TOWARDS HPC-EMBEDDED. CASE STUDY: KALRAY AND MESSAGE-PASSING ON NOC

PEDRO VALERO-LARA*, EZHILMATHI KRISHNASAMY†, AND JOHAN JANSSON ‡

Abstract. Today one of the most important challenges in HPC is the development of computers with a low power consumption. In that sense, recently, new embedded many-core systems have emerged. One of them is Kalray. Unlike other many-core architectures, Kalray is not a co-processor (self-hosted). One interesting feature of the Kalray architecture is the Network on Chip (NoC) connection. Habitually, the communication in many-core architectures is carried out via shared memory. However, in Kalray, the communication among processing elements can also be via Message-Passing on the NoC. One of the main motivation of this work is to present the main constraints to deal with the Kalray architecture. In particular, we focused on memory management and communication. We assess the use of NoC and shared memory on Kalray. Unlike shared memory, the implementation of Message-Passing on NoC is not transparent from programmer point of view. To facilitate the understanding of our work, codes are included in the paper. The synchronization among processing elements and NoC is other of the challenges to deal with in the Karlay processor. Although the synchronization using Message-Passing is more complex and consuming time than using shared memory, we obtain an overall speedup close to 6 when using Message-Passing on NoC with respect to the use of shared memory. Additionally, we have measured the power consumption of both approaches. Despite of being faster, the use of NoC presents a higher power consumption with respect to the approach that exploits shared memory. This additional consumption in Watts is about a 50% more. However, the reduction in time by using NoC has an important impact on the overall power consumption as well. In consequence, we obtained a better power consumption using NoC than using shared memory.

1. Introduction. Advanced strategies for the efficient implementation of computationally intensive numerical methods have a strong interest in industrial and academic community. In the last decade, we have lived a spectacular growth in the use of many-core architectures for HPC applications [8]. However, the appearance of other (low-power consumption) embedded many-core architectures such as Kalray [6] has created new challenges and opportunities for performance optimization in multiple applications. In this work, we have explored some of these new opportunities towards a supercomputing on a chip era.

Kalray integrates its own OS and is not in need of a co-processor as in the case of other many-core processors [3, 6]. Highly expensive memory transfers from host main memory to co-processor memory are not necessary in Kalray. Besides, this architecture offers the possibility to communicate each of the processing elements via a Network on Chip (NoC) connection composed by links and routers [3, 6]. Kalray has been previously used for video encoding and Monte Carlo applications [1]. However, these works lack information of how to implement these applications and what are the most efficient programming strategies and architectonic features to deal with our embedded processor. The NoCs have been recently used as a level in-between the computing cores and shared memory [4, 11, 7]. The NoCs in these systems can be configurable depending on the particular needs of the applications. However, the NoC

in Kalray is completely different. In Kalray, there are two different and independent inter-connectors, one bus which connects each of the processing elements to shared memory and one NoC which connects the different processing elements (clusters) among them.

We have chosen as a test case a widely known and extended problem, that is Jacobi method [10].

The main motivation of this work is twofold. While, on one hand, this work presents the main challenges to deal with the Kalray architecture. On the other hand, we present two different approaches to implement the communication among the different processing elements of our Kalray processor, one based on using shared memory and other based on using a Network on Chip which works as interconnection among the set of processing cores. We detail and analyze deeply each of the approaches presenting theirs advantages and disadvantages. Moreover, we include measurements for power consumption in both approaches.

This paper is structured as follows. Section 2 briefly introduces the main features of the architecture at hand, Kalray. Then, we detail the techniques performed for an efficient implementation of the Jacobi method on Kalray processor in Section 3. Finally, Section 4 contains a performance analysis of the proposed techniques in terms of consuming time, speed-up and power consumption. At the end of this work, we outline some conclusions.

