I dedicate this thesis to my parents, whose example is my treasure, and whose love, my inspiration.

ACKNOWLEDGEMENTS

I would like to express my deepest gratitude to all the people who have made this PhD possible. I would particularly like to thank my advisors Dr. Mario Binelli and Dr. Jo Leroy. I was fortunate to train under two great scientists and I will be forever indebted to both of you for the critical sense, personal and professional skills I have developed under your supervision.

To my mentor, Dr. Mario Binelli, who gave the knowledge and tools to pursue the highest academic degree, thank you for your continued support and guidance. It has been an honor learning from your scientific philosophy. Thank you for the opportunity to work with a great and respected team. Dear Mario, thank you for teaching me that we should not be afraid of embracing new challenges. Your integrity and resilience deeply inspire me.

To my step mentor, Dr. Jo Leroy, thank you for receiving me in your wonderful research group, and for all the time, knowledge and belief that you invested in me. Thank you for having taught many aspects about mentorship under your navigation. Dear Jo, thank you for all the self-reflections. Your efficiency managing your time and the way you care about your PhD-students beyond their academic lives are remarkable and inspiring.

.

I am grateful to the graduate programs of the University of São Paulo and University of Antwerp for providing me all the conditions to conduct my research. It has been an honor to be part of two Universities of excellence. I would also like to extend my gratitude to the Department of Animal Sciences, University of Florida, for receiving me in the last months of my PhD. Being among a diverse scientific community represents a unique and enriching opportunity in my short scientific career and I will always be grateful for that.

I would like to thank all the people from the international offices, represented by Isabela Furegatti at the University of São Paulo, and Simone Kramer at the University of Antwerp, that made the double-PhD possible and for their endless support with the bureaucratic parts of the process.

I would also like to thank all the professors, staff and colleagues from the Department of Animal Reproduction, University of São Paulo, and from the Department of Veterinary Sciences, University of Antwerp.

I was very fortunate to have had the opportunity to work with two great research teams along this journey. I want to thank all my LFEM-mates: Estela, Milena, Mae, Saara, Moana, Everton, Roney, Rafaela, Bia, Angela, Cecilia, Veerle, Guilherme and Emiliana. Each and every one of you has a space in my memories and in my heart. Thank you for all the good moments and for your friendship.

To my GRC-mates, Waleed, Jessie, Anouk, Lies, Karolien, Anniek, Chiara and Lotte, thank you all for welcoming me and for making my stay in Belgium lighter and funnier. To Dr. Peter Bols, thank you for your hospitality during my stay at the Gamete Research Centre. It was a pleasure to meet you and to listen to your many stories about Brazil. Els and Silke, thank you very much for your

outstanding technical assistance in performing the *in vitro* experiments. You are the best! Britt, thank you for all your help with the paperwork to keep me legal in Belgium. You all together made my research stay incredibly memorable.

To my LFEM/Florida-mattes, Gabriela and Felipe, thank you for bringing lightness to our routine.

I would also like to acknowledge all the LMMD colleagues for always being supportive and for sharing their facilities and equipment with us.

A special thank you to my guinea pigs Nathália and Jens. I hope you both learned as much as I did during our time working together in the lab.

.

This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES) - Finance Code 001 (PDSE program; 88881.132730/2016-01). I am grateful to CNPq and the Special Research Fund of the University of Antwerp for the scholarships granted during my PhD.

.

To the jury members, Drs. Felipe Percin, Marcella Pecora Milazzotto, and Mayra Elena Ortiz D'Avila Assumpção, thank you for your time, critical reading, advice and suggestions to improve the quality of this thesis.

.

To my family, who supported me through the process. Specially, to my wonderful parents, Benhur and Rosi, who have all my admiration. Thank you for having taught me that I have to do my best always. Thank you for allowing me to fly and pursuit my dreams, even though for many times I was absent. Thank you for the example, support and encouragement.

To my sister, Julhana, and my brother, Mateus, thank you for filling my life with love and joy. I am very proud of what you both became. I consider myself the luckiest one in the world for having both of you by my side. Thank you for being there when I was missing.

To my brother-in-law Nelson, and my sister-in-law July, for completing our family.

To my family-in-law, specially D. Norma, who has taught me many lessons about life. You are an inspiring human being. Thank you for taking care of Nina better than I would do.

.

To my friends, both near and far, for the good moments, for keeping me sane and grounded.

To my beloved Belgian family, Julie, Shanty and Billy. You were there!

.

Finally, I thank my husband Thiago for his ever-sustaining support, encouragement and love. You are my balance and my ground. You are an example of human being in any aspect and it has been a privilege to share my life with you.

.

I extend my sincere gratitude to all the animals that were part of the experiments during these years.

RESUMO

SPONCHIADO, M. **Decifrando o interactoma materno-embriônico:** Programação do funcionamento do endométrio dependente do embrião durante a gestação inicial em bovinos. 224 p. Tese (Doutorado em Ciências e Ciências Veterinárias) – Faculdade de Medicina Veterinária e Zootecnia, Universidade de São Paulo, São Paulo, e Faculdade de Ciências Farmacêuticas, Biomédicas e Veterinárias, Universidade da Antuérpia, Antuérpia, 2019.

O sucesso gestacional depende do programa embrionário intrínseco, operando em conjunto com fatores extrínsecos que emanam do trato reprodutivo materno, bem como de uma coordenada interação entre as unidades materna e embrionária. Atualmente, o conhecimento sobre a programação do funcionamento do endométrio dependente do embrião pré-elongado é limitado. A hipótese central desta tese é que embriões bovinos são capazes de modular a função endometrial no dia 7 após o estro. No primeiro estudo, regiões espacialmente definidas do transcriptoma endometrial foram interrogadas quanto a respostas a um embrião no dia 7 *in vivo*. Amostras de endométrio foram coletadas da junção útero-tubárica, região anterior, medial e posterior do corno uterino ipsilateral ao corpo lúteo 7 dias após o estro de vacas Nelore artificialmente inseminadas e confirmadas gestantes, ou de vacas em que a inseminação foi mimetizada. A abundância de 12 dos 87 transcritos analisados foi modulada no endométrio de animais gestantes, incluindo genes estimulados por interferon (ISGs) e genes associados à biossíntese de eicosanoides. As alterações foram predominantemente nas porções mais craniais do corno uterino, onde o embrião estava localizado. Além disso, a abundância de 71 transcritos variou de acordo com a região do trato reprodutivo, independentemente da presença do embrião. Quantificação baseada em espectrometria de massa de 205 metabólitos no fluido luminal uterino (ULF) recuperado da porção mais cranial do corno uterino ipsilateral mostrou que a exposição ao embrião altera a composição do ULF no dia 7 *in vivo*. Modulações induzidas pelo embrião incluem aumento nas concentrações de metabólitos derivados da via das lipoxigenases e diminuição nas concentrações de aminoácidos, aminas biogênicas, acilcarnitinas e fosfolípidios. Alterações na composição do ULF podem ser devido à secreção ou depleção de moléculas específicas, executadas pelo embrião ou pelo endométrio, mas iniciadas por sinais provenientes do embrião. No segundo estudo, um modelo *in vitro* foi usado para estudar as alterações induzidas por embriões no transcriptoma de células epiteliais endometriais bovinas (BEEC) e investigar modos de comunicação molecular entre tecidos. Mórulas produzidas *in vitro* foram co-cultivadas em justaposição ou sem contato direto com BEECs. Grupos de BEECs ou embriões sozinhos

foram cultivados como controles. Independentemente da justaposição à monocamada, o co-cultivo com BEECs melhorou as taxas de blastocistos no dia 7,5. A proximidade física entre embriões e a monocamada de células, no entanto, alterou a natureza e a intensidade das alterações induzidas pelos embriões no transcriptoma das células endometriais. Embriões justapostos modularam a transcrição de 1.797 versus 230 genes em BEECs não contactando diretamente os embriões, quando comparadas às células cultivadas na ausência de embriões. Vias moduladas pela presença de embriões incluíram resposta imune mediada por interferon, regulação do ciclo celular e apoptose, sinalização via prolactina e biossíntese de prostanoides. Coletivamente, a partir dos resultados obtidos nesta tese, concluímos que embriões bovinos pré-elongamento são capazes de modular a função endometrial. A presente tese fornece vias candidatas que parecem ser importantes para o condicionamento do ambiente uterino para o desenvolvimento do conceito. A sinalização embrionária precoce pode ser necessária para garantir o desenvolvimento ideal e o estabelecimento da gestação em bovinos.

OVERZICHT

SPONCHIADO, M. **Ontcijferen van de embryo-maternale interactoom:** Embryo-afhankelijke programmering van endometriale werking gedurende de vroege dracht bij runderen. 224 p. Tese (Doutorado em Ciências) – Faculdade de Medicina Veterinária e Zootecnia, Universidade de São Paulo, São Paulo, e Faculdade de Ciências Farmacêuticas, Biomédicas e Veterinárias, Universidade da Antuérpia, Antuérpia, 2019.

Een succesvolle dracht is afhankelijk van de intrinsieke embryonale programmering en collaboreert met de extrinsieke signalen die het maternale voortplantingsstelsel afgeeft, alsook door een gecoördineerde interactie tussen de embryonale en de moedereenheden. Actuele kennis is beperkt van de pre verlengende embryonaal afhankelijke programmering van de endometriale werking in runderen. De algemene hypothese is dat embryo's van runderen vanaf ten vroegste dag 7 na de bronst de endometriale werking kunnen regelen. In de eerste studie werden ruimtelijk gedefinieerde regio's van het endometrium transcriptoom geobserveerd voor responsen op een dag 7 embryo *in vivo*. Endometriale stalen werden verzameld van de uterotubale aansluiting, de anterieure, mediale en posterieure regio's van de baarmoederlijke hoorn, ipsilateraal tegenover de corpus luteum 7 dagen na de bronst van schijn geïnsemineerde of kunstmatige geïnsemineerde, bevestigd zwangere Nelore koeien. Een aanzienlijke 12 van de 87 geanalyseerde transcripten waren gemoduleerd in het bevruchte endometrium, inclusief klassieke interferon-opgewekte genen en transcripten die geassocieerd worden met eicosanoïde biosynthese. De voornaamste veranderingen vonden plaats in de craniale portie van de baarmoederlijke hoorn, waar de embryo's gelegen zijn. Bovendien varieerde het merendeel van de 71 transcripten in overeenstemming met de regio van het voortplantingsgestel, onafhankelijk van de drachtstatus. Gerichte massa spectrometrie-gebaseerde kwantificatie van 205 metaboliëten in het baarmoederlijk lumaal vocht, gerecupereerd van het meest craniale deel van de ipsilaterale baarmoederlijke hoorn, toonde aan dat blootstelling aan een dag-7 embryo de baarmoederlijk lumaal vocht (ULF) composiet *in vivo* verandert. Embryonaal opgewekte modulatie zorgde voor een stijging van de concentraties van lipoxygenase-afgeleide metaboliëten en een daling van de concentratie van aminozuren, biogenische amines, acylcarnitiënen en fosfolipiden. De veranderde samenstelling van de ULF kan afhankelijk zijn van afscheiding of afname van specifieke moleculen, veroorzaakt door ofwel de embryo of het endometrium, maar geïnitieerd door de signalen die het embryo uitstuurt. Voor de tweede studie werd een *in vitro* model gebruikt om

de embryonaal opgewekte veranderingen in runder-endomitriale epitheliale cellen (BEECs) transcriptoom door te lichten en te onderzoeken op welke manieren de tussenweefsel moleculaire communicatie gebeurt. *In vitro*-geproduceerde morulae werden samen gekweekt in juxtapositie of zonder direct contact met een BEEC-monolaag. Extra groepen BEECs of enkelvoudige embryo's warden gekweekt als controle. Onafhankelijk van de juxtapositie tegenover de cellulaire monolaag, verbeterde co-cultuur met BEECs blastocysten ratio's op dag 7.5. Echter, de fysieke nabijheid tussen de embryo's en de BEEC-monolaag wijzigde de natuur en de intensiteit van de embryonaal opgewekte veranderingen op het BEEC transcriptoom. Embryo's juxtapositioneerden gemoduleerde transcriptie van 1,797 versus 230 genen in BEECs zonder direct contact, in relatie tot cellen die zonder nabijheid van embryo's gewekt werden. Trajecten die gemoduleerd waren door de nabijheid van embryo's bevatten interferon-gemedieerde immuunreacties, celcyclus regulatie en apoptose, prolactine signalisatie en prostanoid biosynthese. Uiteindelijk, op basis van de behaalde resultaten gedurende deze thesis, concluderen wij dat peri-ontwikkelde runderembryo's de endomitriale functie moduleren. Op basis hiervan voorzien wij kandidaat systemen die belangrijk kunnen zijn om de baarmoederlijke omgeving te conditioneren voor conceptus ontwikkeling. Vroege embryonale signalisatie kan nodig zijn om optimale ontwikkeling en de succesvolle aantoning van dracht in runderen te garanderen.

ABSTRACT

SPONCHIADO, M. **Deciphering the embryo-maternal interactome:** Embryo-dependent programming of endometrial function during early pregnancy in cattle. 224 p. Tese (Doutorado em Ciências e Ciências Veterinárias) – Faculdade de Medicina Veterinária e Zootecnia, Universidade de São Paulo, São Paulo, e Faculdade de Ciências Farmacêuticas, Biomédicas e Veterinárias, Universidade da Antuérpia, Antuérpia, 2019.

A successful pregnancy is dependent on the intrinsic embryonic program, operating in conjunction with extrinsic signals emanating from the maternal reproductive tract, as well as on a coordinated interaction between the embryonic and the maternal units. Current knowledge about the pre-elongation embryo-dependent programming of endometrial function in cattle is limited. Central hypothesis is that bovine embryos are able to modulate the endometrial function as early as day 7 after estrus. In the first study, spatially defined regions of the endometrium transcriptome were interrogated for responses to a day 7 embryo *in vivo*. Endometrial samples were collected from the uterotubal junction, anterior, medial and posterior regions of the uterine horn ipsilateral to the corpus luteum 7 days after estrus from sham-inseminated or artificially inseminated, confirmed pregnant Nellore cows. Abundance of 12 out of 87 transcripts analyzed was modulated in the pregnant endometrium, including classic interferon-induced genes and transcripts associated to eicosanoid biosynthesis. Changes were predominantly in the most cranial portion of the uterine horn, where the embryos were located. In addition, abundance of 71 transcripts varied according to region of the reproductive tract, irrespective to the pregnancy status. Targeted mass spectrometry-based quantification of 205 metabolites in the uterine luminal fluid (ULF) recovered from the most cranial portion of the ipsilateral uterine horn showed that exposure to a day-7 embryo changes ULF composition *in vivo*. Embryo-induced modulation included an increase in concentrations of lipoxygenase-derived metabolites and a decrease in concentrations of amino acids, biogenic amines, acylcarnitines and phospholipids. The changed composition of the ULF could be due to secretion or depletion of specific molecules, executed by either the embryo or the endometrium, but initiated by signals coming from the embryo. In the second study, an *in vitro* model was used to probe embryo-induced changes on bovine endometrial epithelial cells (BEECs) transcriptome and investigate modes of inter-tissues molecular communication. *In vitro*-produced morulae were co-cultured in juxtaposition or without a direct contact with a BEEC monolayer. Extra groups of BEECs or embryos alone were cultured as controls.

Irrespective of juxtaposition to the cell monolayer, co-culture with BEECs improved blastocyst rates on day 7.5. Physical proximity between embryos and the BEEC monolayer, nevertheless, did alter nature and intensity of embryo-induced changes on BEEC transcriptome. Embryos juxtapositioned modulated transcription of 1,797 versus 230 genes in BEECs not contacting embryos directly, in relation to cells cultured in the absence of embryos. Pathways modulated by presence of embryos included interferon-mediated immune responses, cell cycle regulation and apoptosis, prolactin signaling, and prostanoid biosynthesis. Overall, from the results obtained in the course of this thesis, we conclude that peri-hatching bovine embryos modulate the endometrial function. Herein, we provide candidate systems that might be important for conditioning the uterine environment for conceptus development. Early embryonic signaling might be necessary to guarantee optimal development and successful establishment of pregnancy in cattle.

CHAPTER 1
GENERAL INTRODUCTION

1 GENERAL INTRODUCTION

Reproductive efficiency is a major factor impacting the profitability of livestock systems. Subfertility often manifests as early embryonic death. This is especially true in cattle. Indeed, up to 40% of all pregnancies are terminated before maternal recognition of pregnancy, which occurs around day 16 post-estrus (Diskin *et al.*, 2011), indicating that early embryonic mortality is a major cause of reproductive inefficiency in the bovine species. One major reason for this is the disturbance of the embryo-maternal dialogue. Fundamentally, a successful pregnancy requires a balance between a properly programmed embryo and a receptive endometrium. Although both mother and embryo contribute to the establishment of pregnancy, in the present thesis the role of the maternal unit will be the main subject, with emphasis on the endometrium.

The overall hypothesis of this Thesis is that bovine embryos are able to modulate the endometrial function as early as day 7 after conception. The existence of a complex embryo-maternal interactome between a pre-elongation embryo and the endometrium provides the theoretical basis for the present thesis. The concept of embryo-maternal interactome comprises molecular processes by which the embryo may affect the mother and vice versa. **The central objective of this Thesis was to characterize/gain insights into the embryo-induced changes on the endometrial function during early gestation in cattle.** In this Introduction, aspects of early gestation in cattle will be discussed, with a focus on individual and mutual contributions of the embryonic and the maternal units to the establishment of a successful pregnancy. Further, evidences from other studies in literature of an early cross-talk between the embryo and the maternal reproductive tract that supported our central hypothesis will be provided. Last, we will discuss the microenvironment that surrounds the embryo *in vivo* and the possible modes of inter-tissues molecular communication. The studies that were conducted to test the central and specific hypotheses of this Thesis are presented in three Chapters, each organized as a scientific manuscript. The final pages of this PhD Thesis have been reserved for a General Discussion, which summarizes the main findings presented in the previous chapters, and provides directions for future research.

1.1 THE ENDOMETRIUM, THE EMBRYO, AND THEIR INTERACTOME: A SYSTEM OF ADDITIVE COMPLEXITY

The embryo starts to interact directly with the endometrium around days 4-5 after insemination/breeding, when the zona-enclosed morula enters the lumen of the uterine horn ipsilateral to the ovary containing the corpus luteum (CL; Bazer *et al.*, 1991). From then onwards, the embryo *in utero* undergoes rapid and dynamic morphological changes including blastulation, hatching from the zona pellucida, elongation, apposition and attachment to the uterine epithelium, around day 20 after insemination/breeding, leading to initial formation of the placenta. An overview of the main events taking place in the uterus during the pre-implantation period in the cow is provided in Figure 1. From its arrival in the uterus, the embryo grows from approximately 200 μm in diameter to several centimeters in length by day 16 of pregnancy. At that time, the elongated conceptus (embryo and associated membranes) becomes able to abrogate the endometrium-driven, pre-programmed release of pulses of $\text{PGF}_{2\alpha}$ that cause luteolysis. Once maternal recognition of pregnancy has occurred, the uterus stays under the long-term influence of luteal progesterone and pregnancy is maintained.

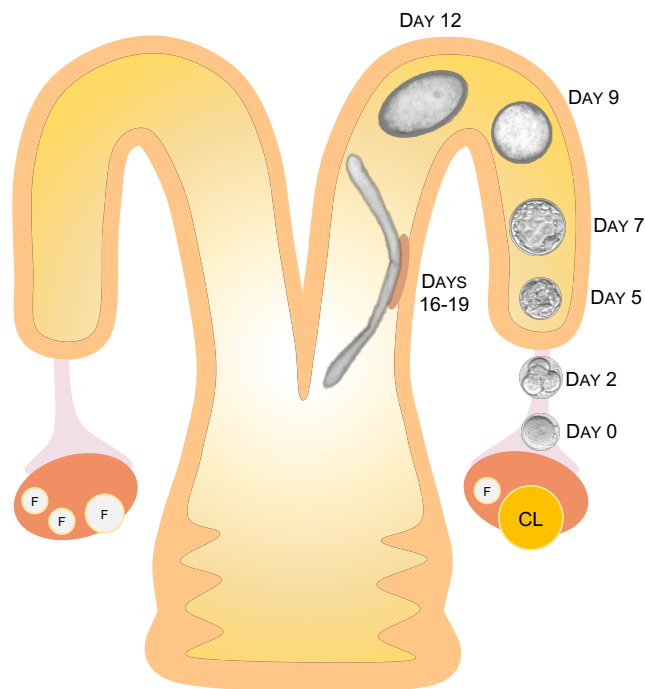

Figure 1. Overview of embryo/conceptus development in relation to position in the female reproductive tract during early pregnancy in cattle. Following ovulation, fertilization of the bovine oocyte takes place in the oviduct. The resulting zygote moves towards the utero-tubal junction as it undergoes the first cellular divisions. The zona pellucida-enclosed morula enters the uterus on days 4-5 after estrus and is only about 120-200 μm in diameter. The blastocyst is formed by day 7, and consists of an inner cell mass which forms the embryo/fetus, and a blastocoele surrounded by a monolayer of trophoblast, which gives rise to the extraembryonic membranes. The hatched-blastocyst (day 9) grows and changes in morphology from a spherical to an ovoid shape (day 12). By day 14, the 6 mm conceptus (embryo and extraembryonic membranes) elongates to a filamentous form, and reaches a length of several cm by day 19. The elongation process marks the beginning of an anatomical union between the embryonic and maternal units, which involves apposition (day 16), transient attachment (day 17-18) and adhesion (day 19-21) of the trophoblast cells to the lining endometrium (Guillomot, 1995). F Follicles, CL Corpus luteum.

The bovine embryo that develops successfully utilizes a set of mechanisms that depend on its intrinsic capacity to develop, as well as on external cues originating from the surrounding tissues.

On the **embryonic side**, it is well conceived that a successful embryo maintains basic tools for its own development. Decades of *in vitro* embryo production have taught us that embryos of a variety of species can thrive successfully beyond the blastocyst stage in culture, independently of exposure to the maternal reproductive tract. Moreover, the fact that a relatively simple culture medium composition allows embryo survival leads to the idea that the uterus might provide not more than a permissive milieu for the early developing embryo. However, it is clear that the maternal reproductive tract, including the uterus, exerts considerable control over the ability of a conceptus to develop. For example, several studies have demonstrated that *in vivo* cultured embryos are of superior quality compared to their *in vitro*-produced counterparts in many aspects, including quality and developmental competence (Rizos *et al.*, 2002a), morphology (Van Soom & De Kruif, 1992), incidence of chromosome abnormalities (Viuff *et al.*, 1999), relative transcript abundance (Rizos *et al.*, 2002b; Lonergan *et al.*, 2003), and cryotolerance (Fair *et al.*, 2001). Additionally, exposure to uterus-derived factors seems to be a prerequisite for conceptus elongation post-hatching in domestic ruminants. This is based on the fact that elongation does not occur in the absence of uterine glands (Gray *et al.*, 2000) and that attempts to artificially induce elongation of bovine conceptuses *in vitro* have been unsuccessful (Brandao *et al.*, 2004).

The uterine lumen contains a unique milieu that has embryotrophic properties. Endocrine factors that regulate the maternal reproductive tract function have been investigated extensively. In this respect, it is known that the **ovarian sex-steroids** (i.e. estradiol and progesterone) exert temporal and spatial control over many uterine functions that support embryonic development. For example, progesterone produced by the CL, acts on its cognate receptors in the endometrial tissue in a classical endocrine fashion, regulating endometrial secretions essential for stimulating and mediating changes in conceptus growth and differentiation throughout early pregnancy (Carter *et al.*, 2008; Clemente *et al.*, 2009; Forde *et al.*, 2009; Forde *et al.*, 2010; Forde *et al.*, 2011a; Mesquita *et al.*, 2015). Aspects of the spatial-programming of endometrial function exerted by ovarian steroids and systemic factors are discussed in **Chapter 2 of the present thesis**, entitled "Pre-hatching embryo-dependent and -independent programming of endometrial function in cattle".

In addition to the endocrine, sex-steroidal control of endometrial function, we hypothesize that the developing embryo/conceptus *in uterus* provides local signals that

program the endometrium towards a more receptive status. Although specific factors orchestrating the embryo-maternal interactome are currently unknown, it is reasonable to conceive that the embryonic contribution to the embryo-maternal interactome would primarily depend upon the intrinsic competence of the embryo to develop, and on its capacity of synthesis and secretion of signaling molecules. In this scenario, the endometrial contribution would rely on an appropriate exposure of the maternal genital tract to sex steroids to ensure endometrial receptivity to the developing embryo and responsiveness to the embryo-derived signals.

1.2 EMBRYO-MATERNAL COMMUNICATION IN CATTLE PRIOR TO ELONGATION: IS THE ENDOMETRIUM THE SOLE SPEAKER?

While the influence of the uterine milieu on proper embryo development and pregnancy establishment is well accepted, the embryonic contribution in modulating the endometrium has not been investigated to the same extent. Holistic analysis comparing the bovine endometrium transcriptome of pregnant versus cyclic animals was first reported by Klein *et al.* (2006). In this study, endometrial tissues collected on day 18 of pregnancy from monozygotic twin heifers that were sham-transferred or had a confirmed pregnancy were compared by using a combination of subtraction cDNA libraries and cDNA array hybridization. A number of 87 genes were identified as upregulated in pregnant animals. Authors stated that almost one half of the genes that were upregulated in pregnant animals are known to be stimulated by type I interferons. Subsequently, a number of studies reported that embryos of different developmental fates elicited different responses from the endometrial transcriptome on day 18 of pregnancy (Bauersachs *et al.*, 2009; Mansouri-Attia *et al.*, 2009). Forde *et al.* (2011b) conducted a critical study comparing the endometrial transcriptome between cyclic and inseminated (pregnant) heifers on days 5, 7, 13 or 16 of pregnancy/estrous cycle. A clear separation between cyclic and pregnant endometrial transcriptome profiles was only detectable on day 16, coinciding with the window of maternal pregnancy recognition. In agreement with previous reports later in pregnancy, Forde and coauthors (2011) found that the abundance of transcripts increased to the greatest extent in pregnant endometria were associated with type I interferon-signaling. Taken together, these studies supported the idea that embryo-mediated modulation of endometrial function would occur after conceptus elongation in cattle. Earlier communication between embryo and endometrium seems not to be present.

In vitro studies, however, indicate that the pre-elongation bovine embryo is active in releasing a range of signaling factors into the culture medium (reviewed by Wydooghe *et al.*, 2011). These molecules, referred as to embryotropins, are secreted in several ways including passive outflow, regulated or constitutive active secretion, bound to a carrier molecule or transport within extracellular vesicles (Wydooghe *et al.*, 2017). Embryotropins have the potential to act upon the embryo itself in an autocrine way, or on maternal tissues, in juxtacrine, paracrine or endocrine fashion. It is reasonable, nonetheless, to assume that the capacity of synthesis and secretion of signals by the pre-elongation embryo is limited to its size or cellular machinery of roughly 200 cells. In this regard, the lack of differences on the endometrial transcriptome triggered by the pre-elongation embryo might be attributed to its disproportional small size and limited capacity of secretion of factors in the context of the uterine horn, that is several centimeters in length. Thus, the pre-elongation embryo is hypothesized to evoke local effects, confined to the surrounding tissues.

In the past few years a number of studies have shown that pre-hatching bovine embryos are able to induce transcriptional changes in the oviduct *in vivo* (Almiñana *et al.*, 2014; Maillo *et al.*, 2015) and *in vitro* (García *et al.*, 2017). In the study of Maillo *et al.* (2015), the authors failed to detect an effect of a single 8-cell embryo on the transcriptome of the oviduct; conversely, when 50 embryos were laparoscopically transferred per heifer, in an attempt to amplify and detect putative local oviductal responses to embryos, significant transcriptome changes were detected. Therefore, the authors attributed the failure to detect changes in the oviductal transcriptome in the presence of a single embryo to the fact that any effects of the embryo on the oviduct would be spatially restricted and would not be detected due to the miniscule “embryo to oviduct tissue ratio”. Furthermore, the migratory feature of the embryo inside the oviduct could lead to a transitory change on the local oviductal transcriptome. The emerging indication of a local effect elicited by the embryo from its vicinities drove the first hypothesis of the present thesis. **We hypothesized that exposure to an embryo changes the abundance of specific transcripts in the endometrial regions in closest proximity to the embryo in the pregnant uterine horn.** Therefore, in our first study, we interrogated spatially defined regions of the ipsilateral uterine horn for responses to a day 7 embryo *in vivo*. We demonstrated for the first time that a day 7 embryo modulates interferon signaling and eicosanoid biosynthesis pathways in the endometrium, at the transcriptional level, and that most changes were found in the most cranial portions (i.e. uterotubal-junction and anterior third) of the ipsilateral uterine horn, where the embryos were

located (Sponchiado *et al.*, 2017). This *in vivo* study was conducted at the University of São Paulo, Pirassununga, São Paulo – Brazil, and composes the **Chapter 2 of this Thesis**.

A remaining open question was whether the embryo-induced changes in the endometrial transcriptome *in vivo* lead to changes in the uterine luminal fluid (ULF) composition. The ULF is the ultimate link between the pre-implantation embryo and the uterus. Thus, the second study was centered in the **hypothesis that the embryo modulates the biochemical composition of the ULF in the most cranial portion of the uterine horn ipsilateral to the CL**. Using a mass spectrometry-based quantification of over 200 compounds, we demonstrated that the pre-hatching embryo changes uterine luminal metabolite composition *in vivo*. These results are compiled and discussed in **Chapter 3 of this Thesis**, entitled “The pre-hatching bovine embryo transforms the uterine luminal metabolite composition *in vivo*”, that has been submitted for publication in Nature Scientific Reports journal.

How does the embryo communicate with the surrounding tissues; what are the molecules involved in this process; and whether the embryo would benefit from the local cross-talk with the endometrium during its journey throughout the uterine lumen are examples of the many unanswered questions that remain in this topic. To understand how the embryo interacts with the underlying endometrium, we first needed to probe the microenvironment that surrounds it in the uterine lumen *in vivo*.

1.3 THE EMBRYO-MATERNAL INTERACTOME IN A UNIQUE INTERFACE

When one thinks about the context of the preimplantation embryo *in uterus*, the image that comes will likely show the pre-hatching embryo bathing in maternal secretions. However, this does not represent the *in vivo* situation. Ultrasound images in the horse, for example, show that a day-12 blastocyst is tightly surrounded by the maternal endometrium (Herrler *et al.*, 2003). The fact is that the embryo-maternal interface during early pregnancy is poorly known for most mammalian species, including cattle.

The embryo-endometrial interactome comprises dynamic molecular processes elicited by the embryo on the endometrium and vice-versa. Signaling molecules are understood to play an important role in the cross-talk between the maternal and the embryonic units. The concept of communication implies in a **cellular origin of the signaling agent**, a **cellular target that is able to decode the message**, and ultimately a **response triggered by the primary signal or associated messengers**.

Regarding signaling agents, they are molecules that play a functional role in the early embryo-maternal communication in cattle, given that there is no anatomical adhesion between the non-invasive embryo and the underlying endometrium until day 20 of pregnancy. Signaling factors involved in the embryo-maternal dialogue are secreted by the embryo to act on the maternal tissue, and vice-versa, in four putative mechanisms. Fundamentally, a signaling factor can activate receptors on the cell of its origin in a so-called **autocrine** stimulation, or it can be released into the extra-cellular milieu, spreading through the surrounding tissue in a **paracrine** fashion, or it can be secreted in the blood stream and reach the target cell or tissue in an **endocrine** mode. Additionally, effector cells may communicate with adjacent recipient cells in a **juxtacrine** fashion. Figure 2 illustrates the mechanism by which embryo-derived molecules could participate in the embryo-maternal dialogue. One classical example of paracrine and endocrine signaling triggered by the bovine embryo towards the mother is Interferon-tau (IFN τ). The conceptus-derived IFN τ is released into the uterine lumen and exerts paracrine antiluteolytic effects on the endometrium inhibiting the upregulation of oxytocin receptors in the endometrial epithelia, thereby preventing the production of luteolytic prostaglandin F2 alpha (PGF $_{2\alpha}$) pulses. Also, IFN τ upregulates a large number of classical interferon-stimulated genes (ISGs) and regulates expression of many other genes in a cell-specific manner in the endometrium that are likely important for conceptus elongation, implantation and establishment of pregnancy. Further, IFN τ has endocrine effects on extrauterine cells and tissues, such as the CL, and blood cells (reviewed by Hansen *et al.* 2017).

Figure 2. Schematic illustration of putative mechanisms by which embryo-derived signaling molecules would act in the maternal reproductive tract.

Effects of the embryo on the directly adjacent endometrial cells are poorly defined. In the **third study of this Thesis** we addressed the question of whether the endometrial responses differ between the juxtacrine and the non-juxtacrine fashion. **We hypothesized that embryo-induced changes on endometrial transcriptome depend on physical proximity between the embryos and the endometrium.** Therefore, we used an *in vitro* co-culture system of bovine endometrial epithelial cells (BEEC) and morula-to-blastocyst embryos to interrogate the embryo-maternal interface for embryo-induced changes on the endometrial epithelial cells transcriptome. This study was carried out at the Gamete Research Centre, University of Antwerp – Belgium, and composes the **Chapter 4** of this thesis, entitled “The bovine embryo-endometrium interactome deciphered *in vitro*”.

2 PRE-HATCHING EMBRYO-DEPENDENT AND -INDEPENDENT PROGRAMMING OF ENDOMETRIAL FUNCTION IN CATTLE

2.1 ABSTRACT

The bovine pre-implantation embryo secretes bioactive molecules from early development stages, but effects on endometrial function are reported to start only after elongation. Here, we interrogated spatially defined regions of the endometrium transcriptome for responses to a day 7 embryo *in vivo*. We hypothesize that exposure to an embryo changes the abundance of specific transcripts in the cranial region of the pregnant uterine horn. Endometrium was collected from the uterotubal junction (UTJ), anterior (IA), medial (IM) and posterior (IP) regions of the uterine horn ipsilateral to the CL 7 days after estrus from sham-inseminated (Con) or artificially inseminated, confirmed pregnant (Preg) cows. Abundance of 86 transcripts was evaluated by PCR using a microfluidic platform. Abundance of 12 transcripts was modulated in the Preg endometrium, including classical interferon-stimulated genes (*ISG15*, *MX1*, *MX2* and *OAS1Y*), prostaglandin biosynthesis genes (*PTGES*, *HPGD* and *AKR1C4*), water channel (*AQP4*) and a solute transporter (*SLC1A4*) and this was in the UTJ and IA mainly. Additionally, for 71 transcripts, abundance varied according to region of the reproductive tract. Regulation included downregulation of genes associated with proliferation (*IGF1*, *IGF2*, *IGF1R* and *IGF2R*) and extracellular matrix remodeling (*MMP14*, *MMP19* and *MMP2*) and upregulation of anti-adhesive genes (*MUC1*) in the cranial regions of uterine horn. Physical proximity to the embryo provides paracrine regulation of endometrial function. Embryo-independent regulation of the endometrial transcriptome may support subsequent stages of embryo development, such as elongation and implantation. We speculate that successful early embryo-dependent and -independent programming fine-tune endometrial functions that are important for maintenance of pregnancy in cattle.

