ABSTRACT: We compute three-point correlators between the stress-energy tensor and conserved currents of conformal field theories (CFTs) in 2+1 dimensions. We first compute the correlators in the large-flavor-number expansion of conformal gauge theories and then do the computation using holography. In the holographic approach, the correlators are computed from an effective action on 3+1 dimensional anti-de Sitter space (AdS_4), and depend upon the co-efficient, γ , of a four-derivative term in the action. We find a precise match between the CFT and the holographic results, thus fixing the values of γ . The CFTs of free fermions and bosons take the values $\gamma = 1/12, -1/12$ respectively, and so saturate the bound $|\gamma| \leq 1/12$ obtained earlier from the holographic theory; the correlator of the conserved gauge flux of $U(1)$ gauge theories takes intermediate values of γ . The value of γ also controls the frequency dependence of the conductivity, and other properties of quantum-critical transport at non-zero temperatures. Our results for the values of γ lead to an appealing physical interpretation of particle-like or vortex-like transport near quantum phase transitions of interest in condensed matter physics. This paper includes appendices reviewing key features of the AdS/CFT correspondence for condensed matter physicists.

1 Introduction

This paper is a contribution to the program of connecting strongly interacting condensed matter systems to theories based upon the methods of gauge-gravity duality [1, 2]. Such methods offer powerful tools to describe dynamics at non-zero temperatures, and far from equilibrium, in regimes far-removed from any quasiparticle theory. But they have been rigorously established only for strongly interacting non-Abelian gauge theories which are very different from those relevant for condensed matter applications. For the latter, the simplest context in which the connections may be made are conformal field theories (CFTs) in 2+1 dimensions [3] which are dual to gravity theories on AdS_4 . Myers *et al.* [4] proposed extending the gauge-gravity methods to a wider class of systems by viewing the gravity theory as a phenomenological effective field theory on 3+1 dimensional anti-de Sitter space (AdS_4), with physical observables to be computed in the gravity theory at tree level. The effective field theory was expanded in powers of spacetime gradients, and all terms with up to 4 gradients were retained; such a field theory was also considered earlier by Ritz and Ward [5]. In this

Figure 1. Illustration of the AdS-CFT correspondence in the context of quantum critical transport at finite temperatures. The present paper is concerned with the upper blue arrow: we fix couplings by matching correlators of the CFT to those of the gravity theory. The bottom blue arrow is addressed in Refs. [4] and [7], which computed the relevant conductivities and quasi-normal modes of the gravity dual for general values of the couplings in Eq. (1.7).

paper, we will pin down the values of the coupling constants in this holographic theory by a matching procedure based upon the computation of 3-point correlators of the stress-energy tensor and the conserved currents at zero temperature (T) [6]. This allows us to relate CFTs of interest in condensed matter to a specific holographic action. And it paves the way for predictions on the non-zero T and non-equilibrium dynamics for condensed matter systems from holographic methods as illustrated in Fig. 1.

We have written this paper for readers with a background in condensed matter theory, and a knowledge of general relativity. Readers with no prior knowledge of gauge-gravity duality are referred to a recent review article [8] for an overall perspective, and to Appendix B for a description of the correspondence between correlators of the CFT and the theory on AdS_4 .

While our results are quite general, it is useful to express them in the context of a particular CFT which has numerous condensed matter applications [9, 10, 11]. The matter sector has Dirac fermions ψ_α , $\alpha = 1 \dots N_f$, and complex scalars, z_a , $a = 1 \dots N_s$. We will

always take the large N_f limit with N_s/N_f fixed, and use the symbol N_F to refer generically to either N_s or N_f . These matter fields are coupled to each other and a U(1) gauge field a_i by a Lagrangian of the form

$$\mathcal{L} = \sum_{\alpha=1}^{N_f} i\bar{\psi}_\alpha \gamma^i D_i \psi_\alpha + \sum_{a=1}^{N_s} \left(|D_i z_a|^2 + s|z_a|^2 + \frac{u}{2} (|z_a|^2)^2 \right) + \dots, \quad (1.1)$$

where $D_i = \partial_i - ia_i$ is the gauge covariant derivative, the Dirac matrices obey $\text{Tr}(\gamma^i \gamma^j) = 2\eta^{ij}$ where η^{ij} is the Minkowski metric, and the ellipses represent additional possible contact-couplings between the fermions and bosons. The scalar ‘‘mass’’ term, s , has to be tuned to reach the quantum critical point, which is described by a CFT at the renormalization group (RG) fixed point; fermion mass terms can be removed by imposing discrete symmetries. So the scalar mass is the only relevant perturbation at the CFT fixed point and only a single parameter has to be tuned to access the fixed point. All other couplings, such as u and the Yukawa coupling, reach values associated with the RG fixed point, and so their values are immaterial for the universal properties of interest in the present paper.

This CFT has three globally conserved currents. There is the $\text{SU}(N_s)$ scalar flavor current

$$J_{s,i}^\ell = -iz_a^* T_{ab}^\ell (D_i z_b) + i (D_i z_a)^* T_{ab}^\ell z_b, \quad (1.2)$$

where T^ℓ are the generators of $\text{SU}(N_s)$ normalized by $\text{Tr}(T^\ell T^m) = \delta^{\ell m}$. Similarly there is the fermion $\text{SU}(N_f)$ flavor current

$$J_{f,i}^\ell = \bar{\psi}_\alpha T_{\alpha\beta}^\ell \gamma_i \psi_\beta. \quad (1.3)$$

Finally, there is the topological U(1) current

$$J_{t,i} = \frac{1}{2\pi} \epsilon_{ijk} \partial^j a^k. \quad (1.4)$$

We will use the symbol J_i to generically refer to any one of these three currents. A basic property of the CFT [12] is that the two-point correlator of a conserved current obeys

$$\langle J_i(\mathbf{k}) J_j(-\mathbf{k}) \rangle = -C_J |\mathbf{k}| \left(\eta_{ij} - \frac{k_i k_j}{|\mathbf{k}|^2} \right), \quad (1.5)$$

where \mathbf{k} is a spacetime momentum, $\eta_{ij} = \text{diag}(-1, 1, 1)$ is the Minkowski metric, and C_J is a dimensionless universal constant associated with the CFT and the current. Similarly, the

stress-energy tensor, T_{ij} , of the CFT has the two-point correlator [13]

$$\begin{aligned} \langle T_{ij}(\mathbf{k})T_{uv}(-\mathbf{k}) \rangle = C_T |\mathbf{k}|^3 & \left(\eta_{iu}\eta_{jv} + \eta_{ju}\eta_{iv} - \eta_{ij}\eta_{uv} + \eta_{ij} \frac{k_u k_v}{|\mathbf{k}|^2} + \eta_{uv} \frac{k_i k_j}{|\mathbf{k}|^2} \right. \\ & \left. - \eta_{iu} \frac{k_j k_v}{|\mathbf{k}|^2} - \eta_{ju} \frac{k_i k_v}{|\mathbf{k}|^2} - \eta_{iv} \frac{k_j k_u}{|\mathbf{k}|^2} - \eta_{jv} \frac{k_i k_u}{|\mathbf{k}|^2} + \frac{k_i k_j k_u k_v}{|\mathbf{k}|^4} \right), \end{aligned} \quad (1.6)$$

where C_T is another universal constant characterizing the CFT.

