Pure type systems with judgemental equality

ROBIN ADAMS*

Abstract

In a typing system, there are two approaches that may be taken to the notion of equality. One can use some external relation of convertibility defined on the terms of the grammar, such as β-convertibility or $\beta\eta$-convertibility; or one can introduce a judgement form for equality into the rules of the typing system itself. For quite some time, it has been an open problem whether the two systems produced by these two choices are equivalent. This problem is essentially the problem of proving that the Subject Reduction property holds in the system with judgemental equality. In this paper, we shall prove that the equivalence holds for all functional Pure Type Systems (PTSs). The proof essentially consists of proving the Church-Rosser Theorem for a typed version of parallel one-step reduction. This method should generalise easily to many typing systems which satisfy the Uniqueness of Types property.

1 Introduction

When defining a typing system with dependent types, there are two approaches that may be taken to the notion of equality. Firstly, we can use some external syntactic relation defined on the terms of the grammar, such as β-convertibility or $\beta\eta$-convertibility, as our criterion for equality. This is the method followed by Pure Type Systems (Barendregt, 1992; van Benthem Jutting, 1993), as well as the Calculus of Constructions (Coquand & Huet, 1988) and the Edinburgh Logical Framework (Harper *et al.*, 1993). In such a system, we typically have a rule of the following form, for replacing a type with a convertible type:

$$\frac{\Gamma \vdash M : A \quad \Gamma \vdash B \text{ type}}{\Gamma \vdash M : B} \, (A \simeq B)$$

where $\simeq$ denotes the external convertibility relation, defined without reference to the judgement forms. We shall refer to such systems as type theories with *external equality*.

The second approach is to introduce separate judgement forms,

$$\Gamma \vdash M = N : A \text{ and } \Gamma \vdash A = B,$$

for equality of objects and types, and use these judgement forms in the system's rules of deduction. This is the way in which Martin-Löf's Type Theory and Logical

---

Framework (Nordström *et al.*, 1990) are normally presented, as well as the recent logical framework PAL$^+$ (Luo, 2003), for example. In such a type theory, the rule above is typically replaced with a rule such as

$$\frac{\Gamma \vdash M : A \quad \Gamma \vdash A = B}{\Gamma \vdash M : B}$$

making use of the judgement form for equality of types. We shall refer to such systems as type theories with *judgemental equality*.

For some time, it has been an open question whether the two systems thus produced are equivalent. It would certainly seem to be an important problem, for the presentation with judgemental equality is usually the more convenient to use for theoretical considerations, while almost every implementation of a type system uses an external relation of convertibility to decide equality of terms or types.

The only difficulty in proving the equivalence of the two systems is the establishment of the Subject Reduction property for the system with judgemental equality:

Subject Reduction
If $\Gamma \vdash M : A$ and $M \twoheadrightarrow_\beta N$, then $\Gamma \vdash M = N : A$.

For such a system, Subject Reduction is essentially the claim that every reduction possible within the external notion of reducibility is reflected by an appropriate equality judgement. Subject Reduction is an important property of type theories with external equality, and establishing that it holds for systems with judgemental equality would also seem to be an important problem.

The problem of the equivalence of the two approaches to equality is mentioned for PTSs with $\beta\eta$-convertibility in Geuvers (1993). The first positive result in this direction was in Coquand (1991), where the equivalence for the system there called Type Theory follows easily as a corollary of the main result. It is also possible, for some systems, to prove the equivalence using the technique of typed operational semantics (Goguen, 1994; Goguen, 1999).

However, both these proof methods rely essentially on the normalisation properties of the type system concerned. This limits the class of systems to which such methods can be applied: normalisability does not hold for every type system, and is notoriously difficult to establish when it does.

In this paper, we shall prove that the equivalence holds for all functional Pure Type Systems (PTSs) (Barendregt, 1992), both normalising and non-normalising; indeed, the proof method is entirely independent of normalisability.

The proof relies essentially on mimicking, in a typed environment, the proof of the Church-Rosser theorem for untyped reduction that uses *parallel reduction*. We define a relation of *typed parallel one-step reduction* (TPOSR)

$$\Theta \models M \rhd N : A,$$

and prove that it satisfies the diamond property. For the system with judgemental equality, we find ourselves able to prove subject reduction with respect to this typed reduction, whereas we were unable to do so with untyped reduction. Once we have

this result, the remainder of the proof is straightforward. Subject Reduction with respect to the untyped reduction follows easily as a corollary.

The method relies heavily on the Uniqueness of Types property, so it does not seem likely it could be extended to an arbitrary PTS; however, it would seem very plausible that it could be adapted to a large number of typing systems that satisfy Uniqueness of Types but cannot be defined as PTSs; for example, the method should easily adapt to cope with the local definitions of PAL$^+$ (Luo, 2003), or the inductive types of UTT (Luo, 1994).

2 Pure type systems

Given a specification **S**, we form the PTS λ**S** as usual, with a single judgement form, $\Gamma \vdash M : A$. We also form a system $\lambda_=$**S**, a *PTS with equality*, with two judgement forms, $\Gamma \vdash^e M : A$ and $\Gamma \vdash^e M = N : A$. We shall give these details fairly briefly; there is a wealth of literature on PTSs, and there is not too much that is innovative in the definition of $\lambda_=$**S**.

2.1 Grammar

A *PTS specification* **S** consists of:

- A set $\mathscr{S}$ of *sorts*. We shall use s and t, possibly adorned with subscripts or accents, as metavariables for sorts.
- A binary relation $\mathscr{A} \subseteq \mathscr{S}^2$ of *axioms*. We write the axiom (s, t) as

$$s : t$$

  Informally, the axiom $s : t$ indicates that the sort s is an object whose type is the sort t.
- A ternary relation $\mathscr{R} \subseteq \mathscr{S}^3$ of *rules*.
  Informally, the rule (s_1, s_2, s_3) indicates that, whenever A is of type s_1 and, given $x : A$, B is of type s_2, then $\Pi x : A.B$ exists and has type s_3.

We also provide ourselves with an infinite set $\mathscr{V}$ of *variables*. We shall use x, y and z, possibly adorned, as metavariables for variables.

Given a specification **S** – in fact, given just the set $\mathscr{S}$ of sorts – the set of *terms* is defined by the grammar

$$\text{Term } M ::= x \mid s \mid \Pi x : M.M \mid \lambda x : M.M \mid MM$$

where x denotes an arbitrary variable and s an arbitrary sort. x is bound within B but not A in the terms $\Pi x : A.B$ and $\lambda x : A.B$. We identify terms up to α-convertibility. We shall use capital letters as metavariables for terms.

We define the relations of

one-step beta reduction	$\rightarrow_\beta$
beta reduction	$\twoheadrightarrow_\beta$
beta conversion	$\simeq_\beta$
parallel one-step reduction	$\twoheadrightarrow^1_\beta$

as usual, based on the contraction

$$(\lambda x : A.M)N \rightsquigarrow_\beta [N/x]M$$

For reference, the inductive definitions we are using for these relations are given in Appendix A.

Theorem 2.1 (*Church-Rosser*)
If $M \simeq_\beta N$, then there exists a term P such that $M \twoheadrightarrow_\beta P$ and $N \twoheadrightarrow_\beta P$.

Proof
There are many different proofs of this theorem. In Barendregt (1992), a proof is given that uses the technique of *underlining*. For a simpler proof using parallel reduction (see Luo, 1994). □

A *context* Γ is a sequence of pairs

$$x_1 : A_1, \ldots, x_n : A_n$$

where $x_1, \ldots, x_n$ are variables, all distinct, and $A_1, \ldots, A_n$ are terms. Its *domain*, dom Γ, is defined to be the set

$$\{x_1, \ldots, x_n\}$$

We also recall that we say a specification **S** is *functional* iff the following two conditions hold:

- If $s : t, s : t' \in \mathscr{A}$, then $t \equiv t'$.
- If $(s_1, s_2, s_3), (s_1, s_2, s_3') \in \mathscr{R}$, then $s_3 \equiv s_3'$.

In Barendregt (1992), it is proven that a PTS with a functional specification has the Uniqueness of Types property.

2.2 Pure type systems

Given a specification **S**, the *Pure Type System* (*PTS*) λ**S** is the system defined as follows.

A *judgement* in λ**S** is an expression of the form

$$\Gamma \vdash M : A$$

where Γ is a context and M and A are terms. The rules of deduction of λ**S** are given in Figure 1.

The best reference for the basic metatheory of PTSs is still Barendregt (1992), and we shall freely use results from this paper. The only result about PTSs we shall need that is not explicitly given there is Context Conversion:

Lemma 2.2 (*Context Conversion*)
If $\Gamma, x : A, \Delta \vdash M : B$, $\Gamma \vdash A' : s$, and $A \simeq_\beta A'$, then

$$\Gamma, x : A', \Delta \vdash M : B.$$

This result is an easy corollary of the Weakening and Transitivity lemmas proved in Barendregt (1992).