2.2 INTRODUCTION

In cattle, pre-implantation embryo development starts after successful fertilization and continues until initial migration of giant trophoblast cells from the conceptus trophoderm to the maternal luminal epithelium and lasts approximately 20 days (Spencer *et al.*, 2007). The morula-stage embryo reaches the uterus 4 to 5 days post-estrus, develops to the blastocyst stage by day 7, hatches from the zona pellucida on days 9-10 and develops into a tubular conceptus that begins to elongate on day 15 to a filamentous form that occupies the entire length of the ipsilateral uterine horn by day 19 (Guillomot, 1994). Around day 16 the apposition and transient attachment of the trophoblastic cells to the uterine epithelium begins. After day 19, the elongating conceptus is adhered to the luminal epithelium and placentation starts (Guillomot *et al.*, 1981).

An important feature of the pre-implantation embryo development in cattle is that the embryo/conceptus relies solely on uterine secretions (i.e., the histotroph) to supply required nutrients and growth factors. The histotroph is composed of molecules synthesized and secreted by the endometrial glandular and luminal epithelia as well as selectively transported from blood (Bazer *et al.*, 2011). Endometrial secretion and transport of molecules to the uterine lumen are spatially and temporally programmed processes. Programming can be put forth by embryo-independent and -dependent factors and their interaction.

Fluctuations of sex steroid concentrations during the periovulatory period and throughout pre-implantation development exert classical endocrine, embryo-independent programming, while secretions from the developing embryo/conceptus act on a paracrine fashion inside the uterine lumen to modulate endometrial function. Dysregulation of this complex interplay leads to early embryonic mortality, which ranges from 25 to 30% in beef cattle (Diskin & Sreenan, 1980).

Regarding embryo/conceptus-mediated programming of endometrial function, a critical unanswered question is when in pre-implantation development does it start (Thatcher *et al.*, 2001). It is well established that after starting elongation, there is an increasing capacity of the conceptus to secrete interferon-tau (IFN τ ; Kubisch *et al.*, 1998), which modulates prostaglandin synthesis in the endometrium to block luteolytic pulses of prostaglandin F $_{2\alpha}$ (PGF $_{2\alpha}$) and to favor prostaglandin E $_2$ (PGE $_2$) secretion (Arosh *et al.*, 2016; Spencer *et al.*, 2013). However, to the best of our knowledge, there is no evidence that the embryo affects endometrial function before elongation, which begins 13 days after AI (Forde *et al.*, 2011). However, *in vitro* culture studies demonstrated that preimplantation embryos secrete a range

of biochemical messengers that act in concert to promote embryonic development, referred to as embryotropins (reviewed by Wydooghe *et al.*, 2015). Interestingly, many of these factors have cognate receptors expressed in the uterus. Activation of such receptors could lead to cellular and tissue responses such as transcription and *de novo* synthesis of proteins and metabolites, as well as post-transcriptional and post-translational modifications of molecules pre-existing in the endometrium (Salamonsen *et al.*, 2013). It is reasonable to expect that pre-elongation embryo-derived factors regulate endometrial transcription in regions that are in close physical association to the embryo. In the present study we interrogated spatially defined regions of the endometrium transcriptome for responses to a day 7 embryo *in vivo*. We hypothesize that exposure to an embryo changes the abundance of specific transcripts in the cranial region of the pregnant uterine horn.

Regarding sex-steroid programming of endometrial function, (1) manipulation of pre-ovulatory follicle growth and associated changes in proestrus estradiol (E2) and diestrus progesterone (P4) concentrations (Mesquita *et al.*, 2015; Ramos *et al.*, 2015; Scolari *et al.*, 2016) and (2) exogenous supplementation of P4 during early diestrus regulates the endometrial transcriptome and function (Forde *et al.*, 2009, 2010), and fertility (Pugliesi *et al.*, 2016). More importantly, the effects of sex steroid hormones depend on their bioavailability to the endometrium and the nature and abundance of specific receptors in the endometrium. Regarding bioavailability, anatomical evidence indicates a distinct sex-steroids input according to the region of the reproductive tract. Specifically, the vascular arrangement of vessels that irrigate the uterus allows a greater input of ovarian steroids to the cranial portion of the uterine horn ipsilateral to the ovary containing the CL compared to the cranial portion of the contralateral horn and compared to the mid-caudal region of either horn (Pope *et al.*, 1982). Araújo *et al.* (2015) proposed that such spatial changes in ovarian steroid input regulate local endometrium gene expression and function. Furthermore, they showed decreasing endometrial abundance of *PGR* and *ESR2* transcripts from the cranial to the caudal region of the uterine horn. This suggests that responsiveness to steroids may also be regionally controlled. Despite the clear implications of such regional specificities on the regulation of uterine function to support conceptus development, there is a lack of information on target pathways that could be modulated along the uterine horn.

Objective was to measure pre-hatching embryo-dependent and -independent effects on the abundance of select transcripts associated with uterine function to support gestation along the uterine horn in beef cows.

2.3 MATERIALS AND METHODS

Experiments were carried out at the University of São Paulo in Pirassununga, São Paulo, Brazil. All experimental procedures involving animals were approved by the Ethics and Animal Handling Committee of the School of Veterinary Medicine and Animal Science of the University of São Paulo (CEUA-FMVZ/USP, n3167260815). Protocol was in accordance with the ethical principles in animal research.

2.3.1 Reproductive management and treatments

All animals were maintained in a single *Brachiaria brizantha* pasture, supplemented with chopped sugarcane, concentrate and minerals to fulfill their maintenance requirements and received water *ad libitum*.

The estrous cycles of reproductively normal multiparous Nelore (*Bos taurus indicus*, n = 36; average body weight 531 ± 12 kg) cows were synchronized by insertion of an intravaginal P4-releasing device (1 g; Sincrogest®, Ourofino Saúde Animal, Cravinhos, São Paulo, Brazil) and i.m. administrations of PGF_{2α} analogue (500 µg of sodium cloprostenol; Sincrocio®, Ourofino Saúde Animal) and estradiol benzoate (2 mg; Sincrodiol®, Ourofino Saúde Animal) on day -10 (D-10; Fig. 1). At the time of P4-device removal (D-3), animals received an i.m. administration of PGF_{2α} and an Estroject™ heat detector patch (Rockway, Inc. Spring Valley, WI, USA). Cows were visually observed for signs of estrus activity twice a day between 48 and 84 h after P4-releasing device withdrawal. Cows observed in standing heat or presenting an activated heat detector patch were considered in estrus (n = 30; D0 of the study). Animals were allocated randomly to one of two experimental groups 12 h after standing estrus. In the control group (Con; n = 8), cows were sham-inseminated with deposition of semen extender in the uterine body; in the Pregnant group (Preg; n = 16), cows were artificially inseminated with frozen-thawed semen from the same batch of a bull of proven fertility. All procedures were performed by a single technician. Ovulation was checked 12 hours later by B-mode transrectal ultrasonography, and only cows with a confirmed, single ovulation were maintained in the experiment (n = 24).

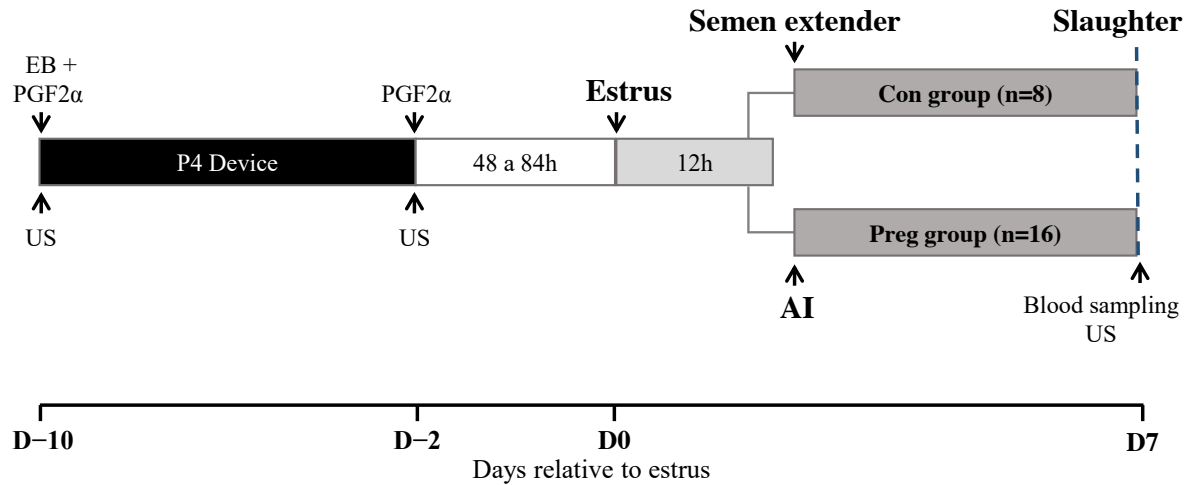

Figure 1. Experimental design. The estrous cycles of Nelore cows ($n = 36$) were synchronized using an 8-day progesterone-releasing intravaginal device. On day -10 (D -10), cows received a progesterone-releasing device (1 g; Sincrogest; Ourofino) and an injection of 2 mg estradiol benzoate (EB; Sincrodiol, Ourofino) and an injection of prostaglandin F 2α (PGF 2α ; 500 μ g of sodium cloprostenol; Sincrocio, Ourofino). On D -3 , when the progesterone-releasing device was removed, all cows received an extra injection of PGF 2α . At estrus (D0), cows were allocated to one of two experimental groups: Control (Con), cows were sham-inseminated and received semen extender; Pregnant (Preg), cows were inseminated with semen from the same batch of semen from a bull of proven fertility, 12 h post-estrus. All cows were slaughtered on D7.

Transrectal ultrasonography (7.5-MHz transducer, DP-50 vet; Mindray, Shenzhen, Guangdong, China) was also performed to measure CLs and follicles on D -10 and D -3 , side and size of the preovulatory follicle and ovulation on D0 and D1, and to confirm the CL development on D7.

2.3.2 Endometrial sample collection

Animals were slaughtered on D7 after estrus. Between 4 and 8 animals, from both experimental groups, were slaughtered in each of four independent sessions. Reproductive tracts were isolated and transported on ice to the laboratory within 10 min to uterus processing. Uterus were trimmed free of surrounding tissues. The ipsi and contralateral horns relative to ovary containing the CL were isolated. Average uterine horns length was 27.12 ± 0.70 cm [mean \pm SEM]. For each uterine horn, always starting from the horn ipsilateral to the CL, forceps were placed every 8 cm starting from the utero-tubal junction (UTJ) to delimit the anterior, medial and posterior uterine thirds (Fig. 2). The anterior, medial and posterior thirds were individually washed with 3, 5 and 6 mL of PBS, respectively, and the flushing was recovered in a petri dish. The presence and location of an embryo in the flushings was verified under a stereomicroscope in the Preg group animals. All embryos found ($n = 10/16$) were at

the expected stage of development (compact morula or early, not-hatched blastocyst) and were in the flushing obtained from the anterior third. Inseminated cows from which no embryo was recovered ($n = 6$) were excluded from the experiment.

Figure 2. Schematic representation of sites selected for collection of endometrial samples. Panel A: Endometrial tissue samples were collected from 8 regions of the uterus: uterotubal junction (UTJ) ipsi and contralateral to the ovary containing the CL and the intermediate portion of the anterior, medial and posterior thirds of the ipsilateral uterine horn, that were further divided in mesometrial (M) and antimesometrial (A) sides. Panel B: Representative cross-section of the uterine horn indicating the sites for endometrium collection according to the mesometrium insertion.

After flushing, the ipsilateral uterine thirds were incised longitudinally at the mesometrial insertion. From each third, a 1 cm-wide strip of intercaruncular endometrium was dissected transversally from the lengthwise intermediate portion of the third. Then, each strip was subdivided in mesometrial and antimesometrial sides. Endometrial component of the ipsi and contralateral UTJ was collected, but not further subdivided. Once collected, the endometrial samples were immediately transferred to cryotubes and snap frozen in liquid nitrogen. Samples were stored at -80°C until further processing. Only intercaruncular endometrium was collected because there are no caruncles in the UTJ region. In addition, only intercaruncular endometrium contains endometrial glands, which are functional units that play a major role on histotroph secretion.

2.3.3 Blood sampling and progesterone concentration measurements

Prior to slaughter, blood samples were collected via jugular venipuncture for subsequent measurement of P4. Blood samples were collected into 10 mL heparinized evacuated tubes (BD, São Paulo, SP, Brazil) and were maintained in ice for 1 hour until plasma separation. Samples were centrifuged at 4 °C, 1,500 x g for 15 min and plasma was extracted and stored in sterile 2 mL vials at -20 °C until assayed.

Plasma P4 concentrations were measured by solid-phase radioimmunoassay (Immuchem Double Antibody Progesterone Kit, MP Biomedicals, Germany GmbH, Eschwege) according to manufacturer's instructions. The intra-assay coefficients of variation were 0.17% (low concentration reference) and 7.39% (high concentration reference). The detection limit (sensitivity) of the assay was 0.1 ng/mL.

2.3.4 RNA extraction and quality analysis

Endometrial fragments (~40mg) were mechanically macerated in liquid nitrogen using a stainless-steel apparatus. Subsequently, the macerate was homogenized in lysis buffer from PureLink® RNA mini kit (Ambion™, Life Technologies, Carlsbad, California, USA) and further RNA extraction performed as per manufacturer's instructions. To maximize lysis, tissue suspension was passed at least ten times through a 21-ga needle, and centrifuged at 12,000 g for 1 min at 4 °C for removal of cellular debris. Supernatant was loaded and processing in RNeasy columns. Total RNA was eluted with 30 µL of RNase free water. Concentration and purity of total RNA in extracts were evaluated using spectrophotometry (NanoVue™ Plus Spectrophotometer, GE Healthcare, UK) by the absorbance at 260 nm and the 260/280 nm ratios, respectively.

RNA integrity was assessed using automated capillary gel electrophoresis on a Bioanalyzer 2100 with RNA 6000 Nano Lab-chips (Agilent Technologies Ireland, Dublin, Ireland) according to manufacturer's instructions. Absorbance ratios (28S/18S) and RNA integrity values recorded for all RNA samples extracted ranged between 1.8 and 2.0, and 6.9 and 9.8, respectively.

Samples of RNA (200 ng) were treated for contaminating genomic DNA using DNase I Amplification Grade (Invitrogen™, Life Technologies) in accordance with manufacturer's guidelines supplied. First strand cDNA was synthesized using the High Capacity cDNA Reverse Transcription kit (Applied Biosystems™, Life Technologies) with RNaseOUT

Recombinant Ribonuclease Inhibitor (Invitrogen™, Life Technologies) according to manufacturer's instructions. Total RNA was reverse transcribed using random hexamers and incubated at 25 °C for 10 min, followed by incubation at 37 °C for 2 h and reverse-transcriptase inactivation at 85 °C for 5 min. The cDNA was stored at -20 °C for subsequent analyses.

2.3.5 Primers pairs selection and validation

Transcript abundance was determined by microfluidic dynamic array using BioMark HD (Fluidigm, South San Francisco, CA, USA) platform in a 96.96 Dynamic Array™ Integrated Fluidic Circuits (Fluidigm), which enables reaction of 96 cDNA samples with 96 genes assays in a single run. Representative genes were selected from 11 key pathways known to influence endometrial function, in addition to endogenous controls (Table 1). Primer details are provided on Supplemental S1 Table.

Table 1. Representative genes selected from key pathways known to influence endometrial function and endogenous controls.

Optimized primer pairs were designed using the Primer Express 3.0 based on GenBank Ref-Seq mRNA sequences of target genes. Oligos were aligned by Primer-BLAST (<http://www.ncbi.nlm.nih.gov/tools/primer-blast/>), to verify their identity and homology to the bovine genome. Oligonucleotides were commercially synthesized as purified salt-free products by Invitrogen (Life Technologies, São Paulo, SP, Brazil). All primer pairs were tested for their sensitivity and specificity first in conventional Real Time qPCR analysis to verify amplification conditions. Briefly, reactions were carried out in 96-well plates sealed with MicroAmp optical adhesive cover (Life Technologies) using the Step One Plus apparatus (Applied Biosystems Real-Time PCR System; Life Technologies). Reactions were conducted in a final volume of 20 μ L using 10 μ L of Power SYBR Green PCR Master Mix (Life Technologies). The PCR program consisted of an initial denaturation step at 95 °C for 10 min, followed by 40 cycles of 15 seconds at 95 °C and annealing at 60 °C for 1 min. Melting curves were obtained by stepwise increases in the temperature from 60 to 95 °C. Primer validation consisted of meeting the following criteria: i) a melt curve containing a sharp peak and devoid of additional peak(s), ii) efficiency of the standard curve ranging between 85% and 115% (based on the slope calculated for 3-fold serial dilution of a pooled cDNA sample), and iii) no amplification of the negative control (diethyl pyrocarbonate treated water replacing template cDNA on the qPCR reaction). The qPCR products identities were confirmed by sequencing and agarose gel electrophoresis for all target genes.

2.3.6 Transcript abundance analysis

Transcript abundance analysis in endometrial samples was performed using pre-selected bovine-specific primers. The mRNA abundance of 86 genes was analyzed, as indicated in Table 1, according to functional categories. Prior to qPCR thermal cycling, each sample was submitted to sequence-specific pre-amplification process as follows: 0.5 μ L assay (bovine-specific primer forward and reverse, final concentration of 500nM), 2.5 μ L 2X TaqMan[®] PreAmp Master Mix (Applied Biosystems, Foster City, CA, USA), 0.75 μ L DNase-free water and 1.25 μ L cDNA. The reactions were activated at 95 °C for 10 min followed by denaturing at 95 °C for 15 s, and annealing and amplification at 60 °C for 4 min for 10 cycles. After thermal-cycling, the pre-amplification reactions products were submitted to the process of clean up with Exonuclease I (New England BioLabs, Ipswich, MA, New England): 1.4 μ L DNase-free water, 0.2 μ L Exonuclease I Reaction Buffer and 0.4 μ L Exonuclease I, 20 U/ μ L, the digest phase was performed by 30 minutes at 37°C, followed by inactivate phase at 80 °C

for 15 minutes. The final product was diluted 7-fold prior to qPCR analysis. For gene expression analysis, the sample solution prepared consisted of 2.25 μL cDNA (pre-amplified products), 2.5 μL of SsoFast EvaGreen Supermix with low ROX (Bio-Rad, Hercules, CA, EUA) and 0.25 μL of 20X DNA Binding Dye (Fluidigm); and the assay solution: 0.25 μL of 100 μM combined forward and reverse primers, 2.25 μL of 1X DNA Suspension Buffer and 2.5 μL of 2X Assay Loading Reagent (Fluidigm). The 96.96 Dynamic Array™ Integrated Fluidic Circuits (Fluidigm) chip was used to data collection. After priming, the chip was loaded with 5 μL of each assay solution and 5 μL of each sample solution. The qPCR thermal cycling was performed in the Biomark HD System (Fluidigm) running 25 cycles using the protocol GE Fast 96x96 PCR+Melt. A negative control (diethyl pyrocarbonate treated water) was included and a primer pair (*GAPDH*) was assayed in duplicate. Quantitative analysis was carried out by using the crossing point (Cq) values during the log-linear phase of the reaction at which fluorescence increased above background for each primer assay.

Analysis of putative reference genes for qPCR studies was carried out using GeNorm version 3.5 Microsoft Excel Add in (Microsoft, Redmond, WA; Vandesompele *et al.*, 2002). The stability of the transcript abundance of reference genes including peptidylprolyl isomerase A (*PPIA*), actin beta (*ACTB*) and glyceraldehyde-3-phosphate dehydrogenase (*GAPDH*) was investigated across all samples in this study. Relative abundance was obtained after normalization of the target genes Cq values by the geometric mean of *PPIA*, *GAPDH* and *ACTB* transcript abundance values.

2.3.7 Statistical analysis

Data were analyzed using the Statistical Analysis Systems software package (SAS Inst. Inc., Cary, NC, USA) version 9.3. Continuous data were tested with Shapiro-Wilk and Levene's test to check the normality of residues and homogeneity of variances, respectively. Group effect (Con *vs.* Preg) was determined by one-way ANOVA using Type III sums of squares.

Transcript abundance data were analyzed by repeated measures in space using the MIXED procedure in two distinct models. The first model estimated the effects of group and uterine regions by Split-plot ANOVA. Fixed effects included the main plot: experimental groups (Con *vs.* Preg); sub-plot: regions (UTJ *vs.* IA *vs.* IM *vs.* IP) and the group by region interaction. The experimental unit was a plot with its unique combination of experimental group and region. Animal within treatment was used as the error term. The type of variance-

covariance structure was chosen according to the magnitude of the Akaike information criterion corrected (AICc). The matrix with the least AICc value to each variable was deemed best. When the effect of a categorical variable was significant, the Pdiff *post-hoc* test was used to determine differences between means. In the case of a significant interaction, the slice command was incorporated to the procedure to measure group effects within each region. In these analyzes, the mean relative abundance of a transcript on the antimesometrial and mesometrial sides within each uterine region was calculated to represent the region on comparisons.

The second repeated-measures analyzes aimed to compare transcript abundance between groups, uterine regions and sides, by Split-split-plot ANOVA. Fixed effects included the main plot: experimental groups (Con *vs.* Preg); sub-plot: regions (IA *vs.* IM *vs.* IP); sub-sub-plot: sides (Antimesometrial *vs.* Mesometrial) and the resulting double and triple interactions. The experimental unit was a plot with its unique combination of experimental group, region and side. Animal within treatment was used as the error term. The criteria to select the variance-covariance structure and means test were the same as described above.

Pearson's coefficient of correlation was calculated by CORR procedure. All data are expressed as means \pm standard error of the mean (\pm SEM). Treatment differences with $P \leq 0.05$ were considered significant and probability of $0.05 < P \leq 0.10$ were considered to approach significance.

2.3.8 Cluster analysis by region

Transformed group means were used for K-means clustering by Euclidian distances using the multivariate tool in Minitab statistical software (Minitab Inc., State College, PA, USA) version 17.1.0. Dendrogram was used for preliminary assessments of the number of gene clusters. Genes with significant group by region interaction were excluded from this analysis.

2.4 RESULTS

2.4.1 Animal model, ovarian and endocrine variables

Hormonal synchronization successfully generated groups of animals presenting similar ovarian morphologies and sex steroid endocrine profiles (Table 2), as expected. Specifically,

POF diameter and CL area, plasma P4 concentration and diameter of the largest follicle on D7 were similar between groups ($P > 0.1$). In the present study, plasma E2 concentrations were not quantified, but the similar largest follicle diameter measured both prior to ovulation and on D7 indicated that groups experienced similar exposure to E2 both during pre-ovulatory period and early diestrus.

Table 2. Size of ovarian structures and P4 concentrations in pregnant (Preg) and sham inseminated (Con) cows. Values are expressed as means \pm SEM.

Variables	Group		P-value
	Con (n = 8)	Preg (n = 10)	
Pre-ovulatory follicle diameter (mm)	13.57 \pm 0.71	13.87 \pm 0.41	0.70
CL area on D7 (cm ²)	2.84 \pm 0.24	2.69 \pm 0.17	0.62
Plasma P4 concentrations on D7 (ng/mL)	3.67 \pm 0.52	3.43 \pm 0.45	0.72
Largest follicle diameter on D7 (mm)	11.90 \pm 0.45	11.56 \pm 0.51	0.68

2.4.2 Confirmation of transcript abundance data generated by the microfluidic dynamic array method

To measure the repeatability of measurements taken by the Biomark HD system, the same primer pair for a reference gene (*GAPDH*) was ran twice in the same assay for all samples. The correlation coefficient (r) of this test was $r = 0.99$. To validate transcript abundance results measured by the Biomark microfluidic dynamic array system, abundance of *PPIA*, *IRF6*, *MX2* and *ISG15* transcripts from the same samples were measured by conventional Real time PCR. For each primer pair the correlation between Cqs obtained from Step One Plus and BioMark HD PCR analysis was 0.89, 0.94, 0.93 and 0.89 for *PPIA*, *IRF6*, *MX2* and *ISG15*, respectively.

2.4.3 Pre-hatching embryo modulation of endometrial transcript abundance

There was no main effect of group (Con vs. Preg) for the abundance of any of the transcripts measured; but there was a significant group by region (UTJ, IA, IM or IP) interaction for 12 of the 83 transcripts (Table 3). Interpretation of these interactions revealed that the group effect manifested predominantly in the regions in which the embryos were found (i.e. UTJ and anterior third). Remarkably, four differentially expressed genes were

classical interferon stimulated genes. The abundances of *ISG15*, *MX1*, *MX2* and *OAS1Y* mRNAs were respectively 1.98, 1.77, 2.00 and 1.50-fold greater in the UTJ of Preg vs. Con cows, but abundances were similar between groups in the remaining regions (Fig. 3). These results suggest that early embryo-derived IFNT locally induced the expression of ISGs in the endometrium. Furthermore, three differentially expressed genes were related to eicosanoid biosynthesis. The abundance of *PTGES* (a PGE₂ synthase) in the UTJ from Preg cows was upregulated (1.35-fold). Further, in the IA region from Preg group the abundance of *AKR1C4* (a PGF_{2α} synthase) and *HPGD* (an enzyme involved in prostaglandin catabolism) transcripts was reduced 0.67 and 0.76-fold, respectively (Fig. 4). Such expression patterns are consistent with the early embryo-mediated induction of PGE₂ and inhibition of PGF_{2α} synthesis in the endometrium. The proportion of transcript abundance between Preg and Con groups for the remaining genes differentially expressed ($P \leq 0.1$) in the UTJ were *AQP4* (1.58-fold), *ITGAV* (1.30-fold) and *SLC1A4* (0.52-fold). Transcripts abundance for *AMD1* (0.72-fold), *APQ4* (1.64-fold) and *ITGB1* (0.83-fold) differed ($P < 0.05$) between groups in the IA region. Only *AMD1* mRNA differed (0.77-fold; $P < 0.05$) in the IM region. A summary of embryo-dependent regional modulation of endometrial transcript abundance is presented in Figure 5.

To confirm that the up regulation of ISGs abundance in Preg UTJ was not caused by the presence or passage of sperm, we compared the abundances of *ISG15*, *MX1* and *MX2* transcripts in the UTJ from the uterine horn contralateral to the CL between Preg (contacted sperm but not the embryo) and Con (did not contact sperm or embryo) groups. Abundance of ISGs was similar between groups for all genes tested ($P > 0.1$; data in Figure S1) in the contralateral horns. Therefore, group effect noted in the ipsilateral horn was due the passage or presence of the embryo, which was unique to the ipsilateral horn and not sperm, which contacted both uterine horns.

PRE-HATCHING EMBRYO-DEPENDENT AND -INDEPENDENT PROGRAMMING
OF ENDOMETRIAL FUNCTION IN CATTLE

Table 3. Effects of Group (Preg vs. Con), Region (UTJ, IA, IM vs. IP) and Group by Region in the abundance of transcripts showing significant Group by Region (G*R) interaction.

Within each region, the abundance of each transcript was compared between Pregnant (Preg) and Control (Con) groups.

^aMagnitude of effect of group (Preg vs. Con) within each region is indicated by: ** $P \leq 0.01$; * $P \leq 0.05$; × $P \leq 0.1$.

^bData are presented as the ratio of mean transcript abundance between Preg and Con groups

^cNot significant ($P > 0.1$).

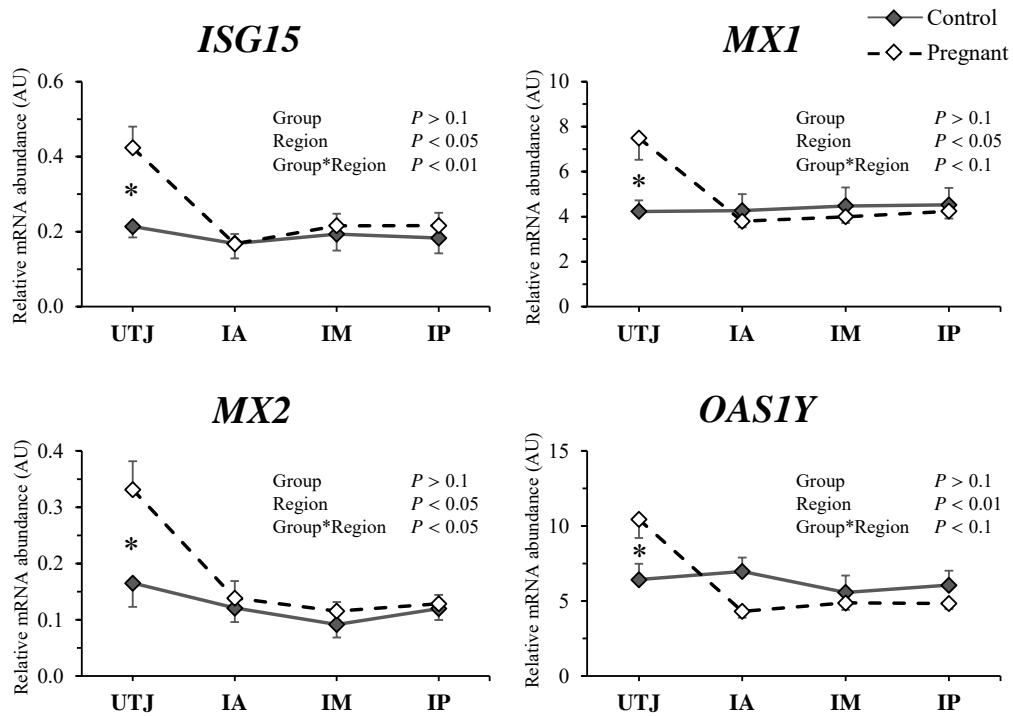

PRE-HATCHING EMBRYO-DEPENDENT AND -INDEPENDENT PROGRAMMING
OF ENDOMETRIAL FUNCTION IN CATTLE

Figure 3. Relative mRNA abundance of interferon-stimulated genes (arbitrary units; AU; mean \pm SEM) for control (solid lines) and pregnant (dashed lines) cows in the uterotubal junction (UTJ), anterior (IA), medial (IM) and posterior (IP) regions of the uterine horn ipsilateral to the CL. * $P < 0.05$ and * $P < 0.1$ denotes that significant differences were reached or approached, respectively, between groups at each specific region.

Figure 4. Relative mRNA abundance of eicosanoid biosynthesis related genes (arbitrary units; AU; mean \pm SEM) for control (solid lines) and pregnant (dashed lines) cows in the uterotubal junction (UTJ), anterior (IA), medial (IM) and posterior (IP) regions of the uterine horn ipsilateral to the CL. * $P < 0.05$ and * $P < 0.1$ denotes that significant differences were reached or approached, respectively, between groups at each specific region.

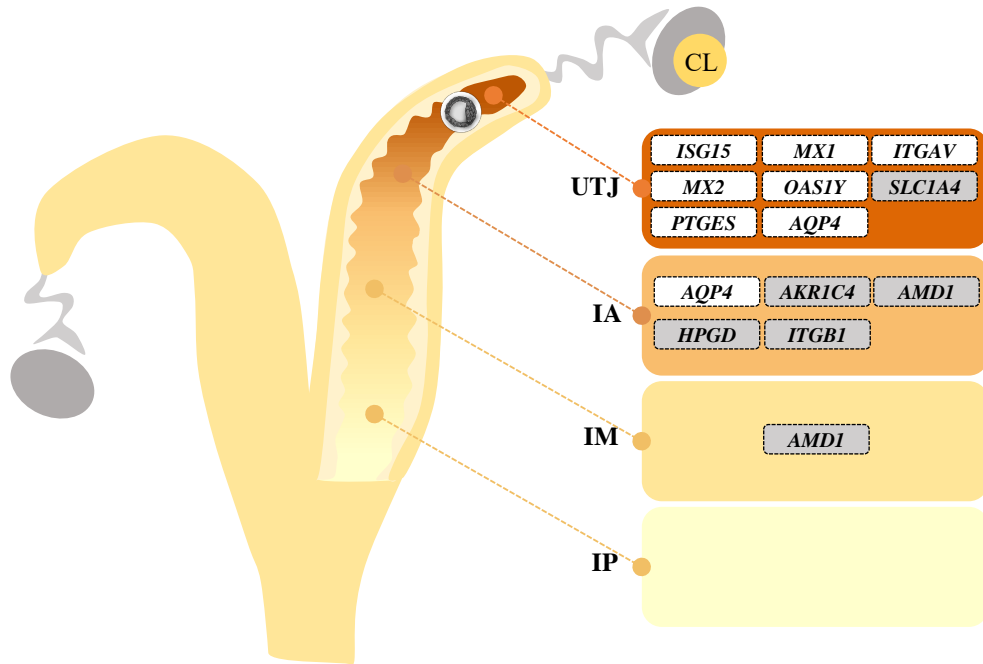

Figure 5. Summary of embryo-dependent effects. Schematic representation of distribution of transcripts affected by Group by Region (UTJ, uterotubal junction; IA, anterior; IM, medial; IP, posterior) interaction in the uterine horn ipsilateral to the CL. The position of each differentially expressed gene in the figure indicate an upregulation (placed inside a white box) or downregulation (placed inside a gray box) in the Pregnant compared to Control cows within each region.

