Summary

The primary goal of the Arkansas Cotton Variety Test is to provide unbiased data regarding the agronomic performance of cotton varieties and advanced breeding lines in the major cotton-growing areas of Arkansas. This information helps seed companies establish marketing strategies and assists producers in choosing varieties to plant. These annual evaluations will then facilitate the inclusion of new, improved genetic material in Arkansas cotton production. Adaptation of varieties is determined by evaluating the lines at five University of Arkansas System Division of Agriculture research sites (Manila, Keiser, Judd Hill, Marianna, and Rohwer). Entries in the 2019 Arkansas Cotton Variety Test were evaluated in two groups—transgenic and conventional varieties. The 50 entries in the transgenic test included 9 B2XF, 25 B3XF, 13 W3FE, and 3 GLTP lines which were evaluated at all five locations. The conventional test included 15 entries which were evaluated at all locations except Manila. Reported data include lint yield, lint percentage, plant height, percent open bolls, yield component variables, fiber properties, leaf pubescence, stem pubescence, and bract trichome density. All entries in the experiments were evaluated for response to tarnished plant bug and bacterial blight in separate tests at Keiser. This 2019 report includes results of large-plot variety tests in 10 counties that were coordinated by Bill Robertson.

Introduction

The purpose of the University of Arkansas System Division of Agriculture's Cotton Variety Testing Program is to provide unbiased comparisons of cotton varieties and advanced breeding lines over a range of environments. Data from these tests help to identify the potential adaptability of varieties to particular cotton-growing regions of the state. Bourland et al. (2000) documented several unintentional biases that are inherent to the Arkansas cotton variety testing program. These include management associated with varieties expressing herbicide and insect resistance. The biases tend to cancel each other so that no great advantage is given to any particular variety. Since evaluation of genetic differences among entries is the ultimate goal of the evaluations, all varieties are treated identically within the primary locations (Manila, Keiser, Judd Hill, Marianna, and Rohwer) of the variety test. No specialized production inputs were employed with respect to the various genetically enhanced varieties. All entries in the tests at Manila possessed the RF or G genes and were uniformly treated with Round-up. Since the plots were over-sprayed with Round-up, the conventional varieties were not evaluated at Manila.

Materials and Methods

The 50 entries in the transgenic test included 9 B2XF, 25 B3XF, 13 W3FE, and 3 GLTP lines, of which 23 were included in the 2018 Arkansas Cotton Variety Test (Table 1). The conventional test included 15 entries, 8 of which were in the 2018 test. All entries were replicated 4 times at each test site.

Test sites included the Northeast Research and Extension Center at Keiser; the Judd Hill Cooperative Research Station at Judd Hill (near Trumann); the Lon Mann Cotton Research Station at Marianna; the Manila Airport Cotton Research Farm at Manila; and the Rohwer Research Station at Rohwer. The transgenic test was evaluated at each site, and the conventional test was evaluated at all sites

except Manila. The conventional tests were in the same fields as the transgenic test, but were in different areas of the fields. Cultural practices and weather data (heat units and rainfall) associated with the test sites are listed in Table 2 and Table 3, respectively.

Originators of seed supplied double-treated (two fungicides) seed for all entries. Prior to planting, all seed were treated with imidacloprid (Gaucho[®]) at a rate of 6 oz/100 lb seed by the originator or the testing personnel. Plots were planted with a constant number of seed (about 4 seed/row ft). All varieties were planted in 2-row plots on 38-inch centers and ranged from 40 to 50 feet in length. Experiments were arranged in a randomized complete block. Although exact inputs varied across locations, cultural inputs at each location were generally based on University of Arkansas System Division of Agriculture Cooperative Extension Service recommendations for cotton production, including COTMAN rules for insecticide termination. All plots were machine-harvested with 2-row or 4-row cotton pickers modified with load cells for harvesting small plots.