(axioms)	$$\dfrac{}{\vdash s : t}$$	$(s : t \in \mathscr{A})$
(start)	$$\dfrac{\Gamma \vdash A : s}{\Gamma, x : A \vdash x : A}$$	$(x \notin \operatorname{dom} \Gamma)$
(weak)	$$\dfrac{\Gamma \vdash M : A \quad \Gamma \vdash B : s}{\Gamma, x : B \vdash M : A}$$	$(x \notin \operatorname{dom} \Gamma)$
(product)	$$\dfrac{\Gamma \vdash A : s_1 \quad \Gamma, x : A \vdash B : s_2}{\Gamma \vdash \Pi x : A.B : s_3}$$	$((s_1, s_2, s_3) \in \mathscr{R})$
(application)	$$\dfrac{\Gamma \vdash M : \Pi x : A.B \quad \Gamma \vdash N : A}{\Gamma \vdash MN : [N/x]B}$$	
(abstraction)	$$\dfrac{\Gamma, x : A \vdash M : B \quad \Gamma \vdash A : s_1 \quad \Gamma, x : A \vdash B : s_2}{\Gamma \vdash \lambda x : A.M : \Pi x : A.B}$$	$((s_1, s_2, s_3) \in \mathscr{R})$
(conversion)	$$\dfrac{\Gamma \vdash M : A \quad \Gamma \vdash B : s}{\Gamma \vdash M : B}$$	$(A \simeq_\beta B)$

Fig. 1. The rules of deduction of a pure type system.

2.3 Pure type systems with judgemental equality

The system $\lambda_= \mathbf{S}$, a *Pure Type System with Equality*, is defined as follows.

A *judgement* of $\lambda_= \mathbf{S}$ is an expression either of the form

$$\Gamma \vdash^e M : A$$

or

$$\Gamma \vdash^e M = N : A.$$

The rules of deduction of $\lambda_= \mathbf{S}$ are given in Figures 2 and 3. Note that they do not make use of any externally-defined notion of convertibility.

We can develop the metatheory of PTSs with equality quite some way; several lemmas are proven in the Appendix B. However, we find ourselves unable to prove Subject Reduction. See section 3.1 for further discussion on this point.

Our aim in this paper is to prove the following theorem (Theorem 4.6):

Theorem

If $\mathbf{S}$ is a functional specification, then

1. $\Gamma \vdash^e M : A$ iff $\Gamma \vdash M : A$.
2. $\Gamma \vdash^e M = N : A$ iff $\Gamma \vdash M : A$, $\Gamma \vdash N : A$, and $M \simeq_\beta N$.

One direction – left-to-right – is easy in each case, and can be proven for an arbitrary PTS:

(ax)	$$\overline{\vdash^e s : t}$$	$(s : t \in \mathscr{A})$
(var)	$$\frac{\Gamma \vdash^e A : s}{\Gamma, x : A \vdash^e x : A}$$	$(x \notin \operatorname{dom} \Gamma)$
(weak)	$$\frac{\Gamma \vdash^e M : A \quad \Gamma \vdash^e B : s}{\Gamma, x : B \vdash^e M : A}$$	$(x \notin \operatorname{dom} \Gamma)$
(weak-eq)	$$\frac{\Gamma \vdash^e M = N : A \quad \Gamma \vdash^e B : s}{\Gamma, x : B \vdash^e M = N : A}$$	$(x \notin \operatorname{dom} \Gamma)$
(prod)	$$\frac{\Gamma \vdash^e A : s_1 \quad \Gamma, x : A \vdash^e B : s_2}{\Gamma \vdash^e \Pi x : A.B : s_3}$$	$((s_1, s_2, s_3) \in \mathscr{R})$
(prod-eq)	$$\frac{\Gamma \vdash^e A = A' : s_1 \quad \Gamma, x : A \vdash^e B = B' : s_2}{\Gamma \vdash^e \Pi x : A.B = \Pi x : A'.B' : s_3}$$	$((s_1, s_2, s_3) \in \mathscr{R})$
(lambda)	$$\frac{\Gamma, x : A \vdash^e M : B \quad \Gamma \vdash^e A : s_1 \quad \Gamma, x : A \vdash^e B : s_2}{\Gamma \vdash^e \lambda x : A.M : \Pi x : A.B}$$	$((s_1, s_2, s_3) \in \mathscr{R})$
(lambda-eq)	$$\frac{\Gamma, x : A \vdash^e M = M' : B \quad \Gamma \vdash^e A = A' : s_1 \quad \Gamma, x : A \vdash^e B : s_2}{\Gamma \vdash^e \lambda x : A.M = \lambda x : A'.M' : \Pi x : A.B}$$	$((s_1, s_2, s_3) \in \mathscr{R})$
(app)	$$\frac{\Gamma \vdash^e M : \Pi x : A.B \quad \Gamma \vdash^e N : A}{\Gamma \vdash^e MN : [N/x]B}$$	
(app-eq)	$$\frac{\Gamma \vdash^e M = M' : \Pi x : A.B \quad \Gamma \vdash^e N = N' : A}{\Gamma \vdash^e MN = M'N' : [N/x]B}$$	

Fig. 2. The rules of deduction of a pure type system with equality.

Theorem 2.3

1. If $\Gamma \vdash^e M : A$, then $\Gamma \vdash M : A$.

2. If $\Gamma \vdash^e M = N : A$, then $\Gamma \vdash M : A$, $\Gamma \vdash N : A$, and $M \simeq_\beta N$.

The proof is by induction on the derivation of the premise in $\lambda_=\mathbf{S}$. No case is very difficult, if we have the results of Barendregt (1992) to hand.

The right-to-left direction would be just as simple if only we could use Subject Reduction for the system with judgemental equality. Without it, the proof is very difficult; the remainder of this paper is devoted to this proof (Theorem 4.5). Subject Reduction shall follow as a corollary of this work (Corollary 5.3).

$$\text{(ref)} \quad \frac{\Gamma \vdash^e M : A}{\Gamma \vdash^e M = M : A}$$

$$\text{(sym)} \quad \frac{\Gamma \vdash^e M = N : A}{\Gamma \vdash^e N = M : A}$$

$$\text{(trans)} \quad \frac{\Gamma \vdash^e M = N : A \quad \Gamma \vdash^e N = P : A}{\Gamma \vdash^e M = P : A}$$

$$\text{(conv)} \quad \frac{\Gamma \vdash^e M : A \quad \Gamma \vdash^e A = B : s}{\Gamma \vdash^e M : B}$$

$$\text{(conv-eq)} \quad \frac{\Gamma \vdash^e M = N : A \quad \Gamma \vdash^e A = B : s}{\Gamma \vdash^e M = N : B}$$

$$\text{(beta)} \quad \frac{\Gamma, x : A \vdash^e M : B \qquad \Gamma \vdash^e N : A}{\Gamma \vdash^e A : s_1 \qquad \Gamma, x : A \vdash^e B : s_2}{\Gamma \vdash^e (\lambda x : A.M)N = [N/x]M : [N/x]B} \quad ((s_1, s_2, s_3) \in \mathscr{R})$$

Fig. 3. The rules of deduction of a pure type system with equality.

3 Typed parallel one-step reduction

3.1 Digression: The naïve solution

To provide extra motivation for the various definitions we are about to introduce, and to show from where the idea for our proof method came, let us examine what goes wrong in a naïve attempt to solve the problem we have outlined. We attempt to prove

$$\text{If } \Gamma \vdash M : A \text{ then } \Gamma \vdash^e M : A$$

by induction on the derivation of $\Gamma \vdash M : A$. The only case that gives any difficulty is the rule

$$\text{(conversion)} \frac{\Gamma \vdash M : A \quad \Gamma \vdash B : s}{\Gamma \vdash M : B} (A \simeq_\beta B)$$

By the induction hypothesis, $\Gamma \vdash^e M : A$ and $\Gamma \vdash^e B : s$. We can also show that $\Gamma \vdash^e A : t$ for some sort t.

By Church-Rosser, there is a term C such that

$$A \twoheadrightarrow_\beta C, \quad B \twoheadrightarrow_\beta C$$

If only we could prove Subject Reduction for $\lambda_= \mathbf{S}$:

Conjecture 1 (*Subject Reduction*)
If $\Gamma \vdash^e M : A$ and $M \twoheadrightarrow_\beta N$, then $\Gamma \vdash^e M = N : A$.

Then we could conclude $\Gamma \vdash^e A = C : t$ and $\Gamma \vdash^e B = C : s$, and the result $\Gamma \vdash^e M : B$ would follow by two applications of (conv). Unfortunately, Subject Reduction is very difficult to prove for $\lambda_= \mathbf{S}$.

What goes wrong when we try to prove Subject Reduction by the same method that we use for ordinary PTSs? That is, we attempt to prove simultaneously

1. If $\Gamma \vdash^e M : A$ and $\Gamma \to_\beta \Delta$, then $\Delta \vdash^e M : A$.
2. If $\Gamma \vdash^e M : A$ and $M \to_\beta N$, then $\Gamma \vdash^e M = N : A$.

The difficult case, as is to be expected, is where the premise is derived by

$$\text{(app)}\ \frac{\Gamma \vdash^e \lambda x : A.M : \Pi x : B.C \quad \Gamma \vdash^e N : B}{\Gamma \vdash^e (\lambda x : A.M)N : [N/x]C}$$

and the reduction involved is $(\lambda x : A.M)N \to_\beta [N/x]M$.

Inverting the first premise, there must be a rule $(s_1, s_2, s_3) \in \mathcal{R}$ such that the premise was derived from

$$
\begin{aligned}
\Gamma, x : A \quad &\vdash^e \quad M : D \\
\Gamma \quad &\vdash^e \quad A : s_1 \\
\Gamma, x : A \quad &\vdash^e \quad B : s_2
\end{aligned}
$$

followed by several judgements of the form:

$$\Gamma \vdash^e \Pi x : A.D = X_1 : t_1,\ \Gamma \vdash^e X_1 = X_2 : t_2, \ldots, \Gamma \vdash^e X_n = \Pi x : B.C : t_{n+1} \quad (1)$$

We wish to conclude

$$\Gamma \vdash^e (\lambda x : A.M)N = [N/x]M : [N/x]C.$$

The obvious way to do so is to use the (beta) rule. To do so, we can try to derive the premise

$$\Gamma \vdash^e N : A$$

to yield $\Gamma \vdash^e (\lambda x : A.M)N = [N/x]M : [N/x]D$, then try to prove $\Gamma \vdash^e [N/x]C = [N/x]D : t$ for some t. Or we can try to derive

$$\Gamma, x : B \vdash^e M : C,$$

from which the desired conclusion would follow immediately.