The primary focus of the present paper will be on the structure of the 3-point correlator $\langle T_{i_1 j_1}(\mathbf{k}_1) J_{i_2}(\mathbf{k}_2) J_{i_3}(\mathbf{k}_3) \rangle$. The general form of this correlator for a CFT was specified by Osborn and Petkou [12] in position space: they showed that it was fully determined by the values of C_J , C_T , and a single additional constant. Such a position space correlator was matched to holographic results by Hofman and Maldacena [6], and we will follow their methods in Section 6. However, we will first perform this computation in momentum space. It is not a simple matter to take the Fourier transform of the earlier position space result [12], and we will therefore compute this correlator directly from the CFT, and from its holographic partner.

Our purpose is to relate the conserved current correlators of the CFT (1.1) to the effective holographic theory of Refs. [4, 5]. The theory is defined on AdS_4 , and has a (non-Abelian or Abelian) gauge field A_μ , and corresponding gauge flux $F_{\mu\nu}$, associated with each of the conserved currents J_i . (Our convention is that Greek indices run over all directions in the bulk, while Latin indices are used to denote boundary directions.) We note that there is no direct relationship between the bulk gauge field A_μ and the boundary gauge field a_i . The 4-derivative action for each bulk gauge field is

$$S = \frac{1}{g_4^2} \int d^4x \sqrt{-g} \text{Tr} \left[-\frac{1}{4} F_{\mu\nu} F^{\mu\nu} + \gamma C_{\mu\nu\rho\sigma} F^{\mu\nu} F^{\rho\sigma} \right], \quad (1.7)$$

where Tr is the trace over $SU(N_s)$ or $SU(N_f)$ indices (if present), $g_{\mu\nu}$ is the metric of AdS_4 and $C_{\mu\nu\rho\sigma}$ is the Weyl curvature tensor. As we will review below, matching the two-point correlator of the current between (1.1) and (1.7) fixes the value of the coupling g_4 . The coupling crucial for our purposes is γ ; it was shown that the stability of the theory S requires $|\gamma| \leq 1/12$. The structure of the 3-point correlator $\langle T_{i_1 j_1}(\mathbf{k}_1) J_{i_2}(\mathbf{k}_2) J_{i_3}(\mathbf{k}_3) \rangle$ is determined by γ , and so γ will play the role of the additional constant noted by Osborn and Petkou [12] (the explicit relation to their constants is specified in Section 6). Comparison with the CFT computation yields the value of γ . An overview of the correlation functions needed to fix the values of the coupling constants in Eq. (1.7) is given in Fig. 2.

Coupling	Correlator
G_N	$\frac{\langle TJJ \rangle}{\sqrt{\langle TT \rangle} \langle JJ \rangle}$
g_4^2	$\langle JJ \rangle$
γ	$\frac{\langle TJJ \rangle^{---}}{\langle TJJ \rangle^{--+}}$

Figure 2. Correlators (with helicity projections) that fix the numerical values of the couplings in the holographic action specified by Eqs. (1.7) and (B.22). These correlators are evaluated in the present paper in the boundary conformal field theory.

Our results for the values of γ for the currents in (1.2), (1.3), and (1.4) are

$$\begin{aligned}
\gamma_f &= \frac{1}{12} + \mathcal{O}(1/N_F), \\
\gamma_s &= -\frac{1}{12} + \mathcal{O}(1/N_F), \\
\gamma_t &= \frac{N_s - N_f}{12(N_s + N_f)} + \mathcal{O}(1/N_F).
\end{aligned}
\tag{1.8}$$

It is interesting that the free CFT results (γ_f and γ_s at $N_F = \infty$) saturate the bound on γ in the large N_F limit. We recall that a similar feature was observed in earlier computations of three-point correlators of the stress energy tensor, where the free field results also saturate the bounds obtained from the holographic higher derivative theory [14, 15].

For $N_f = 0$ we have $\gamma_s = -\gamma_t$. This change in sign of γ is consistent with the expectations [4] of its transformation under particle-vortex duality, and the interpretation of J_{ti} as the matter current in the dual theory. Further discussion on the physical consequences of these values of γ appear in Section 7.

We note that 3-point correlators of CFTs have also played an important role in recent investigations of theories with higher-spin conserved currents [16]. Our 3-point correlator is similar, but our holographic considerations follow a different route.

The outline of the rest of the paper is as follows. In Section 2 we describe the setting, in which we will perform our correlation function calculations. Section 3 will present the computation of the 3-point correlator in the large N_F limit of the CFT. In Section 4 we will present the holographic computation of the 3-point correlator implied by the AdS₄ action of Myers *et al.* at tree level. The two sets of results will be matched in Section 5. Section 6 will present another derivation of our values of γ for the free field theories, using the methods of Ref. [6]. In Section 7, we explore some of the consequences of these results.

2 Setting

In this section, we introduce our momentum space notation for the 3-point correlators and briefly recapitulate the spinor-helicity projections that we perform in the CFT as well as in the holography computation. The momentum space expressions of the 3-point correlator are obtained by Fourier transforming along the boundary directions:

$$\begin{aligned} \mathcal{K}^{i_1 j_1 i_2 i_3}(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3) &= \langle T^{i_1 j_1}(\mathbf{k}_1) J^{i_2}(\mathbf{k}_2) J^{i_3}(\mathbf{k}_3) \rangle \\ &\equiv \int \langle \mathcal{T} \{ T^{i_1 j_1}(\mathbf{x}_1) J^{i_2}(\mathbf{x}_2) J^{i_3}(\mathbf{x}_3) \} \rangle e^{i \sum_{m=1}^3 \mathbf{k}_m \cdot \mathbf{x}_m} d^3 x_m, \end{aligned} \quad (2.1)$$

where \mathcal{T} is the time-ordering symbol and the integral runs over the three flat directions on the boundary. (The time-ordered correlator is what we would get by computing the Euclidean correlation function and then Wick-rotating to Lorentzian space.)

