5 University of Helsinki, Finland

6

7 Running title: Foodborne pathogens in wild boars

8 **Abstract**

9

10 Wild boar populations around the world have increased dramatically over past decades. Climate
11 change, generating milder winters with less snow, may affect their spread into northern regions.
12 Wild boars can serve as reservoirs for a number of bacteria, viruses, and parasites, which are
13 transmissible to humans and domestic animals through direct interaction with wild boars,
14 through contaminated food or indirectly through contaminated environment. Disease
15 transmission between wild boars, domestic animals, and humans is an increasing threat to
16 human and animal health, especially in areas with high wild boar densities. This article reviews
17 important foodborne zoonoses including bacterial diseases (brucellosis, salmonellosis,
18 tuberculosis, and yersiniosis), parasitic diseases (toxoplasmosis and trichinellosis), and the viral
19 hepatitis E. The focus is on the prevalence of these diseases and the causative microbes in wild
20 boars. The role of wild boars in transmitting these pathogens to humans and livestock will also
21 be briefly discussed.

22

23 **Keywords:** wild boar/pig/swine, feral pig/swine, foodborne pathogen, zoonotic infection

24 **Introduction**

25 Wild boars (*Sus scrofa*), including Eurasian wild boars (*Sus scrofa* Linnaeus), feral pigs
26 (*Sus scrofa domesticus*), and hybrids between the two, are present on all continents except
27 Antarctica (Ruiz-Fons, 2017). Many countries have witnessed dramatic increases in wild boar
28 populations during past decades (Brown *et al.*, 2018). They have also increased within urban
29 areas causing car accidents and damages in parks and gardens (Toger *et al.*, 2018). Wild boar
30 populations have exploded due to lack of predation, low hunting pressure, rapid reproductive
31 rate, favorable climatic conditions, and food available including supplementary feeding of wild
32 boars (Massei *et al.*, 2015, Oja *et al.*, 2015). They are omnivores, eating mostly (around 90%)
33 plant material, but can adapt their diet to whatever is available including live and dead animals
34 (Ballari & Barrios-García, 2014).

35 Wild boars can be infected with several pathogens, some of which are transmissible to
36 domestic animals and humans (Cantlay *et al.*, 2017, Cleveland *et al.*, 2017). Cross-species
37 disease transmission between wild animals, domestic animals, and humans is an increasing
38 threat to human and animal health (Miller *et al.*, 2017). An increase in the outdoor farming of
39 domestic food-producing animals may raise the contact risk between domestic and wild animals
40 and thus the transmission of pathogens. Concurrently with increasing wild boar populations,
41 wild boar hunting and the consumption of wild boar meat has increased in popularity (Ruiz-
42 Fons, 2017). Contact with infected wild boars and consuming contaminated wild boar meat can
43 be a source of brucellosis, salmonellosis, toxoplasmosis, trichinellosis and tuberculosis in
44 humans and other animals (Brown *et al.*, 2018, EFSA, 2013). These zoonoses are among the
45 top 10 diseases at the wildlife-livestock interface based on the number of publications
46 (Wiethoelter *et al.*, 2015).

47 The most important zoonotic pathogens transmitted by pork to humans in Europe are
48 *Salmonella*, *Yersinia*, *Toxoplasma*, and *Trichinella* (EFSA, 2011, Felin *et al.*, 2015). *Brucella*

49 *suis* and *Mycobacterium tuberculosis* complex (MTC), found in domestic pigs and wild boars,
50 can also be transmitted through contaminated meat to humans (Brown *et al.*, 2018). Brucellosis
51 and tuberculosis are two severe zoonotic diseases in humans, which are monitored in food-
52 producing animals in several countries, especially countries free of tuberculosis and brucellosis
53 in livestock. Eighteen of 28 European Union (EU) member states were officially declared free
54 from bovine tuberculosis and bovine, ovine and caprine brucellosis in 2016 (EFSA and ECDC,
55 2017).

56 There are also other pathogenic bacteria such as *Campylobacter*, *Listeria monocytogenes*
57 and shigatoxin-producing *Escherichia coli*, which may be transmitted through contaminated
58 meat (Ruiz-Fons, 2017). Several zoonotic viruses have been detected in domestic pigs and wild
59 boars, but only hepatitis E virus (HEV) is transmitted through contaminated pork (Ruiz-Fons,
60 2017, Syed *et al.*, 2018).

61 In this manuscript, the prevalence of the most important foodborne infections in Europe
62 and the causative microbes in wild boars will be reviewed. The role of wild boars in transmitting
63 these pathogens, and finally, present measures for controlling these pathogens will be shortly
64 discussed.

65

66 **Materials and methods**

67 The literature search was performed in Scopus using the keywords wild boar OR wild pig
68 OR wild swine OR feral pig OR feral swine AND salmonella OR yersinia OR brucella OR
69 mycobacterium OR trichinella OR toxoplasma OR HEV. Papers published from 2014 onwards
70 including research papers and reviews, which were written in English, were reviewed.

