Insecta Mundi is a journal primarily devoted to insect systematics, but articles can be published on any non-marine arthropod. Topics considered for publication include systematics, taxonomy, nomenclature, checklists, faunal works, and natural history. *Insecta Mundi* will not consider works in the applied sciences (i.e. medical entomology, pest control research, etc.), and no longer publishes book reviews or editorials. *Insecta Mundi* publishes original research or discoveries in an inexpensive and timely manner, distributing them free via open access on the internet on the date of publication.

Insecta Mundi is referenced or abstracted by several sources, including the Zoological Record and CAB Abstracts. *Insecta Mundi* is published irregularly throughout the year, with completed manuscripts assigned an individual number. Manuscripts must be peer reviewed prior to submission, after which they are reviewed by the editorial board to ensure quality. One author of each submitted manuscript must be a current member of the Center for Systematic Entomology.

Guidelines and requirements for the preparation of manuscripts are available on the *Insecta Mundi* website at <http://centerforsystematicentomology.org/insectamundi/>

lbarringer@pa.gov

Abstract. An abundance-based checklist of eastern Buprestidae (Coleoptera) was compiled from collection records from invasive insect surveys conducted during 2010–2018. Reported are 111 species in 17 genera based on 33,047 specimens examined from 10 states. Sixty-three new state records in nine states are reported. Collection date ranges by month for each state are provided.

Key words. New record, collection ranges, metallic wood borers, bycatch

Introduction

The jewel beetles (Coleoptera: Buprestidae) have been of great interest in North America, especially since the detection and spread of the pestiferous emerald ash borer (EAB) (*Agrilus planipennis* Fairmaire) across the continent. Other jewel beetles, such as the goldspotted oak borer (*Agrilus auroguttatus* Schaeffer), European oak borer (*Agrilus sulcicollis* Lacordaire), and oak splendor beetle (*Agrilus biguttatus* Fabricius) also pose risks to North America's forests and are the focus of surveys by governmental agencies (Haack et al. 2009; Cooperative Agricultural Pest Survey 2019). The resulting extensive surveys, trap efficacy studies, and collections have produced thousands of records of Buprestidae, both native and introduced.

The Buprestidae of North America north of Mexico have been recently assessed and summarized by Nelson et al. (2008). Paiero et al. (2012) updated this for northeastern North America with their field guide for east of the Mississippi River, and there have been many other recent additions to the fauna east of the Mississippi River (e.g. Hansen et al. 2011; Rutledge et al. 2013; Barringer and Ciafré 2014; Harpootlian and Bellamy 2014; Klingeman et al. 2015; Swink et al. 2015; Westcott and Thomas 2015; Barringer 2016a, 2016b, 2017; Hoebeke et al. 2017; Carlton et al. 2018; Bohne et al. 2019; Hanson et al. 2019). The emerald ash borer's expansion across North America is also continuously updated and tracked by USDA APHIS (Bopp 2019). Large gaps still exist in distributions for many species with large swathes of host plant ranges seemingly unused. Cryptic and technically difficult taxa can also mask diversity for many groups, especially genera such as *Chrysobothris* Eschscholtz and *Agrilus* Curtis.

Buprestidae are collected most often by sweeping, panel traps, flight intercept traps, predatory wasp surveys, Lindgren funnels, and rearing. Buprestidae can also be collected as bycatch in traps intended for insects in other orders. Sticky cards and bands, bucket traps, and delta traps can occasionally yield Buprestidae by chance due to the diversity of this family's host plants. All these pieces can be compiled to give a more complete picture of their total diversity and life histories.

This paper collects the efforts of agricultural pest surveys from various commodities, targeted pests, and states processed by the Pennsylvania Department of Agriculture (PDA) during 2010–2018. The department was either involved in collecting the samples themselves (Pennsylvania records) or cooperated with state and federal agencies to provide identification services for survey and research. These survey efforts, often employing trapping methods not associated with or targeting Buprestidae, were all screened for target pest groups resulting in their retention and identification. These records are intended to provide abundance-based data for Buprestidae using traditional and nontraditional sampling methods, contribute to their life history in the eastern United States, and update the list of known species for the surveyed states.

Materials and Methods

Trapping methods. Methodology for surveys covered a wide variety of pests over the trapping seasons (2010–2018). Most specimens were collected using standard trapping methods for wood-boring insect pests such as Cerambycidae (Coleoptera), Buprestidae (Coleoptera), Scolytinae (Coleoptera: Curculionidae), and Siricidae (Hymenoptera). Incidental captures were also recorded from traps meant to catch other taxa (Lepidoptera; Hymenoptera: Vespidae; and Diptera: Agromyzidae).

