The complete molecule of the binuclear title complex, bis $[\mu-1 H-1,2,4$-triazole$5(4 H)$-thione $\left.-\kappa^{2} S: S\right]$ bis $\{($ thiocyanato- $\kappa S)[1 H-1,2,4-$ triazole- $5(4 H)$-thione- $\kappa S]$ silver $(\mathrm{I})\}$, $\left[\mathrm{Ag}_{2}(\mathrm{SCN})_{2}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{~N}_{3} \mathrm{~S}\right)_{4}\right]$, is generated by crystallographic inversion symmetry. The independent triazole-3-thione ligands employ the exocyclic-S atoms exclusively in coordination. One acts as a terminal S-ligand and the other in a bidentate $\left(\mu^{2}\right)$ bridging mode to provide a link between two $\mathrm{Ag}^{\mathrm{I}}$ centres. Each $\mathrm{Ag}^{\mathrm{I}}$ atom is also coordinated by a terminal S-bound thiocyanate ligand, resulting in a distorted $\mathrm{AgS}_{4}$ tetrahedral coordination geometry. An intramolecular $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ (thiocyanate) hydrogen bond is noted. In the crystal, amine- $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ (thione), $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ (triazolyl) and $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ (thiocyanate) hydrogen bonds give rise to a three-dimensional architecture. The packing is consolidated by triazolyl- $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ (thiocyanate), triazolyl- $\mathrm{C}-\mathrm{H} \cdots \mathrm{N}$ (thiocyanate) and S $\ldots$ S $[3.2463$ (9) $\AA$ ] interactions as well as face-to-face $\pi-\pi$ stacking between the independent triazolyl rings [inter-centroid separation $=$ 3.4444 (15) Å]. An analysis of the calculated Hirshfeld surfaces shows the three major contributors are due to $\mathrm{N} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{N}, \mathrm{S} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{S}$ and $\mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C}$ contacts, at $35.8,19.4$ and $12.7 \%$, respectively; $\mathrm{H} \cdots \mathrm{H}$ contacts contribute only $7.6 \%$ to the overall surface.

## 1. Chemical context

The title binuclear $\mathrm{Ag}^{\mathrm{I}}$ complex, (I), containing $1 H-1,2,4-$ triazole-5(4H-thione) and thiocyanate ligands has been synthesized and its crystal and molecular structures determined as part of our on-going studies in this area (Kodcharat et al., 2013). Interest in the 1,2,4-triazole-based heterocyclic thione derives from the various medical applications and extensive biological activity exhibited by Schiff base molecules derived from 1,2,4-triazoles. For example, these molecules are known for their anti-fungal, anti-bacterial, anti-tumour, anticonvulsant, anti-inflammatory and analgesic properties (AlSoud et al., 2003; Walczak et al., 2004; Almasirad et al., 2004; Amir \& Shikha, 2004; Turan-Zitouni et al., 2005). In addition, the synthesis and biological activities of coordination complexes of these molecules continue to attract significant attention as coordination often enhances the biological activity of the organic molecules (Dharmaraj et al., 2001; Singh et al., 2006; Altundas et al., 2010; Amer et al., 2013; Bheeter et al., 2016).

1H-1,2,4-Triazole-5(4H-thione), the heterocyclic ligand in (I) and hereafter referred to as HtrzSH, has attracted relatively little attention in the literature although recently the anti-cancer potential of derivatives of this were described (Büyükekşi et al., 2018). The crystallographic study of (I) described herein is complemented by an analysis of the calculated HOMO and LUMO and an analysis of the calculated Hirshfeld surfaces and energy frameworks.

