Using the linear fractional transformation, connecting effective conductivities $\hat{\sigma}_e$ of isotropic two-phase systems with and without magnetic field, explicit approximate expressions for $\hat{\sigma}_e$ in a magnetic field are obtained. They allow to describe $\hat{\sigma}_e$ of various inhomogeneous media at arbitrary phase concentration x and magnetic fields. The x-dependence plots of $\hat{\sigma}_e$ at some values of inhomogeneity and magnetic field are constructed. Their behaviour is qualitatively compatible with the existing experimental data. The obtained results are applicable for different two-phase systems (regular and nonregular as well as random), satisfying the symmetry and self-duality conditions, and admit a direct experimental checking.

1. Introduction

Last time, under investigation of magneto-resistive properties of new materials, which are connected with the high-temperature superconductivity (such as oxide materials with the perovskite type structure), it was established that they often have unusual transport properties. For example, the magnetoresistance becomes very large (the so called colossal magnetoresistance in such materials as manganites) [1] or grows approximately linearly with magnetic field up to very high fields (in silver chalcogenides) [2]. There is an opinion that these properties take place due to phase inhomogeneities of these materials [2]. For this reason a calculation of the effective conductivity σ_e of inhomogeneous heterophase systems without and with magnetic field at arbitrary partial conductivities and phase concentrations is very important problem. Unfortunately, the existing effective medium approximations (EMA) cannot give an explicit simple formulas for magneto-resistivity convenient for description of the experimental results in a wide range of partial parameters even for two-phase random systems [3]. Such formulas can be obtained for some systems only in high magnetic field [3, 4].

The situation is much better for 2D inhomogeneous systems in the perpendicular magnetic field. Here, due to their exact duality properties, not only a few exact results have been obtained for the effective conductivity of random inhomogeneous systems [5-10], but also the transformations, connecting effective conductivities of isotropic two-phase inhomogeneous systems with and without magnetic field, have been constructed [9, 11]. This transformation, in principle, permits to obtain the explicit expressions for σ_e in a magnetic field, if the

1

corresponding expressions are known for σ_e without magnetic field. Such explicit approximate expressions for σ_e have been obtained earlier in some limiting cases, for example, at small concentration of one phase, for weakly inhomogeneous media [11], for inclusions of super- or non-conducting phases [6-8,11]. In this letter we will present the explicit approximate expressions for $\hat{\sigma}_e$ at arbitrary phase concentrations and in a wide region of partial conductivities, using the full dual transformation recently constructed in [10] and the corresponding expressions for σ_e at $\mathbf{H} = 0$ from [12]. We will give also the x-dependence plots of $\hat{\sigma}_e$ at some characteristic values of magnetic field $\mathbf{H}$, which show very interesting behaviour, compatible with experimental results from [1, 2].

2. Dual transformation between systems with $\mathbf{H} \neq 0$ and $\mathbf{H} = 0$

The effective conductivity of two-phase isotropic systems in a magnetic field has the following form

$$\hat{\sigma} = \sigma_{ik} = \sigma_d \delta_{ik} + \sigma_t \epsilon_{ik}, \quad \sigma_d(\mathbf{H}) = \sigma_d(-\mathbf{H}), \quad \sigma_t(\mathbf{H}) = -\sigma_t(-\mathbf{H}), \quad (1)$$

here δ_{ik} is the Kronecker symbol, ϵ_{ik} is the unit antisymmetric tensor. The effective conductivity $\hat{\sigma}_e$ of 2-phase self-dual (random or regular symmetric) systems with the partial conductivities σ_{id}, σ_{it} ($i = 1, 2$) (we assume that $\sigma_{id} \geq 0$) and concentrations x_i must be a symmetric function of pairs of arguments $(\hat{\sigma}_i, x_i)$ and a homogeneous (a degree 1) function of $\sigma_{di,ti}$. For this reason it is invariant under permutation of pairs of partial parameters

$$\hat{\sigma}_e(\hat{\sigma}_1, x_1 | \hat{\sigma}_2, x_2) = \hat{\sigma}_e(\hat{\sigma}_2, x_2 | \hat{\sigma}_1, x_1). \quad (2)$$

The effective conductivity of 2-phase systems must also reduce to some partial $\hat{\sigma}_i$, if $x_i = 1$ ($i = 1, 2$).