In either case, we would seem to need a lemma of this form:

Conjecture 2 (*Injectivity of* Π)
If $\Gamma \vdash^e \Pi x : A.D = \Pi x : B.C : s_3$, then there are sorts s_1, s_2 such that $(s_1, s_2, s_3) \in \mathcal{R}$, and

$$\Gamma \vdash^e A = B : s_1, \qquad \Gamma, x : A \vdash^e D = C : s_2 \quad (2)$$

There is no obvious way to prove this statement, as the premise may have been derived via the (trans) rule from a series of judgements of the form

$$\Gamma \vdash^e \Pi x : A.C = X_1 : Y_1,\ \Gamma \vdash^e X_1 = X_2 : Y_2,\ \cdots,\ \Gamma \vdash^e X_n = \Pi x : B.D : Y_{n+1}$$

and the terms $X_1, X_2, \ldots, X_n$ may not be Π-terms. Of course, they must reduce to Π-terms; but, as we have not yet proven Subject Reduction, this fact is of little use to us.

We meet a similar problem when proving Subject Reduction for traditional PTSs; we must conclude, from

$$\Pi x : A.D \simeq_\beta \Pi x : B.C,$$

that

$$A \simeq_\beta B, \quad C \simeq_\beta D.$$

This is quite easily done, using the Church-Rosser Theorem.

Can we do something similar for PTSs with equality? The Church-Rosser Theorem can be proven using parallel one-step reduction. Can we find a relation that plays the same role for PTSs with equality? We need a relation $\Gamma \models M \rhd N : A$ that:

- satisfies the diamond property: if $\Gamma \models M \rhd N : A$ and $\Gamma \models M \rhd P : A$, then there is a term Q such that $\Gamma \models N \rhd Q : A$ and $\Gamma \models P \rhd Q : A$;
- generates the judgemental equality: $\Gamma \vdash^e M = N : A$ is the symmetric, transitive closure of $\Gamma \models M \rhd N : A$;
- respects the formation of Π-types: if $\Gamma \models \Pi x : A.B \rhd C : s_3$, then there are terms A', B' and sorts s_1, s_2 such that $(s_1, s_2, s_3) \in \mathscr{R}$, $\Gamma \models A \rhd A' : s_1$, $\Gamma, x : A \models B \rhd B' : s_2$, and $C \equiv \Pi x : A'.B'$.
- satisfies Uniqueness of Types: if $\Gamma \models M \rhd N : A$ and $\Gamma \models M \rhd P : B$, then either A and B are the same sort, or $\Gamma \models A \simeq B : s$ for some sort s.

(Here, $\Gamma \models A \simeq B : s$ is the equivalence relation generated by $\Gamma \models A \rhd B : s$.) If so, then we could prove Conjecture 2 above.

It so happens we can give such a relation for a set of *labelled* terms, in which each application is tagged with the codomain of the applied function. That is, the term constructor for application is of the form

$$\mathrm{app}_{(x)B}(MN)$$

for M a term of type $\Pi x : A.B$ and N a term of type A.

We shall call the relation $\Theta \models M \rhd N : A$ *typed parallel one-step reduction*, or *TPOSR*, thanks to the analogy between its definition and the definition of parallel one-step reduction in the untyped case. As long as we have the Uniqueness of Types property, the obvious translation from labelled to unlabelled terms

$$M \mapsto |M|$$

is a bijection (up to β-convertibility) between the typable unlabelled terms and the labelled terms typable by TPOSR.

We can define the relation of typed parallel one-step reduction for such a set of terms; the definition is in Figure 4. We could now go on to complete the proof via the method sketched out above. However, now that we have the relation of typed parallel one-step reduction and its Church-Rosser property, a more direct method is open to us. We establish the following lemmas:

Completeness of TPOSR for PTSs If $\Gamma \vdash M : A$, then there exist Γ^+, M^+, A^+ such that $|\Gamma^+| \equiv \Gamma$, $|M^+| \equiv M$, $|A^+| \equiv A$, and $\Gamma^+ \models M^+ \rhd M^+ : A^+$. (Theorem 4.4)

Subject Reduction If $\Theta \models M \vartriangleright X : A$ and $M \twoheadrightarrow^1_\beta N$, then $\Theta \models M \vartriangleright N : A$. (Theorem 3.10)

Soundness of TPOSR for PTSs with Equality If $\Theta \models M \vartriangleright N : A$ then $|\Theta| \vdash^e |M| = |N| : |A|$. (Theorem 3.5)

Given these three lemmas, the proof of the correspondence between PTSs and PTSs with equality is quite simple (Theorem 4.5).

The Need for Labelled Terms It is perhaps worth noting where exactly the proof breaks down if we try to use unlabelled terms rather than labelled terms.

Let us denote by $\Theta \models A \simeq B : s$ the symmetric, transitive closure of the relation $\Theta \models A \vartriangleright B : s$. We shall need the following three results about TPOSR:

Uniqueness of Types (UT)
  If $\Theta \models M \vartriangleright N : A$ and $\Theta \models M \vartriangleright P : B$, then either $A \equiv B$, or there is a sort s such that $\Theta \models A \simeq B : s$.

Church-Rosser (CR)
  If $\Theta \models M \vartriangleright N : A$ and $\Theta \models M \vartriangleright P : B$, then there exists Q such that

$$\Theta \models N \vartriangleright Q : A \qquad\qquad \Theta \models P \vartriangleright Q : A$$
$$\Theta \models N \vartriangleright Q : B \qquad\qquad \Theta \models P \vartriangleright Q : B$$

Injectivity of Π (Inj(Π))
  If $\Theta \models \Pi x : A.B \simeq \Pi x : C.D : s_3$, then there are sorts s_1, s_2 such that $(s_1, s_2, s_3) \in \mathscr{R}$ and

$$\Theta \quad \models \quad A \simeq C : s_1$$
$$\Theta, x : A \quad \models \quad B \simeq D : s_2$$

With unlabelled terms, we are able to prove the circle of implications:

$$\text{UT} \Rightarrow \text{CR} \Rightarrow \text{Inj}(\Pi) \Rightarrow \text{UT}$$

but we find ourselves unable to prove any one of these individually. In particular, we require Injectivity of Π to prove Uniqueness of Types in the case where M is an application.

With labelled terms, we have a way in: we are able to prove Uniqueness of Types. In particular, in the case in which M is a (labelled) application, $\text{app}_{(x)D}(QR)$, say, then A and B must each be convertible with $[R/x]D$.

The idea of adding typing information to applications has been used several times before; Streicher (1991), for example, uses typed applications to give semantics to the Calculus of Constructions, and examines in detail the relationship between such a system and a system with untyped application.

We have chosen to label applications only with the codomain, not the domain: we do not give applications the form

$$\text{app}_{\Pi x : A.B}(MN).$$

If we did, then the reduction rule for labelled terms would not be *left-linear*, in the terminology of Combinatory Reduction Systems. We would need to decide when we

could contract a redex of the form

$$\text{app}_{\Pi x:A.B}((\lambda x : C.M)N).$$

Do we insist that A and C be identical terms, convertible terms, or do we impose no restriction? Each of these choices leads to some added complication.

Having finished describing our plan of attack, we proceed with the details of the proof.

3.2 *Typed parallel one-step reduction*

Definition 3.1 (*Labelled Terms*)
Define the set of *labelled terms* $\mathscr{T}^+$ by the grammar

$$\text{Labelled term } M^+ ::= x \mid s \mid \lambda x : M^+.M^+ \mid \Pi x : M^+.M^+ \mid \text{app}_{(x)M^+}(M^+ M^+)$$

We shall refer to the terms we have been dealing with heretofore as *unlabelled terms* when we wish to distinguish them from labelled terms.

We shall use all the capital letters as metavariables for labelled terms, as well as for unlabelled terms. This should hopefully not cause any confusion; it should be clear from which kind of term is intended in each case.

x is bound within B but not A in $\lambda x : A.B$ and $\Pi x : A.B$. It is bound within C but not A or B within $\text{app}_{(x)C}(AB)$. We identify labelled terms up to α-convertibility.

We define a translation

$$M \mapsto |M|$$

that maps labelled terms to unlabelled terms thus:

$$
\begin{aligned}
|x| &\equiv x \\
|s| &\equiv s \\
|\lambda x : A.M| &\equiv \lambda x : |A|.|M| \\
|\Pi x : A.B| &\equiv \Pi x : |A|.|B| \\
|\text{app}_{(x)A}(MN)| &\equiv |M||N|
\end{aligned}
$$

We define a *labelled context* Θ to be a sequence of pairs $x_1 : A_1, \ldots, x_n : A_n$, where $x_1, \ldots, x_n$ are distinct variables, and $A_1, \ldots, A_n$ are labelled terms. We shall use Θ and Φ as metavariables for labelled contexts.

We extend the translation above to contexts in the obvious manner:

$$|x_1 : A_1, \ldots, x_n : A_n| \equiv x_1 : |A_1|, \ldots, x_n : |A_n|$$

We define β-reduction, conversion, etc. on labelled terms as we did for unlabelled terms, based on the contraction

$$\text{app}_{(x)B}((\lambda x : A.M)N) \rightsquigarrow_\beta [N/x]M$$

Again, the definitions are written out in full in Appendix A for reference.

