12 **Abstract**

13 Herbicide resistance has become an increasing problem, and at the same time pesticide usage is
14 declining due to stringent EU pesticide legislation which aims to reduce the impact on environment
15 and human health. For these reasons, new alternative integrated weed management approaches are
16 becoming increasingly relevant. Formulations based on Brassica defatted seed meals (DSMs) and
17 glycerin, have previously been shown to be effective in reducing the germination of lettuce seed.

18 In this work five DSMs, formulated with and without crude glycerin, were chosen for *in vitro* and
19 glasshouse experiments: i) *Brassica nigra*, ii) *Brassica tournefortii*, iii) *Eruca sativa*, iv) *Rapistrum*
20 *rugosum* and v) *Sinapis alba*. Black-grass (*Alopecurus myosuroides*), a weed demonstrating
21 extensive herbicide resistance, was used as a target, and the germination inhibition caused on this
22 weed by Brassica defatted seed meals was assessed.

23 In both *in vitro* and *in vivo* experiments, the most effective DSM for inhibiting germination of both
24 lettuce and black-grass seeds was the sinigrin containing DSM, *Brassica nigra*.

25 The aim of the manuscript was to suggest a new high value application for Brassicas derived DSM
26 as a co-products from the vegetable oil production chain. The proposed treatments could represent
27 an interesting and 100% novel natural alternative to the conventional herbicides.

31

32

33 **1. Introduction**

34 Despite different land use contexts, from agriculture to urban settings, weed control remains a major
35 problem. In particular, weed control in amenities such as parks and schools should be undertaken
36 without threatening health and environment. At the same time, whilst herbicide resistance has
37 become an increasing problem (Service, 2013), EU policy is demanding a significant reduction of
38 pesticide usage. In fact, several high impact chemical products used in European agriculture are in
39 phase out or under scrutiny following the Directive 2009/128/EC on “Sustainable use of pesticides”,
40 and the Regulation (CE) no. 1907/2006 (REACH) on Registration, Evaluation, Authorization and
41 Restriction of Chemicals. In the Article 14 concerning Integrated Pest Management, the REACH
42 clearly reports that “Member States shall take all necessary measures aimed at promoting low
43 pesticide-input pest management, giving wherever possible priority to non-chemical methods”.

44 At the same time, a wide range of fossil-based products could be substituted by bio-based products
45 and materials derived from different biomasses such as energy crops, agricultural and forestry
46 residues and waste (Maity, 2015).

47 The most abundant co-products of industrial vegetable oil production for bioenergy and green
48 chemistry are defatted seed meals (DSMs) derived from seed defatting procedures. Among oilseed
49 crops, biofumigant *Brassicaceae* crops have shown great potential within integrated pest
50 management and organic farming solutions. In fact, some Brassica DSMs contain high level of

51 glucosinolates (GSLs) and, after a patented procedure (Lazzeri et al., 2010), they proved to be
52 suppressive against a variety of soil-borne fungal pathogens (Lazzeri et al., 2003), nematodes
53 (Lazzeri et al., 2009; Ngala et al., 2015) and wire-worms (Furlan et al., 2010). In their native form,
54 GSLs are stable and marginally reactive, while in the presence of water and the endogenous enzyme
55 myrosinase (MYR) they are quickly hydrolyzed with the production of a series of bioactive
56 breakdown products, mainly isothiocyanates (ITCs) and, to a lesser extent, nitriles, epithionitriles
57 and thiocyanates, depending on the reaction conditions (Bones and Rossiter, 2006; Agerbirk and
58 Olsen, 2012). Thanks to this natural process, *Brassicaceae* species have been widely studied for
59 applications in the so called biofumigation technique (Kirkegaard et al., 1993). Since the inhibitory
60 influence of aqueous extracts from parts of *Brassica oleracea* plants on the germination and growth
61 of clover (*Trifolium repens* L.) and rye-grass (*Lolium* spp.) was first described by Campbell (1959),
62 many other studies on the allelopathic effects of GSL degradation products were carried out.
63 Angelini et al. (1998) reported a total inhibition of seed germination of different weeds by the
64 hydrolysis products of glucoerucin and glucoraphanin. In the same study, seeds treated with the
65 hydrolysis products of epi-progoitrin, mainly 5-vinyloxazolidine-2-thione, gave a high percentage
66 of abnormal seedlings. The allelopathic potential of several species and cultivars of Brassica on
67 wheat, in laboratory and field trials, has been reported by Mason-Sedun et al. (1986) and Mason-
68 Sedun and Jeppson (1988). More recent papers have shown the allelopathic effect of Rapeseed
69 (*Brassica napus* L.) water extracts on *Phalaris minor* (Retz.), *Convolvulus arvensis* (L.) and
70 *Sorghum halepense* (L.) (Aliko et al., 2014).