There are several advantages of working in momentum space. Some of these will become apparent below, but let us comment on one immediate benefit. In 2.1, we have many free indices. In particular, for the stress-tensor, the Ward identities tell us that if we contract i_1 and j_1 in (2.1), this will yield a known answer in terms of lower point correlators. Similarly (2.1) is symmetric in i_1, j_1 up to contact terms that again involve two-point functions. However, this still naively leaves us with 5 degrees of freedom in the stress-tensor and 3 in each of the currents.

However, both the stress-tensor and the currents are conserved. In position space, this leads to differential Ward identities. In momentum space, these identities become algebraic: they translate to the simple statement that, for $m = 1, 2, 3$, the contraction $k_{m, i_m} \mathcal{K}^{i_1 j_1 i_2 i_3}$ is determined in terms of lower-point correlators.

This means that we can extract all the physical information in (2.1) by contracting the stress-tensor with any two symmetric and traceless polarization tensors that are transverse to the momentum \mathbf{k}_1 , and the two currents with polarization vectors that are transverse to \mathbf{k}_2 and \mathbf{k}_3 respectively. So, we can instead consider

$$\mathcal{K}(\mathbf{e}_1, \mathbf{k}_1, \boldsymbol{\epsilon}_2, \mathbf{k}_2, \boldsymbol{\epsilon}_3, \mathbf{k}_3) = e_{1, i_1 j_1} \epsilon_{2, i_2} \epsilon_{3, i_3} \langle T^{i_1 j_1}(\mathbf{k}_1) J^{i_2}(\mathbf{k}_2) J^{i_3}(\mathbf{k}_3) \rangle. \quad (2.2)$$

Here \mathbf{e}_1 is a polarization-tensor for the stress-tensor, and $\boldsymbol{\epsilon}_2$ and $\boldsymbol{\epsilon}_3$ are polarization vectors for the currents. We choose these to be transverse to the momentum carried by the corresponding operator, and it will also be convenient for us to choose them to be null:

$$\boldsymbol{\epsilon}_m \cdot \mathbf{k}_m = \boldsymbol{\epsilon}_m \cdot \boldsymbol{\epsilon}_m = 0. \quad (2.3)$$

We can choose the polarization tensor \mathbf{e}_1 to be just an outer product of two polarization

vectors for \mathbf{k}_1 :

$$e_{1,ij} = \epsilon_{1,i}\epsilon_{1,j}. \quad (2.4)$$

So, the use of momentum space drastically cuts down the number of independent indices that we need to deal with and allows us to directly engage with the physical quantities in (2.2).

To simplify the algebra even further, we will use the *spinor-helicity* formalism to write down explicit expressions for the polarization tensors and, later, to simplify the correlators. The spinor-helicity formalism was initially introduced to study four dimensional scattering amplitudes, as a means of efficiently encoding the kinematics of the external particles. (See Ref. [17] and references there.) It was adapted to the study of correlators in three-dimensional conformal field theories by Maldacena and Pimentel [18].

Our conventions are different from those of Ref. [18], and we provide a detailed introduction to this formalism in Appendix C. Here, we excerpt a few of the essential details to help the reader parse the formulas in this paper.

Given a three vector $\mathbf{k} = (k_0, k_1, k_2)$, we consider the 2×2 matrix

$$k_{\alpha\dot{\alpha}} = k_0\sigma_{\alpha\dot{\alpha}}^0 + k_1\sigma_{\alpha\dot{\alpha}}^1 + k_2\sigma_{\alpha\dot{\alpha}}^2 + i|\mathbf{k}|\sigma_{\alpha\dot{\alpha}}^3, \quad (2.5)$$

where $|\mathbf{k}| \equiv \sqrt{\mathbf{k} \cdot \mathbf{k}} = \sqrt{k_1^2 + k_2^2 - k_0^2}$. By construction, this 2×2 matrix has rank 1 and so it can be decomposed into the outer product of a 2×1 and a 1×2 vector:

$$k_{\alpha\dot{\alpha}} = \lambda_\alpha \bar{\lambda}_{\dot{\alpha}}. \quad (2.6)$$

The λ and $\bar{\lambda}$ are called spinors, and instead of giving the momentum 3-vectors for each operator insertion, we can instead give these spinors.

We can define dot products of these spinors via:

$$\langle \lambda_1, \lambda_2 \rangle = \epsilon^{\alpha\beta} \lambda_{1\alpha} \lambda_{2\beta} = \lambda_{1\alpha} \lambda_2^\alpha, \quad \langle \bar{\lambda}_1, \bar{\lambda}_2 \rangle = \epsilon^{\dot{\alpha}\dot{\beta}} \bar{\lambda}_{1\dot{\alpha}} \bar{\lambda}_{2\dot{\beta}} = \bar{\lambda}_{1\dot{\alpha}} \bar{\lambda}_2^{\dot{\alpha}}. \quad (2.7)$$

Finally, one other advantage of this formalism is that the polarization vectors we referred to above can be written quite easily in terms of these spinors:

$$\epsilon_{\alpha\dot{\alpha}}^+ = 2 \frac{\bar{\lambda}_\alpha^\dagger \bar{\lambda}_{\dot{\alpha}}}{[\lambda, \bar{\lambda}]} = \frac{\bar{\lambda}_\alpha^\dagger \bar{\lambda}_{\dot{\alpha}}}{i|\mathbf{k}|}, \quad \epsilon_{\alpha\dot{\alpha}}^- = 2 \frac{\lambda_\alpha \lambda_{\dot{\alpha}}^\dagger}{[\lambda, \bar{\lambda}]} = \frac{\lambda_\alpha \lambda_{\dot{\alpha}}^\dagger}{i|\mathbf{k}|}, \quad (2.8)$$

where we have labeled the polarization vectors by a ‘‘helicity’’ that can either be positive or negative. We refer the interested reader to Appendix C for further details.

