**Key words:**

Crohn's disease; ulcerative colitis; relapse; stopping; TNF $\alpha$ -antagonist; infliximab; adalimumab

**ABSTRACT:****Background:**

Little data exist on the long-term prognosis of patients with inflammatory bowel disease (IBD) after stopping TNF $\alpha$ - blocking therapy in deep remission. Existing data indicate that approximately 50% of patients on combination therapy who discontinued TNF $\alpha$ - blockers are still in remission 24 months later. The aims of this follow-up analysis was to evaluate the long-term remission rate after cessation of TNF $\alpha$ -blocking therapy, the predicting factors of a relapse and the response to restarting TNF $\alpha$  blockers.

**Methods:**

The first follow-up data of 51 IBD patients (17 Crohn's disease [CD], 30 ulcerative colitis [UC] and 4 inflammatory bowel disease type unclassified [IBDU]) in deep remission at the time of cessation of TNF $\alpha$ -blocking therapy have been published earlier. The long-term data was collected retrospectively after the first follow-up year to evaluate the remission rate and risk factors for the relapse after a median of 36 months.

**Results:**

After the first relapse-free year, 14 out of the remaining 34 IBD patients relapsed (41%; 5/12 [42%] CD and 9/22 [41%] UC/IBDU). Univariate analysis indicated no associations with any

1  
2  
3 predictive factors. Re-treatment was effective in 90% (26/29) of patients.  
4  
5  
6

7  
8 **Conclusion:**

9  
10 Of IBD patients in deep remission at the time of cessation of TNF $\alpha$ -blocking therapy, up to  
11  
12 60% experience a clinical or endoscopic relapse after a median follow-up time of 36 months  
13  
14 (95% CI 31-41 months). No individual risk factors predicting relapse could be identified.  
15  
16 However, the initial response to a restart of TNF $\alpha$ -blockers seems to be effective and well  
17  
18 tolerated.  
19

20  
21  
22  
23 **INTRODUCTION**

24  
25  
26  
27 The chronic nature of inflammatory bowel disease (IBD) and lack of recommendations for  
28  
29 cessation of TNF $\alpha$ -blocking therapy may lead to long-term maintenance therapy with  
30  
31 TNF $\alpha$  blockers as early treatment recommendations have become more widely accepted.  
32  
33 With patients achieving remission, the potential severe side effects (i.e. infections, acute  
34  
35 infusion reactions, delayed hypersensitivity reactions, risk of neoplasia, and safety issues  
36  
37 during pregnancy) and economic issues prompt the questions on cessation of TNF $\alpha$ -  
38  
39 blocking therapy.<sup>1,2,3,4</sup> In addition, it is nowise certain that the benefits of TNF $\alpha$ -blocking  
40  
41 agents are permanent in the long run.  
42  
43  
44

45  
46  
47  
48 Several studies show that the overall risk of relapse after discontinuation of TNF $\alpha$ -blocking  
49  
50 agents is 44% for Crohn's disease (CD, follow-up range of 6-125 months) and 38% for  
51  
52 ulcerative colitis (UC, follow-up range of 6-24 months).<sup>5,6,7,8,9,10,11,12,13,14,15</sup> The  
53  
54 relapse risk seems to be lower in IBD patients who are in deep remission (clinical,  
55  
56 biological and endoscopic remission) at the time of cessation of TNF $\alpha$ -blocking therapy  
57  
58  
59  
60

