHP	0.02 ^b – 1 ^b	Significantly promotes hydrate formation uptake without the use of energy-intensive mixing.	(Cai et al., 2017)
61	L-norvaline	CO ₂	nonpolar	C ₁₀ H ₁₉ NO ₄	-	KHP	0.02 ^b – 1 ^b	Promotes hydrate formation with similar promotion impact as L-norleucine	
62	L-norleucine	CO ₂	nonpolar	C ₆ H ₁₃ NO ₂	-	KHP	0.02 ^b – 1 ^b	Promotes hydrate formation	
63	2-aminoheptanoic acid	CO ₂	acid	C ₇ H ₁₅ NO ₂	-	KHP	0.02 ^b – 1 ^b	Promotes hydrate formation but with less promotion impact compared with L-norleucine	
64	n-hexanoic acid	CO ₂	acid	CH ₃ (CH ₂) ₄ COOH	-	KHP	0.02 ^b – 1 ^b	Promotes hydrate formation with similar promotion impact as 2-aminoheptanoic acid	
65	n-hexylamine	CO ₂	nonpolar	CH ₃ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ NH ₂	-	KHP	0.02 ^b – 1 ^b	Promotes hydrate formation	(Veluswamy et al., 2017)
66	L-tryptophan	CH ₄	nonpolar	Ph-NH-CH=C-CH ₂ -	-0.9	KHP	0.01 ^b – 0.3 ^b	Shows good kinetic hydrate formation enhancement effect in both stirred and unstirred systems.	
67	L-histidine	CH ₄	basic polar	NH-CH=N-CH=C-CH ₂	-3.2	KHP	0.03 ^b – 1 ^b	Shows hydrate formation promotion effect similar to arginine but less than tryptophan. Higher hydrophobic amino acids show less hydrate promotion effect.	
68	L-arginine	CH ₄	basic polar	HN=C(NH ₂)-NH-	-4.5	KHP	0.03 ^b – 1 ^b	Shows hydrate formation promotion effect	

				(CH ₂) ₃					
69	Lysine	CH ₄	basic polar	H ₂ N-(CH ₂) ₄ -	-3.9	THI	5 ^b -10 ^b	Shows THI effect with increasing concentration.	(Mannar et al., 2017)
70	Lysine	CO ₂	basic polar	H ₂ N-(CH ₂) ₄ -	-3.9	THI	5 ^b -10 ^b	Shows THI effect with increasing concentration.	
71	Arginine	CH ₄	basic polar	HN=C(NH ₂)-NH-(CH ₂) ₃	-4.5	THI/KHP	1 ^b - 5 ^b	Slightly inhibits methane hydrate phase boundary as well as promoting hydrate formation uptake	(Bavoh et al., 2018c)
72	Valine	CH ₄	nonpolar	-CH(CH ₃) ₂	4.2	THI/KHP	1 ^b - 5 ^b	Slightly inhibits methane hydrate phase boundary as well as promoting hydrate formation uptake. Shows high uptake than arginine.	
73	Valine,	CO ₂	nonpolar	-CH(CH ₃) ₂	4.2	KHP	0.5 ^b	Promotes hydrate formation uptake about 1.2 times.	(Prasad and Kiran, 2018a)
74	Phenylalanine	CO ₂	nonpolar	Ph-CH ₂ -	2.8	KHP	0.5 ^b	Shows no significant hydrate promotion effect	
75	Cysteine	CO ₂	nonpolar	HS-CH ₂ -	2.5	KHP	0.5 ^b	Promotes hydrate formation uptake about 1.2 times.	
76	Methionine	CO ₂	nonpolar	CH ₃ -S-(CH ₂) ₂ -	1.9	KHP	0.5 ^b	Promotes hydrate formation uptake about 1.2 times.	
77	Threonine	CO ₂	polar	CH ₃ -CH(OH)	-0.7	KHP	0.5 ^b	Shows no significant hydrate promotion effect	
78	Methionine	CO ₂	nonpolar	CH ₃ -S-(CH ₂) ₂ -	1.9	KHP/XRD	0.5 ^b	Shows efficient hydrate kinetics conversion rate, thus improving the hydrate formation uptake.	(Prasad and Kiran, 2018)
79	Phenylalanine	CO ₂	nonpolar	Ph-CH ₂ -	2.8	KHP/ XRD	0.5 ^b	Shows less hydrate kinetics conversion rate, thus gives less hydrate formation uptake.	
80	Methionine	CH ₄	nonpolar	CH ₃ -S-(CH ₂) ₂ -	1.9	KHP/XRD	0.5 ^b	Shows efficient hydrate kinetics conversion rate, thus improving the hydrate formation uptake.	
81	Phenylalanine	CH ₄	nonpolar	Ph-CH ₂ -	2.8	KHP/ XRD	0.5 ^b	Shows efficient hydrate kinetics conversion rate, thus improving the hydrate formation uptake.	
82	Methionine	CH ₄ + CO ₂	nonpolar	CH ₃ -S-(CH ₂) ₂ -	1.9	KHP/XRD	0.5 ^b	Shows efficient hydrate kinetics conversion rate, thus improving the hydrate formation uptake.	
83	Phenylalanine	CH ₄ + CO ₂	nonpolar	Ph-CH ₂ -	2.8	KHP/ XRD	0.5 ^b	Shows efficient hydrate kinetics conversion rate, thus improving the hydrate formation uptake.	
84	Glycine + ethylene glycol	CH ₄	nonpolar	-H	-0.4	THI	1 ^b - 30 ^b 1:1 mixtures	Glycine can enhance the thermodynamic inhibition strength of ethylene glycol, shows strong synergic inhibition effect.	(Long et al., 2018)
85	Glycine	CH ₄	nonpolar	-H	-0.4	MD simulation	0.45 ^b - 1.5 ^b	Shows hydrate kinetics inhibition effect but less than serine.	(Maddah et

86	Alanine	CH ₄	nonpolar	-CH ₃	1.8	MD simulation	0.45 ^b - 1.5 ^b	Shows hydrate kinetics inhibition	al., 2018)
87	Serine	CH ₄	polar	-HO-CH ₂	-0.8	MD simulation	0.45 ^b - 1.5 ^b	Shows efficient hydrate kinetics inhibition via interruption of the hydrogen bond network of water.	
88	Proline	CH ₄	nonpolar	-NH-(CH ₂) ₃	-1.6	MD simulation	0.45 ^b - 1.5 ^b	Shows hydrate kinetics inhibition effect as alanine	
89	L-leucine	CH ₄ and NG	nonpolar	-CH ₂ CH(CH ₃)	3.8	KHP	0.1 ^b - 1 ^b	Very efficient in promoting hydrate formation kinetics than all studied amino acids at low concentrations for both structure I and structure II natural gas hydrates systems.	(Liu et al., 2015)
90	L-isoleucine	CH ₄	nonpolar	-CH(CH ₃)C ₂ H ₅	4.5	KHP	0.5 ^b	Exhibits good hydrate promotion ability similar to phenylalanine.	
91	L-valine	CH ₄	nonpolar	-CH(CH ₃) ₂	4.2	KHP	0.5 ^b	Enhances hydrate formation kinetics.	
92	L-threonine	CH ₄	polar	CH ₃ -CH(OH)	-0.7	KHP	0.5 ^b - 10 ^b	Enhances hydrate formation with decreasing concentration.	
93	L-alanine	CH ₄	nonpolar	-CH ₃	1.8	KHP	0.5 ^b - 2 ^b	Exhibits negligible hydrate promotion effect with increasing concentration.	
94	L-proline	CH ₄	nonpolar	-NH-(CH ₂) ₃	-1.6	KHP	0.5 ^b	Exhibits less hydrate promotion effect.	
95	L-methionine	CH ₄	nonpolar	CH ₃ -S-(CH ₂) ₂ -	1.9	KHP	0.5 ^b	Shows good hydrate promoters strength.	
96	L-tryptophan	CH ₄	nonpolar	Ph-NH-CH=C-CH ₂ -	-0.9	KHP	0.5 ^b	Shows good hydrate promoters strength.	
97	L-phenylalanine	CH ₄	nonpolar	Ph-CH ₂ -	2.8	KHP	0.5 ^b	Shows good hydrate promoters strength.	
98	L-arginine	CH ₄	basic polar	HN=C(NH ₂)-NH-(CH ₂) ₃	-4.5	KHP	0.5 ^b	Able to promote hydrate formation kinetics with decreasing stability.	
99	L-glutamic acid	CH ₄	acidic polar	HOOC-(CH ₂) ₂ -	-3.5	KHP	0.5 ^b	Able to promote hydrate formation kinetics with decreasing stability.	
100	L-histidine	CH ₄	basic polar	NH-CH=N-CH=C-CH ₂	-3.2	KHP	0.5 ^b	Able to promote hydrate formation kinetics with decreasing stability.	
101	L-serine	CH ₄	polar	-HO-CH ₂	-0.8	KHP	0.5 ^b	Exhibits less hydrate promotion effect	
102	L-aspartic acid	CH ₄	acidic polar	-CH ₂ COOH	-3.5	KHP	0.5 ^b	Exhibits less hydrate promotion effect	
103	L-valine	CH ₄	nonpolar	-CH(CH ₃) ₂	4.2	THI	1 ^b - 5 ^b	Shows less thermodynamic hydrate inhibition, however may increase with concentration depending on its solubility.	(Bavoh et al., 2018a)
104	L-threonine	CH ₄	polar	CH ₃ -CH(OH)	-0.7	THI	1 ^b - 5 ^b	Shows less thermodynamic hydrate inhibition, however may	

								increase with concentration depending on its solubility.	
105	Asparagine	CH ₄	polar	-CH ₂ CONH ₂	-3.5	THI	1 ^b - 5 ^b	Shows less thermodynamic hydrate inhibition, however may increase with concentration depending on its solubility.	
106	L-phenylalanine	CH ₄	nonpolar	Ph-CH ₂ -	2.8	THI	1 ^b - 5 ^b	Shows less thermodynamic hydrate inhibition, however may increase with concentration depending on its solubility.	
107	Glycine	C ₂ H ₆	nonpolar	-H	-0.4	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect	(Roosta et al., 2018)
108	L-serine	C ₂ H ₆	polar	-HO-CH ₂	-0.8	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect	
109	L-histidine	C ₂ H ₆	basic polar	NH-CH=N- CH=C-CH ₂	-3.2	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect	
110	Glutamine	C ₂ H ₆	polar	H ₂ N-CO-(CH ₂) ₂	-3.5	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit promotion effect	
111	Glycine	CH ₄ + C ₃ H ₈	nonpolar	-H	-0.4	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect and enhances the inhibition effect of PVP more than serine	
112	L-serine	CH ₄ + C ₃ H ₈	polar	-HO-CH ₂	-0.8	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect but slightly enhances PVP hydrate inhibition impact.	
113	L-histidine	CH ₄ + C ₃ H ₈	basic polar	NH-CH=N- CH=C-CH ₂	-3.2	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect	
114	Glutamine	CH ₄ + C ₃ H ₈	polar	H ₂ N-CO-(CH ₂) ₂	-3.5	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit promotion effect	
115	Glycine	CH ₄ + THF	nonpolar	-H	-0.4	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect	
116	L-serine	CH ₄ + THF	polar	-HO-CH ₂	-0.8	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect	
117	L-histidine	CH ₄ + THF	basic polar	NH-CH=N- CH=C-CH ₂	-3.2	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit weak hydrate inhibition effect	
118	Glutamine	CH ₄ + THF	polar	H ₂ N-CO-(CH ₂) ₂	-3.5	KHI/KPI	0.5 ^b - 1.5 ^b	No significant effect	
119	Glycine	CH ₄	nonpolar	-H	-0.4	KHI	1 ^b - 7 ^b	Poor kinetic hydrate inhibitor on the bases of induction time and hydrate formation onset temperature even at high concentrations.	(Xu et al., 2017)
120	PVCap + Glycine	CH ₄ + THF	nonpolar	-H	-0.4	KHI	1 ^b : 1 ^b - 5 ^b	Efficiently improves PVCap hydrate inhibition strength to about 16 time.	

121	Glycine	CH ₄	nonpolar	-H	-0.4	KHDP	0.01 ^b – 5 ^b	Efficiently enhances methane hydrate dissociation kinetics.	(Kumar et al., 2017)
122	L-serine	CH ₄	polar	-HO-CH ₂	-0.8	KHDP	0.01 ^b – 5 ^b	Enhances methane hydrate dissociation kinetics.	
123	L-histidine	CH ₄	basic polar	NH-CH=N-CH=C-CH ₂	-3.2	KHDP	0.01 ^b – 5 ^b	Efficiently enhances methane hydrate dissociation kinetics, with high methane recovery potential.	
124	L-threonine	CH ₄	polar	CH ₃ -CH(OH)	-0.7	KHDP	0.01 ^b – 5 ^b	Enhances methane hydrate dissociation kinetics.	
125	L-tryptophan	CH ₄	nonpolar	Ph-NH-CH=C-CH ₂ -	-0.9	KHDP	0.01 ^b – 5 ^b	Enhances methane hydrate dissociation kinetics.	
126	L-threonine	CH ₄	polar	CH ₃ -CH(OH)	-0.7	KHDP	0.01 ^b – 5 ^b	Enhances methane hydrate dissociation kinetics.	
127	Proline	CH ₄	nonpolar	-NH-(CH ₂) ₃	-1.6	KHDP	0.01 ^b – 5 ^b	Poorly enhances methane hydrate dissociation kinetics.	
128	Glycine + 1-Ethyl-3-methylimidazolium chloride	CH ₄	nonpolar	-H	-0.4	THI	5 ^b + 5 ^b	Glycine + 1-Ethyl-3-methylimidazolium chloride has negligible effect on their pure system phase boundary. However, they inhibit methane hydrate formation.	(Bavoh et al., 2018c)

^a mol%; ^b wt.%; ^c ppm; ^d extracted from reference (Kyte and Doolittle, 1982);
 THI refers to Thermodynamic hydrate inhibitor; THP refers to Thermodynamic hydrate promoter; KHI refers to Kinetic hydrate inhibitor; KHP refers to Kinetic hydrate promoter; KHDP refers to Kinetic hydrate dissociation promoter.

157 2.1. Role of amino acids in hydrate thermodynamics (phase behaviour)

158 2.1.1 Amino acids as thermodynamic inhibitors

159 Generally, the Hydrate – Liquid – Vapor Equilibrium (HL_wVE) curve is determined by authors to
 160 evaluate the thermodynamic effect of amino acids as gas hydrate inhibitors/promoters. Seven
 161 amino acids (proline, glycine, alanine, arginine, serine and valine, lysine) have been studied as
 162 THIs for CO₂, CH₄, and NG (CH₄ – 93.0%, C₂H₆ – 5.0%, C₃H₈ – 2.0%) (Bavoh et al., 2018b;
 163 Bavoh et al., 2017, 2016b; Mannar et al., 2017; Sa et al., 2016, 2011) as shown in Table 2 The
 164 experimental details of all reported measured HL_wVE data in amino acids are presented in Table
 165 2.

