

CERVICAL LENGTH IN MIDPREGNANCY AND LABOUR OUTCOME

Dissertation submitted to

The Tamil Nadu Dr. M.G.R Medical University

In partial fulfillment for the award of the Degree of

M.S. OBSTETRICS AND GYNECOLOGY

BRANCH II

**THE TAMIL NADU Dr.M.G.R MEDICAL UNIVERSITY
INSTITUTE OF OBSTETRICS AND GYNAECOLOGY,
GOVT WOMEN AND CHILDREN HOSPITAL,
MADRAS MEDICAL COLLEGE AND
RESEARCH INSTITUTE.**

APRIL - 2017

BONAFIDE CERTIFICATE

This is to certify that this dissertation entitled “**CERVICAL LENGTH IN MIDPREGNANCY AND LABOUR OUTCOME**” is the bonafide work done by **Dr.M.Aruna**, post graduate in the Department of Obstetrics and Gynaecology, Institute of Obstetrics and Gynaecology, Government Women and Children Hospital, Madras Medical College, Chennai, towards partial fulfillment of the requirements of The Tamil Nadu Dr.M.G.R University for the award of M.S Degree in Obstetrics and Gynaecology.

Prof. Dr. S. Usha Rani, MD., DGO., DNB
Professor,
Institute of Obstetrics and Gynaecology,
Govt. Women and Children Hospital,
Madras Medical College,
Chennai – 600 005.

Prof.Dr.S.Baby Vasumathi. MD.,DGO.,
Director and Superintendent
Institute of Obstetrics and Gynaecology,
Govt. Women and Children Hospital,
Madras Medical College,
Chennai – 600 005.

Dr.M.K. Muralidharan, MS., MCH.,
Dean
Madras Medical College,
Chennai- 600 003

DECLARATION

I, Dr. M. Aruna, solemnly declare that the dissertation titled, **“CERVICAL LENGTH IN MIDPREGNANCY AND LABOUR OUTCOME”** has been done by me. I also declare that this bonafide work or part of this work was not submitted by me for any award, degree, diploma to any other university either in India or abroad.

This is submitted to The Tamil Nadu Dr.MGR medical University, Chennai in partial fulfillment of the rules and regulations for the award of M.S Degree (Obstetrics and Gynaecology) held in April 2017.

Place:

Date:

Dr. M. ARUNA

ACKNOWLEDGEMENT

I gratefully acknowledge and sincerely thank **Dr.M.K. Muralidharan, MS., MCH.,** Dean, Madras Medical College and Research Institute, Chennai for allowing me to use the facilities and clinical materials available in the hospital.

My sincere thanks and gratitude to **Dr.S.Baby Vasumathi, M.D., D.G.O.,** Director and Superintendent, Institute of Obstetrics and Gynaecology, for granting me permission to utilize the facilities of the institute for my study.

I am extremely grateful to our Professor, **Dr. S. Usharani, M.D., D.G.O.,DNB.,** Institute of Obstetrics and Gynaecology and Government Women and Children hospital, Egmore, Chennai for her valuable guidance, motivation, and encouragement given during the study.

I thank the former Director of Institute of Obstetrics and Gynaecology, Govt Women and Children hospital, **Dr.Umashanthi, M.D., D.G.O.,** for her valuable guidance.

My sincere thanks to **Dr.N.Mohanram. MDRD.,** for his guidance and valuable suggestions which helped me in this assignment.

My sincere thanks to the Professors and Assistant Professors of the Department of Obstetrics and Gynaecology for their help during this study.

My sincere thanks to **Mr.Padmanaban**, Statistician for helping me in analysing the results of my study.

I am immensely grateful to all the patients who took part in the study.

Introduction

INTRODUCTION

Normal parturition at term is dependent on the programmed development of the cervix early in pregnancy. The cervix undergoes preparative changes weeks before the onset of labour. It is well known that a reduced midtrimester cervical length is associated with an increased risk of spontaneous preterm birth. By extrapolating this, an increased midtrimester cervical length would be associated with an increased risk of prolonged pregnancies, failure of spontaneous onset of labour and caesarean delivery during labour.

The caesarean section rates have risen exponentially all over the world in recent years. The major cause of primary caesarean delivery at term is poor progress in labour. More than 85% of primary caesarean deliveries are performed for three reasons – dystocia, fetal distress and abnormal fetal presentation. A number of factors that lead to poor progress in labour have been identified like increasing maternal age, increased body mass index and prolonged pregnancy. The biological mechanisms that are actually responsible for poor labour progress are yet to be fully understood.

Cervical length has been investigated for its role in predicting preterm labour for over two decades. It is a simple, non-invasive and easily accessible tool and it can be combined with the routine anomaly scans.

Since both preterm labour and prolonged pregnancies as well as caesarean deliveries are associated with increased perinatal mortality and morbidity, their early prediction would be helpful in improving their management and outcome.

Aims and Objectives

AIMS AND OBJECTIVES

AIM:

To study the relationship between cervical length in midpregnancy and labour outcome.

PRIMARY OBJECTIVE:

The objective is to study the relationship between cervical length at midpregnancy and

- 1) Gestational age at delivery
- 2) Onset of labour, whether spontaneous or induced
- 3) Mode of delivery
- 4) Caesarean section due to failed induction

SECONDARY OBJECTIVE:

To determine the mean cervical length in our population.

Overview

OVERVIEW

The word “cervix” is derived from the Latin word ‘cervix uteri’ meaning “neck of the womb”. The cervix is the lower cylindrical portion of the uterus, which enters the vagina and lies at right angles to it. It measures 2 to 4cm in length. Its junction with the uterus is marked by a constriction of the lumen called isthmus. Anteriorly, the cervix is related to the bladder and separated from it by a layer of fatty tissue. Posteriorly, the cervix is covered by peritoneum, which extends to the posterior vaginal wall and then reflects on to the rectum, forming the posterior cul de sac. Laterally the cervix is connected to the parametria and the broad ligament. The cervical canal extends from the internal os, where it joins the uterine cavity, to the external os, which projects into the vagina. Many of these anatomic features are seen on transvaginal ultrasound.