71 Furthermore, Brassica DSMs have shown a good synergy with crude glycerin (CG), a
72 underestimated co-product derived from the biodiesel chain. D'Avino et al. (2015a) reported the
73 first attempts to apply CG as an active ingredient for germination inhibition (GI), even if high doses
74 were required for a significant inhibition activity. On the other hand, the DSMs, activated by a
75 patent procedure (Lazzeri et al. 2010), were easily formulated with CG solutions, maintaining a
76 high GSLs conversion rate and a sufficient retention capacity of the biologically active compounds.

77 In this way, the synergic effect of CG and DSMs allowed a strong reduction of CG in the
78 formulations.

79 Black-grass (*Alopecurus myosuroides* Huds.), a major annual grass weed of winter cereals, was
80 chosen as a potentially interesting target. Its winter annual growth habit is well adapted to winter
81 cereal production, and recent crop management techniques such as earlier fall planting and intensive
82 cereal rotation have led to rapid increases in black-grass populations, (Holm et al., 1997). One of
83 the first cases of resistance to herbicides registered in Europe was in early 1980s, in Essex, UK
84 (Moss and Cussans, 1985). Nowadays, herbicide resistance in black-grass populations is reported in
85 a number of EU countries, including populations that demonstrate multiple resistance to a range of
86 herbicides with different modes of action, including photosystem II inhibitors, ACCase inhibitors,
87 and ALS inhibitors (Henriet and Marechal, 2009; Keshtkara et al., 2015).

88 The aim of this work was to evaluate the GI activity on black-grass of different Brassica DSMs in
89 formulation with and without CG. Before the evaluation of the effect of five Brassica DSMs on
90 black-grass, a preliminary screening by *in vitro* and glasshouse trials on lettuce was set up to
91 evaluate the antigerminative capability of twenty GSL containing DSMs from the CREA-CI
92 collection. The proposed treatments could represent an interesting and novel natural alternative to
93 conventional approaches in weed control.

94

95 **2. Materials and methods**

96 *2.1 Materials*

97 The CG was purchased from Cerealdocks S.p.A. (Vicenza, Italy), an industrial biodiesel company
98 and its composition was previously published (D'avino et al. 2015b). *Berteroa incana* (L.) DC.,
99 *Brassica oleracea* L., *Brassica rapa* L., *Brassica tournefortii* Gouan, *Eruca sativa* Mill., *Erysimum*
100 *pseudorhaeticum* Polatschek, *Hesperis matronalis* L., *Lepidium campestre* (L.) W.T. Aiton,
101 *Lepidium densiflorum* Schrad., *Lepidium sativum* L., *Lesquerella fendleri* L., *Limnanthes alba*
102 Benth., *Raphanus sativus* L., *Rapistrum rugosum* (L.) All., *Camelina sativa* (L.) Crantz, *Cleome*

103 *hassleriana* Chodat, *Reseda lutea* L., and *Sisymbrium officinale* (L.) Scop. DSMs derived from the
104 CREA-CI *Brassicacae* collection (Lazzeri et al., 2013) were defatted with hexane (1/3, W/V)
105 overnight at room temperature ($21 \pm 1^\circ\text{C}$). Before defatting, *Rapistrum rugosum* seeds were
106 scarified with a grinder (Bühler-Miag, MLI-204) to remove the very corky no-GSLs containing
107 silique. *Sinapis alba* L. DSM from the CREA-CI *Brassicacae* collection, and *Brassica nigra* (L.)
108 W.D.J. Koch DSM purchased by Agrium Italia S.p.A (Livorno), were produced after seed defatting
109 by an endless screw press in which temperature was kept lower than 75°C (Lazzeri et al., 2010).
110 Lettuce (*Lactuca sativa* L. cv. Cosmic) was purchased from SAIS S.p.A. (Cesena, Italy), whilst
111 *Alopecurus myosuroides* Huds. black-grass, (population: Blackgrass Foxtail, Slender) was
112 purchased from Herbiseed (Reading, UK).