3 CFT computation of 3-point correlators

In this section, we compute the three-point correlators of each of the conserved currents (1.2), (1.3), and (1.4) for the CFT Lagrangian (1.1) with its stress-energy tensor:

$$T_{ij} = T_{s,ij} + T_{f,ij}, \quad (3.1)$$

which consists of a scalar, bosonic contribution

$$T_{s,ij} = \sum_{a=1}^{N_s} \left((D_i z_a)^* (D_j z_a) + (D_j z_a)^* (D_i z_a) - \frac{1}{4} (\partial_i \partial_j + \eta_{ij} \partial^2) |z_a|^2 \right), \quad (3.2)$$

and the fermionic contribution

$$T_{f,ij} = \frac{i}{4} \sum_{\alpha=1}^{N_f} \left(\bar{\psi}_\alpha \gamma_i (D_j \psi_\alpha) + \bar{\psi}_\alpha \gamma_j (D_i \psi_\alpha) - (D_i^* \bar{\psi}_\alpha) \gamma_j \psi_\alpha - (D_j^* \bar{\psi}_\alpha) \gamma_i \psi_\alpha \right). \quad (3.3)$$

We evaluate the correlators by summing over all possible Wick contractions of the constituent operators of $\langle TJJ \rangle$ defined in (2.1) in the limit of large flavor number N_F . As expected, we will see that the leading contractions with the flavor currents are those of the free CFT. For the topological currents the first non-vanishing contractions appear at $\mathcal{O}(1/N_F)$. All contractions involve tensor-valued one-loop integrations in momentum space which we evaluate using Davydychev recursion relations [19]. Finally, the full tensor-valued expressions are contracted with the polarization or helicity operators defined in Sec. 2 to bring them to a form that facilitates comparison with the corresponding helicity projections from the holographic calculation (performed in Sec. 4).

We refer the readers to Appendix A for a review of the computations of the two-point functions, $\langle JJ \rangle$ and $\langle TT \rangle$, leading to (1.5, 1.6) and the final results after contracting with the corresponding polarization tensors.

3.1 $\langle TJJ \rangle$ for $SU(N_s)$ scalar flavor current

Evaluating Wick's theorem for the scalar correlator yields two non-vanishing contractions depicted diagrammatically in Fig. 3. The full expression for the two diagrams is:

$$\begin{aligned} \mathcal{K}_s^{i_1 j_1 i_2 i_3}(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3) &= \int \frac{d^3 P}{8\pi^3} \frac{4}{P^2 (\mathbf{P} + \mathbf{k}_1)^2 (\mathbf{P} - \mathbf{k}_2)^2} (2\mathbf{P} - \mathbf{k}_2)^{i_2} (2\mathbf{P} + \mathbf{k}_1)^{i_3} \\ &\quad \times \left[\frac{1}{2} (\mathbf{P} - \mathbf{k}_2)^{i_1} (\mathbf{P} + \mathbf{k}_1)^{j_1} + \frac{1}{2} (\mathbf{P} - \mathbf{k}_2)^{j_1} (\mathbf{P} + \mathbf{k}_1)^{i_1} \right. \\ &\quad \left. + \frac{1}{8} (|\mathbf{k}_3|^2 \eta^{i_1 j_1} + (\mathbf{k}_1 + \mathbf{k}_2)^{i_1} (\mathbf{k}_1 + \mathbf{k}_2)^{j_1}) \right], \end{aligned} \quad (3.4)$$

Figure 3. One-loop triangle diagrams for the scalar contribution to $\langle TJJ \rangle$. The top corner of the respective triangles are (momentum-dependent) stress-tensor vertices while the bottom two corners represent current vertices.

Figure 4. Momentum structure of the stress tensor (top) and current vertex (bottom) after contracting with transverse and traceless polarization tensors.

with $\mathbf{k}_1 + \mathbf{k}_2 + \mathbf{k}_3 = 0$. The momentum dependence in the numerator of (3.4) comes from derivative operators of the fields at each vertex. We are only interested in certain polarization projections of this expression and we now explain how this simplifies the momentum structure considerably.

Quite generally, a current insertion with momentum \mathbf{k} at a vertex where one line brings in \mathbf{P} (Fig. 4) and the other line carries away $\mathbf{P} + \mathbf{k}$ leads to an effective vertex: $(2P_i + k_i)$. However, since this correlator will finally be dotted with a transverse polarization vector, one can drop the k_i term on the right hand side in the computations below. Also, here and below we have dropped the $SU(N_s)$ generator T^ℓ because it only yields factors of unity after tracing over $SU(N_s)$ indices. Similarly, a stress-tensor insertion carrying momentum \mathbf{k} at a vertex where one line brings in the loop-momentum \mathbf{P} (Fig. 4) and the other line carries away $\mathbf{P} + \mathbf{k}$ results in a vertex that we are finally going to contract with a polarization tensor that is *transverse and traceless*. Since this tensor will satisfy $e^{ij}\eta_{ij} = 0 = e^{ij}k_i$, we can drop

the terms proportional to η_{ij} and also the terms proportional to k_i and k_j above. Using this logic, the expressions for the effective stress tensor and current vertex, respectively, become quite simple (see Fig. 4) and from Eq. (3.4) we only need to consider

$$8N_s e_{i_1 j_1} \epsilon_{i_2} \epsilon_{i_3} \int \frac{d^3 P}{8\pi^3} \left[\frac{P_{i_1} P_{j_1} (\mathbf{P} + \mathbf{k}_1)_{i_2} P_{i_3}}{P^2 (\mathbf{P} + \mathbf{k}_1)^2 (\mathbf{P} - \mathbf{k}_3)^2} + \frac{P_{i_1} P_{j_1} (\mathbf{P} + \mathbf{k}_1)_{i_3} P_{i_2}}{P^2 (\mathbf{P} + \mathbf{k}_1)^2 (\mathbf{P} - \mathbf{k}_2)^2} \right]. \quad (3.5)$$

These integrals can be done by automating the Davydychev recursion relations [19]. The resulting expressions are quite lengthy, as shown in the attached Mathematica file [20]. However, after we dot this answer with polarization tensors and rewrite it using the spinor helicity formalism, our final answers are quite simple. The interested reader should again consult the Mathematica file for details. We find the following results for N_s complex scalars, which we will later compare to the results obtained from holography:

$$\frac{1}{N_s} \mathcal{K}_s^{+--} = \frac{-\langle \lambda_3, \lambda_2 \rangle^4}{32 \langle \lambda_2, \lambda_1 \rangle^2 \langle \lambda_3, \lambda_1 \rangle^2 |\mathbf{k}_1|^2 |\mathbf{k}_2| |\mathbf{k}_3|} \left[(|\mathbf{k}_1|^2 - (|\mathbf{k}_2| - |\mathbf{k}_3|)^2) (|\mathbf{k}_2| + |\mathbf{k}_3|) \right]. \quad (3.6)$$