1  
2  
3 compared to those in clinical remission only.<sup>9</sup> Available data are insufficient for giving  
4  
5 strong recommendations on at what point safely cease TNF $\alpha$ -blocking therapy. Therefore  
6  
7 the decisions should be based on assessment of the patient's individual risks and benefits.  
8  
9 In CD several factors have been investigated to identify patients who are more likely to  
10  
11 achieve long-term remission after discontinuation of TNF $\alpha$ -blocking agents. The factors  
12  
13 that have been associated with a higher risk of relapse are younger age, smoking, longer  
14  
15 disease duration, fistulising phenotype, perianal disease, short duration of remission,  
16  
17 previous surgical operation, endoscopically active disease, ileocolonic disease at  
18  
19 diagnosis and previous TNF $\alpha$ -blocking therapy, high markers of inflammation and high  
20  
21 infliximab trough level. On the other hand, mucosal healing, colonic CD, a shorter interval  
22  
23 between disease diagnosis and starting anti-TNF, concomitant immunosuppressive therapy  
24  
25 and absence of antibodies to TNF $\alpha$ -blocking agents seem to decrease the risk of relapse  
26  
27 after discontinuation of TNF $\alpha$ -blocking agents.<sup>6,7,10,12,13, 14,15,16</sup> A study by Waught  
28  
29 and co-workers shows that 35% of the CD patients with a follow-up for nearly seven years  
30  
31 after discontinuation of therapy remained in sustained clinical remission. No specific factor  
32  
33 was associated with the duration of CD remission.<sup>17</sup> In patients receiving TNF $\alpha$ -blocking  
34  
35 agents for the prevention of post-operative CD recurrence, the risk of relapse after  
36  
37 discontinuation is very high (>75%) and the ceasing decision should be based on very  
38  
39 good reasons.<sup>18</sup> Importantly, restarting of TNF $\alpha$ -blocking therapy for those who relapsed  
40  
41 after stopping treatment seems to be effective and well-tolerated.<sup>5,6,9,10,12</sup>

## 8 9 **MATERIALS AND METHODS**

### 10 11 **Patients and study design**

12  
13  
14 All 51 IBD patients in this follow-up analysis were primarily recruited in a prospective  
15  
16 multicenter study which was carried out at nine gastroenterological centers in Finland  
17  
18 during the period from February 2010 to June 2013.<sup>9</sup> At the time of inclusion all patients  
19  
20 were in deep remission (i.e. clinical, endoscopic and faecal calprotectin -based [FC  
21  
22 <100 $\mu$ g/g] remission). After the primary study, one UC patient was dropped from the  
23  
24 follow-up due to no available data on a patients' report. Clinical notes of all enrolled  
25  
26 patients were retrospectively reviewed for this long-term follow-up. All patients had an  
27  
28 established IBD diagnosis, had received TNF $\alpha$ -blocking maintenance therapy for a  
29  
30 minimum of one year (the median duration of infliximab [IFX] therapy was 13 [n = 46,  
31  
32 range 11-77] months and adalimumab [ADA] therapy 27 [n = 5, range 16-36] months), had  
33  
34 been in corticosteroid-free remission over a 6-months period prior to the inclusion, were in  
35  
36 clinical, FC-based (FC <100  $\mu$ g/g) and endoscopic remission at the time of inclusion. Due  
37  
38 to its small size, the subgroup IBDU of four patients was combined with the UC group.  
39  
40  
41  
42  
43  
44  
45  
46

47  
48 Given the retrospective design of this study, clinical disease activity was assessed by the  
49  
50 physicians' global assessment (asymptomatic patients vs. symptomatic patients indicating  
51  
52 active IBD) in patients relapsing after the first year of follow-up and 12 months after the  
53  
54 restart of TNF $\alpha$ -blocking therapy. At relapse endoscopic findings were scored, as in our  
55  
56 earlier study<sup>9</sup>, according to the SES-CD<sup>19</sup> in CD and endoscopic Mayo score in UC and  
57  
58  
59  
60

1  
2  
3 IBDU.<sup>20</sup> An SES-CD of 3-6 was defined as mildly active disease, 7-15 as moderately  
4  
5 active disease, and  $\geq 16$  as severely active disease.<sup>21</sup> Endoscopic Mayo subscore of  $\geq 2$   
6  
7 defined active disease.<sup>22</sup>  
8  
9

10  
11  
12 In a case of a clinical and/or endoscopic relapse after the first year of follow-up, TNF $\alpha$ -  
13  
14 blocking therapy was restarted at the same dose and frequency as prior to withdrawal in  
15  
16 exception of two patients, whose relapses were treated with oral corticosteroids or  
17  
18 mesalazine. Ileocolonoscopy was performed 12 months after the restart of TNF $\alpha$ -blocking  
19  
20 therapy in exception of four patients with normal fecal calprotectin levels. Endoscopic  
21  
22 activity was defined as mild, moderate, or severe by an experienced gastroenterologist.  
23  
24  
25  
26  
27