71

72 **Results**

73 In total, 423 articles, which met the search criteria, were published between 2014 and
74 2018 (until 6.8.2018) (Fig. 1). Totally, 157 papers, which were dealing with prevalence,
75 transmission routes and control, were used in this review. Additionally, two more articles about
76 public health hazard in pigs and farmed game from 2011 and 2013, respectively, were included
77 because of the important background information presented in the introduction part.

78 Number of reviewed articles dealing with hepatitis E virus was highest (46/157, 29%)
79 (Fig. 2). Only 13 reviewed articles (8%) were dealing with *Yersinia*.
80

81 **Foodborne bacteria in wild boar**

82 ***Brucella suis***

83 *Brucella* is a gram-negative zoonotic pathogen causing brucellosis, which is a significant
84 public health problem in many areas where the bacterium mainly persists in ruminants
85 (Godfroid *et al.*, 2014). Humans can acquire the infection through contact with infected food-
86 producing animals, via inhalation of bacteria in aerosols, or consumption of contaminated food
87 products. *B. suis* belonging to biovars 1, 2, and 3 are responsible for brucellosis in pigs but
88 biovar 2 is mainly found in wild boars in Europe (Godfroid *et al.*, 2014, Grantina-Ievina *et al.*,
89 2018). Infected pigs are usually asymptomatic, but the disease can cause abortion, orchitis, and
90 infertility (Risco *et al.*, 2014). Especially *B. suis* of biovars 1, 3, and 4 infect humans, causing
91 chronic disease with undulating fever and joint pain (Godfroid *et al.*, 2014). *B. suis* biovar 2 is
92 rarely causing disease in humans probably due its lower virulence among humans. However,
93 illnesses caused by *B. suis* biovar 2 has been reported in hunters (Mailles *et al.*, 2017).

94 Brucellosis has mostly been eradicated from livestock, including domestic pigs in
95 developed countries, and several European countries have even achieved a brucellosis-free
96 status (EFSA and ECDC, 2017, Godfroid *et al.*, 2014). However, brucellosis has been reported
97 in wild boar populations in Australia, Europe and USA, with seroprevalence ranging between

98 <1% and 59% (Tables 1 and 1S) (Pedersen *et al.*, 2014, Ridoutt *et al.*, 2014, Risco *et al.*, 2014).
99 The highest seroprevalence (59%) was reported in southwestern Spain (Risco *et al.*, 2014).
100 False-positive serological results can occur due to a cross-reaction with *Yersinia enterocolitica*
101 serotype O:9 (Grantina-Ievina *et al.*, 2018). Seroprevalence in eastern Latvia was estimated at
102 23% after considering the cross-reactivity with *Y. enterocolitica* (Grantina-Ievina *et al.*, 2018).
103 Increased seropositivity has been associated with older wild boars (Brown *et al.*, 2018, Pilo *et*
104 *al.*, 2015). High wild boar density in summer, age over two years, and female gender were risk
105 factors associated with high (>50%) seroprevalence in Spain (Risco *et al.*, 2014).

106 Twenty two percent of wild boars in Georgia, USA, were recently reported to excrete *B.*
107 *suis* in their feces (Lama & Bachoon, 2018). *B. suis* was also frequently found in lymph nodes
108 (Pedersen *et al.*, 2017a). Biovar 2 was detected in 4% of genital (testicular or vaginal) swabs of
109 wild boars in Spain (Risco *et al.*, 2014). This same type was also found in wild boar tonsils in
110 Austria and in wild boar spleens in eastern Latvia (Glawischnig *et al.*, 2018, Grantina-Ievina *et*
111 *al.*, 2018). Biovars 1 and 3, which are highly pathogenic to humans, were found in wild boars
112 in the USA (Pedersen *et al.*, 2014).

113

114 ***Mycobacterium tuberculosis* complex**

115 Tuberculosis is a chronic infection caused by acid-fast mycobacterium: *Mycobacterium*
116 *tuberculosis*, *Mycobacterium bovis*, *Mycobactrium caprae*, and other members of the MTC
117 (Díez-Delgado *et al.*, 2018, Gagneux, 2018). *M. bovis* and *M. caprae* are the main causes of
118 tuberculosis in farm and wild animals (Santos *et al.*, 2015). They are genetically closely related
119 to *M. tuberculosis*, which is mainly adapted to humans (Orgeur & Brosch, 2018). Eradication
120 of bovine, ovine and caprine tuberculosis has not been achieved in several European countries
121 despite eradication programs (EFSA and ECDC, 2017). Tuberculosis in animals can cause
122 infections in humans and economic losses for livestock production (Maciel *et al.*, 2018, Rivière

123 *et al.*, 2017). Tuberculosis is transmitted mainly as an aerosol, but can also be transmitted
124 through handling and consumption of contaminated food or handling of contaminated slaughter
125 waste (Cano-Terriza *et al.*, 2018).

