19
20 The synthesis of three novel families of pyrrolo[2,1-c][1,4]benzodiazepine-5-ones is described.
21
22 The compounds were prepared according to a three-step sequence, involving an Ugi reaction,
23
24 building of the pyrrolo nucleus and reduction-cyclisation to the corresponding diazepine.
25
26 Depending on the amine employed in the synthesis of the Ugi adducts, different unsaturation
27
28 degrees could be obtained in the pyrrolo ring (saturated or with *endo* or *exo* unsaturations), a
29
30 key feature determining their biological activity, as it affected the affinity of the
31
32 pyrrolobenzodiazepines towards DNA and thus their cytotoxicity. This synthetic methodology
33
34 represents a significant improvement with respect to those described in the literature so far,
35
36 as it uses inexpensive and commercially-available starting materials without needing
37
38 derivatization or the use of protecting groups.

Introduction

Pyrrolobenzodiazepines (PBDs) constitute an important class of compounds thoroughly studied due to their activity as antitumour antibiotics.¹ The cytotoxicity displayed by these compounds is related to their ability to bind covalently to DNA.² Indeed, these compounds have been demonstrated to bind to DNA's minor groove.³ A key feature for this interaction with DNA, and thus the cytotoxicity of these compounds, is the presence of an imine carbon, or equivalent, at the C11 position. This importance is underscored by the negligible cytotoxicity of analogous compound lacking this imine function. This occurs for instance when the imine group is replaced by an amide, as in PBD dilactames, or by a secondary amine.⁴ Examples of naturally-occurring PBD compounds displaying intriguing pharmacological properties include anthramycin,⁵ chicamycin⁶ and tomaymycin,⁷ all of them featuring an imine carbon, or equivalent, at the C11 position (Figure 1). From the biological perspective it is interesting to remark that the unsaturation degree of the pyrrole core affects the affinity of these systems

towards DNA as well as their cytotoxicity, both in compounds presenting *exo*⁸ and *endo*⁹ unsaturations, like tomaymycin and anthramycin, respectively.

Figure 1. Examples of naturally-occurring bioactive pyrrolobenzodiazepines.

Numerous methodologies have been developed to synthesize these compounds,¹⁰ reflecting their interest. The commonest route starts with L-proline, which allows the introduction of the five-membered core. This route was used for the synthesis of DC-81, an antitumor antibiotic produced by *Streptomyces* species,¹¹ following two different strategies: (1) the synthesis of the PBD dilactame as intermediate, followed by the reduction of the carboxylic group derived from proline,¹² or (2) the formation of the PBD system in the last step, after the proline's carboxylic acid group had been reduced (**Figure 2**).¹³

Figure 2. Intermediates in the synthesis of DC-81 starting from L-proline (blue fragment) or L-glutamic acid (red fragment)

1
2
3 Nevertheless, few results are found in the literature where the precursor of the pyrrole
4 system is an acyclic compound. In these cases, all the fragments which lead to the PBD are
5 linked before the pyrrolo and diazepine cores are obtained, with derivatives of L-glutamic acid
6 as precursors of the pyrrolo system being usually employed. This is the case of the synthetic
7 route starting from L-glutamic acid 5-methyl ester, where the pyrrolo nucleus is obtained in
8 the last step, in a sequence with a low global yield (10%).¹⁴ In an effort to improve this yield, a
9 methodology was described employing as a starting material the dithioester derived from L-
10 glutamic acid, an unstable compound. This strategy allowed the simultaneous building of the
11 five- and seven-membered rings in the last step, increasing the global yield up to 33% (**Figure**
12 **2**).¹⁵ The third alternative, the construction of the pyrrolo nucleus before the diazepine core,
13 has also been described, but all the methodologies reported so far involve many steps, as well
14 as using specific and usually non-commercial substrates and/or protecting groups, which
15 makes them less appealing than the previous ones.¹⁶

