## Abstract

The human coronaviruses (HCoVs) are an important etiology of community-acquired respiratory tract infections. Community-acquired pneumonia (CAP) may be caused by serotypes of endemic HCoVs or highly pathogenic HCoVs. In this review we compared the clinical characteristic, management, outcomes, and infection control practices for patients with CAP due to endemic HCoVs versus patients with CAP due to 2019 novel coronavirus (SARS-CoV-2).

## Introduction

There are four serotypes of HCoVs that are endemic and three highly pathogenic HCoVs (**Figure 1**). Endemic HCoVs cause respiratory tract infection in children and adults globally. We recently reported our experience with adults hospitalized with CAP due to endemic HCoVs in the city of Louisville, Kentucky.[1] The first cases of CAP due to highly pathogenic HCoVs, the severe acute respiratory syndrome coronavirus (SARS-CoV), were identified in China in 2002.[2] Cases of CAP due to a second highly pathogenic HCoV, the Middle East respiratory syndrome coronavirus (MERS-CoV), were identified in Saudi Arabia and Qatar in 2012.[3,4] More recently, cases of CAP due to the 2019 novel coronavirus (2019-nCoV) were identified in the city of Wuhan, China at the end of 2019. [5] Based on phylogeny, this new coronavirus is recognized as a sister of the SARS-CoV, and the Coronavirus Study Group of the International Committee on Taxonomy of Viruses is proposing to designate this new virus as severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2).[6] The World Health Organization is now officially calling the disease COVID-19 (**CO** for corona, **VI** for virus, **D** for disease, and **19** for the year 2019). Having a name for the virus (2019-nCoV or SARS-CoV-2) and a different name for the disease (COVID-19) will help with the nomenclature of future coronavirus outbreaks. The spectrum of disease for patients presenting with COVID-19 is depicted in **Figure 2**.

In this manuscript we first compared the clinical characteristics and outcomes of patients with CAP due to endemic HCoVs admitted to hospitals in the city of Louisville [1] versus patients with CAP due to the 2019-nCoV admitted to hospitals in the city of Wuhan.[7] We subsequently reviewed our current understanding of the risk factors, diagnosis, infection control practices, and management of patients with CAP due to endemic HCoVs and the 2019-nCoV or SARS-CoV-2.

## Clinical Presentation and Outcomes

The demographics, comorbidities, and signs and symptoms of 42 patients hospitalized with endemic HCoVs as the only etiology of CAP from the city of Louisville [1] and the first 41 patients reported in the literature with CAP due to the 2019-nCoV from the city of Wuhan [7] are depicted in **Table 1**. The age distribution of both groups is depicted in

**Figure 1.** Serotypes of HCoVs globally endemic and highly pathogenic. SARS-CoV: Severe acute respiratory syndrome coronavirus. MERS-CoV: Middle East respiratory syndrome coronavirus. 2019-nCoV: 2019 novel coronavirus or SARS-CoV-2: Severe acute respiratory syndrome coronavirus 2.

**Figure 2.** Spectrum of disease for patients presenting with COVID-19.

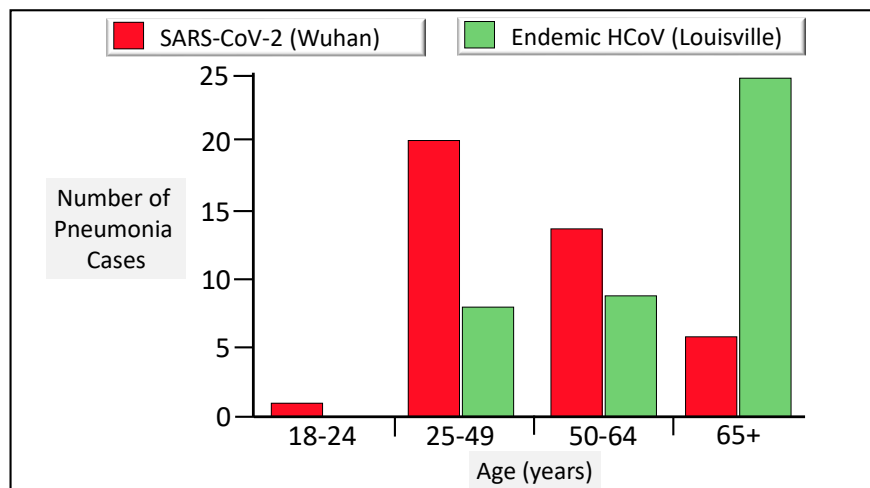

**Figure 3.** Patients infected with the 2019-nCoV are younger and present with less comorbidities when compared to patients infected with endemic HCoVs. **Table 2** compares the laboratory and radiographic findings of both groups. Patients with CAP due to 2019-nCoV presented with lower white blood cells count and higher elevations in liver enzymes. In both groups of patients, procalcitonin levels were low, as expected of patients with viral CAP. The presence of pulmonary infiltrates with bilateral involvement was present in almost 100% of patients in both groups. The treatments and outcomes of both groups are depicted in **Table 3**. In the initial report of CAP due to 2019-nCoV, the high mortality of 15% was likely a reflection of a more critically ill population of patients being initially recognized with the disease. A second case series, including 139 hospitalized patients with 2019-nCoV, reported a mortality of 4%.<sup>[8]</sup> This mortality is similar to the one that we reported for hospitalized patients with endemic HCoVs of 2%.