The following lemma is easily proven:

Lemma 3.2
For labelled terms M, N, if $M \rightarrow_\beta N$ then $|M| \rightarrow_\beta |N|$.

It is not that difficult to prove the following converse, either:

Lemma 3.3
Let M^+ be a labelled term, and N an unlabelled term. If $|M^+| \rightarrow_\beta N$, then there exists N^+ such that $|N^+| \equiv N$ and $M^+ \rightarrow_\beta N^+$.

Similar results hold for the relations $\twoheadrightarrow_\beta^1$ and $\twoheadrightarrow_\beta$.

We now define the formal system *Typed Parallel One-Step Reduction* (TPOSR), whose judgement forms are

$$\Theta \text{ valid and } \Theta \models M \triangleright N : A,$$

where Θ is a labelled context and M, N, A labelled terms. The rules of deduction of TPOSR are given in Figure 4. Note, in particular, the (red) and (exp) rules: we make the definition of typed parallel one-step reduction self-contained, by using the relation as its own criterion for convertibility of types.

We shall use $\Theta \models J$ to indicate either of the judgement forms Θ valid and $\Theta \models M \triangleright N : A$.

We write

$$\Theta \models M \triangleright ? : A$$

for $\exists N \; \Theta \models M \triangleright N : A$.

We define $\Theta \models X \triangleright^+ Y : Z$ to be the transitive closure of $\Theta \models X \triangleright Y : Z$; that is, the relation $\Theta \models X \triangleright^+ Y : Z$ is defined inductively by

$$\frac{\Theta \models X \triangleright Y : Z}{\Theta \models X \triangleright^+ Y : Z} \qquad \frac{\Theta \models W \triangleright^+ X : Z \quad \Theta \models X \triangleright^+ Y : Z}{\Theta \models W \triangleright^+ Y : Z}$$

We also define $\Theta \models X \simeq Y : s$ to be the symmetric, transitive closure of $\Theta \models X \triangleright Y : s$; that is, the relation $\Theta \models X \simeq Y : s$ is defined inductively by

$$\frac{\Theta \models X \triangleright Y : s}{\Theta \models X \simeq Y : s} \qquad \frac{\Theta \models X \simeq Y : s}{\Theta \models Y \simeq X : s} \qquad \frac{\Theta \models X \simeq Y : s \quad \Theta \models Y \simeq Z : s}{\Theta \models X \simeq Z : s}$$

Of course, the (red) and (exp) rules give us:

Lemma 3.4
If $\Theta \models M \triangleright N : A$ and $\Theta \models A \simeq B : s$ then $\Theta \models M \triangleright N : B$.

We can immediately establish that the translation $X \mapsto |X|$ is a sound translation from typed parallel one-step reduction to PTSs with equality:

Theorem 3.5
If $\Theta \models M \triangleright N : A$ then $|\Theta| \vdash^e |M| = |N| : |A|$.

$$\text{(emp)} \quad \frac{}{\langle\rangle \text{ valid}}$$

$$\text{(ctxt)} \quad \frac{\Theta \models A \triangleright A' : s}{\Theta, x : A \text{ valid}} \quad (x \notin \text{dom}\,\Theta)$$

$$\text{(var)} \quad \frac{\Theta \text{ valid}}{\Theta \models x \triangleright x : A} \quad (x : A \in \Theta)$$

$$\text{(ax)} \quad \frac{\Theta \text{ valid}}{\Theta \models s \triangleright s : t} \quad (s : t \in \mathscr{A})$$

$$\text{(prod)} \quad \frac{\Theta \models A \triangleright A' : s_1 \quad \Theta, x : A \models B \triangleright B' : s_2}{\Theta \models \Pi x : A.B \triangleright \Pi x : A'.B' : s_3} \quad ((s_1, s_2, s_3) \in \mathscr{R})$$

$$\text{(lambda)} \quad \frac{\Theta, x : A \models M \triangleright M' : B \quad \Theta \models A \triangleright A' : s_1 \quad \Theta, x : A \models B \triangleright B' : s_2}{\Theta \models \lambda x : A.M \triangleright \lambda x : A'.M' : \Pi x : A.B} \quad ((s_1, s_2, s_3) \in \mathscr{R})$$

$$\text{(app)} \quad \frac{\Theta \models M \triangleright M' : \Pi x : A.B \quad \Theta \models N \triangleright N' : A \quad \Theta \models A \triangleright A' : s_1 \quad \Theta, x : A \models B \triangleright B' : s_2}{\Theta \models \text{app}_{(x)B}(MN) \triangleright \text{app}_{(x)B'}(M'N') : [N/x]B} \quad ((s_1, s_2, s_3) \in \mathscr{R})$$

$$\text{(beta)} \quad \frac{\Theta \models A \triangleright A' : s_1 \quad \Theta, x : A \models B \triangleright B' : s_2 \quad \Theta, x : A \models M \triangleright M' : B \quad \Theta \models N \triangleright N' : A}{\Theta \models \text{app}_{(x)B}((\lambda x : A.M)N) \triangleright [N'/x]M' : [N/x]B} \quad ((s_1, s_2, s_3) \in \mathscr{R})$$

$$\text{(red)} \quad \frac{\Theta \models M \triangleright N : A \quad \Theta \models A \triangleright B : s}{\Theta \models M \triangleright N : B}$$

$$\text{(exp)} \quad \frac{\Theta \models M \triangleright N : B \quad \Theta \models A \triangleright B : s}{\Theta \models M \triangleright N : A}$$

Fig. 4. Typed parallel one-step reduction.

Proof
We prove:

1. If Θ valid then

$$(\forall s : t \in \mathscr{A})|\Theta| \vdash^e s : t$$
$$(\forall x : A \in \Theta)|\Theta| \vdash^e x : |A|$$

2. If $\Theta \models M \triangleright N : A$, then $|\Theta| \vdash^e |M| = |N| : |A|$.

simultaneously by induction on the derivation of the premise. All cases are straight-forward. □

We prove several other metatheoretic results about typed parallel one-step reduction in the Appendix C.

3.3 The Church-Rosser theorem

We need the following result before we are able to prove the Church-Rosser Theorem for TPOSR. *From now on, we shall always be assuming that* **S** *is a functional specification.*

Lemma 3.6 (*Uniqueness of Types*)
Suppose **S** is a functional specification. If $\Theta \models M \rhd ? : A$ and $\Theta \models M \rhd ? : B$, then either $A \equiv B$ or there is a sort s such that $\Gamma \models A \simeq B : s$.

Proof
The proof is by induction on M, using Generation (Lemma C.15).

The case where M is a λ-term uses Uniqueness of Sorts (Corollary C.1.4) and the Functionality of Π (Lemma C.17).

In the case $M \equiv \mathrm{app}_{(x)C}(NP)$, Generation shows that A and B are each convertible with $[P/x]C$ within their respective sorts; Uniqueness of Sorts then gives the result we need. $\square$

We are now able to prove the diamond property for typed parallel one-step reduction in the following form.

Theorem 3.7 (*Church-Rosser*)
If $\Theta \models M \rhd N : A$ and $\Theta \models M \rhd P : B$, then there exists Q such that

$$\Theta \models N \rhd Q : A \qquad\qquad \Theta \models P \rhd Q : A$$
$$\Theta \models N \rhd Q : B \qquad\qquad \Theta \models P \rhd Q : B$$

Proof
The proof is by double induction on the two premises. The only difficult case is where one premise was derived using (app), and the other using (beta):

So we assume the last steps in the two derivations were

$$\text{(beta)} \quad \frac{\Theta \models A \rhd A' : s_1 \qquad \Theta, x : A \models B \rhd B' : s_2 \qquad \Theta, x : A \models M \rhd M' : B \qquad \Theta \models N \rhd N' : A}{\Theta \models \mathrm{app}_{(x)B}((\lambda x : A.M)N) \rhd [N'/x]M' : [N/x]B} \ ((s_1, s_2, s_3) \in \mathscr{R}) \quad (3)$$

and

$$\text{(app)} \quad \frac{\Theta \models \lambda x : A.M \rhd P'' : \Pi x : C.B \qquad \Theta \models N \rhd N'' : C \qquad \Theta \models C \rhd C'' : t_1 \qquad \Theta, x : C \models B \rhd B'' : t_2}{\Theta \models \mathrm{app}_{(x)B}((\lambda x : A.M)N) \rhd \mathrm{app}_{(x)B''}(P''N'') : [N/x]B} \ ((t_1, t_2, t_3) \in \mathscr{R}) \quad (4)$$

Now, Uniqueness of Types gives either $A \equiv C$ or $\Theta \models A \simeq C : t$ for some sort t; in either case, Uniqueness of Sorts gives

$$s_1 \equiv t_1$$

Further, by Context Conversion,

$$\Theta, x : A \models B \rhd B'' : t_2, \qquad \Theta, x : C \models B \rhd B' : s_2, \tag{5}$$

and so Uniqueness of Sorts gives

$$s_2 \equiv t_2$$

(Functionality therefore gives $s_3 \equiv t_3$, but we shall not need this fact.)

Applying Generation to the premise $\Theta \models \lambda x : A.M \rhd P'' : \Pi x : C.B$, there exist A'', M'', D, D'' such that the given derivation of that premise has subderivations of

$$\Theta \quad \models \quad A \rhd A'' : s_1 \tag{6}$$
$$\Theta, x : A \quad \models \quad M \rhd M'' : D \tag{7}$$
$$\Theta, x : A \quad \models \quad D \rhd D'' : s_2$$

Further, $P'' \equiv \lambda x : A''.M''$, and $\Theta \models \Pi x : C.B \simeq \Pi x : A.D : s_3$. (Again, Uniqueness of Sorts shows that it must be the same rule (s_1, s_2, s_3) used here.)