33 Prompted by the antitumor activity displayed by these molecules and taking into
34 consideration our previous work with different benzodiazepines,¹⁷ we envisaged the possibility
35 of synthesizing various pyrrolo[2,1-c][1,4]benzodiazepine-5-ones following analogous
36 methodologies, based on Ugi's reaction. Employing this reaction provides a solution to some of
37 the above-mentioned issues, as it permits the use of commercial reagents which do not need
38 to be derivatized, performing the synthesis under mild conditions and without the use of
39 protecting groups. The compatibility of the isocyanide group with a large number of functional
40 groups allows the introduction of doubly functionalized fragments in the molecule, eventually
41 leading to the desired compounds. Herein, we describe the synthesis of three families of
42 pyrrolo[2,1-c][1,4]benzodiazepine-5-ones derivatives with different unsaturation patterns in
43 the pyrrolo nucleus (**Figure 3**). The synthetic strategy involves a three-step sequence, namely,
44 an Ugi reaction/pyrrolo synthesis/reduction-cyclization to the diazepines in which the different

unsaturation degrees on the pyrrolo nucleus is controlled by the nature of the amine and the cyclization methodology employed in the second step.

Figure 3. Pyrrolo[2,1-c][1,4]benzodiazepine-5-ones synthesized in this work (R^1 : alkyl, Ar: aryl).

Results and discussion

The first step in the described synthesis was the Ugi reaction. Three doubly functionalized reagents, two common in all reactions, 2-nitrobenzoic acid derivatives **2** and arylglyoxals **3**, and a different functionalized amine **1** depending on the desired unsaturation degree, namely, 3-bromopropylamine (used as its bromide salt) **1a**, propargylamine **1b** or 1-amino-3-butyne **1c**, were reacted with the isocyanide **4**, allowing the assembly of all the atoms which became part of the final systems in a single step (**Scheme 1**, **Table 1**).

Scheme 1. Linking all the fragments through the Ugi reaction.

^a 5a, 5c-5e, 5g-5i Ugi adduct intermediates for the synthesis of 6a, 6c-6e, 6g-i were not isolated but used directly in the next step

The results were similar regardless of the starting amine and the substitution of the other components. Interestingly, no spontaneous cyclization was observed upon the formation of Ugi adducts 5a-i, derived from 3-bromopropylamine 1a as it was described for the 3-bromopropionic acid derivatives.^{17b}

The second step in these syntheses was the construction of the pyrrolo core from the Ugi adducts, which underscores the importance of the functionalization in the Ugi reactants to carry out the post-condensation reactions towards the desired intermediates.

In order to obtain the pyrrolidines 6, Ugi adducts 5b and 5f were isolated, in 70 and 80% yield respectively, (Table 1, entries 1 and 2) and treated with cesium carbonate (1.5 equiv.), yielding the corresponding pyrrolidine almost quantitatively (93 and 94 % yield of isolated pure pyrrolidines 6b and 6f respectively). However, the overall yield was improved when the Ugi/cyclization was carried out in a single step, i. e., adding the cesium carbonate to the reaction mixture in the Ugi reaction (Table 2, entries 2 and 6). This is probably due to the loss of the Ugi adduct during the purification process. In this way, pyrrolidines 6a-i were

synthesized in a single step from the four reactants through an Ugi reaction, followed by a base-promoted intramolecular nucleophilic substitution (**Scheme 2**).

Scheme 2. Synthesis of pyrrolidines **6a-i** from 3-bromopropylamine.

^a The two-steps overall yield was 65% for **6b** and 64% for **6f**.

The synthesis of dihydropyrroles was carried out from the Ugi adducts derived from propargylamine **1b**. Two different strategies were examined as shown in **Scheme 3** and **Table 3**: (a) addition of metal salts, which would favor the formation of a complex between the dicarbonyl system, the alkyne and the metal ion; coordination would make the alkyne an

1
2
3 electrophile and would increase the nucleophilicity of the enol (**Scheme 4**),¹⁸ and (b) addition
4 of bases, which would favor the formation of the allene from the propargyl anion, hence
5 making the terminal carbon an electrophile due to a hyperconjugative effect, as well as an
6 enolate (**Scheme 5**).¹⁹

^a Ratio obtained by ¹H NMR spectroscopy.