Hegar, in 1895, first described that, at 4-6 weeks gestation, there is a palpable softening of the lower uterine segment and he used this sign to diagnose pregnancy. As early as within one month of conception, there is pronounced softening and cyanosis in the cervix. This could be attributed to the increased vascularity and oedema that occurs in the cervix, along with cervical glandular hypertrophy and hyperplasia (Straach, 2005). The major component of cervix is the connective tissue with a small amount of smooth muscle. This collagen rich connective tissue undergoes rearrangement and

remodelling and this is essential for the diverse functions of the cervix like preservation of a pregnancy to term, dilatation to aid labour, and repair following parturition, so that a successful pregnancy can occur again. Cervical ripening process involves connective tissue remodelling that decreases collagen and proteoglycan concentrations and increases water content compared with nonpregnant cervix. Local estrogen and progesterone metabolism appears to at least partly regulate this process.

There is marked proliferation of the cervical glands and towards the end of pregnancy, nearly half of the entire cervical mass is occupied by the cervical glands. This contrasts with their rather small fraction in the nonpregnant state. Soon after conception, the profuse tenacious mucous that is secreted by the endocervical mucosal cells close the cervical canal. This profuse tenacious secretion is rich in immunoglobulins and cytokines. These molecules may function as an immunological barrier and thus guard the uterine contents from getting infected. The cervical mucus consistency also changes during pregnancy. These changes are essential for the normal onset and progress of labour.

The cervix has a vital role in pregnancy and does multiple key functions that include 1) Functions as a barrier to preserve and protect reproductive tract from infection. 2) Preservation of cervical competence to protect the contents from the increasing gravitational forces.

3) Orchestration of changes in the extracellular matrix that permit the tissue compliance to progressively increase. Thus, for continuing a normal pregnancy to term, maintenance of the normal cervical anatomy and structural integrity is crucial.

The length of the cervix can be also measured by digital examination. The main drawback of the examining finger is its inability to evaluate the supravaginal portion. Initial changes in the cervix may start with dilatation and funnelling at the internal os level. To detect these subtle changes by digital examination is difficult.

ULTRASOUND MEASUREMENT OF CERVICAL LENGTH:

Ultrasound today, is an integral part of the obstetrician's armamentarium and virtually an extension of the examining finger. It was developed by Professor Langevin during the First World War to combat the growing menace of submarines. Sir Ian Donald was the first to demonstrate the application of this technology to medical diagnosis. Ultrasound assessment of the uterine cervix began in the 1970's and the transvaginal probe which was introduced a decade later enriched the accuracy of measurement and its diagnostic value.

In sagittal plane, the cervix appears cylindrical in shape with moderate echogenicity and has a central canal. The anterior and posterior lips of cervix can sometimes be outlined as it protrudes into the vagina,

which is at right angles to it. In the pregnant state, the internal os is identified with the amniotic membrane or presenting part just superior to it. The cervical canal is surrounded by a hyperechoic or hypoechoic zone identified as cervical gland area. This zone is consistently seen until 31 weeks gestation and disappears as pregnancy advances. In transverse view, the cervix is circular, moderately echogenic structure with a central point corresponding to the cervical canal. Lateral to the cervix, branches of uterine artery can be identified using power doppler imaging.

TECHNIQUE

There are 3 ways to view the uterine cervix by sonography namely transabdominal, transvaginal and tranlabial(transperineal)

TRANSABDOMINAL SONOGRAPHY:

The cervical length is measured by identifying an echogenic line that denotes the endocervical canal and extends from the external cervical os to the internal cervical os. The cervix is best visualised when the bladder is full. But an over distended bladder falsely increases the cervical length by compressing the lower uterine segment. In addition, the over distended bladder may create false funnelling. This limitation is overcome by re-evaluation after partial bladder emptying or by using the transvaginal or tranlabial approach. Uterine contractions may cause focal narrowing of the uterine cavity inferior to it, stimulating dilatation of the endocervix or

bulging membranes. This limitation may be overcome by waiting for the contraction to subside or by bladder emptying, which may hasten the disappearance of these focal contractions. Visualisation of the cervix may also be limited by maternal habitus and overshadowing by the presenting part.

Figure 1 : Normal cervix. Transabdominal full-bladder technique.

Figure 2 : Normal cervix. Transabdominal empty bladder technique. Longitudinal midline image of the cervix obtained by scanning through the amniotic fluid. The cervical canal is indicated by calipers.

Despite these limitations, transabdominal sonography introduced the concept of sonographic evaluation of the cervix and paved the way for a more accurate diagnostic method, the transvaginal sonography.

TRANSVAGINAL SONOGRAPHY

Transvaginal sonographic (TVS) assessment of the uterine cervix is the standard reference technique. It is the reference because dimensions and characteristics of the cervix can be accurately determined transvaginally and in nearly all cases, it gives a very clear image of the cervix. It has a high acceptability rate among patients and over 90% of the patients report that, during the procedure there is only minimal uneasiness or embarrassment.

For a transvaginal study, the patient empties her bladder. She is in a supine position with her hips abducted or placed on stirrups with her hips elevated on a cushion or a wedge. A 3.5 to 8 MHz transvaginal transducer covered with a condom is inserted halfway between the introitus and the cervix oriented in a longitudinal plane. Usually, the transducer is inserted only 3 to 4cm into the vagina to avoid contact with the cervix so that the images will have the cervix within the effective focal range of the transducer. Obtaining a true longitudinal view may require some manipulation of the probe because the cervical axis often does not line exactly up with the maternal sagittal axis.

In order to measure the length of the cervix, the internal os and the external os are identified. The internal os is the site where the echogenic cervical canal, the hypoechoic amniotic sac and the presenting parts meet. The external os is the site where the anterior and posterior lips of the cervix meet. In the presence of funnelling or dilatation of the internal os, the residual cervical length is measured.

Figure 3A, Transvaginal scan of normal cervix. Suggested placement of cursors for measuring cervical length.

Figure 3B : Normal cervical glandular area. The cervical canal is seen as an echogenic line (arrow) surrounded by a hypoechoic zone resulting from endocervical glands

It is recommended that one first obtain a satisfactory image of the cervix, then the probe is withdrawn till the image is blurred and then the image is restored by reapplying enough pressure. This repositioning of the transducer avoids the error of falsely elongating the cervix with too much pressure of the probe on the anterior cervix.

In cases where the cervix looks curved, the cervical length must be calculated as the sum of multiple individual measurements rather than a line of best fit.

Prolonged observation for 3 to 5 minutes is recommended because dynamic changes such as dilatation of the internal os or funnelling, followed by shortening of the cervical canal can occur in the course of examination.

To ensure measurement of cervical length is reproducible, the following standardised criteria have been developed.