Data Collected at Single Location

Leaf Pubescence. Leaf pubescence was visually rated on a scale of 1 (smooth leaf) to 9 (pilose, very hairy) in the irrigated experiments at Keiser using the system described by Bourland et al. (2003). A full-sized main-stem leaf located about 5-6 nodes from plant apex was rated for 6 plants per plot for all 4 replications during August.

Stem Pubescence. Stem pubescence was visually rated on a scale of 1 (smooth stem) to 9 (very hairy) in the irrigated experiments at Keiser using a system similar to that used for leaves. After harvest, the upper 5-6 inches of the plant apex was rated for 6 plants per plot for all 4 replications.

Bract Trichomes. As all plants approached physiological cutout, a bract from a 1st position white flower was

¹F. Bourland is a professor and Altheimer chair for cotton research and development; A. Beach and E. Brown are program technicians at the Northeast Research and Extension Center; C. Kennedy is resident director at the Lon Mann Cotton Research Station; L. Martin is a program technician at the Rohwer Research Station; and B. Robertson is a cotton agronomist at the Newport Extension Center.

sampled from 6 random plants per plot (4 replications) in the Keiser experiments. Each bract was examined for marginal trichome density (no. of trichomes/cm) as described by Bourland and Hornbeck (2007). Means for the 6 bracts were evaluated as plot means.

Tarnished Plant Bug (TPB). Entries in the two variety tests were evaluated for response to TPB in a separate field at Keiser. The TPB test included 8 replications of 1-row plots (20-feet long on 38-inch wide rows). Four rows of a highly susceptible Frego-bract line were planted between the tests on May 18. The TPB tests were planted on June 3 and received no insecticide treatment for TPB infestations. Early flowering in the susceptible Frego-bract strips encouraged TPB populations to increase, then to migrate from the strips as the test plots began to flower. Response to TPB was determined by examining white flowers (6 flowers/plot/day for 6 days in late August) for presence of anther damage. Accumulative percentage of damaged flowers ("dirty flowers") was determined for each plot.

Bacterial Blight. Entries in the two variety tests were planted in flats (3 replications, 13 seed/plot) in the greenhouse, and scratch inoculated with *Xanthomonas citri* pv. *malvacearum*. The inoculum was obtained from naturally infected leaves collected at the 2018 Keiser location. Scratches were examined for water-soaking, and percent of susceptible plants was determined.

Verticillium Wilt. Relative yields of varieties over years at Judd Hill should be indicative of tolerance to Verticillium wilt.

Data Collected at All Locations

Plant Height. Plant height measurements (in cm) were collected after harvest was completed. Average plant heights for varieties were determined by measuring from the soil surface to the terminal of one average-sized plant in each of the two rows. Plot means (average of the two measurements) were evaluated.

% Open Bolls. Near the time of first application of defoliants, percentage of open bolls was estimated from the front and back of each plot, then averaged for each plot.

Boll Samples and Lint Percentage. Prior to mechanical harvest, hand-harvested samples were obtained from 2 replications at each location. Within each row of 2-row plots, a site having average or above average plant density was chosen and 20 bolls (5 bottom, 10 mid-canopy and 5 top bolls) were harvested and bulked to form a 40-boll sample. The 40-boll samples were ginned (lab gin without the use of lint cleaners) to determine lint fraction (the percentage of lint weight to seed cotton weight).

Fiber Properties. Fiber samples were taken from each boll sample and were evaluated using HVI classification. Parameters included micronaire, fiber length, length uniformity index (UI), strength, and elongation. To reflect market demand for fiber quality, a weighted quality score (Q-score) was calculated as described by Bourland et al. (2010). Parameters (and weighting) included in Q-score were fiber length (50%), micronaire (25%), length uniformity index (15%), and strength (10%).

Seed Index. Two sets of 25 fuzzy seed from the ginned seed of each 40-boll sample were counted and weighed. If the two weights varied more than 0.2 g, a second set of samples was taken. Two consistent weights of 25 seed were used to calculate fuzzy seed index (weight of 100 seed).