### 28 **Fecal calprotectin assays**

29  
30 FC was measured using the quantitative enzyme immunoassay (the CALPRO®  
31  
32 Calprotectin ELISA Test [ALP; Calpro AS, Lysaker, Norway]). The values quoted as  
33  
34 normal were  $< 100 \mu\text{g/g}$ .<sup>23</sup>  
35  
36  
37  
38

### 39 **Statistics**

40  
41 The Statistical Package for the Social Sciences (SPSS version 23) for Windows software  
42  
43 (SPSS, Chicago, IL, USA) was used for data analyses. Fisher's exact test was used to  
44  
45 determine differences in binary variables. The significance was set at  $p < 0.05$  and two-  
46  
47 tailed tests were used. Kaplan-Meier survival analysis was employed in estimation of  
48  
49 relapse-free survival rates, and the log-rank test was used to determine the differences  
50  
51 between the groups. The Cox regression of proportional hazards was used to calculate  
52  
53 univariate hazard ratios for categorical and continuous variables. The results were given  
54  
55 as percentages, as median and range, or as mean and standard deviation (SD).  
56  
57  
58  
59  
60

### Ethical statement

The study protocol and all documents of the prior prospective multicenter study were approved by the ethics committee at Helsinki University Hospital and at each participating university central hospital. Because this follow-up study was a retrospective reviewing of patients' medical records, no separate application for ethics committee was needed.

### RESULTS

The baseline characteristics are described in Table 1. As established in earlier publication, during the first 12-month follow-up, up to 33% of patients (5/17 [29%] CD and 12/34 [35%] UC/IBDU) in deep remission relapsed.<sup>10</sup> After the first relapse-free year, 14 of the remaining 34 IBD patients relapsed (40%; 5/12 [42%] CD and 9/22 [41%] UC/IBDU) during median follow-up period of 36 months (1-69; in CD 38 months [3-68] and in UC 35 months [1-69]). Of the 14 relapsed patients, endoscopic data were available on 13 at the time of a relapse. Out of five relapsed CD patients, one experienced a severe clinical relapse without endoscopic documentation, two experienced both clinical and endoscopic relapse (SES-CD 8 and 10) and two experienced moderate endoscopic relapse without clinical symptoms mean (SES-CD 7 and 9). All UC patients experienced both clinical and endoscopic relapse (mean endoscopic Mayo score 2 [2-3]).

The time-to-relapse curves of all patients are shown in Figure 1. No significant difference was found in the relapse rate between CD and UC/IBDU,  $p = 0.919$ .

### The risk factors for relapse

1  
2  
3 Based on univariate analysis (Cox model) risk factors such as diagnosis, gender, disease  
4 duration, localization, behavior, smoking, family history, previous surgery, the TNF $\alpha$ -  
5 blocking agents used, concomitant medications or duration of the used TNF $\alpha$ -blocking  
6 agents were not associated with the risk of relapse, Table 2.  
7  
8  
9  
10

### 11 **Restarting TNF $\alpha$ -blocking therapy**

12  
13  
14  
15  
16  
17 The response after restarting TNF $\alpha$ -blocking therapy was evaluated in all 29 of 51 IBD  
18 patients, Figure 2. The median time of follow-up after retreatment with TNF $\alpha$ -blocking  
19 agents was 12 (range 3-19) months. One relapsed UC patient was treated with  
20 corticosteroid and another with mesalazine instead of TNF $\alpha$ -blocking agents. After the  
21 restarting TNF $\alpha$ -blocking therapy, all except one UC patient achieved clinical remission or  
22 response at three months. During the follow-up period, three patients were operated on:  
23 one UC patient underwent colectomy less than two months after the restart of TNF $\alpha$ -  
24 blocking therapy due to nonresponse and another UC patient underwent colectomy after  
25 one year of TNF $\alpha$ -blocking therapy due to loss of response. Furthermore, one CD patient  
26 underwent ileo-cecal resection after one year of TNF $\alpha$ -blocking therapy due to a  
27 symptomatic stricture. After a restart of IFX, two UC patients experienced an infusion  
28 reaction (one during the second IFX infusion without anti-drug antibody measurement and  
29 the other one six months after restarting developing anti-drug antibodies) and were treated  
30 with another TNF $\alpha$ -blocking agent. In addition, despite a combination therapy with  
31 thiopurins, three patients (one CD and two UC patient) developed low concentrations of  
32 anti-drug antibodies, but achieved a clinical response by dose escalation (one CD and one  
33 UC patient) or by switching to another TNF $\alpha$ -blocking agent (one UC patient). Twelve  
34 months after the restart of TNF $\alpha$ -blocking therapy 20 patients (39%; 8 CD, 12 UC) were  
35 still in clinical remission. Six patients with CD and 11 patients with UC underwent a 12-