2.4.4 Pre-hatching embryo-independent regional regulation of endometrial transcript abundance

We evaluated transcript abundance of 83 key genes associated with endometrial receptivity to the embryo in 4 regions along the ipsilateral uterine horn and established a spatial signature of endometrial transcript abundance. There was an effect of region in the expression pattern of most genes (85.5% [71/83]; Supplemental S2 Table). Genes with similar abundance patterns along the ipsilateral uterine horn were grouped by K-means analysis in four clusters. Regional patterns of expression are represented in Figure 6; a list of gene symbols assigned to each cluster is in Table 4. In general, we observed a contrasting pattern of transcript abundance in the UTJ compared to the other regions. It is remarkable that in the UTJ region there were many genes that were downregulated compared to the remaining regions, in which the expression patterns were more balanced (Clusters 2 and 3). Specifically, Cluster 1 presents a strikingly different pattern of expression in comparison to Clusters 2 and 3; there are 11 genes upregulated in the UTJ region, which are associated with developing embryo support, (*FGF2*, *PTGIS* and *SLCO2A1*), interferon signaling (*IFNAR2* and *IFI6*) and adhesive glycoproteins (*FNI* and *MUC1*). Cluster 2 was composed of 25 genes that were

downregulated in the UTJ and whose expression increased gradually in the IA, IM and IP thirds. Interestingly, some of these genes are associated with a non-receptive endometrium. For example, *IGF1*, *IGF1R*, *IGF2*, *IGF2R*, and *KDR* are associated with proliferation, and *MMP14*, *MMP19*, *MMP2* and *TIMP3* are linked to extracellular matrix remodeling. The Cluster 3 included 11 genes whose expression was drastically downregulated in the UTJ and similar among others regions, including *AKR1B1*, *ANPEP*, *SLC13A5* and *SLC5A6*. Finally, the genes in cluster 4 (24 genes) presented similar expression pattern across the four uterine regions.

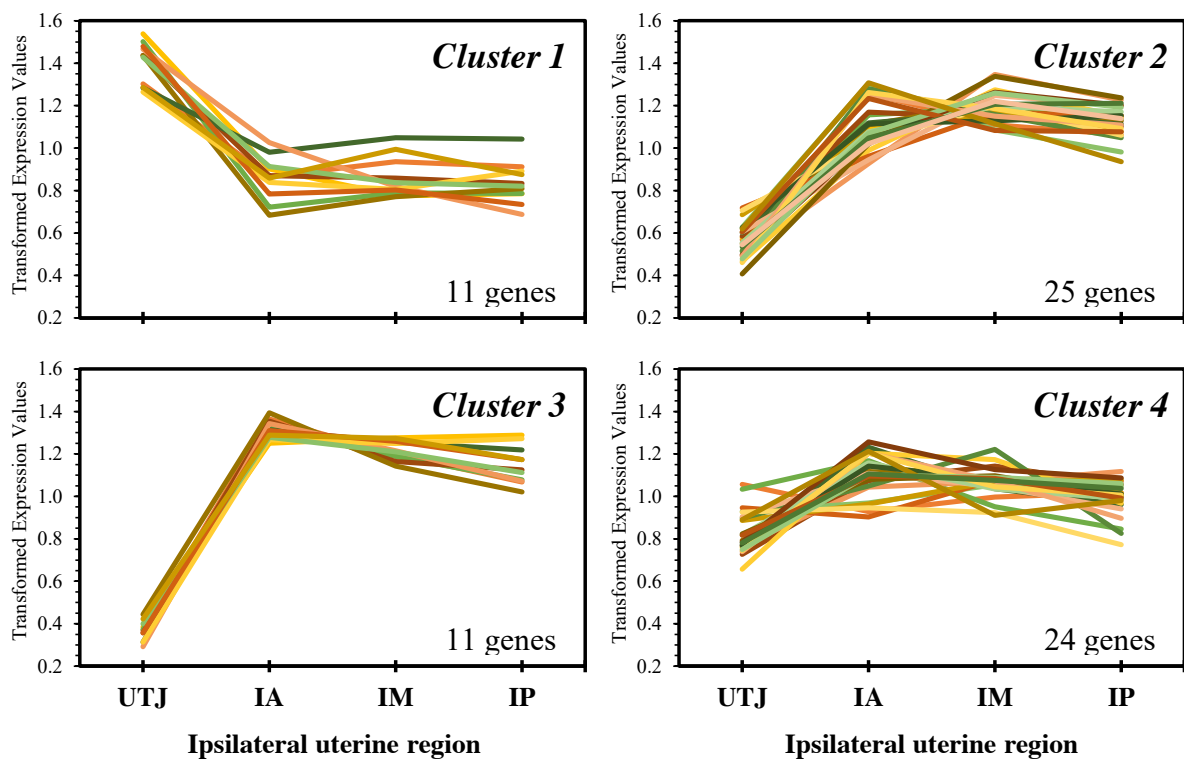

Figure 6. Cluster analysis showing uterine spatial signatures of transcript abundance in the uterotubal junction (UTJ), anterior (IA), medial (IM) and posterior (IP) regions of the ipsilateral uterine horn. Relative expression was mean-centered and clustered by K-means. Genes present in each cluster are in Table 4.

Table 4. Genes representing clusters shown in Figure 6.

2.4.5 Pre-hatching embryo-independent side regulation of endometrial transcript abundance

Transcript abundance in the mesometrial and antimesometrial sides of the uterine horn was evaluated on IA, IM and IP uterine thirds. In general, the effect of side was slight. From the 83 genes evaluated, the abundance of only eight genes [$\sim 10\%$ (8/83)] was affected by side (Fig. 7A) and the abundance of nine genes [$\sim 11\%$ (9/83)] was affected by a region by side interaction (Fig. 7B). These analyzes revealed that the main effect of side was predominant in the IM and IP uterine thirds. In general, transcript abundance was less in the mesometrial side, indicating the presence of inhibitory effects in proximity to larger vessel blood supply. A summary of side-dependent modulation of endometrial transcript abundance is presented in Figure 8.

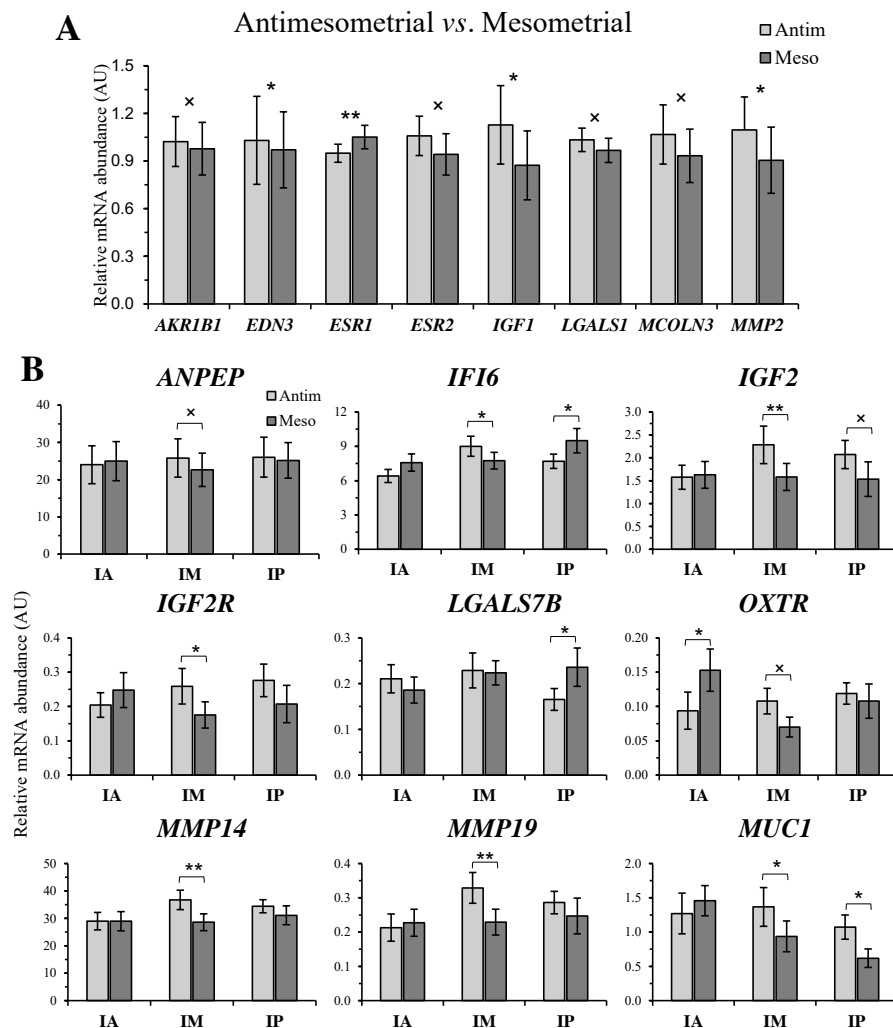

Figure 7. Relative mRNA abundance of genes affected by Side (antimesometrial vs. mesometrial; Panel A; arbitrary units: AU; mean \pm SEM) and by the Side by Region (IA, IM vs. IP; Panel B; arbitrary units: AU; mean \pm SEM) interaction in the uterine horn ipsilateral to the CL. * $P < 0.05$ and * $P < 0.1$ denotes that significant differences were reached or approached, respectively, between sides at each specific region.

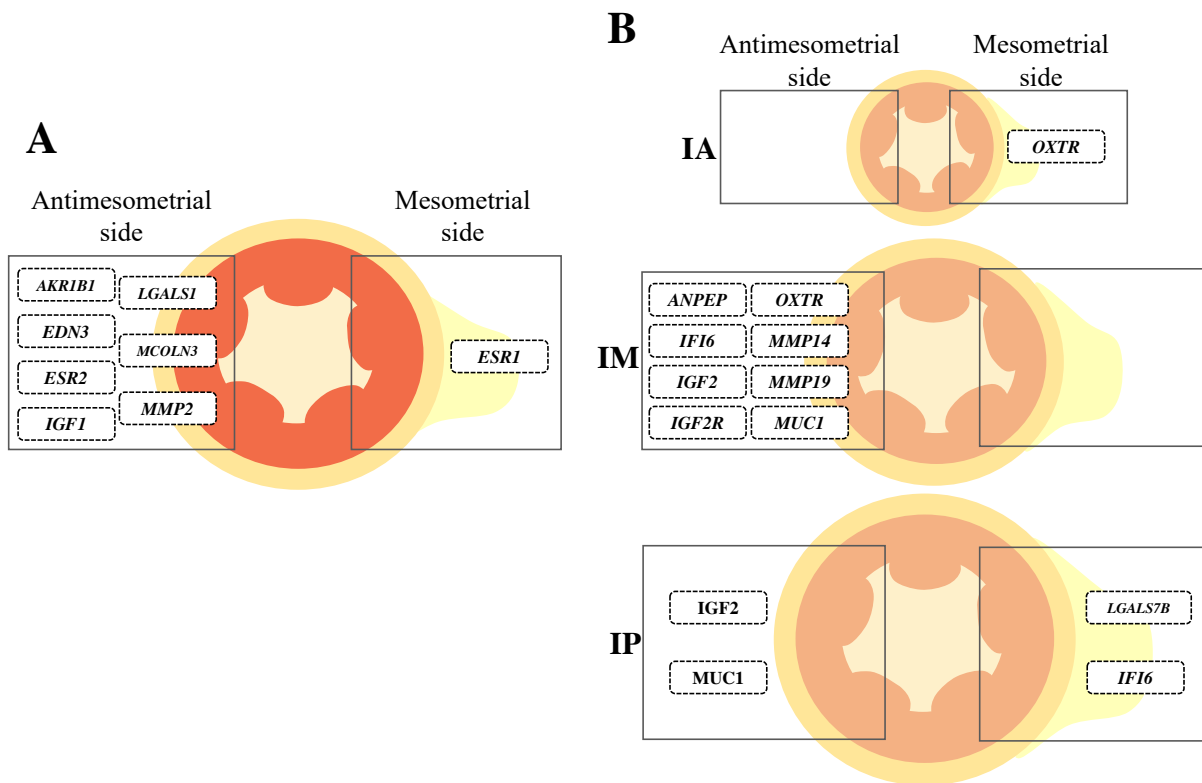

Figure 8. Summary of side-dependent differences in gene expression. Schematic representation of distribution of genes affected by Side (antimesometrial *vs.* mesometrial; Panel A) and by the Side by Region (IA, anterior; IM, medial; IP, posterior; Panel B) interaction in the uterine horn ipsilateral to the CL. The position of each differentially expressed gene in the figure indicate an upregulation in the side.

2.5 DISCUSSION

A critical unanswered question surrounding early pregnancy in cattle is how early is the embryo able to regulate endometrial function to favor its development. Studies over the past 20 years have indicated the existence of complex paracrine and endocrine *in vivo* communication between early embryo and the maternal tract in mammals (Kane *et al.*, 1997; Hardy & Spanos, 2002). *In vitro* culture studies demonstrated that preimplantation embryos secrete a range of biochemical messengers that act in concert to promote embryonic development, referred to as embryotropins (reviewed by Wydooghe *et al.* 2015). The aim of the present study was to compare the abundance of specific transcripts between cycling and pregnant bovine endometria to elucidate whether presence of a pre-hatching embryo might influence the endometrial function at a time-point coinciding with apical uterine position of the embryo. We demonstrated for the first time that a day 7 embryo was able to locally regulate interferon signaling and eicosanoid biosynthesis pathways in the endometrium.

Furthermore, embryo-independent, uterine region and side regulation of transcript abundance was discovered.

The pre-hatching, day 7 embryo is located in the cranial portion of the uterine horn ipsilateral to the CL, that comprehended the UTJ and cranial-most 8 cm of the horn. In agreement, Dinskin & Sreenan (Diskin & Sreenan, 1980) reported that embryos recovered 8 days post-estrus were located at the tip of the uterine horn, close to the UTJ, in inseminated beef cows. The dynamic of migration of the early bovine embryo along the uterine horn remains poorly known. According to Wolf *et al.* (2003) the embryo does not float in a recognizable volume of maternal secretions, but is surrounded tightly by the endometrium through a thin fluid layer stabilized by glycoproteins.

Exposure to a day 7 embryo stimulates local expression of classic interferon-induced genes. The fact that the abundance of transcripts for ISGs (*ISG15*, *MX1*, *MX2* and *OAS1Y*) was increased in the UTJ region of Preg cows is suggestive of signaling by embryo secreted interferon-tau. Furthermore, there was a greater abundance of transcripts for *IFNAR2*, a classical interferon type I receptor, in the UTJ than other uterine regions. This could be associated with a more pronounced interferon-mediated response in this region. The expression of *IFNT* mRNA and protein is first evident as the trophoblast cell lineage develops at the late morula and early blastocyst stage in cattle (D6–7 of pregnancy; Farin *et al.*, 1989; Lonergan *et al.*, 2003). *In vivo* or *in vitro* derived day 7 bovine blastocysts produce very low amounts of IFNT (~ 100 to 1000 pM/day) as measured by antiviral cell protection assay (Kubisch *et al.*, 1998). Indeed, *in vitro* stimulation of endometrial cells with 25 nmol of IFNT was needed to increased *ISG15* mRNA and ISG15 protein abundance (Austin *et al.*, 1996). Thus, it is remarkable that such early embryos were capable to change endometrial transcript abundance as reported here. Probably, such limited capacity of synthesis and secretion of signals by the early embryo (Robinson *et al.*, 2006) is the reason of the locally restricted effects verified. Substantial endometrial expression of ISGs was reported previously (Dorniak *et al.*, 2011) in embryo recipients on D13 after estrus.

To rule out the possibility of non-specific ISGs stimulation by exposure to sperm in Preg cows, we compared ISGs expression between Con and Preg cows in the contralateral UTJ. The similar ISGs transcript abundances between the groups further indicated that the significant differences found in the ipsilateral UTJ were induced by the embryo. Thus, although IFNT signaling is likely to have occurred in the present study, functional relevance of such early communication is currently unknown.

Exposure to a day 7 embryo changes the abundance of eicosanoid metabolism transcripts to favor a greater PGE₂/PGF_{2α} ratio. Prostaglandins evidently regulate endometrial functions and conceptus elongation during early pregnancy (Robinson *et al.*, 2006). Dorniak *et al.* (2011) showed that intrauterine infusion of meloxicam, a selective PTGS2 inhibitor, prevented conceptus elongation in early pregnant sheep. In the present report, the expression of *PTGES* (prostaglandin E synthase) was upregulated, while that of *AKR1C4* (aldo-keto reductase family 1, member C4) and *HPGD* [hydroxyprostaglandin dehydrogenase 15-(NAD)] was downregulated in pregnant endometria. The PTGES enzyme converts PGH₂ to PGE₂ and is mainly responsible for the production of the PGE₂ in the bovine endometrium (Arosh *et al.*, 2004). The AKR1C4 enzyme converts PGH₂ to PGF_{2α}, while HPGD is responsible for prostaglandins catabolism (Parent *et al.*, 2006). Interpretation of these data suggests an increase in PGE₂ synthesis and secretion and decrease in PGF_{2α} synthesis, which is a pro-gestation phenotype. Indeed, PGE₂ has been associated to multiple roles as an embryo and luteotrophic signal and as an important mediator in endometrial receptivity, myometrial quiescence, and immune function at the fetal-maternal interface during the establishment of pregnancy (Arosh *et al.*, 2006; Magness *et al.*, 1981; Emond *et al.*, 1998). Conversely, uterine production of PGF_{2α} has a direct negative effect on continued embryonic development (Senna *et al.*, 2004). Seals *et al.* (1998) verified that most susceptible period of embryonic growth to the negative effects of PGF_{2α} was during the development from morula to blastocyst, which happens at the apical uterine portion. Consistent with our findings, Beltman *et al.* (2010) analyzed the tip of the uterus and verified that the expression of *PTGES* was upregulated in the endometria of heifers with a viable embryo compared to that of a retarded embryo, while the expression of *HGPD* was significantly decreased in this group.

Remaining transcripts regulated by the embryo locally were *ITGB1* (in the IA region) and *AMD1* (in the IA and IM regions), both downregulated in the Preg group, and *AQP4* (in the UTJ and IA regions), upregulated by the embryo. The integrin subunit beta 1 (ITGB1) is a glycoprotein involved in the cell-cell adhesion, cell-extracellular matrix adhesion and signal transduction, and is expressed along the basolateral membranes of the luminal and glandular epithelial cells as well as around the blood capillaries throughout the endometrium (Pfarrer *et al.*, 2003). Guillomot (1999) provided evidence that major components of the ECM and the ITGB1 are lost in a progressive local pattern during the trophoblastic adhesion process in the caprine endometrium. The adenosylmethionine decarboxylase 1 is an enzyme coded by *AMD1* gene and is implicated in polyamine biosynthesis. The biological relevance of this finding during early pregnancy has not been established. However, Heald (1979) observed

that local embryonic signals seems to regulate polyamine synthesis in the pregnant uterus of rats. The embryo-induced regulation of *AQP4* transcripts indicates an increased water transport to the portion of the horn containing the embryo. The aqueous transport through the aquaporin channel is driven by osmotic gradients. Secretion, absorption and homeostasis of uterine fluid are crucial for embryo development (Zho *et al.*, 2014).

Regional differences in transcript abundance along the uterine horn ipsilateral to the CL define a functional spatial signature associated with receptivity to the embryo. Cluster analysis grouped four patterns of transcript abundance along the ipsilateral uterine horn. Cluster 1 represents 11 genes that showed overexpression in the UTJ region and that support the developing embryo, such as *FGF2*, *FGFR2*, *PTGIS* and *SLCO2A1*, are associated with interferon response (*IFNAR2* and *IFI6*) and provide embryo adhesiveness (*FNI* and *MUC1*). *FGF2* has been described as a strong mediator of IFNT production in bovine trophoderm cells and blastocyst-stage bovine embryos (Michael *et al.*, 2006) and greater amounts of *FGF2* mRNA in the ipsilateral apical uterine horn can be a reasonable explanation to support the early embryo development. Excess mucin, coded by the *MUC1* gene, prevents embryo attachment to the endometrial luminal epithelium (Bowen *et al.*, 1997; Surveyor *et al.*, 1995). Thus, upregulation of this gene in the Preg UTJ probably stimulates embryo transit to the subsequent regions of the uterine horn.

Cluster 2 was composed of 25 transcripts whose abundance was lowest in the UTJ and continuously increased in the IA, IM and IP regions. Interestingly, some of these transcripts are associated with a non-receptive endometrium, that expresses proliferation- (*IGF1*, *IGF1R*, *IGF2*, *IGF2R*, and *KDR*) rather than secretion-associated genes (Mesquita *et al.*, 2015) and extracellular matrix remodeling genes (*MMP14*, *MMP19*, *MMP2* and *TIMP3*; Scolari *et al.*, 2016). The gradual uterine cranial-wise downregulation of these genes may be related to local requirements of the embryo, that are specific to each stage of development. The UTJ-IA location of embryos in the present report are consistent with the concept that an endometrium that is less engaged in proliferation and remodeling is receptive compatible with early embryo requirements. Findings were similar to those described by Bauersachs *et al.* (2005), which identified differential mRNA expression between different regions (anterior, middle and posterior) of the ipsi and contralateral uterine horns. Specifically, that study showed an increase in *UTMP* (also known as *SERPINA14*) transcripts abundance at the cranial ipsilateral uterine horn, similarly to our study. Regulation of region-specific transcript profiles may be exerted through differential vascularization along the uterine horn. Specifically, there is a preferential input of blood draining the ovaries to the cranial region of the uterus compared to

the mid and posterior regions (Pope *et al.*, 1982). Thus, sex steroid regulation of endometrial transcription may explain regional differences in transcript abundance (Araújo *et al.*, 2015).

A collective finding that was consistent to clusters 1 to 3 relates to the uniqueness of the transcription profile in the UTJ compared to the remaining regions of the uterus. To the best of our knowledge, there are no studies comparing the gene expression of UTJ with the remaining uterine horn. The bovine UTJ is composed of three parts: terminal isthmic segment, transition region proper and uterine apex (Wrobel *et al.*, 1983). The uterine apex extends to the point of the first caruncles, approximately 1-1.5 cm caudally to the oviductal transition into the uterine horn. Only the endometrial component of the UTJ was collected and analyzed in this study. The luminal epithelium of the bovine UTJ consists of a simple columnar epithelium containing ciliated and non-ciliated cells, and its surface is covered by varying amounts of a mucous secretion that tends to agglomerate the cilia and microvilli (Wrobel *et al.*, 1983). The existence of glands in the bovine UTJ remains controversial (Hook & Hafez, 1968), although we clearly detected glands in histologic sections of the uterus (data not shown). Discrepant differences verified at transcriptional level may be due to differences in cellular compartments between regions.

Side differences in transcript abundance along the uterine horn ipsilateral to the CL define a second layer of functional spatial signature associated with receptivity to the embryo. Because the main blood vessels supplying the bovine uterus are inserted through the mesometrium, we hypothesized that there would be a greater input of systemic factors and ovarian steroids in the endometrium close to the mesometrium insertion (Dyce *et al.*, 2004). Perhaps this could evoke side-specific regulation of gene expression. Furthermore, to the best of our knowledge, there are no reports showing evidence of differential gene expression between mesometrial and antimesometrial sides in the bovine endometrium during pre-hatching embryo development. In the present study, abundance of eight transcripts was affected by side, seven of which were upregulated in the antimesometrial side. One such gene is endothelin 3 (*EDN3*), which is a potent vasoconstrictor. The *EDN3* is synthesized by endometrial stromal and glandular epithelial cells and acts in a paracrine manner in the uterine vasculature (Cameron *et al.*, 1993, 1995). A decrease in *EDN3* mRNA abundance in the mesometrial side of endometrium may point to a local vasodilatation and, thus, increased blood supply in this region. Study of region by side interactions revealed additional 9 genes (Fig. 7B) whose transcript abundance was regulated between sides in least one uterine region (IA, IM or IP). Interpretation of interactions showed that the majority of side effects are concentrated in the IM and IP regions in comparison to the IA. It is possible that because the

caudal-wise increase in the uterine horn diameter, the distance between the mesometrial and antimesometrial sides are greater and regulation is more prone to occur. In many rodents, including mice and rats, attachment always occurs at the antimesometrial side of the uterine lumen, opposite the entry site of blood vessels into the uterus, whereas implantation is mesometrial in bats, mare and pigs (Spencer & Hansen *et al.*, 2015). However, relevance of side-specific transcript abundance in cattle is unknown and remains to be discovered. Although not examined in the present study, there are probably embryo-dependent and -independent effects on caruncular endometrium function. Such effects were reported earlier before (Correia-Alvarez *et al.*, 2015) and at implantation (Mansouri-Attia *et al.*, 2009).

The functional relevance of uterine programming during pre-hatching early embryo development can be questioned due to the fact that *in vitro* produced bovine embryos can be caudally transferred to the uterus and are able to establish gestations successfully. However, it has been demonstrated clearly in embryo transfer programs that there is a greater pregnancy success when an embryo was transferred deep in ipsilateral uterine horn compared to a shallow transfer (65.9% vs. 29.6%; Beal *et al.*, 1988). Furthermore, Newcomb *et al.* (1980) transferred single embryos surgically, bilaterally on day 7 to a combination of sites (tip or base) of uterine horns in cows. They concluded that the tip of the ipsilateral uterine horn is the optimal site for fetal survival and that to ensure a high twin fetal survival one embryo must have been placed in this site. Collectively, these findings and ours provide evidence that although the sequential exposure of the embryo to a regionally programmed uterus is not absolutely required to establishment of pregnancy, absence of exposure may be implied as a contributing factor to reduced establishment of pregnancy, such as when embryo is transferred caudally in cattle. Thus, exposure to the pre-hatching embryo may fine-tune endometrial function to support subsequent pregnancy events.

In conclusion, the present study showed that the expression pattern of specific genes in the endometrium respond to pre-hatching embryo-dependent and -independent programming (Fig. 9). Embryo-dependent programming requires physical proximity to the embryo probably because of the limited capacity of synthesis and secretion of signals by the early embryo. Clear regional and side changes in transcript abundance were observed in this study and their critical role for further embryo development and survival and, ultimately, pregnancy success, deserves further research. Mechanisms that regulate regional expression of transcripts have not been elucidated, but may include vascular specializations to deliver different sex-steroid concentrations to particular regions of the reproductive tract and specific intrinsic regional programming of expression across the uterine horn. We propose that successful pre-hatching

embryo-dependent and -independent programming of endometrial function fine-tune endometrial functions that are important for a successful pregnancy in cattle.

Figure 9. A working model integrating embryo-dependent (top panel) and -independent (bottom panel) programming of endometrial function 7 days after estrus. Numbers 1 to 9 represent processes and associated key genes whose transcription was modulated in the UTJ and/or apical portion of the uterine horn compared to the medial and posterior portions. Changes in transcript abundance are irrespective of cell type, since they were measured on whole endometrium homogenates. *Embryo-dependent signaling:* (1) Interferon-tau (IFN τ) secreted by the embryo affects the endometrium in a paracrine manner, regulating the transcription of interferon-stimulated genes (*ISG15*, *MX1*, *MX2* and *OAS1Y*); (2) embryo-induced regulation of eicosanoid metabolism genes favor a greater PGE2:PGF2 α ratio; (3) embryo-induced regulation of *AQP4* transcripts indicates an increased water transport to the portion of the horn containing the embryo. *Embryo-independent signaling:* (4) upregulation of the anti-adhesive *MUC1* stimulates transit of the embryo from the UTJ to the more caudal regions of the uterine horn; (5) upregulation of vasodilatation-related gene (*PTGIS*) and downregulation of vasoconstriction-related gene (*EDN3*) indicate greater blood flow to the apical regions of the horn; (6) increase of solute transport (*SLCO2A1*); (7) downregulation of genes associated with cellular proliferation (*IGF1*, *IGF2*, *IGF1R* and *IGF2R*), suggests a change in tissue function to promote (8) synthesis of embryotropins (*FGF2*) and (9) secretion, which is supported by upregulation of glandular secretions-related gene (*GRP*); (10) decrease of extracellular matrix remodeling (*MMP14*, *MMP19*, *MMP2* and *TIMP3*). Collectively, at the transcriptional level, changes are consistent with an endometrial phenotype that is more receptive to the embryo in the apical portion of the uterine horn compared to the medial and posterior portions.

2.6 ACKNOWLEDGMENTS

The authors thank the Administration of the Fernando Costa campus of the University of São Paulo and Ourofino Saúde Animal for providing the animals and the products for pharmacological manipulation of estrous cycle, respectively. We are also thankful to staff of the FMVZ-USP campus Pirassununga, namely MI Silva, RR Santos, MR França, ML Oliveira, A Gonella-Diaza, BP Mello, K Ribeiro, KM Lemes, CMB Membrive, ECC Celeghini and RP Arruda for technical support. Also, PHM Rodrigues and CG de Lima for statistical assistance.

3 THE PRE-HATCHING BOVINE EMBRYO TRANSFORMS THE UTERINE LUMINAL METABOLITE COMPOSITION *IN VIVO*

3.1 ABSTRACT

In cattle, conceptus development after elongation relies on well-characterized, paracrine interactions with the hosting maternal reproductive tract. However, it was unrecognized previously that the pre-hatching, pre-implantation bovine embryo also engages in biochemical signaling with the maternal uterus. Our recent work showed that the embryo modified the endometrial transcriptome *in vivo*. Here, we hypothesized that the embryo modulates the biochemical composition of the uterine luminal fluid (ULF) in the most cranial portion of the uterine horn ipsilateral to the corpus luteum. Endometrial samples and ULF were collected post-mortem from sham-inseminated cows and from cows inseminated and detected pregnant 7 days after estrus. We used quantitative mass spectrometry to demonstrate that the pre-hatching embryo changes ULF composition *in vivo*. Embryo-induced modulation included an increase in concentrations of lipoxygenase-derived metabolites [12(S)-HETE, 15(S)-HETE] and a decrease in the concentrations of amino acids (glycine), biogenic amines (sarcosine), acylcarnitines and phospholipids. The changed composition of the ULF could be due to secretion or depletion of specific molecules, executed by either the embryo or the endometrium, but initiated by signals coming from the embryo. This study provides the basis for further understanding embryo-initiated modulation of the uterine milieu. Early embryonic signaling may be necessary to guarantee optimal development and successful establishment of pregnancy in cattle.

3.2 INTRODUCTION

In cattle, the embryo transits from the oviduct to the uterine lumen and remains loosely attached during the 20-days pre-implantation period. This is a critical window for pregnancy wherein as much as 40% of embryos die (Diskin *et al.*, 2011). After implantation, embryo mortality decreases as hemotrophic nutrition is accomplished through placentation. Causes of mortality that occur before implantation are likely associated with disruptions on the complex biochemical interactions that take place between the developing conceptus (embryo and associated membranes) and the endometrium. Interactions between the endometrium and the conceptus occur through the exchange of secretions from both units into the uterine lumen. Secretions that originate from the endometrium are called the histotroph. The histotroph is composed of hormone-mediated, selective transudation of plasma components and release of locally *de novo* synthesized molecules that reach the uterine lumen through excretion from endometrial glands and transport across the epithelium lining the endometrium (Roberts & Bazer, 1988). The arrival of the embryo into the uterus adds molecular complexity to this scenario, as the conceptus releases additional molecules into the uterine luminal fluid (ULF). Moreover, molecules originating from each unit have the potential to influence the function of each other. The classical example is the effect of conceptus derived interferon-tau that inhibits prominent pulses of prostaglandin-F₂alpha from the endometrium in cattle (Arosh *et al.*, 2016). Furthermore, both the conceptus and the endometrium likely utilize molecules present in the ULF to support cellular proliferation and function. Finally, it is expected that both maternal and embryonic influences on the uterine environment composition change as the pregnancy progresses towards implantation. In summary, the biochemical composition of the ULF dynamically reflects the contributions and the consumption of molecules by both the maternal and the embryonic units during the pre-implantation window.

Exposure to histotroph is a prerequisite for development of the embryo after the hatched blastocyst stage *in vivo*. Indeed, efforts to artificially induce elongation of bovine conceptuses *in vitro* have been unsuccessful (Brandao *et al.*, 2004; Alexopoulos *et al.*, 2006). Furthermore, perturbations of histotroph composition prior to embryo transfer severely impaired embryo survival and pregnancy establishment in cattle (Martins *et al.*, 2018). However, specific luminal metabolite requirements of the earliest phase of embryo development in the uterus are unknown. Nature and concentration of specific molecules likely reflect the changing requirements of the developing embryo in response to a changing

nutrient supply during its migration from the oviduct to the uterus and, subsequently, along the uterine lumen.

Exposure of the endometrium to ULF conditioned by the elongated conceptus is required for the maintenance of pregnancy (Knickerbocker *et al.*, 1986). Conceptus-originated molecules, such as interferon-tau and prostaglandins, re-program function of endometrial cells from luteolytic to pregnancy-supporting. However, the influence of the pre-elongation embryo on endometrial function is poorly understood. *In vitro* studies have shown that pre-implantation embryos release a variety of biochemical signals, referred to as embryotropins (Wydooghe *et al.*, 2015), that act in concert to support embryonic development. The paracrine effects of embryo-derived molecules on the maternal tissue is expected to be limited to the immediate embryo surroundings. This may be attributed to the capacity of synthesis, secretion and diffusion of signaling molecules by the early-embryo, which is expected to be proportional to its cellular machinery (~100 cells at the blastocyst stage). Notwithstanding, we reported previously that the endometrial abundance of specific transcripts was altered by the presence of a day 7-embryo in a spatial-specific manner (Sponchiado *et al.*, 2017). The most pronounced effects were found in the cranial region of the uterine horn ipsilateral to the corpus luteum (CL), where the embryos were located on day 7. The main pathways changed by the embryo included type I interferon-response and genes associated to the prostaglandin metabolism. In agreement, recent *in vitro* studies showed that early bovine embryos were able to modulate gene expression of co-cultured endometrial (Talukder *et al.*, 2017; Gomez *et al.*, 2018; Passaro *et al.*, 2018), oviductal (Maillo *et al.*, 2015), luteal (Bridi *et al.*, 2018) and immune cells (Talukder *et al.*, 2017, 2018; Rashid *et al.*, 2018). However, a critical unanswered question is whether the female tract has the ability to respond to pre-hatching embryo-derived signals beyond the transcription level, to change its transport and secretory functions and ultimately change the composition of the uterine microenvironment.

We hypothesized that the presence of an embryo modulates the biochemical composition of the ULF in the cranial region of the ipsilateral uterine horn. The aim was to assess a spatially-defined region of the uterine luminal environment, at a time-point coinciding with the apical location of the embryo, to compare the concentration of selected metabolites in ULF between pregnant and sham-inseminated cows. More specifically, we aimed to measure the absolute concentrations of targeted metabolites based on their possible role on early pregnancy biology. The analytes panel included amino acids, biogenic amines, acylcarnitines, lipids, hexoses, and eicosanoids and oxidation products of polyunsaturated

fatty acids. Transcripts analyses were performed on endometrial samples to link the findings at the ULF level to the surrounding endometrial tissue.

3.3 MATERIAL AND METHODS

All experimental procedures were performed in accordance with ethical principles in animal research. Protocol was approved by the Ethics and Animal Handling Committee of the School of Veterinary Medicine and Animal Science of the University of São Paulo (CEUA-FMVZ/USP, n3167260815).

