Synthesis of Fluorinated Fused Benzofurans and Benzothiophenes: Smiles-type Rearrangement and Cyclisation of Perfluoro(het)aryl Ethers and Sulfides

Julia Ponce González, Mark Edgar, Mark R.J. Elsegood and George W. Weaver Department of Chemistry, Loughborough University, Loughborough, LE11 3TU UK

Abstract

Lithium-bromine exchange in 2-bromophenyl perfluoroaryl ethers or sulfides affords fused fluorinated benzofurans or benzothiophenes respectively by S_NAr substitution of the adjacent fluorine in the perfluoroaryl substituent. The structures of the new compounds were confirmed by NMR spectroscopy and single crystal X-ray diffraction analysis. In the case of 2-bromophenyl tetrafluoropyrid-4-yl ether, lithiation promoted a Smiles-type rearrangement which led to formation of 4-(2-hydroxyphenyl)tetrafluoropyridine, the structure of which confirmed by X-ray crystallography.

Aromatic nucleophilic substitution in per- and poly-fluorinated arenes^{1,2} is a valuable method for constructing highly functionalised heterocycles and aromatics.³ Such compounds have been widely investigated by Chambers⁴ and Sandford⁵ and have been used as scaffolds for drug discovery.⁶ The mechanistic and synthetic potential of fluorinated arenes has been reviewed.⁷ There is considerable interest in ring closing reactions of substituted polyfluoroarenes as a way of rapidly generating usefully functionalised polycyclic compounds.^{8,9} As part of our investigations in this area we have studied ring closure by lithiation of bromoaryl ethers and sulfides containing a perfluoroarene ring. Reaction of a lithiated binaphthyl with hexafluorobenzene has recently been used in an elegant synthesis of a fluorinated helicene by Piers.¹⁰ In our study lithiation of the easily prepared 2-bromophenyl tetrafluoropyrid-4-yl ether **2** (Scheme 1) was expected to form the pyrido-fused benzofuran derivative **3** by

Scheme 1 Formation and Smiles-type rearrangement of ether 2 lithium-bromine exchange and then intramolecular substitution of the fluorine at C-3 of the pyridine ring to close the furan ring. However treatment of the tetrafluoropyridyl ether 2 with *n*-butyllithium in THF at low temperature afforded a compound which was not the expected tricyclic furan **3**. IR and ¹H NMR spectroscopy indicated the presence of an alcohol group ($\delta_{\rm H}$ 5.01, exchangeable with D_2O) while the ¹⁹F NMR spectrum showed signals for two pairs of fluorine atoms indicating that the tetrafluoropyridine ring was intact. The product was identified as the 2-(tetrafluoropyrid-4-yl)phenol 4 and the structure was confirmed by X-ray crystallography (Figure 1, Table 1) indicating that the reaction had proceeded by a Smiles type^{11,12} rearrangement rather than S_NAr reaction at the 3-position of the pyridine ring. The structure of the biaryl **4** showed a unique hydrogen bond between the phenolic OH group and the weakly basic tetrafluoropyridine nitrogen, resulting in zig-zag chains of molecules. The torsion angle between the two aryl rings is 56.05(3)°. Molecules $\pi \cdots \pi$ stack with centroid-centroid separations of 3.864 and 4.021 Å and a shortest contact of 3.620 Å for N(4)··C(12'). Treatment of the phenol 4 with sodium hydride in DMF gave the fused benzofuran 5 quantitatively with the phenoxide oxygen effecting nucleophilic substitution of the fluorine atom at 3position of the pyridine ring.

Figure 1. Crystal structure of **4** showing $\pi \cdots \pi$ stacking and H-bond intermolecular interactions. O(8)–H(8)····N(4') = 2.846 Å, angle at H(8) = 168 °.