Seed Per Acre. For each plot, an estimate of number of seed per acre was determined by multiplying seed cotton yield (lb/acre converted to g/acre) times average seed percentage (the percentage of seed weight to seedcotton weight in ginned sample, averaged by entry and location over reps), then divided by average seed weight (average seed index by entry over reps divided by 100).

Lint Index. Lint index (weight of lint on 100 seed) was determined from 40-boll sample data by dividing lint weight from ginned sample by the number of seed per sample (estimated using average seed weight) then multiplying by 100.

Fibers Per Seed. Fibers per seed were estimated by dividing lint index by an estimated weight of individual fibers. Weight of an individual fiber was estimated by: fiber length × length uniformity × (micronaire/1,000,000).

Fiber Density. Fiber density, reported as the number of fibers per mm², was estimated by dividing fibers per seed by seed surface area. Seed surface area (SSA) was estimated by the regression equation suggested by Groves and Bourland (2010): SSA = 35.74 + 6.59 SI, where SI is equal to seed index associated with the sample.

Lint Yield. Seed cotton yield per plot (determined by mechanical cotton picker) was converted to seed cotton yield per acre then multiplied by average lint percentage (determined by variety and location) to estimate lint per acre.

Yield Comparisons

Uncontrolled variation is inherent to collection of variety performance data (particularly yield data). In addition to their genetic ability, variation among varieties may be due to slight differences in soil, pest or climatic conditions within a field, various interactions with specific management practices, or experimental error. Statistics allow users to

define the degree of uncontrolled variation and to interpret data. The statistical tool used to compare means in these tests was Fisher's Protected Least Significant Difference (LSD). An LSD was calculated when the F-test value from analysis of variance was significant. Yields of varieties are considered significantly different if the difference between mean yields of two varieties is greater than the LSD value. Differences that are smaller than the LSD may have occurred by chance or may be associated with uncontrolled variation, and are therefore considered not significant.

Additional estimates of variation are provided by measures of R-squared and coefficient of variation (CV). R-squared (times 100) indicates the percentage of variation that is explained by defined sources of variation (e.g., replication and variety effects within a location). Confidence in data increases as R-squared increases. Generally, the meaningfulness of difference among means is questionable when data have R-squared values of less than 50%. Also, confidence in data becomes greater as CV declines.

Results

Entries and participants in the test are listed in Table 1. Cultural inputs and production information for variety trials at Manila, Keiser, Judd Hill, Marianna, and Rohwer are reported in Table 2. Table 3 includes weather information for north, central, and south Arkansas locations during the 2019 production season.

Both heat units and rainfall in 2019 exceeded historical averages at each Arkansas location (Table 3). The warm temperatures in May provided excellent conditions for emergence and early growth of seedlings, but wet conditions delayed plantings. Despite the high heat unit accumulations for the season, temperatures exceeding 95 °F were relatively rare—11 days at Keiser, 7 days at Marianna and 9 days at Rohwer. Most of the days exceeding 95 °F occurred in September and October (10 days at Keiser, 5 at Marianna, and 6 at Rohwer). The absence of extremely high temperature and the occurrence of relatively high rainfall provided excellent growing conditions through the season. The unusually warm September promoted plant development in late-planted sites and in later maturity lines.

Rainfall in 2019 exceeded historical average rainfall at each location (Table 3). Harvest of these tests were completed before much of the October rainfall occurred, but wet conditions hindered fall tillage operations.

Performance data of entries in the 2019 Transgenic Cotton Variety Test at Manila, Keiser, Judd Hill, Marianna

and Rohwer are provided in Tables 4 through 15 with yield and yield-related variables in the even-numbered tables and fiber properties in the odd-numbered tables. Performance data across all 5 locations are presented in Tables 4 and 5. Morphological and host-plant resistance measurements for the transgenic test entries are in Table 16. Two- and three-year yield means for entries evaluated in previous years are in Table 17. Performance data for the 2019 Conventional Cotton Variety Test at Keiser, Judd Hill, Marianna and Rohwer are provided in Tables 18 through 27 with yield and yield-related variables in the even-numbered tables and fiber properties in the odd-numbered tables. Morphological and host-plant resistance measurements for the conventional entries are in Table 28. Two- and three-year yield means for the conventional entries evaluated in previous years are in Table 29.