1. The cervical canal must be visualised along its entire length.
2. The internal cervical os identified must be flat or must have a V-shaped notch.
3. The external cervical os must have be a dimple or an echodense triangular area.
4. The distance between the cervical canal and the surface of the anterior lip must be equal to the distance between the cervical canal and the posterior lip. A difference of width indicates too much pressure on the cervix, which could falsely increase the measurement.

Using these standard criteria, the intraobserver and interobserver variations are as low as 3.5mm and 4.2mm respectively.

The transvaginal technique is far superior to transabdominal technique. Higher frequency transducers and close proximity to the structures allow for better resolution. Transvaginal assessment of cervical

length by three-dimensional ultrasonography has been limited to the development of a normal distribution of cervical length through gestation.

Potential complications of transvaginal technique include increased risk of bleeding in the presence of placenta previa, initiation of preterm labour in women with cervical shortening and chorioamnionitis in the presence of ruptured membranes. Several authors have evaluated these potential risks and found they were not true clinical risks.

TRANSPERINEAL/TRANSLABIAL SONOGRAPHY

Transperineal sonography is done in patients for whom cervix cannot be visualised by transabdominal method or if vaginismus prevents the transvaginal approach. It avoids the potential complications of transvaginal approach and is well tolerated by the patient.

A 3.5 to 5 MHz sector or curvilinear transducer is used. To minimize the risk of infection, the probe is covered with a plastic sheath or condom. With the patient in supine position with the hips abducted, the probe is applied in the sagittal plane between the labia at the vaginal introitus. Partial bladder fullness assists visualisation of the cervix by conveying sound waves towards the cervix and identifies the bladder as a clearly visible landmark.

The vagina courses directly away from the transducer between the bladder and the rectum. The cervical canal is generally oriented at a right angle from the distal vagina. Although the probe is initially situated sagittal on the perineum, rotation of the probe obliquely in a clockwise or counter-clockwise direction may minimize shadows, which obscure the landmarks identifying the internal and external os.

Figure 4 : Transperineal scan of normal cervix. The cervix (calipers) is oriented horizontally, approximately perpendicular to the ultrasound beam. The vagina (V) is oriented in a nearly vertical plane. B, Bladder; R, rectum

Kurtzman et al showed a good correlation between cervical length measurements using transvaginal and transperineal methods. However, transperineal sonography was technically more challenging. The region of the external os may pose difficulty in identification when it is hidden by rectal gas shadows or by the pubic symphysis and the reproducibility of these measurements is poor. These limitations are overcome by elevation of the hips, better application of the transducer on the perineum or changes in the orientation of the probe. Nevertheless, compared with a nearly 100% visualisation using transvaginal sonography, the cervix is adequately visualised in only 90% to 95% of cases with transperineal method.

LABOUR:

The final hours of pregnancy are marked by powerful and painful contractions of the uterus that are essential to cause effective cervical dilatation and effect descent of the fetus through the birth canal. The World Health Organisation defines normal labour as “spontaneous in onset, low risk from the start and remaining so throughout labour and delivery and the infant is born spontaneously in vertex position between 37 and 42 completed weeks of pregnancy, and the mother and infant are in good condition after birth”.

Both the cervix and the uterus undergo extensive preparations long before the onset of this process. In the initial 38 to 40 weeks of a normal

pregnancy, the myometrium of the uterus is in a preparatory process yet it maintains an unresponsive state. Concomitantly, the uterine cervix starts the early stage of remodelling named softening, but still the structural integrity of the cervix is maintained. This long quiescent phase is followed by a transitory phase when there is suspension of the myometrial unresponsiveness and there occurs progressive effacement and changes in the structural integrity of the cervix.

Onset of labour and human parturition are regulated by multiple physiological and biochemical processes, yet the exact mechanisms are not fully known and continue to be defined. A sequence of multiple biochemical changes in the uterus and cervix culminate in labour onset. These biochemical changes are the result of endocrine and paracrine signalling originating from both the mother and the fetus. There are interspecies differences in these biological processes and these differences cause difficulty in elucidation of the exact factors that are involved in regulation of human labour. When there is an abnormality in onset or progress of labour, then preterm labour, dystocia or postterm pregnancy would result. These remain some of the key contributors of neonatal mortality and morbidity.

Review of Literature

REVIEW OF LITERATURE

It is well known that the cervical length influences labor outcome. The most common cause of primary cesarean section at term is poor progression of labor (dystocia). It is well recognised that short cervix is associated with preterm labour. By extrapolating this fact, a few researchers have shown that increase in cervical length is associated with an increase in the risk of lengthened induction to delivery interval and poor progress of labour. Increased cervical length at mid trimester is also an independent predictor of cesarean delivery risk in primiparous women. ⁽¹⁻⁴⁾.

A study by Gordon Smith et al ⁽¹⁾ showed that the rate of caesarean delivery increased with increasing cervical length. 27,472 primigravid women were included in the study. These women had a mean cervical length of 16 mm or more. The cervical length was measured at a median gestational age of 23 weeks. They eventually delivered a live baby at term. They found that the cesarean section rate at term was lowest (16.0%) when the midtrimester cervical length was in the lowest quartile (16 to 30 mm) and the cesarean section rate substantially increased to 18.4% when the cervical length was in the second quartile (31 to 35 mm), 21.7% in third quartile (36 to 39 mm), and 25.7% fourth quartile (40 to 67 mm) (P value <0.001). The odds ratio was 1.81 (95% confidence interval [CI], 1.66 to

1.97). It was calculated by comparing the cesarean section rate of women with cervical length in the fourth quartile with the cesarean section rate of women with cervical length in the first quartile. This odds ratio which was calculated after adjusting for confounding factors like age, BMI, smoking, race or ethnicity, duration of pregnancy, spontaneous or induced labour, birth-weight percentile, and place of delivery was 1.68 (95% Confidence Interval is 1.53 to 1.84; P value <0.001). It was found that procedures performed for poor progress in labour was mainly responsible for the increased risk of cesarean delivery.

A study by Kalu CA⁽²⁾ et al showed that increased cervical length in mid-pregnancy predicts the possibility of caesarean delivery early in pregnancy. They examined 281 primiparous women who had a gestational age of around 22 weeks from the last menstrual period. The cervical length was measured by transvaginal sonography. They were followed upto term. The cervical length was compared with their mode of delivery and was analysed for any association. It was found that 11.7% of patients had a cesarean section at term due to poor progress in labour. The women who had cervical length in the highest quartile (40–67 mm) had a cesarean section rate of about 50% (P value 0.0018 for the trend). 33 women in the study had poor progress in labour and went in for cesarean delivery. Of the 33, 18 women (54.5%) had a midtrimester cervical length that was greater

than 4cm. The likelihood ratio for cesarean delivery at term in view of failed labour progress was 10.28 (P value 0.0013) in women who had their cervical length in the upper quartile. They concluded that cervical length could be of great use in predicting mode of delivery at an early gestational age.