166 Table 2. Amino acids HL_wVE data

Author	Amino acid	Gas	Conc./ mol%	T/K	P/MPa	Data points
Sa et al., 2011 (Sa et al., 2011)	Glycine	CO ₂	0.1	274.55-281.35	1.49-3.51	5
		CO ₂	0.5	274.35-281.05	1.49-3.50	5

167

168 Figures 3 and 4 illustrates the HL_wVE curve of CO₂, CH₄ and natural gas hydrates in the presents

169 of amino acids at concentrations in mol % and wt %. In Figures 3 and 4, the addition of amino

170 acids moves the HL_wVE curve to higher pressure and lower temperature regions. Thus,

171 indicating a hydrate inhibition behavior by all studied amino acids in all studied gas systems. It's

172 interesting to state that no THP effect has been reported on amino acids in open literature. The

173 increasing order of inhibition for CO₂ hydrates is found to be valine > alanine > glycine as

174 shown in Figure 3(a), a similar trend is observed for CH₄ and NG systems in Figure 3(b) and

175 1(c). However, a decreasing magnitude of inhibition of proline, followed by serine, alanine and

176 glycine is observed based on mol %. However, an opposite inhibition strength of amino acids

177 (glycine > alanine > proline > serine > arginine) is reported in Figure 4 for CH₄ hydrate based on

178 wt %. The difference in inhibition trend is due to the choice of concentration units adapted by

179 various researchers. The concentration units adapted for gas hydrate studies are very critical to

180 evaluating and interpreting gas hydrate inhibition impact. Most reported amino acids

181 thermodynamics hydrate based studies are measured in mol % (Sa et al., 2016, 2011). Figures 3 -

182 4, the equivalent concentration in mol % and wt % of amino acids, reveals significant difference

183 in inhibition trend that may be capable of affecting their inhibition impact analyses using either

184 concentration units. An opposing inhibition impact may be observed or reported considering

185 both units, as suggested by Mech et al., (2015). For example, when mol % is used, amino acids

186 with heavy molecular weight (longer side chain) show high inhibition and vice versa. This can be
187 well understood in Table 3. In Table 3, the equivalent wt.% concentration of the amino acids in
188 mole % are low, with higher molecular weight amino acids have the lower mole% concentration
189 values. Based on wt %, the hydrate inhibition impact increases as the molecular weight decreases
190 (shorter side chain length) as shown in Figures 3 and 4. However, in most industrial applications
191 wt % is used (Yousif, 1998). Therefore, for industrial focus research, using wt % might be
192 appropriate as interpretation will contribute more towards practical field applications.

193 Based on wt %, glycine is the best amino acid THI. Long *et al.* (Long et al., 2018) found that,
194 glycine is also able to improve the thermodynamic inhibition performance of ethylene glycol (a
195 commercial THI) on CH₄ hydrates. They reported that 20 wt% glycine solution shows a methane
196 hydrate phase boundary deviation temperature of 2.9 K (Bavoh et al., 2016b), while a
197 combination of 10 wt% glycine and 10 wt% ethylene glycol shows 5.2 K (Long et al., 2018) as
198 shown in Figure 5. Interestingly, the inhibition impact of 5 wt% glycine plus 5 wt% ethylene
199 glycols and 10 wt% glycine is found to be in the same range in Figure 5. Thus, the
200 thermodynamic inhibition enhancement of ethylene glycol by glycine is more evident at mixed
201 concentrations above 5 wt%. However, synergy of glycine and 1- Ethyl-3-methylimidazolium
202 chloride (ionic liquid) at 10 wt.% (50/50) has negligible effect on the phase behavior of their
203 pure compositions at the same concentration (Bavoh et al., 2018b). In addition, the inhibition
204 effect of lysine was in the same range as alanine for methane and carbon dioxide at 10 wt%
205 (Mannar et al., 2017). Meanwhile, valine shows very less methane hydrate and carbon dioxide
206 hydrate inhibition, probably due to its longer alkyl side chain length (Bavoh et al., 2018c; Sa et
207 al., 2011). The thermodynamic effect of threonine, valine, phenylalanine, and asparagine are not
208 comparable to glycine and alanine at 5 wt.% for CH₄ hydrate formation (Bavoh et al., 2018a).

209 However, these amino acids are mostly methane hydrate kinetic promoters. For instance, in
 210 carbon dioxide hydrate systems, asparagine and phenylalanine is known to act as promoters with
 211 phenylalanine being able to promote CH₄ hydrate as well (Prasad and Kiran, 2018a; Sa et al.,
 212 2015). Similarly, threonine and valine are able to promote CH₄ hydrates kinetically (Bavoh et al.,
 213 2018b; Prasad and Kiran, 2018a, 2018b). The amino acids thermodynamic inhibition
 214 mechanism is due to their electrostatic force of interactions via zwitterion interaction and
 215 hydrogen bonding with water molecules. Thus, disturbing water role in hydrate formation and
 216 resulting in hydrate inhibition (Bavoh et al., 2016b; Sa et al., 2015, 2011). An ANOVA analysis
 217 at 95% confidence level indicted that, the amino acid thermodynamic inhibition impact is not
 218 dependent on the type of guest compound (for only methane and carbon dioxide systems) and
 219 that the thermodynamic inhibition impact of amino acids is solely due to its molecular
 220 interactions with water molecules in the liquid phase. The amino acids gas hydrate phase
 221 behavior inhibition strength is found to be influenced by their hydrophobicity, solubility in
 222 water, side chain length, and concentration (Sa et al., 2011). However, all tested amino acids
 223 inhibits hydrate with increasing concentration (Bavoh et al., 2016b; Sa et al., 2011).

224 Table 3. Variations in some studied amino acids concentration units

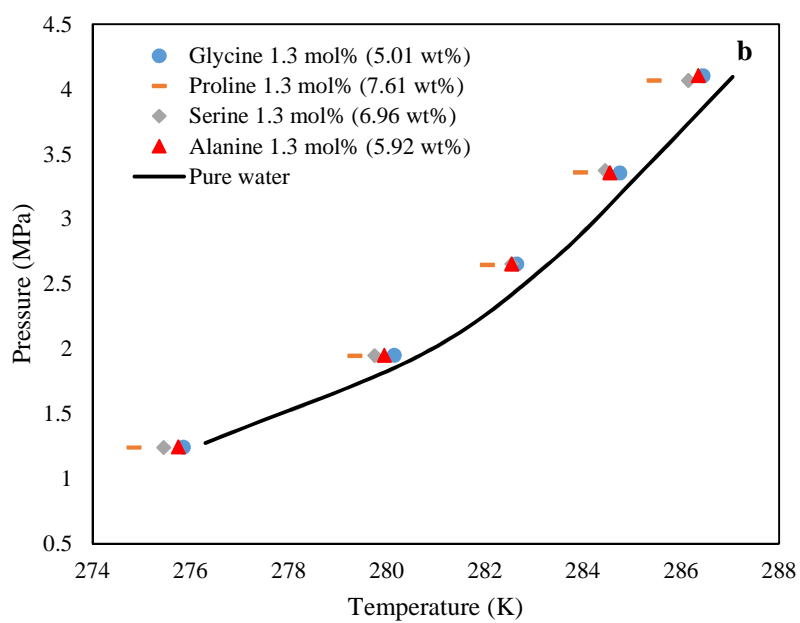

Wt. %	Mol %				
	Glycine	Alanine	Proline	Serine	Valine
5	1.25	1.05	0.82	0.89	0.80
10	2.60	2.20	1.71	1.87	1.68
15	4.06	3.45	2.69	2.94	2.64
20	5.66	4.81	3.76	4.11	3.70

239 Figure 5. The inhibition impact of pure glycine and glycine + ethylene glycol on the HL_wVE data of CH_4 hydrates;
 240 Pure water and glycine data are taking from Bavoh et al., (2016b), glycol from Mohammadi and Richon, (2010), and
 241 glycine + ethylene glycol data from Long et al., (2018).

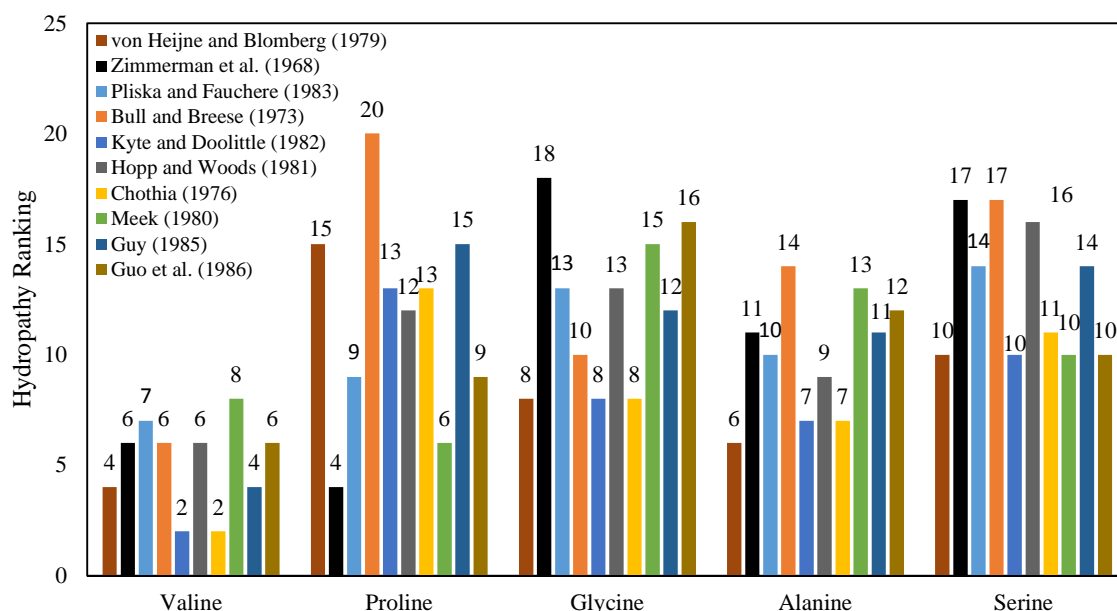

242 The affinity of each natural amino acid for water has been evaluated based on various
 243 physicochemical and interaction properties. These studies led to the development of amino acids
 244 side chain hydrophobic scale. There are several of such scales available (Dacheng et al., 1986;
 245 Zimmerman et al., 1968) as authors study different amino acid properties (e.g. surface tension,
 246 solubility, accessible surface areas, the energy of transfer of amino acids from water to a less
 247 polar environment, etc.) to propose/determine their hydrophobicity. Some authors (Naeiji et al.,
 248 2014b; Sa et al., 2015, 2011) have suggested that the inhibition effect of amino acids on gas
 249 hydrate is influenced by their hydrophathy/hydrophobicity. The hydrophathy of compounds has
 250 significant effect on their gas hydrate inhibition strength. This is well established in ionic liquids,
 251 as hydrate inhibition increases with decreasing hydrophathy, which is related to the alky chain

252 length of compounds (Bavoh et al., 2016). Notwithstanding, with regards to amino acids, there
253 are several amino acid hydrophathy scales available in literature as summarized in Figure 6.
254 However, a less agreement exists amongst all the hydrophathy scales reported on amino acids as
255 shown in Figure 6 which indicates that, amino acids hydrophathy is less understood. Results in
256 difficulties in the selection of a suitable hydrophathy scale for gas hydrate data analysis and hence
257 may possibly lead to the misinterpretation of results or errors in gas hydrate data analysis.

258 The hydrophathy of a compound (amino acid) basically refers to hydrophilicity and
259 hydrophobicity. This describes the ability of amino acids to have access to water molecules and
260 or hinder their access to interact with water (Kyte and Doolittle, 1982). Amino acids
261 hydrophathy has been a difficult area of study as there are different hydrophathy scales available in
262 literature based on various properties such as solubility and surface tension etc. In these scales,
263 numbers are assigned to each amino acid to describe its hydrophathy strength. Higher hydrophathy
264 values represent strong hydrophobicity while lower values represent strong hydrophilicity.

265 Generally, gas hydrate researchers (Sa et al., 2015, 2011) adapt the amino acid hydrophathy scales
266 suggested by Kyte and Doolittle, (1982). Reasons for choosing these scales are not stated.
267 Perhaps because it is the most widely used amino acid hydrophathy scale in literature. Figure 7
268 shows the correlation between amino acids gas hydrate inhibition (average temperature
269 depression) impact and their hydrophathy scale proposed by Kyte and Doolittle, (1982). In Figure
270 7(a), an R^2 of 0.46 and 0.38 are observed for methane and natural gas hydrate inhibition
271 respectively, while and R^2 of 0.67 is shown for methane in Figure 7(b). It can be observed that
272 the strength of hydrate inhibition of amino acids does not strongly correlate with their respective
273 hydrophathy in Figure 7. Meanwhile, this hydrophathy scale is generally the basis for analyzing
274 hydrate inhibition impact in the presence of amino acids by researchers (Sa et al., 2011). Such

275 analysis is misleading and may result in data analytical errors, hence, we suggest further studies
 276 in selecting/developing a best amino acid hydrophathy scale for hydrate inhibition purposes. It
 277 must be stated that, the R^2 values in Figure 7 may be affected by the number of data points
 278 employed for the correlation analysis, as limited data are currently available in open literature.
 279 Therefore, more experimental hydrate phase equilibrium data of amino acids are required to fully
 280 comprehend the effect of amino acid hydrophathy on their inhibition impact. Compared to
 281 glycine, serine is less effective in preventing hydrate formation though it has very low
 282 hydrophathy value (-0.8) compared to glycine (0.4). Hence, relying on only the hydrophathy scale
 283 to justify the hydrate inhibition effect of amino acids is not sufficient. Other characteristics such
 284 as amino acids pH level (acidity), side chain polarity, and side chain group type (acyclic,
 285 aliphatic, aromatic, containing sulfur or hydroxyl etc.) should critically be considered when
 286 discussing the inhibition or promotion impact of amino acids on gas hydrate formation.

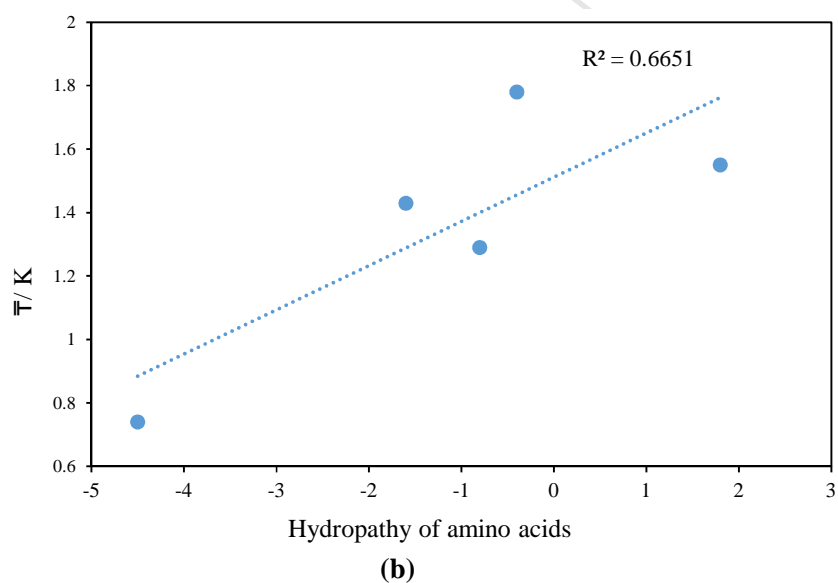

287

288 Figure 6. Hydrophathy ranking of studied for gas hydrate inhibition. Data is taken from Wilce et al., (1995). The
 289 hydrophathy of amino acids decreases with increasing ranking number.