## 2. Structural commentary

The binuclear complex, $\left[\mathrm{Ag}(\mathrm{HtrzSH})_{2}(\mathrm{SCN})\right]_{2}(\mathrm{I})$, Fig. 1, crystallizes in the monoclinic space group $P 2_{1} / n$ and is disposed about a crystallographic centre of inversion. The HtrzSH molecules only employ their exocyclic thione-sulfur atoms in coordination, there being no Ag...N contacts of note. Each $\mathrm{Ag}^{\mathrm{I}}$ atom is coordinated by a terminally bound HtrzSH molecule and by two thione-sulfur atoms derived

Figure 1

from two $\mu_{2}$-bridging HtrzSH molecules. The coordination of each $\mathrm{Ag}^{I}$ atom is completed by a terminal, S-bound thiocyanate anion. The geometry around the silver centre defined by the $\mathrm{S}_{4}$ donor set is distorted tetrahedral with the $\mathrm{S}-\mathrm{Ag}-\mathrm{S}$ bond angles spanning about $25^{\circ}$, i.e. from a narrow 91.60 (2) ${ }^{\circ}$ for $\mathrm{S} 1-\mathrm{Ag}-\mathrm{S} 1^{\mathrm{i}}$, being subtended by the bridging S 1 atoms, to a wide $127.43(2)^{\circ}$ for $\mathrm{S} 2-\mathrm{Ag}-\mathrm{S} 3$; symmetry operation (i): $1-x, 1-y, 1-z$. The $\mathrm{Ag}_{2} \mathrm{~S}_{2}$ core has the shape of a distorted rhombus as the $\mathrm{Ag}-\mathrm{S} 1$ bond length of 2.5596 (7) $\AA$ is significantly shorter than the $\mathrm{Ag}-\mathrm{S} 1^{\mathrm{i}}$ bond of 2.8188 (7) $\AA$. The $\mathrm{Ag}-\mathrm{S}$ bond lengths fall in two distinct classes, with the $\mathrm{Ag}-\mathrm{S1}_{\mathrm{b}}$ and $\mathrm{Ag}-\mathrm{S}_{\mathrm{t}}(\mathrm{b}=$ bridging, $\mathrm{t}=$ thiocyanate $)$ bond lengths being similar and shorter than $\mathrm{Ag}-\mathrm{S}_{1}{ }_{\mathrm{b}}$ (Table 1). Despite the different modes of coordination of the thione-S atoms, the $\mathrm{C} 1-\mathrm{S} 1$ and $\mathrm{C} 3-\mathrm{S} 2$ bond lengths are indistinguishable at 1.698 (3) $\AA$. Each of the $\mathrm{C} 1-\mathrm{S} 1$ and C3-S2 bond lengths in (I) are marginally longer than 1.6836 (19) $\AA$ found in the structure of the free molecule (Büyükekşi et al., 2018). This small difference is reflected in the observation that no significant differences are evident in bond lengths within the five-membered rings in (I) and those in the uncomplexed molecule (Büyükekşi et al., 2018).

The five-membered rings lie prime to either side of the $\mathrm{Ag}_{2} \mathrm{~S}_{2}$ core, with the dihedral angles between the core and the N1- and N4-rings being 88.99 (11) and $85.16(11)^{\circ}$, respectively. The independent rings are close to being co-planar, exhibiting a dihedral angle of $8.38(16)^{\circ}$. Finally, the N1-amine is orientated to be in close proximity to the S3-thiocyanato atom, enabling the formation of an intramolecular amine-N $\mathrm{H} \cdots \mathrm{S}$ (thiocyanato) hydrogen bond (Table 2). While the N4amine is similarly oriented, the $\mathrm{H} \cdots \mathrm{S}$ separation of $3.31 \AA$ is not indicative of a significant interaction.

Figure 2

## 3. Supramolecular features

The crystal of (I) consists of a three-dimensional network of hydrogen bonds and other non-covalent contacts as summarized in Table 2. The second amine-N - H atom of the S1-thione molecule [the first is engaged in an intramolecular $\mathrm{N}-$

Figure 3
The face-to-face $\pi-\pi$ stacking of (I).
$\mathrm{H} \cdots \mathrm{S}$ (thiocyanate) hydrogen bond and a second, weaker $\mathrm{N}-$ $\mathrm{H} \cdots \mathrm{N} 5$ (triazolyl) interaction] forms a hydrogen bond to the thione-S2 atom. By contrast, the amine-N-H atoms of the S2thione molecule form $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ (triazolyl) and $\mathrm{N}-$ $\mathrm{H} \cdots \mathrm{N}$ (thiocyanate) hydrogen bonds. The hydrogen bonds combine to sustain a three-dimensional architecture as shown in Fig. 2. Further stability to the molecular packing is provided by triazolyl-C-H. S (thiocyanate) and triazolyl-C$\mathrm{H} \cdots \mathrm{N}$ (thiocyanate) interactions along with face-to-face $\pi-\pi$ stacking (Fig. 3). The latter occur between the independent triazolyl rings [inter-centroid separation: (N1$\mathrm{N} 3, \mathrm{C} 1, \mathrm{C} 2) \cdots(\mathrm{N} 4-\mathrm{N} 6, \mathrm{C} 3, \mathrm{C} 4)^{\mathrm{ii}}=3.4444(15) \AA$ and angle of inclination $=6.81(16)^{\circ}$ for (ii) $\left.\frac{3}{2}-x, \frac{1}{2}+y, \frac{3}{2}-z\right]$.