113

114 2.2. Defatted seed meals characterization

115 All DSMs were produced by a patented procedure (Lazzeri et al., 2010) aimed at optimizing the
116 enzymatic system that catalyzes GSL hydrolysis. The preparation details must be considered as
117 commercially confidential and their property is of Agrium Italia S.p.A (Livorno). The DSMs were
118 analyzed according to the following methods:

- 119 - Dry matter was determined by oven-drying the DSM at 105°C for 12 h and evaluating the
120 difference in weight before and after treatment;
- 121 - Residual oil content was determined by the standard Soxhlet extraction method using
122 hexane as solvent;
- 123 - Nitrogen content was determined by the Kjeldahl method (Standard UNI 22604, 1992),
124 using a Tecator digestion system 20 and an automatic Büchi distillation unit (B-324);
- 125 - Glucosinolate content was determined following the ISO 9167-1 method (ISO 9167), with
126 some minor modifications in the extraction phase, as described in Lazzeri et al. (2011).

127 All data are reported as mean \pm standard deviation of four determinations.

128

129 *2.3. In vitro trials: extract preparation and hydrolysis product GC-MS identification*

130 *2.3.1 Extract preparation*

131 Water suspensions of each DSM (15 g L^{-1}) were kept under agitation on an orbital shaker, 0.22 g for
132 40 minutes, at room temperature ($21 \pm 1^\circ\text{C}$). The suspensions were centrifuged at 3893 g, for 30
133 minutes and filtered with filter paper (Filter-Lab, 1248).

134 *2.3.2 Deactivation of defatted seed meals*

135 A small batch of DSM was treated in sealed borosilicate glass containers by an autoclave (20
136 minutes, 120°C) in order to deactivate the myrosinase enzyme and prevent GSLs hydrolysis to
137 bioactive compounds. Extracts from deactivated DSMs were prepared as reported above.

138 *2.3.3 Hydrolysis product GC-MS identification*

139 Samples of the obtained aqueous extracts (500 μL) were mixed with ethyl acetate (LC-MS
140 Chromasolv®) at a ratio of 1:1 and after agitation with a vortex for 3 min were centrifuged for 10
141 min at 1240 g. One μL of the upper organic phase was then collected and injected in a Bruker
142 GC451 Gas Chromatograph equipped with a HP-5 fused silica capillary column (30 m, 0.25 mm
143 inside diameter, 0.25 μm film thickness, Scientific Inc, Folsom, CA) connected to a quadrupole
144 mass detector Bruker SCION SQ Premium (Bruker Daltonics, Macerata, Italy). The oven
145 temperature was set at 40°C and maintained for 4 min, then it was programmed to rise from 40 to
146 220°C at $10^\circ\text{C min}^{-1}$ and finally held at 220°C for 4 min. Transfer line 280°C , ion source 220°C ,
147 split injection (1:20), carrier gas (Helium) 1 ml min^{-1} were applied. The mass spectrometer was
148 operated in electron impact mode at 70 eV, scanning range 10-250 Mz, full scan acquisition mode.
149 Compounds were identified by matching the recorded mass spectra with the NIST/EPA/NIH Mass
150 Spectral Database (NIST11, GAITHERSBURG, MD) and by comparing retention time and spectra
151 with reference standard compounds (Santa Cruz Biotechnology) analyzed in the same conditions.

152

153 *2.4 Preliminary in vitro trials: lettuce germination inhibition*

154 Preliminary *in vitro* trials on lettuce were set up to evaluate the antigerminative capability of twenty
155 GSL containing DSMs from the CREA-CI collection. The experimental conditions in the trials were
156 those reported in D'Avino et al. (2015a). The *in vitro* trials were carried out following the
157 UNICHIM protocol (UNICHIM, 2003) with minor modifications. Ten lettuce seeds were placed in
158 each Petri dish containing a filter paper (Filter-Lab, 1300/80, diam. 90mm) with 1.8 ml of DSM
159 extract. The Petri dishes were kept in the dark at $20 \pm 1^\circ\text{C}$. After 7 days, the number of germinated
160 seeds was counted. Each treatment was replicated five times. The extracts from deactivated DSMs
161 were applied as control in the same experimental conditions in order to verify that the observed
162 germination inhibition was mainly due to the GSL hydrolysis products activity. At the end of the
163 trial, besides the number of germinated seeds, the epicotyl and primary root lengths of lettuce
164 seedlings, treated with deactivated DSMs, were measured.