2. Kalray Architecture. Kalray architecture [1] is an embedded many-core processor. It integrates 288 cores on a single 28 nm CMOS chip with a low power consumption per operation. We have 256 cores divided into 16 clusters which are composed by 16+1 cores each. 4 quad-core I/O subsystems (1 core per cluster) are located at the periphery of the processing array (Figure 3.1-left). They are used as DDR controller for accessing to up to 64GB of external DDR3-1600. These subsystems control a 8-lane Gen3 PCI Express for a total peak throughput of 16GB/s full duplex. The 16 compute clusters and the 4 I/O subsystems are connected by two explicitly addressed Network on Chip (NoC) with bi-directional links, one for data and the other for control [1, 2]. NoC traffic does not interfere with the memory buses of the underlying I/O subsystem or compute cluster. The NoC is implemented following a 2-D torus topology.

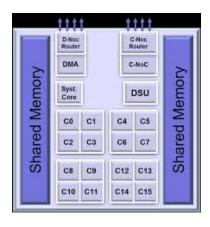

FIGURE 2.1. Kalray MPPA many-core (left) and compute cluster (righ) architecture [1].

The compute cluster (Figure 3.1-right) is the basic processing unit of our architec-

ture [1]. Each cluster contains 16 processing cores (C0,C1,C2,...,C15 in Figure 3.1-right) and one resource management (Syst. Core in Figure 3.1-right) core, a shared memory, a direct memory access (DMA) controller, a Debug & System Unit (DSU), and two routers, one for data (D-NoC) and one for control (C-NoC). The DMA is responsible to transfer data among shared and the NoC with a total throughput of 3.2GB/s in full duplex. The shared memory compromises 2MB organized in 16 parallel banks, and with a bandwidth of 38.4 GB/s. The DSU supports the debug and diagnosis of the compute cluster.

Each processing or resource management core is a 5-way VLIW processor with two arithmetic and logic units, a multiply-accumulate & floating point unit, a load/store unit, and a branch & control unit [1]. It enables up to 2GOPS or 800MFLOPS at 400MHz, which supposes almost 13 GFLOPS per cluster and almost 205GFLOPS in total by using the 16 clusters. These five execution units are connected to a shared register file which allows 11 reads and 4 writes per cycle. Each core is connected to two (data & instruction) separate 2-way associate caches (8KB each).

Kalray provides a software development kit, a GNU C/C++ & GDB development tool for compilation and debugging. Two programming models are currently supported. A high level programming model based on data-flow C language called \sum C [5], where programmers do not care about communication, only data dependencies must be expressed. The other programming model supported is a POSIX-Level programming model [3, 6]. It distributes on I/O subsystems the sub-processes to be executed on the compute clusters and pass arguments through the traditional argc, argv, and environ variables. Inside compute clusters, classic shared memory programming models such as POSIX threads or OpenMP pragmas are supported to exploit more than one processing core. Specific IPC takes advantage of the NoC connection. Unlike \sum C, the POSIX-Level programming model presents more important challenges from programmer side, however it allows us to have more control over hardware and optimize both, communication and computation. In the present work, the authors have followed the programming model based on POSIX.

3. Jacobi Method Implementation on Kalray. We have chosen as test case the Jacobi method [10]. This is a good example which allow us to study and evaluate different strategies for communication. The parallelization is implemented following a coarse-grained distribution of (adjacent) rows across all cores. This implementation is relatively straightforward using a few OpenMP pragmas on the loops that iterate over the rows of our matrix (see Algorithm 1).

One of the most important challenges in Kalray is the communication and memory management. To address the particular features of Kalray architecture, we use the Operating System called NodeOs [6], provided by Kalray. NodeOs implements the Asymmetric Multi-Processing (AMP) model. AMP takes advantage of the asymmetry found in the clusters between the Resource Management Core (RMC) and the Processing Element Cores (PEC). RMC runs the operating system (kernel and NoC routines) on the set of RM (single-core). PEC are dedicated to run user threads, one thread per PEC. PEC can also call functions, such as syscall that are in need of OS support, which are received and compute by RMC. When a PEC executes a syscall call, it sends an event and it is locked until it receives an event from the RMC. This process is necessary to know that the syscall has been processed. Data and parameters are exchanged using shared memory. We have two codes, one to be computed in RMC (IO code) and other (cluster code) which is executed in PECs. The work is distributed following a master/slave model that is well suited to Kalray architecture.