Futher it will be more convenient to use the complex representation for coordinates and vector fields [13]

$$z = x + iy, \quad j = j_x + ij_y, \quad e = e_x + ie_y, \quad \sigma = \sigma_d + i\sigma_t.$$

The complex conductivity transforms as [5]

$$\sigma' = T(\sigma) = \frac{c\sigma - ib}{-id\sigma + a}, \quad (3)$$

where a, b, c, d are the real numbers. This transformation generalizes the inversion transformations of systems without magnetic field. Thus, the dual transformations (DT) in systems with magnetic field have a more richer structure due to the fact that they are connected with some subgroup of group of linear fractional transformations, conserving the imaginary axis in the complex conductivity plane [5,7,9]. The transformation T depends on 3 real parameters (since one of 4 parameters can be factored due to the fractional structure of T). There are various ways to choose 3 parameters. In our treatment it will

be convenient to factor d. This gives 3 parameters $\bar{a} = a/d, \bar{b} = b/d, \bar{c} = c/d$, determining a transformation T.

The transformation (3) has the following form in terms of conductivity components σ_d and σ_t

$$\sigma_d' = \sigma_d \frac{ac + bd}{(d\sigma_d)^2 + (a + d\sigma_t)^2} = \bar{c}\sigma_d \frac{\bar{a} + \bar{b}/\bar{c}}{(\sigma_d)^2 + (\bar{a} + \sigma_t)^2},$$

$$\sigma_t' = \frac{cd\sigma_d^2 + (a + d\sigma_t)(c\sigma_t - b)}{(d\sigma_d)^2 + (a + d\sigma_t)^2} = \bar{c} \frac{\sigma_d^2 + (\bar{a} + \sigma_t)(\sigma_t - b/c)}{(\sigma_d)^2 + (\bar{a} + \sigma_t)^2}. \tag{4}$$

These DT allow to construct the transformation, connecting effective conductivities of two-phase systems with magnetic field and without it. Analogous connections have been found firstly on a basis of solutions of the corresponding Laplace and boundary equations [11], but it has some ambiguity problems with a determination of the parameters of the intermediate artificial system. Later, this transformation has been constructed directly from the DT under two simplifying conjectures in [9]. Recently, it was constructed in the full form, using all 3 parameters and explicitly reproducing the known exact values for σ_e, in [10]. The parameters of such transformation (let us call it T_h, we will also omit the bars over its parameters) $a, b' = b/c, c$ depend on the partial conductivities and have the following form

$$a_\pm = \frac{|\sigma_2|^2 - |\sigma_1|^2 \pm \sqrt{B}}{2(\sigma_{1t} - \sigma_{2t})}, \quad b_\pm' = \frac{|\sigma_1|^2 - |\sigma_2|^2 \pm \sqrt{B}}{2(\sigma_{1t} - \sigma_{2t})}, \quad c = -a,$$

$$B = [(\sigma_{1t} - \sigma_{2t})^2 + (\sigma_{1d} - \sigma_{2d})^2][(\sigma_{1t} - \sigma_{2t})^2 + (\sigma_{1d} + \sigma_{2d})^2], \tag{5}$$

where $|\sigma_i|^2 = \sigma_{id}^2 + \sigma_{it}^2$, and, evidently, $B \geq 0$. The diagonal (or real) parts of σ_i transform under T_h as

$$\sigma_{id}' = \sigma_{id} \frac{c(a + b')}{(\sigma_{id})^2 + (a + \sigma_{it})^2} = \frac{c\sigma_{id}}{\sigma_{ai}}, \quad \sigma_{ai} = a + \sigma_{it}. \tag{6}$$