The most common collection methods were panel traps, flight intercept panel traps, and Lindgren funnel traps. A summary of the methodology for PDA trapping was provided in Barringer (2015), elaborated on in Barringer and Bartlett (2018), and can generally be applied to the other states. Specific trapping methods in some states can be found in Francese et al. (2013), Crook et al. (2014), and Ray et al. (2019). The preservative agent in the collection cups was propylene glycol. Collections were conducted during February through December, with most of the trapping taking place between April and October, especially in the Northeast. All traps in these surveys were serviced every two weeks. Samples collected outside this window were either destructive samples from host trees (Pennsylvania) or from lower latitudes which extended the trapping season.

Incidental trapping for other invasive insects included spotted lanternfly, *Lycorma delicatula* White (Hemiptera: Fulgoridae), Asian giant hornet, *Vespa mandarina* Smith (Vespidae: Hymenoptera), Allium leafminer, *Phytomyza gymnostoma* Loew (Agromyzidae: Diptera), grape commodity pests, and tomato commodity pests. Spotted lanternfly incidentals were captured using brown paper sticky bands (Hoebeke et al. 2017). For the Asian giant hornet surveys insects were collected in plastic jugs, typically one gallon in volume, baited with water mixed with brown sugar. Allium leafminer traps were yellow sticky cards placed in fields of *Allium* spp., typically *A. cepa* L. or *A. sativum* L. (Barringer et al. 2018). The grape and tomato commodities were a combination of bucket traps for Lepidoptera (green, white, or multi-color (green, white, and yellow)), sticky cards for Psyllidae (Hemiptera) (typically yellow), brown paper deltas, and white paper deltas (Lepidoptera). Unlike the hornet (brown sugar scent) and allium traps (visual cue) the grape and tomato traps used pheromone lures and some visual cues (for Lepidoptera) as their attractants. Grape traps were placed on trellises in vineyards and tomato traps were placed on nearby fence posts or installed metal posts.

Identification. All adult Buprestidae were extracted, identified to species when possible, and voucher specimens deposited in the Pennsylvania Department of Agriculture Collection, Harrisburg, Pennsylvania, USA (PADA). Duplicate specimens collected prior to 2016 were also dispersed by PADA to other collections. Material has been passed on to the following collections: The American Museum of Natural History (AMNH), Denver Museum of Natural History (DMNS), University of California (EMEC), Mississippi State University (MEM), The Natural History Museum (NHMUK), New York Botanical Garden (NYBG), Ohio State University (OSUC), Pennsylvania State University (PSUC), and Purdue University (PURC), University of Delaware (UDCC). A portion was also distributed to private collections and universities (Georgia College, New York Botanical Garden) without collection codens.

Certain taxa were identified only to genus (typically females of *Agrilus* and *Chrysobothris*), even if males of similar appearance were collected in the same sampling event. In situations where all females looked similar they were recorded as “sp.,” while unidentified females of multiple morphospecies in a single sample were recorded as “spp.” Specimens were identified by comparison to materials in the PADA collection and with published descriptions and illustrations (notably Wellso et al. 1976; Bright 1987; McCrae 1991; Paeiro et al. 2012). Sex was sporadically recorded during 2010–2012, and explicitly recorded during 2013 onwards. All sex determination was done by examination of the genitalia and no external morphologies were considered. If genitalia were unavailable to be examined, it was recorded as undetermined. Authors of included genera and species are provided in Table 1 and are otherwise not duplicated in other tables.

Results

Of 33,047 specimens examined from ten states, 17 genera and 111 species were identified, including 63 new state records (Table 2). Louisiana was the only state without a new record. The total count

of specimens includes individuals identifiable to genus only (typically females) but were not tallied as individual species for diversity for each state (Tables 3–12). Pennsylvania supplied the largest portion of specimens (48%) as it was the only state that had material collected every year, and had multiple surveys processed every year. The next most numerous states were Massachusetts (19%), Ohio (16%), and Michigan (12%), all of which implemented surveys specifically targeting Buprestidae. The month of July had the highest catch at 15,911 specimens (48%), followed by June 10,488 (32%) and August 3,244 (10%) (Table 1).

Agrilus was the most numerous genus collected (24,112, 73%), and included the highest diversity with 47 species. The next most numerous were *Chrysobothris* (4,371 specimens, 13%), *Dicerca* Eschscholtz (1,635 specimens, 5%), and *Anthaxia* Eschscholtz (1506 specimens, 4.6%). After *Agrilus*, the most speciose genera were *Chrysobothris* (15), *Dicerca* (12), *Buprestis* L. (8), and *Anthaxia* (7). The most common species collected were *Agrilus plannipennis* (36%), *A. bilineatus* (Weber) (8.1%), *Chrysobothris femorata* (Olivier) (6.5%), and *C. sexsignata* (Say) (5.8%) (Table 1). If unidentified *Agrilus* specimens were treated as one species, they would account for 10.2% of the total abundance. All other specimens identified only to genus was accounted for 0.5% of the total.