A study by Glovenco T et al ⁽³⁾ showed that an increased cervical length at midtrimester scan is associated with increase in the caesarean section rate. However, it was found that there was no statistically significant association between midtrimester cervical length and mode of delivery, induction of labour or prolonged pregnancy.

A retrospective study was conducted with 1384 women who were admitted in Toowoomba hospital from the 1st of April 2011 to the 31st of December 2012. They measured the transvaginal cervical length at 18 weeks pregnancy. The patients were followed upto delivery and their mode of delivery was analysed for any association. At midtrimester, women who had a caesarean section had a mean cervical length of 3.87 and those who had a vaginal delivery had a mean cervical length of 3.74. They found that this association was statistically significant and had a P-value of <0.001. In women who had spontaneous onset of labour, the mean cervical length at midpregnancy was 3.77 and for those who did not have spontaneous labour onset, the mean cervical length was 3.78. They found that this association

was not statistically significant (P-value: 0.873}. The mean length of the cervix in women who had prolonged labour was 3.78 and did not have prolonged labour was 3.77. This association was not found to be statistically significant and had a p-value of 0.931. The mean length of the cervix in women who had postterm pregnancy was 3.78 and did not have postterm pregnancy was 3.74. This association was not found to be statistically significant with a P-value of 0.361. They concluded that length of the cervix measured by transvaginal sonography at midtrimester scan is an independent predictor of the risk of caesarean delivery at term. However there was no statistically significant association between cervical length at mid trimester and induction of labour or prolonged pregnancy.

E. Jung et al⁽⁴⁾ showed that increase in the length of cervix at midtrimester was significantly related to an increased risk of failure of labour induction.

It was retrospective cohort study. 518 women who had a singleton pregnancy were included in the study. These women had a transvaginal cervical length measurement around 19 and 24 weeks of pregnancy. These women had then undergone induction of labour at or later than 33 completed weeks. Cervical length was measured by transvaginal ultrasound both at mid-pregnancy and also around the time of labour induction.

Primary outcome was failed labour induction. All known confounding factors causing failed induction of labour were taken into account in the analysis. The study found that induction of labour failed in 23.9% of pregnancies. It was found that women who had longer cervical lengths at mid-pregnancy had a significantly higher rate of failed induction. It was also found that primigravida and those who had a higher BMI, and an earlier gestational age at induction had an increased chance of failed labour induction.

They did a multivariate analysis which showed that increasing midtrimester cervical length at mid-trimester was significantly associated with failed labour induction after adjusting for confounding factors like BMI, gestational age and nulliparity. When Receiver Operator Characteristic curve was drawn, it was seen that the area under curve for the cervical length at induction of labour was significantly greater than that drawn for the cervical length measured at mid-pregnancy.

A study by Mamta Rath Datta et al⁽⁵⁾ found that measurement of transvaginal cervical length at mid pregnancy could be used to determine the risk of primary cesarean section, failure of spontaneous onset of labour and the risk of failed labour induction.

It was a prospective study conducted in the Obstetrics Department of Tata Main Hospital .100 antenatal women who had attended out-patient department, from 1st December 2011 to 1st December 2012 were included in the study. Transvaginal ultrasonography was performed between 18 and 26 weeks. Cervical length was measured and recorded. The patients were followed upto term and their labour details were recorded. The duration of pregnancy, mode of labour onset, either spontaneous or induced, duration of labour and mode of delivery whether vaginal or caesarean and the cause for caesarean delivery were recorded.

They found that there was an increase in the cesarean section rate when the cervical length ≥ 4 cm (P value : <0.0001). About 57.1% of cesarean deliveries occurred when the cervix length was >4 cm. They found that those who had spontaneous labor onset had a mean cervical length of 3.11 ± 0.85 cm and those who had need for induced labor had a mean cervical length of 4.36 ± 1.11 cm (P value ≤ 0.001).

They performed a multivariate analysis to analyse the outcome variable of caesarean or vaginal delivery. They found that the length of cervix measured at midtrimester and the induction to delivery interval are independent predictors of the mode of delivery. By using the receiver operating characteristic (ROC) curve analysis, cervical length more than 4cm was considered as the optimum cut-off criterion for the prediction of

primary cesarean section. When cervical length was used as predictor of the mode of delivery, it was found that sensitivity was 54.8%, specificity was 91.4%, positive predictive value was 82.1% and negative predictive value was 73.6%.

N. S. Fox et al ⁽⁷⁾ studied the cervical length in twin pregnancies. They found a significant association between increased transvaginal cervical length at 30-32 weeks and the chance of caesarean section in labour at term. When the analysis was done adjusting for confounding factors like age, race, parity, chorionicity, assisted reproduction and induced labour, the length of cervix measured transvaginally at 30-32 weeks was an independent predictor of caesarean section.

A study by A. J. Van der Ven et al⁽⁹⁾ found that increased cervical length at midpregnancy was associated with a significantly increased chance of both prolonged pregnancy and emergency caesarean delivery. They did a multicentre cohort study involving 5321 nulliparous women. They measured cervical length by transvaginal ultrasonography between 16 and 22 weeks of gestation. From this cohort, only women who delivered after 34 weeks were included. The cervical length measured was divided into quartiles. The probability of emergency caesarean section increased with increasing quartiles of cervical length from 9.4% in the first quartile to 14.9% in the fourth quartile ($P=0.01$). This association was seen only when caesarean

section was taken up for failed induction and not when done for fetal distress.

A meta-analysis by Hatfield AS et al, based on 19 trials in 3061 women found that a short cervical length predicts preterm labour and an increased cervical length is associated with failed labour induction. It had a positive likelihood ratio of 1.66(95% Confidence Interval 1.20-2.31) and a negative likelihood ratio of 1.51(95% Confidence Interval 0.39-0.67).