3.3.1 Experimental design

The experimental design aimed to generate a group of pregnant and a group of non-inseminated cows 7 days after estrus as previously described in Sponchiado *et al.* (2017). Thirty-six reproductively normal, cycling, non-lactating, multiparous Nelore (*Bos taurus indicus*) cows were used in this study. Animals were maintained under grazing conditions, supplemented with concentrate, chopped sugarcane, and minerals to fulfil their maintenance requirements. Animals had free access to water. Briefly, estrous cycles were synchronized by i.m. administrations of 500 µg sodium cloprostenol (PGF_{2α} analogue; Ourofino Saúde Animal, Cravinhos, São Paulo, Brazil) and 2 mg estradiol benzoate (Ourofino Saúde Animal), followed by insertion of an intravaginal P4-releasing device (1 g; Ourofino Saúde Animal). Eight days apart, the P4-releasing device was withdrawn, animals received an i.m. administration of 500 µg sodium cloprostenol and an Estrotect (Rockway, Inc. Spring Valley, WI, USA) heat detector patch. Between 48 and 84 h after P4-device removal, cows were checked for signs of estrus activity twice a day. Only animals detected in estrus were maintained in the experiment. On day zero (D0 = estrus), cows were randomly assigned to the experimental groups: (i) Pregnant group (Preg; n = 16), cows were intracervically inseminated 12 h after estrus, with frozen-thawed commercial semen of a proven fertility bull; or (ii) Control group (Con; n = 8), cows were sham-inseminated with semen extender. On D7, all animals were slaughtered.

Transrectal B-mode ultrasonography (7.5-MHz transducer) exams were conducted at 5 time points: at the time of P4-releasing device insertion and removal to measure follicles and to check the presence of a CL; on D0 and D1 to measure the size of the preovulatory follicle and to confirm ovulation. The side of the preovulatory follicles were recorded. On D7, CL

area and the first-wave largest follicle diameter were evaluated. As expected, pre-ovulatory follicle and first-wave largest follicle diameters (on D7) did not differ between the two groups, nor the CL area and plasma P4 concentrations (on D7), as reported previously (Sponchiado *et al.*, 2017).

3.3.2 Uterine flushing and endometrial sample collection

Animals were slaughtered by conventional captive bolt stunning followed by jugular exsanguination. The reproductive tracts were collected and transported on ice to the laboratory within 10 min. The uteri were trimmed free of adjacent tissues and processed to ULF and endometrial samples collection, as described previously (Sponchiado *et al.*, 2017) and illustrated in Figure 1. Briefly, the uterine horn ipsilateral to the ovary containing the CL was isolated. Starting from the utero-tubal junction (UTJ), locking tweezers were clamped every 8 cm to delimit the anterior, medial and posterior uterine thirds. Each portion was individually flushed by injecting ice-cold PBS into the cranial extremity and collecting the ULF at the caudal end in a petri dish. The anterior, medial and posterior thirds were flushed with 3, 5 and 6 mL of PBS, respectively. Pregnancy status of the inseminated cows was confirmed by visualization of an embryo in the ULF under a stereomicroscope. All embryos found (n = 10 out of 16) were in the ULF recovered exclusively from the ipsilateral anterior third, and were at the expected developmental stage (compact morula or early blastocyst). Only inseminated cows from which an embryo was recovered were kept in the analyses. Uterine flushings were clarified by centrifugation at 1,000 x g for 10 min at 4 °C. The supernatant was gradually transferred into cryotubes, snap frozen and stored at -80 °C until analysis.

Figure 1. Diagram of sample collection procedure. (A) After slaughter, reproductive tracts were trimmed free of connective tissues; (B) The uterine horn ipsilateral to the corpus luteum was isolated. Starting from the utero-tubal junction (UTJ), locking tweezers were positioned every 8 cm to clamp the anterior, medial and posterior uterine thirds. (C) Ipsilateral anterior thirds were individually flushed by injecting 3 mL of PBS into the UTJ edge. (D) Intercaruncular endometrial samples were dissected from the UTJ (black arrow) and from the lengthwise intermediate region (white arrow) of the third, at the mesometrial side.

For endometrial samples collection, the ipsilateral anterior third was opened longitudinally along the mesometrial line. The endometrial side was exposed and photographed for further surface area measurements. Intercaruncular endometrial fragments were dissected from the uterotubal junction (UTJ) and from the lengthwise intermediate region of the third, at the mesometrial side (Fig. 1). Tissue samples were transferred to cryotubes, snap frozen and stored at -80°C until further processing.

3.3.3 Targeted metabolomic measurements

We applied a targeted, quantitative metabolomics approach to analyze ULF samples (Con = 8; Preg = 10) from the anterior ipsilateral uterine third by using the AbsoluteIDQ p180, and Eicosanoid & Oxidized lipids mass spectrometry-based assays (Biocrates Life Sciences AG, Innsbruck, Austria). These validated, targeted assays enabled the simultaneous identification and quantification of up to 205 endogenous metabolites from seven analytic groups including 21 amino acids, 21 biogenic amines, 40 acylcarnitines, 90 glycerophospholipids, 15 sphingolipids, sum of hexoses, and 17 eicosanoids and oxidation products of polyunsaturated fatty acids. The assay procedure and metabolite nomenclature have been described in detail (Römisch-Margl *et al.*, 2012). Briefly, the measurements were carried out in a 96-well plate with seven calibration standards and three quality control samples included. Amino acids and biogenic amines were analyzed by UPLC (Waters ACQUITY UPLC, Waters Corporation, USA) system coupled with Xevo tandem quadrupole (TQ; Waters Corporation) and Xevo TQ-S mass spectrometers in positive mode. Acylcarnitines, glycerophospholipids, and sphingolipids were quantified by Waters tandem quadrupole mass spectrometers (Xevo TQ and Xevo TQ-S MS) by flow injection analysis (FIA) in positive mode, whereas hexoses were analyzed using a subsequent acquisition in negative mode. Detection and quantification of the analytes was achieved using internal standards in multiple reaction monitoring (MRM) mode. Calculation of the metabolite concentrations analyzed by FIA (acylcarnitines, glycerophospholipids, sphingolipids, and hexoses) was performed using *MetIDQ* software (Version 5– 4-8-DB100-Boron-2607, Biocrates Life Sciences AG). Analysis of peaks obtained by UPLC (amino acids and biogenic amines) was performed using TargetLynx Application Manager, and the results were imported into *MetIDQ* software for further processing.

Eicosanoids and related compounds were detected by Biocrates triple quadrupole MS-based platform in negative multiple-reaction monitoring detection mode as per a method

reported previously (Unterwurzacher *et al.*, 2008). Oxidized polyunsaturated fatty acids were extracted from ULF samples by methanolic protein precipitating process. Analysis was performed by HPLC MS/MS on a Sciex 5500 QTRAP™ (AP Sciex, Darmstadt, Germany) instrument. Metabolites were quantified by comparison to structurally similar molecules labelled with stable isotopes added to the samples in defined concentrations as internal standards in MRM mode.

3.3.4 Metabolites panel

Throughout the article, amino acids are abbreviated based on their international notation. Acylcarnitines (Cx:y) are notated according to the fatty acid that is bound. Glycerophospholipids (sn) are classified according to the presence of ether (alkyl) or ester (acyl) residues attached to the glycerol moiety. The prefix ‘lyso’ denotes a single fatty acid or fatty alcohol bond on the sn-1 position of the glycerol moiety, as denoted by a single letter (acyl, a; alkyl, e). Two letters (diacyl, aa; acyl-alkyl, ae) means that the sn-1 and sn-2 positions on the glycerol moiety are each bound to a fatty acid or fatty alcohol residue. Sphingomyelins (SM) and hydroxysphingomyelins (SM-OH) are abbreviated based on the lipid chain composition (x:y). Biochemical name, abbreviation and PubChem CID of metabolites are listed in Supplemental Table S3 by class.

In addition to individual metabolite assessment, groups of metabolites were computed by sums or ratios of the amounts of analytes belonging to certain families or chemical structures to provide detailed insight into a wide range of functions. Details of ratios calculated and functional groups are provided in Supplementary Table S4.

3.3.5 Total RNA isolation and transcript abundance analysis

Using a stainless-steel apparatus, frozen endometrial fragments (~40 mg) were mechanically minced. Immediately after, the macerate was homogenized with lysis buffer from PureLink® RNA mini kit (Ambion, Life Technologies, Carlsbad, California, USA), following manufacturer’s guidelines. The homogenate was passed ten times through a 21-ga needle accoupled to a 3 mL syringe to maximize lysis. Cell debris were removed by centrifugation at 12,000 g for 1 min at 4 °C. Subsequently, the supernatant was loaded in RNeasy columns for further RNA isolation. Final RNA was eluted with 30 µL diethyl pyrocarbonate (DEPC)-treated water. Total RNA yield and purity were evaluated using

NanoVue Plus Spectrophotometer (GE Healthcare, UK) by the absorbance at 260 nm and the 260/280 nm ratio, respectively.

Samples of RNA (400 ng) were subjected to treatment with DNase I Amplification Grade (Thermo Fisher Scientific) as per manufacturer's instructions. Total RNA was reverse transcribed using Oligo(dT)12-18 Primers (Invitrogen) and dNTP Mix (Thermo Fisher Scientific). Samples were incubated at 65 °C for 5 min. First strand cDNA was synthesized adding the SuperScript IV Reverse Transcriptase (Thermo Fisher Scientific) to the RNA-primer mix, followed by incubation at 55 °C for 10 min and inactivation at 80 °C for 10 min. cDNA samples were stored at -20 °C.

The abundance of specific transcripts was determined by Real-Time PCR. Optimized primers were designed based on GenBank Ref-Seq (*Bos taurus*) mRNA sequences. Only primer pairs with an efficiency ranging from 90 to 110% were used. Primers assay efficiency was calculated based on the slope obtained from a standard curve (5-point serial dilution). Primers details are presented on Supplementary Table S5. Reactions were performed in triplicates, in 96-well plates (Life Technologies), in a final volume of 20 µL. PCR amplification was carried out using the Step One Plus (Applied Biosystems, MA, USA) thermal cycler, using Power SYBR Green PCR Master Mix (Life Technologies). Cycling conditions were as follows. Initial denaturation was performed at 95 °C for 10 min, followed by 40 cycles of denaturation at 95 °C for 15 s and annealing reaction at 60 °C for 60 s. Melting curve analyses (from 60 to 95 °C) was performed to evaluate the amplification product. Negative controls (DEPC water replacing cDNA) were included in every run. Cycle thresholds (Cts) were determined using the LinReg PCR software as described by Ruijter *et al.* (2009). Target genes Ct values were normalized by the geometric mean of reference genes actin beta (*ACTB*), peptidylprolyl isomerase A (*PPIA*), and glyceraldehyde-3-phosphate dehydrogenase (*GAPDH*) transcript abundance values using the equation described by Pfaffl (Pfaffl, 2001).

3.3.6 Data preparation: Endometrial area measurements and normalization

To circumvent possible inaccuracies resulting from the flushing procedure due to different size of the uterine thirds between cows, we normalized the metabolite concentration values to the respective endometrial area. Endometrial area was measured with Image J 1.50i (National Institutes of Health, USA; <http://rsb.info.nih.gov/ij/>) software with the polygon

selections. Prior to statistical analysis, metabolite concentration (nmol) values were adjusted by endometrial area (cm²) of the uterine third and are expressed as nmol/cm².

3.3.7 Bioinformatics and statistical analyses

For statistical analyses, only metabolites with more than 70% of their concentration values in the dynamic range were considered. Metabolic pathways and Multivariate data analysis were carried-out using the web-based metabolomic data processing tool MetaboAnalyst 4.0 (Xia & Wishart, 2016). Metabolite concentrations were Pareto scaled and the method K-Nearest Neighbours was used to impute the missing values to generate the heatmap, sparse partial least squares-discriminate (sPLS-DA) and Metabolite Sets Enrichment analyses. Heatmap was set considering P-values between the two groups and the Ward's methodology as clustering algorithm. For biological interpretation of the metabolite dataset, we mapped the quantified metabolites to the KEGG pathway database (Kyoto Encyclopedia of Genes and Genomes; www.genome.jp/kegg/). Metabolite Sets Enrichment Analysis was conducted on metabolite data mapped according to Human Metabolome Database (HMDB).

Univariate data analyses were carried-out using SAS software v. 9.3 (SAS Inst. Inc., Cary, NC, USA). Normal distribution and homogeneity of variances were ensured by Shapiro-Wilk and Welch's test, respectively. Variables presenting heterogeneity of variances were transformed using natural logarithm. Concentrations and relative mRNA abundance were analyzed for the main effect of group (Con vs. Preg) by two-tailed one-way ANOVA. To further validate the statistical significance, metabolite concentration results were subjected to False Discovery Rate (FDR) correction for multiple comparisons. The Q-value for FDR controlling procedure was set to 0.25 (Reiner *et al.*, 2003). Statistical significance was stated at $P \leq 0.05$, and a probability of $0.05 < P \leq 0.10$ indicates a trend towards significance. Results are presented as means \pm SEM.

3.4 RESULTS

3.4.1 Metabolite profiling of ULF between Pregnant vs. Control cows

Targeted MS metabolomics was used to address the influence of one pre-hatching embryo on metabolite composition of ULF recovered from the ipsilateral anterior third on day 7 after estrus. Of the 205 metabolites quantified, 167 were included in the analyses.

Metabolites that were not detected in more than 30% of samples of both experimental groups were excluded from analyses.

3.4.1.1 Multivariate analyses: Discriminant metabolomic signatures in the ULF from Control vs. Pregnant cows

The heatmap shown in Fig. 2A revealed that: (i) the metabolomic profile of Preg cows is associated with an overall decrease of metabolite concentrations in the ULF compared to the Con group, and (ii) the clustering was affected mainly by compounds belonging to phospholipids, eicosanoids, acylcarnitines, amino acids and biogenic amines classes.

Metabolite Sets Enrichment Analysis was performed to determine, within the specific classes of metabolites measured, which biologically meaningful pathways were overrepresented. The dataset was mainly enriched for molecules involved in lipid and amino acid metabolism. The three top-score enrichment category were, in order of decreasing significance, (i) arachidonic acid metabolism; (ii) alpha linolenic acid and linoleic acid metabolism; and (iii) glycine, serine and threonine metabolism (Fig. 2B).

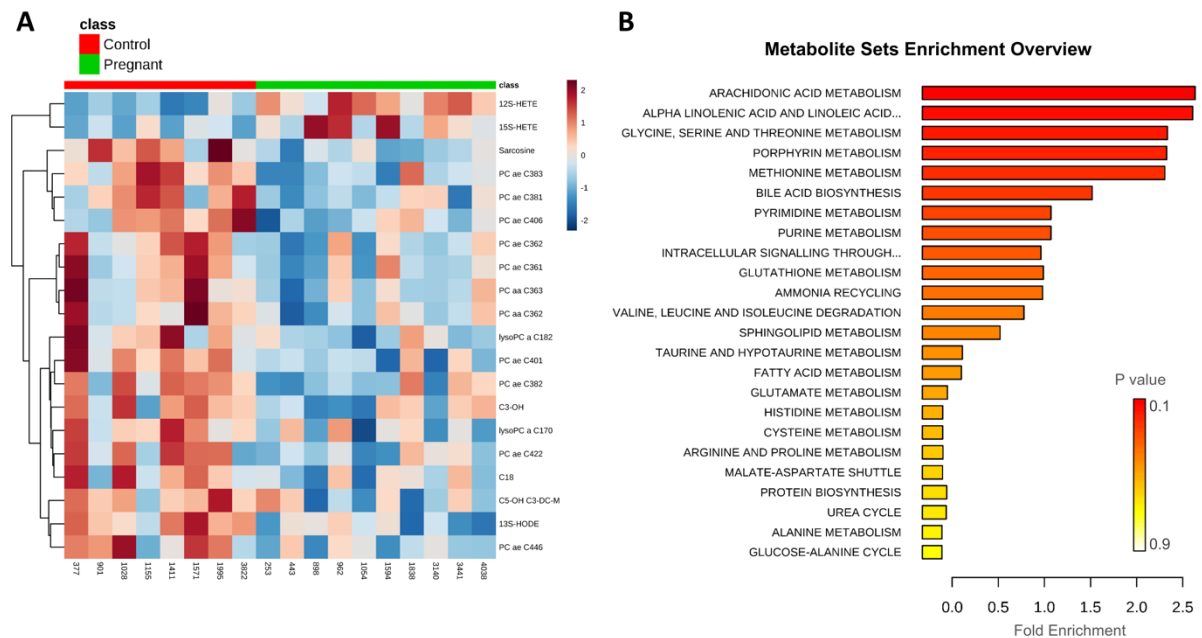

Figure 2. (A) Heatmap depicting the top 20 metabolites differently abundant between Pregnant and Control ULF samples based on *P*-values. (B) Quantitative Enrichment Analysis highlighted the metabolic pathways that were enriched in the Pregnant compared to the Control group, using the MetaboAnalyst 4.0 functional interpretation tools. The horizontal bars summarize the main metabolite sets identified in this analysis; the bars are colored based on their *P* values and the length is based on the -fold enrichment.

Ortho PLS-DA performed on the metabolomics data revealed a clear discrimination between Preg and Con ULF profiles (Fig. 3), with the following parameters: $R^2X = 0.114$, $R^2Y = 0.544$, and $Q^2 = 0.348$. All metabolites that passed quality control were included in this analysis. The top-seven most discriminant metabolites contributing to this model were: 12(S)-HETE, 15(S)-HETE, PC ae C42:5, DHA, LysoPC a C26:0, arachidonic acid (AA) and PGF_{2a} .

Figure 3. Ortho PLS-DA scatter plot depicting different ULF metabolomic profiles between Control and Pregnant cows on day 7 after oestrus. Each dot in the plot represents an animal according to the metabolite profile and groups are identified with ring ellipses corresponding to 95% confidence intervals.

3.4.1.2 Univariate analyses

We examined differences in concentrations of single analytes and groups of analytes of a common biochemical classification between the two experimental groups. Univariate analysis followed by FDR correction showed that, out of 167 metabolites that passed quality control, 22 (approximately 13%) showed significantly different concentrations ($P \leq 0.05$; FDR corrected) between Con versus Preg cows. Remarkably, only two of these 22 metabolites were found in significantly increased concentration in ULF of Preg cows. Comparisons between the abundances of each metabolite according to pregnancy status are presented in Supplementary Tables S4 through S7 and Figures 4 to 7, according to biochemical classification.

3.4.1.3 Recoverable amounts of amino acids and biogenic amines in ULF

Concentrations of individual amino acids and biogenic amines according to group are presented in full on Supplemental Table S6. The non-essential amino acid glutamate was the most abundant in the uterine flushings (5323 nmol/cm² of endometrial area) from both Con and Preg cows, followed by glycine (4293 nmol/cm²) and alanine (1182 nmol/cm²). Regarding the biogenic amines, taurine was the most prevalent (3705 nmol/cm²), followed by sarcosine (407 nmol/cm²) and putrescine (323 nmol/cm²). Total recoverable amounts of amino acids and biogenic amines (Table 1) were similar between ULF of Con and Preg cows. Of the amino acids and biogenic amines quantified, only glycine (0.7-fold; $P \leq 0.05$) and sarcosine (0.6-fold; $P \leq 0.01$), respectively, showed significantly decreased concentration in the ULF of Preg compared to Con cows, as shown in Figure 4. Interestingly, glycine and sarcosine are both part of the glycine, serine and threonine metabolism pathway. Sums of small neutral and osmotic-stress protection amino acids were lower ($P \leq 0.05$) 0.74 and 0.75-fold, respectively, in the Preg group compared to the controls.

Table 1. Sums and ratios of amino acids (AA) and biogenic amines (BA) concentrations in uterine luminal fluid from Control (Con) and Pregnant (Preg) cows. Values are expressed as nmol/cm² of endometrial area; mean \pm SEM. Metabolite groups definitions are on Supplementary Table S4.

Metabolite groups	Group		P value ^a	Log2 Fold-change ^b
	Con (n = 8)	Preg (n = 10)		
Total AA	19325.27 \pm 1563.99	17447.25 \pm 1895.85	0.36	-0.15
Non-essential AA	18861.09 \pm 1469.75	17136.99 \pm 1859.45	0.37	-0.14
Acidic AA	6766.67 \pm 720.65	6154.43 \pm 578.02	0.51	-0.14
Small Neutral AA	10951.75 \pm 903.36	8130.94 \pm 655.04	0.02	-0.43
Osmotic-stress protection AA	11807.05 \pm 940.68	8808.92 \pm 710.92	0.02	-0.42
Glucogenic AA	6538.66 \pm 630.91	5201.54 \pm 661.67	0.17	-0.32
Glutathione precursors AA	11229.58 \pm 997.77	9936.98 \pm 996.13	0.39	-0.18
Total BA	5342.97 \pm 442.49	4989.55 \pm 675.82	0.70	-0.10
Spermidine/Putrescine ^c	0.18 \pm 0.04	0.17 \pm 0.02	0.83	-0.09
Spermine/Spermidine ^d	0.78 \pm 0.16	0.57 \pm 0.11	0.30	-0.43

Groups of metabolites in bold were different between Con and Preg.

^aStatistical analyses were carried out by one-way ANOVA.

^bData are represented as fold-change of the metabolite concentration between Preg and Con groups.

^cRatio of Spermidine to Putrescine was calculated to access the activity of Spermidine synthase.

^dRatio of Spermine to Spermidine was calculated to access the activity of Spermine synthase.

THE PRE-HATCHING BOVINE EMBRYO TRANSFORMS THE UTERINE LUMINAL
METABOLITE COMPOSITION *IN VIVO*

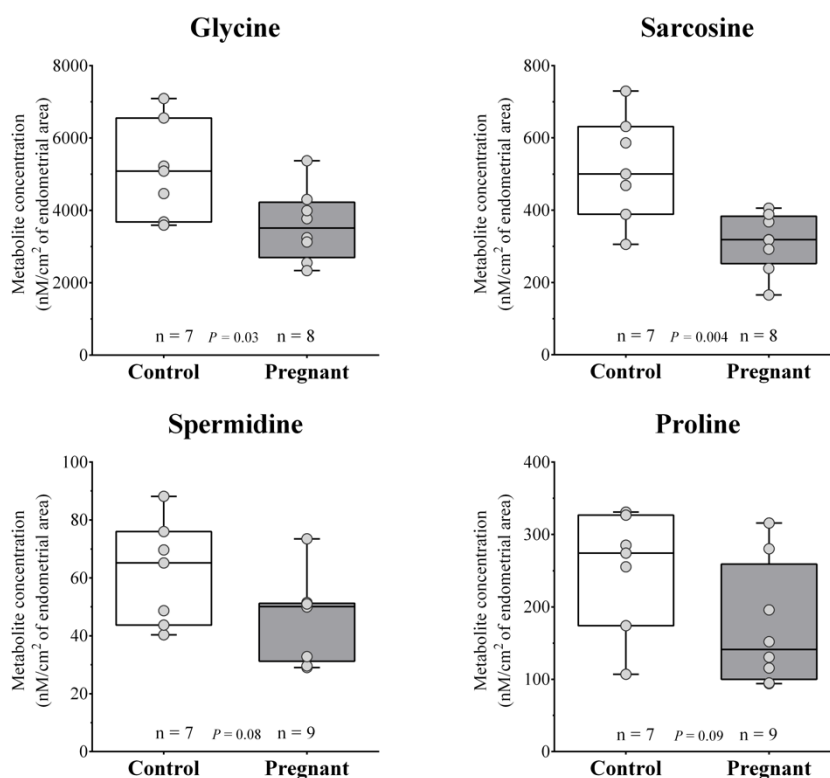

Figure 4. Box and whisker plots of amino acids and biogenic amines that show significant ($P \leq 0.05$) or approaching ($P \leq 0.1$) difference between Control and Pregnant uterine luminal fluids.

3.4.1.4 Recoverable amounts of Acylcarnitines in ULF

Concentrations of individual acylcarnitines according to group are presented in full on Supplemental Table S7. Short-chain acylcarnitines were the most abundant in ULF, followed by medium- and long-chain acylcarnitines (Table 2). Three acylcarnitines [Hydroxypropionylcarnitine (C3-OH), hydroxyisovalerylcarnitine (C5-OH), and hydroxyhexadecanoylcarnitine (C16-OH)] of the 40 identified were found to be in significantly lower concentrations in the ULF from Preg cows (Fig. 5). Remarkably, all three metabolites that were different between the study groups were acylcarnitine esters derived from hydroxylated acids.

THE PRE-HATCHING BOVINE EMBRYO TRANSFORMS THE UTERINE LUMINAL
METABOLITE COMPOSITION *IN VIVO*

Table 2. Sums and ratios of carnitine and acylcarnitines (AC) concentrations in uterine luminal fluid from Control (Con) and Pregnant (Preg) cows. Acylcarnitines were categorized in esters derived from dicarboxylic acids (DC), esters derived from hydroxylated acids (OH), total short-chain acylcarnitines, total medium-chain acylcarnitines and total long-chain acylcarnitines. Values are expressed as nmol/cm² of endometrial area; mean \pm SEM. Metabolite groups definitions are on Supplementary Table S4.

Metabolite groups	Group		P value ^a	Log2 Fold-change ^b
	Con (n = 8)	Preg (n = 10)		
Total Recoverable Amounts of AC	239.56 \pm 37.22	221.77 \pm 25.88	0.69	-0.10
Total short-chain AC	75.86 \pm 9.22	74.46 \pm 9.22	0.92	-0.03
Total medium-chain AC	15.07 \pm 1.23	13.43 \pm 0.63	0.23	-0.17
Total long-chain AC	5.44 \pm 0.52	4.80 \pm 0.43	0.35	-0.18
Acylcarnitine/Free carnitine	0.68 \pm 0.07	0.57 \pm 0.04	0.22	-0.25
Total short-chain AC/Free carnitine	0.70 \pm 0.07	0.64 \pm 0.06	0.55	-0.14
CPT-I([C16+C18]/C0)	0.046 \pm 0.004	0.040 \pm 0.004	0.32	-0.22

3.4.1.5 Recoverable amounts of Phosphatidylcholines and Lysophosphatidylcholines in ULF

Concentrations of individual phospholipids according to group are presented in full on Supplementary Table S8. LysoPC a C14:0 was the most abundant phosphatidylcholine measured (243 nmol/cm²). Lysophosphatidylcholines represent 58% (Table 3) of the total phosphatidylcholines recovered in the ULFs. Total abundance of phosphatidylcholines (calculated by the sum of lyso-, diacyl- and acyl-alkyl-phosphatidylcholines; Table 3) was similar between ULF of Con and Preg cows. Total diacyl-phosphatidylcholines (P = 0.08) and polyunsaturated glycerophosphocholines (PUFA; P = 0.07) concentrations approached a significant reduction in the Preg group (Table 3). The ratio between PUFA and saturated (SFA) phosphatidylcholines showed a significant decrease in the Preg ULF samples (Table 3). This indicated that the activity of fatty acid desaturases of the endometrium might also be altered by pregnancy. There were 14 phosphatidylcholines identified with decreased concentration in the Preg group compared to its counterparts (Fig. 6), comprising 2 lyso-, 3 diacyl- and 9 acyl-alkyl-phosphatidylcholines. Interestingly, from the metabolites in different concentrations between groups, LysoPC a C18:2 and the diacyl-phosphatidylcholines (PC aa C36:0, PC aa 36:3, PC aa 36:5 and PC ae 36:2) are composed by one or two chains of stearic acid, a saturated fatty acid with an 18-carbon chain.

Table 3. Sums and ratios of Phospholipids concentrations in uterine luminal fluid from Control (Con) and Pregnant (Preg) cows. Phospholipids were grouped in Phosphatidylcholines (PC) and Lysophosphatidylcholines (LysoPC), diacyl- (PC aa) or acyl-alkyl- (PC ae) phosphatidylcholines, saturated (SFA), monounsaturated (MUFA) and polyunsaturated (PUFA) glycerophosphocholines. Values are expressed as nmol/cm² of endometrial area; mean \pm SEM. Metabolite groups definitions are on Supplementary Table S4.

Metabolite groups	Group		P value ^a	Log2 Fold-change ^b

3.4.1.6 Recoverable amounts of sphingolipids in ULF

Concentrations of individual sphingolipids according to group are presented in full on Supplemental Table S9. We detected six species of sphingomyelins (C16:0, C16:1, C18:0, C18:1, C24:0 and C24:1) and four species of hydroxysphingomyelins (C16:1, C22:1, C22:2 and C24:1) in ULF obtained from both groups. Sphingomyelin C16:0 was the most abundant in the uterine flushings (19.84 nmol/cm² of endometrial area). There was no difference in the concentration of any sphingolipid between Con and Preg cows. However, the total

recoverable amount of hydroxysphingomyelins tended to be lower (0.67-fold; $P \leq 0.1$; Table 4) in the Preg ULF samples.

Table 4. Sums and ratios of Sphingolipids concentrations in uterine luminal fluid from Control (Con) and Pregnant (Preg) cows. Metabolites were grouped in sphingomyelins (SM) and hydroxysphingomyelins (SM-OH) and according to the unsaturation. Values are expressed as nmol/cm² of endometrial area; mean \pm SEM. Metabolite groups definitions are on Supplementary Table S4.

Metabolite groups	Group		P value ^a	Log2 Fold-change ^b
	Con (n = 8)	Preg (n = 10)		
Total SM	36.87 \pm 6.50	28.84 \pm 4.49	0.31	-0.36

3.4.1.7 Recoverable amounts of hexoses in ULF

In this study, hexoses were the most abundant metabolite class identified in the ULF (334,474.62 nmol/cm² of endometrial area). There was no difference in hexoses concentration between Con and Preg ULF samples (Supplemental Table S10).

3.4.1.8 Recoverable amounts of eicosanoids and oxidation products of polyunsaturated fatty acids in ULF

Eicosanoid and oxidation products of polyunsaturated fatty acids profiling in ULF from Con and Preg cows is presented in Tables 5 and 6. Arachidonic acid, an omega-6 fatty acid, was the most abundant polyunsaturated fatty acid in uterine flushings from both Con and Preg groups, followed by Docosahexaenoic acid, an omega-3 fatty acid. Multiple cyclooxygenase, lipoxygenase, and cytochrome P450 metabolite products were identified. Regarding cyclooxygenase metabolite products, only PGF_{2 α} and PGI₂ (inferred from measurement of 6-keto-Prostaglandin F1 α) were detected in the ULF samples, while PGE₂, PGD₂, PGEM and TXB₂ were below the limit of detection. Univariate analysis revealed a main effect of group between Con and Preg ULF for lipoxygenase metabolite products, 12(S)-HETE, 15(S)-HETE and 13(S)-HODE, wherein 12(S)-HETE and 15(S)-HETE were 2.54 and 2.84-folds greater in the Preg ULF, respectively. However, 13(S)-HODE was 0.46-fold in lower concentration in ULF from the Preg group. Regarding

THE PRE-HATCHING BOVINE EMBRYO TRANSFORMS THE UTERINE LUMINAL
METABOLITE COMPOSITION *IN VIVO*

cyclooxygenase metabolite products, PGF_{2α} concentration tended to be higher (1.18-fold) in the Preg group.

Table 5. Eicosanoids and oxidation products of polyunsaturated fatty acids concentration in uterine luminal fluid from Control (Con) and Pregnant (Preg) cows. Values are expressed as nmol/cm² of endometrial area; mean ± SEM. Biochemical name, abbreviation and PubChem CID of metabolites are listed in Supplemental Table S3 by class.

Metabolites	Group		P value	FDR significance ^a	Log2 Fold-change ^b

3.4.2 Transcript abundance on endometrial samples

Because of the significantly greater abundance of lipoxygenase-related metabolites in ULF from pregnant cows, we measured the abundance of transcripts coding for Lipoxygenase enzymes (*ALOX5*, *ALOX5AP*, *ALOX15B* and *ALOX12*), and lipoxygenase metabolite targets (*PPARG*, *RXRA* and *LPL*) in endometrial samples by Real Time PCR. Additionally, because of the lower abundance of glycine in the ULF from pregnant cows, we measured the abundance of a Glycine Transporter (*SLC6A9*) mRNA. Transcripts for *ALOX12* and *ALOX15B* were respectively 2.56-folds up-regulated and 0.54-fold down-regulated in the UTJ from Pregnant animals (Fig. 8). All the Lipoxygenases addressed in this study were similar between groups in the endometrium collected from the intermediate region of the anterior third. However, a downregulation of *SLC6A9* (a Glycine transporter; 0.76-fold) transcripts was found in the Preg endometrial tissue in the intermediate region, suggesting an embryo-modulated, endometrial response that was consistent with the lower Glycine concentration in the ULF. Transcripts for *PPARG* and *RXRA* were detected in endometrial tissue, as expected, but there was no effect of group on mRNA abundance of *PPARG* and *RXRA* in neither the UTJ or the intermediate anterior third endometrial samples. Similarly, mRNA abundance of *LPL*, a target-gene of PPARG-RXRA complex activation was not affected by group.

Figure 8. Relative mRNA abundance of Lipoxygenases, PPARG-pathway associated genes and Glycine Transporter in Control and Pregnant endometrial samples dissected from the uterotubal junction and the lengthwise intermediate portion of the anterior third of the ipsilateral uterine horn. Data are shown as arbitrary units; mean ± SEM.

3.5 DISCUSSION

Accumulating evidence supports the idea that the early bovine embryo is more than a passive passenger through the maternal reproductive tract. Embryo-induced effects, at transcriptional level, on oviductal (Maillo *et al.*, 2015), endometrial (Sponchiado *et al.*, 2017;

Talukder *et al.*, 2017; Gomez *et al.*, 2018; Passaro *et al.*, 2018), luteal (Bridi *et al.*, 2018) and immune (Talukder *et al.*, 2018; Rashid *et al.*, 2018) cells have been reported. In the present study, we further advanced the understanding of the embryo effects in early pregnancy. We demonstrated for the first time that the pre-hatching embryo changes the uterine microenvironment as early as day 7 after estrus *in vivo*. In the present study, we had the unique opportunity to collect ULF from the anterior third of the uterine horn. Consequently, metabolite concentrations measured represent the local concentrations. This is critical because due to the cranial-most localization of the embryo at day 7, it is possible that a greater magnitude of effects of the embryo were manifest in its closest proximity. Such modulation included changes in concentrations of lipoxygenase-derived metabolites, amino acids, biogenic amines, acylcarnitines and phospholipids. The changed composition of the ULF could be due to secretion or depletion of specific molecules, executed by either the embryo or the endometrium, but initiated by signals coming from the embryo. Another major contribution of our study is the expanded inventory and absolute quantification of naturally occurring compounds on ULF. This is important, because most published metabolomics-based investigations are either restricted to one class of analytes and only relative abundances are reported.