Firstly, different reaction conditions were tried in the presence of In(III), a well-known Lewis acid,²⁰ as its chloride salt. Although 3-pyrroline **7a** was systematically obtained, it was not the only product. Unexpectedly, methyleneazetidinone **9** was also formed (**Table 3**, entry 1). The mechanism that drives the formation of both compounds would be similar: In(III) would coordinate simultaneously to the 1,3-dicarbonyl system and the alkyne (σ and π -coordination, respectively) and then the enolate would attack the triple bond intramolecularly (**Scheme 4**). However, the formation of **7** is favored over that of **9**, since the former takes place through a 5-*endo*-dig attack and the latter through a 4-*exo*-dig one although, according to Baldwin's rules,²¹ the 4-*exo*-dig attack is not favored.

Scheme 4. Cyclization mechanism of Ugi adducts derived from 3-propargylamine promoted by InCl₃.

Interestingly, when the reaction was conducted in boiling chloroform in the presence of silver(I) perchlorate instead of indium(III) chloride, only the 5-*endo*-dig cyclization occurred; however, the debenzoylated product **10** was obtained together with the desired 3-pyrroline **7a** (Table 3, entry 2). In order to avoid the formation of the former, the reaction was performed in boiling toluene, a solvent with lower water content than chloroform; in this way, 3-pyrroline **7a** was obtained exclusively (Table 3, entry 3).

To address the cyclization reaction from a second perspective, i. e., the addition of bases, potassium *tert*-butoxide and sodium carbonate were tried. The former is a common reagent for the formation of allenes from propargyl systems so, initially, 2.5 equiv. of

potassium *tert*-butoxide were added to a solution of **5j** in THF and the reaction was carried out at room temperature. Although 2,3-dihydropyrrole **8** would be the expected product,²² a mixture of **7a** and **10** was obtained, the latter being the major one (Table 3, entry 4). In view of this, the amount of base was reduced to one equivalent while keeping the remaining conditions (Table 3, entry 5), resulting in that, although **7a** became the major product, the debenzoylated one **10** was still formed due to the nucleophilicity of the base.

Scheme 5. Proposed mechanism for the formation of 3-pyrrolines **7a** and **10** promoted by bases

In an attempt to explain the formation of the 3-pyrroline **7a** instead of the expected 2-pyrroline **8**,²² Vazquez and colleagues have proposed a mechanism for an analogous system according to which the enolate would attack the alkyne's terminal carbon.²³ However, the

1
2
3 base-induced isomerization of propargyl amides to allenamides is well documented²⁴ and,
4
5 moreover, it is favoured in our reaction conditions (**Table 3**, entries 4 and 5).²⁵ In this way, a
6
7 plausible mechanism would start with the isomerization to the allenamide (**A**), which would
8
9 undergo an intramolecular attack on the terminal carbon from the enolate (*5-endo-trig*
10
11 cyclization), thus giving rise to vinyl carbanion **B**. The translocation of the allyl proton would
12
13 originate an allyl anion (**C**), thus accounting for the isomerization of the double bond.²⁶ The
14
15 protonation of **C** would lead to 3-pyrroline **7a** since they are more stable than 2-pyrrolines.²⁷
16
17 The retro-Claisen reaction on this 3-pyrroline **7a** would yield the debenzoylated 3-pyrroline **10**
18
19 (**Scheme 5**).

20
21
22
23
24 With the aim of avoiding the debenzoylation reaction, the less nucleophilic sodium
25
26 carbonate was employed as the base. Sodium carbonate is also less basic, so the temperature
27
28 was increased. Typically, this kind of bases requires the use of boiling DMF,²⁸ or of THF
29
30 combined with a microwave oven,²⁹ but surprisingly the reaction leading to 3-pyrroline **7a** was
31
32 quantitative in boiling acetonitrile (**Table 3**, entry 6). This approach is also safer and more
33
34 ecofriendly than the use of silver(I) perchlorate. Therefore, a series of 3-pyrrolines was
35
36 synthesized according to **Scheme 6** with good yields (**Table 4**).