290

291

292

293 Figure 7. Regression between average depression temperature (\bar{T}) and commonly used amino acid hydropathy scale
 294 proposed by Kyte and Doolittle, (1982); (a) data from Sa et al., (2016) and (b) data from Bavoh et al., (2016b).

295

296 The solubility of THIs in water is critical in inhibiting gas hydrate. Conditions such as low
 297 temperature during hydrate formation and acidic environment in the solutions caused by the
 298 dissolved gases such as carbon dioxide decrease the solubility of the amino acids. Sa et al.,

299 (2011) determined the solubility of amino acid using the van'tHoff equation to account for amino
300 acid solubility reduction due to the acidic environment. They suggested that, the amino acid
301 solubility reduction due to acidic environment is negligible and therefore only the effect on
302 decreasing temperature should be considered. Hence, the hydrate inhibitory efficiency of each
303 amino acid increases with concentrations within their respective solubility in water.

304 *2.2 Role of amino acids in hydrate kinetics*

305 *2.2.1 Amino acids as kinetic inhibitors*

306 Unlike thermodynamic studies, relatively many studies are available on the kinetics of amino
307 acid on gas hydrate mitigation/enhancement. The kinetic data gathered was considered
308 differently since gas hydrate formation kinetics is very probabilistic, and dependent on factors
309 such as apparatus design, experimental procedure, reactor wall roughness, driving force, and
310 impurities in sample (Sloan and Koh, 2007). Generally, the three main kinetic indicators used to
311 evaluate the inhibition/ promotion performance of amino acids are nucleation time, rate and gas
312 uptake during hydrate formation. Mostly, nucleation time is preferred among the others as it
313 characterizes the efficiency of amino acids in delaying hydrate formation. It must be stated that,
314 on the bases of kinetic measurements, amino acids are very poor gas hydrate kinetic inhibitors.
315 They are more kinetic promoters than inhibitors. However, their kinetic inhibition strength lies
316 in their ability to delay the hydrate formation growth rate and gas uptake. The kinetic inhibition
317 parameters usually determined by authors are induction time (Bhattacharjee et al., 2016; Kakati
318 et al., 2016a; Naeiji et al., 2014a; Rad et al., 2015; Talaghat, 2014) and onset hydrate formation
319 temperature (subcooling temperature) (Kakati et al., 2016a; Perfeltd et al., 2014; Sa et al., 2016).
320 Also, gas uptake (Bhattacharjee et al., 2016; Kakati et al., 2016a; Roosta et al., 2016; Sa et al.,

2016, 2015, 2013) and hydrate rate of formation (Roosta et al., 2016) are determined. Sa et al., (2013) studied the effect of 5 amino acids (Alanine, glycine, leucine, valine, and isoleucine) on CO₂ hydrates at 0.1 mol% by determining their subcooling temperature and gas uptake for fresh and memory water systems. Their findings showed that, glycine best inhibited CO₂ hydrates then alanine, followed by valine, leucine and isoleucine. Furthermore, the inhibition effect of glycine increased with increasing concentration. Sa et al., (2015) further extended their study on the inhibition impact of amino acids on CO₂ hydrate formation growth and nucleation kinetics at 0.01 and 0.1 mol% using five electrically charged and/or hydrophilic side chains amino acids namely: alanine, asparagine, aspartic acid, histidine, and phenylalanine. Asparagine and aspartic acid efficiently inhibits hydrate than alanine based on gas uptake at 0.01 mol%, while at 0.1 mol%, histidine exhibits strong inhibition, with alanine and phenylalanine next to histidine. According to Sa et al., (2015), the hydrate nucleation and growth inhibition trends of these amino acids correlated with their hydropathy index showed similar trends at both low (0.01 mol%) and high (0.1 mol%) studied concentration. In addition, histidine performed better than alanine in delay hydrate nucleation time and growth. However, phenylalanine was less efficient in preventing hydrate formation compared with alanine. Phenylalanine virtual had no significant impact in delaying hydrate nucleation process. Interestingly, unlike glycine (in Sa et al., (2013) previous study), the inhibition impact of aspartic acid and asparagine decreased at increasing concentration due to their solubility limitations leading to residuals of excess (unreacted) amino acid in the system, which serves as site for enhancing hydrate formation. Hence, reducing their (aspartic acid and asparagine) kinetic inhibitory efficiency. Roosta et al., (2016) reported that, the kinetic inhibition effect of amino acids on CO₂ hydrates is due their side chain hydrophobicity and electrically charge. Thus, histidine showed high inhibition impact than

344 glycine, followed by proline, whose inhibition strength is in the same range with serine and
345 threonine but higher than glutamine. It must be stated that, the correlation between the amino
346 acids side chain properties and inhibition impact is not well understood and requires further
347 studies. However, amino acids with polar side chains generally seem to show better CO₂ hydrate
348 inhibition than non-polar ones.

349 Perfeldt et al., (2014) reported that valine exhibits slightly higher CH₄ hydrate inhibition than
350 threonine. They could inhibit CH₄ hydrate than some anti-freeze proteins. However, a recent
351 study has shown that glycine, serine, proline, and alanine could inhibit methane and natural gas
352 (93% CH₄, 5% C₂H₆, 2% C₃H₈) hydrate at 0.1 mol% on the basis of onset temperature and gas
353 uptake evaluation. Proline was the best among all the studied amino acids. Talaghat, (2014)
354 suggested that, tyrosine could delay the induction time of NG hydrate better than PVP via a mini
355 flow loop apparatus at 200 ppm. Furthermore, they augured that, the addition of tyrosine to PVP
356 increased the inhibition impact of PVP. A study by Kakati et al., (2016a) reported that the
357 incorporation of tyrosine synergically with PVP is able to boost the kinetic inhibition efficiency
358 of PVP for NG hydrate system. Xu et al., (2017) argued via methane hydrate formation kinetics
359 that, glycine poorly mitigates hydrate formation than PVCap. However, it can improve the
360 efficiency of PVCap in many folds (of about 16 times). This demonstrates the ability of amino
361 acids to inhibit gas hydrate and at the same time boost the performance of conventional kinetic
362 inhibitors in the oil and gas industry. On contrary to the poor performance of amino acids in
363 delaying hydrate nucleation time when applied in their pure state, they are able to increase the
364 induction time of conventional kinetic inhibitors when mixed together. In the presence of THF
365 and C₂H₆ hydrates, amino acid (glycine) is believed to act a strong kinetic hydrate inhibitor than

366 l-leucine (Naeiji et al., 2014a). Thus, glycine seems to stand tall among all the studied amino
367 acids as the best kinetic inhibitor in different hydrate formers systems.

368 One the other hand, amino acids have been applied as gas hydrate dissociation promoter
369 (inhibition) for methane hydrate production. Kumar et al., (2017) filed a patent on natural
370 methane hydrate recovery via amino acids; glycine, histidine, proline, tyrosine, serine, threonine,
371 and tryptophan. The patent claims, all tested amino acids efficiently promote methane hydrate
372 dissociation kinetics after 18 minutes at 283 K in comparison with the base sample (pure water).
373 However, in a stirred reactor, glycine and histidine show high hydrate dissociation enhancement
374 impact. Histidine generally exhibits high methane recovery after 30 minutes with proline posing
375 as the poorest in promoting methane hydrate dissociation. However, histidine could not beat the
376 efficiency of ethylene glycol (a commercial hydrate thermodynamic inhibitor). This is because
377 ethylene glycol effectively destabilizes hydrate phase better than histidine. In addition, the
378 methane recovery further enhances with increasing additives (amino acids) injection rate (10 ml/
379 min and 30 ml/ min).

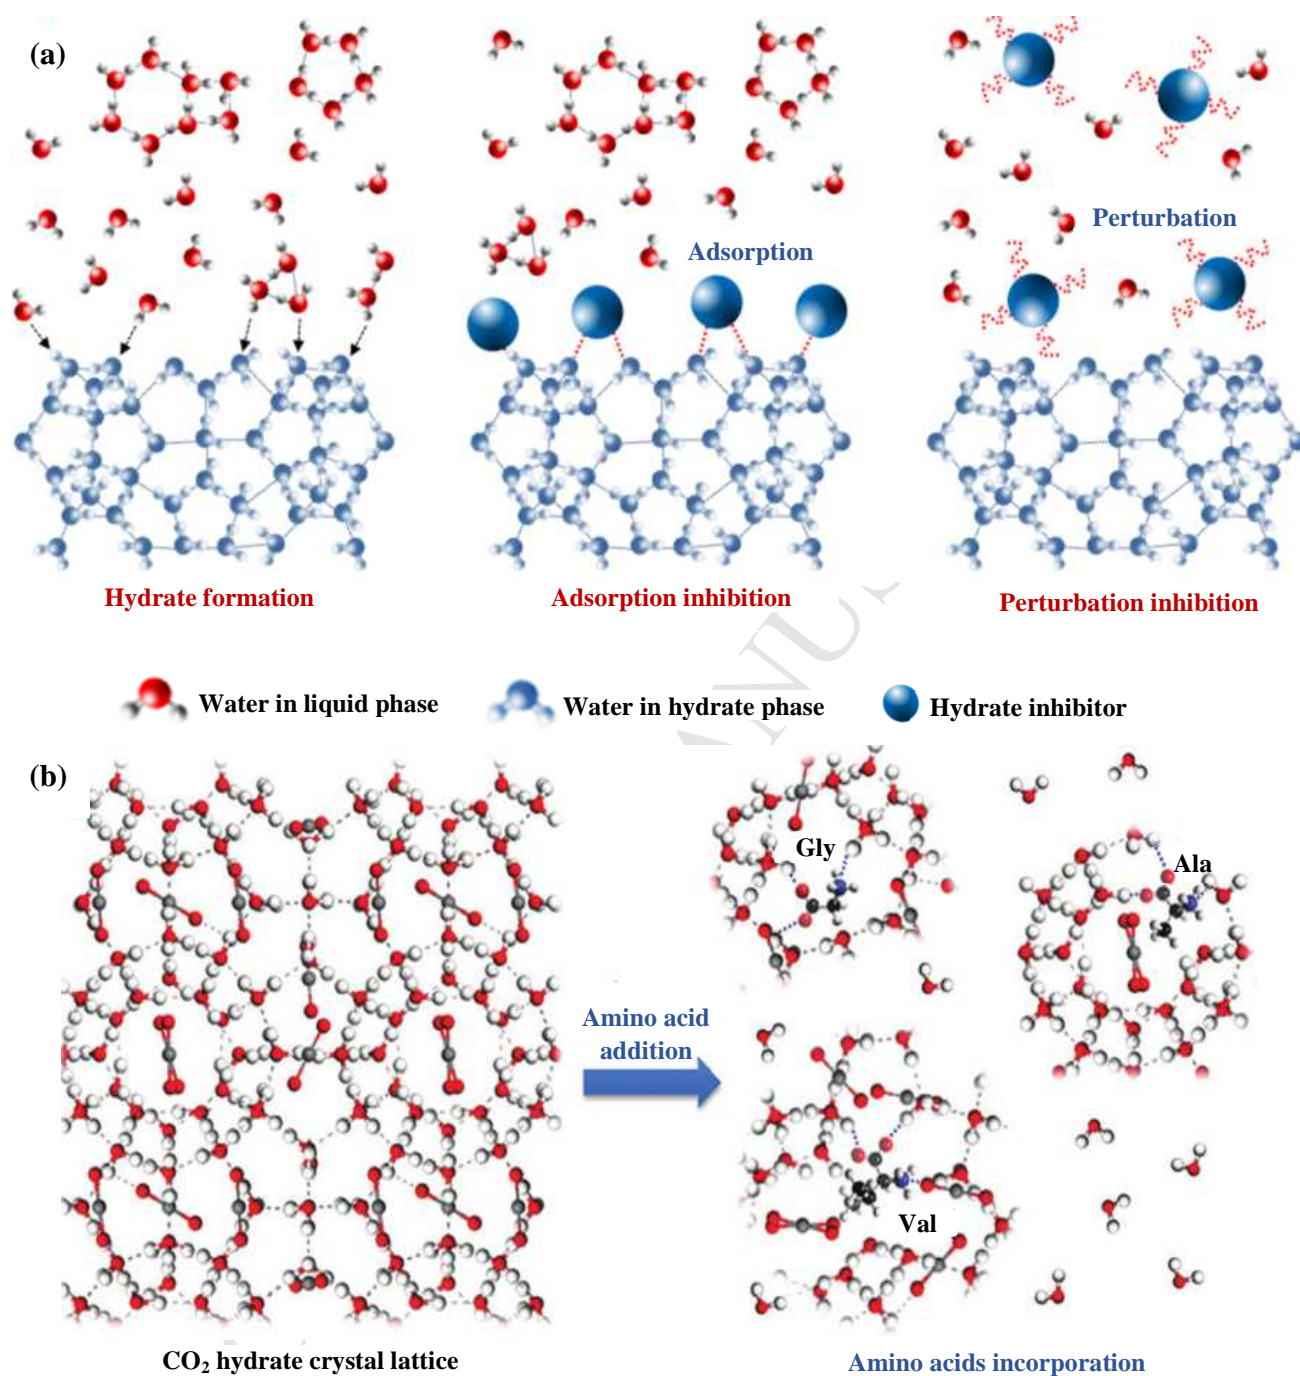

380

381 *2.2.1.1 Amino acid kinetic inhibition mechanism*

382 It's generally believed that commercially used gas hydrate kinetic inhibitors (polymers), inhibit
383 hydrate by adsorption (Sloan and Koh, 2007). However a different inhibition mechanism is
384 proposed by Sa et al., (2013) for amino acids by studying the effect of amino acid on CO₂
385 hydrate using synchrotron powder X-ray diffraction (PXRD) to identify the crystal structure of
386 CO₂ hydrates and their lattice parameters. It was hypothesized that amino acids may have a
387 hydrate growth inhibition mechanism different from that of PVP which is essentially driven by

388 adsorption. This growth inhibition mechanism is derived by perturbation of the local water
389 structure by amino acid hydrophilic terminal groups and the hydrophobic side chains via
390 hydrogen bonding as shown in Figure 8(a). Sa et al., (2015) further studied the perturbation
391 effect of amino acids on local water structure by obtaining the polarized Raman spectra of
392 aqueous amino acids solutions. Their findings revealed that amino acids perturbed the structure
393 of liquid water causing kinetic inhibition of gas hydrate formation nucleation and growth.
394 However, the intensity of perturbation depends on the amino acid side chain properties. Amino
395 acids with electrically charged and/or hydrophilic side chains were observed to disrupt the low
396 temperature liquid water structure, whereas those with hydrophobic side chains strengthened this
397 structure. Sa et al., (2014) studied crystallization phenomena of CO₂ hydrate in the presence of
398 amino acids using PXRD, ¹³C cross-polarization (CP) nuclear magnetic resonance (NMR), and
399 Raman spectroscopy and results obtained was in contrary to the previously proposed gas hydrate
400 mitigation mechanism (perturbation of local water structure) in literature (Sa et al., 2015, 2013).
401 It was found that, amino acids form hydrogen bonds with water molecules, displacing the water
402 molecules in the hydrate crystal lattice, and incorporating themselves in the hydrate structure.
403 This incorporation of amino acids in hydrate lattice results in lattice distortion and expansion.
404 However, as the lattice sites for incorporation are saturated, those that are not incorporated into
405 the hydrate crystal lattice are excluded and crystallized among themselves. The excluded
406 crystallized amino acids may act as site for gas hydrate formation enhancement. It must be stated
407 that amino acid does not form semiclathrate hydrates, they only take part in lattice formation (see
408 Figure 8(b)). This has also been confirmed via estimation of the hydrate enthalpy of dissociation
409 using the Clausius-Clapeyron equation indicating that, amino acids do not participate in hydrate
410 cage occupation and structure during hydrate formation (Bavoh et al., 2017, 2016b). It must be