The parameters a, b, c satisfy also the additional relations [10]

$$A = \left[1 + \left(\frac{\sigma_{1t} - \sigma_{2t}}{\sigma_{1d} + \sigma_{2d}}\right)^2\right]^{1/2} = \frac{(a + b')(\sigma_{a1}\sigma_{a2})^{1/2}}{\sigma_{1d}\sigma_{2d} + \sigma_{a1}\sigma_{a2}}, \tag{7}$$

$$\frac{\sigma_{1d}\sigma_{2t} + \sigma_{2d}\sigma_{1t}}{\sigma_{1d} + \sigma_{2d}} = c\frac{\sigma_e'^2 - ab'}{\sigma_e'^2 + a^2} = c\frac{\sigma_{1d}\sigma_{2d} - (b'/a)\sigma_{a1}\sigma_{a2}}{\sigma_{1d}\sigma_{2d} + \sigma_{a1}\sigma_{a2}}, \tag{8}$$

which ensure the reproduction of the exact results for σ_e at the equal phase concentrations $x_1 = x_2 = 1/2$. The relations (7) and (8) give us a highly nontrivial check of a self-consistency of the transformation. The direct check of them is a rather complicated task. Fortunately, as it was conjectured in [9] and shown in [10], T_h transforms a circumference (see fig.1.) with a radius R, centered on the
3

Fig.1. A schematic picture of the chord, defining a geometrical sense of the factor A from the expression for the real part of the exact σ_e .

imaginary axis at iz_0 and passing through the two points σ_1 and σ_2, where

$$R = \frac{|a+b'|}{2} = \frac{\sqrt{B}}{2|\sigma_{1t} - \sigma_{2t}|}, \quad z_0 = \frac{-a+b'}{2} = \frac{|\sigma_1|^2 - |\sigma_2|^2}{2(\sigma_{1t} - \sigma_{2t})}, \tag{9}$$

into the real axis and the real axis into this circumference. All equalities necessary for fulfillment of (7),(8) correspond to the known equalities between lengths of various chords, their projections on a diameter and the radius of the circles. For example, the equality (7) takes the form

$$A = \frac{2R\sigma_a}{\sigma_a^2 + \sigma_{1d}\sigma_{2d}} = 1/(1 - \delta/2R\sigma_a), \quad \sigma_a^2 = \sigma_{a1}\sigma_{a2}, \tag{10}$$

where σ_a^2 is a squared geometrical average of σ_{ai}, $(i = 1, 2)$ (this interpretation is possible due to the fact that σ_{ai} always have the same sign [9]), and δ defines a difference between $\sigma_x^2 = 2R\sigma_a - \sigma_a^2$, a squared real projection of the chord, having an imaginary projection σ_a, and a squared geometric average of σ_{id}

$$\delta = \sigma_x^2 - \sigma_{1d}\sigma_{2d}. \tag{11}$$

3. Inhomogeneous systems with compact inclusions

Now, having all formulas for the transformation, one can construct the explicit expressions for σ_e of inhomogeneous system in a magnetic field. Below, in order to simplify a view of the subsequent formulas, we will omit the subindex

d in the partial diagonal parts σ_{id} $(i = 1, 2)$. Firstly we consider the case of compact inclusions of one phase into another. The corresponding effective conductivity σ_e has the next form $(x_1 = x, x_2 = 1 - x)$ [12]

$$\sigma_e(\{\sigma\}, \{x\}) = \sigma_1^x \sigma_2^{1-x} \qquad (12)$$

Substituting the primed partial conductivities into (12), one obtains the diagonal primed effective conductivity

$$\sigma'_{ed}(\{\sigma\}, \{x\}) = c \left(\frac{\sigma_1}{\sigma_{a1}}\right)^x \left(\frac{\sigma_2}{\sigma_{a2}}\right)^{1-x} \qquad (13)$$