Algorithm 1 Jacobi OpenMP code.

```
1: jacobi(A, Anew, NX, NY)
2: float err;
3: #pragma omp parallel for
 4: for int i = 1 \rightarrow NY - 1 do
       for int j = 1 \rightarrow NX - 1 do
          Anew[i*NX + j] = 0.25*(A[i*NX + (j-1)] + A[i*NX + (j+1)]
6:
                                  +A[(i-1)*NX+j]+A[(i+1)*NX+j]);
7:
          err = maxf(err, fabs(A_{new}[i*NX + j] - A[i*NX + j]));
8:
9:
       end for
10: end for
   #pragma omp parallel for
11:
   for int i = 1 \rightarrow NY - 1 do
12:
       for int j = 1 \rightarrow NY - 1 do
13:
          A[i*NX+j] = Anew[i*NX+j];
14:
       end for
15:
16: end for
```

The *IO* code is the master. It is in charge of launching the code and sending data to be computed by slaves. Finally they wait for the final results. Otherwise, the *cluster* code are the slaves. They wait for data to be computed and send results to IO cluster.

The POSIX-Level programming model of Kalray (NodeOs) allows us to implement the communication among different clusters in two different ways. While shared memory (accessible by all clusters) is used for the communication in the first approach (SM), in the second approach (NoC), we use channels (links) and routers. For sake of clarify, we include several pseudocodes in which we detail the main steps of each of the approaches. Pseudocodes 2 and 3 illustrates the IO and cluster codes for the SM approach and Pseudocodes 4 and 5 for the NoC approach.

The communication is implemented by using some specific objects and functions provided by NodeOS. Next, we explain each of these objects and functions. The transfers from/to global/local memory are implemented via portals. These portals must be initialized using specific paths (one path per cluster) as A_portal in Pseudocode 2. Then, they must be opened (mppa_open) and synchronized (mppa_ioctl) before transferring (mppa_pwrite in Pseudocode 2 and mppa_aio_read in Pseudocode 3) data from/to global/local memory. The slaves are launched from master via mppa_spawn which include parameters and name of the function/s to be computed by cluster/s. The communication among cluster via links (NoC) is implemented by using of channel. Similar to the use of portals, channels must be initialized using one path per channel (see C0_to_C1_channel in Pseudocode 2).

On the other hand, the synchronization is implemented by using of *sync*. They are used to guarantee that some resources are ready to be used or cluster are ready to start computing (for instance, see *mppa_ioctl* in Pseudocodes 2, 3, 4 and 5).

In order to minimize the number of transfers among main and local memory (SM approach) as well as among clusters through links (NoC approach), the matrix is divided into rectangular sub-blocks (Figures 3.1 and 3.2). In particular, the distribution of the workload and communication implemented in the NoC approach avoid multilevel routing, connecting each of the cluster with its adjacent clusters via a direct link

Although, the ghost cells strategy is usually used for communication in distributed memory systems [9], we have used this strategy in Kalray processor to avoid race

Algorithm 2 Shared Memory I/O code.