Reaction of pentafluoropyridine and sodium 2-bromobenzenethiolate in DMF (Scheme 2) gave the corresponding sulfide **6** (50%) together with a small amount (17%) of the product of trisubstitution **7**. The latter was identified as the 2,4,5-tri(2-bromophenylthio)-3,6-difluoropyridine, and the substitution pattern, which differs¹³

Scheme 2 Formation and cyclisation of sulfide 6

from that usually found¹⁴ for pentafluoropyridine, was shown by the ¹⁹F NMR spectrum (δ_F 45.6 and 99.0), and was confirmed by X-ray crystallography (Figure 2, Table 1). Compound **7** crystallised as the hemi-toluene solvate and exhibits no $\pi \cdots \pi$ stacking but two types of halogen…halogen interactions (F(3)…Br(3') = 3.248; Br(3)…Br(3'') = 3.880 Å). None of the 2,4-disubstituted product was isolated. Lithiation of sulfide **6** (Scheme 2) gave a pyrido-fused benzothiophene in 79% yield, which was shown by X-ray crystallography (Figure 3, Table 1) to be compound **8** rather than the alternatively fused tricycle **10**. In this case direct intramolecular substitution of the C-3 fluorine in the pyridine ring occurred rather than Smiles rearrangement, which would have formed thiolate **9** that could have undergone ring closure to form isomer **10**.

Figure 2. Crystal structure of **7** showing halogen…halogen interactions. Toluene of crystallisation omitted for clarity.

Figure 3. Crystal structure of **8** showing fluorine… fluorine {F(3)…F(6") = 2.800 Å} and H-bond {C(12')–H(12')…N(5) = 2.54 Å; angle at H(12') = 157 °} intermolecular interactions. Not shown: $\pi \dots \pi$ stacking interactions parallel to *a* with a spacing of *a*/2 = 3.61 Å.

In the case of the ether **2**, reaction of the lithiated intermediate **11** (Scheme 3) must have proceeded with a Smiles-type rearrangement (path B) with attack at the ipso position occurring, even though this would involve the strained four-membered intermediate **13**. Smiles rearrangements involving five-membered intermediates have been reported for perfluoroarene derivatives,¹⁵ and a radical Smiles rearrangement has

Scheme 3 Possible reaction pathways for lithiated ether 11

been described by Zard¹⁶ which proceeds through a four-membered cyclic intermediate. Dudley¹⁷ has recently reported a rearrangement of 2-benzyloxypyridines to 2-pyridyl carbinols on treatment with LDA which involves a 3-membered intermediate. Attack at the ipso position in **11** must occur to avoid the unfavourable repulsion effect^{18,19,20} the 6-fluoro substituent would have on the pyridyl anion **12** if attack at C-3 occurred (path A). In the case of the lithiated thioether **15** (Scheme 4), the stabilising effect²¹ of the sulfur atom at C-4 must outweigh the destabilising influence of the fluorine at C-6 allowing attack at C-3 through a less strained fivemembered intermediate (**17** \leftrightarrow **18**), rather than attack at C-4 forming **16**. The longer C–S bonds in **15** may also make it harder to close the four-membered ring in **16**. It is not clear why the initially formed phenoxide **14** (Scheme 3), generated in the lithiation promoted Smiles rearrangement of **2**, did not cyclise to **5** under the reaction conditions, but complexation of the alkoxide by lithium in the relatively non-polar THF may have diminished its reactivity.

Scheme 4 Mechanism of formation of 8

We then investigated reaction of hexafluorobenzene **19** with 2-bromophenol or 2bromobenzenethiol in the presence of sodium hydride. With the phenol it proved difficult to isolate the mono-substitution product **21** (Scheme 5). Replacement of the

4-fluorine atom in the first-formed product occurred, and the major product formed was the 1,4-bis ether **20**. Only by using ten equivalents of hexafluorobenzene could we isolate the mono-ether **21** in a moderate 58% yield, and **20** was still formed in trace amount. Since bis-ether **20** could be readily formed in quantity, we decide to investigate lithiation of this substrate (Scheme 6). Treatment of **20** with two

Scheme 6 Cyclisation of bis-ether 20 to benzo[1,2-*b*:4,5-*b*']bis[*b*]benzofuran 22

equivalents of *n*-butyllithium in THF at -78 °C followed by warming to room temperature gave, after aqueous work-up and crystallisation, a non-phenolic, high melting (279-280 °C) crystalline product in low yield (19%). ¹H and ¹⁹F NMR spectroscopy showed the compound to be a symmetrical molecule with four proton resonances and a single fluorine signal (δ_F 14.7 ppm). X-ray crystallography showed the product to be the centro-symmetric pentacyclic fused bis furan **22** (Figure 4, Table 1). The small, thin, weakly diffracting crystals required synchrotron radiation for data collection. The molecules pack in a herring-bone fashion exhibiting both halogen…halogen and $\pi \dots \pi$ stacking interactions.