165

166 2.5 Preliminary glasshouse trial: lettuce germination and growth inhibition

167 The preliminary glasshouse experiment was performed in Bologna, Italy ($44^\circ31'N$ $11^\circ21'E$) at
168 CREA-CI. In this experiment, five DSMs (*Brassica tournefortii*, *Brassica nigra*, *Eruca sativa*,
169 *Rapistrum rugosum*, and *Sinapis alba*) were chosen among the most effective in previous trials, also
170 depending on quantity of stocked seed for DSM production. The DSMs were applied, formulated
171 with and without CG, in plastic pots (high 9 cm, diameter 9.5 cm, 250 ml). The pots were filled
172 with 200 g of a mixture of 50% of sandy-loamy soil (clay13%, silt 18%, sand 69%), 50% of peat
173 (Floradur®, raised-bog-peat with CaCl_2 , pH ranging from 5 to 6.5) and 710 mg of each DSM were
174 mixed to the soil (2.7 ± 1 g of DSM L^{-1} of soil). The DSM dose and the target seed were defined
175 according to previous experiments, reported in D'Avino et al. (2015a) in which a similar glasshouse
176 trial was performed. In each pot, 20 lettuce seeds were sown 1 cm deep in the dry soil. The
177 experiment was carried out in a glasshouse under controlled conditions at $22 \pm 2^\circ\text{C}$. The pots were
178 watered with 24 ml of tap water, a dose lower than soil field capacity, or treated only once with the
179 same amount of a CG solution at 10% (9.2 ml/L of soil). The number of germinated seeds was

180 measured 27 days after sowing. The root and above-ground biomass yield (on dry matter) were
181 measured to assess the effect on the following plant growth. Each treatment was replicated three
182 times.

183

184 *2.6 Black-grass in vitro trial*

185 A Petri dish trial was set up preparing an extract as above reported. Since the black-grass seeds need
186 more time to germinate and, as other weeds, have a long dormancy, a different approach to the *in*
187 *vitro* experiment was necessary. For these reasons, some modification to the protocol were defined:
188 150 black-grass seeds were soaked in the extracts for 24h and kept in a growth chamber (Cooled
189 Incubator MIR-154-PE, Panasonic Healthcare Co., Ltd, Jp), in the dark, at 20±1°C. The day after,
190 20 seeds were surface sterilized with sodium hypochlorite 5%, rinsed 2 times with sterile distilled
191 water, and then placed in a Petri dish containing 3 ml of distilled water. Each treatment was
192 replicated five times. The Petri dishes were sealed with parafilm (Parafilm® M) and kept in the
193 dark, in the same growth chamber, at 20°C. The number of germinated seeds was counted after 14
194 days.

195

196 *2.7 Black-grass glasshouse trial*

197 Further glasshouse experiments were performed at Harper Adams University, Newport, Shropshire,
198 UK (52°46'N 2°25'W). The effect on black-grass germination of five different DSMs (*B.*
199 *tournefortii*, *B. nigra*, *E. sativa*, *R. rugosum*, and *S. alba*) formulated with and without CG was
200 evaluated. The DSMs were applied in a pot experiment, mixed into the soil before sowing. Each pot
201 (c.ca 300 ml volume) used in this trial was filled with 200 g of a mix of 50% Horticultural Silver
202 Sand (silica sand, CEM-SPEC LTD, Harby, Leics., UK) + 50% John Innes No.2 soil-based
203 compost for potting plants (J. Arthur Bower's products, William Sinclair Horticulture Ltd, Lincoln,
204 UK). Three doses for each DSM were applied: i) 1.4±1; ii) 2.7±1; and iii) 5.5±1 g L⁻¹ of soil. Fifty
205 black-grass seeds were sown in each treated pot. The same three doses of DSM were applied in

206 formulation with CG. In these pots 28 ml of a 10% CG solution was poured into the soil after
207 sowing. The pots were kept in a glasshouse under controlled conditions, with light 16 hour a day
208 (High Pressure Sodium lamp SON-T 400, with ignitor, 48000 Lm) and a temperature of 22±2°C.
209 The amount of CG used was based on a previous experience (D'Avino et al., 2015a). Each
210 treatment was replicated three times. After 8 days the number of germinated seeds was counted and
211 plant heights and the dry matter produced by each pot were measured.