Scheme 6. Synthesis of 3-pyrrolines **7a-f** from Ugi adducts **5j-o**.

Table 4. Global yields for the synthesis of 3-pyrrolines **7a-f** from Ugi adducts **5j-o**.

Entry	5 (R ¹ , R ² , R ³ , R ⁴)	7 (%)

3	5l (H, H, OCH ₃ , cC ₆ H ₁₁)	7c (82)
4	5m (H, H, H, <i>t</i> Bu)	7d (72)
5	5n (H, Cl, H, cC ₆ H ₁₁)	7e (77)
6	5o (Cl, H, H, cC ₆ H ₁₁)	7f (87)

Finally, the syntheses of the pyrrolidines incorporating an *exo* unsaturation in the pyrrolo core were conducted from Ugi adducts **5p-r** derived from 1-amino-3-butyne **1c**. Although the Ugi adducts were initially subjected to a basic treatment, employing both sodium carbonate and sodium *tert*-butoxide, in order to obtain the desired 3-methylenepyrrolidines, these trials were unsuccessful and the starting materials were recovered. The formation of the allene in these conditions is not favored, as the hydrogen atoms of the methylene group adjacent to the triple bond are not as acidic as are those of the propargylic position. This also confirmed that the attack of the enolate to the triple bond, which would eventually lead to the formation of the pyrrolic ring, is not favored. In light of these results, a study similar to that described in the previous section was performed. Hence, Ugi adduct **5p** was dissolved in boiling toluene and indium(III) chloride or silver(I) perchlorate (0.05 equiv.) were added to the solution. These conditions favored the 5-*exo*-dig cyclization reaction, driving to the regioselective and exclusive formation of 3-methylenepyrrolidine **11a**. Thus, we chose the safer indium(III) chloride as catalyst affording thereby the corresponding 3-methylenepyrrolidine in good yields (**Scheme 7, Table 5**).

16 **Scheme 7.** Synthesis of 3-methylenepyrrolidines **11a-c** from Ugi adducts **5p-r**.

28
29 The final cyclisation step furnishing the diazepine ring was carried out in a similar way
30 for all the different pyrrolo systems, **6**, **7** and **11**. Reduction of the nitro group with tin(II)
31 chloride in the presence of HCl in hot ethanol lead to a spontaneous intramolecular
32 cyclization.¹⁷ The generated amino group undergo a nucleophilic addition to the carbonyl
33 group of the molecule giving rise to an imine fragment. This process generated compounds
34
35
36
37
38
39
40 **12a-r** in good to moderate yields (**Scheme 8**).

Scheme 8. Synthesis of pyrrolobenzodiazepine-5-ones **12a-r** from different pyrrolo systems.

X-ray diffraction studies of compound **12i** showed that the conformation adopted by these systems is determined by the configuration of the stereogenic centre C3 (3*S*-(*M*)- and 3*R*-(*P*)-conformers), as the largest substituent, the amide group derived from the isocyanide component in the Ugi reaction, prefers the pseudoaxial orientation (**Figure 4**).³⁰

Figure 4. Crystal packing in the X-ray structure of compound **12i**. Hydrogen atoms and two chloroform molecules have been omitted for the sake of simplicity. The ORTEP plot is at the 30% probability level. The molecule on the left side of the image is the 3*R*-(*P*)- conformer, while that on the right side is the 3*S*-(*M*)- conformer.