411 stated that Sa et al., (2015), (2014), (2013) findings requires more direct evidences and further
412 molecular level confirmations to reveal amino acids hydrate inhibition mechanism. Since they
413 basically relate the ice lattice Bragg peaks to sI hydrates, which may reflect the water to hydrates
414 conversion rate in the system. Which could also be influence by the system driving force
415 (especially at 3.6 MPa for CO₂ hydrates), stirring rate, gas to water ratio reactor design, etc.
416 Moreover, the study on lattice incorporation by Sa et al., (2014) lacks quantitative analyses and
417 provides limited crystalline information. It only provides profile refinement. Thus, a careful
418 analysis of the lattice incorporation phenomena of amino acids in hydrate lattice structure is
419 required because once it occurs, an adverse effect or change may happen in many lattice
420 refinement parameters such as lattice parameter (a, b, c, $\langle\alpha\rangle$, $\langle\beta\rangle$, $\langle\gamma\rangle$), atomic site
421 occupancies, atomic positions (x, y, z), profile parameters (U, V, W), etc which could change the
422 structure. In addition, the idea of the incorporation of amino acids into hydrate lattices structures
423 is expected to result in thermodynamic inhibition effect and not kinetic inhibition as suggested
424 by Sa *et al* (Sa et al., 2014). This might be due to the perturbation kinetic inhibition mechanism
425 discussed earlier in this section. Basically, the thermodynamic inhibition effect and the
426 perturbation kinetic hydrate inhibition mechanism are all driven by the hydrogen bonding
427 interaction between the hydrogen bonded water crystalline structure and the amino acids
428 molecules. Hence, a large perturbation effect is caused with kinetically reduces the hydrate
429 crystalline nucleation and growth rate.

435

436 *2.2.2. Amino acids as kinetic promoters*

437 Gas hydrate promoters are additives that enhance hydrate formation. They either do so
438 thermodynamically or kinetically. Such additives are important for implementing gas hydrate-
439 based technologies such as natural gas storage and transportation, CO₂ capture, storage and
440 sequestration. One critical problem that limits the implementation of these technologies is how to
441 form hydrate very fast. The conventional gas hydrate promoters are THF (Sefidroodi et al., 2011;
442 Sowa et al., 2014; Strobel et al., 2006) and SDS (Kakati et al., 2016b; Partoon et al., 2013).
443 However, these promoters do not form hydrates so fast as may be required for their applications.
444 In addition, they are not environmentally friendly and their presence may result in foam
445 formation in process plants (Veluswamy et al., 2017). Recent, amino acids studies suggest that
446 amino acids are potential gas hydrate promoters. Most importantly the presence of amino acids
447 do not favour foam formation, thus can be applied in hydrate based commercial operations
448 (Veluswamy et al., 2017).

449 In this section, only kinetic amino acid based hydrate promoters are reported. Liu et al., (2015)
450 are among the first research group to report natural amino acids as methane hydrate promoters, at
451 low concentrations up to 1 wt%. According to the study, leucine showed the highest CH₄ hydrate
452 promotion effect than methionine, tryptophan, and phenylalanine, arginine, glutamic acid, and
453 histidine at 0.5 wt%. Leucine could convert about 95% water into methane hydrate with a
454 gravimetric capacity of 144 mgg⁻¹ at an optimum concentration of 0.5 wt%. The presence of
455 leucine did not cause foaming upon degassing. However, l-serine, l-aspartic acid, and l-proline,
456 alanine show very less methane hydrate uptake (behaved as inhibitors as demonstrated by Sa et
457 al., (2016). Further details on the morphology changes of leucine during methane hydrate
458 formation and dissociation was studied by Veluswamy et al., (2016). However, no hydrate

459 enhancement effect was detected below 0.3 wt%. Veluswamy et al., (2017) further demonstrated
460 that, tryptophan could promote methane hydrate formation than histidine and arginine but could
461 not beat leucine. They argued that, the amino acid side chain properties play critical role in
462 hydrate promotion as amino acids with aromatic side chains that enhanced hydrate formation
463 better than those with aliphatic side chain. The combination of aromatic and hydrophobic side
464 chain could better promote hydrate formation. This may be true for methane hydrates, as the
465 amino acids promotion effect is composition dependent. All studied amino acids with aromatic
466 sided chain and hydrophobic nature (tryptophan, leucine, phenylalanine) have shown significant
467 methane hydrate promotion. However, leucine shows poor promotion effect (inhibition effect) in
468 ethane and THF hydrates (Naeiji et al., 2014a; Rad et al., 2015). Likewise phenylalanine is
469 reported to slightly inhibit CO₂ hydrates formation kinetics (Sa et al., 2015). In addition,
470 histidine is reported to show kinetic promotion effect on CH₄ hydrate (Bhattacharjee et al.,
471 2016). On the contrary, histidine is reported to kinetically inhibit CO₂ hydrates (Roosta et al.,
472 2016; Sa et al., 2015), indicating that, the kinetic promotion/inhibition effect of amino acids is
473 meaningfully dependent on the type of guest compound present. This composition dependent
474 hydrate promotion effect of amino acids provides selectivity opportunities for gas hydrate based
475 mixed gases separation and CO₂ capture applications. Interestingly, tryptophan and methionine
476 are able to promote both CH₄ and CO₂ hydrates (Cai et al., 2017). Other factors that contribute to
477 the promotion/inhibition effect of amino acids are their side chain length and hydropathy index.
478 Authors claim there is an optimum side chain length of hydrophobic amino acid in hydrate
479 kinetic promotion/inhibition (Cai et al., 2017; Sa et al., 2013). However, the optimum side chain
480 length is not clearly defined in current studies. According to Cai et al., (2017), L-methionine
481 could promote CO₂ hydrate formation better than L-norvaline, L-norleucine, 2-aminoheptanoic

482 acid, n-hexanoic acid, and n-hexylamine at 0.2 wt%. The gravimetric capacity of CO₂ hydrate
483 formation was about 356 mgg⁻¹ in 1000 min for 81 mgg⁻¹ bulk water system. It is worth noting
484 that, the promotion effect of amino acids is concentration dependent, which vary for every amino
485 acid in different gas system. For every gas system, all amino acids have an optimum
486 concentration above which their promotion/inhibition impact is decreased. For instant, the
487 optimum promotion impact of leucine in CH₄ hydrate is in the range of 0.3 – 0.5 wt% (Liu et al.,
488 2015; Veluswamy et al., 2016). In CH₄ hydrate system, the optimum concentration for
489 tryptophan is 0.3 wt%, while that for histidine and arginine is 1 wt% (Veluswamy et al., 2017).
490 In CO₂ hydrate L-methionine has an optimum concentration of 0.2 wt% (Cai et al., 2017). It is
491 recommended that authors optimize the effective promotion/inhibition concentration for amino
492 acids and compare them as such.

493 In Bhajan's lab, the effect of valine and arginine on CH₄ hydrates shows that, both valine and
494 arginine promote CH₄ hydrate formation more than SDS. Valine exhibits the most efficient
495 average methane hydrate promotion impact of about 10 and 1.3 times moles consumption of CH₄
496 than pure water and SDS. But the induction time for CH₄ hydrate nucleation was less compared
497 to SDS (Bavoh et al., 2018c). Prasad and Kiran, (2018a) also studied the effect of five amino
498 acids (L-valine, L-phenylalanine, L-cysteine, L-methionine and L-threonine) on CO₂ hydrate
499 formation under isochoric conditions in both stirring and non-stirring mode. They found that L-
500 valine, L-cysteine, and L-methionine increased the CO₂ uptake of water over about 20%, with
501 phenylalanine and threonine having negligible promotion or inhibition effect of CO₂ hydrate at
502 0.5 wt% in both stirring and non-stirring mode. Thus, showing that valine is able to promote both
503 CH₄ and CO₂ hydrate formation (Bavoh et al., 2018b; Prasad and Kiran, 2018a). A follow up
504 study with methionine and phenylalanine by Prasad and Kiran, (2018) on CH₄, CO₂ and their

505 mixture at 0.5 wt% using a non-stirred and isochoric mode reported that, the hydrate conversion
506 efficiency in phenylalanine is very low for CO₂ hydrate but both methionine and phenylalanine
507 show significant hydrate conversion efficiency in CH₄ and mixed CH₄ + CO₂ system. The
508 presence of methionine and phenylalanine enhanced the formation kinetics of hydrate formation
509 with about 90% gas to hydrate conversion and over 85% water to hydrate conversion within an
510 hour. Nonetheless, methionine promotes hydrate formation better than phenylalanine in both the
511 gas systems, but, phenylalanine is more recommended for methane hydrates only. The findings
512 further confirms that of Sa *et al.* (Sa et al., 2014) that amino acids form structure I hydrates. This
513 finding presents interesting bio potentials for the separation of CH₄ gas from CO₂+CH₄ gas
514 mixtures and natural gas storage.

515 *2.2.2.1 Amino acid kinetic promotion mechanism*

516 The amino acids hydrate promotion mechanism is controlled by lots of factors which are not
517 fully understood yet (Liu et al., 2015). The proposed amino acids hydrate promotion effect is
518 speculated by authors to arise from their surface activity and surface adsorption behavior via
519 capillary action (Cai et al., 2017; Liu et al., 2015; Veluswamy et al., 2017). The surface activity
520 of amino acids resulting in hydrate formation enhancement is similar to conventional surfactants.
521 Most amino acids molecular structure consist of both hydrophilic and hydrophobic nature arising
522 from the presence of amine and carboxylic acid groups and side chain. Furthermore, the amino
523 acids side chain may also vary based on its polarity, charge, and structure. This makes them
524 amphiphilic molecules; hence they can act as surfactants. (For example, leucine which is one of
525 the best reported amino acids promoter has a hydrophilic amine and carboxylic acid groups, and
526 a hydrophobic aliphatic isobutyl side chain). In addition, some amino acids (arginine and valine)
527 act as bio-surfactants and protein aggregation suppression (Tsutomu et al., 2007; Infante et al.,

2004, 1997; Pinazo et al., 2011). This surfactant behavior enables such amino acids to prevent/or break the formation and agglomeration of hydrate nucleus crystals film at the gas/liquid interface. Thus, allowing more gas to dissolve in the liquid phase for high hydrate gas uptake. Linga's lab demonstrated that, hydrates formed in amino acids solution are very flexible and porous in nature, which is responsible for their hydrate promotion effect (Veluswamy et al., 2016). The presence of porous and flexible hydrates increases the surface adsorption ability at the gas/liquid interface. This allows the sucking of more liquids to the gas/liquid interface via improved capillary effect, resulting in high gas uptake into hydrate formation.

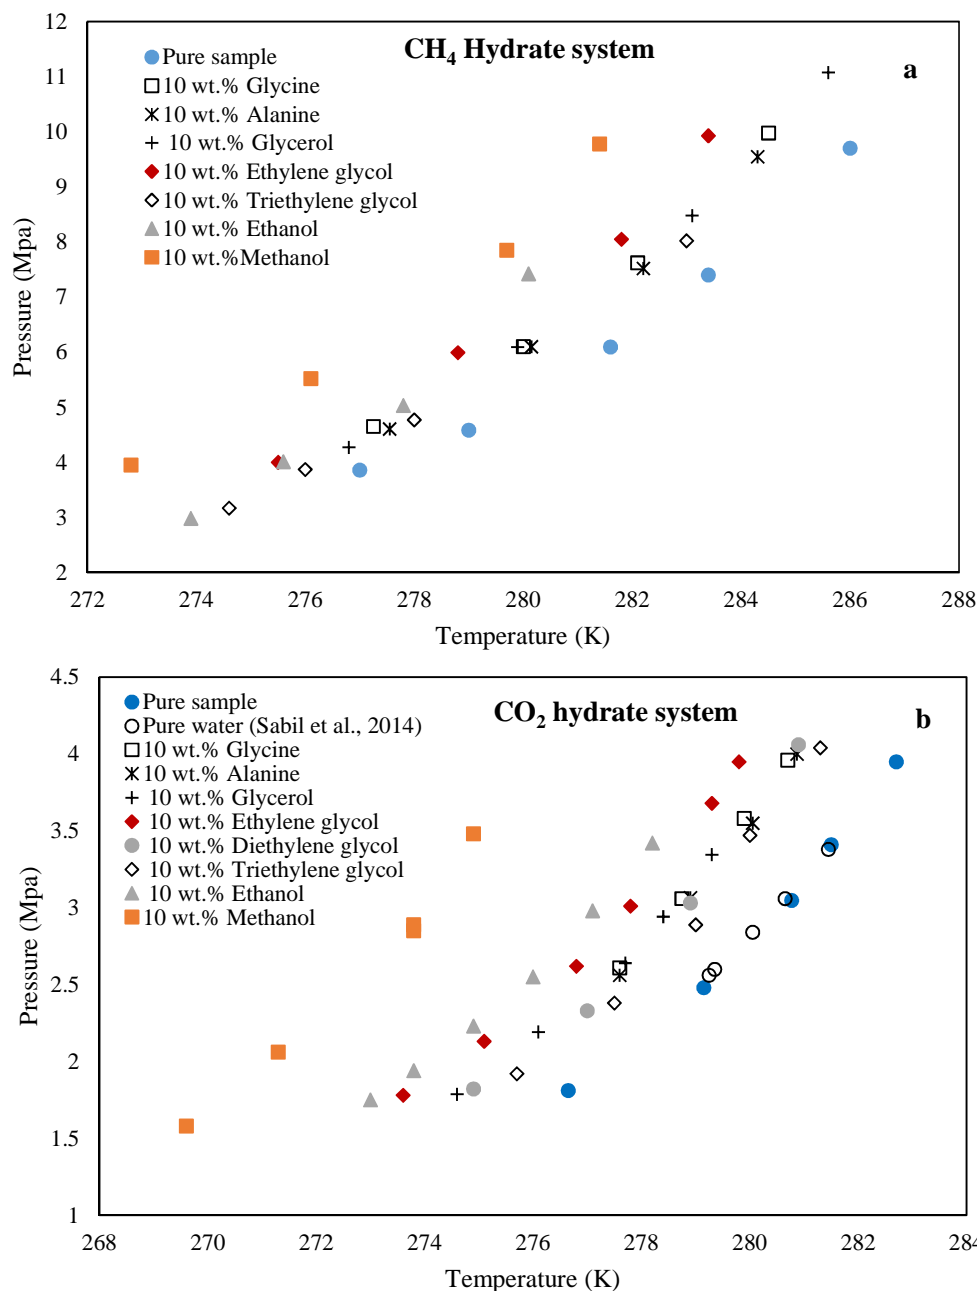

It is important to state that, amino acids promotion/inhibition mechanism in CO₂ systems is partly influenced or controlled by the reaction between amino acids and CO₂ molecules. Details on the reaction between amino acids and CO₂ is summarized by Zhang et al., (2018). Zwitterionic reaction mechanism is mainly observed between amino acids and CO₂. In this process, the amine group in the amino acids first reacts with the CO₂ to obtain intermediates as zwitterions. The presence of any base (such as amine groups or water) in the system will result in the formation of amino acids salts via reaction between the zwitterions and the base (Zhang et al., 2018). Generally, the rate constant of the reaction describes the CO₂ adsorption rate, which is related to the CO₂ hydrate formation rate and uptake. Thus, amino acids with fast rate of reaction will potential promote hydrate formation and vice versa.