14: mppa\_aiocb\_t \ Anew\_portal\_aiocb[1] = \{MPPA\_AIOCB\_INITIALIZER\}
                                 (Anew\_portal\_fd, Anew, sizeof(Anew[0]) * SIZE);
15:
16: mppa_aiocb_set_trigger(Anew_portal_aiocb, CLUSTER_COUNT);
17: status = mppa\_aio\_read(Anew\_portal\_aiocb);
18: // - LAUNCHING\_SLAVES - -//
19: char \ arg0[10], arg1[10];
20: const\ char\ *argv[] = arg0, root\_sync, A\_portal, Anew\_portal, 0;
21: for int \ rank = 1 \rightarrow CLUSTER\_COUNT \ do
       sprintf(arg0, "\%d", rank);
22:
       status = \mathbf{mppa\_spawn}(rank, NULL, cluster\_executable, argv, 0);
23:
24: end for
25: // Wait for the cluster portals to be initialized.
26: status = mppa\_read(root\_sync\_fd, \&dummy, sizeof(dummy));
27: // Distribute slices of array A over the clusters.
28: for int \ rank = 0 \rightarrow CLUSTER\_COUNT \ do
       status = \mathbf{mppa\_ioctl}(A\_portal\_fd, MPPA\_TX\_SET\_RX\_RANK, rank);
29:
       status| = \mathbf{mppa\_pwrite}(A\_portal\_fd, (A+rank*SIZE\_LOCAL) - (NX\_LOCAL*)
30:
   2),
31:
       sizeof(float) * SIZE\_LOCAL, 0);
32: end for
33: // Wait for the cluster contributions to arrive in array |Anew|.
34: status = mppa\_aio\_wait(Anew\_portal\_aiocb);
35: return\ status < 0;
```

conditions among each of the sub-blocks assigned to each clusters. The use of ghost cells consists of replicating the borders of all immediate neighbors blocks. These ghost cells are not updated locally, but provide stencil values when updating the borders of local blocks. Every ghost cell is a duplicate of a piece of memory located in neighbors nodes. To clarify, Figures 3.1 and 3.2 illustrate a simple scheme for our interpretation of the ghost cell strategy applied to both approaches, SM and NoC, respectively.

Following these strategies, we ease the programming effort and decrease the pressure on communication.

Figure 3.1 graphically illustrates the strategy followed by the SM approach. It consists of dividing the matrix into equal blocks which are sent from main memory to local memory. To avoid race condition, each of the blocks includes 2 additional rows (gray and white rows in Figure 3.1) which correspond to the upper and lower adjacent rows of the block. These additional rows work as ghost cell only in local memory.

Algorithm 3 Shared Memory CLUSTER code.

```
1: int mainCLUSTER(int argc, char * argv[])
2: int \ i, j, status, rank = atoi(argv[0]);
3: const\ char\ *root\_sync = argv[1], *A\_portal = argv[2], *Anew\_portal = argv[3];
4: float A[SIZE_LOCAL], Anew[SIZE_LOCAL]; long long slice_offset;
5: slice\_offset = sizeof(float) * (CHUNK * NX\_LOCAL +
                           ((rank-1)*(CHUNK-1)*NX\_LOCAL));
7: // Each cluster contributes a different bit to the root_sync mask.
8: long\ long\ mask = (long\ long)1 << rank;
9: //-- OPENING_PORTAL --//
10: int\ root\_sync\_fd = \mathbf{mppa\_open}(root\_sync, O\_WRONLY);
11: int A\_portal\_fd = \mathbf{mppa\_open}(A\_portal, O\_RDONLY);
12: int\ Anew\_portal\_fd = \mathbf{mppa\_open}(Anew\_portal, O\_WRONLY);
13: //-- PREPARE_FOR_INPUT --//
14: mppa\_aiocb\_tA\_portal\_aiocb[1] =
         MPPA\_AIOCB\_INITIALIZER(A\_portal\_fd, A, sizeof(A));
15:
16: status = mppa\_aio\_read(A\_portal\_aiocb);
17: //--UNLOCK\_MASTER--//
18: status = mppa\_write(root\_sync\_fd, \&mask, sizeof(mask));
19: // Wait for notification of remote writes to local arrays |A|.
20: status = mppa\_aio\_wait(A\_portal\_aiocb);
21: //- JACOBIANCOMPUTE - -//
22: jacobi(A, Anew, NX\_LOCAL, NY\_LOCAL);
23: // Contribute back local array Anew into the portal of master array Anew.
24: status = mppa_pwrite(Anew_portal_fd, & Anew[NX_LOCAL],
                          sizeof(Anew) - sizeof(float) * 2 * NX\_LOCAL, slice\_offset);
26: mppa\_exit((status < 0)); return 0;
```

The blocks transferred from local memory to global memory (Figure 3.1-right) do not include these additional rows (ghost rows).

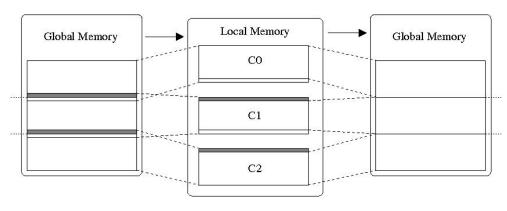

Figure 3.1. Master (Global Memory) \leftrightarrow Slave (Local Memory) Communication.

Otherwise the communication among global and local memory is not necessary in the NoC approach. The master (IO code) is only used for synchronizing. The synchronization is necessary at the beginning and at the end of each master code. I/O core and the rest of cores in each of the clusters must be also synchronized. In particular the synchronization between IO core and computing cores (I/O->

Algorithm 4 NoC I/O code.