126 Wild boars have mainly been infected by *M. bovis* and *M. caprae*, but also by
127 *Mycobacterium microti*, which is a member of the MTC (Amato *et al.*, 2018, Boniotti *et al.*,
128 2014). Mortality due to tuberculosis is high (30%) among adult wild boars in an endemic area
129 with a high-density wild boar population in Spain (Barasona *et al.*, 2016). Recently,
130 tuberculosis due to *M. tuberculosis* was reported in a dead wild boar in Korea (Seo *et al.*, 2017).
131 *M. bovis* was fairly recently detected in the lymph nodes and organs (lungs, liver, spleen, and
132 kidney) of wild boars in Brazil, Korea, Spain, and Portugal using polymerase chain reaction
133 (PCR) and culturing (Gortázar *et al.*, 2017, Jang *et al.*, 2017, Maciel *et al.*, 2018, Matos *et al.*,
134 2016) (Tables 2 and 2S). A large number of MTC bacteria was excreted in the feces of wild
135 boars in Portugal (Santos *et al.*, 2015). In Spain, MTC was detected in fecal (4.5 %), oral
136 (13.6%) and nasal swabs (4.5%) showing that wild boars can shed mycobacteria in the
137 environment by different routes (Barasona *et al.*, 2017).

138 Several serological studies have recently been conducted in Spain, and seroprevalence
139 varied between 21% and 88% in these studies (Barasona *et al.*, 2016, Barasona *et al.*, 2017,
140 Cano-Manuel *et al.*, 2014, Cano-Terriza *et al.*, 2018, Che'Amat *et al.*, 2015, Pérez de Val *et al.*,
141 2017) (Tables 1 and 1S). In areas where wild boar population density was very high,
142 tuberculosis prevalence among wild boars exceeded 50% (Barasona *et al.*, 2016). In
143 Switzerland, tuberculosis prevalence in wild boars was low (2 %) even though it is a re-
144 emerging disease in dairy population (Beerli *et al.*, 2015). The exposure to MTC in wild boars
145 was low also the USA (Pedersen *et al.*, 2017c).

146

147 ***Salmonella enterica***

148 *Salmonella* are gram-negative enteric bacteria causing salmonellosis, which is a serious
149 public health concern in both developed and developing countries (Pires *et al.*, 2014). Illnesses
150 are most commonly attributed to exposure to contaminated food. *Salmonella* have a variety of
151 animal reservoirs and are able to infect a wide range of domestic and wild animals, including
152 wild boars.

153 Antibodies to *Salmonella* were detected in wild boars in some studies, with
154 seroprevalence varying between 4% and 49% (Baroch *et al.*, 2015, Cano-Manuel *et al.*, 2014,
155 McGregor *et al.*, 2015, Touloudi *et al.*, 2015) (Tables 1 and 1S). In Spain, a higher
156 seroprevalence among female compared to male wild boars was probably related to higher
157 intraspecific contacts and earlier breeding age in females compared to males (Cano-Manuel *et*
158 *al.*, 2014).

159 The isolation rates of *Salmonella* in wild boar varied between 5% and 44% (Cummings
160 *et al.*, 2016, Dias *et al.*, 2015, Glawischnig *et al.*, 2018, Sannö *et al.*, 2014, Sannö *et al.*, 2018)
161 (Tables 2 and 2S). *Salmonella* was also isolated sporadically from the carcass meat of hunted
162 wild boars (Mirceta *et al.*, 2017). Sannö *et al.* (2014, 2018) isolated *Salmonella* in the feces,
163 tonsils, and lymph nodes of hunted wild boars in Sweden, and reported the highest isolation
164 rates in the tonsils.

165

166 ***Yersinia***

167 Yersiniosis is a gastrointestinal infection in humans caused by *Yersinia enterocolitica* or
168 *Yersinia pseudotuberculosis* (Fredriksson-Ahomaa, 2015). Human yersiniosis due to *Y.*
169 *enterocolitica* bioserotype 4/O:3 is frequently reported in Europe (EFSA and ECDC, 2017).
170 The infection is mostly characterized with a self-limiting enteritis and abdominal pain due to
171 mesenteric lymph adenitis. Yersiniosis typically occurs through the consumption of pork
172 contaminated with *Y. enterocolitica* 4/O:3, which has frequently been found in fattening pigs.

173 However, bioserotype 4/O:3 appears to be a rare finding in wild boars (Bancerz-Kisiel et al.,
174 2015).

175 *Y. enterocolitica* biotype 1A, which is not regarded as pathogenic, was isolated from
176 tonsils and feces of wild boars, with a prevalence varying between 17% and 27% (Bancerz-
177 Kisiel et al., 2015, Szczylo et al., 2018, von Altrock et al., 2015). Atypical *Y. enterocolitica*
178 strains were found on wild boar carcasses in Poland (Bancerz-Kisiel et al., 2016). Wild boars
179 also carry *Y. enterocolitica* serotype O:9, which is associated with human infections, in their
180 tonsils and lymph nodes (Weiner et al., 2014), and sporadically excrete human pathogenic
181 bioserotypes 2/O:9 and 4/O:3 in their feces (Bancerz-Kisiel et al., 2015, Szczylo et al., 2018).
182 Antibodies to serotype O:9 of *Y. enterocolitica* may cross-react with *Brucella* antibodies,
183 complicating the serology by false-positive results.