## 4. Analysis of the Hirshfeld surfaces

The Hirshfeld surface analysis (McKinnon et al., 2004; Tan et al., 2019) of (I) was performed using Crystal Explorer 17 (Turner et al., 2017) to give further insight into the important intermolecular contacts normalized by van der Waals radii through a red-white-blue surface colour scheme where these colours denote the close contacts shorter than, equal to and longer than the sun of the respective van der Waals radii.
As seen in Fig. 4(a) of the Hirshfeld surface plotted over $d_{\text {norm }}$ for (I), the red regions of the surface represent close contacts corresponding to the $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ hydrogen-bonding interactions mentioned above. An additional feature, i.e. $\mathrm{S} \cdots \mathrm{S}$ contacts, are noted. The closest of these, i.e. $\mathrm{S} 1 \cdots \mathrm{~S} 1^{\mathrm{iii}}=3.2463$ (9) $\AA$ [symmetry operation: (iii) $2-x, 1-y, 1-z$ ], link the binuclear molecules into chains along the $a$-axis direction. On the Hirshfeld surface mapped over electrostatic potential (DFT 3-21G) shown in Fig. 4(b), the faint-red and light-blue regions correspond to negative and positive electrostatic potential, respectively,

The full and delineated $(\mathrm{H} \cdots \mathrm{H}, \mathrm{N} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{N}, \mathrm{S} \cdots \mathrm{S}$, $\mathrm{S} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{S}$ and $\mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C})$ two-dimensional fingerprint plots are shown in Fig. $5(a)-(f)$, respectively. The $\mathrm{N} \cdots \mathrm{H} /$ $\mathrm{H} \cdots \mathrm{N}$ contacts, at $35.8 \%$, are the major contributor to the Hirshfeld surface. The $\mathrm{S} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{S}$ contacts (19.4\%) also make a significant contribution. Other significant contributions come from the $\mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C}(12.7 \%)$ and $\mathrm{S} \cdots \mathrm{S}(8.3 \%)$ contacts with $\mathrm{H} \cdots \mathrm{H}$ contacts, occurring at distances beyond the sum of the van der Waals radii, contributing only $7.6 \%$. The next most significant contribution is made by $\mathrm{N} \cdots \mathrm{C} /$

(a)

Figure 4
A view of the Hirshfeld surface for (I) mapped over (a) $d_{\text {norm }}$ and (b) the electrostatic potential; the red and blue regions represent negative and positive electrostatic potentials, respectively.

Table 3
Summary of interaction energies ( $\mathrm{kJ} \mathrm{mol}^{-1}$ ) calculated for (I).

| $R(\AA)$ | $E_{\text {ele }}$ | $E_{\text {pol }}$ | $E_{\text {dis }}$ | $E_{\text {rep }}$ | $E_{\text {tot }}$ | Symmetry operation |
| :--- | ---: | :---: | ---: | ---: | :--- | :--- |
| 11.06 | -142.4 | -31.6 | -39.9 | 77.9 | -138.4 | $\frac{1}{2}-x, \frac{1}{2}+y, \frac{1}{2}-z$ |
| 10.68 | -89.0 | -31.2 | -54.8 | 43.5 | -125.0 | $\frac{1}{2}-x, \frac{1}{2}+y, \frac{1}{2}-z$ |
| 4.87 | -50.3 | -50.1 | -120.3 | 176.8 | -48.9 | $x, y, z$ |
| 16.68 | 22.9 | -3.0 | -1.8 | 0.0 | 19.8 | $x, y, z$ |
| 15.95 | 42.9 | -7.4 | -7.5 | 0.8 | 32.8 | $x, y, z$ |

$\mathrm{C} \cdots \mathrm{N}$ contacts $(6.7 \%)$ arising in the main from the $\pi-\pi$ stacking interactions between triazolyl rings.

