#### Abstract

$\mathrm{C}_{23} \mathrm{H}_{39} \mathrm{NO}_{5}$, monoclinic, $P 2_{1} / c$ (no. 14), $a=26.1698(4) \AA$, $b=9.4863(2) \AA, \quad c=9.0929(2) \AA, \quad \beta=97.376(2)^{\circ}$, $V=2238.67(8) \AA^{3}, Z=4, R_{\mathrm{gt}}(F)=0.0539, w R_{\mathrm{ref}}\left(F^{2}\right)=0.1580$, $T=100(2) \mathrm{K}$.

CCDC no.: 1957130
The molecular structure is shown in the figure. Table 1 contains crystallographic data and Table 2 contains the list of the atoms including atomic coordinates and displacement parameters.

## Source of material

The melting point of the compound was measured on a MelTemp II digital melting point apparatus and was uncorrected. The IR spectrum was recorded using a Perkin-Elmer RX1 spectrophotometer as a Nujol mull in a KBr cell from 4000 to $400 \mathrm{~cm}^{-1}$. The ${ }^{1} \mathrm{H}$ NMR spectrum was recorded in $\mathrm{CDCl}_{3}$ solution on a Jeol JNM-ECA 400 MHz NMR spectrometer with chemical shifts relative to tetramethylsilane.

4-Dodecyloxy-2-hydroxybenzaldehyde was synthesized according to a literature procedure [5]. The prepared aldehyde ( $0.31 \mathrm{~g}, 1.0 \mathrm{mmol}$ ) was added to an ethanolic solution ( 10 mL ) of tris(hydroxymethyl)aminomethane (Tokyo

Chemical Industry, $0.12 \mathrm{~g}, 1.0 \mathrm{mmol}$ ) and refluxed for 3 h . The filtrate was evaporated slowly until a yellow precipitate was formed. The precipitate was recrystallized from methanolhexane by slow evaporation to yield yellow crystals. Yield: 0.16 g (39.1\%). M.pt: 383-384 K. IR (cm ${ }^{-1}$ ) 3233 (br) v(O-H), 1634 (s) $v(\mathrm{C}-\mathrm{N}), 1525$ (s) $v(\mathrm{C}-\mathrm{O}), 1047$ (s) $v(\mathrm{C}-\mathrm{O}), 1016$ (m) $v(\mathrm{C}-\mathrm{O}) .{ }^{1} \mathbf{H}$ NMR $\left(\mathrm{CDCl}_{3}, \mathrm{ppm}\right): \delta 0.86\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH}_{3}\right), 1.24-1.79$ $\left(\mathrm{m}, 20 \mathrm{H}, \mathrm{CH}_{2}\right), 3.70-4.00\left(\mathrm{~m}, 8 \mathrm{H}, \mathrm{OCH}_{2}\right), 6.40(\mathrm{~d}, 1 \mathrm{H}, \mathrm{Ph}-\mathrm{H})$, $6.51(\mathrm{~d}, 1 \mathrm{H}, \mathrm{Ph}-\mathrm{H}), 7.37(1 \mathrm{H}, \mathrm{Ph}-\mathrm{H}), 8.41(\mathrm{~s}, 1 \mathrm{H}, \mathrm{N}=\mathrm{CH}) ; \mathrm{OH}$ and NH protons were not observed.

## Experimental details

The C-bound H atoms were geometrically placed (C-$\mathrm{H}=0.95-0.99 \AA$ ) and refined as riding with $U_{\text {iso }}(\mathrm{H})=1.2-$ $1.5 U_{\text {eq }}(\mathrm{C})$. The $\mathrm{O}-$ and N -bound H -atoms were located in a difference Fourier map but were refined with distance restraints of $\mathrm{O}-\mathrm{H}=0.84 \pm 0.01 \AA$ and $\mathrm{N}-\mathrm{H}=0.88 \pm 0.01 \AA$, respectively, and with $U_{\text {iso }}(\mathrm{H})$ set to $1.5 U_{\text {eq }}(\mathrm{O})$ and $1.2 U_{\text {eq }}(\mathrm{N})$, respectively. As evident from the figure, the long chain suffers from typical disorder. Careful modelling did not reveal any chemically useful information and so, the simpler model was retained.

## Comment

In connection with recent studies of diorganotin Schiff bases derived from tris[(hydroxymethyl)aminomethane] [6, 7], largely motivated by the promising cytotoxicities they exhibit [6], the structure of the title tris[(hydroxymethyl) aminomethane] Schiff base derivative, featuring an appended $n$-dodecyl substituent, was prepared and studied crystallographically.

The molecular structure is shown in the figure (50\% displacement ellipsoids) and crystallography confirms the molecule existing as a zwitterion in the solid-state.