Figure 4. Crystal structure of **22** showing stepped chains via fluorine…fluorine $\{F(1) \cdots F(1') = 2.833 \text{ Å}\}$ interactions and head-to-tail $\pi \cdots \pi$ interactions $\{\text{centroid} \cdots \text{centroid} = 3.902 \text{ Å}, \text{closest atom} \cdots \text{atom separations ca. } 3.42 \text{ Å}\}.$

It is not clear if this compound is formed by direct S_NAr substitution of the adjacent fluorine atoms ($20 \rightarrow 22$), or if Smiles rearrangement has taken place first at both ether linkages, forming the bis-phenoxide 26 which could have undergone ring closure to 22. None of the other possible products of cyclisation which could have shed light on to whether cyclisation occurred directly 23, with rearrangement 24, or with a combination of both 25, were isolated. An experiment to determine if rearrangement occurred during this reaction was carried out by treating bis-ether 20 with a single equivalent of *n*-butyllithium with the expectation that isolation of 27 would demonstrate direct cyclisation occurred, whereas formation of 28 would show that Smiles rearrangement had preceded cyclisation. Unfortunately this experiment was inconclusive with a complex mixture forming from which no identifiable products could be obtained. Treatment of the pentafluorophenyl ether 21 (Scheme 7) with *n*-butyllithium gave a fluorinated benzofuran in moderate yield (66% crude, 25% after crystallisation). Since excess *n*-butyllithium was employed in this reaction addition

Scheme 7 Reaction of bromophenyl pentafluorophenyl ether 21 with *n*-BuLi

of an *n*-butyl group to the fluorinated ring also occurred. The structure of the product was assigned as the 3-butyl derivative **29** (numbering shown) with the butyl group adding most likely *para* to carbon rather than oxygen (giving **30**) assuming the addition occurred after ring closure. The low melting point (48 °C) of this compound precluded formation of suitable crystals for X-ray diffraction analysis, but detailed analysis of the long range carbon-fluorine coupling constants²² in the ¹³C NMR spectrum supported the assignment of the structure as **29**. Calculation of the Mulliken charges in 1,2,3,4-tetrafluorodibenzofuran (structure optimised using Gaussian 03 at the B3LYP/6-31G* level)²³ indicated C-3 (+0.261) to be more slightly electrophilic than C-4 (+0.258) also supporting assignment as **29**. The values for C-1 and C-4 were +0.250 and +0.255 respectively.

Reaction of 2-bromobenzenethiol (two equivalents), sodium hydride and hexafluorobenzene in DMF gave the 1,4-disubstitution product **31** (Scheme 8) in 81% crude yield (70% after crystallisation). The monosubstitution product could not be formed even when a large excess of hexafluorobenzene was employed. Treatment of **31** with a single equivalent of *n*-butyllithium afforded the 2-(bromophenylthio)-1,3,4trifluorodibenzothiophene 32 showing that cyclisation had occurred without initial

Scheme 8 Direct cyclisation of bis-sulfide 31 with 1 equivalent of *n*-BuLi

Smiles rearrangement as was observed for the pyridyl ether. None of the isomer **33** was detected. The structure of the dibenzothiophene **32** was confirmed by X-ray crystallography which showed that the sulfur atoms retained their original 1,4-relationship. The compound crystallised as two monoclinic polymorphs (**32A** – rod-shaped crystals and **32B** – plate-shaped) (Figures 5 and 6, Table 1). Both polymorphs have 3D supramolecular structures, but the balance of $\pi \cdots \pi$ and halogen…halogen interactions differs. In **32A** there are both types: Br(1)…Br(1") = 3.268, F(3)…F(3"") = 2.879 Å and centroid…centroid separations of 3.688 and 3.547 Å for ring C(15)–C(20) with its symmetry equivalent and ring C(8)–C(13) with ring C(2')–C(7') respectively. In **32B** there are no halogen…halogen interactions, although there is an F(6)…S(1') = 3.260 Å short contact; however there are more $\pi \cdots \pi$ interactions: ring C(15)–C(20) with its symmetry equivalent (centroid… centroid = 3.716 Å) and head-to-tail interactions between the three fused rings and their symmetry equivalents (centroid… centroid = 3.586 Å).