212

213 2.8 Statistics

214 All the experiments were organized in a randomized experimental design. In *in vitro* and *in vivo*
215 trials, the effects on both lettuce and black-grass germination were expressed as germination
216 inhibition (GI) percentages, a calculation of the germination reduction referred to the untreated
217 control according to the Schneider-Orelli's formula (Püntener, 1981), as reported in the following
218 equation:

$$219 \quad GI (\%) = \left(\frac{\text{Mortality \% in treated Petri dish} - \text{Mortality \% in Control}}{100 - \text{Mortality \% in Control}} \right) * 100 \quad (1)$$

220 Germination inhibition percentages, stem and root lengths and biomass weight measured in the
221 trials were subjected to ANOVA and Tukey's post hoc test performed with R software (R version
222 3.00.00, The R Foundation for Statistical Computing) and P<0.05 was considered statistically
223 significant. The values are expressed as mean per Petri dish/pot ± standard error (SE).

224 Data collected from the black-grass glasshouse trials were calculated as percentages of reduction:

225 i) GI: Schneider-Orelli's formula, equation (1);

226 ii) Height reduction (HRED)

$$227 \quad HRED (\%) = \left(\frac{\text{mean plant height in treated pot} - \text{mean plant height in untreated control}}{\text{mean plant height in untreated control}} \right) * 100 \quad (2);$$

228 iii) Dry matter reduction (DMRED)

$$229 \quad DMRED (\%) = \left(\frac{\text{mean DM per plant in treated pot} - \text{mean DM per plant in untreated control}}{\text{mean DM plant in untreated control}} \right) * 100 \quad (3).$$

230

231 The measured parameters GI, HRED, and DMRED were subjected to Factorial ANOVA performed
232 with R software (R version 3.00.00, The R Foundation for Statistical Computing), considered as a
233 result of the following separate factors: i) type of DSM, ii) DSM concentration and iii) CG. As a
234 significant level, a P value<0.001 was adopted.

235

236 **3. Results and Discussion**

237 *3.1. Degradation products from defatted seed meals and their efficacy in germination inhibition of* 238 *lettuce seeds*

239 Among the twenty tested DSMs in the preliminary *in vitro* experiment, nine meals, reported in the
240 grey box (table 1), were considered effective according to their GI percentage. The evaluation of
241 different DSM extracts evidenced very different behavior for the effectiveness in GI, that was
242 linked to the total GSLs content, as much as to the type of GSLs profile.

243

244 *Insert Table 1 here*

245

246 The five DSMs chosen for further experiments are reported in bold in table 1. An appreciable
247 nitrogen content was found in each DSM, ranging from 6.1±0.1% (*B. tournefortii* DSM) to
248 7.8±0.1% (*R. rugosum* DSM), as reported in table 2. This feature could possibly represent an
249 interesting integration of N from conventional fertilizer, in open field conditions. Furthermore,
250 Snyder et al. (2010) clearly reported that a high GSLs containing biomass incorporated in soils,
251 through its capability to inhibit microbial respiration due to the GSLs degradation products release
252 reduces the soil N nitrification. This support the importance of these Brassica DSMs as interesting
253 fertilizing input. The composition and the low residual oil amount, lower than 10%, could not imply
254 a phytotoxic effect itself (Gauvirt & Cabanne, 1993).

255

256 *Insert Table 2 here*

257

258 After some preliminary GC-MS analyses of the degradation products in the DSM extracts applied in
259 the *in vitro* trials, some interesting results emerged. As expected, in the experimental reaction
260 conditions, the main degradation product of the *B. nigra* DSM extract was 2-propenyl ITC. The
261 main degradation products in *B. tournefortii*, *R. rugosum* and *E. sativa* DSM extracts were 3-
262 methylsulfinylpropyl (iberin), 3-methylsulphonylpropyl (cheirolin) and 4-methyltiobutyl (erucin)
263 ITCs, respectively. All the ITCs showed to remain stable for more than 24 h in a sealed bottle after
264 the extract production, the same time spent to soak the black-grass seeds in *in vitro* trial (§ 2.6),
265 except for those from *S. alba*. In fact, no ITCs were found in the *S. alba* extract, according to the
266 wide documented instability of 4-hydroxybenzyl ITC in aqueous solutions which results in a quick
267 hydrolysis to benzylic alcohols and thiocyanate ion (Agerbirk and Olsen., 2012). Besides this paper,
268 other studies had already shown an interesting effectiveness in weed containment induced by *S.*
269 *alba* (Rice et al., 2016; Boydston et al., 2011), and even in the preliminary tests of this study *S. alba*
270 DSM showed an interesting containment effect as well. In fact, in the *in vitro* trials, the active *S.*
271 *alba* DSM totally inhibited lettuce seed germination as other DSMs, but the same meal after MYR
272 deactivation did not shown any GI (table 3), confirming the fundamental role of GSL- MYR system
273 (Angelini *et al.*, 1998).