Then, substituting σ'_{ed} into (4) and remembering that the primed transverse effective conductivity $\sigma'_{et} = 0$, one obtains for the diagonal part σ_{ed} of the effective conductivity of these systems in a magnetic field the following expression

$$\sigma_{ed}(\{\sigma\}, \{x\}) = \frac{\sigma'_{ed}(ac + b)}{(\sigma'_{ed})^2 + a^2} = \frac{(a + b')\left(\frac{\sigma_1}{\sigma_{a1}}\right)^{x_1}\left(\frac{\sigma_2}{\sigma_{a2}}\right)^{x_2}}{1 + \left(\frac{\sigma_1}{\sigma_{a1}}\right)^{2x_1}\left(\frac{\sigma_2}{\sigma_{a2}}\right)^{2x_2}}. \qquad (14)$$

One can check, using the relation (7), that (14) correctly reduces to σ_i, when $x_i = 1$ and to the exact formula for σ_e at $x_1 = x_2 = 1/2$. For example, at $x_1 = 1, x_2 = 0$ (14) reduces to

$$\sigma_{ed}(\{\sigma\}, x_1 = 1) = \frac{\sigma_1}{\sigma_{a1}} \frac{(a + b')}{1 + \left(\frac{\sigma_1}{\sigma_{a1}}\right)^2} = \sigma_1,$$

where at the last step we have used the relation (7) at $\sigma_1 = \sigma_2$.

Analogously, for the transverse part σ_{et} one obtains

$$\sigma_{et}(\{\sigma\}, \{x\}) = c \frac{(\sigma'_{ed})^2 - ab'}{(\sigma'_{ed})^2 + a^2} = \frac{b' - a\left(\frac{\sigma_1}{\sigma_{a1}}\right)^{2x_1}\left(\frac{\sigma_2}{\sigma_{a2}}\right)^{2x_2}}{1 + \left(\frac{\sigma_1}{\sigma_{a1}}\right)^{2x_1}\left(\frac{\sigma_2}{\sigma_{a2}}\right)^{2x_2}}. \qquad (15)$$

Again, using now the relation (8), one can check that (15) correctly reproduces boundary values at $x_i = 1$ $(i = 1, 2)$ as well as the exact value at equal concentrations $x_1 = x_2 = 1/2$.

4. Inhomogeneous systems with a "random parquet" structure

In this section we present analogous formulas for 2D isotropic inhomogeneous systems with the structure of the inhomogeneities of the "random parquet" type [12]. The effective conductivity of such systems without a magnetic field is [12]

$$\sigma_e(\{\sigma\}, \{x\}) = \sqrt{\langle\sigma\rangle/\langle\sigma^{-1}\rangle} = \sqrt{\sigma_1\sigma_2}\left(\frac{x_1\sigma_1 + x_2\sigma_2}{x_1\sigma_2 + x_2\sigma_1}\right)^{1/2} \qquad (16)$$

5

Then the diagonal part of the primed effective conductivity σ'_e has the form

$$\sigma'_{ed}(\{\sigma\},\{x\}) = c \left(\frac{\sigma_1}{\sigma_{a1}}\frac{\sigma_2}{\sigma_{a2}}\right)^{1/2} \left(\frac{x_1\left(\frac{\sigma_1}{\sigma_{a1}}\right)+x_2\left(\frac{\sigma_2}{\sigma_{a2}}\right)}{x_1\left(\frac{\sigma_2}{\sigma_{a2}}\right)+x_2\left(\frac{\sigma_1}{\sigma_{a1}}\right)}\right)^{1/2} \tag{17}$$

Its substitution into (4) gives for the diagonal part of the effective conductivity σ_{ed}

$$\sigma_{ed}(\{\sigma\},\{x\}) = (a+b')\frac{\left(\frac{\sigma_1}{\sigma_{a1}}\frac{\sigma_2}{\sigma_{a2}}\right)^{1/2}\left(\frac{x_1\left(\frac{\sigma_1}{\sigma_{a1}}\right)+x_2\left(\frac{\sigma_2}{\sigma_{a2}}\right)}{x_1\left(\frac{\sigma_2}{\sigma_{a2}}\right)+x_2\left(\frac{\sigma_1}{\sigma_{a1}}\right)}\right)^{1/2}}{1+\frac{\sigma_1}{\sigma_{a1}}\frac{\sigma_2}{\sigma_a}\left(\frac{x_1\left(\frac{\sigma_1}{\sigma_{a1}}\right)+x_2\left(\frac{\sigma_2}{\sigma_{a2}}\right)}{x_1\left(\frac{\sigma_2}{\sigma_{a2}}\right)+x_2\left(\frac{\sigma_1}{\sigma_{a1}}\right)}\right)} \tag{18}$$