By the induction hypothesis, we conclude that there exist labelled terms A_0, B_0, M_0, N_0 such that

$$\Theta \models A' \rhd A_0 : s_1 \qquad\qquad \Theta \models A'' \rhd A_0 : s_1$$
$$\Theta, x : A \models B' \rhd B_0 : s_2 \qquad\qquad \Theta, x : A \models B'' \rhd B_0 : s_2$$
$$\Theta, x : A \models M' \rhd M_0 : B \qquad\qquad \Theta, x : A \models M'' \rhd M_0 : B$$
$$\Theta \models N' \rhd N_0 : A \qquad\qquad \Theta \models N'' \rhd N_0 : A$$

(If (3) is the derivation of our first premise, then we have applied the induction hypothesis to its premises. If (4) is the derivation of our first premise, then we have applied the induction hypothesis both to its premises and to (6) and (7), which occur in the derivation of one of its premises.)

Substitution now gives

$$\Theta \models [N'/x]M' \rhd [N_0/x]M_0 : [N'/x]B.$$

We can derive the judgements

$$\Theta, x : A'' \quad \models \quad B'' \rhd B_0 : s_2$$
$$\Theta, x : A'' \quad \models \quad M'' \rhd M_0 : B''$$

and (beta) then gives

$$\Theta \models \mathrm{app}_{(x)B''}((\lambda x : A''.M'')N'') \rhd [N_0/x]M_0 : [N''/x]B'';$$

i.e.

$$\Theta \models \mathrm{app}_{(x)B''}(P''N'') \rhd [N_0/x]M_0 : [N''/x]B''.$$

It remains only to adjust the types of these two conclusions, using Reflexivity, Substitution and (exp). $\square$

Corollary 3.8
If $\Theta \models A \simeq B : s$, there exists C such that $\Theta \models A \rhd^+ C : s$ and $\Theta \models B \rhd^+ C : s$.

We have the following two very important corollaries of the Church-Rosser Theorem:

Corollary 3.9 (Injectivity of Π)
If $\Theta \models \Pi x : A.B \simeq \Pi x : A'.B' : s_3$, then there are sorts s_1, s_2 such that $(s_1, s_2, s_3) \in \mathscr{R}$ and

$$\Theta \quad \models \quad A \simeq A' : s_1$$
$$\Theta, x : A \quad \models \quad B \simeq B' : s_2$$

Proof
By Church-Rosser, there are sequences of terms $X_1, \ldots, X_m$ and $Y_1, \ldots, Y_n$ such that

$$\Theta \models \Pi x : A.B \triangleright X_1 \triangleright X_2 \triangleright \cdots \triangleright X_m \triangleright Z : s_3$$

and

$$\Theta \models \Pi x : A'.B' \triangleright Y_1 \triangleright Y_2 \triangleright \cdots \triangleright Y_n \triangleright Z : s_3.$$

By Generation, each X_i, Y_j, and Z itself is a Π-term; hence, by Generation and Uniqueness of Sorts, A and A' both reduce to the domain of C, and B and B' to its codomain. $\square$

Theorem 3.10 (Subject Reduction)
If $\Theta \models M \triangleright ? : A$ and $M \twoheadrightarrow_\beta^1 N$, then $\Theta \models M \triangleright N : A$.

Proof
Induction on the relation $M \twoheadrightarrow_\beta^1 N$, using Generation. The case $M \equiv N$ is handled by Left-Hand Reflexivity. All the remaining cases apart from the β-contraction case are straightforward.

The β-contraction case is handled as follows:

Suppose $M \equiv \text{app}_{(x)C}((\lambda x : B.P)Q)$ and $N \equiv [Q'/x]P'$, where $P \twoheadrightarrow_\beta^1 P'$, $Q \twoheadrightarrow_\beta^1 Q'$. By Generation, there exists D and a rule $(s_1, s_2, s_3) \in \mathscr{R}$ such that

$$\Theta \quad \models \quad D \triangleright ? : s_1$$
$$\Theta \quad \models \quad Q \triangleright ? : D$$
$$\Theta, x : D \quad \models \quad C \triangleright ? : s_2$$
$$\Theta \quad \models \quad A \simeq [Q/x]C : s_2$$

and either

$$\Theta \models \lambda x : B.P \triangleright ? : \Pi x : D.C$$

or $D \equiv B$ and

$$\Theta, x : B \models P \triangleright ? : C.$$

In either case (using Generation in the first case), there exists E such that

$$\Theta, x : B \models P \triangleright ? : E, \quad \Theta \models \Pi x : B.E \simeq \Pi x : D.C : s_3.$$

Therefore, by Π-injectivity,

$$\Theta \models B \simeq D : s_1$$
$$\Theta, x : B \models E \simeq C : s_2$$

The induction hypothesis gives us

$$\Theta \models Q \rhd Q' : D$$
$$\Theta, x : B \models P \rhd P' : E$$
$$\therefore \Theta \models \mathrm{app}_{(x)C}((\lambda x : B.P)Q) \rhd [Q'/x]P' : [Q/x]C \qquad \text{(beta)}$$
$$\therefore \Theta \models \mathrm{app}_{(x)C}((\lambda x : B.P)Q) \rhd [Q'/x]P' : A \qquad \text{((red) and (exp))} \qquad \square$$

4 The translation from typed reduction to pure type systems

Now that we are armed with the Church-Rosser Theorem, we can establish that the translation

$$M \mapsto |M|$$

is a sound and complete translation from TPOSR to PTSs, and also from TPOSR to PTSs with equality. Together, these two results will establish the correspondence between PTSs and PTSs with equality that we desire.

We first need to establish that two typable labelled terms that have identical translates are convertible, in the following sense:

Lemma 4.1
Suppose $\Theta \models M \rhd ? : A$, $\Theta \models N \rhd ? : B$, and $|M| \equiv |N|$. Then there exists P such that

$$\Theta \models M \rhd^+ P : A \qquad\qquad \Theta \models N \rhd^+ P : A$$
$$\Theta \models M \rhd^+ P : B \qquad\qquad \Theta \models N \rhd^+ P : B$$

Proof
The proof is by induction on M. We deal here with the most difficult case: $M \equiv \mathrm{app}_{(x)D}(PQ)$. Then $N \equiv \mathrm{app}_{(x)D'}(P'Q')$, where $|P| \equiv |P'|$ and $|Q| \equiv |Q'|$. By Generation, there exist labelled terms C, C' and rules $(s_1, s_2, s_3), (t_1, t_2, t_3) \in \mathcal{R}$ such that

$$\Theta \models C \rhd ? : s_1 \qquad\qquad \Theta \models C' \rhd ? : t_1$$
$$\Theta, x : C \models D \rhd ? : s_2 \qquad\qquad \Theta, x : C' \models D' \rhd ? : t_2$$
$$\Theta \models Q \rhd ? : C \qquad\qquad \Theta \models Q' \rhd ? : C'$$
$$\Theta \models A \simeq [Q/x]D : s_2 \qquad\qquad \Theta \models B \simeq [Q'/x]D' : t_2$$
$$\Theta \models P \rhd ? : \Pi x : D.C \qquad\qquad \Theta \models P'\rho? : \Pi x : C'.D'$$

Therefore, by induction hypothesis, there exist P^*, Q^* such that

$$\Theta \models P \rhd^+ P^* : \Pi x : C.D \qquad\qquad \Theta \models P' \rhd^+ P^* : \Pi x : C.D$$
$$\Theta \models P \rhd^+ P^* : \Pi x : C'.D' \qquad\qquad \Theta \models P' \rhd^+ P^* : \Pi x : C'.D'$$
$$\Theta \models Q \rhd^+ Q^* : C \qquad\qquad \Theta \models Q' \rhd^+ Q^* : C$$
$$\Theta \models Q \rhd^+ Q^* : C' \qquad\qquad \Theta \models Q' \rhd^+ Q^* : C'$$

Hence, by Uniqueness of Types, we have

$$\Theta \models \Pi x : C.D \simeq \Pi x : C'.D' : s_3, \qquad \Theta \models C \simeq C' : s_1$$

and also $s_1 \equiv t_1$, $s_2 \equiv t_2$, $s_3 \equiv t_3$. By Π-injectivity,

$$\Theta, x : C \models D \simeq D' : s_2.$$

Hence, by Church-Rosser, there exists D^* such that

$$\Theta, x : C \models D \triangleright^+ D^* : s_2, \qquad \Theta, x : C \models D' \triangleright^+ D^* : s_2.$$

Therefore,

$$\Theta \models \mathrm{app}_{(x)D}(PQ) \triangleright^+ \mathrm{app}_{(x)D^*}(P^*Q^*) : [Q/x]D,$$
$$\Theta \models \mathrm{app}_{(x)D'}(P'Q') \triangleright^+ \mathrm{app}_{(x)D^*}(P^*Q^*) : [Q'/x]D'$$

As we also have $\Theta \models A \simeq [Q/x]D \simeq [Q'/x]D' \simeq B : s_2$, the desired conclusion follows.   □

Corollary 4.2
If $\Theta \models A \triangleright ? : s$, $\Theta \models B \triangleright ? : t$, and $|A| \equiv |B|$, then $s \equiv t$ and $\Theta \models A \simeq B : s$.

Corollary 4.3
If $\Theta \models M \triangleright N : A$, Φ valid, and $|\Theta| \equiv |\Phi|$, then $\Phi \models M \triangleright N : A$.

Proof
By Corollary 4.2 and Context Conversion.   □

We are now ready to establish the correspondence between PTSs and TPOSR.