274

275 *Insert Table 3 here*

276

277 As reported in Borek et al. (2005), 4-hydroxybenzylisothiocyanate hydrolyzes to
278 parahydroxybenzyl alcohol and SCN⁻ in presence of alkaline pH values, and this compound is
279 probably responsible for the observed phytotoxicity. At the same time, there is a light effect on the
280 subsequent development of the sprouts treated with deactivated DSMs, on which a reduction of root
281 and epicotyl lengths was observed. This activity could be probably due to other compounds
282 involved in the phytotoxic effect (fig. 1).

283

284

Insert Figure 1 here

285

286 The *in vivo* trials confirmed an interesting efficacy of the DSMs formulated with CG in controlling
287 lettuce seed germination (fig. 2): from 95% of *B. nigra* and *E. sativa* treatments, to 80% of *S. alba*,
288 even the CG applied alone showed a GI of 78%. In this trial, only the addition of *B. nigra* or *E.*
289 *sativa* to the formulation implied a statistically consistent reduction in germination compared to the
290 CG applied alone, whilst the other meals had a slighter effect. In addition, all treatments, CG alone
291 included as control, showed a dramatic reduction in dry biomass yield, from 20 to 100 times lower
292 if compared to the biomass yield in the control pots (fig.2).

293

294

Insert Figure 2 here

295

296 *3.2 Effectiveness of defatted seed meal extracts in black-grass germination inhibition: in vitro trials*

297 The *in vitro* trials confirmed the potential effectiveness of Brassicas derived water extracts in weed
298 control (Aliko et al., 2014) on both monocotyledons and dicotyledons. Furthermore, strong
299 differences among DSM extracts in their efficacy in inhibiting black-grass germination (fig.3)
300 emerged. In fact, after 15 days *S. alba*, *R. rugosum* and *E. sativa* DSMs did not differ from the
301 untreated control showing a GI of 0%, 12% and 20%, respectively. *Brassica nigra*, instead, totally
302 inhibited the seed germination of black-grass (GI = 100%), confirming the high efficacy observed
303 on lettuce in previous trials.

304

305

Insert Figure 3 here

306

307 An unexpected result was related to the *B. tournefortii* DSM extract which, in Petri conditions,
308 showed a GI of -48%.

309

310 *3.3 Effectiveness of defatted seed meals formulated with glycerin in black-grass germination and*
311 *growth inhibition: in vivo trials*

312 The application of the DSM formulated with and without CG in semi-controlled conditions in
313 greenhouse added some new information for a practical application of Brassica DSMs in weed
314 control. The CG used in the trials had a glycerol content of around 80% and a residual water content
315 of 14%.The remaining components were mainly inorganic (ash 4%) and no hazardous compounds
316 were found, except for very low traces (D'Avino et al., 2015b). In this experiment, *B. nigra* DSM
317 (5.5 g L^{-1} of soil) formulated with a solution of CG at 10% (9.2 ml L^{-1} of soil) completely inhibited
318 the germination and the subsequent seedlings development until 4 weeks after the treatment. Even
319 the *B. nigra* DSM, applied without CG, at the highest dose showed a GI of 97.9% after 4 weeks.
320 Furthermore, with regard to the GI, *B. nigra* DSM applied both with and without CG showed a very
321 clear dose/response effect on GI percentage (Fig. 4), unlike the other DSMs.