Figure 5 Crystal structure of **32A** showing $\pi \cdots \pi$ and halogen \cdots halogen interactions.

Figure 6 Crystal structure of **32B** showing $\pi \cdots \pi$ and fluorine \cdots sulfur interactions.

When the bis-sulfide **31** was treated with two equivalents of *n*-butyllithium (Scheme 9) cyclisation occurred between both bromophenyl groups and the central fluorinated benzene ring to give the pentacyclic 6,12-difluorobenzo[1,2-*b*:4,5*b*']bis[*b*]benzothiophene **34** in high yield (95%). No evidence for formation of any of the other possible cyclisation products (**35**, **36** or **37**) was obtained. The benzo[1,2*b*:4,5-*b*']bis[*b*]benzothiophene ring system has recently been synthesised by acid catalysed ring closure of a methylsulfinyl group onto an adjacent benzene ring.²⁴ The structure of **34** was confirmed by X-ray crystallography (Figure 7, Table 1) supporting ring closure by direct S_NAr reaction at C-2 and C-5 without initial rearrangement. The crystals of **34** were very thin and flexible and the crystal structure showed $\pi \cdots \pi$ stacking parallel to *b* with the closest atom...atom contact being 3.50 Å.

Figure 7 Crystal structure of **7** showing $\pi \cdots \pi$ stacking parallel to *b*.

isomers not observed

Scheme 9 Cyclisation of **31** to benzo[1,2-*b*:4,5-*b*']bis[*b*]benzothiophene **34**

In conclusion we have shown that lithiation of aryloxy- or arylthio-substituents on perfluorinated arenes can be used to rapidly build up usefully functionalised polycyclic structures. Cyclisation can occur by direct attack of the initially formed carbanion on the neighbouring position by S_NAr reaction, and this seems to be the norm for groups attached through a sulfur atom. In the case of fluoroaryl ethers Smiles-type rearrangement of the initially formed carbanion can occur, although the scope of this process needs to be investigated further. The crystal structures of key examples reveal a fine balance between halogen…halogen and $\pi \dots \pi$ stacking interactions and polymorphism in one case. Further work on the mechanistic aspects of these reactions, and results on the cyclisation of corresponding perfluoroarylamines will be reported in due course.

We thank Loughborough University for support, the Socrates Programme which allowed JPG to study in Loughborough and the EPSRC National Mass Spectrometry service at the University of Swansea, and John Kershaw and Sheena Grainger (Loughborough University) for recording mass spectra. We also thank STFC for beam time at Daresbury Laboratory where Dr.s J.E. Warren and P.J. Rizkallah provided scientific support.

Experimental

General

Commercial dry solvents were used in all reactions except for light petroleum and ethyl acetate which were distilled from CaCl₂, dichloromethane which was distilled from CaH₂, and THF which was distilled from sodium and benzophenone. Light petroleum refers to the fraction boiling between 40-60 °C fraction. Sodium hydride was a 60% dispersion in mineral oil. A 1.6 or 2.5 M solution of *n*butyllithium in hexane was used. Melting points were determined on a Stuart Scientific SMP3 melting point apparatus and are uncorrected. Infrared spectra were recorded on a Perkin-Elmer Paragon 1000 FT-IR spectrophotometer on NaCl plates. ¹H (400 MHz), ¹³C (100 Hz) and ¹⁹F (376 MHz) NMR spectra were recorded on a Bruker DPX-400 instrument. ¹⁹F NMR spectra are referenced to hexafluorobenzene as internal standard. Spectra were obtained from solutions in CDCl₃ unless otherwise specified. Chemical shifts are given in parts per million (ppm) and *J* values in hertz (Hz). Assignments were made using a combination of COSY, HMQC and HMBC analysis. Mass spectra were recorded on a Jeol SX102 high resolution mass spectrometer, a ThermoFisher ExactiveTM Orbitrap instrument equipped with an Advion TriVersa NanoMate[®], or were run by the EPSRC MS Service at the University of Wales, Swansea. TLC using silica as absorbent was carried out with aluminium backed plates coated with silica gel (Merck Kieselgel 60 F₂₅₄), and TLC using alumina as absorbent was carried out with aluminium backed plates coated with neutral aluminium oxide (Merck 150 F₂₅₄,TypeT). Silica gel (Merck Kieselgel 60 H silica) was used for column chromatography.