The energy frameworks were simulated (Turner et al., 2017) in order to analyse the specific intermolecular interactions identified above for each molecule-to-molecule contact. This was achieved by summing up four different energy components (Turner et al., 2017) for each pair of molecules, i.e. electrostatic $\left(E_{\text {ele }}\right)$, polarization $\left(E_{\mathrm{pol}}\right)$, dispersion $\left(E_{\text {dis }}\right)$ and exchange-repulsion ( $E_{\text {rep }}$ ); these were obtained using the wave function calculated at the $\mathrm{HF} / 3-21 \mathrm{G}$ level of theory. The results are summarized in Table 3. The greatest energy of attraction between molecules amounts to $138.4 \mathrm{~kJ} \mathrm{~mol}^{-1}$, having a major electrostatic contribution ( $-142.4 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ), and is associated with the following interatomic contacts: $\mathrm{C} 2-$ $\mathrm{H} 2 \cdots \mathrm{~N} 7, \mathrm{C} 4-\mathrm{H} 4 \cdots \mathrm{~N} 7$ and $\pi-\pi$ stacking of between triazole rings. The next most significant contribution, with a total energy of $-125.0 \mathrm{~kJ} \mathrm{~mol}^{-1}$, arises from conventional hydrogen bonds, i.e. $\mathrm{N} 1-\mathrm{H} 1 N \cdots \mathrm{~N} 5, \mathrm{~N} 4-\mathrm{H} 4 N \cdots \mathrm{~N} 2$ and $\mathrm{N} 6-\mathrm{H} 6 N \cdots \mathrm{~N} 7$ as well as $\mathrm{C} 2-\mathrm{H} 2 \cdots \mathrm{~S} 3$ interactions. The next attractive interaction, with $E_{\mathrm{tot}}=-48.9$ and $E_{\mathrm{dis}}=$ $-120.3 \mathrm{~kJ} \mathrm{~mol}^{-1}$, respectively, reflects the $\mathrm{N} 3-\mathrm{H} 3 N \cdots \mathrm{~S} 2$ hydrogen bonding and $\mathrm{S} 1 \cdots \mathrm{~S} 1$ secondary bonding contact.

The magnitudes of intermolecular energies, i.e. the $E_{\text {ele }}, E_{\text {dis }}$ and $E_{\text {tot }}$ components, are represented graphically in Fig. 6(a)(c), respectively, by energy framework diagrams whereby the cylinders join the centroids of molecular pairs using a red, green and blue colour scheme; the radius of the cylinder is proportional to the magnitude of interaction energy.

Figure 5
(a) A comparison of the full two-dimensional fingerprint plot for (I) and those delineated into (b) $\mathrm{H} \cdots \mathrm{H},(c) \mathrm{N} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{N},(d) \mathrm{S} \cdots \mathrm{S}$, (e) $\mathrm{S} \cdots \mathrm{H} /$ $\mathrm{H} \cdots \mathrm{S}$ and $(f) \mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C}$ contacts.

## 5. Molecular orbital calculations

The HOMO and LUMO energies for the atom positions in the crystal structure of (I) were calculated using a pseudopotential plane-wave DFT method (Parr \& Yang, 1994) implemented in the NWChem package (Valiev et al., 2010). The plane wave basis set and PBE exchange-correlation functional were chosen for the calculations on the experimental structure, i.e. without geometry optimization. The HOMO and LUMO of (I) are illustrated in Fig. S1 in the supporting information and their energies were calculated to be 3.011 and 6.173 eV , respectively. The HOMO is delocalized across the thiocyanato groups and the bridging region between the two dimers. The LUMO includes the delocalization around the triazole rings.