184 *Y. pseudotuberculosis* is mainly associated with wildlife worldwide (Reinhardt et al.,
185 2018). *Y. enterocolitica* and *Y. pseudotuberculosis* were frequently detected in tonsils, but also
186 in lymph nodes and feces of wild boars in Europe using PCR (Table 2S). Recently, antibodies
187 to enteropathogenic *Yersinia*, including *Y. enterocolitica* and *Y. pseudotuberculosis*, were
188 detected in 52% to 69% of wild boars in the Czech Republic, Latvia, and Spain (Arrausi-Subiza
189 et al., 2016, Grantina-Ievina et al., 2018, Lorencova et al., 2016).

190

191 **Foodborne parasites in wild boar**

192 ***Toxoplasma***

193 *Toxoplasma* is a zoonotic protozoan parasite, which is widely distributed worldwide and
194 can infect all mammalian and avian species including wildlife (Ferroglio et al., 2014, Hadfield
195 & Guy, 2017, Waap et al., 2016). Three distinct genotypes (I, II, and III) of *Toxoplasma* are
196 circulating in wildlife and livestock (Battisti et al., 2018). Genotypes II and III predominate in
197 humans. Toxoplasmosis may have serious consequences in certain groups, causing abortion

198 and fetal abnormality in pregnant women, and encephalitis, brain abscesses, and death in
199 immunocompromised patients (Rostami *et al.*, 2017b). Cats and other felids are the only known
200 definitive hosts, while wild boars can be intermediate hosts. An intermediate host is infected
201 after ingestion of food or water contaminated with sporulated oocysts or by ingesting meat
202 containing *Toxoplasma* cysts (Hadfield & Guy, 2017). This pathogen may be directly
203 transmitted between domestic pigs and wild boars through cannibalistic behavior. It can be
204 transmitted to humans via raw or undercooked meat of wild boars.

205 *Toxoplasma* seroprevalence in wild boars was reported to be between 5% and 51%
206 (Tables 1 and 1S). The highest prevalence (> 20%) was reported in Europe (Czech Republic,
207 Estonia, Italy, Poland, Portugal, Slovakia, Spain and Sweden), South Korea and the USA
208 (Calero-Bernal *et al.*, 2016, Coelho *et al.*, 2014, Gazzonis *et al.*, 2018, Gerhold *et al.*, 2017,
209 Hill *et al.*, 2014, Jeong *et al.*, 2014, Jokelainen *et al.*, 2015, Malmsten *et al.*, 2018, Racka *et al.*,
210 2015, Reiterová *et al.*, 2016, Wallander *et al.*, 2015, Witkowski *et al.*, 2015). A lower
211 prevalence ($\leq 10\%$) was reported in Canada, China and Greece (Luo *et al.*, 2017, McGregor *et*
212 *al.*, 2015, Touloudi *et al.*, 2015). In most studies, older animals had higher seroprevalences than
213 younger ones probably due to their greater exposure to the parasite (Roqueplo *et al.*, 2017).
214 However, in northern China, the prevalence was highest among farmed wild boar piglets (Bai
215 *et al.*, 2017). Wild boars in Spain were frequently infected with *T. gondii* genotypes I and II
216 (Calero-Bernal *et al.*, 2015). Genotype II was also identified in wild boars in Italy (Papini *et*
217 *al.*, 2018).

218

219 ***Trichinella***

220 Trichinellosis is a parasitic zoonosis caused by *Trichinella* larvae, which affect human
221 health. Fever, muscular pain, and diarrhea are the most typical symptoms (Heaton *et al.*, 2018).
222 The disease is mostly self-limiting, but can also be fatal (Messiaen *et al.*, 2016). *Trichinella* has

223 a worldwide distribution, and infects both domestic pigs and wild animals such as wild boars
224 (Rostami *et al.*, 2017a). However, *Trichinella* has been largely eliminated from domestic pigs
225 in most developed countries due to improved pork production practices (Holzbauer *et al.*, 2014).

226 *Trichinella* infections in humans have still been reported in eastern European countries,
227 but cases have significantly decreased in the past five years (Flis *et al.*, 2017, Turiac *et al.*,
228 2017). Humans typically become infected after eating raw or undercooked meat from domestic
229 pigs raised under non-controlled housing conditions or wild boars containing *Trichinella* larvae
230 (Van De *et al.*, 2015). Wild boar meat is currently the second most important source of human
231 trichinellosis, and has been responsible for several human outbreaks (Table 3). Examining wild
232 boar meat for the presence of *Trichinella* before processing and marketing in Europe has been
233 mandatory since 1992; however, wild boar meat intended for private use is not necessarily
234 tested (Kärssin *et al.*, 2016, Messiaen *et al.*, 2016). *Trichinella spiralis*, *Trichinella britovi*,
235 *Trichinella nativa*, and *Trichinella pseudospiralis* have been identified in wild boars (Bilska-
236 Zajac *et al.*, 2016, Bilska-Zajac *et al.*, 2017, Pozio, 2015, Rostami *et al.*, 2017a).