A study by Datta MR et al⁽⁶⁾ found that in nulliparous women, a longer cervical length in midtrimester was associated with greater chance of prolonged pregnancy. It was a prospective cohort study. 9165 women with a singleton pregnancy were included in the study. Transvaginal cervical length was measured in these women at around 18 and 24 weeks. The women were then divided into groups based on the quartiles of cervical length measured. The association of cervical length with postterm pregnancy was analysed by bivariate and multivariate analysis. They concluded that women with increasing quartiles of cervical length had a significantly greater risk of having a postterm pregnancy.

A meta analysis by Verhoeven CJ et al⁽¹⁰⁾ found that transvaginal ultrasonographic measurement of cervical length at term or near term when

done before induction of labour can be used to predict the outcome of labour.

Numerous studies have shown correlation between midtrimester cervical length and preterm labour. A systematic review by Crane JM (11) et al found that transvaginal ultrasonographic measurement of cervical length in asymptomatic high-risk women can be used to predict spontaneous preterm birth before 35 weeks. They studied fourteen articles involving 2258 women who met the criteria of the systematic review. When they used a smaller cut-off of cervical length, there was a higher positive likelihood ratio (LR). Cervical length < 25 mm was the most commonly used cut-off. When this value was used to predict preterm birth before 35 weeks, it had a positive likelihood ratio (LR+) of 4.31 (95% Confidence Interval, 3.08-6.01); when measured at 20-24 weeks, it had an LR+ = 2.78 (95% Confidence Interval, 2.22-3.49); and when measured at > 24 weeks, LR+ = 4.01 (95% Confidence Interval, 2.53-6.34). Thus, they concluded that cervical length measured by transvaginal ultrasonography predicts spontaneous preterm birth.

Another systematic review by Honest H et al ⁽¹²⁾ studied the accuracy with which transvaginal cervical sonography predicts spontaneous preterm birth. They studied 46 primary articles. This involved around 31,577 antenatal women, from 33 studies involving asymptomatic and 13 studies

involving symptomatic women. This systematic review concluded that it is possible to predict spontaneous preterm birth by using transvaginal sonographic cervical length measurement. But, there was marked variation between studies with regard to gestational age at which cervical length was measured, what was the cervical length cut-off taken and when it was labelled as preterm labour. Testing was most commonly done in asymptomatic women before 20 weeks gestation, using cervical length cut off of 25 mm and spontaneous preterm birth defined as that occurring before 34 completed weeks.

The Likelihood Ratio for this entire group was 6.29 (95% Confidence Interval, 3.29-12.02). Thus, they concluded that it is possible to predict spontaneous preterm birth in asymptomatic women by using cervical length measurement and funneling, either alone or in combination and it must be performed in all high risk antenatal women.

Materials and Methods

MATERIALS AND METHODS

It is a prospective study conducted in Institute of Obstetrics and Gynaecology, Egmore, Chennai. Informed written consent was obtained from all antenatal women who had participated in this study.

Subject Selection:

Subjects were selected from the antenatal clinic, Institute of Obstetrics and Gynaecology.

Duration of the study: 1 year 6 months

Inclusion Criteria:

- 1) Asymptomatic primigravida with singleton pregnancies between 19-24 weeks attending the antenatal clinic.
- 2) No medical disorders
- 3) No factors predisposing to preterm labour like previous preterm labour, surgery on cervix, pre eclampsia

Exclusion Criteria:

1. Women unsure of dates
2. Multiple pregnancy
3. Women with previous history of caesarean section
4. Polyhydramnios

5. Women with Haemoglobin <8g%
6. Women with suspected foetal abnormalities
7. Extremely short statured women
8. Women with skeletal abnormalities
9. Smokers

Assessment of parameters:

- i) Clinical variables – Patient details like age, socio economic status, maternal weight, height, body mass index, gravidity , parity, any history of abortion, and medical complications were recorded
- ii) Cervical length at 20 – 24 weeks
- iii) Labour outcome

Screening Procedures/ Visits

I) Determination of cervical length:

This was done between 19 to 24 weeks. The gestational age was calculated from the Last Menstrual Period(LMP) and confirmed by the first trimester ultrasound measurement of fetal crown rump length. Cervical length was measured by transvaginal ultrasound.

The women were examined with an empty bladder in dorsal position. The internal os, external os, cervical canal and endocervical mucosa were

identified. The endocervical mucosa was used to define the site of the internal os. The image was magnified. The distance between the internal and external os was measured.

Three measurements were taken over a period of 3 minutes to observe any dynamic changes in the cervix and the mean of these three measurements was considered. The presence of funneling and diameter of internal os was noted.

II) Follow up procedure:

The women were followed upto term. They were subsequently managed according to hospital protocol. Data on labour outcome including the gestational age at delivery, mode of onset of labour whether spontaneous or induced, mode of delivery and indication for cesarean section were recorded.

Preterm labour is defined by ACOG as the onset of regular, painful, frequent, uterine contractions causing progressive effacement and dilation of cervix occurring before 37 completed weeks of gestation from the period of viability.

Postterm pregnancy is defined by ACOG as pregnancies longer than 42 completed weeks or longer than 294 days from the first day of last

menstrual period. Prolonged pregnancy is taken in our study as longer than 40 completed weeks or 280 days from the first day of last menstrual period.

Poor progress in labour is defined as failure of cervical dilatation to progress at 1cm per hour during active phase labour in the presence of adequate uterine contractions (even after augmentation with oxytocin) in the absence of cephalo pelvic disproportion. Failed induction is defined as failure of onset of active phase of labour after one cycle of treatment (one dose of Prostaglandin tablets or gel followed by a second dose after 6 hours if labour is not established up to a maximum of two doses)

Analysis of Results

ANALYSIS OF RESULTS

In this study, 500 antenatal women were enrolled and cervical length was measured at 19-24 weeks. The patients were followed up to delivery and their outcome was analysed

Sample size : 500

| Table 1 : MEAN CERVICAL LENGTH IN THE STUDY POPULATION | | | | |
|---|-----|-------|----------------|-----------------|
| | N | Mean | Std. Deviation | Std. Error Mean |
| CERVIX LENGTH AT 19 TO 24 WEEKS | 500 | 3.632 | .4703 | .0210 |

The mean cervical length in our study population of 500 antenatal women was 3.632 with a standard deviation of 0.4703.

Table 2 : PRETERM LABOUR

| PRETERM | Frequency | Percent | Valid Percent | Cumulative Percent |
|----------------|------------------|----------------|----------------------|---------------------------|
| NO | 470 | 94.0 | 94.0 | 94.0 |
| YES | 30 | 6.0 | 6.0 | 100.0 |
| Total | 500 | 100.0 | 100.0 | |

Of the 500 women in the study, 30(6%) went in for preterm labour.