Proton transfer has occurred from the phenol group to the imine-nitrogen atom (see the figure). An intramolecular, charge-assisted medium-strong imine-N-HNO (phenoxide) hydrogen bond is evident [ $\mathrm{N} 1-\mathrm{H} 1 \mathrm{n} \cdots \mathrm{O}$ : $\mathrm{H} 1 \mathrm{n} \cdots \mathrm{O}=1.918(17) \AA, \mathrm{N} 1 \cdots \mathrm{O}=2.639(2) \AA$ with angle at $\left.\mathrm{H} 1 \mathrm{n}=138.9(19)^{\circ}\right]$. The C5-N1 imine bond length is 1.303(3) $\AA$ and the configuration about this bond is $E$. The imine residue is co-planar with the phenyl ring to which it is connected with the N1-C5-C6-C11 and N1-C5-C6-C7 torsion angles being $-175.12(18)$ and $0.5(3)^{\circ}$, respectively. The alpha-methylene atom of the $n$-dodecyl chain is co-planar with the phenyl ring as seen in the values of the $\mathrm{C} 12-\mathrm{O} 5-\mathrm{C} 9-\mathrm{C} 8$ and $\mathrm{C} 12-\mathrm{O} 5-$ C9-C10 torsion angles of $0.9(3)$ and $-179.71(17)^{\circ}$, respectively. A kink is then evident in the chain with the $05-\mathrm{C} 12-\mathrm{C} 13-$ C 14 and $\mathrm{C} 12-\mathrm{C} 13-\mathrm{C} 14-\mathrm{C} 15$ torsion angles of $-61.5(2)$ and $-61.9(3)^{\circ}$, respectively, being indicative of - syn-clinal conformations. The remaining methylene atoms of the chain have an almost all-trans conformation with the maximum deviation in torsion angles being -169.7(2) ${ }^{\circ}$, for $\mathrm{C} 13-\mathrm{C} 14-\mathrm{C} 15-\mathrm{C} 16$.

There is a single literature precedent for the structure reported herein, that is, with a methyl rather than a $n$-dodecyl substituent [8]. This is also zwitterionic and was characterised as a monohydrate.

In the crystal, the 01-hydroxy group forms a chargeassisted hydrogen bond with the phenoxide-O atom [01$\mathrm{H} 10 \cdots 4^{\mathrm{i}}: \mathrm{H} 10 \cdots \mathrm{O} 4^{\mathrm{i}}=1.766(18) \AA, 01 \cdots 4^{\mathrm{i}}=2.5927(19) \AA$ with angle at $\mathrm{H} 1 \mathrm{o}=167.5(18)^{\circ}$ for symmetry operation (i) $x$, $3 / 2-y,-1 / 2+z]$ while the other hydroxy groups participate in hydroxy-O-H... O(hydroxy) hydrogen bonds [02$\mathrm{H} 2 \mathrm{o} \cdots \mathrm{O}^{\mathrm{ii}}: \mathrm{H} 2 \mathrm{o} \cdots \mathrm{O}^{\mathrm{ii}}=1.90$ (2) $\AA, \mathrm{O} 2 \cdots \mathrm{O}^{\mathrm{ii}}=2.7279(19) \AA$ with angle at $\mathrm{H} 2 \mathrm{o}=166(2)^{\circ}$ and $\mathrm{O} 3-\mathrm{H} 3 \mathrm{o} \cdots \mathrm{O}^{\text {iii }}$ : $\mathrm{H} 30 \cdots \mathrm{O} 2^{\mathrm{iii}}=1.93(2) \AA$ A $03 \cdots \mathrm{O} 2^{\text {iii }}=2.7600(19) \AA$ with angle at $\mathrm{H} 3 \mathrm{o}=176(3)^{\circ}$ for (ii) $x, 5 / 2-y, 1 / 2+z$ and (iii) $2-x$, $2-y, 2-z]$. The molecules assemble head-to-head to form a bi-layer, in the $b c$-plane, sustained by the aforementioned hydrogen bonding interactions. This allows for the inter-digitation of the $n$-dodecyl chains.

Using established procedures [9] and Crystal Explorer 17 [10], the calculated Hirshfeld surfaces were analysed as were the full and delineated two-dimensional fingerprint plots. The presence of multiple conventional hydrogen bonding interactions is reflected in a significant contribution of $\mathrm{H} \cdots \mathrm{O} / \mathrm{O} \cdots \mathrm{H}$ contacts, that is, $15.4 \%$ to the overall surface.

This notwithstanding, by far the greatest contribution is made by $\mathrm{H} \cdots \mathrm{H}$ contacts, at $72.9 \%$, reflecting the hydrophobic interactions in the inter-layer region. The only other contribution to the surface contacts of note are from $\mathrm{H} \cdots \mathrm{C} / \mathrm{C} \cdots \mathrm{H}$ contacts of $10.9 \%$, which arise largely from methylene-C3$\mathrm{H} \cdots \pi$ (phenyl) and methyl-C23-H $\cdots \pi$ (phenyl) interactions within the bi-layer constructed from the $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonding.