2  
3 month follow-up ileocolonoscopy, showing either endoscopic remission (4 CD, 9 UC) or  
4  
5 mild activity (3 CD, 2 UC). The remaining three patients (2 CD, 1 UC) had normal  
6  
7 calprotectin levels serving as surrogate markers to endoscopic remission.  
8  
9

## 10 11 **DISCUSSION**

12  
13  
14  
15  
16 It is well known that TNF $\alpha$ -blocking therapy is effective in inducing and maintaining  
17  
18 remission in IBD patients with moderate to severe CD and UC and therefore, for  
19  
20 responders the long-term maintenance therapy is recommended.<sup>24,25</sup> However, life-long  
21  
22 TNF $\alpha$ -blocking therapy in IBD patients in clinical remission or in deep remission is still  
23  
24 questioned, since early treatment with an immunomodulator and/or TNF $\alpha$ -blocking agonist  
25  
26 are nowadays recommended <sup>26</sup> and long-term safety issues are still debated.  
27  
28  
29  
30  
31

32 According to this follow-up study almost 60% of patients relapsed after a median follow-up  
33  
34 time of 36 months. No statistically significant difference in the relapse rates between CD  
35  
36 and UC was found. Several studies, mainly with CD patients, have been published on the  
37  
38 duration of remission after a discontinuation of TNF $\alpha$ -blocking therapy, and only few of  
39  
40 these studies have assessed endoscopic activity during a long-term follow-up. It is  
41  
42 interesting to note, that across all studies reporting on anti-TNF withdrawal of adult IBD  
43  
44 patients in clinical remission, despite heterogeneous study designs and patient  
45  
46 populations, the one and two -year relapse rates were reasonably consistent ranging from  
47  
48 21-39% and from 37%-56% respectively.<sup>6,7,8,9,10,11,12,13</sup> These findings are in line  
49  
50 with our results despite the fact that no baseline endoscopic remission was required in the  
51  
52 majority of those earlier studies. However, recently published long-term data of the  
53  
54 patients included in the STORI trial seem to indicate poorer remission rates after cessation  
55  
56  
57  
58  
59  
60

1  
2  
3 of IFX for sustained remission: the vast majority of CD patients (85%) had to restart the  
4  
5 treatment over the course of time.<sup>27</sup> The longest follow-up periods reported are 10 years  
6  
7 in CD<sup>14</sup> and 7 years in UC.<sup>15</sup> Cumulative relapse rates in all studies rise over time.  
8  
9