## 6. Database survey

A survey of the Cambridge Structural Database (Groom et al., 2016) for coordination complexes of HtrzSH yielded seven structures. Monodentate coordination via the thione-S atom, as in (I), has been identified in six structures. The first three of these are neutral and mononuclear, namely $\left[\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{2} \mathrm{Cu}(\mathrm{HtrzSH}) \mathrm{Cl}\right] \cdot \mathrm{CH}_{3} \mathrm{CN}$, (NEPPOP; Wani et al., 2013), $\left[\mathrm{Ag}(\mathrm{HtrzSH})\left(\mathrm{NO}_{3}\right)\right] \cdot \mathrm{CH}_{3} \mathrm{OH}$ (GISHUN; Wattanakanjana et al., 2014) and $\left[\mathrm{Cd}(\mathrm{HtrzSH})\left(\mathrm{H}_{2} \mathrm{Edta}\right)\right] \cdot \mathrm{H}_{2} \mathrm{O}$ (LOFKAT; Zhang et al., 2008); $\mathrm{H}_{4} \mathrm{Edta}$ is ethylenediamine tetracarboxylic acid. The mononuclear $\mathrm{Fe}^{\mathrm{III}}$ complex, $\mathrm{Fe}(\mathrm{NO})_{2}(\mathrm{HtrzS})(\mathrm{HtrzSH}) \cdot 0.5 \mathrm{H}_{2} \mathrm{O}$ (EYABOV01; Aldoshin et al., 2008) contains both neutral and mono-anionic forms of HtrzSH. The fifth structure featuring monodentate coordina-

Figure 6
The colour interaction mapping and energy frameworks for (I) showing the (a) electrostatic potential force, $(b)$ dispersion force and $(c)$ total energy diagrams. All cylindrical radii were adjusted to the same scale factor of 100 with a cut-off value of $-50.0 \mathrm{~kJ} \mathrm{~mol}^{-1}$ within a $3 \times 3 \times 3$ unit cell and their sizes are proportional to the relative strength of the corresponding energies.
tion of HtrzSH is a two-dimensional coordination polymer, i.e. $\left\{\left[\mathrm{Cd}_{2}\left(\mathrm{O}_{2} \mathrm{CCO}_{2}\right)_{2}(\mathrm{HtrzSH})_{2}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}\right\}_{n}$ (ZIVBOX; Liang et al., 2014); there are two distinct $\mathrm{Cd}^{\mathrm{II}}$ atom coordination environments. Two distinct coordination modes for HtrzSH are noted in the structure of $\left[\mathrm{Cd}(\mathrm{HtrzSH})_{2} \mathrm{Cl}_{2}\right]_{n}$ (LOFJEW; Zhang et al., 2008), i.e. monodentate, as for the above, as well as bidentate, $\mu_{2}$-bridging as one of the triazolyl-N atoms also coordinates $\mathrm{Cd}^{\mathrm{II}}$ in this polymeric structure. In the final structure with HtrzSH, tridentate coordination for HtrzSH via the thione-S atom only has been observed in $[\mathrm{Ag}(\mathrm{HtrzSH}) \mathrm{Cl}]_{n}$ (XINDUV; Kang et al., 2013), which is a two-dimensional coordination polymer.

As indicated above for $\mathrm{Fe}(\mathrm{NO})_{2}(\mathrm{HtrzS})(\mathrm{HtrzSH}) \cdot 0.5 \mathrm{H}_{2} \mathrm{O}$ (EYABOV01; Aldoshin et al., 2008), mono-anionic forms of HtrzSH are known. Here, HtrzS functions as a monodentate thiolate-S ligand. A monodentate thiolate-S mode of coordination is also seen in $\left(3-\mathrm{ClC}_{6} \mathrm{H}_{4} \mathrm{CH}_{2}\right)_{3} \mathrm{Sn}(\mathrm{HtrzS})$ (SUXSAG; Keng et al., 2010). The three remaining structures feature a tridentate coordination mode leading to coordination polymers. In $[\mathrm{Cu}(\mathrm{HtrzS})]_{n}$ (TEHYIQ; Zhang et al., 2012), this is achieved by bidentate, $\mu_{2}$-bridging by the thiolate-S atom and the participation of one of the triazolyl-N atoms in coordination. In $\left[\mathrm{Pb}(\mathrm{HtrzS})\left(\mathrm{NO}_{3}\right) \mathrm{OH}_{2}\right]_{n}$ (MOKKAA; Imran et al., 2015), the thiolate-S and two triazolyl-N atoms are involved in coordination. A similar coordination mode is found for one of the independent anions in $\left[\mathrm{Cd}_{2}(\mathrm{HtrzS})_{2}\left(\mathrm{SO}_{4}\right)\right]_{\mathrm{n}}$ (LOFJUM; Zhang et al., 2008). The second anion is tetradentate as the thiolate-S atom is bidentate, $\mu_{2}$-bridging. From the foregoing, it is evident that $\mathrm{HtrzSH} / \mathrm{HtrzS}$ ligands adopt a wide range of coordination modes in the relatively few structures in which they have been characterized, suggesting further work in this area is warranted.