### Risk Factors and Diagnosis

The incubation period of 2019-nCoV is thought to range from 3 to 14 days, with most patients developing clinical manifestations within the first week following exposure. Since an infected person may be asymptomatic for up to 14 days, a patient with fever and/or symptoms of respiratory tract infection should be considered at risk of 2019-nCoV infection if: 1) the patient, within the prior 14 days, resided in or traveled to China, or 2) the patient, within the prior 14 days, had close contact with a confirmed or suspected case of 2019-nCoV infection. In a patient at risk of 2019 nCoV infection, the diagnosis is confirmed by performing a PCR of specimens from the upper respiratory tract (e.g. nasopharyngeal or

oropharyngeal secretions) using 2019-nCoV primers.

### Infection Control Measures

There are four areas of infection control practice that are relevant for the safety of healthcare workers caring for patients with CAP due to endemic HCoVs as well as the 2019-nCoV. They include early recognition and isolation, selection and use of personal protective equipment, performance of hand hygiene, and environmental infection control. The specific infection control recommendations for endemic HCoVs and 2019-nCoV are depicted in **Table 4**.

In a recent report of 138 patients hospitalized with 2019-nCoV infection, the authors estimated that nosocomial transmission of the virus may have occurred in 40% of the patients.[8] They considered transmission from patient to patient in 17 patients (12%) and transmission from patient to health care worker in 40 patients (29%). It is important that several patients in this report were not placed in respiratory isolation at the time of hospital admission because the initial patient’s complaints were related to atypical abdominal symptoms. As depicted in **Figure 2**, some patients may have a gastrointestinal syndrome as initial presentation of Covid-19. In these cases, the virus may be transmitted via the fecal-oral route.

### ICU Management

Some parallels can be made to the prior two epidemic strains, MERS-CoV and SARS-CoV in transmission and clinical features and thus ICU management strategies implemented in those epidemics could be applied currently. Clinicians at University of Toronto described specific challenges in oxygenating patients with SARS-CoV.[9] The use of oxygen therapy with aerosol humidifiers was suspected to increase the risk of droplet transmission. Additional routine ICU proce-

dures were deemed high risk due to infection control concerns including intubation and extubation, nasopharyngeal swab, bag-valve-mask ventilation, suctioning, non-invasive positive pressure ventilation (NIPPV), and high frequency oscillation. Disconnection from the ventilator and manual bag ventilation was discouraged due to concerns for droplet spread even in cases of cardiac arrest unless an obvious mechanical failure was suspected.

Ventilator management of SARS-CoV mirrored that of acute respiratory distress syndrome (ARDS). Similar observations were made with the MERS-CoV outbreak as described by clinicians in Jeddah, Saudi Arabia.[10] Management of respiratory failure with NIPPV was strongly discouraged as it almost always lead to intubation and also carried significant risk of droplet spread.

In patients who develop ARDS leading to invasive ventilation, we consider a strategy of low tidal volume (4 to 6 ml/Kg of predicted body weight) and the use of positive-end-expiratory pressure titrated according to the requirement of oxygen. The plateau pressure should be maintained at less than 30 cmH2O.[11] We also consider monitoring driving pressure, since higher driving pressure values have been associated with higher mortality in patients with ARDS.[12] In the setting of refractory hypoxia, other strategies should be considered such as prone position and extracorporeal membrane oxygenation.[13,14]

## Therapy

The majority of the proposed therapies for CAP due to human coronavirus came to light during the SARS-CoV and MERS-CoV outbreaks in 2003 and 2012, respectively. Treatment options evaluated in clinical studies included antivirals, such as ribavirin, antiretrovirals such as lopinavir/ritonavir, steroids, interferon, and macrolides. In most reports, these therapies have been used in combination without a clear clinical benefit.

Remdesivir is a novel nucleotide analogue with activity against SARS and MERS-CoV in vitro and in animal studies.[15] Remdesivir was utilized as a compassionate use investigational drug in the first described US case of 2019-nCoV in January 2020. The patient had mild initial symptoms that progressed to pneumonia on the ninth day of admission, with rapid clinical improvement after treatment with remdesivir. This novel agent is being considered for further randomized clinical trials in China to establish efficacy in humans during the current 2019-nCoV outbreak. Investigators from the National Institute of Allergy and Infectious Diseases (NIAID) are preparing to test remdesivir, as well as lopinavir/ritonavir (Kaletra), and interferon-beta for their activity against 2019-nCoV.[16]

## Prospect for a Vaccine

The NIAID Vaccine Research Center is leading the efforts to develop a vaccine for the 2019-nCoV. Investigators are using a messenger RNA platform to produce the viral spike protein of 2019-nCoV. The NIAID anticipates the experimental vaccine will be ready for testing in a phase 1 trial in the coming months.[16]

## Conclusions

Patients with CAP due to 2019-nCoV tend to be younger, and with less comorbidities than patients with CAP infected with endemic HCoVs, however, the clinical presentation and outcomes for both groups of patients is similar. Optimal implementation of infection control practices is important to contain the 2019-nCoV spread in the community and hospital setting. Patients hospitalized with CAP due to 2019-nCoV have a mortality of approximately 3%, very similar to the mortality of hospitalized patients with CAP due to endemic HCoVs. Mortality of hospitalized patients with CAP due to 2019-nCoV is expected to decrease as new therapeutic strategies are developed.