10  
11  
12 Cessation of TNF $\alpha$  -blocking therapy may be considered for patients with a low relapse  
13  
14 risk. The relapse risk may be minimized using predictors that identify those at a clinically  
15  
16 meaningful risk of relapse. Achieving deep remission is currently considered to be the  
17  
18 most important protective factor in disease relapse after TNF $\alpha$  -blocking therapy  
19  
20 withdrawal.<sup>28</sup> Many of the risk factors shown in previous studies have been associated  
21  
22 with incomplete remission with ongoing inflammatory disease activity at the time of  
23  
24 discontinuation. It seems likely that not only the disease activity at the time of cessation of  
25  
26 TNF $\alpha$  -blocking therapy but also previous disease history may have an impact on the risk  
27  
28 of disease relapse following TNF $\alpha$  -blocking therapy withdrawal. Factors affecting the  
29  
30 duration of a clinical remission after discontinuing anti-TNF therapy remain questionable  
31  
32 even today. Moreover, it is very likely that patients' initial response to TNF $\alpha$  -blocking  
33  
34 therapy and tendency to maintain sustained remission after therapy withdrawal is based  
35  
36 on a patient-unique genetic type of IBD disease.<sup>29,30</sup> Future studies are needed to  
37  
38 analyze the correlation of patients' genotype and the duration of remission after  
39  
40 discontinued TNF $\alpha$  -blocking therapy. As clear and widely accepted recommendations for  
41  
42 discontinuing TNF $\alpha$  -blocking therapy are lacking, it has been stated that biological therapy  
43  
44 should not be stopped in patients who have undergone multiple previous operations,  
45  
46 demonstrated intolerance to conventional drugs or in whom the disease is difficult to  
47  
48 control.<sup>31</sup> A multidisciplinary European expert panel (European Panel on the  
49  
50 Appropriateness of Crohn's Disease Treatment II, EPACT-II) considered discontinuing  
51  
52 TNF $\alpha$ -blocking therapy to be appropriate after four years, but also after two years if the  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 patient was in deep remission.<sup>32</sup> The results of our previous study suggested that  
4  
5 withdrawal of TNF $\alpha$ -blocking therapy after one year could be possible in IBD patients with  
6  
7 deep remission as the duration of TNF $\alpha$ -blocking therapy did not influence the relapse risk  
8  
9 over time.<sup>9</sup> Nevertheless, considering the possible adverse events after stopping TNF $\alpha$ -  
10  
11 blocking therapy, withdrawal should be considered carefully and discussed with the  
12  
13 patient.  
14  
15

16  
17  
18  
19 After a drug-holiday, the risk of immunization resulting in infusion reactions and loss of  
20  
21 response should be considered.<sup>33,34</sup> Unfortunately, most of the studies report only short-  
22  
23 term outcomes and therefore more evidence is needed to demonstrate the real efficacy  
24  
25 and safety of re-treatment. The studies including longer follow-up periods have reported  
26  
27 remission rates from 80 to 92%.<sup>7,8</sup> These findings are in line with our study, all but one of  
28  
29 the patients achieved clinical remission or response at three months and the remission  
30  
31 rate at one year was considerably high (97%). However, the risk of developing anti-drug  
32  
33 antibodies may lead to infusion reaction and loss of response followed by severe  
34  
35 problems. In our study, three patients underwent surgery due to no response to re-  
36  
37 treatment and five patients developed either anti-drug antibodies and/or experienced an  
38  
39 infusion reaction. Taking this into account, withdrawal of TNF $\alpha$ -blocking therapy needs to  
40  
41 be considered carefully.  
42  
43  
44  
45

46  
47  
48 Our study has some limitations. The patient group is limited and heterogeneous and the  
49  
50 number of patients in the subgroups low. Moreover, cut-off levels used for endoscopic  
51  
52 remission (SES-CD score and endoscopic Mayo score) may have allowed mild  
53  
54 endoscopic activity at baseline and also during the follow-up. However, we consider that  
55  
56 low baseline FC value as another criterion of remission ruled out patients with notable  
57  
58  
59  
60

1  
2  
3 inflammatory activity.<sup>35</sup> Furthermore, clinical and endoscopic data after one year of  
4  
5 stopping TNF $\alpha$ -blocking therapy was not collected for the study purpose. Therefore clinical  
6  
7 scores were not available for all patients at the time of relapse and clinical and endoscopic  
8  
9 scores were not available after the restart of TNF $\alpha$ -blocking therapy for all patients.  
10  
11 However, the strength of this study is a long term surveillance after cessation of TNF $\alpha$ -  
12  
13 blocking therapy in a clinical setting and endoscopic verification of a relapse.  
14  
15

16  
17  
18 The long-term follow-up demonstrates a fairly high relapse rate after cessation of TNF $\alpha$ -  
19  
20 blocking therapy among IBD patients in deep remission. However, two out of five patients  
21  
22 seem to remain in sustained clinical remission after cessation of TNF $\alpha$ -blocking therapy,  
23  
24 but selecting these patients among potential relapsers is challenging. In relapsers, the  
25  
26 response to a restart of TNF $\alpha$  antagonists seems to be effective and fairly well tolerated,  
27  
28 even if the formation of anti-drug antibodies may result in to dose escalation or a change  
29  
30 of TNF $\alpha$ -blocking agent. Therefore withdrawal of TNF $\alpha$ -blocking therapy should be  
31  
32 considered carefully on individual bases.  
33  
34  
35  
36  
37