One can check, using the relation (7), that (18) reduces to the right values at $x_i = 1$, $(i = 1, 2)$ as well as for $x_1 = x_2 = 1/2$. For the transverse part σ_{et} one obtains

$$\sigma_{et}(\{\sigma\},\{x\}) = \frac{b'-a\left(\frac{\sigma_1}{\sigma_{a1}}\frac{\sigma_2}{\sigma_{a2}}\right)\left(\frac{x_1\left(\frac{\sigma_1}{\sigma_{a1}}\right)+x_2\left(\frac{\sigma_2}{\sigma_{a2}}\right)}{x_1\left(\frac{\sigma_2}{\sigma_{a2}}\right)+x_2\left(\frac{\sigma_1}{\sigma_{a1}}\right)}\right)}{1+\left(\frac{\sigma_1}{\sigma_{a1}}\frac{\sigma_2}{\sigma_{a2}}\right)\left(\frac{x_1\left(\frac{\sigma_1}{\sigma_{a1}}\right)+x_2\left(\frac{\sigma_2}{\sigma_{a2}}\right)}{x_1\left(\frac{\sigma_2}{\sigma_{a2}}\right)+x_2\left(\frac{\sigma_1}{\sigma_{a1}}\right)}\right)}. \tag{19}$$

Again, using now the relation (8), one can check that (19) correctly reproduces boundary values as well as the exact value at equal concentrations.

<u>5. Effective medium approximation in a magnetic field</u>

In this section we find out for a completness a "magnetic" transformation for the traditional effective medium approximation (EMA) for the effective conductivity. The EMA for σ_e in inhomogeneous two-phase self-dual systems without a magnetic field has the form [14]

$$\sigma_e(\{\sigma\},\{x\}) = (x-\frac{1}{2})\sigma_- + \sqrt{(x-\frac{1}{2})^2\sigma_-^2 + \sigma_1\sigma_2}, \tag{20}$$

where $\sigma_- = (\sigma_1 - \sigma_2)$. Then, the primed effective conductivity will be

$$\sigma'_{ed}(\{\sigma\},\{x\}) = c\left((x-\frac{1}{2})\sigma_{a-} + \sqrt{(x-\frac{1}{2})^2\sigma_{a-}^2 + \frac{\sigma_1}{\sigma_{a1}}\frac{\sigma_2}{\sigma_{a2}}}\right), \tag{21}$$

here $\sigma_{a-} = \frac{\sigma_1}{\sigma_{a1}} - \frac{\sigma_2}{\sigma_{a2}}$. Substituting (21) into (4), one obtains for the diagonal part σ_{ed} the next expression

$$\sigma_{ed}(\{\sigma\},\{x\}) = \frac{(a+b')\left((x-\frac{1}{2})\sigma_{a-} + \sqrt{(x-\frac{1}{2})^2\sigma_{a-}^2 + \frac{\sigma_1}{\sigma_{a1}}\frac{\sigma_2}{\sigma_{a2}}}\right)}{1+\left((x-\frac{1}{2})\sigma_{a-} + \sqrt{(x-\frac{1}{2})^2\sigma_{a-}^2 + \frac{\sigma_1}{\sigma_{a1}}\frac{\sigma_2}{\sigma_{a2}}}\right)^2}. \tag{22}$$

One can check, using the relation (7), that (22) correctly reduces to σ_i, when $x_i = 1$ and to the exact formula for σ_e at $x_1 = x_2 = 1/2$. For example, at $x_1 = 1, x_2 = 0$ (22) reduces to

$$\sigma_{ed}(\{\sigma\}, x_1 = 1) = \frac{(a + b')\sigma_1\sigma_{a1}}{\sigma_{a1}^2 + \sigma_1^2} = \sigma_1.$$