## 7. Synthesis and crystallization

Silver nitrate $(0.21 \mathrm{~g}, 1.24 \mathrm{mmol})$ and potassium thiocyanate $(0.12 \mathrm{~g}, 1.23 \mathrm{mmol})$ were dissolved in acetronitrile ( 25 ml ) and a white precipitate formed. This mixture was heated at 323325 K for 30 min . Then, a clear solution of $1 \mathrm{H}-1,2,4$-triazole-3thiol ( $0.25 \mathrm{~g}, 2.47 \mathrm{mmol}$ ) in distilled water ( 5 ml ) was added followed by heating for 4.3 h during which time the precipitate slowly dissolved. The clear solution was filtered and kept to evaporate at ambient temperature. After a few days, colourless trapezoidal prisms of (I) formed, which were filtered off and dried in vacuo. M.p.: 413-417 K. IR (solid KBr pellet, $\left.\mathrm{cm}^{-1}\right): 2108(s)(\mathrm{C} \equiv \mathrm{N}), 1479(s)(\mathrm{C}=\mathrm{N}), 1248(w)(\mathrm{C}-\mathrm{N})$, $1054(m)(\mathrm{C}-\mathrm{S})+(\mathrm{C}-\mathrm{N})$.

## 8. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 4. The H atoms were found in difference Fourier maps and their positions refined resulting in distances of $\mathrm{N}-\mathrm{H}=0.80(4)-0.877(10) \AA$ and $\mathrm{C}-\mathrm{H}=$ $0.89(4)-0.91$ (4) $\AA$, and with $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{N}, \mathrm{C})$. The maximum and minimum residual electron density peaks of

| Z | 2 |
| Radiation type | $\mathrm{Cu} K \alpha$ |
| $\mu\left(\mathrm{mm}^{-1}\right)$ | 20.35 |
| Crystal size (mm) | $0.41 \times 0.14 \times 0.11$ |
| Data collection |  |
| Diffractometer | Rigaku Oxford Diffraction SuperNova, Dual, Cu at zero, AtlasS2 |
| Absorption correction | Gaussian (CrysAlis PRO; Rigaku OD, 2015) |
| $T_{\text {min }}, T_{\text {max }}$ | 0.097, 0.453 |
| No. of measured, independent and observed $[I>2 \sigma(I)]$ reflections | 18122, 2266, 2242 |
| $R_{\text {int }}$ | 0.039 |
| $(\sin \theta / \lambda)_{\text {max }}\left(\mathrm{A}^{-1}\right)$ | 0.633 |
| Refinement |  |
| $R\left[F^{2}>2 \sigma\left(F^{2}\right)\right], w R\left(F^{2}\right), S$ | $0.025,0.066,1.17$ |
| No. of reflections | 2266 |
| No. of parameters | 163 |
| No. of restraints | 10 |
| H -atom treatment | Only H-atom coordinates refined |
| $\Delta \rho_{\text {max }}, \Delta \rho_{\text {min }}\left(\mathrm{e} \AA^{-3}\right)$ | 0.96, -1.04 |

Computer programs: CrysAlis PRO (Rigaku OD, 2015), SHELXT (Sheldrick, 2015), SHELXL2014/7 (Sheldrick, 2015), Mercury (Macrae et al., 2008), DIAMOND (Brandenburg, 2006), WinGX (Farrugia, 2012) and publCIF (Westrip, 2010).
0.96 and $1.04 \mathrm{e}^{\AA^{-3}}$, respectively, were located 0.83 and $0.77 \AA$ from the N3 and Ag atoms, respectively.