```
1: const\ char\ *global\_sync = "/mppa/sync/128 : 1";
2: const\ char\ *IO\_to\_C0\_sync="/mppa/sync/0:2"; \dots
3: const\ char\ *C0\_to\_C1\_channel = "/mppa/channel/1:1/0:1";...
4: static\ const\ char\ *exe[CLUSTER\_COUNT] = {"mainCLUSTER0"},
               "mainCLUSTER1", . . . };
6: int mainIO(int \ argc, const \ char \ * argv[])
7: // Global sync.
8: int\ ret, global\_sync\_fd = \mathbf{mppa\_open}(global\_sync, O\_RDONLY);
9: long\ long\ match = -(1 << CLUSTER\_COUNT);
10: mppa_ioctl(qlobal_sync_fd, MPPA_RX_SET_MATCH, match));
11: // - -IO_TO_C#_SYNC - -//
12: int\ IO\_to\_CO\_sync\_fd = mppa\_open(IO\_to\_CO\_sync, O\_WRONLY);
13: int\ IO\_to\_C1\_sync\_fd = \mathbf{mppa\_open}(IO\_to\_C1\_sync, O\_WRONLY); \dots
14: // - LAUNCHING\_SLAVES - -//
15: for int i = 0 \rightarrow CLUSTER\_COUNT do
16:
      mppa\_spawn(i, NULL, exe[i], argv, 0);
17: end for
18: // Wait for other clusters to be ready.
19: mppa_read(global_sync_fd, NULL, 8);
20: // Write into I/O->C\# sync to unlock C\# cluster.
21: mask = 1; mppa\_write(IO\_to\_CO\_sync\_fd, \&mask, sizeof(mask));
22: mppa_write(IO\_to\_C1\_sync\_fd, \&mask, sizeof(mask)); ...
23: // - -WAITING TO THE END OF CLUTERS EXECUTION - -//
24: for int i = 0 \rightarrow CLUSTER\_COUNT do
      ret = mppa\_waitpid(i, \&status, 0); mppa\_exit(ret);
26: end for
```

C1 sync section in Pseudocode 5) is necessary to guarantee that there are no cluster reading into channels before the corresponding cluster has opened the channel. After computing the Jacobi method in each of the clusters, some rows of the local blocks must be transferred to/from adjacent clusters. The first row computed (white upper row C1 in Figure 3.2) must be transferred to the upper adjacent cluster (C0) to be stored in the last row. Also, the last row computed (gray lower row C1 in Figure 3.2) must be transferred to the lower adjacent cluster (C2) to be stored in the first row. This pattern must be carried out in all clusters except the first and last clusters where a lower number of transferences is necessary.

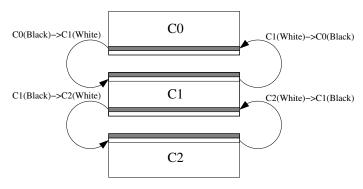

Figure 3.2. Pipeline (Bus) Communication.

Algorithm 5 NoC CLUSTER code