Conclusion

In this work we have described the use of Ugi/post-condensation methodologies to provide straightforward access to three novel families of pyrrolobenzodiazepine-5-ones. Selecting the appropriate amine, it is possible to obtain saturated and unsaturated pyrrolic cores bearing *endo* or *exo* unsaturations in just three steps. This methodology represents a remarkable improvement with respect to those starting from acyclic compounds previously reported, as the starting materials are affordable and commercially available, and there is no need for derivatization, neither to use protecting groups. This allows the syntheses of three different

1
2
3 pyrrolobenzodiazepine-5-one families with high atom economy and high to moderate global
4
5 yields.

Experimental section

General methods

Melting points have not been corrected. ^1H and ^{13}C NMR spectra were recorded in CDCl_3 at 300 and 75 MHz, respectively, on a Varian Mercury 300 system; DEPT-135 experiments were conducted to assign carbon-13 signals. Chemical shifts are reported in parts per million with respect to residual solvent protons and coupling constants in hertz. High resolution mass spectra were recorded in positive ion mode by electronic impact (EI; Agilent 7010 mass spectrometer with a triple quadrupole analyzer) at 70 eV or electrospray ionization (ESI; Agilent 6545 with a quadrupole-time-of-flight analyzer).

General procedure for the synthesis of Ugi adducts 5b,f,j-r. The corresponding amine **1a-c** (1.0 mmol, 1.0 equiv.) (3-bromopropylamine **1a** should be obtained from the treatment of the commercial 3-bromopropylamine hydrobromide (1.1 mmol, 1.1 equiv.) with sodium hydroxide (1.0 mmol, 1.0 equiv.) in methanol) and the corresponding arylglyoxal **3a-d** (1.0 mmol, 1.0 equiv., 0.1 M) which were dissolved in methanol (10 mL) and the resulting solution was stirred at room temperature for 15 minutes to preform the imine. Subsequently, the corresponding 2-nitrobenzoic acid **2a-c** (1.0 mmol, 1.0 equiv.) and isocyanide **4a-c** (1.0 mmol, 1.0 equiv.) derivatives were added, and the mixture was stirred at room temperature for 24 hours. The precipitate formed, corresponding to the different Ugi adducts **5**, was isolated by vacuum filtration and dried. Note: as two rotamers are observed in the NMR spectra of these compounds, the terms "major" and "minor" are used to indicate to which of the rotamers the corresponding signal is assigned.

10 **General procedure for the synthesis of pyrrolidines 6a-i.** 1.0 mmol (1.0 equiv.) of sodium
11 hydroxide was added to a solution of 3-bromopropylamine hydrobromide **1a** (1.1 mmol, 1.1
12 equiv.) in methanol (10 mL). Subsequently, the corresponding arylglyoxal **3a-d** (1.0 mmol, 1.0
13 equiv., 0.1 M) was added, followed by the addition of the corresponding 2-nitrobenzoic acid
14 **2a-c** (1.0 mmol, 1.0 equiv.) and the corresponding isocyanide **4a-c** (1.0 mmol, 1.0 equiv.). The
15 resulting solution was stirred at room temperature for 24 hours and, then, cesium carbonate
16 (1.5 mmol, 1.5 equiv.) was added. The mixture was stirred at room temperature for one hour
17 and the solvent was removed under reduced pressure. The raw product was dissolved in
18 dichloromethane and washed with acidified water. The organic phase was dried over
19 anhydrous sodium sulfate, filtered and concentrated to dryness, thus yielding the
20 corresponding pyrrolidine **6a-i**.

47 **General procedure for the synthesis of 3-pyrrolines 7a-f.** A mixture of the corresponding Ugi
48 adduct **5j-o** (1.0 mmol, 1.0 equiv., 0.1 M) and Na₂CO₃ (1.0 mmol, 1.0 equiv.) in boiling ethanol
49 (10 mL) was stirred for 6 hours, after which the solvent was removed by rotary evaporation.
50 The raw product was dissolved in dichloromethane and washed with acidified water. The
51 organic phase was dried over anhydrous sodium sulfate, filtered and concentrated to dryness,
52 thus yielding the corresponding 3-pyrrolines **7a-f**.