Other observations associated with each test site include:

Manila (Tables 6 and 7). The tests at Manila were in the same field used since 2014, and in the same area of the field used since 2015. Plots were planted on May 30, and achieved good stands and high yields. The warm September and October temperatures were particularly beneficial to this site.

Keiser (Tables 8, 9, 20, and 21). The 2019 variety tests were moved back to a field (N6) on the north end of the station where variety tests had been conducted for several previous years. Nitrogen was low in this field because much of the field was planted to corn in 2018 and because some nitrogen was lost to heavy rainfall in May.

Judd Hill (Tables 10, 11, 22 and 23). Wet field conditions caused planting of the Judd Hill plots to be delayed until May 28. Excellent stands were achieved, and plants grew well and established excellent boll loads. Intensity of Verticillium wilt was moderate (similar to 2018), and much lower than experienced in 2017.

Marianna (Tables 12, 13, 24 and 25). For the fourth consecutive year, a cereal rye cover crop was used in the tests at Marianna. The cover crop was planted on Nov. 19, 2018, and terminated on April 22, 2019, using glyphosate (3 pt/acre). Pigweed pressure was very light in the tests. Average lint yields at Marianna were higher than at other test sites in 2019.

Rohwer (Tables 14, 15, 26 and 27). The Rohwer location was planted on May 7, and excellent stands were achieved. The plants grew well and produced good yields.

Acknowledgments

We express our appreciation to the directors, program technicians and staff at the University of Arkansas System Division of Agriculture's Northeast Research and Extension Center, Lon Mann Cotton Research Station, and the Rohwer Research Station. Annually, the Judd Hill Foundation generously provides the test site for experiments at Judd Hill. We are particularly grateful to the City of Manila for making land available for testing, and to the Mississippi County Cooperative Extension Agents and Wildy Farms for assisting with the test site at the Manila Airport. Annual evaluation of cotton varieties is made possible by the work of the research assistants and technicians at these locations, and by the contributions of seed companies participating in the Arkansas Cotton Variety Test.

^a Leaf and stem pubescence rated at Keiser irrigated test (6 plants per plots, 4 replications) using a scale of 1 (smooth leaf) to 9 (pilose, very hairy).

^b Marginal trichome density of bracts determined on 6 bracts/plot (4 replications) at Keiser irrigated test.

^c Response to tarnished plant bug was determined by examining white flowers (6 flowers/plot/day for 6 days) for presence of anther damage. Plots were 1-row, replicated 8 times.

^d Varieties/breeding lines were planted in flats (3 replications, 10 seed/plot) in a greenhouse, and scratch inoculated with *Xanthomonas citris* pv. *malvacearum*. The inoculum was obtained from naturally infected leaves collected at the 2018 Keiser location. Scratches were examined for water-soaking, and percent of susceptible plants was determined.

^a Leaf and stem pubescence rated at Keiser irrigated test (6 plants per plots, 4 replications) using a scale of 1 (smooth leaf) to 9 (pilose, very hairy).

^b Marginal trichome density of bracts determined on 6 bracts/plot (4 replications) at Keiser irrigated test.

^c Response to tarnished plant bug was determined by examining white flowers (6 flowers/plot/day for 6 days) for presence of anther damage. Plots were 1-row, replicated 8 times.

^d Varieties/breeding lines were planted in flats (3 replications, 10 seed/plot) in a greenhouse, and scratch inoculated with *Xanthomonas citris* pv. *malvacearum*. The inoculum was obtained from naturally infected leaves collected at the 2018 Keiser location. Scratches were examined for water-soaking, and percent of susceptible plants was determined.