## 38 **DISCLOSURES**

39  
40  
41  
42  
43 Statement of authorship: study design (PM, MF, TS), data collection (PM, HK, TB, AJ),  
44  
45 statistical analysis (PM, HM), drafting the manuscript (PM, TS), final reading and approval  
46  
47 of the manuscript (all authors).  
48  
49

50  
51  
52 PM received lecture fees from Abbvie, Ferring and MSD and consulting fees from Abbvie,  
53  
54 MSD and Takeda. MF received consulting fees from MSD, Abbvie, Janssen, Orion  
55  
56 Pharma, Medivir and Roche, and lecture fees from MSD, Abbvie, Bayer, Janssen and  
57  
58  
59  
60

1  
2  
3 Tillots Pharma. TB received lecture fees from Abbvie and Tillotts Pharma and consulting  
4 fees from Abbvie. AJ received lecture fees from Abbvie, Ferring, MSD, Takeda and Tillotts  
5 Pharma and consulting fees from Abbvie, Hospira, MSD, Takeda and Tillotts Pharma. TS  
6  
7 received lecture fees from Abbvie, AstraZeneca, Ferring, Medac, MSD, Pfizer, Tillots  
8 Pharma and Vifor Pharma and consulting fees from Hospira, Takeda, MSD and Tillotts  
9 Pharma. HK and HM declare no conflicts of interest.

<b>Infliximab</b>	34 (100)	12 (71)
<b>Adalimumab</b>		5 (29)

6-MP = 6-Mercaptopurine

Table 2. Predictors for disease relapse in the study population.

Variable	P- value	Hazard Ratio	95% CI lower	upper
Diagnosis; CD versus UC/IBDU	0.919	1.042	0.469	2.316
Male sex	0.780	0.899	0.425	1.899
Age at diagnosis	0.341	0.977	0.931	1.025
Age at diagnosis; <25 y versus ≥25 y	0.073	0.492	0.227	0.069
Age at diagnosis; < 20 y versus ≥ 20 y	0.090	0.508	0.232	1.112
Localisation of CU	0.280	1.704	0.648	4.483
Localisation of CD	0.345	1.000		
L3 versus L1	0.243	3.888	0.398	38.017
L3 versus L2	0.464	0.453	0.054	3.778
Disease behavior (CD)	0.995	1.000		
B1 versus B2	0.793	0.802	0.154	4.177
B1 versus B3	0.995	1.008	0.107	9.470
B1 versus B2 + perianal disease	0.242	2.391	0.555	10.298
Smoking	0.252	1.000		
No versus <10 cigrarets / day	0.125	0.383	0.112	1.306
No versus smoker	0.356	0.644	0.253	1.640
No versus smoker or previous smoker	0.117	0.524	0.233	1.177
Age at induction	0.375	0.981	0.941	1.023
Age at induction; < 30 versus ≥ 30 - 40	0.361	0.662	0.273	1.605
Age at induction; < 30 versus ≥ 41	0.927	0.956	0.362	2.526
Duration of the disease at induction	0.974	1.001	0.949	1.055
Duration of the disease; > 5 - 10 years	0.173	1.876	0.760	4.630
Duration of the disease; ≥ 11 years	0.447	1.451	0.556	3.784
Previous surgery	0.577	0.739	0.255	2.140
Positive family history	0.791	0.876	0.331	2.324
TNF α-blocking therapy used; IFX vs. ADA	0.573	1.418	0.421	4.782
Duration of the TNFα-blocking therapy; median	0.995	1.000	0.977	1.024
CRP at discontinuation; median	0.450	0.935	0.785	1.113
Hemoglobin at discontinuation; median	0.434	1.010	0.985	1.036

CD = Crohn's Disease; UC = Ulcerative Colitis; IBDU = Inflammatory Bowel Disease type Unclassified; TNF = Tumour Necrosis Factor; IFX = Infliximab; ADA = Adalimumab; CRP = C-reactive protein