237 Antibodies to *Trichinella* were detected in wild boars from 4 continents (Tables 1 and
238 1S). In most of the countries (Australia, Greece, South Korea and the USA) the seroprevalence
239 was between 3% and 13% (Cuttell *et al.*, 2014, Hill *et al.*, 2014, Kim *et al.*, 2015, Lee *et al.*,
240 2015, Pedersen *et al.*, 2017b, Touloudi *et al.*, 2015). A high seroprevalence of 42% and 17% in
241 Estonian wild boars was reported using ELISA and Western blot, respectively (Kärssin *et al.*,
242 2016). In Italy, the seroprevalence was 22% and 10% using ELISA and Western blot,
243 respectively (Gómez-Morales *et al.*, 2014). Clearly lower prevalence of *Trichinella* has been
244 reported in the muscle tissue by digestion method (Table 2S). The highest detection rates were
245 between 2% and 4% reported in Latvia, Romania, Vietnam, Iran and the USA (Hill *et al.*, 2014,
246 Kirjušina *et al.*, 2015, Nicorescu *et al.*, 2015, Rostami *et al.*, 2018, Thi *et al.*, 2014).

247

248 **Foodborne viruses in wild boar**

249 **Hepatitis E virus**

250 Hepatitis E is a zoonotic disease caused by HEV, a single-stranded RNA virus of the
251 *Hepeviridae* family (Aprea *et al.*, 2018, Syed *et al.*, 2018). This species currently includes seven
252 genotypes, HEV1–7, of which HEV1-4 have been identified in humans. HEV3 has mainly been
253 identified in pigs and wild boars worldwide (Pavio *et al.*, 2017, Prpic *et al.*, 2015). HEV3 strains
254 from wild boars circulating in Italy have shown to be genetically related to human and pig
255 strains in Italy (Aprea *et al.*, 2018, Caruso *et al.*, 2015, Di Profio *et al.*, 2016). HEV causes
256 acute hepatitis, which is typically self-limiting, but can sometimes lead to chronic infection and
257 hepatic failure (Pavio *et al.*, 2017). Hepatitis E is an important human disease in developing
258 countries, but is also considered an emerging disease in many industrial countries (Clemente-
259 Casares *et al.*, 2016, Spahr *et al.*, 2018, Syed *et al.*, 2018).

260 More than 16% of the German and Swedish population have antibodies to HEV (Roth *et*
261 *al.*, 2016, Weigand *et al.*, 2018). In Germany and Poland, 22% of the hunters carried antibodies
262 to HEV but in Estonia only 4% (Baumann-Popczyk *et al.*, 2017, Ivanova *et al.*, 2015, Schielke
263 *et al.*, 2015). HEV is transmitted through direct contact with infected pigs and the consumption
264 of contaminated raw or undercooked pork products including wild boar meat (Brown *et al.*,
265 2018, Faber *et al.*, 2018, Pavio *et al.*, 2017). Liver from an infected pig is regarded as the main
266 infection source (Mazzei *et al.*, 2015, Renou *et al.*, 2014, Risalde *et al.*, 2017). Certain hepatitis
267 E outbreaks have recently been reported due to contaminated wild boar meat (Renou *et al.*,
268 2014, Rivero-Juarez *et al.*, 2017) (Table 3).

269 High seroprevalences of hepatitis E (>30%) in wild boars were reported in Japan and
270 several European countries (Charrier *et al.*, 2018, Hara *et al.*, 2014, Kukielka *et al.*, 2016,
271 Larska *et al.*, 2015, Mazzei *et al.*, 2015, Motoya *et al.*, 2016, Schielke *et al.*, 2015, Spancerniene
272 *et al.*, 2016, Thiry *et al.*, 2017, Weiner *et al.*, 2016, Žele *et al.*, 2016) (Tables 1 and 1S). In

273 North-Central Italy, the seroprevalence of hepatitis E varied significantly between provinces:
274 the lowest prevalence in wild boars was 4% and the highest 49% (Martinelli *et al.*, 2015).
275 Substantial differences between geographical areas were also reported in Switzerland (Burri *et*
276 *al.*, 2014).

277 HEV was recently detected in 2% to 34% of wild boars studied in Europe using PCR
278 (Table 2). HEV was mostly detected in liver and blood samples but also in fecal and muscle
279 samples (Table 2S). High detection rates of HEV (>20%) were reported in Czech Republic,
280 France, Germany, Italy, Lithuania, Poland, Portugal and Spain (Anheyer-Behmenburg *et al.*,
281 2017, Dorn-In *et al.*, 2017, Jori *et al.*, 2016, Kubankova *et al.*, 2015, Mesquita *et al.*, 2016,
282 Montagnaro *et al.*, 2015, Rivero-Juarez *et al.*, 2018, Spancerniene *et al.*, 2018).