Table 3 : PROLONGED PREGNANCY

| PROLONGED PREGNANCY | Frequency | Percent | Valid Percent | Cumulative Percent |
|----------------------------|------------------|----------------|----------------------|---------------------------|
| NO | 396 | 79.2 | 79.2 | 79.2 |
| YES | 104 | 20.8 | 20.8 | 100.0 |
| Total | 500 | 100.0 | 100.0 | |

Of the 500 women in the study, 104 (20.8%) had prolonged pregnancy. The rest of the patients delivered before their Expected Date of Delivery.

Table 4 : ONSET OF LABOUR

| ONSET OF LABOUR | Frequency | Percent | Valid Percent | Cumulative Percent |
|------------------------|------------------|----------------|----------------------|---------------------------|
| SPONTANEOUS | 346 | 69.2 | 69.2 | 69.2 |
| INDUCED | 154 | 30.8 | 30.8 | 100.0 |
| Total | 500 | 100.0 | 100.0 | |

Of the 500 women in the study, 346 (69.2%) had spontaneous onset of labour. In the rest, labour was induced due to a varied indications.

Table 5 : MODE OF DELIVERY

| MODE OF DELIVERY | Frequency | Percent | Valid Percent | Cumulative Percent |
|-------------------------|------------------|----------------|----------------------|---------------------------|
| VAGINAL | 225 | 45.0 | 45.0 | 45.0 |
| CESAREAN | 275 | 55.0 | 55.0 | 100.0 |
| Total | 500 | 100.0 | 100.0 | |

Of the 500 women in the study, 225(45%) had vaginal delivery including operative vaginal delivery, 275 (55%) had caesarean delivery.

Table 6 : CESAREAN SECTION DUE TO FAILED INDUCTION

| Cesarean section due to failed induction | Frequency | Percent | Valid Percent | Cumulative Percent |
|---|------------------|----------------|----------------------|---------------------------|
| NO | 393 | 78.6 | 78.6 | 78.6 |
| YES | 107 | 21.4 | 21.4 | 100.0 |
| Total | 500 | 100.0 | 100.0 | |

Of the 500 women in the study, 107 (21.4%) had caesarean section due to failed induction. The rest of the women had either vaginal delivery or caesarean delivery for other indications.

RECEIVER OPERATOR CHARACTERISTIC CURVE

The mean cervical length for patients who had caesarean delivery is 3.772. The mean cervical length for patients who did not have caesarean delivery is 3.461. There exists a statistically significant association between the cervical length and caesarean delivery. By using Receiver Operator Characteristic curve, cervical length >3.4 predicts caesarean delivery with a sensitivity of 73.5% and specificity of 53.8%.

The probability of caesarean section due to failed induction increases 4 fold with 1cm increase in cervical length and increases twice when the pregnancy is prolonged.

Discussion

DISCUSSION

This study analysed the cervical length of 500 antenatal women by transvaginal ultrasonography between 19 to 24 weeks and its association with labour outcome.

The maternal characteristics like age, body mass index and socioeconomic status were analysed for any confounding factors. Labour outcome analysed were the onset of labour whether spontaneous or induced, gestational age at delivery whether preterm or prolonged beyond 40 weeks, mode of delivery and the caesarean section due to failed induction.

MEAN CERVICAL LENGTH IN THE POPULATION:

The mean cervical length in our study population was 3.632 with a standard deviation of 0.4703. (Table 1)

MATERNAL AGE AND LABOUR OUTCOME:

The mean age in our study population was 24.364 with 4.2%(21) below 19 years, 50%(250) at 20-24 years, 36.2% (181) at 25-29 years and 9.6% (48) at more than 30 years. It was found that there was no statistically significant association between maternal age and labour outcome.

MATERNAL BODY MASS INDEX (BMI) AND LABOUR

OUTCOME:

The mean body mass index in our study population was 22.013. BMI less than 22.99 was seen in 66.8% (334), 23-27.99 in 31.6% (158) and more than 28 in 1.6% (8). It was found that there was no statistically significant association between maternal body mass index and labour outcome.

MATERNAL SOCIOECONOMIC STATUS AND LABOUR

OUTCOME:

Socio economic status was analysed by modified Kuppusamy's classification. 8%(40) were in socioeconomic class III, 52.6%(263) in class IV and 39.4%(197) in class V. It was found that there was no statistically significant association between maternal socioeconomic status and labour outcome.

CERVICAL LENGTH IN MIDPREGNANCY AND PRETERM

LABOUR:

Of the 500 women in the study, 30(6%) went in for preterm labour (Table 2). There exists a statistically significant association between the cervical length and preterm labour with a P value <0.001. Lower the cervical length, higher is the risk of preterm labour.

The mean cervical length for patients who went into preterm labour is 3.263. The mean cervical length for patients who did not go into preterm

labour is 3.655 (Table 31). Area under Receiver Operator Characteristic curve is 0.740071. Cervical length <3.2cm predicts preterm labour with a sensitivity of 56.7% and specificity of 78.9%.

CERVICAL LENGTH IN MIDPREGNANCY AND PROLONGED PREGNANCY:

Of the 500 women in the study, 104 (20.8%) had prolonged pregnancy beyond 40 weeks. There exists a statistically significant association between the cervical length and prolonged pregnancy with P value <0.0001.

The mean cervical length for patients who had prolonged pregnancy is 3.836. The mean cervical length for patients who did not have prolonged pregnancy is 3.578 (Table 32). Area under Receiver Operator Characteristic curve is 0.634336. Cervical length >3.9 (optimum cut-off) predicts prolonged pregnancy with a sensitivity of 42.3% and specificity of 80.1% whereas the specificity increases to 90% at a cervical length of >4.08cm and 97% at a cervical length of >4.5cm.

This is similar to the study conducted in Towoomba hospital where the mean cervical length for patients who had prolonged pregnancy is 3.78cm whereas those who delivered before dates had a mean cervical length of 3.77cm.

CERVICAL LENGTH IN MIDPREGNANCY AND ONSET OF LABOUR:

Of the 500 women in the study, 346 (69.2%) had spontaneous onset of labour (Table 4). There exists a statistically significant association between the cervical length and onset of labour. Increasing cervical length is associated with a failure of spontaneous onset of labour. Cervical length >4cm is associated with 88.7%, >4.5cm with 97.1% and >5cm with 99.4% failure of spontaneous onset of labour.