Multivariate analyses showed a clear separation between animals pertaining to the two experimental groups. This indicates that the pre-hatching embryo changes the global ULF metabolome profile *in vivo*. Eicosanoids and oxidation products of polyunsaturated fatty acids was the main biochemical class contributing to the discriminant model. Univariate analyses revealed 22 metabolites displaying different concentrations between Preg and Con ULF samples after FDR correction. If all comparisons showing $P \leq 0.05$ were considered regardless of FDR correction, we would have detected 33 analytes with different abundances between Preg and controls. Out of the 22 metabolites showing different concentrations among the two experimental groups, 20 were in lower concentration in the ULF recovered from Pregnant animals. *In vivo*, the ULF composition is modulated by both the endometrial and embryonic units, as well as their molecular interactions. Lower concentrations of metabolites in ULF samples could be attributed to at least four possibilities: (1) a hypermetabolic state of the endometrium, that resulted in increased consumption of substrates by the endometrial tissue with a consequent reduced transport towards the lumen; (2) an overall down-regulation of transport activity in the endometrial epithelia; (3) an increased resorption of metabolites from the uterine lumen towards the lining endometrial epithelium; (4) intake of compounds present in the uterine fluid by the embryo; or combinations of the above. Validation of such

hypothetical mechanisms requires further investigation. Most pregnancy-induced differences were found in eicosanoids, amino acids, biogenic amines, acylcarnitines and phospholipid classes.

The pre-hatching embryo modulates the eicosanoid metabolism in the uterine lumen. Pregnant animals presented greater concentrations of 12(S)-HETE and 15(S)-HETE, but decreased amounts of 13(S)-HODE. These metabolites are products of the oxidative metabolism of arachidonic and linoleic acids generated by the lipoxygenases (LOX) enzymes. Biological activities of lipoxygenase-products include neovascularization and vasodilatation, regulation of inflammatory response and immune function, control of oxidative stress and lipid metabolism (Singh & Rao, 2018). Synthesis of lipoxygenase products by uterine tissues and their role on early embryo development have not been studied extensively. In mice, it has been shown that complete blockade of uterine 12/15-LOX activity by a specific inhibitor reduced uterine levels of arachidonic acid metabolites and impaired implantation by 80% compared to untreated controls (Li *et al.*, 2004). In cattle, Ribeiro *et al.*, (2016) have shown that the ULF recovered from pregnant dairy cows had increased amounts of 15(S)-HETE compared to their non-pregnant counterparts on day 15. In the present study, we showed for the first time that presence of the pre-implantation embryo is capable of modulating the abundance of lipoxygenase-derived metabolites in the uterine lumen. This entices us to speculate that such metabolites may induce changes in function of target tissues, such as the embryo and the endometrium.

We next explored whether changes in the ULF abundance of lipoxygenase-derived metabolites were associated with changes in LOX transcript abundance in the endometrium. Endometrial abundances of *ALOX12* and *ALOX15B* transcripts were respectively up- and downregulated in the UTJ of Preg vs. Con animals. In our previous study, we demonstrated that the main effects of the D7 embryo on the endometrial transcriptome were mainly in the UTJ (Sponchiado *et al.*, 2017). Our findings are consistent with those from a recent study comparing the transcriptome response of the endometrium to pregnancy between high fertile- and subfertile-classified heifers (Moraes *et al.*, 2018). In that study, the pregnant endometrium displayed an up-regulated expression of *ALOX5AP* and *ALOX12*, and a down-regulation in the expression of *ALOX15* and *ALOX15B* compared to non-pregnant endometrium on day 17 (Moraes *et al.*, 2018). Moreover, an upregulation of *ALOX5AP* was detected on endometrial tissue of pregnant heifers on day 16 of pregnancy compared to non-pregnant endometrium (Forde *et al.*, 2011). Taken together, these studies prompt to the idea that embryo/conceptus-derived signals are capable to modulate the endometrial expression of

lipoxygenases and, ultimately, affect the lipoxygenase-derived concentration in the ULF. Studies are needed to elucidate the mechanisms of regulation and potential roles of Lipoxygenase-derived metabolites, as well as their associated signaling systems, in the endometrium and in the embryo during early pregnancy.

We subsequently investigated whether the changed abundance of lipoxygenase-derived metabolites influenced PPAR γ signaling in the endometrium. Both 12(S)-HETE and 15(S)-HETE have been shown to be endogenous ligands/activators of PPAR γ transcription factor *in vivo* (Li *et al.*, 2004) and *in vitro* (Huang *et al.*, 1999). In the report by Li *et al.* (2004), the impaired implantation in mice pre-treated with 12/15-LOX inhibitor was restored by the administration of rosiglitazone, a PPAR γ agonist. In the present paper, we initially confirmed the expression of *PPARG* and *RXRA* mRNA in the endometrium on day 7. Next, we examined the endometrial abundance of *LPL* mRNA, a PPAR γ target-gene, but failed to detect a difference in the abundance of that transcript between Preg and Con samples. This suggests a lack of regulation of this system by the embryo at this stage of pregnancy.

The pre-hatching embryo decreases abundance of specific amino acids and biogenic amines in the uterine lumen. Of the amino acids and biogenic amines quantified, glycine and sarcosine were present in significantly reduced concentrations in the ULF of Preg cows. We also verified that the sum of small neutral and osmotic-stress protection amino acids was lower in Preg compared to the Con group. This may seem at odds with evidence in the literature that amino acids are increased in the uterine lumen in cattle (Groebner *et al.*, 2011; Forde *et al.*, 2014) and sheep (Gao *et al.*, 2009) during the peri-implantation period which is mediated via upregulation of amino acid transporters in the endometrium. However, compared with previous work, the present samples were collected approximately one week earlier in gestation. Interestingly, glycine and sarcosine are both part of the glycine, serine and threonine metabolism pathway. Sarcosine is an intermediate and byproduct in glycine synthesis and degradation. Glycine is inter-convertible to Serine and Alanine and is furthermore necessary for protein and DNA synthesis (i.e., for cell proliferation), also acts as an intracellular regulator and as an organic osmolyte (Steves *et al.*, 2003). Brison *et al.* (2004) found that Glycine is less abundant in the culture medium of human embryos that resulted in successful IVF pregnancies. Regarding the mediated transport of Glycine to the uterine lumen, Hugentobler *et al.* (2007) have shown that ULF concentration of glycine on day 6 of the estrous cycle was greater and not correlated to its concentration in blood plasma. This pattern indicates that glycine is actively transported by the endometrial epithelia towards the uterine lumen. In the present study, we detected a downregulation of *SLC6A9* (Glycine

transporter, also known as *GLYT1*) transcript in the Preg endometrial tissue, suggesting an endometrial origin of regulation that was consistent with the lower Glycine concentration in the ULF. Mechanisms by which the embryo regulates this process are currently unknown.

Presence of a day-7 embryo decreases the concentration of acylcarnitines and phospholipids in the ULF. Acylcarnitines are key molecules enrolled in fatty acids transport and energy metabolism. Notably, three acylcarnitines (C3-OH, C5-OH and C16-OH), that were found in different concentrations between groups, are esters derived from hydroxylated acids. Hydroxylated acylcarnitine status is an important indicator of lipid metabolism by the fatty acid omega-oxidation pathway and may represent an important biomarker of fatty acid metabolism (Su *et al.*, 2005). Phospholipids are important structural components of plasma lipoproteins and cell membranes, and have important roles in the regulation of cell function and signaling (Edidin, 2003). The ratio between PUFA and SFA showed to be decreased in Preg ULF samples. This finding indicates that the activity of fatty acid desaturases between Con and Preg endometria may be altered. Decreased levels of phospholipids in biological fluids might be attributable to enhanced cell membrane synthesis in the lining cellular compartments (Santos & Schulz, 2012). Differences in lipid profile in the endometrium at late diestrus between pregnant and nonpregnant ewes (Meyer *et al.*, 1997), and between gravid and nongravid horns of pregnant cows (Meyer *et al.*, 2011) have been reported before. In our study, we showed that both LysoPC a C17:0 and LysoPC a C20:3 fatty acids were significantly lower in abundance in ULF recovered from Preg compared to Con cows. It is possible that these lipids were partially retained by the lining endometrium. Meier *et al.* (2009) have shown that endometrial tissue from pregnant cows displayed greater concentrations of C17:0 and C20:3 fatty acids compared to their cyclic counterparts on day 17 after estrus. The C20:3 fatty acid acts as precursors for prostaglandin synthesis (Leaver & Poyser, 1981). Additionally, the total recoverable amount of hydroxysphingomyelins tended to be greater in the Con ULF samples. Stimulated synthesis of sphingolipids is related to a pro-apoptotic status of endometrium in women (Knific *et al.*, 2018). At the present time, we can only speculate on the functional relevance and regulation of changes in the abundance of specific lipids. Much more research is needed on the topic of lipid biology of pregnancy.

In conclusion, we produced evidence to sustain the view that the bovine embryo modulates the biochemical composition of the uterine microenvironment as early as day 7 *in vivo*. Such modulation seems to be local and includes changes in concentrations of lipoxygenase-derived metabolites, amino acids, biogenic amines, acylcarnitines and phospholipids (Fig. 9). Although the endometrial or embryonic origin of the modulated

biochemical processes can only be speculated, it is clear that regulation is complex and interactive. Intensity and extent of embryo signaling capacity is expected to increase dynamically throughout the window of pre-implantation development, in order to cover its changing needs. Altogether, the data of our *in vivo* model highlighted key pathways involved in early embryo-induced alteration in the luminal uterine metabolome. Of particular interest, the products of the lipoxygenase-pathway seem to play an important role in early pregnancy. This novel finding warrants further investigation.

Figure 9. Summary and integration of the main results. Metabolomic measurements reveal an overall decrease on substrate concentration in uterine luminal fluid recovered from pregnant (Preg) compared to control cyclic (Con) cows on day 7 post estrus. (1) Concentration of two metabolites 12(S)-HETE and 15(S)-HETE, associated to the Lipoxygenases pathway, were significantly greater in the Preg group. Transcripts for lipoxygenases were up- (*ALOX12*) and downregulated (*ALOX15B*) in the uterotubal junction of Preg animals, suggesting an endometrial origin of regulation of Lipoxygenases-derived metabolites in ULF. (2) Glycine and sarcosine were significantly lower in abundance in ULF recovered from Preg compared to Con cows. A downregulation of *SLC6A9* (a Glycine transporter) transcripts was found in the Preg endometrial tissue, that was consistent with the lower Glycine concentration in ULF. Exposure to a day 7 embryo modulates the concentration of (3) phospholipids and (4) acylcarnitines concentration in ULF. We propose that metabolite composition of the ULF changes in response to a pre-hatching embryo *in vivo*.

3.6 ACKNOWLEDGEMENTS

This study was funded in part by Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) and by Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP; Grant Number 2011/03226-4). MS was partly supported by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil (CAPES; Finance Code 88881.132730/2016-01) and by the Special Research Fund (Uantwerpen, 2018) joint-PhD program. The authors thank the Administration of the Fernando Costa campus (University of

São Paulo) for providing the animals, and the technical assistance of FMVZ-USP staff and students to collect samples.

3.7 AUTHOR CONTRIBUTIONS

MS conceived the study, performed statistical analysis and wrote the manuscript. AMG-D assisted with sample processing and data analysis. CCR performed PCR analysis. EGLT contributed with mass spectrometric measurements and provided expertise in metabolomic data analysis and interpretation. GP and JLMRL contributed with critical review of the manuscript. MB is the PI of the project, provided the financial support, expertise in experimental design, analysis and corrected the manuscript. All authors reviewed and approved the manuscript.

4 THE BOVINE EMBRYO-ENDOMETRIUM INTERACTOME DECIPHERED *IN VITRO*

4.1 ABSTRACT

In cattle, pregnancy establishment is ultimately dependent upon fine-tuned cellular and molecular interactions between a competent embryo and a receptive endometrium. Current understanding of the factors and mechanisms involved in the complex embryo-maternal interactome is limited. It is unknown, for example, whether a physical contact between the embryo and the endometrial epithelia is needed to elicit changes in both embryonic and maternal units. We hypothesized that nature and intensity of embryo-induced changes on endometrial transcriptome depend on a juxtaposition between the embryos and the endometrium. Hereto, we used an *in vitro* approach to decipher the very local embryo-endometrial interface for embryo-induced changes on the bovine endometrial epithelial cells (BEEC) transcriptome. *In vitro*-produced day-5.5 morulae were cultured in the absence of endometrial cells (NoBEEC group), juxtapositioned on top of BEECs (Juxt), or in transwells (Non-juxt), for 48 h. An extra group of BEEC cultured in the absence of embryos (NoEmbryos) was included. At BEEC transcriptome level, NoEmbryos versus Juxt comparison yield 1,797 DEGs. Interestingly, transcriptome changes were rather limited between NoEmbryos versus Non-juxt, with 230 genes being differentially regulated. Interferon-mediated pathways were enriched in either Juxt and Non-Juxt. Biological processes exclusively enriched in Non-juxt versus Juxt comparison include regulation of cell cycle, estrogen biosynthesis, mitochondrial dysfunction and pregnenolone biosynthesis. Co-culture with BEEC improved blastocyst rates on day 7.5, regardless of Juxt or Non-juxt conditions. In conclusion, nature and intensity of embryo-induced effects on bovine endometrium varies according to physical proximity of the embryos.

4.2 INTRODUCTION

Fundamentally, a successful pregnancy depends on the quality of the blastocyst and on a receptive endometrium. Moreover, tightly coordinated cellular and molecular interactions between the competent embryo and the receptive endometrium need to be established to safeguard the pregnancy in eutherian mammals. Disturbances in this complex communication can result in early embryonic losses and, therefore, subfertility. This is of special importance in cattle, since up to 40% of pregnancies fail within the first three weeks of pregnancy (Diskin *et al.*, 201; Diskin *et al.*, 2016).

The concept of embryo-maternal interactome implies dynamic processes precisely coordinated by both the maternal and the embryonic unit. In the cow, it is expected that the developing embryo starts to interact with the endometrium around day 5 post-fertilization when the zona pellucida-enclosed morula enters into the uterus (Guillomot *et al.*, 1994). The embryo *in utero* is tightly surrounded by the endometrial luminal epithelium (Wolf *et al.*, 2003), however, until day 20, there is no anatomical union between the conceptus (embryo and associate membranes) and the endometrium. Thus, signaling molecules are understood to play an important role in the early embryo-maternal communication in cattle. The actions of those molecules can be directed from the embryo towards the maternal tissue, and vice-versa, in a paracrine or a juxtacrine fashion. One well known example of paracrine signaling is the embryo-produced Interferon-tau (IFN τ) which is released into the uterine lumen and acts in the endometrium to abrogate the luteolytic cascade (Bazer *et al.*, 1997). Effects of the embryo on the adjacent endometrial cells are poorly defined.

Regarding this dialogue, it is well conceived that a successful embryo maintains basic tools for its own development, given the fact that the bovine embryo can thrive successfully up until the blastocyst stage *in vitro*, independently of exposure to the maternal reproductive tract. However, it is clear that the maternal genital tract, including the uterus itself, exerts considerable control over the ability of a conceptus to develop. For example, several studies have demonstrated that *in vivo* cultured embryos differ to their *in vitro* produced counterparts in terms of developmental competence, morphology, metabolism, gene expression profile, and cryotolerance (reviewed by Rizos *et al.*, 2017). Moreover, exposure to the uterine environment at the post-hatching stage is a prerequisite for embryo elongation, given that elongation of bovine conceptuses do not occur *in vitro* (Brandao *et al.*, 2004).

On the maternal side, it is well established that the maternal reproductive tract function is primarily controlled by ovarian steroids. Estradiol and progesterone, from pre-

ovulatory follicles and corpus luteum (CL), exert classical endocrine control of morphological and functional changes in the endometrium that affect embryo development and pregnancy success (Carter *et al.*, 2008; Forde *et al.*, 2009; Mesquita *et al.*, 2015). Although the classical endocrine regulation of endometrial function has been extensively investigated, the programming of endometrial function exerted by the embryo has not been interrogated to the same extent.

In this regard, it has been shown that the endometrium senses the embryo quality (Macklon & Brosens, 2014). For example, the bovine endometrial transcriptome changes when exposed to *in vitro*- versus *in vivo*-produced embryos (Mansouri-Attia *et al.*, 2009), and when exposed to standard *in vitro*-produced versus cloned embryos (Bauersachs *et al.*, 2009). In fact, accumulating evidence supports the idea that the early embryo is more than a passenger throughout the uterine lumen and that it has the capacity to elicit changes from the endometrium. We have shown that the endometrial transcriptome responds locally to a pre-hatching embryo presence as early as day 7 *in vivo* (Sponchiado *et al.*, 2017). Other *in vitro* studies have shown that early embryos modulate the abundance of specific transcripts in endometrial epithelial cells (Talukder *et al.*, 2017; Gómez *et al.*, 2018). Specific pathways modulated by the embryo include transcripts for interferon stimulated genes (ISGs) and prostaglandin metabolism. The question still remains whether the endometrial responses of the juxtacrine differs of the non-juxtacrine fashion. We hypothesized that nature and intensity of embryo-induced changes on endometrial transcriptome depend on physical proximity between the embryos and the endometrium. Therefore, we aimed to interrogate the unique embryo-maternal interface for embryo-induced changes on the endometrial epithelial cells transcriptome. A second aim was to investigate the effects of co-culture with endometrial cells on embryo development from morula to blastocyst stage. Hereto, we used an *in vitro* co-culture system of embryos juxtapositioned to bovine endometrial epithelial cells (BEECs) to elucidate basic mechanisms involved in the early embryo-maternal interactome. Non-juxtacrine condition was accomplished by using a transwell insert. The importance of physical proximity between the embryos and the endometrial cells was investigated in terms of embryonic development and BEEC transcriptome profiles.

4.3 MATERIAL AND METHODS

Chemicals used to prepare cell and embryo culture medium were purchased from Life Technologies (Thermo Fisher Scientific, Waltham, USA) or from Sigma Chemical Co. (St Louis, MO, USA), unless otherwise stated.

4.3.1 Overview of experimental model

For the purpose of this study, we established a straight forward bovine endometrial epithelial cell (BEEC)-embryo coculture as a research model to investigate the very early embryo-maternal interactions *in vitro*. An overview of the experimental procedures used in the present study is given in Figure 1. In addition to the experimental set up, a characterization regarding cell-origin markers and functional key transcripts in the cell model was performed for validation purposes.

Figure 1. Schematic overview of experimental model. Bovine endometrial epithelial cells (BEECs) were isolated from uteri *ex vivo*, pooled, and used for the primary culture. BEECs were cultured until passage 3, when assigned to experimental conditions (Experiment 1 and 2). For means of characterization, cells from each passage were simultaneously cultured in 24-well plates for further PCR analyses. At passage 2, BEECs were then frozen-and-thawed to be co-cultured with embryos (Experiment 1), or to generate BEEC-conditioned medium (Experiment 2), in a manner that in all replicates, aliquots containing cells originated from the same bunch were applied. Detailed descriptions of procedures and outcomes for each step are given in the next sections.

4.3.2 Experiment One

In this experiment, we compared the effects of juxtaposition versus non-juxtaposition between embryos from morula to blastocyst stage and endometrial cells on BEEC transcriptome and embryo development. Embryos were co-cultured with BEEC monolayers from day 5.5 p.i. (post insemination) until day 7.5 p.i. The timing of exposure of the endometrial cells to embryos (i. e. day 5.5 p.i.) coincides with the embryo's arrival into the uterus *in vivo* in the cow (Bazer *et al.*, 1991). Juxtacrine interaction was accomplished by placing 15 embryos directly on top of BEEC monolayers. Non-juxtacrine interaction was accomplished by placing 15 embryos in a 96-well cell-culture insert (IncuCyte® by Sartorius, USA). The insert membrane avoided the direct physical contact between the embryos and the endometrial monolayer. Additionally, the low pore density (<2% of the surface area; 8.0 µm pore size) of the insert membrane limited the diffusion of secreted signaling molecules between the upper (containing the embryos) and the basal (containing the BEEC monolayer) compartments. This feature was desirable because a dilution factor is expected to occur in non-adjacent, paracrine signaling *in vivo*. The distance between the basal plate and the insert is 1.425 mm.

In vitro produced day-5.5 morulae and early blastocysts were selected under stereomicroscope and transferred towards the 96-well ClearView reservoir plate containing 90% confluent, untreated BEEC monolayers according to the treatments: (i) **NoBEEC**: groups of 15±1 morulae/early blastocysts, without BEECs; (ii) **Juxt**: groups of 15±1 morulae/young blastocysts placed directly on top of a BEEC monolayer; (iii) **Non-juxt**: groups of 15±1 morulae/young blastocysts on cell culture transwells, without contact with the BEEC monolayer; or (iv) **NoEmbryos**: BEECs in the absence of embryos (Figure 1). Embryos were transferred using mouth-controlled, fine pore glass capillaries to minimize the volume of media transferred to the wells. Embryos/cell cultures (for all the experimental conditions) were conducted in 150 µL of SOF medium supplemented with 5% of fetal bovine serum (FBS), for 48 h (from day 5.5 p.i. until day 7.5 p.i.) in humidified atmosphere of 5% CO₂ and 20% O₂ at 38.5 °C. On day 7.5, embryos and BEEC monolayers were evaluated and processed as described below. Experiment was performed in 6 replicates and 2 to 4 wells of each condition were included in each replicate.

4.3.2.1 Sample evaluation and processing

On day 7.5, embryo developmental stages were recorded and expressed as a proportion of total number of morulae assigned initially to the treatments. All morphological

assessments were conducted using an inverted Olympus CKX41 microscope (Olympus, Belgium). Blastocysts were either fixed in paraformaldehyde for immunostaining or snap frozen. Embryos were fixed in 4-well plates containing 500 μL of buffered 4% paraformaldehyde for 30 min at room temperature, and stored in PBS-PVP 1% at 4 $^{\circ}\text{C}$. Groups of 5 embryos were washed in PBS-PVP 1%, snap frozen in (RNase/DNase free) microtubes and stored at -80°C . BEEC monolayers were detached and retrieved by trypsinization. Briefly, cell monolayers were washed with pre-warmed PBS (Ca^{2+} Mg^{2+} free) to remove serum traces and detached cells. Cells were then incubated with 100 μL of pre-warmed TrypLE express (Thermo Fisher Scientific) for 6 min at 38.5°C . The reaction was stopped by adding 200 μL of PBS (Ca^{2+} Mg^{2+} free) to the wells. Trypsin-BEECs mixtures were transferred towards 1.5 mL (RNase/DNase free) microtubes and centrifuged at $200 \times g$ for 10 min at 24 $^{\circ}\text{C}$. The supernatants were carefully removed, cell pellets were snap frozen and stored at -80°C for further processing.

4.3.3 Experiment Two

In this experiment, we aimed to isolate potential non-specific embryo supportive effects elicited by BEECs on embryo development. By using conditioned medium from mice fibroblasts, we tested whether heterologous, unspecific feeder cells could also affect embryo development. Secondly, by using conditioned medium from BEECs, we eliminated the potential effect of a reduced O_2 tension caused by the BEEC monolayer that may have favored embryo development in experiment 1. Therefore, *in vitro* produced day-5.5 morulae/early blastocysts were cultured with fresh conditioned medium from BEECs and mice fibroblasts as described below. Experiment was performed in 5 replicates and 2 to 5 wells of each condition were included in each replicate.

4.3.3.1 Conditioned medium preparation and treatments

DMEM/F12-based culture medium of BEEC and mice fibroblast subconfluent monolayers was replaced by SOF medium supplemented with 5% of FBS. Additional wells containing only SOF-5% FBS medium were included. After 24 h, the spent/control medium from 6 wells per condition were collected, pooled and centrifuged at $200 \times g$ for 5 min at 24 $^{\circ}\text{C}$ to remove cell debris. After 30 min of equilibration in the incubator, 150 μL of BEEC- and fibroblasts-conditioned medium were distributed in 0.1% gelatin-coated 96-well ClearView

Reservoir Plate (IncuCyte® by Sartorius). Subsequently, groups of 15±1 day-5.5 morulae/early blastocysts were assigned to the following treatments: (i) **Control**: Culture medium (SOF-5% FBS); (ii) **BEECcond**: BEEC-conditioned SOF-5% FBS medium; or (iii) **FIBRcond**: fibroblast-conditioned SOF-5% FBS medium. Embryos were transferred using mouth-controlled fine pore glass capillaries to minimize the volume of media transferred to the wells. *In vitro* embryo culture was conducted in humidified atmosphere at 38.5 °C in 5% CO₂ and 20% O₂ from day 5.5 until day 7.5 p.i.. The medium was replaced with freshly prepared conditioned (or control) medium in 50% of the volume after 24 h. On day 7.5, embryos were scored according to their developmental stages.

4.3.4 Isolation and culture of bovine endometrial epithelial cells (BEECs)

4.3.4.1 Cell collection and primary culture

Reproductive tracts at early luteal phase of the estrous cycle were collected from *Bos taurus* beef cows at a local slaughterhouse, inspected for absence of reproductive abnormalities or disorders, and transported to the laboratory at 30 °C. Four uteri were trimmed free of surrounding tissues and externally decontaminated with 70% ethanol. The uterine horns ipsilateral to the ovary containing the corpus hemorrhagicus were longitudinally opened at the mesometrial insertion with decontaminated scissors and then, the endometrial luminal surface was carefully scraped with sterile glass slides. Cells collected from the four uteri were pooled in equilibrated, pre-warmed cell culture medium. The cell culture medium consisted of DMEM/F-12 phenol red-free medium (Product number 11039-021; Gibco, Thermo Fisher Scientific) supplemented with 10% FBS (Product number F9665, Sigma-Aldrich), 2% Penicillin/Streptomycin, and 1% Fungizone. The cell suspension was centrifuged at 200 x g for 5 min at 24 °C, the supernatant was discarded and erythrocytes were subsequently lysed by incubation with a hyper-osmotic Lysis buffer (1 mM EDTA disodium salt, 150 mM NH₄CL and 100 mM NaHCO₃) for 1 min. The resulting cell pellet was resuspended in pre-warmed culture medium and centrifuged. After two washing steps, cells were plated in 25 cm² culture flasks at a density of 1 x 10⁶ cells/mL and pre-incubated in humidified atmosphere of 5% CO₂ at 38.5 °C for 1 h 30 min. The pre-incubation step aimed to remove the contaminating non-epithelial cells. The supernatant containing non-attached, epithelial cells was transferred towards fresh 25 cm² culture flasks and maintained in humidified atmosphere of 5% CO₂ at 38.5 °C. After the adhesion process started, culture

medium was changed every 48 h. Flasks were checked daily for signs of contamination and to visually estimate the monolayer's confluence by inverted light microscopy.

4.3.4.2 Subculture and freezing procedure

Cells were subcultured when primary monolayers reached 95% of confluence. Monolayers were washed once with PBS (Ca^{2+} Mg^{2+} free; Gibco) to remove residual serum. Cells were then trypsinized (TrypLE Express; Gibco, Thermo Fisher Scientific) for 6 min, retrieved and centrifuged at 200 x g for 5 min at 25 °C. Cell count and viability were determined in a Bürker Counting Chamber (W. Schreck, Hofheim, Germany) by trypan blue exclusion test. BEECs were seeded at a density of 1×10^6 viable cells/flask into fresh 75 cm² culture flasks and cultured as described for primary culture. When 95% of confluence was reached, BEEC monolayers were washed with PBS (Ca^{2+} Mg^{2+} free) and trypsinized as described previously. BEECs at passage 2 were plated at a density of 1.5×10^6 viable cells/flask into fresh 75 cm² culture flasks. BEEC culture was conducted as described for primary culture. Subconfluent (90%) monolayers were then washed with PBS (Ca^{2+} Mg^{2+} free) and trypsinized as described previously. The resulting cell pellet was diluted in cryopreservation medium at a concentration of 1×10^6 viable cells/mL. The cryopreservation medium was based on DMEM/F-12 phenol red free medium supplemented with 15% FBS, 10% DMSO (Invitrogen, Thermo Fisher Scientific), 2% Penicillin/Streptomycin, and 1% Fungizone. Cryovials containing BEECs were placed in a freezing container (Nalgene® Cryo, Thermo Fisher Scientific) and kept at -80 °C overnight, afterward, stored in liquid nitrogen. Experiments 1 and 2 were performed using BEECs at passage 3 thawed from the same batch.

4.3.4.3 BEEC cell line characterization

BEEC cultures were conducted in 24-well plates in order to evaluate the presence of epithelial and mesenchymal cell markers and abundance of functional key transcripts from primary culture to passage 3. Cells were seeded at a density of 3×10^4 viable cells/well into 24-well plates for further trypsinization and retrieval for gene expression analysis, or on sterile glass coverslips for further fixation and immunostaining analysis. Cell cultures were conducted as described before (please check *Cell collection and primary culture*, and *Subculture and freezing procedures* sections). Subconfluent BEEC monolayers were washed twice with PBS (Ca^{2+} Mg^{2+} free). Monolayers grown on coverslips were fixed in buffered 4%

paraformaldehyde for 30 min at room temperature, washed twice with ice-cold PBS and stored at 4 °C for further immunostaining analysis (see below). The remaining wells containing cells were trypsinized for 6 min, retrieved and centrifuged at 200 x g for 5 min at 25 °C. Cell pellets were snap frozen and kept at -80 °C for further processing.

4.3.4.4 BEEC assignment to treatments (Experiments 1 and 2)

Vials containing BEECs at passage 3 were thawed and seeded in 0.1% gelatin-coated 96-well ClearView Reservoir Plate (IncuCyte® by Sartorius) at a density of 1.5×10^4 cells/well. Cells were maintained in DMEM/F-12 phenol red free medium supplemented with 10% FBS, 2% Penicillin/Streptomycin, and 1% Fungizone, in humidified atmosphere of 5% CO₂ at 38.5 °C. The medium was changed every 48 h. Approximately 90 h hours after plating, monolayers at 90% confluency were subjected to treatments as described previously for Experiments 1 and 2.

4.3.5 *In vitro* embryo production

Bovine embryos were *in vitro* produced as previously described (Marei *et al.*, 2019) with minor modifications. Briefly, ovaries were collected at a local slaughterhouse and transported within 1 h of slaughter to the laboratory. Antral follicles with a diameter of 3-8 mm were aspirated. Immature, unexpanded cumulus-oocytes complexes (COCs) were matured *in vitro* (day -1) in groups of 50 ± 5 COCs in 4-well plates (Nunc, Langensfeld, Germany) containing 500 µL of maturation medium per well for 24 h in humidified atmosphere with 5% CO₂ at 38.5 °C. Matured COCs were then co-incubated in groups of 100 ± 10 with spermatozoa at a final concentration of 10^6 sperm cells/mL for 22 h in 500 µL of fertilization medium in humidified atmosphere of 5% CO₂ at 38.5 °C (day 0). For all replicates, thawed semen from the same batch of a proven fertility bull was used following selection of motile spermatozoa by centrifugation on a discontinuous 45%-90% Percoll (Amersham Biosciences, Little Chalfont, UK) gradient. Finally, denuded presumptive zygotes were cultured (day 1) in groups of 25 ± 2 in 75 µL basic synthetic oviductal fluid (SOF) culture medium supplemented with 5% FBS and 50 mg/mL gentamycin. Embryo culture was carried out in half-area 96-well plates under controlled atmosphere of 5% CO₂, 5% O₂, 90% N₂ at 38.5 °C until day 5.5 p.i.

4.3.6 Immunofluorescence

4.3.6.1 BEEC

Samples were fixed in buffered 4% paraformaldehyde for 30 min at room temperature and kept at 4 °C immersed in PBS-PVP. Coverslips were transferred towards a new 24-well plate and BEEC monolayers were permeabilized with 500 µL of PBS containing 1% Triton X-100 and 0.05% Tween-20 for 30 min at room temperature. Monolayers were washed 3 times in wash solution that consisted in 0.5% BSA and 0.05% Tween-20 in PBS. Next, samples were blocked in PBS containing 2% BSA and 0.05% Tween-20, for 45 min at room temperature, then incubated with primary antibodies overnight at 4 °C. Primary antibodies used in the present study were anti-Cytokeratin mouse monoclonal antibody (1:100 in blocking solution; M3515, Dako, CA, USA), and anti-Vimentin rabbit polyclonal antibody (1:100 in blocking solution; ab45939, Abcam, MA, USA). Negative control coverslips were incubated with an equivalent mixture of normal mouse and rabbit IgGs. Monolayers were washed in wash solution and subsequently incubated with the secondary antibodies Texas Red-labeled goat anti-mouse (1:200 in blocking solution; Life Technologies) and FITC-labeled goat anti-rabbit (1:200 in blocking solution; Novex, Life Technologies) for 1 h at 4 °C. Nuclei were counterstained in Hoechst 33342 (30 µg/mL in PBS-PVP 1%) for 10 min at room temperature. Thereafter, coverslips were mounted on glass slides in droplets of 1% DABCO. Images were captured under a fluorescence microscope IX71 (Olympus) and CellSens software with DAPI filter (excitation/emission: 360–370/420–460 nm for Hoechst stained nuclei), FITC filter (460–490/520–540 nm for Vimentin), and RITC filter (510–550/>570 nm for Cytokeratin-positive cells).

4.3.6.2 Embryos

Day 7.5 embryos (n = 91) beyond normal blastocyst stage were differentially stained to count the cells in the inner cell mass (ICM) and trophectoderm (TE) using an immunofluorescence method adapted from Wydooghe *et al.* (2011). Briefly, embryos were permeabilized in 0.1% Triton X-100 and 0.05% Tween-20 in PBS at 4 °C overnight. To avoid any non-specific binding, embryos were incubated in blocking solution (10% normal goat serum in 0.05% Tween-20 in PBS) for 2 h at 4 °C. Blastocysts were incubated overnight at 4 °C in primary antibody solution containing a 1:1 mixture of mouse anti-caudal type

homeobox 2 (CDX2) antibody (ready to use; BioGenex, San Ramon, USA). Negative control embryos were incubated with normal mouse IgG at the same concentration as the primary antibody. All embryos were washed in PBS-PVP 1% and subsequently incubated with the secondary antibody Texas Red-labeled goat anti-mouse (1:200 in blocking solution; Life Technologies) for 4 h at 4 °C. Nuclei were counterstained in Hoechst 33342 (30 µg/mL in PBS-PVP 1%) for 10 min at room temperature. Blastocysts were mounted onto glass slides in droplets of 1% DABCO and covered with coverslips. Images were captured under a fluorescence microscope IX71 (Olympus) and CellSens software with DAPI filter (excitation/emission: 360–370/420–460 nm for Hoechst stained total cells) and RITC filter (510–550/>570 nm for CDX2-positive TE cells).