Theorem 4.4
If $\Gamma \vdash M : A$ then there exist Γ^+, M^+, A^+ such that

$$\begin{aligned} |\Gamma^+| &\equiv \Gamma \\ |M^+| &\equiv M \\ |A^+| &\equiv A \end{aligned}$$

and

$$\Gamma^+ \models M^+ \triangleright M^+ : A^+.$$

Proof
Induction on $\Gamma \vdash M : A$. Most cases are straightforward now that we have Corollary 4.3. We deal here with the case

$$(\text{conversion}) \ \frac{\Gamma \vdash M : A \quad \Gamma \vdash B : s}{\Gamma \vdash M : B} \ (A \simeq_\beta B)$$

By the induction hypothesis, there exist Γ^+, M^+, A^+, Γ_2^+, B^+ such that

$$|\Gamma^+| \equiv |\Gamma_2^+| \equiv \Gamma$$
$$|M^+| \equiv M$$
$$|A^+| \equiv A$$
$$|B^+| \equiv B$$
$$\Gamma^+ \models M^+ \triangleright M^+ : A^+$$
$$\Gamma_2^+ \models B^+ \triangleright B^+ : s$$
$$\therefore \Gamma^+ \models B^+ \triangleright B^+ : s$$

By Type Validity, either A^+ is a sort or there is a sort t such that

$$\Gamma^+ \models A^+ \triangleright \; ? : t.$$

Case 1: A^+ is a sort. In this case, A is a sort. Hence, $B \twoheadrightarrow_\beta A$, and so $B^+ \twoheadrightarrow_\beta A^+$. Therefore, by Subject Reduction,

$$\Gamma^+ \models B^+ \triangleright^+ A^+ : s$$

and so

$$\Gamma^+ \models M^+ \triangleright M^+ : B^+$$

by (exp).

Case 2: $\Gamma^+ \models A^+ \triangleright \; ? : t$ In this case, by Church-Rosser, there is an unlabelled term C such that

$$A \twoheadrightarrow_\beta C, \quad B \twoheadrightarrow_\beta C.$$

By Lemma 3.3, there are labelled terms C_0, C_1 such that

$$A^+ \twoheadrightarrow_\beta C_0, \qquad B^+ \twoheadrightarrow_\beta C_1, \qquad |C_0| \equiv |C_1| \equiv C.$$

By Subject Reduction,

$$\Gamma^+ \quad \models \quad A^+ \triangleright^+ C_0 : t$$
$$\Gamma^+ \quad \models \quad B^+ \triangleright^+ C_1 : s$$

Therefore, by Corollary 4.2,

$$\Gamma^+ \models C_0 \simeq C_1 : s$$

(and also $s \equiv t$). Hence, using (red) and (exp) repeatedly,

$$\Gamma^+ \models M^+ \triangleright M^+ : B^+. \qquad \square$$

Finally, we can put all our results together and prove our main theorem.

Theorem 4.5
1. If $\Gamma \vdash M : A$ then $\Gamma \vdash^e M : A$.
2. If $\Gamma \vdash M : A$, $\Gamma \vdash N : A$, and $M \simeq_\beta N$, then $\Gamma \vdash^e M = N : A$.

Proof

1. By Theorem 4.4, there exist Γ^+, M^+, A^+ such that $|\Gamma^+| \equiv \Gamma$, $|M^+| \equiv M$, $|A^+| \equiv A$, and

$$\Gamma^+ \models M^+ \triangleright M^+ : A^+$$
$$\therefore \Gamma \vdash^e M = M : A \qquad \text{(Theorem 3.5)}$$
$$\therefore \Gamma \vdash^e M : A \qquad \text{(Equation Validity)}$$

2. By Church-Rosser, there exists P such that $M \twoheadrightarrow_\beta P$ and $N \twoheadrightarrow_\beta P$. By Theorem 4.4, there exist Γ^+, M^+, A^+ such that $|\Gamma^+| \equiv \Gamma$, $|M^+| \equiv M$, $|A^+| \equiv A$, and

$$\Gamma^+ \models M^+ \triangleright M^+ : A^+$$
$$\therefore \Gamma^+ \models M^+ \triangleright^+ P^+ : A^+ \qquad \text{(Subject Reduction)}$$
$$\therefore \Gamma \vdash^e M = P : A \qquad \text{(Theorem 3.5 and (trans))}$$

Similarly,

$$\Gamma \vdash^e N = P : A$$
$$\therefore \Gamma \vdash^e M = N : A \qquad \text{((sym) and (trans))} \qquad \square$$

Theorem 4.6
For a functional PTS:

1. $\Gamma \vdash^e M : A$ iff $\Gamma \vdash M : A$.
2. $\Gamma \vdash^e M = N : A$ iff $\Gamma \vdash M : A$, $\Gamma \vdash N : A$ and $M =_\beta N$.

Proof
From Theorems 2.3 and 4.5. $\quad \square$

5 Completing the theory

To round off this long development, we make explicit the relationship between TPOSR and PTSs, and between TPOSR and PTSs with equality.

Theorem 5.1
1. If $\Theta \models M \triangleright N : A$, then $|\Theta| \vdash |M| : |A|$, $|\Theta| \vdash |N| : |A|$, and $|M| \twoheadrightarrow_\beta^1 |N|$.
2. If $\Gamma \vdash M : A$ and $M \twoheadrightarrow_\beta^1 N$, then there exist Γ^+, M^+, N^+, A^+ such that $|\Gamma^+| \equiv \Gamma$, $|M^+| \equiv M$, $|N^+| \equiv N$, $|A^+| \equiv A$, and

$$\Gamma^+ \models M^+ \triangleright N^+ : A^+.$$

Proof
1. Follows from Lemmas 3.2, 3.5 and 2.3.
2. Follows from Theorems 4.5 and 3.10. $\quad \square$

Theorem 5.2
1. If $\Theta \models M \triangleright N : A$, then $|\Theta| \vdash^e |M| = |N| : |A|$ and $|M| \twoheadrightarrow_\beta^1 |N|$.
2. If $\Gamma \vdash^e M : A$ and $M \twoheadrightarrow_\beta^1 N$, then there exist Γ^+, M^+, N^+, A^+ such that $|\Gamma^+| \equiv \Gamma$, $|M^+| \equiv M$, $|N^+| \equiv N$, $|A^+| \equiv A$, and

$$\Gamma^+ \models M^+ \triangleright N^+ : A^+.$$

Proof
1. Follows from Lemmas 3.2 and 3.5.
2. Follows from Theorems 2.3, 4.5 and 3.10.   □

And so we are also able to complete the metatheory of PTSs with equality with the following results, which include the long promised Subject Reduction:

Corollary 5.3 (*Subject Reduction*)
If $\Gamma \vdash^e M : A$ and $M \twoheadrightarrow_\beta N$, then $\Gamma \vdash^e M = N : A$.

Proof
By our main result (Theorem 4.5), $\Gamma \vdash M : A$. By Subject Reduction for PTSs, $\Gamma \vdash N : A$. Therefore, by Theorem 4.5 again, $\Gamma \vdash^e M = N : A$.   □

Corollary 5.4 (*Injectivity of* Π)
If $\Gamma \vdash^e \Pi x : A.B = \Pi x : A'.B' : s_3$, then there are sorts s_1, s_2 such that $(s_1, s_2, s_3) \in \mathscr{R}$ and

$$\Gamma \vdash^e A = A' : s_1, \qquad \Gamma, x : A \vdash^e B = B' : s_2.$$

Proof
By Theorem 4.5, $\Gamma \vdash \Pi x : A.B : s_3$ and $\Gamma \vdash \Pi x : A'.B' : s_3$. Therefore, by Generation for PTSs, there are sorts s_1, s_2, t_1, t_2 such that $(s_1, s_2, s_3), (t_1, t_2, s_3) \in \mathscr{R}$ and

$$\Gamma \vdash A : s_1 \qquad\qquad \Gamma \vdash A' : t_1$$
$$\Gamma, x : A \vdash B : s_2 \qquad\qquad \Gamma, x : A' \vdash B' : t_2$$

Using Uniqueness of Types and Context Conversion, it follows that $s_1 \equiv t_1$ and $s_2 \equiv t_2$. Therefore, by Theorem 4.5,

$$\Gamma \vdash^e A = A' : s_1, \qquad \Gamma, x : A \vdash^e B = B' : s_2.   □$$

6 Conclusion and future work

We have proven the equivalence of a system with an external criterion for equality (the PTS) with one with a judgement form for equality (the PTS with equality) for all functional PTSs. It should be straightforward to extend the result to other type systems with the Uniqueness of Types property.

Such a technically complex proof should be checked mechanically. The author is working on a formalisation of this result in Coq, and has made his partial results available on his website.

The question naturally arises whether this approach could be applied to η-conversion, or to systems with a subtyping relation, such as ECC (Luo, 1994) or the Pure Type Systems with Universes, or γPTSs, studied by Ruiz (1999, 2000). These latter systems do not satisfy Uniqueness of Types; but, under appropriate hypotheses, every typable term has a unique *principal* type, and it may be that this is sufficient for the method to be applied.

It remains to be seen whether the relation of TPOSR can be applied in other areas of the theory of PTSs, or type systems in general. One idea might be to make

some progress on the problem of expansion postponement (Poll, 1998) using the properties of the relation formed by leaving out the (exp) clause in the definition of TPOSR. Unfortunately, the properties of this relation prove difficult to establish. (See Gutiérrez & Ruiz (2003) for the latest progress on expansion postponement.)

There is also an obvious superficial similarity between TPOSR and typed operational semantics (Goguen, 1999). It remains to be seen whether it would be useful to establish a more formal correspondence between the two.