322

323 *Insert Figure 4 here*

324

325 Whilst the effectiveness of the *B. nigra* DSM was clearly observed in our experiments, the high
326 phytotoxic action of 2-propenyl-ITC compared to other ITCs has been reported in other
327 publications. Oleszek (1987) and Bialy (1990), for instance, demonstrated that germinating seeds
328 exposed to either pure 2-propenyl-ITC or the pulverized leaves of *B. juncea* or *B. nigra*, could be
329 inhibited or, at least the overall growth of the seedlings was stunted. Although efficacy largely
330 depends on persistence, release rate and intrinsic biological activity greatly influenced global
331 effectiveness. *Brassica nigra* DSM effectiveness can also be linked to the high volatility of its main
332 GSL degradation product (Sekiyama et al., 1993; Borek et al., 1994). Furthermore, this
333 characteristic have also positive effects on soil such as higher resilience of microbial communities
334 compared to chemical fumigants (D'Avino et al., 2004). On the other hand, different formulations

335 could increase the DSMs effectiveness in GI, improving the mechanisms involved in the active
336 compounds release. Moreover, a more precise dose/GI response assessment must be investigated.
337 Although in the *in vitro* trial an increased number of germinated seeds was measured after two
338 weeks in Petri dishes treated with *B. tounnefortii*, this did not occurred in glasshouse conditions. In
339 fact, none of the three doses of *B. tounnefortii* DSM tested in pot conditions increased the number of
340 black-grass germinated seeds, nor height or dry weight of plants, compared to the untreated test
341 (data not shown). Other studies are ongoing for a better understanding of the processes involved in
342 this phenomenon.

343 All the meals, except for *B. nigra* DSM, did not show a clear dose/effect response, probably due to
344 a reduced effectiveness in these specific assay conditions, but at the same time some meaningful
345 results clearly emerged from the factorial ANOVA applied to the GI, HRED and DMRED
346 measurements.

347 Firstly, the black-grass seed germination was inhibited by a complex interaction of factors. In fact, a
348 statistically significant effect due to the DSM and CG factors, if considered separately, was
349 observed. Although the GI was significantly affected by the interactions between i) ‘*DSM*’ x ‘*DSM*
350 *concentration*’, and ii) ‘*DSM concentration*’ x ‘*CG*’, the ‘*CG*’ was the unique factor which had a
351 significant effect on plant growth parameters HRED and DMRED (Tab. 4).

352

353

Insert Table 4 here

354

355 The greenhouse trial showed how the presence of DSM in the treatments affected mainly the early
356 stages of black-grass seed development. In fact, the interactions between the factors of the factorial
357 ANOVA i) type of ‘*DSM*’, ii) ‘*DSM concentration*’ and iii) presence or absence of ‘*CG*’, which
358 affected seed germination, resulted very complex. Once the seedlings emerged, the subsequent
359 growth (plant height and biomass) was mostly affected by the presence of CG in the formulations.
360 These results confirmed the limited persistence of the effect of GSL degradation products in the soil

361 and consequently the safety of the application of *Brassicaceae* DSMs in weed control. The
362 concerning about CG utilization is based upon methanol and sodium residues, used as catalysts in
363 the biodiesel production process, but few traces were found in the batch used for the trials. Thus,
364 CG is considered a safe product that can be used, for instance, as an energy-rich feed component in
365 animal diets (Alexander et al., 2010).

366 Since the *B. nigra* DSM, the most effective tested meal, showed a total GI at the same concentration
367 and conditions as the other DSMs, higher concentrations were not investigated. As previously
368 stated, the effectiveness of the DSMs depends also on the optimization of the formulation, and
369 under different experimental conditions (e.g. higher concentration, different pH, type of
370 distribution), it could greatly increase.

371

372 **4. Conclusions**

373 Novel alternatives to conventional herbicides are strongly needed. Nowadays, weed control without
374 herbicides is carried out mostly through physical (cultural) methods associated to high energy and
375 time consumption. Whilst studies have been carried out on pests and pathogens with bio-based
376 treatments, fewer studies have been undertaken on weed control. The *in vitro* and *in vivo* results of
377 this study confirmed the effectiveness of a 100% bio-based formulation in the containment of black-
378 grass, a weed with a high resistance to common herbicides.