The mean cervical length for patients who had spontaneous onset of labour is 3.549. The mean cervical length for patients who did not have spontaneous onset of labour is 3.817 (Table 33). Area under ROC curve is 0.668. Cervical length >3.7cm (optimum cut-off) predicts failure of spontaneous onset of labour with a sensitivity of 57.1% and specificity of 68.8%. This is similar to studies conducted in Towoomba Hospital and Tata Hospital.

| STUDY | ONSET OF LABOUR | |
|-------------------|-----------------|---------|
| | SPONTANEOUS | INDUCED |
| OUR STUDY | 3.549cm | 3.817cm |
| TOWOOMBA HOSPITAL | 3.77cm | 3.78cm |
| TATA HOSPITAL | 3.11cm | 4.36cm |

CERVICAL LENGTH IN MIDPREGNANCY AND MODE OF DELIVERY:

Of the 500 women in the study, 275 (55%) had caesarean delivery (Table 5). There exists a statistically significant association between the cervical length and caesarean delivery. Increasing cervical length is associated with increase in incidence of caesarean delivery. Cervical length >4cm predicts caesarean delivery with a specificity of 94.22% and >4.8cm predicts caesarean delivery with a specificity of 100%

The mean cervical length for patients who had caesarean delivery is 3.772. The mean cervical length for patients who did not have caesarean delivery is 3.461 (Table 34). Area under ROC curve is 0.683. Cervical length >3.4cm (optimum cut off) predicts caesarean delivery with a sensitivity of 73.5% and specificity of 53.8%. This is similar to the studies conducted in Towoomba Hospital and Tata Hospital.

| STUDY | MEAN CERVICAL LENGTH | |
|-------------------|----------------------|-------------------|
| | VAGINAL DELIVERY | CESAREAN DELIVERY |
| OUR STUDY | 3.461 | 3.772 |
| TOWOOMBA HOSPITAL | 3.74cm | 3.87cm |
| TATA HOSPITAL | 3.5cm | 4cm |

Multivariate analysis of mode of delivery with BMI, cervical length, gestational age at delivery, prolonged pregnancy, onset of labour was done. It was found that mode of delivery is not influenced by body mass index and gestational age at delivery. The probability of caesarean delivery increases 4 times with 1cm increase in cervical length ($P<0.0001$) and the probability increases twice when the labour is induced ($P=0.0027$) (Table 35).

CERVICAL LENGTH IN MIDPREGNANCY AND CESAREAN SECTION DUE TO FAILED INDUCTION:

Of the 500 women in the study, 107 (21.4%) had caesarean section due to failed induction (Table 6). Increasing cervical length is associated with statistically significant increase in the incidence of caesarean section. This association is more specific when the caesarean section is taken up for failed induction. The specificity increases from 88.5% when cervical length is $>4\text{cm}$ to 97.46% at cervical length $>4.5\text{cm}$ to 99.49% when the cervical length is $>5\text{cm}$.

The mean cervical length for patients who had caesarean delivery due to failed induction is 3.897. The mean cervical length for patients who did not have caesarean delivery due to failed induction is 3.559. Area under ROC curve is 0.702. Cervical length >3.7 predicts caesarean delivery due to failed induction with a sensitivity of 64.5% and specificity of 67.7%.

Multivariate analysis was done between caesarean section due to failed induction and cervical length and prolonged pregnancy. The probability of caesarean section due to failed induction increases 4 fold with 1cm increase in cervical length ($P<0.0001$) and increases 2 fold when the pregnancy is prolonged ($P=0.003$) (Table 37).

Another study conducted by Gordon Smith et al showed 1.8 fold increase in the risk of cesarean section when the cervical length was greater than 4cm.

Summary

SUMMARY

It is a prospective study conducted in the Institute of Obstetrics and Gynecology, Madras medical college from January 2015 to March 2016. 500 antenatal women were included in the study. Transvaginal ultrasound was done between 19-24 weeks and cervical length was recorded. The women were subsequently managed according to the hospital protocol. The women were followed upto term and their labour outcome was recorded.

It was found that age, body mass index and socioeconomic status did not influence the duration of pregnancy, onset of labour or mode of delivery.

Preterm labour is significantly associated with cervical length. Lower the cervical length, higher is the risk of preterm labour.

The risk of prolonged pregnancy increases significantly with increase in cervical length and the risk is greater when the cervical length is more than 3.9cm.

The chances of failure of spontaneous onset of labour increases significantly with increase in cervical length and the risk is greater when the cervical length is more than 3.7cm.

The risk of caesarean delivery increases significantly with increase in cervical length. This association is more specific when the caesarean section is taken up for failed induction and the risk is greater when the cervical length is more than 3.7cm. Increase in cervical length by 1cm is associated with a fourfold increase in the incidence of caesarean delivery.

Conclusion

CONCLUSION

Measurement of cervical length by transvaginal ultrasound at mid trimester can be used as an easy predictive tool to determine the possible outcome of labour and risk of caesarean section. As ultrasound machines are widely available in almost every antenatal clinic, it could be easily implemented in clinical practice. The patients with risk of adverse labour outcome could be referred earlier to higher centres equipped to handle them.

CERTIFICATE OF APPROVAL

To
Dr.Aruna M
Postgraduate M.S.(Obstetrics and Gynaecology)
Madras Medical College
Chennai 600 003

Dear Dr.Aruna M,

The Institutional Ethics Committee has considered your request and approved your study titled **“Cervical length in mid pregnancy and labour outcome” No.38012015.**

The following members of Ethics Committee were present in the meeting held on 20.01.2015 conducted at Madras Medical College, Chennai-3.

- | | |
|---|----------------------|
| 1. Dr.C.Rajendran, M.D., | : Chairperson |
| 2. Dr.R.Vimala, M.D., Dean, MMC, Ch-3 | : Deputy Chairperson |
| 3. Dr.B.Kalaiselvi, M.D., Vice-Principal, MMC, Ch-3 | : Member Secretary |
| 4. Dr.R.Nandini, M.D., Inst.of Pharmacology, MMC | : Member |
| 5. Dr.P.Ragumani, M.S., Professor, Inst.of Surgery, MMC | : Member |
| 6. Dr.Md.Ali, M.D., D.M., Prof. & HOD of Medl.G.E., MMC | : Member |
| 7. Dr.K.Ramadevi, Director, Inst.of Biochemistry, MMC | : Member |
| 8. Dr.Saraswathy, M.D., Director, Pathology, MMC, Ch-3 | : Member |
| 9. Thiru S.Rameshkumar | : Lay Person |
| 10.Thiru S.Govindasamy, B.A., B.L., | : Lawyer |
| 11.Tmt.Arnold Saulina, M.A., MSW., | : Social Scientist |

We approve the proposal to be conducted in its presented form.