## Funding information

We are grateful for financial support from the Research and Development Office, Prince of Songkla University (SCI570390S), the Center for Innovation in Chemistry (PERCH-CIC), the Commission on Higher Education, the Ministry of Education and Department of Chemistry, Faculty of Science, PSU. Sunway University Sdn Bhd is also thanked for financial support of this work through Grant No. STR-RCTR-RCCM-001-2019.

## Computing details

Data collection: CrysAlis PRO (Rigaku OD, 2015); cell refinement: CrysAlis PRO (Rigaku OD, 2015); data reduction: CrysAlis PRO (Rigaku OD, 2015); program(s) used to solve structure: ShelXT (Sheldrick, 2015); program(s) used to refine structure: SHELXL2014/7 (Sheldrick, 2015); molecular graphics: Mercury (Macrae et al., 2008), DIAMOND (Brandenburg, 2006); software used to prepare material for publication: WinGX (Farrugia, 2012) and publCIF (Westrip, 2010).
$\operatorname{Bis}\left[\mu-1 H-1,2,4\right.$-triazole-5(4H)-thione- $\left.\kappa^{2} S: S\right]$ bis\{(thiocyanato- $\left.\kappa S\right)[1 H-1,2,4$-triazole-5(4H)-thione- $\kappa$ S $]$ silver(I) $\}$

## Crystal data

$\left[\mathrm{Ag}_{2}(\mathrm{SCN})_{2}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{~N}_{3} \mathrm{~S}\right)_{4}\right]$
$M_{r}=736.44$
Monoclinic, $P 2_{1} / n$
$a=4.8718$ (1) $\AA$
$b=15.9511$ (1) $\AA$
$c=13.9575$ (1) $\AA$
$\beta=96.945(1)^{\circ}$
$V=1076.69(2) \AA^{3}$
$Z=2$

## Data collection

Rigaku Oxford Diffraction SuperNova, Dual,
Cu at zero, AtlasS2
diffractometer
Mirror monochromator
Detector resolution: 5.2303 pixels $\mathrm{mm}^{-1}$
$\omega$ scans
Absorption correction: gaussian
(CrysAlisPro; Rigaku OD, 2015)
$T_{\min }=0.097, T_{\text {max }}=0.453$

## Refinement

Refinement on $F^{2}$
Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.025$
$w R\left(F^{2}\right)=0.066$
$S=1.17$
2266 reflections
$F(000)=720$
$D_{\mathrm{x}}=2.272 \mathrm{Mg} \mathrm{m}^{-3}$
$\mathrm{Cu} K \alpha$ radiation, $\lambda=1.54184 \AA$
Cell parameters from 13766 reflections
$\theta=3.2-77.1^{\circ}$
$\mu=20.35 \mathrm{~mm}^{-1}$
$T=100 \mathrm{~K}$
Prism, colourless
$0.41 \times 0.14 \times 0.11 \mathrm{~mm}$

18122 measured reflections
2266 independent reflections
2242 reflections with $I>2 \sigma(I)$
$R_{\text {int }}=0.039$
$\theta_{\text {max }}=77.4^{\circ}, \theta_{\text {min }}=4.2^{\circ}$
$h=-6 \rightarrow 5$
$k=-19 \rightarrow 20$
$l=-17 \rightarrow 17$

163 parameters
10 restraints
Primary atom site location: structure-invariant direct methods
Secondary atom site location: difference Fourier map

Hydrogen site location: difference Fourier map
Only H-atom coordinates refined
$w=1 /\left[\sigma^{2}\left(F_{\mathrm{o}}^{2}\right)+(0.0343 P)^{2}+1.905 P\right]$
where $P=\left(F_{\mathrm{o}}{ }^{2}+2 F_{\mathrm{c}}{ }^{2}\right) / 3$

$$
\begin{aligned}
& (\Delta / \sigma)_{\max }=0.001 \\
& \Delta \rho_{\max }=0.96 \mathrm{e}^{-3} \\
& \Delta \rho_{\min }=-1.04 \mathrm{e}^{-3}
\end{aligned}
$$

## Special details

Geometry. All esds (except the esd in the dihedral angle between two 1.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
Refinement. C5 treated with ISOR