Contracting the stress tensor with a negative helicity polarization tensor and both the currents with negative helicity polarization vectors leads to:

$$\frac{1}{N_s} \mathcal{K}_s^{---} = \frac{\langle \lambda_2, \lambda_1 \rangle^2 \langle \lambda_3, \lambda_1 \rangle^2}{32 |\mathbf{k}_1|^2} \left(\frac{8|\mathbf{k}_1|^3}{(|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^4} - \frac{1}{|\mathbf{k}_2|} - \frac{1}{|\mathbf{k}_3|} \right). \quad (3.7)$$

Contracting with a negative helicity for the stress tensor and one of the currents, and a positive helicity for the second current, we find:

$$\begin{aligned} \frac{1}{N_s} \mathcal{K}_s^{--+} &= \frac{\langle \lambda_2, \lambda_1 \rangle^4 (-|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^2}{32 \langle \lambda_3, \lambda_2 \rangle^2 |\mathbf{k}_1|^2 |\mathbf{k}_2| |\mathbf{k}_3| (|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^2} \\ &\times [(|\mathbf{k}_2| + |\mathbf{k}_3|) (|\mathbf{k}_1|^2 + |\mathbf{k}_2|^2 + |\mathbf{k}_3|^2) + 2 (|\mathbf{k}_2|^2 + |\mathbf{k}_3|^2) |\mathbf{k}_1|]. \end{aligned} \quad (3.8)$$

It is worthwhile to point out that all the answers above have the correct Lorentz transformation properties on the boundary and have the correct dimension. They are also symmetric in particles 2 and 3 when those particles have the same helicity.

3.2 $\langle TJJ \rangle$ for $\text{SU}(N_f)$ fermion flavor current

Now, we turn to the computation of the three-point correlator \mathcal{K}_f for the fermion current J_f . The non-vanishing contractions from Wick's theorem are again given by Fig. 3 with fermion loop propagators and the current and stress tensor vertices carrying additional Dirac matrix structure instead of derivative operators, as was the case for scalars. The full expression for

\mathcal{K}_f is given by,

$$\mathcal{K}_f^{i_1 j_1 i_2 i_3}(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3) = -\frac{1}{4} \left[\Upsilon^{i_1 u_3 i_2 v_2 i_3 u_2} \eta^{j_1 v_3} + i_1 \leftrightarrow j_1 \right] \int \frac{d^3 P}{8\pi^3} \frac{(2\mathbf{P} + \mathbf{k}_1 - \mathbf{k}_2)_{v_3} (\mathbf{P} - \mathbf{k}_2)_{u_3} P_{v_2} (\mathbf{P} + \mathbf{k}_1)_{u_2}}{P^2 (\mathbf{P} + \mathbf{k}_1)^2 (\mathbf{P} - \mathbf{k}_2)^2}, \quad (3.9)$$

with a trace over six Dirac matrices given by

$$\Upsilon^{i_1 u_3 i_2 v_2 i_3 u_2} = 2 \text{Tr}[\gamma^{i_1} \gamma^{u_3} \gamma^{i_2} \gamma^{v_2} \gamma^{i_3} \gamma^{u_2}]. \quad (3.10)$$

Again the momentum integral can be done using the Davydychev recursion relations and the trace over Dirac matrices can be carried out using standard identities of the Clifford algebra. After contracting with polarization vectors — the reader should consult the attached Mathematica file [21] for details — and simplifying further, we get:

$$\frac{1}{N_f} \mathcal{K}_f^{+--} = \frac{-\langle \lambda_3, \lambda_2 \rangle^4}{64 \langle \lambda_2, \lambda_1 \rangle^2 \langle \lambda_3, \lambda_1 \rangle^2 |\mathbf{k}_1|^2 |\mathbf{k}_2| |\mathbf{k}_3|} \left[(|\mathbf{k}_1|^2 - (|\mathbf{k}_2| - |\mathbf{k}_3|)^2) (|\mathbf{k}_2| + |\mathbf{k}_3|) \right], \quad (3.11)$$

$$\frac{1}{N_f} \mathcal{K}_f^{---} = \frac{\langle \lambda_2, \lambda_1 \rangle^2 \langle \lambda_3, \lambda_1 \rangle^2}{64 |\mathbf{k}_1|^2} \left(\frac{-16 |\mathbf{k}_1|^3}{(|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^4} - \frac{1}{|\mathbf{k}_2|} - \frac{1}{|\mathbf{k}_3|} \right), \quad (3.12)$$

$$\begin{aligned} \frac{1}{N_f} \mathcal{K}_f^{--+} &= \frac{\langle \lambda_2, \lambda_1 \rangle^4 (-|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^2}{64 \langle \lambda_3, \lambda_2 \rangle^2 |\mathbf{k}_1|^2 |\mathbf{k}_2| |\mathbf{k}_3| (|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^2} \\ &\times [(|\mathbf{k}_2| + |\mathbf{k}_3|) |\mathbf{k}_1|^2 + (|\mathbf{k}_2| - |\mathbf{k}_3|)^2 (2|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)], \end{aligned} \quad (3.13)$$

where we used the same conventions for the helicity superscripts as in the scalar case (3.6).

3.3 $\langle TJJ \rangle$ for U(1) topological current

The contractions involving two topological currents (1.4) necessarily involve two gauge field insertions and the leading diagrams of the $1/N_F$ expansion are shown in Fig. 5. Although there is no bare dynamics in the gauge sector of Eq. (1.1), the gauge field picks an order $1/N_F$ dynamical renormalization from fluctuations of the scalars and fermions [10], and takes the well known “overdamped” form:

$$D_{u_2 v_2}(\mathbf{q}) = \langle a_{u_2} \bar{a}_{v_2} \rangle = \frac{16}{(N_s + N_f)} \frac{1}{|\mathbf{q}|} \left(\eta_{u_2 v_2} - \zeta \frac{q_{u_2} q_{v_2}}{\mathbf{q}^2} \right), \quad (3.14)$$

Figure 5. Feynman diagrams contributing to the 3-point correlator of J_t . The full lines are the bosonic or fermionic matter fields, and the zigzag line is the a_i propagator.