The question of the equivalence of external and judgemental equality remains an open problem for an arbitrary PTS. It is a plausible enough conjecture: the rules for judgemental equality amount to little more than checking that a β-redex is well-typed whenever it is contracted; and, by Church-Rosser, for any two convertible well-typed terms, there is a reduction-expansion sequence between the two in which each redex is well-typed. However, it proves stubbornly difficult to establish in practise. It is quite possible that some pathological PTS will turn out to be a counterexample.

A Reduction relations

The relations

$$
\begin{array}{ll}
\text{one-step beta reduction} & \to_\beta \\

\end{array}
$$

are defined on the set of unlabelled terms inductively by the following clauses:

One-step Beta Reduction

$$\frac{}{(\lambda x : A.M)N \to_\beta [N/x]M}$$

$$\frac{A \to_\beta A'}{\Pi x : A.B \to_\beta \Pi x : A'.B} \qquad \frac{B \to_\beta B'}{\Pi x : A.B \to_\beta \Pi x : A.B'}$$

$$\frac{A \to_\beta A'}{\lambda x : A.M \to_\beta \lambda x; A'.M} \qquad \frac{M \to_\beta M'}{\lambda x : A.M \to_\beta \lambda x : A.M'}$$

$$\frac{M \to_\beta M'}{MN \to_\beta M'N} \qquad \frac{N \to_\beta N'}{MN \to_\beta MN'}$$

Beta-Reduction

$$\frac{M \to_\beta N}{M \twoheadrightarrow_\beta N} \qquad \frac{}{M \twoheadrightarrow_\beta M} \qquad \frac{M \twoheadrightarrow_\beta N \quad N \twoheadrightarrow_\beta P}{M \twoheadrightarrow_\beta P}$$

Beta Conversion

$$\frac{M \to_\beta N}{M \simeq_\beta N} \qquad \frac{}{M \simeq_\beta M} \qquad \frac{M \simeq_\beta N}{N \simeq_\beta M} \qquad \frac{M \simeq_\beta N \quad N \simeq_\beta P}{M \simeq_\beta P}$$

Parallel One-Step Beta Reduction

$$\frac{}{M \twoheadrightarrow^1_\beta M} \qquad \frac{A \twoheadrightarrow^1_\beta A' \quad B \twoheadrightarrow^1_\beta B'}{\Pi x : A.B \twoheadrightarrow^1_\beta \Pi x : A'.B'}$$

$$\frac{A \twoheadrightarrow^1_\beta A' \quad M \twoheadrightarrow^1_\beta M'}{\lambda x : A.M \twoheadrightarrow^1_\beta \lambda x : A'.M'} \qquad \frac{M \twoheadrightarrow^1_\beta M' \quad N \twoheadrightarrow^1_\beta N'}{MN \twoheadrightarrow^1_\beta M'N'}$$

$$\frac{M \twoheadrightarrow^1_\beta M' \quad N \twoheadrightarrow^1_\beta N'}{(\lambda x : A.M)N \twoheadrightarrow^1_\beta [N'/x]M'}$$

The relations

$$
\begin{array}{ll}
\text{one-step beta reduction} & \rightarrow_\beta \\
\text{beta reduction} & \twoheadrightarrow_\beta \\
\text{beta convertibility} & \simeq_\beta \\
\text{parallel one-step beta reduction} & \twoheadrightarrow^1_\beta
\end{array}
$$

are defined on the set of labelled terms as follows:

One-step Beta Reduction

$$\frac{}{\mathrm{app}_{(x)B}((\lambda x : A.M)N) \rightarrow_\beta [N/x]M}$$

$$\frac{A \rightarrow_\beta A'}{\Pi x : A.B \rightarrow_\beta \Pi x : A'.B} \qquad \frac{B \rightarrow_\beta B'}{\Pi x : A.B \rightarrow_\beta \Pi x : A.B'}$$

$$\frac{A \rightarrow_\beta A'}{\lambda x : A.M \rightarrow_\beta \lambda x; A'.M} \qquad \frac{M \rightarrow_\beta M'}{\lambda x : A.M \rightarrow_\beta \lambda x : A.M'}$$

$$\frac{M \rightarrow_\beta M'}{\mathrm{app}_{(x)A}(MN) \rightarrow_\beta \mathrm{app}_{(x)A}(M'N)} \qquad \frac{N \rightarrow_\beta N'}{\mathrm{app}_{(x)A}(MN) \rightarrow_\beta \mathrm{app}_{(x)A}(MN')}$$

$$\frac{A \rightarrow_\beta A'}{\mathrm{app}_{(x)A}(MN) \rightarrow_\beta \mathrm{app}_{(x)A'}(MN)}$$

Beta-Reduction

$$\frac{M \rightarrow_\beta N}{M \twoheadrightarrow_\beta N} \qquad \frac{}{M \twoheadrightarrow_\beta M} \qquad \frac{M \twoheadrightarrow_\beta N \quad N \twoheadrightarrow_\beta P}{M \twoheadrightarrow_\beta P}$$

Beta Conversion

$$\frac{M \rightarrow_\beta N}{M \simeq_\beta N} \qquad \frac{}{M \simeq_\beta M} \qquad \frac{M \simeq_\beta N}{N \simeq_\beta M} \qquad \frac{M \simeq_\beta N \quad N \simeq_\beta P}{M \simeq_\beta P}$$

Parallel One-Step Beta Reduction

$$\frac{}{M \twoheadrightarrow^1_\beta M} \qquad \frac{A \twoheadrightarrow^1_\beta A' \quad B \twoheadrightarrow^1_\beta B'}{\Pi x : A.B \twoheadrightarrow^1_\beta \Pi x : A'.B'}$$

$$\frac{A \twoheadrightarrow^1_\beta A' \quad M \twoheadrightarrow^1_\beta M'}{\lambda x : A.M \twoheadrightarrow^1_\beta \lambda x : A'.M'} \qquad \frac{A \twoheadrightarrow^1_\beta A' \quad M \twoheadrightarrow^1_\beta M' \quad N \twoheadrightarrow^1_\beta N'}{\mathrm{app}_{(x)A}(MN) \twoheadrightarrow^1_\beta \mathrm{app}_{(x)A'}(M'N')}$$

$$\frac{M \twoheadrightarrow^1_\beta M' \quad N \twoheadrightarrow^1_\beta N'}{\mathrm{app}_{(x)B}((\lambda x : A.M)N) \twoheadrightarrow^1_\beta [N'/x]M'}$$

B Metatheory of pure type systems with equality

The following are the results about pure type systems with equality used in this paper. They can be proven in the following order; each proof is by induction on the first-mentioned premise, making use of the previous results.

Lemma B.1 (*Free Variables and Contexts*)
1. If $\Gamma \vdash^e M : A$, then Γ is consistent and $\mathrm{FV}(M) \cup \mathrm{FV}(A) \subseteq \mathrm{dom}\,\Gamma$.
2. If $\Gamma \vdash^e M = N : A$, then Γ is consistent and $\mathrm{FV}(M) \cup \mathrm{FV}(N) \cup \mathrm{FV}(A) \subseteq \mathrm{dom}\,\Gamma$.

Lemma B.2 (*Context Conversion, Preliminary Form*)
If $\Gamma, x : A, \Delta \vdash^e J$, $\Gamma \vdash^e A = B : s$ and $\Gamma \vdash^e B : s$, then $\Gamma, x : B, \Delta \vdash^e J$.

Lemma B.3 (*Substitution*)
If $\Gamma, x : A, \Delta \vdash^e J$ and $\Gamma \vdash^e M : A$, then $\Gamma, [M/x]\Delta \vdash^e [M/x]J$.

Lemma B.4 (*Functionality, Preliminary Form*)
If $\Gamma, x : A, \Delta \vdash^e M : B$, $\Gamma \vdash^e N = P : A$, and $\Gamma \vdash^e N : A$, then $\Gamma, [N/x]\Delta \vdash^e [N/x]M = [P/x]M : [N/x]B$.

Definition B.5
We shall write "$\Gamma \vdash^e X \simeq Y$" for "Either $X \equiv Y$, or there exists a sequence of terms $X_1, \ldots, X_n$ and a sequence of terms $A_0, A_1, \ldots, A_n$ such that

$$\Gamma \vdash^e X = X_1 : A_0, \ \Gamma \vdash^e X_1 = X_2 : A_1, \ldots, \Gamma \vdash^e X_n = Y : A_n."$$

Lemma B.6 (*Generation*)
1. If $\Gamma \vdash^e s : A$, then there is a sort t such that $s : t \in \mathscr{A}$, and $\Gamma \vdash^e A \simeq t$.
2. If $\Gamma \vdash^e x : A$, then $x : B \in \Gamma$ for some B, and $\Gamma \vdash^e A \simeq B$
3. If $\Gamma \vdash^e \Pi x : A.B : C$, then there is a rule $(s_1, s_2, s_3) \in \mathscr{R}$ such that $\Gamma \vdash^e A : s_1$, $\Gamma, x : A \vdash^e B : s_2$, and $\Gamma \vdash^e C \simeq s_3$.
4. If $\Gamma \vdash^e \lambda x : A.M : B$, then there is a rule $(s_1, s_2, s_3) \in \mathscr{R}$ and term C such that $\Gamma \vdash^e A : s_1$, $\Gamma, x : A \vdash^e C : s_2$, $\Gamma, x : A \vdash^e M : C$, and $\Gamma \vdash^e B \simeq \Pi x : A.C$.
5. If $\Gamma \vdash^e MN : C$, then there are terms A and B such that $\Gamma \vdash^e M : \Pi x : A.B$, $\Gamma \vdash^e N : A$, and $\Gamma \vdash^e [N/x]B \simeq C$.