The combined surveys produced a ratio of 1:1.74 (n = 22,827), male to female. Several taxa had strong female capture bias (greater than 1:4). At the generic level *Buprestis* and *Brachys* Dejean were almost exclusively female captures. Of 105 collected *Buprestis* there was a single male of *B. striata* F., and 536 out of 545 *Brachys* were females. Four species individually showed strong female trends across three genera: *Agrilus cuprescens* (Menetries) 1:3.98 (n = 1051), *A. cyanescens* Ratzeburg 1:5.38 (n = 83), *Chrysobothris sexsignata* 1:5.45 (n = 302), *Dicerca divaricata* (Say) 1:5.23 (n = 385).

No genus had a male bias, but individual species did and to a greater extreme than any female bias found. The eight species (in two genera) with sex ratios strongly male were: *Agrilus arcuatus* (Say) 6.17:1 (n = 86), *A. crinicornis* Horn 23.8:1 (n = 149), *A. egenus* Gory 6:1 (n = 30), *A. geminatus* (Say) 25:1 (n = 26), *A. masculinus* Horn 6.46:1 (n = 433), *A. osburni* Knull 37:1 (n = 38), *A. otiosus* Say 14:1 (n = 60), and *Anthaxia quercata* (F.) 2.44:1 (n = 196). It is important to note, however, that these trends are likely due to high numbers of unidentified female specimens in these taxa. For example, over 1700 unidentified female *Agrilus* are reported from Pennsylvania alone.

Collection information is presented for new state records by species and state using the following notation: [State: County, location name: coordinates, date collected (number of individuals collected)]. State abbreviations are as follows: MA = Massachusetts, MD = Maryland, MI = Michigan, MO = Missouri, NH = New Hampshire, NY = New York, OH = Ohio, PA = Pennsylvania, WV = West Virginia. Full collection records, vouchers, and specimen data can be obtained by contacting the PADA collection.

Discussion

Pennsylvania was the only state to be sampled for the entire eight-year period using multiple surveys, therefore the majority of Buprestidae presented are from there. Pennsylvania already had a well-documented fauna with 124 species. The extensive sampling added 12 new state records, bringing the total to 136. Some taxa in the state are still poorly collected, both in historic collections and during these surveys, include *Taphrocerus* Solier, *Paragrilus* Saunders, *Pachyschelus* Solier, and *Phaenops* Dejean. These rare or infrequent groups represent the most likely overlooked taxa in the state. Specialized efforts focusing on hosts at certain times and larval rearing are the most likely option to find these rare taxa.

West Virginia is likely the most under sampled of the 10 states presented. The survey material that PDA processed was small in total Buprestidae screened ($n = 217$) but very productive in terms of number species (18 total, two new state records), an indication that there is a high likelihood that a greater diversity exists. The diversity of adjacent states Ohio and Pennsylvania (96 and 136, respectively) also supports the idea that West Virginia (77) could harbor many unreported species. New Hampshire's collections were extremely productive given the small collection of Buprestids. Five new state records were found from only 48 specimens, a ratio of one out every 10 representing a new state record.

This checklist should not be considered comprehensive as there are likely multiple records housed in entomological institutions that have not yet been assessed. Additionally, the large-scale trapping efforts presented here likely missed portions of the known fauna. These species tended to be ecological specialists or use hosts that inhabit terrain that is not forested or agricultural, such as marshes, barrens, and riparian corridors. Additionally, the semiochemical lures used in trapping may be unattractive or have a repellent effect to non-target taxa.

The emerald ash borer's frequency of over one third of the collected Buprestidae is reflective of the work PDA did for tracking the species' expansion across the state as well as work involving other states. Samples from other states, especially Massachusetts, often emphasized improving trapping efficacy for

capture of emerald ash borer as well as generalized Buprestidae capture (Francese et al. 2013). This trap efficacy program is partly why *Agrilus* accounted for over two thirds of specimens, with specialized trap designs, plant volatiles, and lures.

Surveys that targeted non-woodboring taxa, such as Asian giant hornet, *Allium* leafminer, grape, and tomato commodity pests exhibited no patterns in either traps that captured Buprestidae or with specific Lepidoptera pheromones. These captures (n = 291) were likely a result of chance captures by the trap, presence of suitable hosts nearby, or another unknown effect. The sparse collections do not suggest that these non-targeted traps hold much value for collecting most Buprestidae. One exception, however, is that regarding brown paper sticky bands used for spotted lanternfly (*Lycorma delicatula* White) was reliable in catching the invasive species *Agrilus smaragdifrons* Ganglbauer when symptomatic host trees were present (Hoebeke et al. 2017). Both species share the host tree of heaven (*Ailanthus altissima* (Mill.) Swingle). Sticky traps, such as panel and prism traps, are an effective trap for bycatch, so the additional collection value of sticky bands is limited (Crook et al. 2014).