where ζ is a gauge-fixing parameter that should not appear in the expression for any physical observable. With this gauge propagator, the diagrams in Fig. 5 evaluate to the expressions:

$$\begin{aligned}
\mathcal{K}_t^{i_1 j_1 i_2 i_3}(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3) &= \left(\frac{8}{\pi(N_f + N_s)} \right)^2 \epsilon_{u_2 v_2}^{i_2} \epsilon_{u_3 v_3}^{i_3} \frac{k_2^{u_2} k_3^{u_3}}{|\mathbf{k}_2| |\mathbf{k}_3|} \\
&\times \left[N_f \left\{ \mathcal{K}_f^{i_1 j_1 v_2 v_3}(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3) \right. \right. \\
&\quad \left. \left. + \frac{|\mathbf{k}_3|}{32} [\eta^{v_2 j_1} \eta^{i_1 v_3} + \eta^{v_2 i_1} \eta^{j_1 v_3}] + \frac{|\mathbf{k}_2|}{32} [\eta^{v_3 j_1} \eta^{i_1 v_2} + \eta^{v_3 i_1} \eta^{j_1 v_2}] \right\} \right. \\
&\quad \left. + N_s \left\{ \mathcal{K}_s^{i_1 j_1 v_2 v_3}(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3) \right. \right. \\
&\quad \left. \left. + \frac{|\mathbf{k}_2|}{16} [\eta^{v_2 j_1} \eta^{i_1 v_3} + \eta^{v_2 i_1} \eta^{j_1 v_3}] + \frac{|\mathbf{k}_3|}{16} [\eta^{v_3 j_1} \eta^{i_1 v_2} + \eta^{v_3 i_1} \eta^{j_1 v_2}] \right\} \right], \quad (3.15)
\end{aligned}$$

where the terms proportional to \mathcal{K}_s and \mathcal{K}_f , respectively, originate from the top diagram in Fig. 5. The other terms proportional to products of the metric originate from the loops involving only two internal propagators; these terms are analytic in two of the momenta and give rise to contact terms when Fourier transformed back to position space. A discussion of the nature of these terms appears in Section 5. These contact terms drop out of the final polarization contractions that are compared to the results from holography.

4 Holographic computation of 3-point correlators

In this section we will compute the three-point correlators discussed above, from the bulk theory, using AdS/CFT.

We will work with the Poincare patch of AdS:

$$ds^2 = \frac{dz^2 + \eta^{ij} dx_i dx_j}{z^2}, \quad (4.1)$$

where i, j run over the three boundary directions and we have set the AdS radius to 1. So, all dimensionful quantities that follow are measured in these units.

The computation of the correlator requires us to evaluate the bulk action to non-linear order, in the presence of certain solutions to the linearized equations of motion. This corresponds to evaluating the “Witten diagram” in Fig. 6 which requires a three-point bulk interaction between the gauge fields and the fluctuations of the metric.

Figure 6. Witten diagram illustrating the holographic computation. The disk represent AdS_4 , and the CFT is on its boundary. The holographic co-ordinate, z , is the radial direction. The wavy line is a bulk graviton $h_{\mu\nu}$, and the dashed line is the gauge field A_{μ} .

4.1 Evaluation of the Bulk Action

The first step in our computation is to write down the non-linear three-point interaction terms in the action. We can simplify our calculation by realizing that we are only interested in evaluating this action “on-shell,” (when the gauge field and metric perturbation satisfy linearized equations of motion) and so there are various terms that we can drop, as we will do below.

The relevant part of the action is:

$$S = \frac{1}{g_4^2} \int d^4x \sqrt{-g} \left[-\frac{1}{4} F_{\mu\nu} F_{\rho\sigma} g^{\mu\rho} g^{\nu\sigma} + \gamma C_{\mu\nu\rho\sigma} F_{\alpha\beta} F_{\gamma\delta} g^{\mu\alpha} g^{\nu\beta} g^{\rho\gamma} g^{\sigma\delta} \right]. \quad (4.2)$$

First, we need to expand the Weyl tensor term in terms of the metric perturbation. We will use the conformal transformation properties of the Weyl tensor to write:

$$C_{\alpha\beta\gamma\delta} \left(\frac{\eta_{\mu\nu}}{z^2} + h_{\mu\nu} \right) = \frac{1}{z^2} C_{\alpha\beta\gamma\delta} (\eta_{\mu\nu} + z^2 h_{\mu\nu}). \quad (4.3)$$

For convenience, we define

$$\tilde{h}_{\mu\nu} = z^2 h_{\mu\nu}. \quad (4.4)$$

In what follows below, we will use the notation that:

$$\begin{aligned} C_{\alpha\beta\gamma\delta} &\equiv C_{\alpha\beta\gamma\delta} \left(\frac{\eta_{\mu\nu}}{z^2} + h_{\mu\nu} \right), \\ \tilde{C}_{\alpha\beta\gamma\delta} &\equiv C_{\alpha\beta\gamma\delta} (\eta_{\mu\nu} + \tilde{h}_{\mu\nu}), \end{aligned} \quad (4.5)$$

with similar conventions for other quantities like the Riemann and Ricci tensors. (A tilde comes on top of quantities evaluated in the flat space background metric, with the perturbation \tilde{h} .)

We can choose a gauge — both in flat space, and in AdS — where the metric fluctuation obeys:

$$\tilde{h}^{z\mu} = 0. \quad (4.6)$$

It is easy to check that solutions to the equations of motion must be transverse and traceless:

$$\tilde{h}_{\mu\nu} \eta^{\mu\nu} = 0 = \partial_\rho h_{\mu\nu} \eta^{\mu\rho}. \quad (4.7)$$

If we know that we will only have to evaluate the interaction vertex on wave-functions that obey (4.6) and (4.7), we can simplify the expressions for the Riemann tensor, the Ricci

tensor, and the Ricci scalar in the linearized theory:

$$\begin{aligned}
\tilde{R}_{\alpha\mu\beta\nu} &= \frac{1}{2} \left(\tilde{h}_{\alpha\nu,\mu\beta} + \tilde{h}_{\mu\beta,\nu\alpha} - \tilde{h}_{\mu\nu,\alpha\beta} - \tilde{h}_{\alpha\beta,\mu\nu} \right), \\
\tilde{R}_{\alpha\beta} &= -\frac{1}{2} \eta^{\mu\nu} \partial_\mu \partial_\nu \tilde{h}_{\alpha\beta}, \\
\tilde{R} &= 0.
\end{aligned} \tag{4.8}$$

From this, we can obtain the Weyl tensor, which is: (here d is the *boundary dimension*, and so $d + 1$ is the bulk dimension)

$$\begin{aligned}
\tilde{C}_{\alpha\mu\beta\nu} &= \tilde{R}_{\alpha\mu\beta\nu} - \frac{2}{d-1} \left(\eta_{\alpha[\beta} \tilde{R}_{\nu]\mu} - \eta_{\mu[\beta} \tilde{R}_{\nu]\alpha} \right) + \frac{2}{d(d-1)} \tilde{R} \eta_{\alpha[\beta} \eta_{\nu]\mu} \\
&= \frac{1}{2} \left(\tilde{h}_{\alpha\nu,\mu\beta} + \tilde{h}_{\mu\beta,\nu\alpha} - \tilde{h}_{\mu\nu,\alpha\beta} - \tilde{h}_{\alpha\beta,\mu\nu} + \square \left\{ \eta_{\alpha[\beta} \tilde{h}_{\nu]\mu} - \eta_{\mu[\beta} \tilde{h}_{\nu]\alpha} \right\} \right),
\end{aligned} \tag{4.9}$$

where, we have defined $\square \equiv \eta^{\mu\nu} \partial_\mu \partial_\nu$ and used $d = 3$.