3. Comparison of amino acids with other hydrate-based application additives

In this section, the thermodynamic and kinetic inhibition/promotion effect of amino acids are compared with commercially available inhibitors and promoters to evaluate their efficiency and

549 applicability in industrial operations. The discussion is divided into two sections;
550 Thermodynamics and kinetics. All hydrate phase behavior studies in amino acids have not shown
551 hydrate promotion effect. Hence, only THI effect is compared in this study. The THI effect of
552 the best performed amino acids is compared with commercially used inhibitors such as methanol
553 (Heng-Joo Ng, 1985; Mohammadi and Richon, 2010), ethanol (Maekawa, 2010; Mohammadi et
554 al., 2008a), ethylene glycol (Mohammadi and Richon, 2010)(Maekawa, 2010), diethylene glycol
555 (Maekawa, 2010), triethylene glycol (Maekawa, 2010; Sloan and Koh, 2007), and glycerol
556 (Breland and Englezos, 1996; Mohammadi et al., 2008b) for methane and carbon dioxide
557 hydrates at 10 wt.% as shown in Figure 9.

558 Methanol, ethanol and ethylene glycol are more efficient than amino acids (glycine and alanine)
559 as illustrated in Figure 9. However, amino acids are green compounds and are less expensive in
560 large quantities. On the other hand, amino acids are THIs than triethylene glycol but have similar
561 inhibition performance as glycerol and diethylene glycol in methane and carbon dioxide systems.
562 Therefore, hydrate preventive techniques using glycerol, diethylene glycol and triethylene glycol
563 can be replaced with amino acids as they are efficient and environmentally friendly. However,
564 amino acids are less soluble at high concentrations which might be a limiting factor to their
565 application in large concentrations. Proline is proven to have to exhibit wide solubility in water
566 for hydrate mitigation applications (Sa et al., 2016).

568

569

570

571

572

573

574

575

576

Figure 9. Comparison of the THI efficiency of amino acids and conventional additives for CH₄ and CO₂ hydrate system at 10 wt.%; the pure water data for CH₄ and CO₂ are taken from reference (Bavoh et al., 2017; Bavoh et al., 2016b; Nasir et al., 2014); (a) CH₄ hydrate system; (b) CO₂ hydrate system.

Due to different experimental and pressure conditions and equipment apparatus, the kinetic study comparison of amino acids and conventional KHIs/KHPs are compared as reported in their respective studies in literature and are tabulated in Table 4. General conventional additives are

577 still relatively better than amino acids as shown in Table 4. However, amino acids are still
 578 promising to explore, improve and apply in hydrate-based applications since they are
 579 environmentally friendly (Tao et al., 2006), economical (Mueller and Huebner, 2003), and
 580 demonstrate good performance potentials. In addition, amino acids can combat corrosion
 581 (Barouni et al., 2014; Hamadi et al., 2018) than the current conventional additives (Hourania and
 582 Abo-Hassan, 2016; Mustafa and Mekhamer, 2012) and are biodegradable (Fukumoto et al.,
 583 2005) and preferred to current conventional additives used in hydrate-based application. Thus,
 584 amino acids are worth studying towards commercialization.

585 Table 4. Comparison of the KHI/KHP efficiency of amino acids and conventional additives

Amino acid	Remarks	Reference
Commercial KPIs (SDS)		
Histidine	SDS promotes methane hydrate better than histidine at 1 wt.%.	(Bhattacharjee et al., 2016)
Leucine	leucine is not efficient as SDS in promoting methane hydrate at 0.3 wt.%.	(Veluswamy et al., 2016)
Valine	Valine is an effective methane hydrate promoter than SDS at 1 wt.%.	(Bavoh et al., 2018c)
Arginine	Arginine is a poor promoter of methane hydrate compared with SDS at 1 wt.%.	(Bavoh et al., 2018c)
Histidine	SDS is a good promoter than histidine for ethane hydrate formation. However, histidine effectively promotes methane + propane hydrate than SDS.	(Roosta et al., 2018)
Commercial KHIs (PVP/ PVCap)		
Glycine	Glycine and PVP has similar CO ₂ hydrate inhibition impact efficiency.	(Sa et al., 2013)
Tyrosine	PVP is efficient than tyrosine in preventing natural gas hydrate at 1 wt.%.	(Kakati et al., 2016a)
Tyrosine	PVP is a poor inhibitor compared to tyrosine for methane + ethane hydrate at 0.02 wt.%.	(Talaghat, 2014)
Histidine	Histidine is more efficient than PVP in preventing CO ₂ hydrate formation at 1.5 wt.%, but similar at 1 wt.%.	(Roosta et al., 2016)
Glycine	PVP is slight better than glycine.	(Roosta et al., 2016)
Glycine	Glycine exhibits weak hydrate formation inhibition impact compared to PVP (for pure ethane and mixed methane + propane)	(Roosta et al., 2018)
Glycine	PVCap is more efficient in prevention CH ₄ hydrate formation than glycine at 1 wt.%.	(Xu et al., 2017)

586

587 4. Modeling and simulation of gas hydrate in the presence of amino acids

588 Presently, literatures (Bavoh et al., 2018b; Bavoh et al., 2017) have studied the thermodynamics
 589 modeling of gas hydrate inhibition in amino acids, by adopting the Dickens and Quinby-Hunt,
 590 (1997) model which is an extension of the non-electrolyte hydrate inhibitors model by Piroen
 591 (Piroen, 1955). The model is based on the fact that amino acids behave like salts and thus any
 592 gas hydrate model for salt model can be adopted for amino acids. Details on the model
 593 formulations and assumptions can be found in literature (Bavoh et al., 2017; Dickens and
 594 Quinby-Hunt, 1997; Piroen, 1955). The simplified form of the model is presented in equation
 595 (1):

$$596 \left[\frac{1}{T_w} - \frac{1}{T_{aa}} \right] = \frac{n\Delta H_{FUS(i)}}{\Delta H_d} \left[\frac{1}{T_{f(i)}} - \frac{1}{T_{fa}} \right] \quad (1)$$

597 where $T_{f(i)}$ and T_{fa} are the freezing point temperatures of water (at 273.15 K) and water + amino
 598 acid solution, $\Delta H_{FUS(i)}$ is the heat of fusion of ice (6008 J/mol), ΔH_d is the molar enthalpy of
 599 dissociation of the gas system (which can determined experimentally or via Clausius-Clapeyron
 600 equation), n is the hydration number of the gas system (which can be determined for each gas
 601 system or taken from literature (Anderson, 2004)), R is the gas universal constant, T_w and T_{aa} are
 602 the hydrate phase boundary temperatures in pure water and water + amino acid solution,
 603 respectively. The model is able to predict hydrate phase boundary conditions for methane and
 604 carbon dioxide with AAE less than 0.2 K (Bavoh et al., 2017; Mannar et al., 2017).

605 However, kinetically, Naeiji et al., (2014a) and Rad et al., (2015) modeled THF and ethane
 606 hydrate formation rate adapting the thermodynamic natural path in a constant volume process.
 607 Roosta et al., (2016) recently, modeled the kinetic impact of amino acids on CO₂ hydrates using

608 a chemical affinity model. The model parameters agreed with the experimental results that the
609 rate of CO₂ hydrate formation is reduced in the presence of amino acids. In addition, molecular
610 dynamics simulation study has been reported on CH₄ hydrates by Oluwunmi et al., (2015). The
611 simulation suggests that, asparagine has the ability to inhibit hydrate formation and growth by
612 adsorbing at the water/methane interface due to its hydrophilic in nature. Furthermore,
613 Bhattacharjee et al., (2016) simulated CH₄ hydrate formation in the presence of histidine, which
614 showed good agreement with experimental results. However, the presence of histidine was found
615 to promote CH₄ hydrate formation. A recent MD simulation on the methane hydrate inhibition
616 impact of glycine, proline, serine, and alanine confirms their KHI behavior (Maddah et al.,
617 2018). The study was conducted by evaluating parameters such as the radial distribution
618 function, four-body structural order parameter, potential energy, mean square displacement,
619 density, and hydrogen bond formation. The study reported that the instability of structure I gas
620 hydrate structure responsible for methane hydrate inhibition is due to the van der Waals,
621 potential energy, and electrostatic force of interactions amongst each amino acid and water
622 molecules in the solution. The Conductor like Screening Model for Real Solvents (COSMO-RS)
623 software (Bavoh et al., 2016a; Khan et al., 2016; Klamt, 2016, 2011), an effective and fast
624 method of screening compounds/additives have been proposed as an efficient tool for screen
625 amino acids for gas hydrate studies via hydrogen bonding energies and sigma profile/potential
626 predictions (Bavoh et al., 2017, 2016b).

627 **5. Recommendations for further studies**

628 Amino acids have demonstrated strong and encouraging potentials of being efficient in various
629 gas hydrate-based technologies which may lead to commercialization. Despite weakness in
630 promoting hydrate thermodynamically, they have good hydrate thermodynamic and kinetic

631 inhibition potentials and very efficient in kinetically promoting hydrate formation for natural gas
632 storage, CO₂ capture and gas separation. In addition, they are relatively less costly,
633 biodegradable, environmentally friendly, noncorrosive, and do not produce foams, hence very
634 promising for future industrial gas hydrate-based technology applications. However, to usefully
635 apply amino acids, their hydrate inhibition and promotion efficient must be enhanced to meet
636 industrial requirements. Current studied amino acids do not effectively inhibit and promote gas
637 hydrate formation compared with the conventional additives used by the industry. Hence
638 research towards amino acids commercialization in hydrate-based technology should focus on:

- 639 • The improvement of amino acids hydrate inhibition and promotion effect (both kinetic
640 and thermodynamic) by conducting more laboratory investigations on new amino acids
641 on different hydrate formers, with special attention on unnatural amino acids. Since there
642 are huge data base of unnatural amino acids that have not been studied.
- 643 • In addition, synergic studies involving amino acids and conventional additives or other
644 novel gas hydrate additives (such as ionic liquids etc.) may also aid boost amino acids
645 efficient in various gas hydrate-based technologies.
- 646 • Studies and enhancement of amino acids effect of gas hydrate stability and selectivity (as
647 amino acids inhibition of promotion effect is gas composition dependant). This will be
648 very useful in natural gas storage and gas separation application technologies.
- 649 • More molecular level experimentations and simulations to aid understand the amino acids
650 hydrate formation inhibition and/or promotion effect of amino acids hydrophathy, acidity,
651 polarity, and structure are highly need. These will give more understanding and insight in
652 screening amino acids for hydrate-based technologies. Furthermore, molecular level
653 understanding on the influence of amino acids on gas hydrate cage occupancy and

654 storage capacity will be needed for CO₂ capture and hydrate storage technology
655 development.

656 • Regardless of the positive environmental impact of amino acids, the Cost comparison
657 between amino acids and conventional promoters/inhibitors are need for their industrial
658 consideration. Furthermore, considering amino acids as promoters for CO₂ capture and
659 sequestration and gas storage and transportation pilot scale testing will be a positive step
660 towards commercialization.

661 • Laboratory scale Pilot testing of amino acids will be a step towards commercialization.
662 Specifically, in flow assurance, flow loop testing of amino acids in brine water in natural
663 gas system at low and high amino acids concentrations is highly recommended for
664 industrial applications. In addition, some hydrate inhibitors are not compatible with other
665 industrial additives (e.g. corrosion inhibitors) (Kamal et al., 2016; Kelland, 2006; Kelland
666 et al., 2000). Their application affects the performance of such additives, thus performing
667 compatibility test of amino acids and other industrial additives coupled with economic
668 analysis is important in paving way for the successful application of amino acids in gas
669 hydrate-based application.

670

671 **6. Conclusion**

672 The influence of amino acids on gas hydrate formation have been reviewed based on available
673 data in open literature. Based on the review, it is concluded that: most amino acids promote
674 hydrate formation kinetics, while few (glycine and alanine) inhibit gas hydrate
675 thermodynamically as well as kinetically, thus, they act as dual functional inhibitors, similarly to
676 ILs. Amino acids are generally THIs with no thermodynamic promotion reported. Amino acids

677 promotion/inhibition effect greatly depends on their respective side chain properties (hydrophathy,
678 side chain alkyl, length polarity, functional group, etc.), solubility, concentration, studied
679 concentration units, interaction between the guest molecule, and hydrogen bond and electrostatic
680 force of attraction with water molecules. However, amino acids hydrophathy is less understood,
681 resulting in difficulty in correlating available hydrophathy scales with gas hydrate inhibition
682 impact. Amino acids are generally gas hydrate kinetic promoters, but some amino acids slightly
683 inhibit gas hydrate kinetically by perturbing the local water structure and lattice distortion and
684 expansion by incorporation into hydrate lattice crystals. In addition, the effect of amino acids on
685 hydrate structures characterization is needed for modelling (thermodynamic and kinetic
686 modelling) purposes. Finally, more MD simulation is needed to understand gas hydrate
687 inhibition mechanism in amino acids. Amino acids are potential additive for future hydrate-based
688 applications especially in CO₂ capture and storage and natural gas storage.

List of Tables

Table 1. List of various studied amino acids + studied gas systems, concentrations used and physicochemical properties.