4.3.7 Total RNA isolation and cDNA synthesis

4.3.7.1 BEEC (Experiment 1)

Total RNA was extracted using the PicoPure RNA Isolation Kit (Thermo Fisher) as per manufacturer's instructions with minor modifications. Briefly, BEEC samples were subjected to cell lysis in 50 µL of Extraction Buffer for 30 min at 42 °C. Lysates were added 70% ethanol and loaded into pre-conditioned purification columns and centrifuged for 2 min at 100 g, immediately followed by centrifugation at 12,000 g for 1 min to remove flowthrough. Membranes were subjected to On-column DNase treatment (RNase-Free DNase Set; Qiagen) at room temperature for 15 min according to the standard protocol. After subsequent wash steps, the membrane-bound RNA was eluted in 16 µL of the Elution Buffer provided. Total RNA yield and purity (260/280 nm ratio) were verified by NanoDrop (Thermo Fisher Scientific) spectrophotometer analysis. RNA integrity was assessed using automated capillary gel electrophoresis on a Bioanalyzer 2100 (Agilent Genomics, Dublin, Ireland) with RNA 6000 Nano Lab-chips according to manufacturer's instructions. Absorbance ratios (28S/18S) and RNA integrity values recorded for all RNA samples extracted ranged between 2.0 and 2.6, and 8.5 and 10.0, respectively. The isolated RNA samples were stored at –80 °C until RNA sequencing.

4.3.7.2 Embryos (Experiment 1)

Pools of 15 embryos (developmental stages were distributed equally among samples) were subjected to total RNA isolation using the PicoPure RNA Isolation Kit (Thermo Fisher) as described for BEEC samples. Concentration and purity (260/280 nm ratio) of total RNA in extracts were evaluated by NanoDrop (Thermo Fisher Scientific) spectrophotometer analysis. Total RNA (50 ng) was reverse transcribed using the Sensiscript RT kit (Qiagen) according to manufacturer's instructions with minor modifications. The master mix was composed by the Sensiscript Reverse Transcriptase and the buffer RT supplied in the kit, supplemented with Recombinant RNasin RNase inhibitor (Promega), Oligo-dT (Promega) and Random (Promega) primers at a final concentration of 1 μ M and 10 μ M, respectively, and dNTP mix (Promega) at final concentration of 0.5 mM/each dNTP. Samples were incubated in a thermocycler at 37 °C for 1 h and stored at -20 °C until further analyses.

4.3.7.3 BEEC (Cell line characterization)

Total RNA was isolated using Trizol Reagent (Invitrogen, Thermo Fisher Scientific, CA, USA) in accordance with manufacturer's guidelines. Samples were lysed in 200 μ L of Trizol and placed at room temperature for 5 min. Subsequently, 128 μ L chloroform were added and samples centrifuged at 10,000 g for 15 min at 4 °C for phase separation. The aqueous phase was transferred towards a new microtube and 400 μ L isopropanol were added, for RNA precipitation. At this step, samples were stored overnight at -80 °C to maximize RNA harvest. Samples were centrifuged at 10,000 g for 12 min at 4 °C. The RNA precipitate was resuspended in 400 μ L of 75% ethanol, followed by centrifugation at 10,000 g for 8 min at 4 °C. Air-dried RNA pellets were resuspended in 10 μ L of DEPC water and, subsequently, incubated at 55 °C for 10 min. Extracts containing RNA were kept at -80 °C until use. Total RNA yield and purity (260/280 nm ratio) were evaluated by NanoDrop (Thermo Fisher Scientific) spectrophotometer analysis. Samples of RNA (1 μ g) were treated with DNase I (Promega) according to the standard protocol. Total RNA was reverse transcribed using the High Capacity cDNA Reverse Transcription kit (Invitrogen) according to the manufacturer's instructions. First strand cDNA was synthesized using random hexamers and by incubation at 25 °C for 10 min, followed by incubation at 37 °C for 2 h and reverse-transcriptase inactivation at 85 °C for 5 min. The cDNA was stored at -20 °C until further analyses.

4.3.8 Real Time PCR

Relative abundance of transcripts was analyzed by Real Time PCR. Transcripts analyzed in BEEC samples included cell origin markers (*KRT18* and *VIM*), and key gene associated with endometrial function (*ESR1*, *IFNAR1* and *PTGS2*). Specific pairs of primers were designed based on the *Bos taurus* GenBank Ref-Seq mRNA. Transcripts analyzed in day-7.5 embryos included a marker for trophoblast cells (*CDX2*), interferon-tau (*IFNT2*), and a gene associated with apoptosis (*BAX2*). Reactions were carried out in duplicates in 96-well plates (Bio-Rad Laboratories) sealed with Microseal B PCR plate sealing film (Bio-Rad Laboratories) using the CFX Connect Real-Time PCR detection system (Bio-Rad Laboratories B.V., Netherlands). The PCR reactions were conducted in a final volume of 16 μL , consisting of 8 μL of SsoAdvanced Universal Sybr Green supermix (Bio-Rad Laboratories), 0.4 μL of forward and reverse primers, and 4 μL of cDNA template. Negative control reactions (DEPC-treated water replacing template cDNA) were included in every run. The program consisted of an initial denaturation step at 95 °C for 15 min, followed by 40 cycles each of 30 seconds at 95 °C, annealing at 59-61 °C for 30 seconds, and extension at 72 °C for 20 seconds. After a final extension step of 72 °C for 5 min, melting curves were plotted by stepwise increases in the temperature from 50 to 95 °C. The annealing temperature was optimized for each primer assay. Relative abundances were obtained after normalization of the target genes Cq (Crossing Point) values by the geometric mean of the reference genes Cq values according to the mathematical model described by Pfaffl (2001). *PPIA*, *GAPDH* and *ACTB* were used as reference genes for BEEC samples, while *H2AFZ*, *GAPDH* and *RN18S1* were used for embryos. Primers details are provided in Supplementary Table S11.

4.3.9 RNA-sequencing

Five BEEC samples (Experiment 1) per experimental group were selected for transcriptome analysis. Each sample consisted of a BEEC monolayer retrieved from an individual well. Samples were chosen based on these criteria: (i) samples from the Juxt and Non-juxt groups having embryos developed to similar blastocyst rates and stages; and (ii) samples pertaining to the same replicates. Blastocyst developmental rates for each sample addressed for RNAseq analysis are given in Supplementary Table S12.

Poly-A containing mRNA molecules were purified from total RNA using oligo(dT)-attached magnetic beads and fragmented into small pieces using divalent cations under elevated temperature. First-strand cDNA was synthesized using random hexamer-primed reverse transcription, followed by a second-strand cDNA synthesis using DNA Polymerase I

and RNase H. The synthesized cDNA was subjected to end-repair and 3' adenylation. Adapters were ligated to the ends of 3' adenylated cDNA fragments. cDNA fragments with adapters from previous step were amplified by PCR. The resulting PCR products were purified with Agencourt AMPure XP Beads (Beckman Coulter, Beverly, MA, US), and dissolved in buffer EB. Double stranded PCR products were heat-denatured and circularized by the splint oligo sequence. Single stranded circular DNAs (ssCir DNA) were used for PE100 strand-specific library construction and validation on the Bioanalyzer 2100 (Agilent Genomics). The library was amplified with phi29 and DNA nanoballs (DNBs) were generated with ssCir DNA by rolling circle replication (RCR) to intensify the fluorescent signals during the sequencing process. The DNBs were loaded into the patterned nanoarray and pair-end reads of 100 bp were read on the BGISEQ-500 (Cambridge, MA, US) platform for subsequent data analysis.

4.3.10 Statistical Analyses and Bioinformatics

Statistical analyses were carried out in SAS 9.4 software. Discrete variables (blastocyst rates and the proportion of blastocysts reaching the expanded-stage or beyond) were analyzed by PROC GLIMMIX using binomial distribution. Replicates were included as random effects in the model. When different, means across treatments were compared by DIFF adjusted by Tukey-Kramer test. Continuous variables (PCR data, cell count and ICM:TE ratio) were checked for normality of residues and homogeneity of variances by Shapiro-Wilk and Welch's test, respectively. Variables were transformed by log or root square when necessary to accomplish assumptions. Effects of treatments were determined using PROC MIXED by analysis of variance considering Type III sums of squares. When different, means across treatments were compared using DIFF adjusted by Tukey-Kramer test. A probability of $P \leq 0.05$ indicates a significant difference, and a probability of $P > 0.05$ to $P \leq 0.1$ indicates a tendency. Data are presented as mean \pm SEM, unless otherwise indicated.

Transcriptome analysis was performed in Galaxy (<https://usegalaxy.org>). Quality control was performed by FastQC (version 0.71). Paired reads were mapped to the *Bos taurus* reference genome (UMD 3.1) using HISAT2 (version 2.1.0), after which the counts per gene model was performed with FeatureCounts (version 1.6.2). Expression values were normalized and global and pairwise statistics were performed using DESeq2 (version 1.18.1) using false discovery rate (FDR)-corrected P values.

Canonical pathways of the DEGs was performed using Core Analyses in Ingenuity® Pathway Analysis (IPA, QIAGEN bioinformatics). For that, a cutoff of DEGs with Fold Change ≥ 1.5 and adjusted P value ≤ 0.05 was applied. A detailed description of the IPA analysis is available on the manufacturer's homepage (<https://www.qiagenbioinformatics.com/products/features/>). Heat map was generated with Morpheus software (<https://software.broadinstitute.org/morpheus/>).

4.4 RESULTS

4.4.1 Characterization of bovine endometrial epithelial cells

During primary culture, isolated BEECs attached to the plastic surface of culture dishes and exhibited a mixture of round, spindle and elongated morphologies (data not shown). However, after the first passage, monolayers consisted of a homogeneous population of epithelial-like adherent cells, and that feature remained constant after two subsequent passages.

For means of characterization, the abundance of transcripts for cell-origin and relevant functional markers were addressed by real time PCR in the BEECs from the primary culture and the 3 first passages. Gene expression data revealed a 6-fold increased ($P < 0.001$, Fig. 2) abundance of *VIM* mRNA from primary culture to passage 1, that remained constant until passage 3; however, abundance of transcripts for keratin 18 (*KRT18*), estrogen receptor alpha (*ESR1*), prostaglandin-endoperoxide synthase 2 (*PTGS2*), and interferon alpha and beta receptor subunit 1 (*IFNARI*) remained similar among primary culture and first passages, suggesting that the cells conserved these functional characteristics (Fig. 2). Immunofluorescence staining revealed that the BEECs co-express cytokeratin, a typical cytoplasmic marker for epithelial origin, together with vimentin, a marker of mesenchymal-derived cells (Fig. 3). Taken together, these results indicate that our cell line, despite its dedifferentiated status, constitutes a physiologically relevant model to answer the hypotheses raised in this study.

Figure 2. Relative mRNA abundance of keratin 18 (KRT18), vimentin (VIM), estrogen receptor alpha (ESR1), prostaglandin-endoperoxide synthase 2 (PTGS2), and interferon alpha and beta receptor subunit 1 (IFNAR1) on bovine endometrial epithelial cells at primary culture and first three passages. Data are shown as arbitrary units; mean \pm SEM. a,b Statistically significant difference in mRNA abundance ($P \leq 0.05$, $n = 8$).

Figure 3. Morphology of bovine endometrial epithelial cells (BEEC) at passage 2. Light microscopy images were acquired with x10 magnification. Immunofluorescence staining for an epidermal stem cell marker (cytokeratin, in red) and a stromal cell marker (vimentin, in green). The endometrial cells were positive for both markers. Scale bar = 50 μ m. Negative controls were incubated with an equivalent mixture of normal mouse and rabbit IgGs instead of primary antibodies (top right inserts).

4.4.2 Embryo-induced effects on bovine endometrial epithelial cells transcriptome

Five samples of BEECs from NoEmbryos, Juxt and Non-juxt groups were analyzed (criteria applied to select samples for transcriptome analysis are described in *RNA-sequencing* section). After mapped to the *Bos taurus* reference genome (assembly UMD3.1) and filtering, a total of 19,996 genes were used to identify differentially expressed genes [DEGs; false discovery rate (FDR), $P_{adj} \leq 0.05$]. A list of DEGs ($P_{adj} \leq 0.05$) is provided on Supplementary Datasets S13-S15 along with their respective mean normalized counts per group, Log fold-changes, and adjusted P values. A total of 1,797 ($P_{adj} \leq 0.05$; Fig. 4) genes were differentially expressed in the Juxt group compared to their NoEmbryos counterparts. Whereas, only 230 DEGs were found between Non-juxt compared to the NoEmbryos group (Fig. 4). Notably, from those 230 DEGs, a subset of 225 genes was found to be also differentially expressed in the Juxt versus NoEmbryos comparison, as represented in Figure 4. These 225 overlapping DEGs, therefore, represent the embryo-induced effects on BEEC transcriptome irrespective to juxtaposition.

4.4.2.1 Pathways impacted by embryo presence

Many of the 225 genes commonly responsive to embryo presence, regardless of Juxt or Non-juxt condition, were classical type I interferon stimulated genes (ISGs; Fig. 4 and 5). The 5 most up-regulated genes triggered by the embryo included *MXI* (192-fold), *OASIX* (135-fold), *IFIT1* (123-fold), *OAS1Y* (73-fold), and *IFI27* (86-fold). Presence of embryos also modulated transcription of genes other than interferon-mediated signaling, as for example mRNA abundances for transporters including solute carrier family (*SLC*) 25, member 28 (*SLC25A28*), *SLC25A15*, and *SLC25A30* was increased in the Juxt and Non-Juxt groups compared to the NoEmbryos control. IPA analysis of the DEGs ($P_{adj} < 0.05$; Cutoff fold-change >1.5) yield in the Non-juxt versus NoEmbryos comparison identified 125 enriched biological processes. As expected, the top canonical pathways revealed in this functional analysis are mostly related to interferon-mediated immune responses pathways (e.g. Interferon Signaling, Activation of IRF by Cytosolic Pattern Recognition Receptors, Antigen Presentation Pathway, and Role of PKR in Interferon Induction and Antiviral Response pathway; Fig. 6). Additional relevant pathways identified include Retinoic acid Mediated

Apoptosis Signaling, Protein Ubiquitination Pathway, Prolactin Signaling and Prostanoid Biosynthesis (Fig. 6).

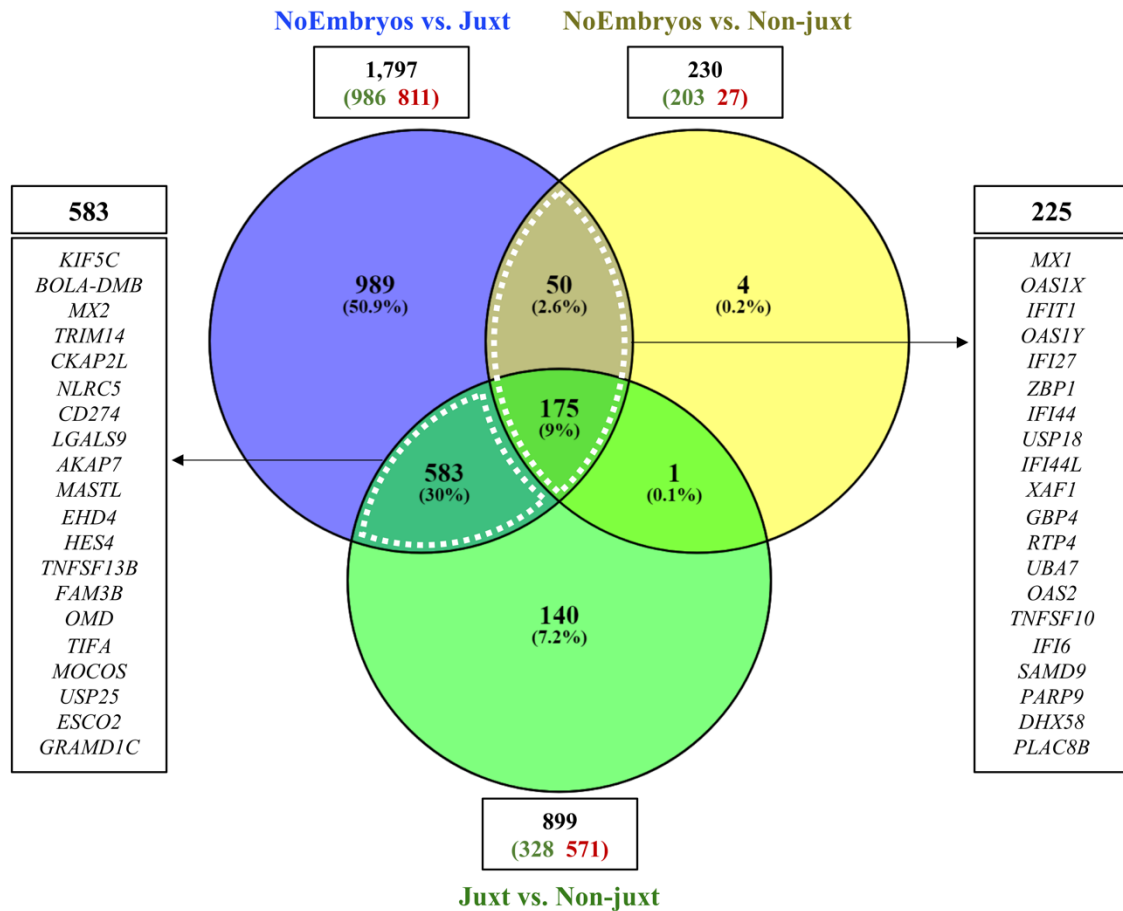

Figure 4. Venn diagram of RNAseq data from bovine endometrial epithelial cells (BEEC; n=5/group) exposed to none (NoEmbryos), juxtapositioned (Juxt) or without contact (Non-juxt) day-5.5 morulae/early blastocysts for 48 h. Differentially expressed genes (DEGs) were selected using adjusted P values ($FDR \leq 0.05$). The number of up- and downregulated genes are shown in green and red, respectively. Embryo-induced effects regardless of juxtaposition are represented by the overlapping 225 DEGs yield in the NoEmbryos vs. Juxt, and NoEmbryos vs. Non-juxt comparisons. Effect of embryos juxtaposition on endometrial transcriptome is represented by the intersected 583 DEGs yield in the NoEmbryos vs. Juxt, and Juxt vs. Non-juxt comparisons. Top-20 DEGs for each dataset are shown. See Supplemental Datasets S13-S15 for a complete list of DEGs.

Figure 5. Heat map depicts the top differentially up- and downregulated genes among the three groups. Reads count data were log₂ transformed and scaled to each row. Samples were clustered by Euclidean distances and are represented in each column.

Figure 6. Overview of canonical pathways returned by Ingenuity Pathway Analysis (IPA) analysis of differentially expressed genes (DEGs; $P_{adj} \leq 0.05$; Cutoff fold-change >1.5) between NoEmbryos versus Non-juxt groups. The charts (y-axis) represent the top significantly enriched canonical pathways. The upper x-axis shows the $-\log$ of the value calculated based on Fisher's exact test. The ratio (bottom x-axis) represented by the orange points is calculated based on the numbers of genes in a given pathway divided by the number of genes pertaining to that pathway. Straight orange vertical line represents the threshold for significance (by default). Canonical pathways shown were selected based on their biological significance.

4.4.2.2 Pathways impacted by juxtaposition with embryos

The comparison between Juxt versus Non-juxt yielded 899 DEGs with 583 (~65%) genes commonly changed in the NoEmbryos versus Juxt comparison (Fig. 4). Effect of embryo juxtaposition on endometrial transcriptome was accessed by these intersected 583 DEGs. The top-5 DEGs include kinesin family member 5C (*KIF5C*), major histocompatibility complex, class II, DM beta (*BOLA-DMB*), *MX2*, tripartite motif containing 14 (*TRIM14*), and cytoskeleton associated protein 2 like (*CKAP2L*). IPA analysis produced 229 enriched biological processes in the Juxt versus Non-juxt comparison. In addition to changes in interferon-mediated immune responses canonical pathways, other pathways identified included: regulation of cell cycle (e.g. Mitotic Roles of Polo-like Kinase, Cell Cycle: G2/M DNA Damage Checkpoint regulation, Cyclins and Cell Cycle Regulation, and Estrogen-

mediated S-phase Entry), mitochondrial metabolism (e.g. Oxidative Phosphorylation, Sirtuin Signaling Pathway, and Mitochondrial Dysfunction), and pregnenolone biosynthesis. An overview of canonical pathways impacted by juxtaposition between embryos and the BEEC monolayer is provided in Figure 7 and 8.

Figure 7. Overview of canonical pathways returned by Ingenuity Pathway Analysis (IPA) analysis of differentially expressed genes (DEGs; $P_{adj} \leq 0.05$; Cutoff fold-change >1.5) between Juxt versus Non-juxt groups. The charts (y-axis) represent the top significantly enriched canonical pathways. The upper x-axis shows the $-\log$ of the value calculated based on Fisher's exact test. The ratio (bottom x-axis) represented by the orange points is calculated based on the numbers of genes in a given pathway divided by the number of genes pertaining to that pathway. Straight orange vertical line represents the threshold for significance (by default). Canonical pathways shown were selected based on their biological significance.

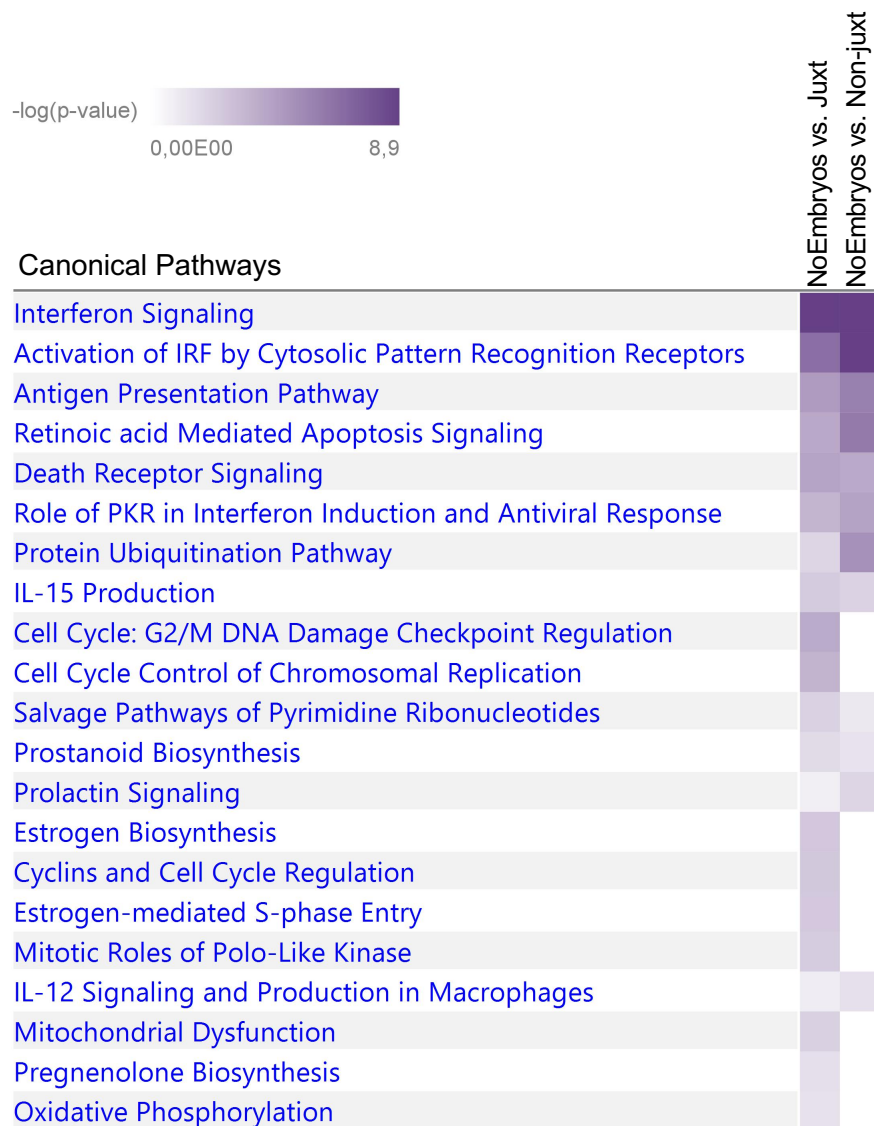

Figure 8. Heatmap analysis depicting IPA canonical pathways significantly modulated by embryos when juxtapositioned (Juxt) or without contact (Non-juxt) with a BEEC monolayer compared to the NoEmbryos control group. P-value scores indicate the significance of the pathway's association with the dataset and are represented by purple scale.

4.4.2.3 Ingenuity Upstream Regulator Analysis

To gain insights on the possible molecules triggering the transcriptome differences observed between Juxt versus Non-juxt conditions, upstream regulator analysis of DEGs (Padj < 0.05, Cutoff fold-change >1.5) was performed in IPA software. The top 20 potential upstream regulators based on DEGs yield in the Juxt versus Non-juxt comparison are shown in Table 1. Results confirmed type I interferon-signaling as an important upstream regulator eliciting differences between Juxt versus Non-juxt transcriptome profiles. Interestingly, other potential upstream regulators include PTGER4 (prostaglandin E receptor 4) and PRL

(prolactin) being activated, and NKX2-3 (NK2 Homeobox 3) and CDKN1A (Cyclin Dependent Kinase Inhibitor 1A) being inhibited in the Juxt group.

Table 1. Top 20 upstream regulators predicted based on the differentially expressed genes (DEGs) yield by transcriptome analysis between Juxt vs. Non-juxt groups. Analysis was performed in IPA software.

Upstream Regulator	Molecule Type	Predicted Activation State	Activation z-score	P-value of overlap
IRF7	transcription regulator	Activated	6.319	4.2 x 10 ⁻⁴⁴
Interferon alpha	group	Activated	5.905	1.34 x 10 ⁻³⁹
IFNL1	cytokine	Activated	4.853	5.73 x 10 ⁻³⁷
IFNA2	cytokine	Activated	5.836	1.51 x 10 ⁻³³

IL1RN	cytokine	Inhibited	-3.683	4.46 x 10 ⁻²¹

4.4.3 Effect of co-culture on embryo development

In vitro produced day 5.5 morulae were cultured for 48 h in SOF-5% FBS in the absence of BEEC (NoBEEC), juxtapositioned on top of subconfluent BEEC monolayers (Juxt), or on transwells, without direct contact with BEEC (Non-juxt). Co-culture with BEEC significantly increased blastocyst rates on day 7.5, regardless of Juxt or Non-juxt condition (Table 2). Additionally, the proportion of blastocyst that reached the expanded, hatching or hatched stages was significantly greater ($P \leq 0.05$) or tented ($P \leq 0.1$) to be greater in the Non-juxt and Juxt groups, respectively, compared to the NoBEEC control. Although the average counts of total cells on day-7.5 blastocysts were similar across treatments, there was an increase on the ICM/TE ratio in blastocysts from Juxt (Table 2). This difference in blastomere cell fate, however, did not impact the abundance of *CDX2* mRNA between the three culture conditions (Fig. 9). Surprisingly, Non-juxt embryos presented a 4-fold increased abundance of

transcripts for *IFNT2* compared to the Juxt group. The Non-juxt condition also increased the abundance of mRNA for *BAX*, an apoptosis-related gene, compared to the NoBEEC and Juxt groups (Fig. 9).

Table 2. Effects of co-culture with bovine endometrial epithelial cells (BEEC) on embryo development. On day 5.5, groups of 15±1 untreated morulae/early blastocysts were cultured in SOF-based medium in the absence of BEEC (NoBEEC), juxtapositioned on top of subconfluent BEEC monolayers (Juxt), or on transwells, without contact with BEEC (Non-juxt). On day 7.5, embryonic development was evaluated. Embryos were evaluated for total cell counting and trophoctoderm (TE) or Inner Cells Mass (ICM) differential immunostaining.

Day-5.5 morulae* assigned to treatments		640/1970 (32.5%)		
Variables	Groups			
	NoBEEC	Juxt	Non-juxt	
Day-7.5 blastocysts**	109/205 (53.2%) ^b	147/225 (65.3%) ^a	134/210 (63.8%) ^a	
Expanded, hatching or hatched blastocysts***	50/109 (45.9%) ^{b,Y}	88/147 (59.9%) ^{a,X}	88/134 (65.7%) ^a	
Total cell counts (mean ± SEM)	111.08 ± 6.07	125.36 ± 5.16	117.86 ± 5.75

Figure 9. Relative mRNA abundance of interferon-tau (*IFNT2*), caudal type homeobox 2 (*CDX2*), and BCL2 associated X, apoptosis regulator (*BAX*) on day 7.5 blastocysts co-cultured with bovine endometrial epithelial cells (BEEC). Each sample consists of a pool of 15 embryos ($n = 4-5$). Data are shown as arbitrary units; mean ± SEM. ^{a,b} Statistically significant difference in mRNA abundance ($P \leq 0.05$).

4.4.4 Specificity of bovine endometrial epithelial cells (BEEC)-induced effects on embryo development

In the second experiment, *in vitro*-derived day 5.5 morulae/early blastocysts were cultured in SOF-based medium (Control), or in SOF medium conditioned by BEEC (BEECcond), or by fibroblasts (FIBRcond). On day 7.5, the number of morulae that became blastocysts was significantly greater in the BEECcond compared to the Control or to the FIBRcond groups (Table 3). However, there was no effect of BEECcond condition on the proportion of blastocysts that reached or surpassed the expanded-stage.

Table 3. Specificity of bovine endometrial epithelial cells (BEEC)-driven effects on embryo development on day 7.5. On day 5.5, groups of 15 ± 1 untreated morulae/early blastocysts were cultured in SOF-based medium (Control), in BEEC-conditioned SOF medium (BEECcond), or in fibroblast-conditioned SOF medium (FIBRcond). On day 7.5, embryonic developmental rates were recorded.

Variables	Groups		
	Control	BEECcond	FIBRcond
Day-5.5 morulae* assigned to treatments	821/2320 (35.4%)

4.5 DISCUSSION

In cattle, there is limited information on the role of the pre-elongation embryo in programming the maternal reproductive tract function. Recent discoveries indicated that the endometrium transcriptome is locally changed by the presence of the embryo as early as day 7 *in vivo* (Sponchiado *et al.*, 2017). Other *in vitro* studies have confirmed that endometrial cells are responsive to embryo-presence (Talukder *et al.*, 2017; Gómez *et al.*, 2018; Passaro *et al.*, 2018). A critical question in this scenario is whether physical proximity of the embryo to the endometrium is necessary to elicit changes on its transcriptome. Alternatively, embryo secretions could act on the surrounding tissues in a classical paracrine manner. Here, by using an explorative approach based on an *in vitro* co-culture system, we were able to address the very local embryo-endometrial interface for embryo-induced changes in endometrial cell transcriptome. Embryos were co-cultured in juxtaposition or without contact with BEEC monolayers for 48 h and the magnitude of effects at the level of the embryo and the BEEC was investigated. It was shown that the embryo development supportive effects of the BEEC cells do not depend on an embryo-BEEC juxtaposition. Nonetheless, our results indicate that

intensity and nature of embryo-induced changes on endometrial epithelial cells transcriptome depended on the physical proximity between embryos and the BEEC monolayer.

We established an endometrial epithelial cell line in a manner that in every replicate, aliquots containing cells originated from the same pool were applied. Regarding the biological accuracy of our *in vitro* model, the co-expression of cytokeratin and vimentin in our BEEC line is in line with previous reports describing the expression of vimentin by cytokeratin-positive epithelial cells maintained in culture (Wang *et al.*, 2000; Zeiler *et al.*, 2007; Li *et al.*, 2016) via a process described as epithelial-mesenchymal transition (Kalluri & Weinberg, 2009). However, even after three passages the BEECs displayed no changes on abundance of transcripts for epithelial-cell origin (*KRT18*) and functional markers (*ESR1*, *IFNARI* and *PTGS2*) rendering our BEEC line valid to address the aims of the study.

By means of RNAseq, we further advanced the understanding on the embryo-endometrial interactome looking at the endometrial-response to the presence of peri-hatching embryos. Juxtaposition between embryos and BEECs elicited substantial changes on BEEC transcriptome, as seen by the high number of DEGs (1,797) yield in the NoEmbryos versus Juxt comparison. Interestingly, transcriptome changes were rather limited between NoEmbryos versus Non-juxt, with only 230 genes being differentially expressed between the two groups. Of note, out of these 230 genes, 225 also had their transcription regulated when embryos were juxtapositioned to the BEECs (Fig. 4). Thus, this group of 225 genes, differentially expressed in both Juxt and Non-juxt groups compared to the NoEmbryos control, likely represent the embryo specific paracrine stimulus exerted on the endometrial monolayer.

Interferon-tau seems to be the key player in the embryo-maternal communication. Most differentially expressed genes were related to classical type I interferon-mediated signaling, regardless of Juxt or Non-juxt condition. Notably, some transcripts for classical ISGs (*MX1*, *OAS1X*, *IFIT1*) showed dramatic fold changes (>100) in our study. There is no consensus about when does the bovine embryo start to produce IFN τ . It has been shown, for example, that bovine blastocysts express and release IFNT into the culture medium (Hernandez-Ledezma *et al.*, 1993). More recently, expression of IFNT at protein level by bovine *in vitro*-produced morulae has been reported (Talukder *et al.*, 2018). Here, we demonstrated that *in vitro*-produced day 7.5 bovine embryos present transcripts for *IFNT2*, as well as, that the BEECs used in our model present mRNA for interferon alpha and beta receptor subunit 1 (*IFNARI*). Early embryo-induced changes in the abundance of ISGs, have been reported in the endometrium *in vivo* (Sponchiado *et al.*, 2017), and in endometrial

(Talukder *et al.*, 2017; Passaro *et al.*, 2018) and immune cells (Talukder *et al.*, 2018) *in vitro*. Other studies later on pregnancy also reported major changes on endometrial transcriptome between pregnant and cyclic cows being induced by IFNT (Bauersachs *et al.*, 2006; Klein *et al.*, 2006; Forde *et al.*, 2011; Sánchez *et al.*, 2019). Although IFNT has been extensively studied based on its ability to mediate pregnancy recognition in ruminants, its potential role in embryo development prior to the pregnancy recognition window is still not completely understood. For instance, it has been shown that deletion of *Isg15* results in 50% pregnancy loss before placentation in mice (Ashley *et al.*, 2010). However, a remaining open question is whether and to which extent classical ISGs have a biological role in programming the endometrium towards a more supportive status for the development of the bovine embryo in the context of early pregnancy (Pestka, 2007).