283

284 **Transmission of foodborne zoonotic pathogens from wild boars to livestock and humans**

285 Foodborne zoonotic pathogens have been detected in wild boars worldwide indicating
286 that wild boars are an important reservoir of foodborne zoonoses. The role of wild boars in
287 transmitting foodborne zoonoses is still poorly understood. Transmission may occur directly
288 through contact with infected wild boars or their carcasses and offal, or through handling and
289 consumption of contaminated wild boar meat (Ruiz-Fons, 2017). Indirect transmission may
290 occur through water, typically water from irrigation ponds, or food, such as agricultural crops,
291 contaminated by feces of infected wild boars. Indirect transmission can also occur through
292 livestock, especially outdoor pigs, and companion animals, such as hunting dogs, infected by
293 wild boars or the meat and offal thereof (Franco-Paredes *et al.*, 2017). Domestic pigs are
294 particularly at risk of inter-population transmission with wild boars because they belong to the
295 same species and share the same community of potential pathogens (Pearson *et al.*, 2014).
296 Transmission can occur through different routes, including oral route, through the respiratory
297 system, and through direct contact e.g. transmission through skin wounds (Ruiz-Fons, 2017).

298 Wild boar hunting and the consumption of wild boar meat are increasing, leading to
299 greater chances of direct human exposure to wild boar zoonoses (Sannö *et al.*, 2018). People
300 handling wild boars, including hunters, slaughterhouse workers and veterinarians, are
301 especially at risk (Franco-Paredes *et al.*, 2017). Direct transmission during hunting, especially
302 during evisceration and skinning, may lead to infection through direct contact with the organs
303 and tissues of infected wild boars. One typical route of *Brucella* infection is cutaneous exposure
304 through skin wounds to body fluids and tissues from infected wild boars during field dressing
305 and butchering of carcasses (Franco-Paredes *et al.*, 2017, Mailles *et al.*, 2017). HEV can also
306 be transmitted to humans through cutaneous exposure to the blood or bloody fluids of infected
307 wild boars during slaughter (Baumann-Popczyk *et al.*, 2017, Caruso *et al.*, 2015, Miller *et al.*,
308 2017, Schielke *et al.*, 2015). Direct transmission of enteric pathogens, such as *Salmonella* and
309 *Yersinia*, can easily occur during field dressing through contaminated hands and equipment
310 (Cummings *et al.*, 2016). *Mycobacterium* is mainly transmitted by aerosol, and especially
311 hunters, slaughterhouse workers and veterinarians are at risk of developing tuberculosis through
312 inhalation (Madeira *et al.*, 2017). However, fecal shedding of wild boars has been reported in
313 Spain and Portugal (Barasona *et al.* 2017, Santos *et al.* 2015).

314 The consumption of wild boar meat increases the risk of human exposure to foodborne
315 infections. The exposure risk is influenced by eating habits, such as eating undercooked wild
316 boar meat or cured and fermented wild boar sausages or other meat products, which are
317 widespread habits among game meat consumers. The handling and consumption of
318 undercooked meat, and especially liver and cured sausages containing the liver of infected wild
319 boars can result in HEV transmission and increase the risk of HEV infection in humans (Khuroo
320 *et al.*, 2016, Miller *et al.*, 2017, Serracca *et al.*, 2015, Szabo *et al.*, 2015). Consumption of raw
321 or undercooked wild boar meat also presents a significant risk for trichinellosis and
322 toxoplasmosis (Calero-Bernal *et al.*, 2016, Murrell, 2016).

323 Wild boars invading agricultural lands in search of food can contaminate crops and water
324 with fecal pathogens. Wild boars excrete *Salmonella* and enteropathogenic *Yersinia* in their
325 feces, which increases the contamination risk of crops and irrigation water (Cummings *et al.*,
326 2016). *B. suis* was recently detected in wild boar feces, indicating that crops and water may also
327 be contaminated with this pathogen through wild boar feces (Lama & Bachoon, 2018). Close
328 contact between wild boars and livestock can result in pathogen transmission to food-producing
329 animals with outdoor access (Jori *et al.*, 2017). Wild boars may play an important role in the
330 dissemination of HEV between domestic pigs and wild boars (Aprea *et al.*, 2018, Jori *et al.*,
331 2016). Biological indicators may help to understand and characterize contacts between wild
332 and domestic animals in the future (Barth *et al.*, 2017).

333

334 **Control of foodborne zoonotic pathogens from wild boars**

335 Wild boars may pose a threat to public and animal health, especially in areas where wild
336 boar density is high. This raises concerns of direct and indirect human exposure to zoonotic
337 agents (Franco-Paredes *et al.*, 2017, Touloudi *et al.*, 2015). Contact between wild boars and
338 domestic animals, especially pigs, should be prevented (Madeira *et al.*, 2017). Controlled
339 housing conditions in pig herds decreases the exposure risk to infections from wild boars
340 (Kärssin *et al.*, 2016). However, outdoor farming may increase due to public demand for more
341 ethical and natural animal production and higher quality meat products (Jori *et al.*, 2017,
342 Murrell, 2016). Especially, pigs with outdoor access in areas of high-density wild boar
343 populations should apply biosecurity practices to prevent contact between them and wild boars
344 (Pearson *et al.*, 2016).