No	Amino Acid	Gas	Side chain Polarity	Side chain	Hydropathy index ^d	Test type	Conc. ^{a,b,c}	Remarks	Ref.
1	Glycine	CO ₂	Nonpolar	-H	-0.4	THI	0.1 ^a – 3.0 ^a	Shows good thermodynamic hydrate inhibition impact.	(Sa et al., 2011)
2	L-Alanine	CO ₂	Nonpolar	-CH ₃	1.8	THI	0.1 ^a – 2.2 ^a	Thermodynamically inhibit CO ₂ hydrates	
3	L-Valine	CO ₂	Nonpolar	-CH(CH ₃) ₂	4.2	THI	0.1 ^a – 0.5 ^a	Shows thermodynamic CO ₂ hydrate inhibition	
4	Glycine	CO ₂	Nonpolar	-H	-0.4	KHI	0.01 ^a – 1.0 ^a	Shows effective KHI impact by increasing the subcooling temperature and can eliminate the memory effect.	(Sa et al., 2013)
5	L-Alanine	CO ₂	Nonpolar	-CH ₃	1.8	KHI	0.1 ^a	Demonstrates kinetic hydrate inhibition impact but less efficient than glycine.	
6	L-Valine	CO ₂	Nonpolar	-CH(CH ₃) ₂	4.2	KHI	0.1 ^a	Shows very less significant hydrate inhibition impact. Longer chains which are more hydrophobic do not inhibit hydrate. This is contrary to the understanding that hydrophobic compounds turns to be good KHIs (especially in ionic liquids (Tariq et al., 2014))	
7	Leucine	CO ₂	nonpolar	-CH ₂ CH(CH ₃) ₂	3.8	KHI	0.1 ^a	Shows very less significant hydrate inhibition impact.	
8	Isoleucine	CO ₂	nonpolar	-CH(CH ₃)C ₂ H ₅	4.5	KHI	0.1 ^a	Shows very less significant hydrate inhibition impact.	
9	Glycine	CO ₂	nonpolar	-H	-0.4	Crystal structure	0.1 ^a – 0.5 ^a	Amino acids inclusion expands the hydrate crystal lattice, causing hydrate inhibition effect. At 2.2 mol% glycine's lattice expansion ability saturation is reached.	(Sa et al., 2014)
10	L-Alanine	CO ₂	nonpolar	-CH ₃	1.8	Crystal structure	0.1 ^a – 0.5 ^a	A structure I hydrate was formed with hydrate inhibition crystallization phenomenon. The lattice expansion magnitude was saturated at 0.5 mol%	
11	L-Valine	CO ₂	nonpolar	-CH(CH ₃) ₂	4.2	Crystal structure	0.1 ^a – 0.5 ^a	All amino acids have a distinct crystal structure. However, the inhibition strength of amino acids depends on whether they act individually or agglomerate during hydrate crystallization.	
12	L-Alanine	CO ₂	nonpolar	-CH ₃	1.8	KHI + spectroscopy	0.01 ^a – 0.1 ^a	Delays hydrate nucleation and growth rate via disruption of the water structure in hydrate formation.	(Sa et al., 2015)

13	Aspartic acid	CO ₂	acidic polar	- CH ₂ COOH	- 3.5	KHI + spectroscopy	0.01 ^a	Delays hydrate nucleation and growth rate better than alanine but similar to asparagine via disruption of the water structure in hydrate formation.	
14	Asparagine	CO ₂	polar	- CH ₂ CONH ₂	- 3.5	KHI + spectroscopy	0.01 ^a	Delays hydrate nucleation and growth rate via disruption of the water structure in hydrate formation.	
15	Phenylalanine	CO ₂	nonpolar	- CH ₂ C ₆ H ₅	2.8	KHI + spectroscopy	0.1 ^a	Relatively shows no effect on the nucleation kinetics of hydrate formation, especially in memory water, due to its water structure hydrogen bonding strengthening ability. However, delays growth process but less than alanine.	
16	Histidine	CO ₂	basic polar	- CH ₂ C ₃ H ₃ N ₂	- 3.2	KHI + spectroscopy	0.1 ^a	Efficient in hydrate inhibition than alanine but less than aspartic acid and asparagine via disruption of the water structure in hydrate formation.	
17	Glycine	C ₂ H ₆	nonpolar	-H	- 0.4	KHI	0.05 ^b - 3 ^b	Shows strong KHI strength due to its lower hydrophobicity	(Rad et al., 2015)
18	Leucine	C ₂ H ₆	nonpolar	-CH ₂ CH(CH ₃)	3.8	KHI	0.05 ^b - 3 ^b	Inhibits hydrate formation kinetics but less than glycine.	
19	Asparagine	CH ₄	polar	- CH ₂ CONH ₂	- 3.5	KHI + MD simulation		Efficiently suppress hydrate formation kinetics. Asparagine do not adsorb on the gas/water interface during hydrate inhibition.	(Oluwunmi et al., 2015)
20	Glycine	THF	nonpolar	-H	- 0.4	KHI	0.05 ^b - 1.5 ^b	Shows strong KHI strength due to its lower hydrophobicity	(Naeiji et al., 2014a)
21	Leucine	THF	nonpolar	-CH ₂ CH(CH ₃)	3.8	KHI	0.05 ^b - 1.5 ^b	Inhibits hydrate formation kinetics but less than glycine.	
22	L-threonine	CH ₄	polar	- CH(OH)CH ₃	- 0.7	KHI	2770 ^c - 1385 ^c	Shows no significant KHI effect in delaying hydrate nucleation in both fresh and memory system.	(Perfeldt et al., 2014)
23	L-valine	CH ₄	nonpolar	-CH(CH ₃) ₂	4.2	KHI	2770 ^c - 1385 ^c	Shows no significant KHI effect in delaying hydrate nucleation in both fresh and memory system.	
24	L-histidine	CH ₄	Basic polar	-NH-CH=N-CH=C-CH ₂	-3.2	KHI	0.1 ^b - 1 ^b	Significantly promotes hydrate formation than SDS.	(Bhattacharjee et al., 2016)
25	PVP and L-Tyrosine	NG	Polar	-HO-Ph-CH ₂	-1.3	KHI	1 ^b	The presence of tyrosine improves the hydrate inhibition impact of NaCl + PVP system.	(Kakati et al., 2016a)
26	PVP and L-Tyrosine	NG	Polar	-HO-Ph-CH ₂	-1.3	KHI	100 ^c - 275 ^c	Tyrosine is a strong inhibitor than PVP and its addition into PVP enhances hydrate nucleation time in several folds.	(Talaghat, 2014)
27	Glycine	CH ₄	nonpolar	-H	-0.4	THI	0.5 ^a - 3 ^a	Inhibits hydrate phase boundary curve with concentration.	(Sa et al., 2016)
28	Alanine	CH ₄	nonpolar	-CH ₃	1.8	THI	0.5 ^a - 2.2 ^a	Inhibits hydrate phase boundary curve with concentration.	

29	Serine	CH ₄	polar	-HO-CH ₂	-0.8	THI	1.3 ^a – 3 ^a	Inhibits hydrate phase boundary curve with concentration.	
30	Proline	CH ₄	nonpolar	-NH-(CH ₂) ₃	-1.6	THI	1.3 ^a – 9 ^a	Inhibits hydrate phase boundary curve with concentration.	
31	Glycine	CH ₄	nonpolar	-H	-0.4	KHI	0.1 ^a	Exhibits hydrate nucleation time and growth rate delay in both fresh and memory water	
32	Alanine	CH ₄	nonpolar	-CH ₃	1.8	KHI	0.1 ^a	Do not inhibit hydrate formation nucleation and growth rate	
33	Serine	CH ₄	polar	-HO-CH ₂	-0.8	KHI	0.1 ^a	Exhibits hydrate nucleation time and growth rate delay in both fresh and memory water	
34	Proline	CH ₄	nonpolar	-NH-(CH ₂) ₃	-1.6	KHI	0.1 ^a	Do not inhibit hydrate formation nucleation and growth rate	
35	Glycine	NG	nonpolar	-H	-0.4	THI	0.5 ^a – 3 ^a	Inhibits hydrate phase boundary curve with concentration.	
36	Alanine	NG	nonpolar	-CH ₃	1.8	THI	0.5 ^a – 2.2 ^a	Inhibits hydrate phase boundary curve with concentration.	
37	Serine	NG	polar	-HO-CH ₂	-0.8	THI	1.3 ^a – 3 ^a	Inhibits hydrate phase boundary curve with concentration.	
38	Proline	NG	nonpolar	-NH-(CH ₂) ₃	-1.6	THI	1.3 ^a – 9 ^a	Inhibits hydrate phase boundary curve with concentration.	
39	Glycine	NG	nonpolar	-H	-0.4	KHI	0.1 ^a	Exhibits hydrate nucleation time and growth rate inhibition effect.	
40	Alanine	NG	nonpolar	-CH ₃	1.8	KHI	0.1 ^a	Do not inhibit hydrate formation nucleation and growth rate	
41	Serine	NG	polar	-HO-CH ₂	-0.8	KHI	0.1 ^a	Could inhibit hydrate formation kinetics better than glycine	
42	Proline	NG	nonpolar	-NH-(CH ₂) ₃	-1.6	KHI	0.1 ^a	Do not inhibit hydrate formation nucleation and growth rate	
43	Glycine	CO ₂	nonpolar	-H	-0.4	KHI	0.5 ^b – 2 ^b	Inhibits hydrate formation rate with increasing concentration	(Roosta et al., 2016)
44	Proline	CO ₂	nonpolar	-NH-(CH ₂) ₃	-1.6	KHI	0.5 ^b – 2 ^b	Inhibits hydrate formation rate with inhibition strength less than glycine but similar with serine and threonine.	
45	Serine	CO ₂	polar	-HO-CH ₂	-0.8	KHI	0.5 ^b – 2 ^b	Inhibits hydrate formation rate	
46	Threonine	CO ₂	polar	CH ₃ -CH(OH)	-0.7	KHI	0.5 ^b – 2 ^b	Inhibits hydrate formation rate	
47	Glutamine	CO ₂	polar	H ₂ N-CO-(CH ₂) ₂	-3.5	KHI	0.5 ^b – 2 ^b	Inhibits hydrate formation rate with the least inhibition strength compared with other studied amino acids.	
48	Histidine	CO ₂	basic polar	NH-CH=N- CH=C-CH ₂	-3.2	KHI	0.5 ^b – 2 ^b	Shows the highest hydrate formation inhibition impact compared with other studies amino acids.	(Bavoh et al., 2016b)
49	Glycine	CH ₄	nonpolar	-H	-0.4	THI	5 ^b – 20 ^b	Shows the highest hydrate phase behavior conditions inhibition compared with other studied amino acids.	

50	Alanine	CH ₄	nonpolar	-CH ₃	1.8	THI	10 ^b	Inhibits gas hydrate thermodynamically.	
51	Serine	CH ₄	polar	-HO-CH ₂	-0.8	THI	10 ^b	Inhibits gas hydrate thermodynamically.	
52	Proline	CH ₄	nonpolar	-NH-(CH ₂) ₃	-1.6	THI	10 ^b	Inhibits gas hydrate thermodynamically.	
53	Arginine	CH ₄	basic polar	HN=C(NH ₂)-NH-(CH ₂) ₃	-4.5	THI	10 ^b	Inhibits gas hydrate thermodynamically.	
54	Glycine	CO ₂	nonpolar	-H	-0.4	THI	5 ^b – 20 ^b	Shows the highest hydrate phase behavior conditions inhibition compared with other studied amino acids.	(Bavoh et al., 2017)
55	Alanine	CO ₂	nonpolar	-CH ₃	1.8	THI	10 ^b	Inhibits gas hydrate thermodynamically.	
56	Serine	CO ₂	polar	-HO-CH ₂	-0.8	THI	10 ^b	Inhibits gas hydrate thermodynamically.	
57	Proline	CO ₂	nonpolar	-NH-(CH ₂) ₃	-1.6	THI	10 ^b	Inhibits gas hydrate thermodynamically.	
58	Arginine	CO ₂	basic polar	HN=C(NH ₂)-NH-(CH ₂) ₃	-4.5	THI	10 ^b	Inhibits gas hydrate thermodynamically.	(Veluswamy et al., 2016)
59	L-Leucine	CH ₄	nonpolar	-CH ₂ CH(CH ₃)	3.8	KHP/morphology	0.1 ^b – 0.5 ^b	Shows kinetic promotion with no promotion effect observed below 0.3 wt%.	
60	L- Methionine	CO ₂	nonpolar	CH ₃ -S-(CH ₂) ₂ -	1.9	KHP	0.02 ^b – 1 ^b	Significantly promotes hydrate formation uptake without the use of energy-intensive mixing.	
61	L-norvaline	CO ₂	nonpolar	C ₁₀ H ₁₉ NO ₄	-	KHP	0.02 ^b – 1 ^b	Promotes hydrate formation with similar promotion impact as L-norleucine	
62	L-norleucine	CO ₂	nonpolar	C ₆ H ₁₃ NO ₂	-	KHP	0.02 ^b – 1 ^b	Promotes hydrate formation	(Cai et al., 2017)
63	2-aminoheptanoic acid	CO ₂	acid	C ₇ H ₁₅ NO ₂	-	KHP	0.02 ^b – 1 ^b	Promotes hydrate formation but with less promotion impact compared with L-norleucine	
64	n-hexanoic acid	CO ₂	acid	CH ₃ (CH ₂) ₄ COOH	-	KHP	0.02 ^b – 1 ^b	Promotes hydrate formation with similar promotion impact as 2-aminoheptanoic acid	
65	n-hexylamine	CO ₂	nonpolar	CH ₃ (CH ₂) ₅ NH ₂	-	KHP	0.02 ^b – 1 ^b	Promotes hydrate formation	
66	L-tryptophan	CH ₄	nonpolar	Ph-NH-CH ₂ -C(CH ₂) ₂ -	-0.9	KHP	0.01 ^b – 0.3 ^b	Shows good kinetic hydrate formation enhancement effect in both stirred and unstirred systems.	(Veluswamy et al., 2017)
67	L-histidine	CH ₄	basic polar	NH-CH ₂ -N(CH ₂) ₂ -CH ₂ -	-3.2	KHP	0.03 ^b – 1 ^b	Shows hydrate formation promotion effect similar to arginine but less than tryptophan. Higher hydrophobic amino acids show less hydrate promotion effect.	