4-(2-Bromophenoxy)tetrafluoropyridine 2

2-Bromophenol (3.46 g, 0.02 mol) was added dropwise to a stirred suspension of sodium hydride (1.0 g, 0.025 mol) in DMF (40 mL) at ice-bath temperature. When gas evolution had stopped pentafluoropyridine (3.38 g, 0.02 mol) was added dropwise and the resulting turbid yellow solution stirred at room temperature overnight for 19 h. Water (100 mL) was added and the mixture extracted with ether (250 mL). The organic layer was dried over MgSO₄, filtered and evaporated to give the title compound as a yellow oil (5.96 g, 92%).

4-(2-Hydroxyphenyl)tetrafluoropyridine 4

A solution of 4-(2-bromophenoxy)tetrafluoropyridine **2** (1.05 g, 0.0033 mol) in anhydrous THF (7 mL) was stirred at -78 °C and treated dropwise with a solution of *n*-butyllithium in hexanes (2.5 M, 1.5 mL, 0.0037 mol). The solution turned orange and then faded to yellow over 50 min. The mixture was stirred and allowed to warm to room temperature overnight. Water (10 mL) was added and the mixture extracted with ether (3 x 20 mL). Brine was added to break up the emulsion which formed during extraction. The combined ether layers were dried over MgSO₄, filtered and evaporated to give a yellow oil (0.9 g) which crystallised on standing. Recrystallisation from dichloromethane and light petroleum gave off-white crystals of the title compound (0.25 g, 31%).

m/z (EI) 338/340 (M⁺) Found 337.9370, C₁₂H₄⁷⁹BrF₅O requires 337.9366

The disubstituted product 20 was also isolated (0.005 g, 1%) on further elution.

6,12-difluorobenzo[1,2-b:4,5-b']bis[b]benzofuran 22

A solution of the bis ether **20** (0.3 g, 0.6 mmol) in anhydrous THF (2 mL) was stirred at -84 °C and treated with *n*-butyllithium in hexanes (2.5 M, 0.5 mL, 1.25 mmol). The solution turned brown in colour and then faded to yellow after 1 h. After 2 h the

mixture was warmed to room temperature and treated with water (2 mL). Extraction with dichloromethane (x 3) and evaporation of the organic phases gave a pale brown solid (0.2 g). Recrystallisation from dichloromethane - light petroleum gave colourless needles of the benzo-bis-benzofuran **22** (0.033 g, 19%).

Crystallography

For each sample, a crystal was mounted in oil on a glass fibre and fixed in the cold nitrogen stream on a Bruker APEX 2 CCD diffractometer equipped with MoK α radiation and a graphite monochromator, except for **22** which was measured at Daresbury Laboratory SRS, Station 9.8 due to tiny crystal size and weak diffraction²⁵. Intensity data were measured by thin-slice ω -scans and corrected for Lp and absorption effects. Data were reduced using the SAINT²⁵ program. The structures were determined by the direct methods routine in the SHELXS-97 program and refined by full-matrix least-squares methods, on F^2 , in SHELXL-97²⁶. The nonhydrogen atoms were refined with anisotropic thermal parameters. H atoms were constrained.

For **4** the absolute structure could not be reliably determined due to the lack of anomalous scatters, so Friedel pairs were merged. Crystals of **7** were non-merohedrally twinned into two domains related by a 180° rotation about real axis [1 0 0]²⁷. The occupancies of the two domains refined to 0.8744:0.1256(6). Crystals of **8** were non-merohedrally twinned into two domains related by a 180° rotation about reciprocal axis [0 0 1]²⁷. The occupancies of the two domains related by a 180° rotation about reciprocal axis [0 0 1]²⁷. The occupancies of the two domains refined to 0.6215:0.3785(8). Compound **32** grows as either rods (**32A**) or plates (**32B**) which are polymorphic. Although both crystallise in space group $P2_1/c$, the unit cell shapes are entirely different and the $\pi \cdots \pi$ and halogen-halogen interactions are also different (see discussion). Crystals of **34** were extremely thin and flexible which led to some absorption correction difficulties and less than ideal anisotropic displacement parameters. Crystal data and refinement results are collated in Table 1.