345 Intensive wild boar management for hunting purposes, including supplementary feeding,
346 increases the prevalence of zoonotic pathogens in wild boars and the transmission risk of
347 pathogens from wild boars to livestock and humans. Maintaining low wild boar population

348 density and restricting the use of supplementary feeding are efficient management tools for
349 controlling the spread of pathogens in the wild boar population and decreasing the transmission
350 risk (Boadella, 2015, Cano-Manuel *et al.*, 2014, Madeira *et al.*, 2017, Risco *et al.*, 2014). These
351 control strategies are especially important for controlling tuberculosis in countries where
352 livestock are considered officially free of the tuberculosis in livestock (Payne *et al.*, 2017).

353 Good hunting hygiene, especially during dressing in the field, is essential for meat safety
354 (Franco-Paredes *et al.*, 2017). People involved with hunting activities are at highest risk, and
355 need to be trained about the potential risks of zoonoses and the importance of proper and careful
356 carcass handling (Holzbauer *et al.*, 2014). Good hygiene practices along the meat chain are
357 required to control the spread of foodborne zoonotic bacteria from wild boars (Pedersen *et al.*,
358 2017b). Systematic meat inspection of wild boar carcasses is essential to control
359 *Mycobacterium* and *Trichinella* infections (Faber *et al.*, 2015, Fichi *et al.*, 2015, Mentaberre *et*
360 *al.*, 2014, Turiac *et al.*, 2017).

361 Wild boar carcasses and offal should not be left in the field during hunting and dressing,
362 because they can serve as infection sources for wild and domestic animals. Proper disposal of
363 hunting waste is very important for controlling wild boar diseases and the transmission of
364 pathogens to other grazing food-producing animals (Cano-Terriza *et al.*, 2018, Carrasco-Garcia
365 *et al.*, 2018). The seroprevalence of MTC is very high in wild boars in areas where hunting
366 waste has not been properly disposed of (Cano-Manuel *et al.*, 2014, Pérez de Val *et al.*, 2017).
367 Infected wild boars may hamper the eradication of tuberculosis, brucellosis, and trichinellosis
368 in livestock with outdoor access, especially in areas where wild boar population density is high
369 (Barasona *et al.*, 2017, Nugent *et al.*, 2015, Rivière *et al.*, 2017).

370 Wild boar meat consumers need to be informed of the potential risks of foodborne
371 diseases and the importance of proper handling and cooking of wild boar meat (Holzbauer *et*
372 *al.*, 2014, Lhomme *et al.*, 2015). Wild boar meat should be heat-treated to an appropriate

373 temperature (internal temperature between 70 and 75C°), and hands and kitchen surfaces should
374 be thoroughly washed after preparing meat. Avoiding consuming raw sausages and salami
375 (especially short-ripened products with high water activity) from wild boars is recommended
376 (Turiac *et al.*, 2017). Freezing meat before heat-treatment is an effective step to reducing the
377 risk of meat-borne infections. *Toxoplasma* is sensitive to freezing and therefore only frozen
378 wild boar meat should be used if raw pork products are consumed.

379

380 **Conclusions**

381 Wild boars may pose a threat to human and animal health, especially in areas where wild
382 boar density is high. The interaction between wild boars and domestic animals facilitates the
383 spread of zoonotic pathogens from wild boars to food-producing animals and the maintenance
384 of zoonotic pathogens in wild boar populations. Wild boars can frequently be infected by
385 foodborne pathogens such as *Brucella*, *Mycobacterium*, *Salmonella*, *Yersinia*, *Trichinella*,
386 *Toxoplasma*, and HEV. However, seroprevalences to these pathogens differ highly between
387 countries and regions. Wild boars may be an important reservoir for these zoonotic pathogens
388 and an emerging threat to food safety. Preventive interventions are therefore needed, such as
389 decreasing wild boar density, restricting supplementary wild boar feeding, and applying
390 adequate biosecurity measures for livestock. Hunters should be trained on hunting hygiene and
391 proper handling and disposal of wild boar carcasses and offal. Wild boar meat consumers
392 should be advised to handle the meat properly and only eat sufficiently heat-treated meat and
393 meat products. Additional research and monitoring of foodborne pathogens in wild boars is
394 needed to better understand the transmission routes and to control the risks to human and animal
395 health.