The exploratory nature of our approach enabled us to further advance the understanding on the potential pathways changed by the embryo at the embryo-endometrial interface in addition to the previously reported type I interferon-mediated signaling. We showed, for example, that presence of embryos increased mRNA abundance for transporters including members of the SLC family 25 (*SLC25A28*, *SLC25A15*, and *SLC25A30*). SLC25 transporters compose a large family of nuclear-encoded membrane-embedded proteins that promote solute transport across the inner mitochondrial membrane. They have been implicated as being responsible for the transport and utilization of glutamate (Palmieri, 2008), and decreases in the levels of these members of the SLC family may affect nutrient transport and utilization in the endometrium.

Intensity and nature of embryo-induced changes on endometrial transcriptome largely depend on juxtaposition between embryos and the BEEC monolayer. Differences in quantity and quality of embryo-induced effects on BEEC transcriptome due to a juxtaposition between the embryos and the endometrial cells might be attributed to three possibilities. One mechanism includes a **diffusion gradient** of embryo-derived signals when embryos were placed on transwell inserts, leading to a less pronounced endometrial response to embryo-derived soluble factors, as for example IFN τ . In this regard, our data showed an up-regulation of ISGs in the Juxt compared to the Non-juxt BEECs. Also, the upstream regulator analysis predicted the interferon-signaling system as a potential candidate of factors depicting transcriptional changes triggered by the juxtapositioned embryos on BEECs (Table 1). Another possibility comprises signaling triggered by **physical contact** between the embryos and the BEEC monolayer. Some of the top DEGs between Juxt versus Non-juxt provide evidence for a local immune response due to juxtaposition of embryos, as for example the up-

regulation of *BOLA-DMB* transcripts in the Juxt BEECs. The bovine leucocyte antigen (BoLA) system refers to the major histocompatibility complex (MHC) of cattle, which initiates an adaptive immune response to specific pathogens. *BOLA-DMB* pertains to the subclass IIb and is involved in antigen processing and transport (Ellis, 2004). The endometrial epithelial BoLA system may play an important role on immune recognition and tolerance of the semi-allogenic embryo within the uterine lumen. It is known, however, that there is no intimate contact (i.e., tissue adhesion) between the pre-implantation, non-invasive embryo and the lining endometrial epithelium in the bovine species (Bazer *et al.*, 1991). It is noteworthy that in this study, at the end of the co-culture period (day 7.5 p.i.), most embryos were still enclosed in the zona pellucida. It is important to point out that the proportion of hatching and hatched blastocysts was similar between Juxt and Non-juxt conditions. Specifically, for the samples that were analyzed by RNAseq, the proportion of hatching and hatched blastocysts on day 7.5 was 17.3% (13/75) and 16% (12/75) for Juxt and Non-juxt, respectively (Supplementary Table S12). Direct cell-to-cell contact at the pre-hatching stage might be provided by membrane extensions through the zona pellucida (Allen & Wright Jr, 1984) and trophoctoderm projections (Gonzales *et al.*, 1996). Furthermore, it has been described that the zona pellucida could also contribute with binding sites and local release of signaling molecules (i.e. growth factors and cytokines) towards the endometrial cells (Denker, 2000; Herrler *et al.*, 2002). Relatively little work has been done on the mechanisms underpinning a possible juxtacrine communication at the embryo-maternal interface prior to zona-hatching in monotocous mammals. A third possible explanation is that embryos juxtaposed to the BEEC monolayer have **distinguished capacities to produce and/or release signaling molecules** in turn. In the present study, no difference was observed between embryos derived from Juxt versus Non-juxt conditions in terms of blastocyst development on day 7.5 p.i.. However, the embryo-BEEC juxtaposition did impact on resulting blastocysts' cell commitment as seen by the increased ICM:TE ratio in the Juxt group, as well as on the abundance of transcripts for *IFNT2* that was 4-fold greater in the Non-juxt embryos compared to the Juxt counterparts. Thus, it is also reasonable to expect that the co-culture conditions affected the signaling capacity of those embryos. Although our experimental set-up does not allow us to distinguish these three possibilities, we speculate that differences on BEEC response to Juxt versus Non-Juxt embryos likely reflect a combination of the above-mentioned mechanisms.

Interestingly, embryos juxtaposed to the BEEC monolayer up-regulated transcription for genes related to cell cycle control and mitotic spindle formation, as for

example *PCNA*, *CKAP2L*, *KIF5C*, *KIF1C*, and *MASTL*. In fact, IPA analysis showed an enrichment for cell cycle-related pathways (e.g. Mitotic Roles of Polo-like Kinase, Cell Cycle: G2/M DNA Damage Checkpoint regulation, Cyclins and Cell Cycle Regulation, and Estrogen-mediated S-phase Entry) in the Juxt group (Fig. 7). Noteworthy, other genes associated with cell-cell adhesion and cytoskeleton were also regulated in the Juxt BEECs, including *XIRP1*, *AKAP7*, *ANXA1*, *AIDA*, and *CKAP2*. Further *in vivo* studies are necessary to address whether the endometrial epithelia changes its proliferation rate and/or its cell morphology in response to the local contact with the embryo/conceptus.

Co-culture with BEEC stimulates embryo development from morula to blastocyst stage. In the present study, morulae/early blastocysts were exposed to BEEC monolayers only on day 5.5 post fertilization to mimic the timing of embryo arrival into the uterus *in vivo* in the cow. In fact, many studies report that embryos at early developmental stages benefit from co-culture with endometrial cells in several species including bovine (Voelkel *et al.*, 1985), human (Rubio *et al.*, 2000), mice (Kauma & Matt, 1995; Lai *et al.*, 1996) and porcine (Allen & Wright Jr, 1984). Although the specific mechanisms by which endometrial cells influence early embryo development remain to be elucidated, they may include five putative mechanisms: (i) **release of embryotrophic factors** into the culture medium, such as nutrients and substrates, including specific glycoproteins, amino acids, pyruvate, cytokines and growth factors (Kurachi *et al.*, 1994; Kauma & Matt, 1995; Lim & Hansel, 1996); (ii) **reducing the concentration of embryo-suppressive components** from the culture medium, such as glucose or heavy metals; (iii) **stabilization of medium physicochemical conditions**, such as pH and osmolarity. Given that embryos-BEECs co-cultures and embryos (alone) cultures were conducted at 20% O₂, which is suboptimal for early embryo development, there is also a fourth possible mechanism that includes (iv) **protection from oxidative stress insults**. The cell monolayer could reduce the O₂ tension of the embryo microenvironment in culture and, therefore, benefit embryo development in a non-specific manner (Nagao *et al.*, 1994); or (v) a combination of several of these mechanisms. The first three mechanisms are experimentally difficult to be distinguished, however, in our second experiment, we circumvent the potential effect of a reduced O₂ tension caused by feeder cell monolayers on embryo development by using conditioned medium.

Our results have shown that in fact the medium conditioned by BEECs had a significant positive effect on the proportion of morulae reaching the blastocyst stage compared to the Control (SOF) group, similar to what was observed in the first experiment. The specificity of the embryo supportive capacity of BEECs can be questioned by the fact that

numerous investigations have demonstrated an improvement in development when embryos were *in vitro* co-cultured with non-endometrial homologous somatic cells, such as oviductal cells (Eyestone, 1987; Thibodeaux *et al.*, 1992), luteal cells (Maruri *et al.*, 2018), granulosa cells (Freeman *et al.*, 1995; Malekshah *et al.*, 2006) or even in co-culture systems with stem cells, such as adipose tissue-derived mesenchymal cells (Miranda *et al.*, 2016). It has been also shown that co-culture with heterologous somatic cells, as for example BRL (buffalo rat liver) cells and Vero (green monkey kidney epithelial) cells, efficiently improve the development of mouse, bovine and human embryos (Ouhibi *et al.*, 1990; Reed *et al.*, 1996; Menck *et al.*, 1997; Duszewska *et al.*, 2000; Kattal *et al.*, 2008). Taken together, these results suggest a non-specific role of bovine endometrial cells, or even homologous cells, on embryo development in co-culture systems. Hereto, we challenged the specificity of the embryo supportive capacity of BEECs by using medium conditioned by heterologous unspecific feeder cells. The mice fibroblast-conditioned medium had no effect on embryo development compared to the Control. These observations suggest that bovine endometrial cells, and perhaps other reproductive tract cells, may provide a relatively specific stimulus for continued development of early embryos in co-culture.

Although the beneficial role of co-culture on embryo development does not seem to be dependent on a juxtaposition with the BEEC monolayer, the embryo-BEEC contact did affect the cell commitment of the resulting blastocysts, as seen by the increased ICM:TE ratio in the Juxt group. In mouse, it has been shown that cell-to-cell interaction can influence the lineage specification of embryonic blastomeres (Lorthongpanich *et al.*, 2012). The greater ICM:TE ratio in Juxt derived blastocysts, however, did not impact on transcripts abundance of *CDX2*, a marker for trophectoderm cells. This could be explained by the fact that only embryos at normal blastocyst stage or beyond were evaluated for differential immunostaining, whereas embryos at all developmental stages (i.e. from morula to hatched blastocyst) were included in gene expression analyses. Additionally, day-7.5 blastocysts that were juxtapositioned to the BEEC monolayer displayed decreased abundances of *IFNT2* and *BAX* mRNA compared to Non-juxt embryos. It has been demonstrated that the attachment of trophectoderm to the uterine epithelium results in a decrease in IFNT expression during the implantation period in cattle (Ezashi & Imakawa, 2017). Also Sakurai *et al.* (2012) reported that co-culture with endometrial epithelial cells resulted in decreased *IFNT2* mRNA abundance in bovine trophoblast cells spheroids. The mechanisms by which the embryo-endometrium juxtaposition during the peri-hatching period could trigger to different patterns in IFNT expression warrants further investigation.

It should be pointed out that, in this study, 15 embryos were co-cultured with the BEEC monolayers. One could argue that this stimulus is though not representative for the physiological *in vivo* condition in the cow, as a monovulatory species. Experiment 1 was designed as an explorative approach for *in vitro* assessment of the embryo-maternal interface. As such, in order to maximize the embryo-BEEC physical contact zone and the stimulus promoted by the early embryo, multiple embryos were co-cultured with the BEEC monolayers. The multiple embryos co-culture strategy was also meant to minimize the individual influence of the quality of the embryo on endometrial response between samples and treatments. Extra attention was paid to select the BEEC samples that were analyzed by RNAseq. As show in Supplementary Table S12, BEEC samples that were co-cultured with embryos at similar developmental stages among the experimental groups were selected.

Collectively, our data provided new insights into the complex embryo-maternal interactome during the very early steps in pregnancy in cattle. We were able to demonstrate for the first time that day-7.5 bovine embryos change the endometrial epithelial cell global transcriptome. Highlighted pathways modulated by embryos presence included type I interferon signaling, regulation of cell cycle, prolactin signaling and prostanoid biosynthesis. Moreover, we can conclude that nature and magnitude of embryo-induced effects are influenced by physical proximity between endometrial cells and embryos. On the embryonic side, the co-culture system applied in this study improved bovine embryonic development from morula to blastocyst stage. This support seems to be BEEC specific and does not rely on a juxtaposition between the embryo and the BEEC monolayer. Nonetheless, juxtaposition with BEECs altered day-7.5 blastocysts' cell fate and *IFNT2* transcripts abundance. Nature of interactions between the lining endometrial epithelium and the non-invasive, pre-implantation embryo warrants further investigation.

4.6 ACKNOWLEDGEMENTS

The outstanding technical assistance of Gamete Research Centre staff and students to generate the embryos is gratefully acknowledged. The authors acknowledge Jens Slootmans for the assistance in performing RNA isolation and PCR analysis.

4.7 DECLARATION OF INTEREST

The authors declare no competing interests.

CHAPTER 5
GENERAL DISCUSSION

5 GENERAL DISCUSSION

The purpose of this chapter is to discuss the general findings arising from this Thesis and how they extend the current knowledge of embryo-maternal communication in cattle. **The existence of a complex embryo-maternal interactome between a pre-elongating embryo and the endometrium provided the theoretical basis for the present research Thesis.** Focus was given on the effects of the embryo on programming the endometrial function during early gestation in cattle. Throughout this Thesis, evidences of embryo-induced changes at transcriptional level in the endometrium *in vivo* (**Chapter 2**), in the uterine microenvironment metabolome composition *in vivo* (**Chapter 3**), and in the global transcriptome of endometrial epithelial cells *in vitro* (**Chapter 4**) were provided. The explorative nature of the three studies has led us to **accept the overarching hypothesis of this Thesis that bovine embryos modulate the endometrial function as early as day 7 of pregnancy.** Herein, this general discussion will first integrate the data obtained from the *in vivo* (endometrial gene expression and uterine luminal fluid metabolome) and the *in vitro* (endometrial cells transcriptome) models; secondly, factors that may contribute to the embryo-endometrial interactome and the relevance of this cross-talk for pregnancy establishment in cattle will be discussed. Based on these findings, insights for future studies and implications will be provided.

5.1 AN OVERVIEW OF THE MAIN FINDINGS OF THIS THESIS

Owing to its untraceable effects within a relatively large uterine lumen, the 120-200 μm in diameter, pre-elongation bovine embryo had been historically considered to be no more than a passenger during its journey throughout the maternal reproductive tract. In the past years, accumulating evidence suggested that the early bovine embryo engages in biochemical signaling with the maternal uterus. This Thesis attempted to characterize and provide insights into the embryo-induced changes in the endometrium during early gestation in cattle. To that end, *in vivo* and *in vitro* experimental approaches associated with state-of-the-art omics technologies were applied to test central and specific hypotheses.

In **Chapter 2**, spatially defined regions of the ipsilateral uterine horn were compared between pregnant and cyclic cows to demonstrated that a day-7 embryo is able to locally regulate transcription of key-genes associated with endometrial function *in vivo*. Out of 86

genes that were evaluated by PCR using a microfluidic platform, 12 transcripts had their abundance modulated in the Pregnant endometrium. Embryo-induced effects included **classical interferon-stimulated genes** (ISGs; *ISG15*, *MX1*, *MX2*, *OAS1Y*), and genes related to **prostaglandin biosynthesis** (*PTGES*, *HPGD*, *AKR1C4*), cell-cell adhesion (*ITGAV*, *ITGB1*), polyamine regulation (*AMD1*), and solute and water transport (*AQP4*, *SLC1A4*). Stimulation of ISGs expression in the pregnant endometrium was attributed to a release of interferon-tau (IFN τ) by the early embryo. A major finding of this study was that changes triggered by the presence of the embryo were mainly in the most cranial portions (uterotubal junction and anterior third) of the uterine horn ipsilateral to the ovary containing the CL, where the embryos were located (Sponchiado *et al.*, 2017). To the best of knowledge, that was the first report of embryo-induced changes on the bovine endometrium, at transcriptional level, *in vivo*.

In **Chapter 3**, we further advanced the understanding on embryo-effects during early pregnancy. Analyses of the metabolite composition of the uterine luminal fluid (ULF) collected from the anterior third of the uterine horn ipsilateral to the CL were carried out to answer whether the presence of the embryo elicits changes in the uterine microenvironment composition *in vivo*. Embryo-induced modulation included an overall decrease in ULF concentrations of amino acids, biogenic amines, acylcarnitines and phospholipids, and an increase in concentrations of **eicosanoids and oxidation products of polyunsaturated fatty acids**. It was noteworthy that two eicosanoids derived from the lipoxygenase pathway, 12(S)-HETE and 15(S)-HETE, were in greater concentrations in the ULF recovered from pregnant animals. Transcripts for *ALOX12* and *ALOX15B* were respectively up- and down-regulated in the endometrial tissue of Pregnant animals. It was further investigated whether the changed amounts of lipoxygenase-derived metabolites influenced PPAR γ (peroxisome proliferator-activated receptor gamma)-RXR (retinoid X receptor) signaling in the endometrium, but no difference was verified in the endometrial abundance of transcripts for *LPL*, a PPAR γ -RXR target gene, between pregnant and cyclic cows.

Next in **Chapter 4**, by means of an *in vitro* model, the embryo-endometrial interface was probed for embryo-induced changes on endometrial cells and the possible modes of inter-tissue molecular communication. Day-5.5 morulae were co-cultured in juxtaposition or in cell culture inserts that prevented direct contact with bovine endometrial epithelial cells (BEECs) for 48 h. The magnitude of effects at the level of the embryos and the BEECs was investigated. Juxtaposition between embryos and the BEEC monolayer altered transcription of 1,797 genes compared to BEECs that were not exposed to embryos (control group).

Interestingly, embryo-induced changes on endometrial transcriptome were rather limited when embryos were not juxtapositioned to the BEEC monolayer. There were 230 genes differentially expressed in relation to BEECs cultured in the absence of embryos, indicating that nature and intensity of embryo-induced changes on bovine endometrial epithelial cell transcriptome *in vitro* depend upon a juxtaposition between embryonic and maternal units. Pathways modulated by presence of embryos included interferon-mediated immune responses, cell cycle regulation and apoptosis, prolactin signaling, and prostanoid biosynthesis. Moreover, it was verified that co-culture with BEECs improves blastocyst rates on day 7.5, irrespective of juxtaposition to the cell monolayer.

Both the *in vivo* and the *in vitro* studies revealed local effects of the embryo to program endometrial function. This is important because the dynamics of intrauterine migration of the pre-implantation embryo remains poorly known in cattle. Nonetheless, it is known that, unlike other species, the bovine embryo does not have an active migration capacity (like equine embryos, that have an acellular glycoprotein capsule, or swine embryos, that produce estrogens, for example). Additionally, anatomy and position of the bovine uterine horns do not seem to favor the process of intrauterine migration of the embryo along the longitudinal axis. Furthermore, the viscous nature of the luminal film makes the uterine microenvironment difficult for the embryo to migrate. Indeed, according to Wolf *et al.* (2003), the bovine embryo is surrounded tightly by the endometrium through a thin fluid layer stabilized by glycoproteins. In our first study (Chapter 2), all embryos were found in the most cranial third of the ipsilateral uterine horn on day 7 post estrus, and this is in agreement with another study that reported that day-8 embryos were located at the tip of the uterine horn, close to the UTJ, in inseminated beef cows (Diskin e Sreenan, 1980), suggesting that the pre-hatching bovine embryo does migrate actively along the uterine horn. Thus, it is presumed that the early embryo could benefit from a local change on the endometrial function. Although the technical approaches to better define this process are challenging, further studies are needed on this topic. In addition, intensity and extent of embryo signaling capacity is expected to increase throughout the window of pre-implantation development as the conceptus develops, in order to supply its changing needs.

Collectively, the studies carried out in this Thesis provided evidences that early bovine embryos are able to change the endometrial function as early as day 7. The functional relevance of embryo-dependent programming of endometrial function to pregnancy establishment can be questioned because day-7 bovine blastocysts are routinely transferred to the uterus of non-pregnant synchronized recipients which, up to that stage, have not seen an

embryo and can establish a pregnancy successfully. Taken to its extreme, it has been shown to be possible to establish a pregnancy in cattle by transferring embryos up to the time when the luteolytic mechanisms would normally be initiated (around day 16) (Betteridge *et al.*, 1980). Indeed, the reproductive tract does not absolutely require exposure to the embryo during that early phase in pregnancy in order for pregnancy to be established. However, pregnancy rates in commercial embryo transfer operations average on 40-45% (Hasler *et al.*, 1995; Pontes *et al.*, 2009; Randi *et al.*, 2016). This contrasts with pregnancy rates to artificial insemination, which are commonly 50-55%, indicating that lack of exposure of the reproductive tract to the embryo during the first week of pregnancy may be implied as a contributing factor to reduced pregnancy success after o embryo transfer. In addition, it has been reported that magnification of embryonic signals by simultaneous transfer of trophoblast vesicles with one blastocyst on day 7 increases pregnancy rates from 43% (control group) to 73% (cotransfer group) in cattle (Heyman *et al.*, 1987). Thus, it is proposed that exposure to the early embryo fine-tunes endometrial function to support subsequent pregnancy events.

From the results obtained in in the *in vivo* and in the *in vitro* studies, it became evident the importance of interferon-mediated signaling and eicosanoids pathways as major players in the embryo-maternal communication. Some aspects regarding these two pathways are discussed below.

5.2 CANDIDATE PATHWAYS

5.2.1 Interferon-mediated signaling

The findings of this Thesis underline the importance of IFN τ as an early embryo-derived pregnancy recognition signal. In addition to the well-conceived antiluteolytic effects, IFN τ acts in a paracrine manner on the endometrium to induce or enhance expression of ISGs that are hypothesized to regulate uterine receptivity and conceptus elongation (Bazer *et al.*; Brooks *et al.*, 2014; Hansen *et al.*, 2017). Other recent studies have shown that the early bovine embryos were able to stimulate ISGs expression in co-cultured endometrial (Talukder *et al.*, 2017; Gómez *et al.*, 2018; Passaro *et al.*, 2018), luteal (Bridi *et al.*, 2018) and immune cells (Rashid *et al.*, 2018; Talukder *et al.*, 2018) *in vitro*, due to release of interferon-tau (IFN τ). Remarkably, a 268-fold increased expression of *MXI* was found in BEECs in the presence of day-7.5 embryos (Chapter 4).

It is possible that factors other than IFN τ could also trigger type I interferon-responses in endometrial cells, as for example prostaglandins (Spencer *et al.*, 2013) or other type I interferons, such as interferon alpha and beta (Platanias, 2005). In the study conducted by Rashid *et al.* (2018), authors stimulated peripheral blood mononuclear cells (PBMCs) *in vitro* with uterine flushings collected from day-7 pregnant (donor) or non-pregnant cows. Treatment with uterine flushings from pregnant donors down-regulated pro-inflammatory cytokines (*TNFA*, *IL1B*) and up-regulated transcription of anti-inflammatory cytokines (*IL10*) and ISGs (*ISG15*, *OAS1*) compared with uterine flushings from non-pregnant cows. Moreover, addition of a specific anti-bovine IFN τ antibody to the uterine flushings inhibited the effects on PBMCs, indicating that IFN τ is a major factor triggering such responses.

Early embryonic losses and pregnancy failure may be attributed to insufficient secretion of IFN τ by the embryo/conceptus. However, accumulating literature supports the idea that embryonic IFN τ expression levels are not necessarily correlated with developmental competence. Kubisch *et al.* (1998) observed a negative relationship between early IFN τ production and developmental competence. For instance, it has been reported that *in vitro*-cultured blastocysts display greater abundance of transcripts for IFN τ compared with those cultured *in vivo* (Wrenzycki *et al.*, 2001; Lonergan *et al.*, 2003). Interestingly, it was found that embryos co-cultured, but not in direct contact with endometrial cells presented a 4-fold increased abundance of IFN τ mRNA compared to those embryos cultured in juxtaposition with cells (Chapter 4). The amount of IFN τ produced is also related to the sex of the embryo. Larson *et al.* (2001) showed that female blastocysts produce twice as much IFN τ as males. In this respect, it has been reported that bovine female conceptuses elongate more compared to their male counterparts and that this difference in growth rate leads to an increased release of IFN τ by the female conceptus later in pregnancy. However, regardless of the distinct capacity to produce and release IFN τ , both female or male conceptuses are able to establish and maintain pregnancy at similar rates. Altogether, these data indicate that, even though IFN τ is critical for the establishment of pregnancy, greater amounts of conceptus-released IFN τ does not warrant greater rates of embryonic survival. This leads to the assumption that early embryo-derived signals other than IFN τ may be involved in the embryo-maternal dialogue in cattle. Indeed, from an evolutionary point of view, it is unlikely that establishment of pregnancy relies on a single molecule synthesized by the embryo. The studies presented in this Thesis indicated alternative systems that might also play a role in the embryo-maternal communication, such as eicosanoid signaling.

5.2.2 Eicosanoids

Eicosanoids undoubtedly play an important role in reproductive processes in cattle, including ovulation, conceptus elongation, maternal recognition of pregnancy and luteolysis (Brooks *et al.*, 2014). Free polyunsaturated fatty acids are oxidized to eicosanoids prominently via three pathways: the cyclooxygenase (COXs) pathway to produce prostanoids, the lipoxygenase (LOXs) pathway to produce hydroxyeicosatetraenoates (HETEs), and the leukotriene pathway via Cytochrome P450 microsomes (CYPs) to generate epoxyeicosatrienoic acids. Among these subfamilies, the roles of prostanoids on coordinating reproductive events have been studied more extensively.

Prostaglandins are produced both by epithelial cells of the endometrium and trophoblast cells of the elongating conceptus in ruminants (Lewis *et al.*, 1982; Charpigny *et al.*, 1997). In addition, prostaglandins are found in much greater concentrations in the uterine lumen of pregnant than cyclic or nonpregnant heifers by day 13 of pregnancy (Spencer *et al.*, 2013). Indeed, prostaglandins are essential for conceptus elongation in ruminants, as intrauterine infusions of a selective PTGS2 (a prostaglandin synthase) inhibitor prevented conceptus elongation in pregnant ewes (Dorniak *et al.*, 2011). In Chapter 2, transcripts related to prostaglandin biosynthesis were detected in different abundances in the endometrium of pregnant versus control animals. Specifically, upregulation of *PTGES* (prostaglandin E synthase), and downregulation of *AKR1C4* (catalyzes the conversion of PGH₂ to PGF_{2 α}) and *HPGD* (catalyzes the catabolism of prostaglandins) in response to the embryo was suggestive of a shift towards a greater PGE₂/PGF_{2 α} ratio in the pregnant endometrium. However, metabolomic analysis of ULF composition carried out in Chapter 3 could not confirm this presumption. Specifically, PGE₂ was under the limit of detection in the ULF and, contrary to our expectation, PGF_{2 α} concentration tended to be greater in the ULF recovered from pregnant cows. Greater concentrations of PGF_{2 α} in ULF in response to the embryo is consistent with other experiments conducted later in pregnancy. Ulbrich *et al.* (2009) reported increased concentrations of PGF_{2 α} and its stable metabolite 15-keto PGF_{2 α} (PGFM) in uterine flushings collected on days 15 and 18 of pregnancy in heifers, compared to their cyclic counterparts. Increased amounts of prostaglandins in ULF close to the implantation period has been suggested to emanate from the embryonic side (Ulbrich *et al.*, 2009; Spencer *et al.*, 2013), as elongating bovine conceptuses synthesize and secrete more prostaglandins than the surrounding endometrium (Lewis *et al.*, 1982). However, Gómez *et al.*, (2015) found that blood PGF_{2 α} concentrations were significantly increased in pregnant

cows on day 8, irrespective of the presence of a single or multiple embryos, suggesting that the effect on $\text{PGF}_{2\alpha}$ concentrations could be due to an early endometrial response.

Concerning *PTGES* mRNA abundance in the endometrium being modulated by the early embryo, other *in vitro* studies have shown that presence of bovine embryos increases expression of *PTGES* in endometrial (Talukder *et al.*, 2017) and immune cells (Talukder *et al.*, 2018). Talukder *et al.* (2017) also reported increased concentrations of PGE_2 in the culture media when bovine endometrial cells were co-cultured with day-7 embryos. Contrary to our results obtained *in vivo*, *PTGES* expression seemed to be down-regulated in BEECs exposed to day-7.5 embryos in our *in vitro* study (Chapter 4). This and other discrepancies were found between the *in vivo* and the *in vitro* results and possible explanations are discussed in the next sections.

Contrary to prostaglandins, the role of lipoxygenase-derived metabolites during early gestation has not been explored extensively. Presence of an embryo changed concentrations of hydroxyeicosatetraenoates in the ULF (Chapter 3). Specifically, 12(S)-HETE and 15(S)-HETE were in greater concentrations in the pregnant ULF, whereas a decreased amount of 13(S)-HODE was verified. Metabolites present in the ULF can arise from either the endometrium or from the embryo, but it is challenging to distinguish embryonic from the endometrial contributions. Distinct concentrations of lipoxygenase-derived metabolites in the ULF were associated with increased and decreased abundances of *ALOX12* and *ALOX15B* mRNA, respectively, in the pregnant UTJ, suggesting an endometrial origin of regulation (Chapter 3). In Chapter 4, co-culture with embryos down-regulated the expression of *ALOX12E* in BEECs. As discussed in Chapter 3, these findings support the idea that bovine embryos modulate the lipoxygenase pathway. Roles of lipoxygenase-derived metabolites on embryo development and establishment of pregnancy warrant further investigation.

5.3 THE UTERINE LUMINAL FLUID TO MEET THE EMBRYONIC NEEDS

The endometrial exchange of molecules into the uterine lumen represents the ultimate maternal influence to the developing pre-implantation embryo. Despite its importance on conceptus elongation and survival, there is limited information on the biochemical composition of the uterine fluid in cattle. In this regard, a major contribution of the quantitative measurement of metabolite concentrations carried out in Chapter 3 is the expanded inventory of naturally occurring compounds in ULF samples collected post-

mortem. This is important, because most published metabolomics-based investigations are either restricted to one class of analytes and only relative abundances are reported.

Intriguingly, quantification of metabolites in ULF between pregnant versus non-pregnant cows showed that presence of an embryo diminishes concentrations of amino acids, biogenic amines, phospholipids and acylcarnitines. In the *in vivo* condition, the ULF composition is modulated by both the endometrial and embryonic units, as well as their molecular interactions. As discussed in Chapter 3, possible explanations for lower concentrations of these compounds in the pregnant uterine lumen include: (i) an increased consumption of substrates by the endometrium; (ii) an overall down-regulation of transport activity in the endometrial epithelia; (iii) an increased resorption of metabolites from the uterine lumen towards the lining endometrial epithelium; or (iv) intake of substrates present in the uterine fluid by the embryo. Although the experimental set-up used in the study does not allow to distinguish these factors, it is speculated that the changes ULF composition likely reflect the combination of the above. Interestingly, results from the *in vivo* (Chapter 2) and the *in vitro* (Chapter 4) studies showed that bovine embryos are able to modulate the transcription of genes associated with active transport of molecules in the endometrium. Figure 1 provides an overview of the ULF metabolites and endometrial transcripts found to be modulated by the embryo. Specifically, transporters of macromolecules, such as amino acids, lipids and carbohydrates, were mainly down-regulated in the presence of the embryo, whereas the majority of mitochondrial carriers (SLC25 family) and antigen transporters was up-regulated by the embryo (Fig. 1).

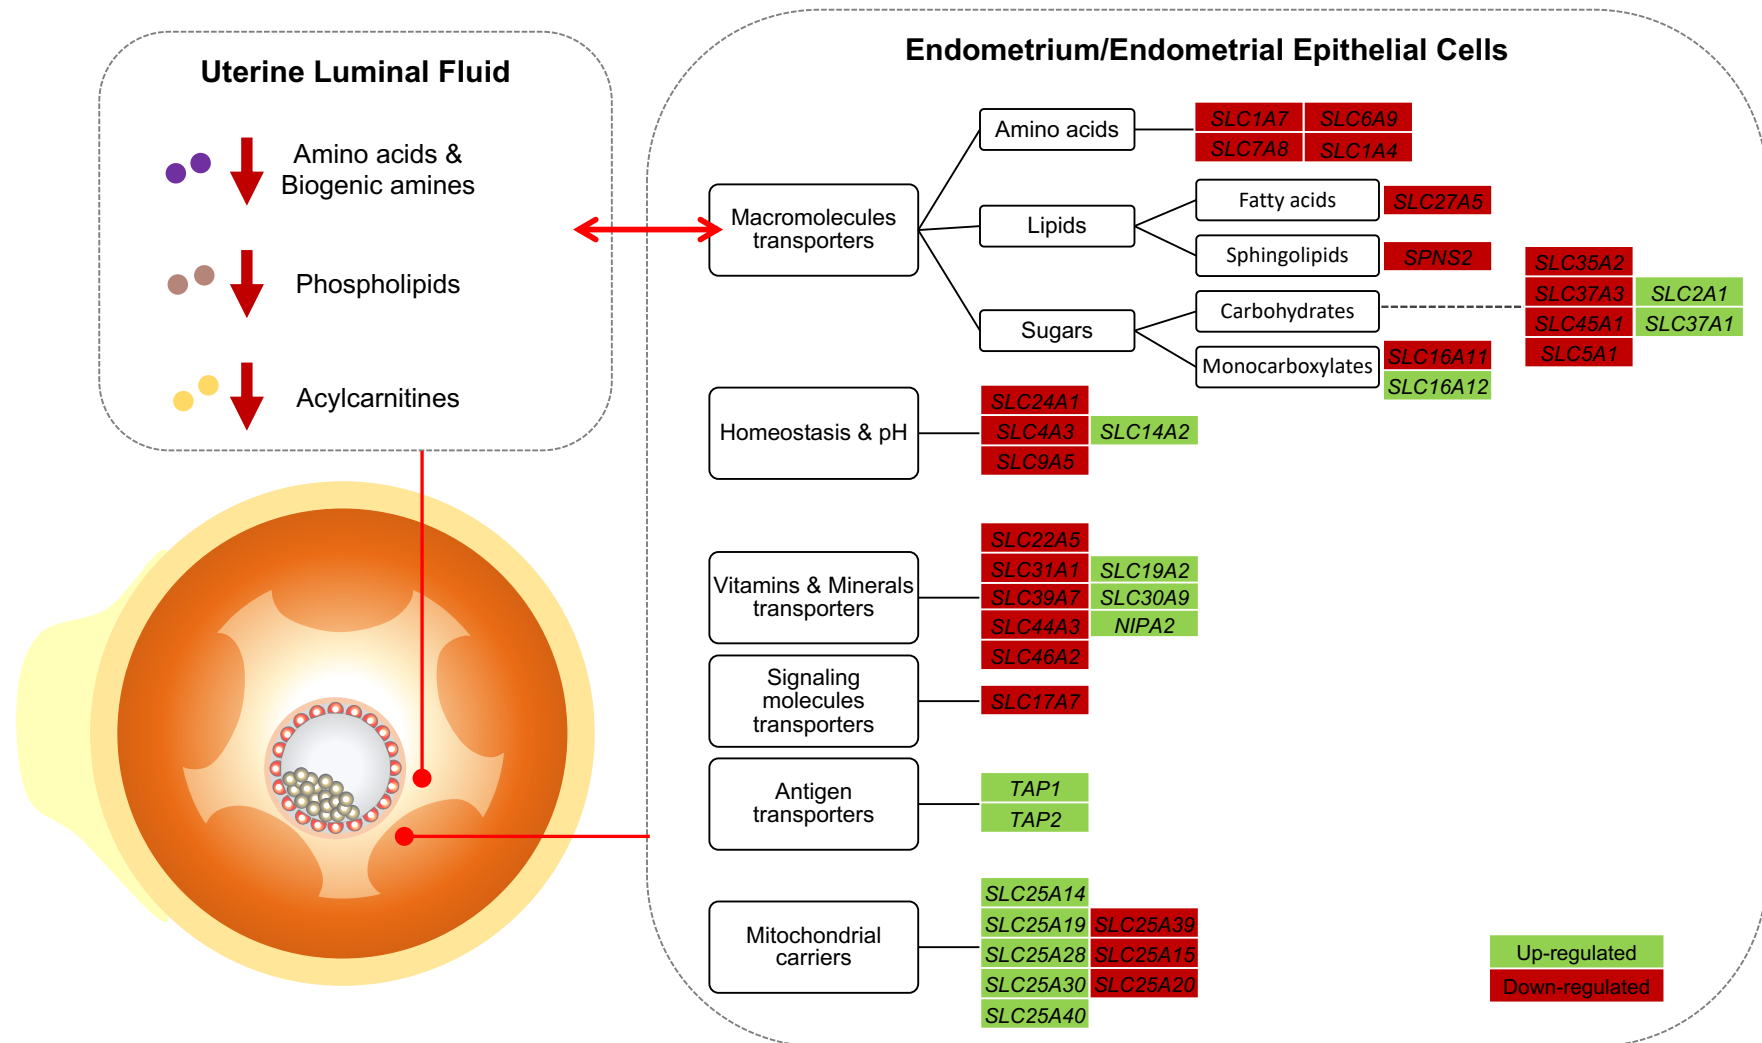

Figure 1. Overview of embryo-induced changes in metabolite concentrations in the uterine luminal fluid (Chapter 3), and abundances of transcripts for transporters in endometrial tissue (*in vivo* study; Chapter 2) or endometrial epithelial cells (*in vitro* study; Chapter 4). Solute Carriers (SLCs) were grouped according to their subfamilies. TAP (Transporter associated with antigen processing). SPNS (Sphingolipid Transporter). NIPA (Magnesium transporter).