The Institutional Ethics Committee expects to be informed about the progress of the study and SAE occurring in the course of the study, any changes in the protocol and patients information/informed consent and asks to be provided a copy of the final report.

MEMBER SECRETARY
INSTITUTIONAL ETHICS COMMITTEE
MADRAS MEDICAL COLLEGE
13/2/15

INFORMATION TO PARTICIPANTS

Title : CERVICAL LENGTH IN MIDPREGNANCY AND LABOUR OUTCOME

Principal Investigator : Dr.M.Aruna

Name of Participant :

Site : INSTITUTE OF OBSTETRICS AND GYNAECOLOGY,
EGMORE, CHENNAI.

You are invited to take part in this study. The information in this document is meant to help you decide whether or not to take part. Please feel free to ask if you have any queries or concerns.

What is the purpose of research?

The objective is to determine the relationship between cervical length in midpregnancy and

- 1) Gestational age at delivery
- 2) Onset of labour, whether spontaneous or induced
- 3) Mode of delivery
- 4) Cesarean section due to failed induction

We have obtained permission from the Institutional Ethics Committee.

The study design

All participating pregnant women will undergo transvaginal ultrasonography between 19 – 24 weeks.

Study Procedures

The study involves evaluation of cervical length by transvaginal ultrasonography between 19 – 24 weeks. You will subsequently be managed according to the hospital protocol. Your mode of delivery and labour outcome will be recorded.

Possible benefits to other people

The results of the research may provide benefits to the society in terms of advancement of medical knowledge and/or therapeutic benefit to future patients.

Confidentiality of the information obtained from you

You have the right to confidentiality regarding the privacy of your medical information (personal details, results of physical examinations, investigations, and your medical history). By signing this document, you will be allowing the research team investigators, other study personnel, sponsors, Institutional Ethics Committee and any person or agency required by law like the Drug Controller General of India to view your data, if required.

The information from this study, if published in scientific journals or presented at scientific meetings, will not reveal your identity.

How will your decision to not participate in the study affect you?

Your decision not to participate in this research study will not affect your medical care or your relationship with the investigator or the institution. You will be taken care of and you will not lose any benefits to which you are entitled.

Can you decide to stop participating in the study once you start?

The participation in this research is purely voluntary and you have the right to withdraw from this study at any time during the course of the study without giving any reasons. However, it is advisable that you talk to the research team prior to stopping the treatment/discontinuing of procedures etc.

Name of the Investigator : **Dr.M.Aruna**
Name of the Participant :
Name of the Institution : **INSTITUTE OF OBSTETRICS AND GYNAECOLOGY,
EGMORE, CHENNAI**

I _____ have read the information in this form (or it has been read to me). I was free to ask any questions and they have been answered. I am over 18 years of age and, exercising my free power of choice, hereby give my consent to be included as a participant in this study.

1. I have read and understood this consent form and the information provided to me.
2. I have had the consent document explained to me.
3. I have been explained about the nature of the study.
4. I have been explained about my rights and responsibilities by the investigator.
5. I have informed the investigator of all the treatments I am taking or have taken in the past months/years including any native (alternative) treatments.
6. I have been advised about the risks associated with my participation in the study.*
7. I agree to cooperate with the investigator and I will inform him /her immediately if I suffer unusual symptoms. *
8. I have not participated in any research study within the past. *
9. I am aware of the fact that I can opt out of the study at any time without having to give any reasoned this will not affect my future treatment in this hospital. *
10. I am also aware that the investigators may terminate my participation in the study at any time, for any reason, without my consent. *
11. I hereby give permission to the investigators to release the information obtained from me as result of participation in this study to the sponsors, regulatory authorities, Govt. agencies, and IEC if required.
12. I understand that my identity will be kept confidential if my data are publicly presented.
13. I have had my questions answered to my satisfaction.
14. I consent voluntarily to participate in the research/study.

I am aware that if I have any question during this study, I should contact the investigator. By signing this consent form, I attest that the information given in this document has been clearly explained to me and understood by me. I will be given a copy of this consent document.

For adult participants

1. Name and signature / thumb impression of the participant (or legal representative if participant incompetent)

Name _____ Signature _____ Date _____

2. Name and Signature of impartial witness (required for illiterate patients):

Name _____ Signature _____ Date _____

Address and contact number of the impartial witness:

3. Name and Signature of the investigator or his representative obtaining consent:

Name _____ Signature _____ Date _____

INTRODUCTION

⁴⁰ Normal parturition at term is dependent on the programmed development of the cervix early in pregnancy. The cervix undergoes preparative changes weeks before the onset of labour. It is well known that a reduced midtrimester cervical length ⁴ is associated with an increased risk of spontaneous preterm birth. By extrapolating this, an increased midtrimester cervical length would ⁸ be associated with an increased risk of prolonged pregnancies, failure of spontaneous onset of labour and caesarean delivery during labour.

The caesarean section rates have risen exponentially all over the world in recent years. The ⁴ major cause of primary caesarean delivery at term is poor progress in labour. More than 85% of primary caesarean deliveries are performed for three reasons - dystocia, fetal distress and abnormal fetal presentation. A number of factors that lead to poor progress in labour have been identified like increasing maternal age, increased body mass index and prolonged pregnancy. The biological mechanisms that are

INTRODUCTION

Normal parturition at term is dependent on the programmed development of the cervix early in pregnancy. The cervix undergoes preparative changes weeks before the onset of labour. It is well known that a reduced midtrimester cervical length is associated with an increased risk of spontaneous preterm birth. By extrapolating this, an increased midtrimester cervical length would be associated with an increased risk of prolonged pregnancies, failure of spontaneous onset of labour and caesarean delivery during labour.

The caesarean section rates have risen exponentially all over the world in recent years. The major cause of primary caesarean delivery at term is poor progress in labour. More than 85% of primary caesarean deliveries are performed for three reasons – dystocia, fetal distress and abnormal fetal presentation. A number of factors that lead to poor progress in labour have been identified like increasing maternal age, increased body mass index and prolonged pregnancy. The biological mechanisms that are actually responsible for poor labour progress are yet to be fully understood.