68	L-arginine	CH ₄	basic polar	HN=C(NH ₂)-NH-(CH ₂) ₃	-4.5	KHP	0.03 ^b – 1 ^b	Shows hydrate formation promotion effect	
69	Lysine	CH ₄	basic polar	H ₂ N-(CH ₂) ₄ -	-3.9	THI	5 ^b -10 ^b	Shows THI effect with increasing concentration.	(Mannar et al., 2017)
70	Lysine	CO ₂	basic polar	H ₂ N-(CH ₂) ₄ -	-3.9	THI	5 ^b -10 ^b	Shows THI effect with increasing concentration.	
71	Arginine	CH ₄	basic polar	HN=C(NH ₂)-NH-(CH ₂) ₃	-4.5	THI/KHP	1 ^b – 5 ^b	Slightly inhibits methane hydrate phase boundary as well as promoting hydrate formation uptake	(Bavoh et al., 2018c)
72	Valine	CH ₄	nonpolar	-CH(CH ₃) ₂	4.2	THI/KHP	1 ^b – 5 ^b	Slightly inhibits methane hydrate phase boundary as well as promoting hydrate formation uptake. Shows high uptake than arginine.	
73	Valine,	CO ₂	nonpolar	-CH(CH ₃) ₂	4.2	KHP	0.5 ^b	Promotes hydrate formation uptake about 1.2 times.	(Prasad and Kiran, 2018a)
74	Phenylalanine	CO ₂	nonpolar	Ph-CH ₂ -	2.8	KHP	0.5 ^b	Shows no significant hydrate promotion effect	
75	Cysteine	CO ₂	nonpolar	HS-CH ₂ -	2.5	KHP	0.5 ^b	Promotes hydrate formation uptake about 1.2 times.	
76	Methionine	CO ₂	nonpolar	CH ₃ -S-(CH ₂) ₂ -	1.9	KHP	0.5 ^b	Promotes hydrate formation uptake about 1.2 times.	
77	Threonine	CO ₂	polar	CH ₃ -CH(OH)	-0.7	KHP	0.5 ^b	Shows no significant hydrate promotion effect	
78	Methionine	CO ₂	nonpolar	CH ₃ -S-(CH ₂) ₂ -	1.9	KHP/XRD	0.5 ^b	Shows efficient hydrate kinetics conversion rate, thus improving the hydrate formation uptake.	(Prasad and Kiran, 2018)
79	Phenylalanine	CO ₂	nonpolar	Ph-CH ₂ -	2.8	KHP/ XRD	0.5 ^b	Shows less hydrate kinetics conversion rate, thus gives less hydrate formation uptake.	
80	Methionine	CH ₄	nonpolar	CH ₃ -S-(CH ₂) ₂ -	1.9	KHP/XRD	0.5 ^b	Shows efficient hydrate kinetics conversion rate, thus improving the hydrate formation uptake.	
81	Phenylalanine	CH ₄	nonpolar	Ph-CH ₂ -	2.8	KHP/ XRD	0.5 ^b	Shows efficient hydrate kinetics conversion rate, thus improving the hydrate formation uptake.	
82	Methionine	CH ₄ + CO ₂	nonpolar	CH ₃ -S-(CH ₂) ₂ -	1.9	KHP/XRD	0.5 ^b	Shows efficient hydrate kinetics conversion rate, thus improving the hydrate formation uptake.	
83	Phenylalanine	CH ₄ + CO ₂	nonpolar	Ph-CH ₂ -	2.8	KHP/ XRD	0.5 ^b	Shows efficient hydrate kinetics conversion rate, thus improving the hydrate formation uptake.	
84	Glycine + ethylene glycol	CH ₄	nonpolar	-H	-0.4	THI	1 ^b – 30 ^b 1:1 mixtures	Glycine can enhance the thermodynamic inhibition strength of ethylene glycol, shows strong synergic inhibition effect.	(Long et al., 2018)
85	Glycine	CH ₄	nonpolar	-H	-0.4	MD simulation	0.45 ^b - 1.5 ^b	Shows hydrate kinetics inhibition effect but less than serine.	(Maddah et

86	Alanine	CH ₄	nonpolar	-CH ₃	1.8	MD simulation	0.45 ^b - 1.5 ^b	Shows hydrate kinetics inhibition	al., 2018)
87	Serine	CH ₄	polar	-HO-CH ₂	-0.8	MD simulation	0.45 ^b - 1.5 ^b	Shows efficient hydrate kinetics inhibition via interruption of the hydrogen bond network of water.	
88	Proline	CH ₄	nonpolar	-NH-(CH ₂) ₃	-1.6	MD simulation	0.45 ^b - 1.5 ^b	Shows hydrate kinetics inhibition effect as alanine	
89	L-leucine	CH ₄ and NG	nonpolar	-CH ₂ CH(CH ₃)	3.8	KHP	0.1 ^b - 1 ^b	Very efficient in promoting hydrate formation kinetics than all studied amino acids at low concentrations for both structure I and structure II natural gas hydrates systems.	(Liu et al., 2015)
90	L-isoleucine	CH ₄	nonpolar	-CH(CH ₃)C ₂ H ₅	4.5	KHP	0.5 ^b	Exhibits good hydrate promotion ability similar to phenylalanine.	
91	L-valine	CH ₄	nonpolar	-CH(CH ₃) ₂	4.2	KHP	0.5 ^b	Enhances hydrate formation kinetics.	
92	L-threonine	CH ₄	polar	CH ₃ -CH(OH)	-0.7	KHP	0.5 ^b - 10 ^b	Enhances hydrate formation with decreasing concentration.	
93	L-alanine	CH ₄	nonpolar	-CH ₃	1.8	KHP	0.5 ^b - 2 ^b	Exhibits negligible hydrate promotion effect with increasing concentration.	
94	L-proline	CH ₄	nonpolar	-NH-(CH ₂) ₃	-1.6	KHP	0.5 ^b	Exhibits less hydrate promotion effect.	
95	L-methionine	CH ₄	nonpolar	CH ₃ -S-(CH ₂) ₂ -	1.9	KHP	0.5 ^b	Shows good hydrate promoters strength.	
96	L-tryptophan	CH ₄	nonpolar	Ph-NH-CH=C-CH ₂ -	-0.9	KHP	0.5 ^b	Shows good hydrate promoters strength.	
97	L-phenylalanine	CH ₄	nonpolar	Ph-CH ₂ -	2.8	KHP	0.5 ^b	Shows good hydrate promoters strength.	
98	L-arginine	CH ₄	basic polar	HN=C(NH ₂)-NH-(CH ₂) ₃	-4.5	KHP	0.5 ^b	Able to promote hydrate formation kinetics with decreasing stability.	
99	L-glutamic acid	CH ₄	acidic polar	HOOC-(CH ₂) ₂ -	-3.5	KHP	0.5 ^b	Able to promote hydrate formation kinetics with decreasing stability.	
100	L-histidine	CH ₄	basic polar	NH-CH=N-CH=C-CH ₂	-3.2	KHP	0.5 ^b	Able to promote hydrate formation kinetics with decreasing stability.	
101	L-serine	CH ₄	polar	-HO-CH ₂	-0.8	KHP	0.5 ^b	Exhibits less hydrate promotion effect	
102	L-aspartic acid	CH ₄	acidic polar	-CH ₂ COOH	-3.5	KHP	0.5 ^b	Exhibits less hydrate promotion effect	
103	L-valine	CH ₄	nonpolar	-CH(CH ₃) ₂	4.2	THI	1 ^b - 5 ^b	Shows less thermodynamic hydrate inhibition, however may increase with concentration depending on its solubility.	(Bavoh et al., 2018a)
104	L-threonine	CH ₄	polar	CH ₃ -CH(OH)	-0.7	THI	1 ^b - 5 ^b	Shows less thermodynamic hydrate inhibition, however may increase with concentration depending on its solubility.	

105	Asparagine	CH ₄	polar	-CH ₂ CONH ₂	-3.5	THI	1 ^b - 5 ^b	Shows less thermodynamic hydrate inhibition, however may increase with concentration depending on its solubility.	
106	L-phenylalanine	CH ₄	nonpolar	Ph-CH ₂ -	2.8	THI	1 ^b - 5 ^b	Shows less thermodynamic hydrate inhibition, however may increase with concentration depending on its solubility.	
107	Glycine	C ₂ H ₆	nonpolar	-H	-0.4	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect	(Roosta et al., 2018)
108	L-serine	C ₂ H ₆	polar	-HO-CH ₂	-0.8	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect	
109	L-histidine	C ₂ H ₆	basic polar	NH-CH=N- CH=C-CH ₂	-3.2	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect	
110	Glutamine	C ₂ H ₆	polar	H ₂ N-CO-(CH ₂) ₂	-3.5	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit promotion effect	
111	Glycine	CH ₄ + C ₃ H ₈	nonpolar	-H	-0.4	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect and enhances the inhibition effect of PVP more than serine	
112	L-serine	CH ₄ + C ₃ H ₈	polar	-HO-CH ₂	-0.8	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect but slightly enhances PVP hydrate inhibition impact.	
113	L-histidine	CH ₄ + C ₃ H ₈	basic polar	NH-CH=N- CH=C-CH ₂	-3.2	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect	
114	Glutamine	CH ₄ + C ₃ H ₈	polar	H ₂ N-CO-(CH ₂) ₂	-3.5	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit promotion effect	
115	Glycine	CH ₄ + THF	nonpolar	-H	-0.4	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect	
116	L-serine	CH ₄ + THF	polar	-HO-CH ₂	-0.8	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit hydrate inhibition effect	
117	L-histidine	CH ₄ + THF	basic polar	NH-CH=N- CH=C-CH ₂	-3.2	KHI/KPI	0.5 ^b - 1.5 ^b	Exhibit weak hydrate inhibition effect	
118	Glutamine	CH ₄ + THF	polar	H ₂ N-CO-(CH ₂) ₂	-3.5	KHI/KPI	0.5 ^b - 1.5 ^b	No significant effect	
119	Glycine	CH ₄	nonpolar	-H	-0.4	KHI	1 ^b - 7 ^b	Poor kinetic hydrate inhibitor on the bases of induction time and hydrate formation onset temperature even at high concentrations.	(Xu et al., 2017)
120	PVCap + Glycine	CH ₄ + THF	nonpolar	-H	-0.4	KHI	1 ^b : 1 ^b - 5 ^b	Efficiently improves PVCap hydrate inhibition strength to about 16 time.	
121	Glycine	CH ₄	nonpolar	-H	-0.4	KHDP	0.01 ^b - 5 ^b	Efficiently enhances methane hydrate dissociation kinetics.	(Kumar et

122	L-serine	CH ₄	polar	-HO-CH ₂	-0.8	KHDP	0.01 ^b – 5 ^b	Enhances methane hydrate dissociation kinetics.	al., 2017)
123	L-histidine	CH ₄	basic polar	NH-CH=N- CH=C-CH ₂	-3.2	KHDP	0.01 ^b – 5 ^b	Efficiently enhances methane hydrate dissociation kinetics, with high methane recovery potential.	
124	L-threonine	CH ₄	polar	CH ₃ -CH(OH)	-0.7	KHDP	0.01 ^b – 5 ^b	Enhances methane hydrate dissociation kinetics.	
125	L-tryptophan	CH ₄	nonpolar	Ph-NH-CH=C- CH ₂ -	-0.9	KHDP	0.01 ^b – 5 ^b	Enhances methane hydrate dissociation kinetics.	
126	L-threonine	CH ₄	polar	CH ₃ -CH(OH)	-0.7	KHDP	0.01 ^b – 5 ^b	Enhances methane hydrate dissociation kinetics.	
127	Proline	CH ₄	nonpolar	-NH-(CH ₂) ₃	-1.6	KHDP	0.01 ^b – 5 ^b	Poorly enhances methane hydrate dissociation kinetics.	
128	Glycine + 1-Ethyl-3-methylimidazolium chloride	CH ₄	nonpolar	-H	-0.4	THI	5 ^b + 5 ^b	Glycine + 1-Ethyl-3-methylimidazolium chloride has negligible effect on their pure system phase boundary. However, they inhibit methane hydrate formation.	(Bavoh et al., 2018c)

^a mol%; ^b wt.%; ^c ppm; ^d extracted from reference (Kyte and Doolittle, 1982); THI refers to Thermodynamic hydrate inhibitor; THP refers to Thermodynamic hydrate promoter; KHI refers to Kinetic hydrate inhibitor; KHP refers to Kinetic hydrate promoter; KHDP refers to Kinetic hydrate dissociation promoter.

Table 2. Amino acids HL_wVE data

Author	Amino acid	Gas	Conc./ mol%	T/K	P/MPa	Data points
Sa <i>et al.</i> , 2011 (Sa <i>et al.</i> , 2011)	Glycine	CO ₂	0.1	274.55 -281.35	1.49-3.51	5
		CO ₂	0.5	274.35-281.05	1.49-3.50	5
		CO ₂	1.3	273.85-280.65	1.49-3.51	5

Table 3. Variations in some studied amino acids concentration units

Wt. %	Mol %				
	Glycine	Alanine	Proline	Serine	Valine
5	1.25	1.05	0.82	0.89	0.80
10	2.60	2.20	1.71	1.87	1.68
15	4.06	3.45	2.69	2.94	2.64
20	5.66	4.81	3.76	4.11	3.70

Table 4. Comparison of the KHI/KHP efficiency of amino acids and conventional additives

Amino acid	Remarks	Reference
Commercial KPIs (SDS)		
Histidine	SDS promotes methane hydrate better than histidine at 1 wt.%.	(Bhattacharjee et al., 2016)
Leucine	leucine is not efficient as SDS in promoting methane hydrate at 0.3 wt.%.	(Veluswamy et al., 2016)
Valine	Valine is an effective methane hydrate promoter than SDS at 1 wt.%.	(Bavoh et al., 2018c)
Arginine	Arginine is a poor promoter of methane hydrate compared with SDS at 1 wt.%.	(Bavoh et al., 2018c)
Histidine	SDS is a good promoter than histidine for ethane hydrate formation. However, histidine effectively promotes methane + propane hydrate than SDS.	(Roosta et al., 2018)
Commercial KHIs (PVP/ PVCap)		
Glycine	Glycine and PVP has similar CO ₂ hydrate inhibition impact efficiency.	(Sa et al., 2013)
Tyrosine	PVP is efficient than tyrosine in preventing natural gas hydrate at 1 wt.%.	(Kakati et al., 2016a)
Tyrosine	PVP is a poor inhibitor compared to tyrosine for methane + ethane hydrate at 0.02 wt.%.	(Talaghat, 2014)
Histidine	Histidine is more efficient than PVP in preventing CO ₂ hydrate formation at 1.5 wt.%, but similar at 1 wt.%.	(Roosta et al., 2016)

Glycine	PVP is slight better than glycine.	(Roosta et al., 2016)
Glycine	Glycine exhibits weak hydrate formation inhibition impact compared to PVP (for pure ethane and mixed methane + propane)	(Roosta et al., 2018)
Glycine	PVCap is more efficient in prevention CH ₄ hydrate formation than glycine at 1 wt.%.	(Xu et al., 2017)

List of Figures

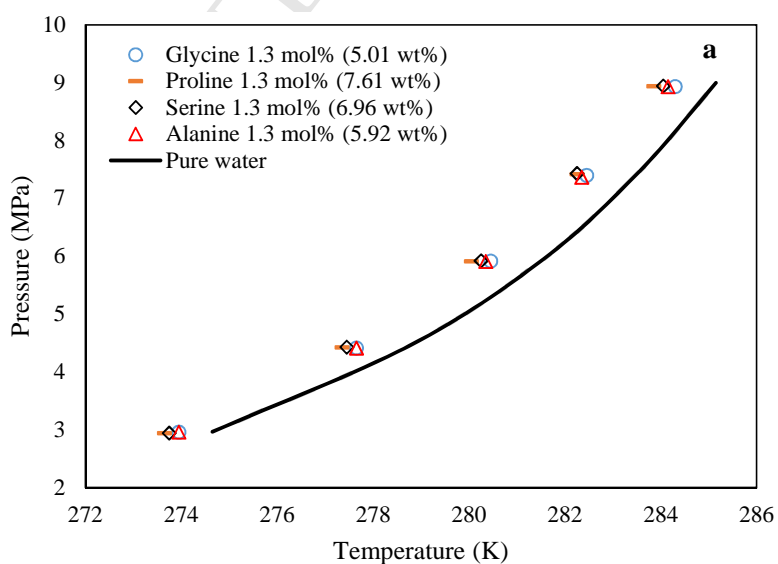

Figure 1. Common gas hydrate crystal structures (Tariq et al., 2014).