	Sweden	90	24	26.7	Tonsils, feces, lymph nodes	PCR	(Sannö et al., 2018)
<i>Yersinia enterocolitica</i>	Sweden	88	9	10.2	Tonsils, feces	PCR+Culture	(Sannö et al., 2014)
	USA	442	194	43.9	Feces	Culture	(Cummings et al., 2016)
	Germany	111	19	17.1	Tonsils	Culture	(von Altrock et al., 2015)
	Poland	434	110	25.3	Feces	Culture	(Syczko et al., 2018)
	Poland	151	40	26.5	Feces	Culture	(Bancerz-Kisiel et al., 2016)
	Spain	72	24	33.3	Tonsils	PCR	(Arrausi-Subiza et al., 2016)
	Sweden	90	28	31.1	Tonsils, feces, lymph nodes	PCR	(Sannö et al., 2018)
<i>Yersinia</i>	Sweden	88	18	20.5	Tonsils, feces	PCR+Culture	(Sannö et al., 2014)
	Germany	503	32	6.4	Tonsils	PCR+Culture	(Reinhardt et al., 2018)

<i>pseudotuberculosis</i>	Spain	72	18	25.0	Tonsils	PCR	(Arrausi-Subiza et al., 2016)
	Sweden	90	20	22.2	Tonsils, feces, lymph nodes	PCR	(Sannö et al., 2018)
<i>Toxoplasma</i>	Sweden	88	17	19.3	Tonsils, feces	PCR+Culture	(Sannö et al., 2014)
	Italy	65	1	1.5	Diaphragm	PCR	(Papini et al., 2018)
	Italy	105	17	16.2	Muscle	PCR	(Ferroglio et al., 2014)
<i>Trichinella</i>	Spain	61	9	14.7	Brain, myocardium	PCR	(Calero-Bernal et al., 2015)
	Canada	22	0	<4.5	Diaphragm, tongue	Digestion	(McGregor et al., 2015)
	Italy	1462	1	0.1	Diaphragm	Digestion	(Gómez-Morales et al., 2014)
	Latvia	3174	80	2.5	Diaphragm, tongue	Digestion	(Kirjušina et al., 2015)
	Poland	1012021	5203	0.5	Muscle	Digestion	(Flis et al., 2017)
	Poland	16737	91	0.5	Diaphragm	Digestion	(Bilska-Zajac et al., 2016)
	Romania	5596	93	1.7	Muscle	Digestion	(Nicorescu et al., 2015)
	Vietnam	62	2	3.2	Diaphragm, masseter	Digestion	(Thi et al., 2014)
	Iran	79	3	3.7	Muscle	Digestion	(Rostami et al., 2018)
<i>Trichinella britovi</i>	USA	330	6	1.8	Tongue	Digestion	(Hill et al., 2014)
Hepatitis E virus	Croatia	536	66	12.3	Blood, liver, spleen	PCR	(Prpic et al., 2015)
	Czech Republic	450	96	21.3	Feces, liver, bile	PCR	(Kubankova et al., 2015)
	France	346	101	29.3	Blood	PCR	(Jori et al., 2016)
	France	352	8	2.3	Liver	PCR	(Jori et al., 2016)
	France	86	5	5.8	Liver	PCR	(Lhomme et al., 2015)
	Germany	104	4	3.8	Blood	PCR	(Weigand et al., 2018)
	Germany	137	33	24.1	Blood	PCR	(Anheyer-Behmenburg et al., 2017)
	Germany	46	7	15.0	Blood	PCR	(Schielke et al., 2015)
	Germany	22	4	18.0	Liver	PCR	(Schielke et al., 2015)
	Germany	22	1	4.5	Muscle	PCR	(Schielke et al., 2015)
<i>Giardia lamblia</i>	Italy	196	3	1.5	Feces	PCR	(Di Profio et al., 2016)
	Italy	291	40	13.7	Liver	PCR	(Aprea et al., 2018)
	Italy	320	12	3.8	Blood, liver	PCR	(Caruso et al., 2015)
	Italy	64	6	9.4	Feces	PCR	(Mazzei et al., 2015)
	Italy	164	55	33.5	Liver	PCR	(Montagnaro et al., 2015)

Italy	372	7	1.9	Liver	PCR	(Serracca et al., 2015)
Japan	68	7	10.3	Blood, feces, liver	PCR	(Motoya et al., 2016)
Japan	112	5	4.4	Blood	PCR	(Hara et al., 2014)
Lithuania	235	62	26.4	Blood	PCR	(Spancerniene et al., 2018)
Lithuania	270	69	25.6	Liver	PCR	(Spancerniene et al., 2018)
Poland	163	42	25.8	Blood	PCR	(Dorn-In et al., 2017)
Poland	53	5	9.4	Feces	PCR	(Dorn-In et al., 2017)
Portugal	80	20	25.0	Liver	PCR	(Mesquita et al., 2016)
Portugal	80	4	10.0	Feces	PCR	(Mesquita et al., 2016)
Slovenia	288	1	0.3	Blood	PCR	(Žele et al., 2016)
Spain	142	33	23.2	Blood	PCR	(Rivero-Juarez et al., 2018)
Spain	58	1	1.7	Blood	PCR	(Risalde et al., 2017)
Spain	58	4	6.9	Liver	PCR	(Risalde et al., 2017)
Spain	158	16	10.1	Blood	PCR	(Kukielka et al., 2016)
Sweden	134	7	5.2	Blood	PCR	(Roth et al., 2016)
Sweden	130	5	3.8	Feces	PCR	(Roth et al., 2016)