379 The potential of Brassica derived DSMs in weed control has to be considered with great attention
380 for different reasons: i) the proposed formulations are completely bio-based products that could be
381 considered not only for conventional farming, but even admitted both in integrated pest
382 management and organic farming (where no herbicides are allowed); ii) they present a combined
383 effect both on weeds and on soilborne pests and diseases; iii) formulated *Brassicaceae* DSMs could
384 also represent an interesting integration to fertilizers with their extremely balanced nitrogen content.
385 All these aspects, applied within a virtuous biofumigant cropping system, make the use of DSMs in
386 agriculture an interesting innovative proposal.

508

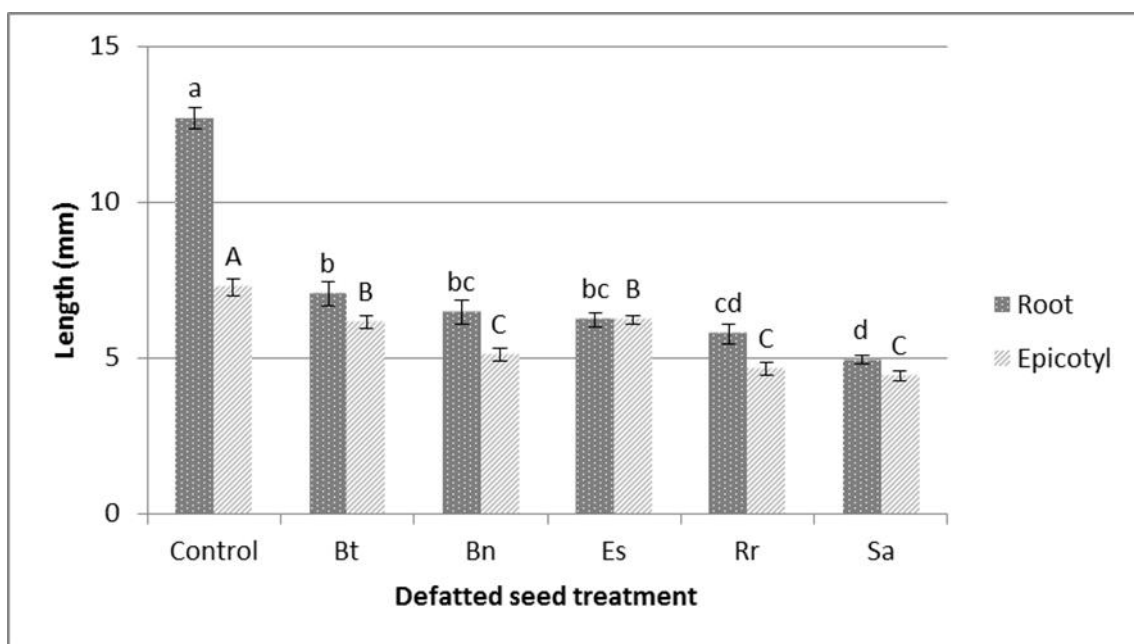

509 Highlights

- 510 • Formulated Brassica defatted seed meals and glycerin reduce black-grass germination.
- 511 • Brassicaceae oilseed cakes could represent an alternative to conventional herbicides.
- 512 • Brassica nigra was the most effective defatted seed meal in germination inhibition.
- 513 • The glucosinolate-myrosinase system could be effectively applied in weed control.

D <i>Rapistrum rugosum</i>	0.0 \pm 0.0	-	-
D <i>Sinapis alba</i>	0.0 \pm 0.0	-	-

569 Abbreviations: Defatted seed meal (DSM); Activated Myrosinase (A); Deactivated Myrosinase (D);
570 GI (germination inhibition); GSL (glucosinolate); ITC (isothiocyanate).

571

572 **Table 4**

573 Interaction between factors and their relevance in black-grass germination and development in the
 574 glasshouse trial.

Factorial ANOVA P value	GI	HRED	DMRED
<i>DSM</i>	<0.001	>0.05	<0.01
<i>DSM concentration</i>	>0.05	<0.05	<0.05
<i>Crude Glycerin</i>	<0.001	<0.001	<0.001
<i>DSM x DSM concentration</i>	<0.001	>0.05	>0.05
<i>DSM x Crude Glycerin</i>	<0.001	<0.05	>0.05
<i>DSM concentration x Crude Glycerin</i>	>0.05	>0.05	>0.05
<i>DSM x DSM concentration x Crude Glycerin</i>	>0.05	>0.05	>0.05

575 Abbreviations: defatted seed meals (DSM); germination inhibition (GI); height reduction (HRED);
 576 dry matter biomass reduction (DMRED).