```
1: int mainCLUSTER1(int argc, char * argv[])
2: float A[SIZE_LOCAL], Anew[SIZE_LOCAL];
3: // Open all the resources needed for transfers.
4: //Global sync.
5: int \ global\_sync\_fd = \mathbf{mppa\_open}(global\_sync, O\_WRONLY);
6: // C1 -> C2 channel.
7: int channel0\_fd = mppa\_open(C1\_to\_C2\_channel, O\_WRONLY);
8: // C2-> C1 channel.
9: int channel1\_fd = mppa\_open(C2\_to\_C1\_channel, O\_RDONLY);
10: // C1 -> C0 channel.
11: int channel2\_fd = \mathbf{mppa\_open}(C1\_to\_C0\_channel, O\_WRONLY);
12: // C0-> C1 channel.
13: int channel3\_fd = mppa\_open(C0\_to\_C1\_channel, O\_RDONLY);
14: // I/O - > C1 sync.
15: int\ IO\_to\_C1\_sync\_fd = \mathbf{mppa\_open}(IO\_to\_C1\_sync, O\_RDONLY);
16: long\ long\ match = -(1 << 1/* We\ sync\ only\ with\ I/O\ cluster\ */);
17: mppa\_ioctl(IO\_to\_C1\_sync\_fd, MPPA\_RX\_SET\_MATCH, match)
18: // Write into global sync to unlock I/O cluster.
19: long\ long\ mask = 1 << mppa_getpid();
20: mppa_write(global_sync_fd, &mask, sizeof(mask))
21: // - \text{WAIT\_FOR\_IO\_TO\_C1\_SYNC} - -//
22: mppa_read(IO\_to\_C1\_sync\_fd, NULL, 8);
23: // -- CLUSTERS COMMUNICATION --//
24: // Write data for cluster 0.
25: mppa\_write(channel0\_fd, &A[NX\_LOCAL * (NY\_LOCAL - 2)], size of(float) *
   NX\_LOCAL);
26: // Read data from C0.
27: mppa\_read(channel1\_fd, A, sizeof(float) * NX\_LOCAL);
28: // Read data from C2.
29: mppa\_write(channel2\_fd, \&A[NX\_LOCAL], sizeof(float) * NX\_LOCAL);
30: // Write data for cluster 2.
31: mppa\_read(channel3\_fd, \&A[NX\_LOCAL * (NY\_LOCAL - 1)], sizeof(float) *
   NX\_LOCAL);
32: mppa_exit(0);
```

4. Performance Study. In this section, we analyze deeply both approaches, SM and NoC, focusing on communication, synchronization and computing separately. In order to find/focus on the performance of both approaches, we have used a relatively small problem which can be full stored in local memory.

Next we present the commands used to compile and launch both approaches: Compiling lines:

```
Compining lines. k1-gcc-O3-std=c99-mos=rtems\ io.c\ -o\ io\_app\ -lmppaipc k1-gcc-O3-std=c99-fopenmp-mos=nodeos\ cluster.c\ -o\ cluster\ -lmppaipc k1-create-multibinary-cluster\ cluster-boot=io\_app\ -T\ multibin Launching line: k1-jtag-runner--multibinary\ multibin--exec-multibin=IODDR0: io\_app
```

The communication among I/O and computing cores in the NoC approach is more complex and it is in need of a higher number of synchronizations. This causes a higher execution time to compute the synchronizations with respect to the SM

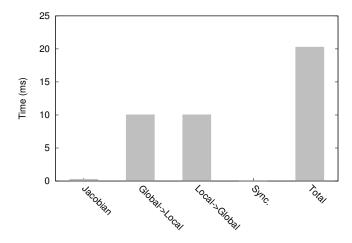

Figure 4.1. Time consumption for the SM approach.

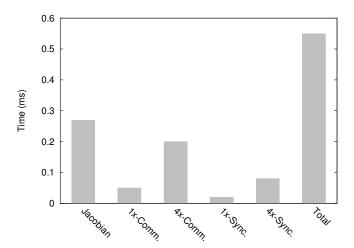

Figure 4.2. Time consumption for the NoC approach.

approach, being almost $2.5 \times$ bigger (Figures 4.1 and 4.2). Note that we use a different vertical scaling in each of the graphics illustrated in Figures 4.1 and 4.2. Despite of the overhead caused by a higher number of synchronizations, the use of the NoC interconnection makes the NoC approach (Figure 4.2) about $55 \times$ faster than the SM approach.

As expected the time consumed for computing the Jacobi method is equivalent in both approaches. The time consumed by synchronization, communication and computing in the NoC approach is more balanced than in the SM approach. This can be beneficial for future improvements, such as asynchronous communication.

Finally, we analyse the performance in terms of GFLOPS. First, we compute the theoretical FLOPS for the Jacobi computation. The variant used in this study performs six flops per update (Algorithm 1). Therefore, the theoretical FLOPS is equal to the elements of our matrix multiplied by six.

In order to evaluate the overhead of each of the strategies, first, we show the GFLOPS achieved by the Jacobi computation without the influence of the synchronization and communication (see Jacobian in Figure 4.3). It achieves almost the peak of performance of our platform (GFLOPS-Peak in Figure 4.3). The computation of the Jacobian method is exactly the same in both approaches (SM and NoC). Next, we include the overhead of the communication. Although both approaches present a fall in performance when taking into account the time consumed by the communication, the fall shown by the NoC approach is not so dramatic as the overhead suffered by the SM approach (Figure 4.3).

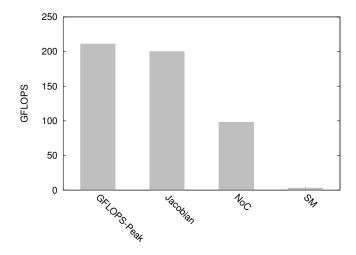

Figure 4.3. GFLOPS achieved by both approaches.

The software development kit provided by Kalray allow us to measure the power consumption of our applications. This is done via this command:

 $k1-power--k1-jtag-runner--multibinary\ multibin--exec-multibin=IODDR0: io_app$

Executing our binary using k1-power we obtain the power achieved in terms of Watts. The average power achieved by the NoC approach is about 8.508W, while the SM approach achieves an average of 5.778W in every execution. This is almost a 50% more power when executing the NoC approach. However, the reduction in execution time obtained by the NoC approach has an important impact on the overall power consumed. Given that the Joules are computing by following the next expression:

 $Joules = Watts \times Time$

We obtain an overall consumption about 0.0047J and 0.16J for the NoC and the SM approaches respectively. This is a 96% less of power consumed by the NoC approach.

5. Conclusions and Future Work. Embedded many-core architectures such as Kalray have emerged as a new HPC platform to deal with the problem of the excessive power consumption.

In this work, we have presented two different approaches to implement the communication among the processing elements of the Kalray architecture. Both approaches implement a ghost-cell strategy to avoid race conditions among the different blocks assigned to each of the processing elements (clusters). This strategy has been adapted to the particular features of our embedded processor and approaches, SM and NoC, to minimize the number of transfers.

Although the communication via shared memory is more habitual and easier to implement on many-core architectures, the particular features of the Kalray architecture, in particular the communication via Message-Passing on NoC connection, offers a much faster alternative. Although, the use of NoC needs a higher power, the reduction in time makes to this approach more efficient in terms of power consumption.

We plan to investigate other problems and more efficient strategies for memory management and data distribution, such as the overlapping of communication and computing via asynchronous transfers. In particular, the NoC approach could take advantage of the asynchronous communication as the time consumed by its major steps is balanced.