Lemma B.7 (*Type Validity and Equation Validity*)
1. If $\Gamma \vdash^e M : A$, then either A is a sort, or there is a sort s such that $\Gamma \vdash^e A : s$.
2. If $\Gamma \vdash^e M = N : A$ then $\Gamma \vdash^e M : A$, $\Gamma \vdash^e N : A$, and either A is a sort, or there is a sort s such that $\Gamma \vdash^e A : s$.

Now that we have Equation Validity, we can remove one premise from two previous lemmas:

Corollary B.8 (*Context Conversion*)
If $\Gamma, x : A, \Delta \vdash^e J$ and $\Gamma \vdash^e A = B : s$, then $\Gamma, x : B, \Delta \vdash^e J$.

Corollary B.9 (*Functionality*)
If $\Gamma, x : A, \Delta \vdash^e M : B$ and $\Gamma \vdash^e N = P : A$, then $\Gamma, [N/x]\Delta \vdash^e [N/x]M = [P/x]M : [N/x]B$.

C Metatheory of typed parallel one-step reduction

The following are the results about the relation of TPOSR used in the paper. In most cases, the proof is a straightforward induction on the derivation of the first premise given, making use of the previously proven lemmas.

Firstly, we can take advantage of the correspondence between TPOSR and PTSs, and the Uniqueness of Types result for PTSs, to prove a Uniqueness of Sorts lemma for typed parallel one-step reduction:

Corollary C.1
1. If $\Theta \models M \rhd N : A$ then $|\Theta| \vdash |M| : |A|$ and $|\Theta| \vdash |N| : |A|$.
2. If $\Theta \models A \simeq B : s$ then $|\Theta| \vdash |A| : s$ and $|\Theta| \vdash |B| : s$.
3. Suppose **S** is a functional specification. If $\Theta \models A \rhd B : s$ and $\Theta \models A \rhd C : t$, then $s \equiv t$.
4. Suppose **S** is a functional specification. If $\Theta \models A \simeq B : s$ and $\Theta \models A \simeq C : t$, then $s \equiv t$.

Proof
Part 1 is a consequence of Theorems 3.5 and 2.3; part 2 follows easily by induction on the premise. Parts 3 and 4 follow from parts 1 and 2 respectively, and the Uniqueness of Types result proven in (Barendregt, 1992). □

It is clear that typed reduction entails untyped reduction:

Lemma C.2
If $\Theta \models X \rhd Y : Z$ then $X \twoheadrightarrow_\beta Y$.

Corollary C.3
If $\Theta \models X \simeq Y : s$ then $X \simeq_\beta Y$.

Lemma C.4 (*Context Validity*)
If $\Theta, \Phi \models J$, then Θ valid.

Lemma C.5 (*Free Variables*)
If $x_1 : X_1, \ldots, x_n : X_n \models J$, then $FV(X_i) \subseteq \{x_1, \ldots, x_{i-1}\}$ and $FV(J) \subseteq \{x_1, \ldots, x_n\}$.

Lemma C.6 (*Weakening*)
If $\Theta \models X \rhd Y : Z$, $\Theta \subseteq \Phi$, and Θ valid, then $\Theta \models X \rhd Y : Z$.

Lemma C.7 (*Context Reduction, Preliminary Form*)
If $\Theta, x : X, \Phi \models J$, $\Theta \models X \rhd X' : s$, and $\Theta \models X' \rhd X' : s$, then $\Theta, x : X', \Phi \models J$.

Lemma C.8 (*Left-Hand Reflexivity*)
If $\Theta \models X \rhd Y : Z$ then $\Theta \models X \rhd X : Z$.

Lemma C.9 (*Substitution*)
  1. If $\Theta, x : X, \Phi$ valid and $\Theta \models W \rhd W' : X$, then $\Theta, [W/x]\Phi$ valid.
  2. If $\Theta, x : X, \Phi \models Y \rhd Y' : Z$ and $\Theta \models W \rhd W' : X$, then $\Theta, [W/x]\Phi \models [W/x]Y \rhd [W'/x]Y' : [W/x]Z$.

Lemma C.10 (*Right-Hand Reflexivity*)
If $\Theta \models X \rhd Y : Z$ then $\Theta \models Y \rhd Y : Z$.

Corollary C.11
If $\Theta \models X \simeq Y : s$, then $\Theta \models X \rhd X : s$ and $\Theta \models Y \rhd Y : s$.

Right-Hand Reflexivity allows us to remove one of the premises in Context Reduction:

Corollary C.12 (*Context Reduction*)
If $\Theta, x : X, \Phi \models J$ and $\Theta \models X \rhd X' : s$, then $\Theta, x : X', \Phi \models J$.

Lemma C.13 (*Context Expansion*)
If $\Theta, x : X', \Phi \models J$ and $\Theta \models X \rhd X' : s$, then $\Theta, x : X, \Phi \models J$.

Corollary C.14 (*Context Conversion*)
If $\Theta, x : X, \Psi \models J$ and $\Theta \models X \simeq Y : s$, then $\Theta, x : Y, \Psi \models J$.

Lemma C.15 (*Generation*)
Suppose **S** is a functional specification.

  1. If $\Theta \models s \rhd X : Y$, then $X \equiv s$, and there exists $t \in \mathscr{S}$ such that $s : t \in \mathscr{A}$, and either $Y \equiv t$ or $\Theta \models Y \simeq t : t'$ for some sort t'.
  2. If $\Theta \models x \rhd X : Y$, then $X \equiv x$, and there exist Z, s such that $x : Z \in \Theta$ and $\Theta \models Y \simeq Z : s$.
  3. Any derivation of $\Theta \models \Pi x : W.X \rhd Y : Z$ has subderivations of

$$\begin{aligned} \Theta &\models W \rhd W' : s_1 \\ \Theta, x : W &\models X \rhd X' : s_2 \end{aligned}$$

    for some labelled terms W', X' and rule $(s_1, s_2, s_3) \in \mathscr{R}$; further, $Y \equiv \Pi x : W'.X'$, and either $Z \equiv s_3$, or $\Theta \models Z \simeq s_3 : t$ for some sort t.
  4. Any derivation of $\Theta \models \lambda x : W.X \rhd Y : Z$ has subderivations of

$$\begin{aligned} \Theta &\models W \rhd W' : s_1 \\ \Theta, x : W &\models V \rhd V' : s_2 \\ \Theta, x : W &\models X \rhd X' : V \end{aligned}$$

    for some labelled terms W', X', V, V' and rule $(s_1, s_2, s_3) \in \mathscr{R}$; further, $Y \equiv \lambda x : W'.X'$, and $\Theta \models Z \simeq \Pi x : W.V : s_3$.

5. Any derivation $\mathcal{D}$ of $\Theta \models \text{app}_{(x)V}(WX) \rhd Y : Z$ has subderivations of

$$\Theta \quad \models \quad U \rhd U' : s_1$$
$$\Theta, x : U \quad \models \quad V \rhd V' : s_2$$
$$\Theta \quad \models \quad X \rhd X' : U$$

for some labelled terms X', U, U', V' and rule $(s_1, s_2, s_3) \in \mathcal{R}$. Furthermore,

$$\Theta \models Z \simeq [X/x]V : s_2$$

and *either*

(a) there exists W' such that $\mathcal{D}$ has a subderivation of

$$\Theta \models W \rhd W' : \Pi x : U.V$$

and $Y \equiv \text{app}_{(x)V'}(W'X')$; *or*

(b) $W \equiv \lambda x : U.T$, and there exists T' such that $\mathcal{D}$ has a subderivation of

$$\Theta, x : U \models T \rhd T' : V$$

and $Y \equiv [X'/x]T'$.

Proof
Straightforward induction on the premise in each case, using the fact that a type can be in only one sort. □

Without the assumption of functionality, we would need to replace each conclusion of the form $\Theta \models X \simeq Y : s$ with "There exist a sequence of labelled terms $Z_1, \dots, Z_n$, and a sequence of sorts $s_1, \dots, s_{n+1}$, such that

$$\Theta \models X \simeq Z_1 : s_1, \ \Theta \models Z_1 \simeq Z_2 : s_2, \ \cdots, \ \Theta \models Z_n \simeq Y : s_{n+1}."$$

Corollary C.16 (*Type Validity*)
If $\Theta \models X \rhd Y : Z$, then either Z is a sort, or there is a sort s and labelled term Z' such that $\Theta \models Z \rhd Z' : s$.

Proof
Inspection of each case of Generation. □

Lemma C.17 (*Functionality of* Π)
If $(s_1, s_2, s_3) \in \mathcal{R}$, $\Theta \models X \simeq X' : s_1$, and $\Theta, x : X \models Y \simeq Y' : s_2$, then $\Theta \models \Pi x : X.Y \simeq \Pi x : X'.Y' : s_3$.

Proof
We prove the two statements:

1. If $\Theta \models X \rhd X : s_1$ and $\Theta, x : X \models Y \simeq Y' : s_2$, then $\Theta \models \Pi x : X.Y \simeq \Pi x : X.Y' : s_3$.
2. If $\Theta \models X \simeq X' : s_1$ and $\Theta, x : X \models Y \rhd Y : s_2$, then $\Theta \models \Pi x : X.Y \simeq \Pi x : X'.Y : s_3$.

These, together with Reflexivity, suffice to prove the lemma. The proofs are by induction on $\Theta, x : X \models Y \simeq Y' : s_2$ in the first case, and $\Theta \models X \simeq X' : s_1$ in the second. □