Analogously, substituting (21) into (4), one obtains for the transverse part of the effective conductivity

$$\sigma_{et}(\{\sigma\}, \{x\}) = \frac{b' - a\left((x - \frac{1}{2})\sigma_{a-} + \sqrt{(x - \frac{1}{2})^2\sigma_{a-}^2 + \frac{\sigma_1}{\sigma_{a1}}\frac{\sigma_2}{\sigma_{a2}}}\right)^2}{1 + \left((x - \frac{1}{2})\sigma_{a-} + \sqrt{(x - \frac{1}{2})^2\sigma_{a-}^2 + \frac{\sigma_1}{\sigma_{a1}}\frac{\sigma_2}{\sigma_{a2}}}\right)^2}. \qquad (23)$$

Again, using now the relation (8), one can check that (23) correctly reproduces boundary values as well as the exact value at equal concentrations.

It follows from the property of the transformation T_h that σ_e belongs to the circumference (9) for all phase concentrations $x \in [0, 1]$ [9, 10]. The effective conductivity maps the concentration segment $[0, 1]$ into the corresponding arc of this circumference, connecting the points σ_1 and σ_2. The different expressions for σ_e correspond to the different mappings. The comparison of these mappings is presented in [15].

6. Effective conductivity in magnetic field

Thus, we have found the desired formulas. Substituting into (14),(15), (18),(19),(22) and (23) the known functions $\sigma_{id}(\mathbf{H}), \sigma_{it}(\mathbf{H})$, $(i = 1, 2)$, one obtains the explicit expressions for the diagonal $\sigma_{ed}(\mathbf{H})$ and transverse $\sigma_{et}(\mathbf{H})$ parts of the effective conductivity of inhomogeneous systems in magnetic field. We give here (see fig.2) their x-dependence plots for 2-phase systems, whose partial conductivities in magnetic field can be approximated by the standart (metallic type) formulas [5, 3]

$$\sigma_{id}(\mathbf{H}) = \frac{\sigma_{i0}}{1 + \beta_i^2}, \quad \sigma_{it}(\mathbf{H}) = \frac{\sigma_{i0}\beta_i}{1 + \beta_i^2}, \quad \beta_i = \mu_i H, \quad i = 1, 2, \qquad (24)$$

where μ_i are the corresponding mobilities. We will assume here, for simplicity, that $\mu_1 \sim \mu_2 \sim 1$. One can see from fig.2 that the behaviour of the effective conductivities, though different for various expressions, has two common characteristic features: 1) absolute values of σ_{ed} are very small, even at high peaks; 2) all values in the regions with noticeable values of σ_e decrease with a growth of H at relatively large H approximately linearly. Since σ_{id} decrease $\sim H^{-2}$, the second feature effectively induces a narrowing of the peaks, which are rather asymmetric and depending on structure of inhomogeneities (i.e. on the form of explicit expressions). Both these properties are qualitatively compatible with the experimental results from [1, 2], which show a large magnetoresistivity and its approximately linear growth with an increase of H. More detailed analysis

and comparisons with experimental results will be presented in the subsequent papers.

7. Conclusion

Using the exact duality transformation we have found three explicit approximate expressions for the effective conductivity of 2D isotropic two-phase systems in a magnetic field. The three plots of the dependence of $\sigma_{ed,et}$ on the phase concentration at the inhomogeneity parameter $\sigma_{20}/\sigma_{10} = 0.01$ and at different values of magnetic field are constructed. They show very interesting behaviour of $\sigma_{ed}(\mathbf{H})$ and $\sigma_{et}(\mathbf{H})$, which is qualitatively compatible with the experimental data from [1, 2]. The obtained results can be applied for a description of σ_e of various two-phase systems (regular and nonregular as well as random), satisfying the symmetry and self-duality conditions, in a wide range of partial conductivities and at arbitrary concentrations and magnetic fields. All these results admit a direct experimental checking.