A major down-regulation of transporters was consistent with lower metabolite concentrations in the ULF of pregnant animals. This may be against the paradigm that metabolites, especially amino acids, are present in higher concentrations in the pregnant uterine lumen in cattle (Groebner *et al.*, 2011; Forde *et al.*, 2014) and sheep (Gao *et al.*, 2009), which is mediated via upregulation of transporters in the endometrium. It is worth noticing that the aforementioned studies were performed later in pregnancy, around the pregnancy recognition window, when an elongated conceptus is present in the uterus. In the *in vivo* study presented in this Thesis, ULF samples were collected approximately one week earlier in gestation, when a pre-hatching embryo was present in the pregnant uterus. At this point, the nutrient demands of the embryo are quantitatively small (Leese *et al.*, 2008) and, perhaps, metabolites that compose the ULF do not need to be in abundant concentrations to cover the embryonic needs. For instance, essential amino acids were in much lower concentrations in ULF, irrespective of pregnancy status, compared to non-essential amino acids (Chapter 3). Only two (threonine and leucine) of the essential amino acids (lysine, methionine, threonine, tryptophan, isoleucine, leucine, histidine, phenylalanine and valine) were detected. While only tyrosine was not detected within non-essential amino acids (alanine, aspartate, asparagine, glutamate, cysteine, glycine, glutamine, proline, serine and tyrosine). This is in agreement with Elhassan *et al.* (2001), where authors found that non-essential amino acids represent more than 60% of the total concentration of amino acids in the bovine uterus on day 7. Supplementation of essential and non-essential amino acids in culture medium for *in vitro* production of bovine embryos is a common practice and contrasts with the relatively poor *in vivo* uterine environment. Specific luminal metabolite requirements of the earliest phases of embryo development in the uterus are currently unknown. It is proposed that embryonic needs are qualitatively specific rather than quantitatively inclined during the first week of gestation.

5.4 APPROACHING THE EMBRYO-MATERNAL INTERFACE: *IN VIVO* VERSUS *IN VITRO* MODELS

Discrepancies found between the *in vivo* and *in vitro* results reported in this Thesis deserve discussion (summarized in Table 1). In the *in vivo* model, the gene expression data were obtained from intercaruncular endometrial tissue, whereas those in the *in vitro* study were from an endometrial epithelial cell line. The endometrium is composed of a mixture of luminal and glandular epithelial cells, stromal cells, as well as endothelial and immune cells.

In this respect, it is reasonable to assume that different cells types present distinct capacities and mechanisms to respond to external signals. It should also be pointed out that in the *in vivo* environment, the endometrial function is under control of a number of systems/factors, in particular, sex steroid hormones. Even though pregnant and control cows presented similar ovarian morphologies and sex steroid endocrine profiles in Chapter 2, it is expected that ovarian hormones have an impact on the endometrial responsiveness to embryo-derived signals. This is a major limitation of hormone-free *in vitro* systems, such as used in Chapter 4. Other remarkable difference between the two experimental models used in this Thesis is that in the *in vivo* study, changes in endometrial transcriptome were caused by a single *in vivo*-generated embryo, whereas changes in the *in vitro* study were triggered by 15 *in vitro*-generated embryos. In this regard, Mansouri-Attia *et al.* (2009) showed that the endometrium responds differently to *in vivo* versus *in vitro* embryos. Furthermore, cells cultured *in vitro* do not necessarily mirror their *in vivo* morphological and functional features. In fact, it was shown that the BEECs used in the *in vitro* model underwent an epithelial-mesenchymal transition, as seen by the co-expression of Cytokeratin and Vimentin (Chapter 4). However, evidences were provided that, despite their dedifferentiated status, the cells preserved functional features linked to their *in vivo* physiology, as for example expression of sex steroid hormones receptors. These limitations do not detract from our findings, as all conclusions drawn were carefully considered but require further substantiation. Even though *in vitro* models present such restraints, they still offer the advantage of surrounding the very local embryo-maternal interface and, therefore, serve as a useful tool to provide first basic insights into the complex embryo-maternal interactome. Development of more *in vivo*-like embryo/endometrial co-culture models will, indisputably, advance our understanding of early embryo-maternal communication.

Table 1. Comparison of results obtained in the *in vivo* versus the *in vitro* study. Green arrows indicate that presence of embryos up-regulated expression of a given gene in the endometrium *in vivo* (Chapter 2) or in bovine endometrial epithelial cells (BEECs) *in vitro* (Chapter 4) compared to the control (no embryo) group; red arrows indicate a down-regulation; Equal signs depict that no changes were observed.

5.5 BACK TO THE ENDOMETRIUM: IS THERE A GOOD/COMPETENT EMBRYO FOR A NON-RESPONSIVE ENDOMETRIUM?

The results discussed in the present Thesis provided novel information on the embryo-maternal communication with emphasis in the embryo-dependent programming of endometrial function. The concept of effective communication implies an origin, a signaling agent, and an ultimate recipient that is able to decode the message. The ability of cells to respond to inducers, normally reflects the presence of cognate receptors and downstream signal transducers to modulate transcription and, ultimately, cell function. The target cells, in turn, can become inductive and trigger neighboring cells via new signals, thus generating sequential inductive events and amplifying the initial stimulus. In that regard, not only insufficient release of factors by the embryo, but also inadequate reaction of the endometrium to embryo-derived signals, can cause early embryonic loss and pregnancy failure. It is surprising that very little is currently known about the endometrial expression pattern of receptors for type 1 interferons (IFNAR1 and IFNAR2), for example, and the regulatory factors involved. It is of paramount importance to understand not only how the embryo

communicates with the endometrium, but also how the endometrium is programmed to respond to the embryo-derived signals.

5.6 THE BICORNUATE BOVINE UTERUS AS A COMPARTMENTALIZED STRUCTURE

Another major contribution of this Thesis is that remarkable regional differences in transcript abundances were detected along the uterine horn ipsilateral to the CL (Chapter 2), in addition to the well characterized functional differences between ipsi and contralateral uterine horns (Araújo *et al.*, 2015). The functional spatial signature of the endometrium can be partially explained by vascular arrangements along the bovine uterine horns. Specifically, there is a preferential input of blood draining the ovaries to the cranial region of the uterus compared to the mid and posterior regions (Pope *et al.*, 1982). These findings should be considered when designing experiments that aim to collect and analyze endometrial and/or uterine luminal fluid samples. Specifically, one should keep in mind that specific regions of the uterus will need to be sampled depending on the specific hypothesis tested.

5.7 HYPOTHETICAL MODEL

Based on the results presented throughout this Thesis, the following hypothetical model of the embryo-endometrial interactome on day 7 of pregnancy in cattle is proposed (Fig. 2).

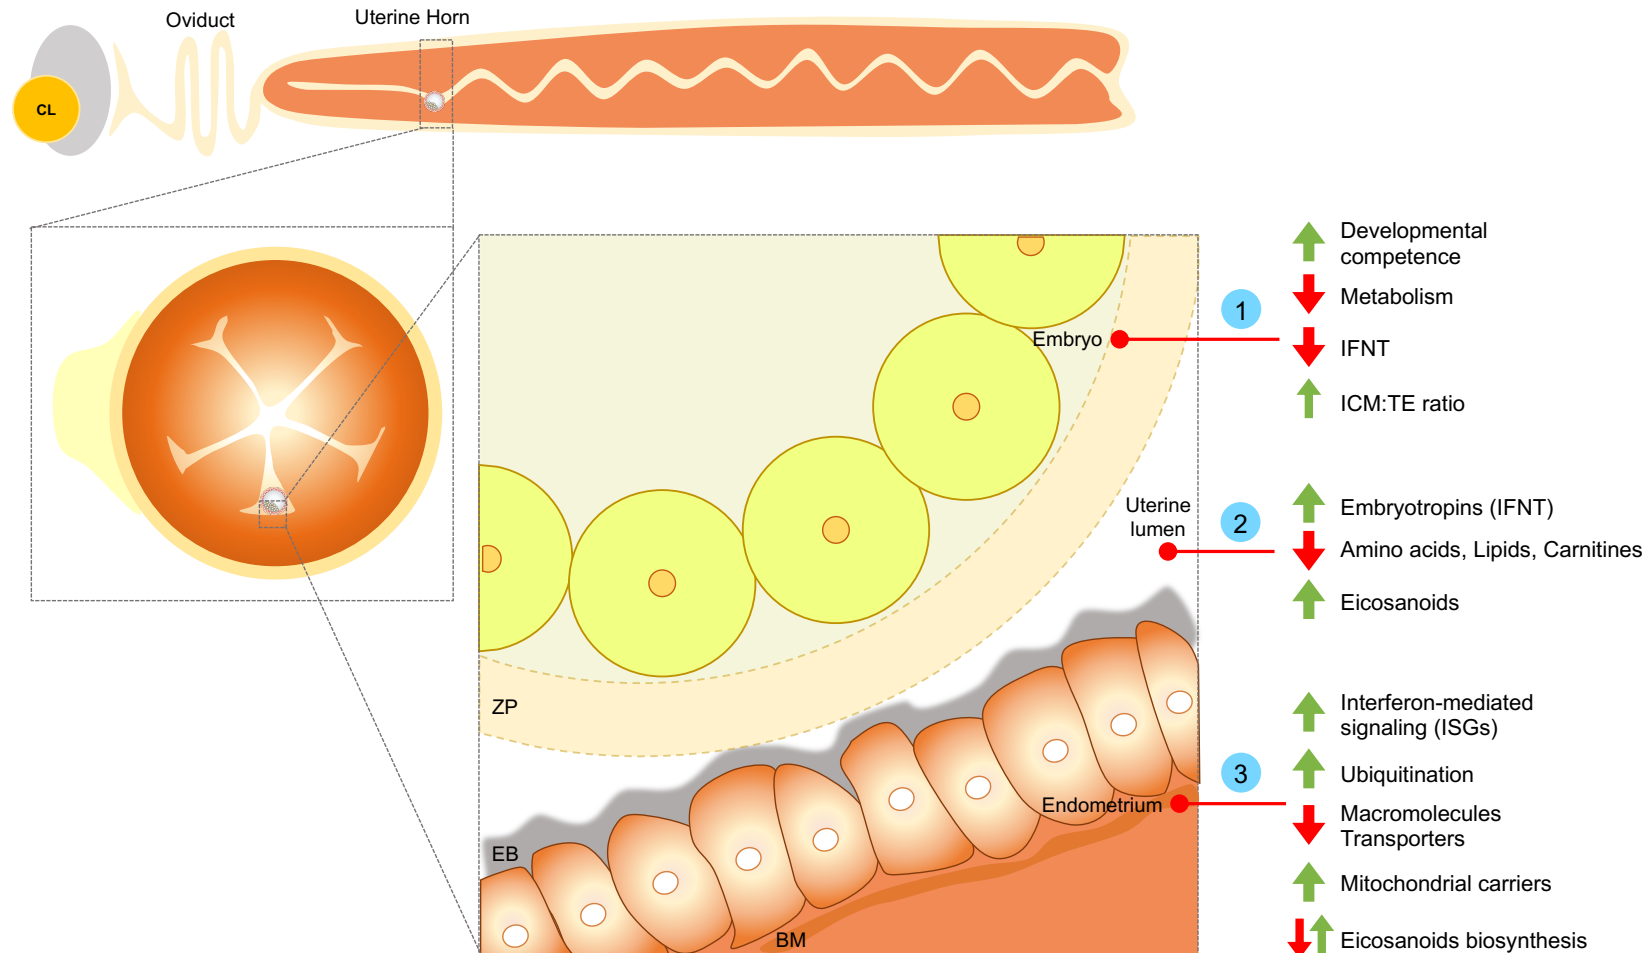

Figure 2. Hypothetical model of the embryo-endometrial interactome on day 7 of pregnancy in cattle. The embryo exerts local effects on the endometrium via juxtacrine and paracrine fashions. (1) The embryo-endometrial interactome affects in the embryo: embryos cultured *in vivo* are of superior quality of their *in vitro* counterparts indicating that the reproductive tract plays a role in embryo development. Embryos co-cultured *in vitro* contacting an endometrial epithelial cell monolayer display increased ICM:TE ratio and reduced abundance of transcripts for interferon-tau (IFNT). **(2) The embryo-endometrial interface represents a pool of stimulatory and response molecules, originated in the embryo and the endometrium:** the embryo releases signaling molecules, referred as to embryotropins, into the uterine lumen, as for example IFNT. Presence of the embryo leads to changes in the uterine luminal fluid composition, including an overall decrease in amino, acids, lipids and carnitines concentration, and an increase in metabolites of the eicosanoids pathway. Changes on the uterine luminal fluid composition might be a consequence of uptake and release of molecules by the embryo itself, and/or represent changes in the endometrial function initiated by the embryo. **(3) The embryo-endometrial interactome affects the endometrium:** embryo-induced effects on the endometrium include (i) stimulation of transcription of interferon stimulated genes (ISGs). Some ISGs are associated with ubiquitination pathways that might become up-regulated in the endometrium; (ii) decreased endometrial expression of transporters for macromolecules, and an increase in the expression of mitochondrial carriers; and (iii) modulation of eicosanoids synthesis by the endometrium. CL corpus luteum. ZP zona pellucida. EB endometrial biofilm. BM basal membrane.

5.8 FUTURE DIRECTIONS

This Thesis has identified a number of research needs. By using a combination of *in vivo* and *in vitro* models with state-of-the-art analytical tools, the early embryo-maternal interactome was explored. The findings presented hereby provide candidate systems that might be important for conditioning the uterine environment for conceptus development and represent starting points for interventional investigations, which are the logical next steps. Recent developments in genetic engineering (knock-out and knock-down models) associated with the well-established *in vitro* production of bovine embryos will facilitate the target validation of particular candidates. For instance, this Thesis identified interferon-mediated signaling and eicosanoids as important pathways intermediating the embryo-maternal cross-talk. Further research to understand the specific roles of these candidate molecules on programming the endometrium towards a more receptive status are needed. A potential scenario could be the temporary knock-down of IFN τ expression using RNA interference (RNAi) in day-7 *in vitro*-produced embryos followed by transfer to synchronized recipients to test whether and to which extent early embryo-derived IFN τ is required to establish pregnancy in cattle.

5.9 IMPLICATIONS

The results and insights generated in this Thesis are helpful for the determination of factors contributing to embryonic losses in cattle. Biotechnological applications in animal breeding could include strategies to either enhance embryonic pregnancy recognition signals or to select females according to markers of uterine responsiveness to embryo-derived signals. Alternatively, important mediating molecules could be generated as recombinant proteins and be transcervically administered into the uterus. Identification of genes, proteins, metabolites or systems that change in response to the embryo/conceptus can further serve as novel markers for early pregnancy diagnosis. For instance, ALOX12, one of the genes up-regulated in the endometrium in response to the embryo presence has been recently patented as one of the seven biomarkers used in a multiple pregnancy marker pattern (MPMP) for early detection of pregnancies on days 17-19 after insemination in lactating cows (Te Pas *et al.*, 2019). Additionally, as a monovulatory species, signaling mechanisms identified in the

bovine can be used as a valuable indication for similar evaluations in other species, including the human.

CHAPTER 6
CONCLUSIONS

6 CONCLUSIONS

In conclusion, the results presented in the course of this Thesis provide evidence of a complex embryo-maternal interactome between the pre-elongation embryo and the endometrium in cattle. Thus, the **overarching hypothesis that bovine embryos are able to modulate the endometrial function as early as day 7 of pregnancy was accepted.**

Specific hypotheses were tested in each of the three studies. In Chapter 2, an *in vivo* experiment was conducted to test the hypothesis that **exposure to an embryo changes the abundance of specific transcripts in the endometrial regions in closest proximity to the embryo in the pregnant uterine horn.** It was shown that transcription of specific genes was modulated in the endometrium in response to a day-7 embryo. Most effects detected were close to the location of the embryo into the uterine horn ipsilateral to the corpus luteum. In Chapter 3, it was hypothesized that **presence of the embryo modulates the biochemical composition of the uterine luminal fluid in the most cranial portion of the pregnant uterine horn.** Quantification of over 200 compounds showed that exposure to an embryo alters the metabolite composition of the uterine microenvironment. Finally, in Chapter 4, hypothesis was that **embryo-induced changes on endometrial transcriptome depend on physical proximity between the embryos and the endometrium.** By means of an *in vitro* model, it was shown that a juxtacrine relationship between embryos and bovine endometrial epithelial cells changes nature and intensity of embryo-induced effects on endometrial cells transcriptome. Co-culture conditions also impacted on embryonic developmental capacity, cell segregation and gene expression. Collectively, the findings discussed herein provide insights into the embryo-induced changes on the endometrial function during early gestation in cattle. Candidate systems that might be important for conditioning the uterine environment for conceptus development were provided and their biological relevance for the establishment of pregnancy warrants further investigation.

Dodecanedioylcarnitine	C12-DC	53481673
Dodecenoylcarnitine	C12:1	53481671
Tetradecanoylcarnitine [= Myristylcarnitine]	C14	53477791
Tetradecenoylcarnitine [= Myristoleylcarnitine]	C14:1	22833575
Hydroxytetradecenoylcarnitine [= Hydroxymyristoleylcarnitine]	C14:1-OH	53481679
Tetradecadienoylcarnitine	C14:2	71464539
Hydroxytetradecadienoylcarnitine	C14:2-OH	71464482
Hexadecanoylcarnitine [= Palmitoylcarnitine]	C16	11953816
Hydroxyhexadecanoylcarnitine [= Hydroxypalmitoylcarnitine]	C16-OH	24779579
Hexadecenoylcarnitine [= Palmitoleylcarnitine]	C16:1	53477817
Hydroxyhexadecenoylcarnitine [= Hydroxypalmitoleylcarnitine]	C16:1-OH	53481779
Hexadecadienoylcarnitine	C16:2	53481687
Hydroxyhexadecadienoylcarnitine	C16:2-OH	53481689
Octadecanoylcarnitine [= Stearyl carnitine]	C18	6426855
Octadecenoylcarnitine [= Oleyl carnitine]	C18:1	53477837
Hydroxyoctadecenoylcarnitine [= Hydroxyoleyl carnitine]	C18:1-OH	53481697
Octadecadienoylcarnitine [= Linoleyl carnitine]	C18:2	53477834
Acetylcarnitine	C2	1
Propionylcarnitine	C3	107738
Hydroxybutyrylcarnitine (Malonylcarnitine)	C3-DC (C4-OH)	22833583
Hydroxypropionylcarnitine	C3-OH	53481613
Propenoylcarnitine	C3:1	53481611
Butyrylcarnitine / Isobutyrylcarnitine	C4	439829
Butenoylcarnitine	C4:1	4151505
Isovalerylcarnitine / 2-Methylbutyrylcarnitine / Valerylcarnitine	C5	6426851
Glutaryl carnitine (Hydroxyhexanoylcarnitine [= Hydroxycaproylcarnitine])	C5-DC (C6-OH)	53481622
Methylglutaryl carnitine	C5-M-DC	128145
Hydroxyisovalerylcarnitine / Hydroxy-2-methylbutyryl / Hydroxyvalerylcarnitine (Methylmalonylcarnitine)	C5-OH (C3-DC-M)	53481628
Tiglylcarnitine / 3-Methyl-crotonylcarnitine	C5:1	22833596
Glutaconylcarnitine / Mesoconylcarnitine	C5:1-DC	53481620
Hexanoylcarnitine [= Caproylcarnitine] (Fumaryl carnitine)	C6 (C4:1-DC)	3246938
Hexenoylcarnitine	C6:1	53481638
Pimelylcarnitine	C7-DC	53481675
Octanoylcarnitine [= Caprylylcarnitine]	C8	11953814
Nonanoylcarnitine [= Pelargonylcarnitine]	C9	53481660

Sphingomyelin with acyl residue sum C24:1	SM C24:1	44260126

Supplementary Table S4. Sums and ratios of metabolites quantified in bovine uterine luminal fluid samples, according to their biochemical classifications. Metabolites are categorized in amino acids (AA), biogenic amines (BA), acylcarnitines (AC), esters derived from dicarboxylic acids (DC), esters derived from hydroxylated acids (OH), Phosphatidylcholines (PC), Lysophosphatidylcholines (LysoPC), diacyl- (PC aa) or acyl-alkyl- (PC ae) phosphatidylcholines, saturated (SFA), monounsaturated (MUFA), polyunsaturated (PUFA) glycerophosphocholines, sphingomyelins (SM), hydroxysphingomyelins (SM-OH), and eicosanoids derived from the cyclooxygenase (COX) and lipoxygenase (LOX) pathways. (Continued)

Biochemical classification	Calculations
Total AA	Sum of the concentrations of Ala, Arg, Asn, Asp, Cit, Gln, Glu, Gly, Leu, Pro, Ser, Thr and Taurine
Non-essential AA	Sum of the concentrations of Ala, Asn, Asp, Gln, Gly, Pro, Ser and Taurine
Acidic AA	Sum of the concentrations of Asp and Glu
Small Neutral AA	Sum of Ala, Asn, Gly, Ser, Thr and Taurine
Osmotic-stress protection AA	Sum of Ala, Gln, Gly, Pro and Taurine
Glucogenic AA	Sum of Ala, Gly and Ser
Glutathione precursors AA	Sum of Glu and Gly
Total BA	Sum of Carnosine, Creatinine, Dopamine, Histamine, Putrescine, Sarcosine, SDMA, Spermidine, Spermine and t4-OH-Pro
Spermidine/Putrescine	Ratio of Spermidine to Putrescine
Spermine/Spermidine	Ratio of Spermine to Spermidine
Total Recoverable Amounts of AC	Sum of the concentrations of all acylcarnitines
Total short-chain AC	Sum of the concentrations of C2, C3, C3:1, C4, C4:1, C5 and C5:1
Total medium-chain AC	Sum of the concentrations of C6:1, C8, C9, C10, C10:1, C10:2, C12 and C12:1
Total long-chain AC	Sum of the concentrations of C14, C14:1, C14:2, C16, C16:1, C16:2, C18, C18:1 and C18:2
Acylcarnitine/Free carnitine	Ratio of Carnitine (C2) to Free carnitine (C0)
Total short-chain AC/Free carnitine	Ratio of total short-chain acylcarnitine (AC) to Free carnitine (C0)
CPT-I([C16+C18]/C0)	Ratio of [C16, C16-OH, C16:1, C16:1-OH, C16:2, C16:2-OH, C18, C18:1, C18:1-OH, C18:2] to Free carnitine (C0)
Total Esters derived from DC/Total AC	Ratio of Esters derived from DC to total AC
Esters derived from HO	Sum of the concentrations of C3-OH, C5-OH(C3-DC-M), C14:1-OH, C14:2-OH, C16-OH, C16:1-OH, C16:2-OH and C18:1-OH
Esters derived from DC	Sum of C3-DC(C4-OH), C5-DC(C6-OH), C5-M-DC, C5:1-DC, C7-DC and C12-DC
Total recoverable amounts of phospholipids	Sum of all phospholipids
Total recoverable amounts of LysoPC	Sum of the concentrations of lysoPC a C14:0, lysoPC a C16:0, lysoPC a C16:1, lysoPC a C17:0, lysoPC a C18:0, lysoPC a C18:1, lysoPC a C18:2, lysoPC a C20:3, lysoPC a C20:4, lysoPC a C24:0, lysoPC a C26:0, lysoPC a C26:1, lysoPC a C28:0 and lysoPC a C28:1

Biochemical classification	Calculations
Total recoverable amounts of PC	Sum of the concentrations of PC aa C24:0, PC aa C26:0, PC aa C28:1, PC aa C30:0, PC aa C32:0, PC aa C32:1, PC aa C32:2, PC aa C32:3, PC aa C34:1, PC aa C34:2, PC aa C34:3, PC aa C34:4, PC aa C36:0, PC aa C36:1, PC aa C36:2, PC aa C36:3, PC aa C36:4, PC aa C36:5, PC aa C36:6, PC aa C38:0, PC aa C38:1, PC aa C38:3, PC aa C38:4, PC aa C38:5, PC aa C38:6, PC aa C40:1, PC aa C40:2, PC aa C40:3, PC aa C40:4, PC aa C40:6, PC aa C42:0, PC aa C42:1, PC aa C42:2, PC aa C42:4, PC aa C42:5, PC aa C42:6, PC ae C30:0, PC ae C30:1, PC ae C30:2, PC ae C32:1, PC ae C32:2, PC ae C34:0, PC ae C34:1, PC ae C34:2, PC ae C34:3, PC ae C36:0, PC ae C36:1, PC ae C36:2, PC ae C36:3, PC ae C36:4, PC ae C38:0, PC ae C38:1, PC ae C38:2, PC ae C38:3, PC ae C38:4, PC ae C38:5, PC ae C40:1, PC ae C40:2, PC ae C40:3, PC ae C40:4, PC ae C40:5, PC ae C40:6, PC ae C42:0, PC ae C42:1, PC ae C42:2, PC ae C42:3, PC ae C42:5, PC ae C44:3, PC ae C44:4, PC ae C44:5 and PC ae C44:6
Total LysoPC/Total PC ^c	Ratio of total LysoPC to total recoverable PC
Total PC aa	Sum of the concentrations of PC aa C24:0, PC aa C26:0, PC aa C28:1, PC aa C30:0, PC aa C32:0, PC aa C32:1, PC aa C32:2, PC aa C32:3, PC aa C34:1, PC aa C34:2, PC aa C34:3, PC aa C34:4, PC aa C36:0, PC aa C36:1, PC aa C36:2, PC aa C36:3, PC aa C36:4, PC aa C36:5, PC aa C36:6, PC aa C38:0, PC aa C38:1, PC aa C38:3, PC aa C38:4, PC aa C38:5, PC aa C38:6, PC aa C40:1, PC aa C40:2, PC aa C40:3, PC aa C40:4, PC aa C40:6, PC aa C42:0, PC aa C42:1, PC aa C42:2, PC aa C42:4, PC aa C42:5 and PC aa C42:6
Total PC ae	Sum of the concentrations of PC ae C30:0, PC ae C30:1, PC ae C30:2, PC ae C32:1, PC ae C32:2, PC ae C34:0, PC ae C34:1, PC ae C34:2, PC ae C34:3, PC ae C36:0, PC ae C36:1, PC ae C36:2, PC ae C36:3, PC ae C36:4, PC ae C38:0, PC ae C38:1, PC ae C38:2, PC ae C38:3, PC ae C38:4, PC ae C38:5, PC ae C40:1, PC ae C40:2, PC ae C40:3, PC ae C40:4, PC ae C40:5, PC ae C40:6, PC ae C42:0, PC ae C42:1, PC ae C42:2, PC ae C42:3, PC ae C42:5, PC ae C44:3, PC ae C44:4, PC ae C44:5 and PC ae C44:6
Total MUFA (PC)	Sum of the concentrations of PC aa C28:1, PC aa C32:1, PC aa C34:1, PC aa C36:1, PC aa C38:1, PC aa C40:1, PC aa C42:1, PC ae C30:1, PC ae C32:1, PC ae C34:1, PC ae C36:1, PC ae C38:1, PC ae C40:1 and PC ae C42:1
Total PUFA (PC)	Sum of the concentrations of PC aa C32:2, PC aa C32:3, PC aa C34:2, PC aa C34:3, PC aa C34:4, PC aa C36:2, PC aa C36:3, PC aa C36:4, PC aa C36:5, PC aa C36:6, PC aa C38:3, PC aa C38:4, PC aa C38:5, PC aa C38:6, PC aa C40:2, PC aa C40:3, PC aa C40:4, PC aa C40:6, PC aa C42:2, PC aa C42:4, PC aa C42:5, PC aa C42:6, PC ae C30:2, PC ae C32:2, PC ae C34:2, PC ae C34:3, PC ae C36:2, PC ae C36:3, PC ae C36:4, PC ae C38:2, PC ae C38:3, PC ae C38:4, PC ae C38:5, PC ae C40:2, PC ae C40:3, PC ae C40:4, PC ae C40:5, PC ae C40:6, PC ae C42:2, PC ae C42:3, PC ae C42:5, PC ae C44:3, PC ae C44:4, PC ae C44:5 and PC ae C44:6
Total SFA (PC)	Sum of the concentrations of PC aa C24:0, PC aa C26:0, PC aa C30:0, PC aa C32:0, PC aa C36:0, PC aa C38:0, PC aa C42:0, PC ae C30:0, PC ae C34:0, PC ae C36:0, PC ae C38:0 and PC ae C42:0
MUFA (PC)/SFA (PC) ^d	Ratio of monounsaturated fatty acids (MUFA) to saturated fatty acids (SFA)
PUFA (PC)/MUFA (PC) ^d	Ratio of polyunsaturated fatty acids (PUFA) to monounsaturated fatty acids (MUFA)
PUFA (PC)/SFA (PC) ^d	Ratio of polyunsaturated fatty acids (PUFA) to saturated fatty acids (SFA)

Biochemical classification	Calculations
Total SM	Sum of all sphingomyelins (SM)
Total SM-OH	Sum of the concentrations of SM (OH) C16:1, SM (OH) C22:1, SM (OH) C22:2, SM (OH) C24:1
Ratio SM/SM-OH	Ratio of total recoverable sphingomyelins (SM) to hydroxysphingomyelins (SM-OH)
Total unsaturated SM	Sum of the concentrations of SM C16:1, SM C18:1 and SM C24:1
Total saturated SM	Sum of the concentrations of SM C16:0, SM C18:0 and SM C24:0
Hexoses	Sum of the concentrations of Glucose; Aldohexose; L-Allopyranose; D-Allose; D-Allopyranose; D-Allose; D-Altropyranose; D-Glucopyranose; alpha-D-Glucopyranose; beta-D-Glucopyranose; D-Mannopyranose; alpha-D; Mannopyranose; L-Gulopyranose; D-Gulopyranose; D-Idopyranose; Alpha-L-Galactopyranose; alpha-D-Galactopyranose; beta-D-Galactopyranose; D-Talose; D-Talopyranose; Ketohexose; D-Psicopyranose; L-Fructofuranose; D-Fructose; D-Fructofuranose; L-Sorbopyranose; D-Sorbopyranose; D-Tagatose; D-Tagatopyranose
COX pathway	Sum of the concentrations of 6-keto-PGF1a and PGF2a
LOX pathway	Sum of the concentrations of 12S-HETE, 15S-HETE and 13S-HODE

Supplementary Table S5. Bovine specific oligonucleotide forward and reverse primer sequences (5'-3') and PCR product length.

Metabolites in bold were different between Con and Preg group by ANOVA followed by FDR correction.

^aStatistical analyses were carried out by one-way ANOVA followed by FDR correction for multiple comparisons. Magnitude of effect is indicated by: ** $P \leq 0.01$; * $P \leq 0.05$; n.s. $P > 0.05$.

^bData are represented as fold-change of the metabolite concentration between Preg and Con groups.

Supplementary Table S9. Sphingomyelins (SM) concentration in uterine luminal fluid from Control (Con) and Pregnant (Preg) cows. Values are expressed as nmol/cm² of endometrial area; mean \pm SEM.

Abstract

The bovine pre-implantation embryo secretes bioactive molecules from early development stages, but effects on endometrial function are reported to start only after elongation. Here, we interrogated spatially defined regions of the endometrium transcriptome for responses to a day 7 embryo *in vivo*. We hypothesize that exposure to an embryo changes the abundance of specific transcripts in the cranial region of the pregnant uterine horn. Endometrium was collected from the uterotubal junction (UTJ), anterior (IA), medial (IM) and posterior (IP) regions of the uterine horn ipsilateral to the CL 7 days after estrus from sham-inseminated (Con) or artificially inseminated, confirmed pregnant (Preg) cows. Abundance of 86 transcripts was evaluated by qPCR using a microfluidic platform. Abundance of 12 transcripts was modulated in the Preg endometrium, including classical interferon-stimulated genes (*ISG15*, *MX1*, *MX2* and *OAS1Y*), prostaglandin biosynthesis genes (*PTGES*, *HPGD* and *AKR1C4*), water channel (*AQP4*) and a solute transporter (*SLC1A4*) and this was in the UTJ and IA mainly. Additionally, for 71 transcripts, abundance varied according to region of the reproductive tract. Regulation included downregulation of genes associated with proliferation (*IGF1*, *IGF2*, *IGF1R* and *IGF2R*) and extracellular matrix remodeling (*MMP14*, *MMP19* and *MMP2*) and upregulation of anti-adhesive genes (*MUC1*) in the cranial regions of uterine horn. Physical proximity to the embryo provides paracrine regulation of endometrial function. Embryo-independent regulation of the endometrial transcriptome may support subsequent stages of embryo development, such as elongation and implantation. We speculate that successful early embryo-dependent and -independent programming fine-tune endometrial functions that are important for maintenance of pregnancy in cattle.