PDA has never used species-specific sex pheromones for Buprestidae in trapping. Sex pheromones for Cerambycidae have been used in some surveys, with and without adjuncts, but no pattern was indicated when examined. Plant volatiles, used in conjunction with visual cues, were used on most traps. Several traps and surveys were designed to target Buprestidae specifically and improve trap efficacy. Plant volatiles would be assumedly equally appealing to both sexes; however, some have been shown to have sex biased responses such as when EAB males responded more strongly to (Z)-3-Hexenol, but at a 2:1 ratio (Grant et al. 2011). However, the PDA traps captured EAB with a female bias ratio of 1:1.31 (n = 11,312) using a variety of lures including (Z)-3-Hexenol. Study of lab-reared populations of *Agrilus* support a 1:1 sex ration (Zang et al. 2017), however little information exists for groups that don't contain pestiferous species.

Unequal sex ratios may be the consequence of overlapping sex pheromones or differences in behavior rather than population-level ratio biases. For example, male EAB spend more time hovering around trees to look for mates, possibly increasing their trap encounter rate (Rodriguez-Saona et al. 2007). Males may also appear to be more common in genera with high proportions of unidentified female specimens (such as *Agrilus*). Trapping date ranges may affect capture rates in species with sexually divergent emergence and behaviors, however trapping occurred before and after most flight periods and should therefore account for this.

Narrow trapping date ranges for some surveys (mainly those outside of Pennsylvania) may also limit what is caught, such as *Agrilus subcinctus* Gory which appeared more frequently in Pennsylvania during the spring (May and June) with capture rates declining in subsequent months. Records from other states only start in June or July and decline as well. Variations in trapping dates also coincided with climatic differences and degree day accumulations. However, only 82 total specimens were examined during February to April, supporting that trapping starting in May (which saw 2,785 specimens) is the earliest month to start trapping to capture early season Buprestidae.

Alternate trapping methods not presented here have been shown to capture a portion of the remaining fauna that static trapping misses. Trapping with *Cerceris fumipennis* Say (Hymenoptera: Crabronidae) by monitoring their nest provisions has become a popular monitoring tool for EAB in low population density areas. While limited by weather and labor intensive, it can be effective tool to supplement panel and prism traps (Careless et al. 2009). Surveys for EAB in New England using *C. fumipennis* resulted in 56 new state records over a 10-year period (Bohne et al. 2019). This methodology resulted in a similar number of collection records to the presented work but with significantly fewer species compared to PDA's efforts. Bohne et al. collected 2,115 specimens (Massachusetts n = 890, New Hampshire n = 1,225) and found four and six new state records in four years. PDA collected 6,310 specimens (Massachusetts n = 6262, New Hampshire n = 48) in six years and found 14 and five state records, respectively.

However, the known fauna of some states such as Michigan, Missouri, Louisiana, New York, and Pennsylvania probably represent a large portion of the total that can be collected through general collecting and passive methods (MacRae 1991; Paiero et al. 2012; Carlton et al. 2018). Further diversity may be found as PDA conservatively identified some taxa of the *Agrilus anxius* (Fisher) and the *Chrysobothris femorata* complexes. Possible new records may be hidden in the taxa left at the generic level (typically females). In most situations, however, it is likely that many of the *Agrilus* left at the generic level could

be reasonably ascribed based on experience and taxa collected from that locality on other dates. The *Chrysobothris*, while not as speciose, may have a higher chance of hiding additional species due to their lower captures rates in the samples.

The destruction of bycatch is often lamented as it is praised as a missed source of information on ecological and economical value (Spears and Ramirez 2015). The ideal goal of complete identifications can be mitigated by narrower, tractable attempts of taxa that are already being screened, such as the examination of Buprestidae here. Work like this can serve as a model to share information that may have been previously been discarded.

Acknowledgments

The author would like to highlight all those who invest the time and energy into creating and updating checklists and thereby providing the basis for so many scientific endeavors to be launched. The efforts of many seasonal and full-time staff at PDA have contributed to this work over the past eight years. The author also thanks Claire M. Ciafré and Joseph A. Francese for revisions to this manuscript. This material was made possible, in part, by a Cooperative Agreement from the United States Department of Agriculture's Animal and Plant Health Inspection Service (APHIS). It may not necessarily express APHIS' views.