Figure 2. Hydrate-based gas separation process (CO₂ capture process) (Zheng et al., 2017)

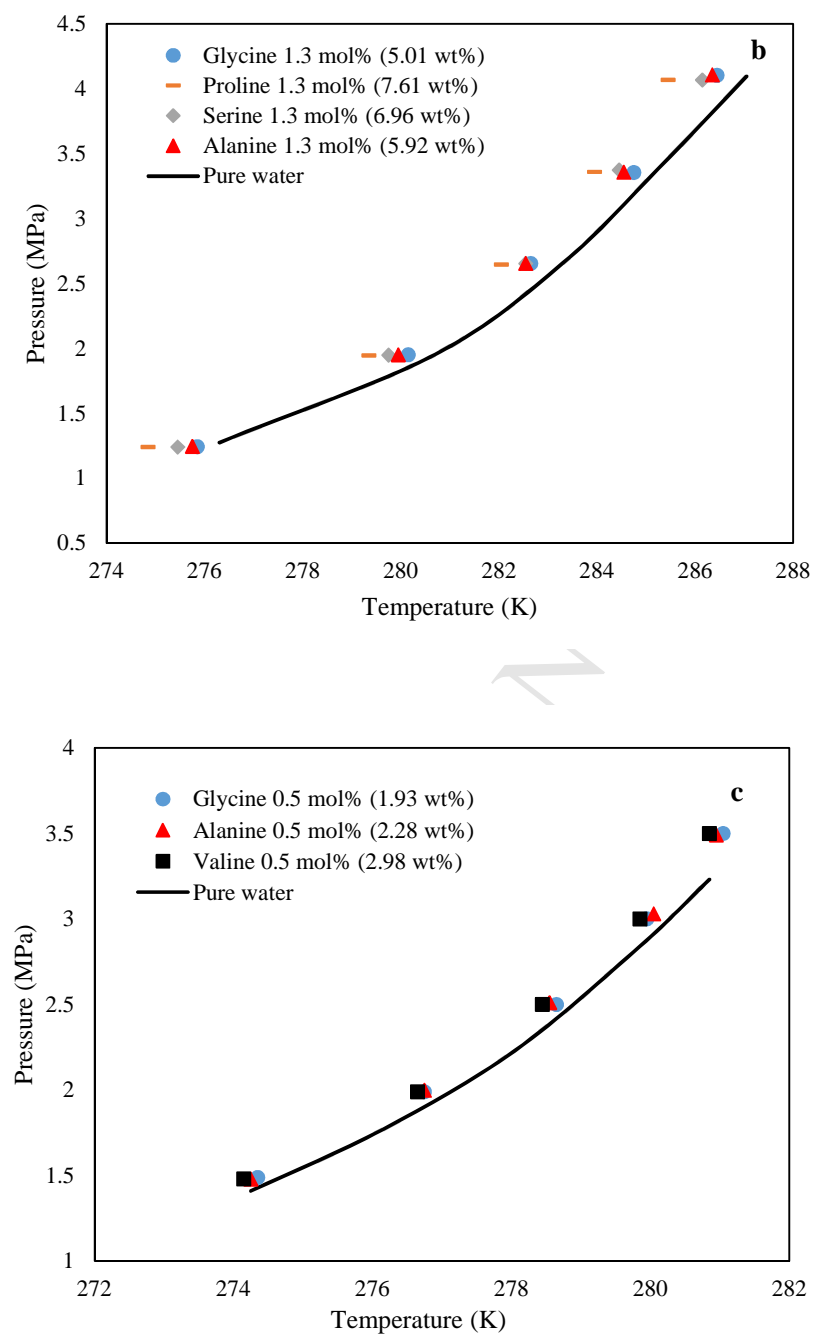

Figure 3. The inhibition strength of amino acids on the HL_wVE curve in various gas systems showing the effect of studied concentration units on inhibition impact. (a) CH_4 (Sa et al., 2016); (b) NG (Sa et al., 2016); and (c) CO_2 (Sa et al., 2011).

Figure 4. The inhibition impact of amino acids on the HL_wVE curve of CH_4 hydrate systems showing the effect of studied concentration units on inhibition impact (Bavoh et al., 2016b).

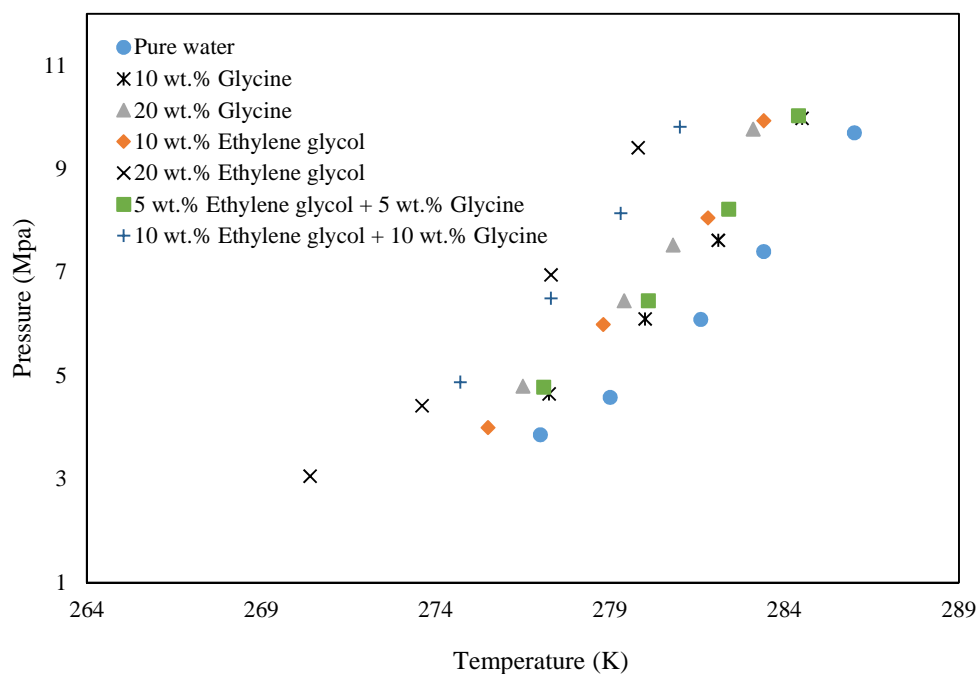

Figure 5. The inhibition impact of pure glycine and glycine + ethylene glycol on the HL_wVE data of CH_4 hydrates; Pure water and glycine data are taking from Bavoh et al., (2016b), glycol from Mohammadi and Richon, (2010), and glycine + ethylene glycol data from Long et al., (2018).

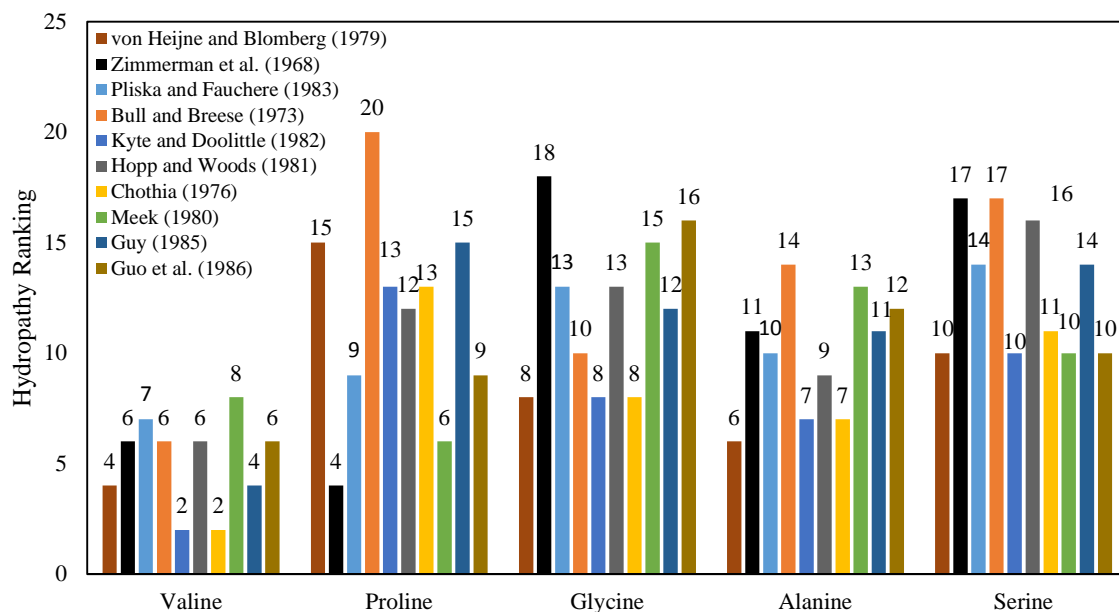

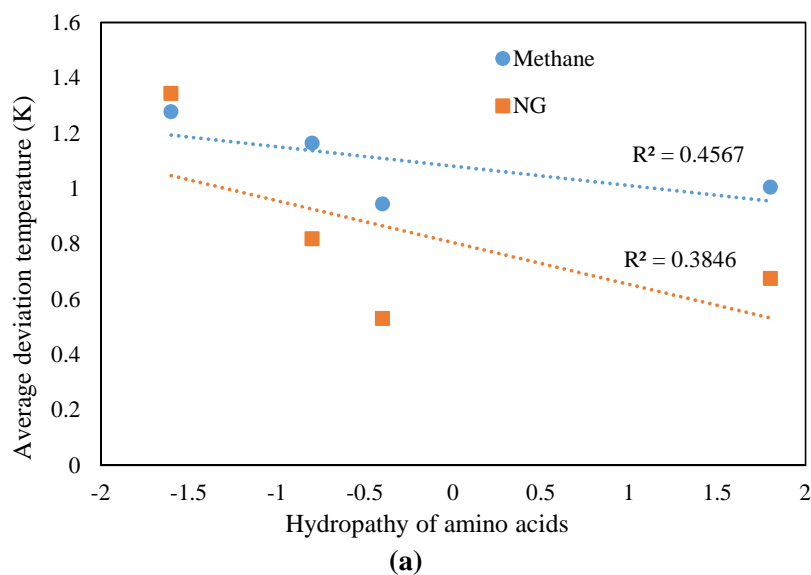

Figure 6. Hydropathy ranking of studied for gas hydrate inhibition. Data is taken from Wilce et al., (1995). The hydropathy of amino acids decreases with increasing ranking number.

Figure 7. Regression between average depression temperature (T) and commonly used amino acid hydrophobicity scale proposed by Kyte and Doolittle, (1982); (a) data from Sa et al., (2016) and (b) data from Bavoh et al., (2016b).

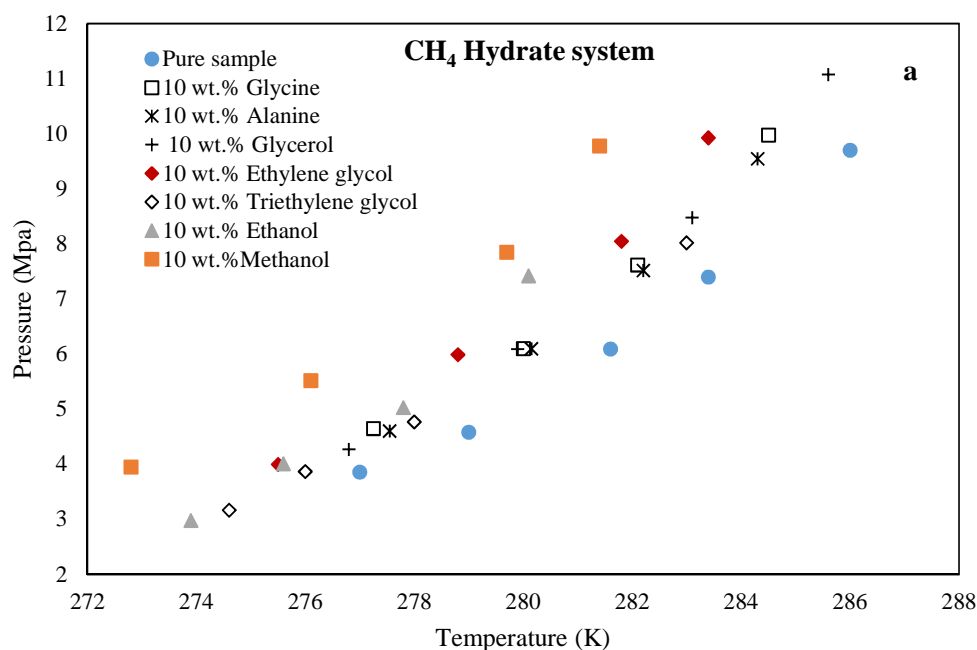

Figure 8. (a) amino acids gas hydrate growth inhibition mechanism by perturbation of the local water structure compared to adsorption inhibition mechanism (Sa et al., 2013); (b) amino acids lattice distortion and expansion inhibition mechanism through incorporation into gas hydrate crystal lattice (Sa et al., 2014). ©Nature Publishing Group. Reproduced by permission of Nature Publishing Group.

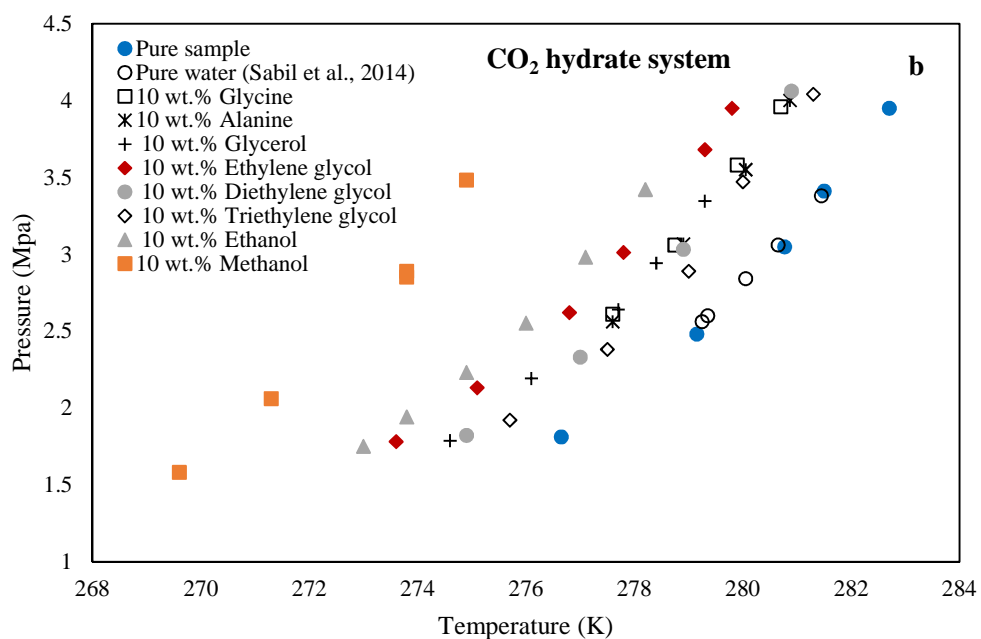

Figure 9. Comparison of the THI efficiency of amino acids and conventional additives for CH₄ and CO₂ hydrate system at 10 wt.%; the pure water data for CH₄ and CO₂ are taken from reference (Bavoh et al., 2017; Bavoh et al., 2016b; Nasir et al., 2014); (a) CH₄ hydrate system; (b) CO₂ hydrate system.

Highlights

1. The state of art on the use of natural amino acids in gas hydrate inhibition and CO₂ capture is presented.
2. Factors that affect amino acids inhibition/promotion effect on gas hydrate formation.
3. Gas hydrate systems, experimental details and data in the presence of amino acids are reported.