However, this expression can be simplified considerably. With the understanding that i, j, k, l run over the *boundary directions* and with z representing the radial-direction, we need the following components of the Weyl tensor:

$$\begin{aligned}
2\tilde{C}_{zizj} &= \frac{1}{2} \left[\sum_l \partial_l^2 - \partial_z^2 \right] \tilde{h}_{ij}, \\
2\tilde{C}_{zijk} &= \partial_k \partial_z \tilde{h}_{ij} - \partial_j \partial_z \tilde{h}_{ik}, \\
2\tilde{C}_{ijkl} &= \frac{1}{2} \left[\partial_z^2 - \sum_l \partial_l^2 \right] \left(\eta_{ik} \tilde{h}_{jl} - \eta_{il} \tilde{h}_{kj} - \eta_{jk} \tilde{h}_{il} + \eta_{jl} \tilde{h}_{ik} \right).
\end{aligned} \tag{4.10}$$

In evaluating the first two lines, we have used the conditions (4.6) and (4.7). In evaluating the last line, we have used the fact that the Weyl tensor vanishes identically in 3-dimensions. This might suggest that only the additional term involving the z -derivatives survives; however, one needs to be careful about the factor in front of the Laplacian, which is dimension dependent. When we take all of this into account, we get the expression above.¹

With these results for the flat-space Weyl tensor, the expression for the Weyl tensor in AdS is also fixed by the relation (4.3). We should point out that while we have not written all the non-zero components above, the components that we have written, and the symmetries of the Weyl tensor fix everything.

To evaluate the interaction vertex, we also note the fact that, for the evaluation of the

¹This almost— but not quite — agrees with the results of Ref. [18]. In particular the first line of (4.10) does not agree with the first line of (2.12) of Ref. [18] in general, and neither does the last line. However, the expressions do agree if we are evaluating this tensor on a solution of the form $h_{ij} = \epsilon_{ij} e^{-|\mathbf{k}|z + ik \cdot x}$, which was the case under consideration in that paper.

three point function under consideration, the non-Abelian terms in the field-strength are unimportant. So, in what follows below, we simply take:

$$F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu, \quad (4.11)$$

and choose a gauge where

$$A_z = 0, \quad \partial_i A^i = 0. \quad (4.12)$$

To finally evaluate the interaction vertex in AdS, we will use the explicit forms of the wave functions for the gauge field and for the graviton. These are given by:

$$\begin{aligned} A_i &= \epsilon_i e^{-|\mathbf{k}|z} e^{i\mathbf{k}\cdot\mathbf{x}}, \\ h_{ij} &= \frac{1}{z^2} e_{ij} e^{-|\mathbf{k}|z} (1 + |\mathbf{k}|z) e^{i\mathbf{k}\cdot\mathbf{x}}, \\ \tilde{h}_{ij} &= e_{ij} e^{-|\mathbf{k}|z} (1 + |\mathbf{k}|z) e^{i\mathbf{k}\cdot\mathbf{x}}. \end{aligned} \quad (4.13)$$

See Ref.[22] for further details on the notation. Below, we will use R_m to denote the radial part of the wave function of the m^{th} particle:

$$R_1 = (1 + |\mathbf{k}_1|z) e^{-|\mathbf{k}_1|z}, \quad R_2 = e^{-|\mathbf{k}_2|z}, \quad R_3 = e^{-|\mathbf{k}_3|z}, \quad (4.14)$$

and also use the notation: $\dot{f} \equiv \frac{\partial f}{\partial z}$.

We now need to evaluate the variation of the action to first order in the metric perturbation h , and second order in the gauge field. This is appropriate, since we wish to compute a three point function involving one stress tensor and two currents. Since the Weyl tensor vanishes in pure AdS, and we have no gauge field background either, the variation in the Weyl-gauge term is simply its value in the presence of the perturbation,

$$\frac{g_4^2}{\gamma} \delta S_1 = \int dz \sqrt{-g} C_{\mu\nu\rho\sigma} F_{\alpha\beta} F_{\gamma\delta} g^{\mu\alpha} g^{\nu\beta} g^{\rho\gamma} g^{\sigma\delta}. \quad (4.15)$$

Let us now evaluate the different contractions that appear in the expression above, keeping track of the numerical factors.

- First of all, we note that given the expressions for the wave functions in (4.13) above, we can always replace a derivative $\partial_j \rightarrow ik_j$. Each term in the contraction has two such spatial derivatives leading to an overall minus sign.
- Secondly, the Weyl tensor is anti-symmetric under the interchange of the first two or the third and fourth indices. Since the field strength is also anti-symmetric, we get a factor of 4 by summing over these permutations.

- Finally, there is a factor of $\frac{1}{2}$ in (4.10), but we have to keep in mind that we need to sum over the two possible permutations of the gauge-fields in the Witten diagram.

Therefore, we have:

$$\begin{aligned}
\delta S_{11} &= C_{zizj} F^{zi} F^{zj} + C_{izjz} F^{iz} F^{jz} + C_{izzj} F^{iz} F^{zj} + C_{zizj} F^{zi} F^{jz} \\
&= -2z^6 (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_2) (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_3) \left(|\mathbf{k}_1|^2 R_1 + \ddot{R}_1 \right) \dot{R}_2 \dot{R}_3, \\
\delta S_{12} &= C_{zijk} F^{zi} F^{jk} + C_{izjk} F^{iz} F^{jk} + C_{ijzk} F^{ij} F^{zk} + C_{ijkz} F^{ij} F^{kz} \\
&= -2z^6 \left[\{ (\mathbf{k}_1 \cdot \boldsymbol{\epsilon}_3) (\mathbf{k}_3 \cdot \boldsymbol{\epsilon}_1) - (\mathbf{k}_1 \cdot \mathbf{k}_3) (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_3) \} (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_2) \dot{R}_1 \dot{R}_2 R_3 \right. \\
&\quad \left. + \{ (\mathbf{k}_1 \cdot \boldsymbol{\epsilon}_2) (\mathbf{k}_2 \cdot \boldsymbol{\epsilon}_1) - (\mathbf{k}_1 \cdot \mathbf{k}_2) (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_2) \} (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_3) \dot{R}_1 R_2 \dot{R}_3 \right], \\
\delta S_{13} &= C_{ijkl} F^{ij} F^{kl} \\
&= -4z^6 \left[(\mathbf{k}_2 \cdot \mathbf{k}_3) (\boldsymbol{\epsilon}_3 \cdot \boldsymbol{\epsilon}_1) (\boldsymbol{\epsilon}_2 \cdot \boldsymbol{\epsilon}_1) - (\mathbf{k}_2 \cdot \boldsymbol{\epsilon}_1) (\mathbf{k}_3 \cdot \boldsymbol{\epsilon}_2) (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_3) \right. \\
&\quad \left. - (\mathbf{k}_3 \cdot \boldsymbol{\epsilon}_1) (\mathbf{k}_2 \cdot \boldsymbol{\epsilon}_3) (\boldsymbol{\epsilon}_2 \cdot \boldsymbol{\epsilon}_1) + (\mathbf{k}_2 \cdot \boldsymbol{\epsilon}_1) (\mathbf{k}_3 \cdot \boldsymbol{\epsilon}_1) (\boldsymbol{\epsilon}_2 \cdot \boldsymbol{\epsilon}_3) \right] \left(\ddot{R}_1 + |\mathbf{k}_1|^2 R_1 \right) R_2 R_3.
\end{aligned} \tag{4.16}$$

Let us make a comment about the overall power of z . We get four-factors of z^2 from the four inverse metric components that are required to raise the indices of F . However, we get one factor of $\frac{1}{z^2}$ from C . This is what leads to the overall z^6 outside. Also, we caution the reader that when we write $\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_2$ above, and other such expressions involving the dot-product of three-dimensional vectors, this dot-product is taken with the flat space metric:

$$\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_2 \equiv \epsilon_{1i} \epsilon_{2j} \eta^{ij}. \tag{4.17}$$

The variation of the full Weyl-gauge term in the action is just the sum of the terms above:

$$\frac{g_4^2}{\gamma} \delta S_1 = \int dz \sqrt{-g} [\delta S_{11} + \delta S_{12} + \delta S_{13}]. \tag{4.18}$$

There is, of course, another term that contributes to the three-point function, which comes from the interaction of the metric perturbation with the stress tensor of the gauge field. This evaluates to:

$$g_4^2 \delta S_2 = \int \sqrt{-g} dz \left[\frac{1}{2} F_{\mu\nu} F_{\rho\sigma} \eta^{\mu\alpha} h_{\alpha\beta} \eta^{\beta\rho} \eta^{\nu\sigma} \right] z^6. \tag{4.19}$$

Note that the conditions (4.6), (4.7) mean we can drop the term that comes from the variation of $\sqrt{-g}$. We also have an overall minus sign because $\delta g^{\mu\nu} = -g^{\mu\rho} h_{\rho\sigma} \delta g^{\sigma\nu}$. The overall factor of z^6 comes from the four inverse metric factors, but it is important to remember that one

needs to include the $\frac{1}{z^2}$ in $h_{\alpha\beta}$ from (4.13).

We can write

$$g_4^2 \delta S_2 = - \int dz \left\{ \left[(\mathbf{k}_2 \cdot \boldsymbol{\epsilon}_1)(\mathbf{k}_3 \cdot \boldsymbol{\epsilon}_1)(\boldsymbol{\epsilon}_2 \cdot \boldsymbol{\epsilon}_3) - (\mathbf{k}_2 \cdot \boldsymbol{\epsilon}_1)(\boldsymbol{\epsilon}_3 \cdot \boldsymbol{\epsilon}_1)(\boldsymbol{\epsilon}_2 \cdot \mathbf{k}_3) \right. \right. \\ \left. \left. - (\mathbf{k}_3 \cdot \boldsymbol{\epsilon}_1)(\boldsymbol{\epsilon}_2 \cdot \boldsymbol{\epsilon}_1)(\boldsymbol{\epsilon}_3 \cdot \mathbf{k}_2) + (\mathbf{k}_2 \cdot \mathbf{k}_3)(\boldsymbol{\epsilon}_2 \cdot \boldsymbol{\epsilon}_1)(\boldsymbol{\epsilon}_3 \cdot \boldsymbol{\epsilon}_1) \right] R_1 R_2 R_3 \right. \\ \left. - (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_2)(\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_3) R_1 \dot{R}_2 \dot{R}_3 \right\}. \quad (4.20)$$

Note that we have regained a minus sign from the two factors of i that get pulled down in the differentiation, although this does not occur in the last term above where we have a z -derivative instead. Also note that all factors of z are gone, when we account for the $\sqrt{-g}$ and the factor of $\frac{1}{z^2}$ in $h_{\alpha\beta}$ from (4.13).

As a final step in evaluating the 3-point function we now need to do the radial integrals in (4.18) and (4.19). First, let us do the radial integrals in (4.18). Note that once we account for the fact that $\sqrt{-g} = \frac{1}{z^4}$, there is an overall factor of z^2 in every radial integral. These are

$$\int z^2 \ddot{R}_1 R_2 R_3 dz = \frac{2|\mathbf{k}_1|^2(2|\mathbf{k}_1| - |\mathbf{k}_2| - |\mathbf{k}_3|)}{(|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^4}, \quad (4.21)$$

$$\int z^2 \dot{R}_1 \dot{R}_2 R_3 dz = \frac{6|\mathbf{k}_1|^2 |\mathbf{k}_2|}{(|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^4}, \quad (4.22)$$

$$\int z^2 \dot{R}_1 \dot{R}_2 \dot{R}_3 dz = \frac{6|\mathbf{k}_1|^2 |\mathbf{k}_3|}{(|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^4}, \quad (4.23)$$

$$\int z^2 R_1 \dot{R}_2 \dot{R}_3 dz = \frac{2|\mathbf{k}_2||\mathbf{k}_3|(4|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)}{(|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^4}. \quad (4.24)$$

$$(4.25)$$

Now, we turn to the radial integrals in (4.19). These are

$$\int R_1 R_2 R_3 dz = \frac{2|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|}{(|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^2}, \quad (4.26)$$

$$\int R_1 \dot{R}_2 \dot{R}_3 dz = |\mathbf{k}_2||\mathbf{k}_3| \frac{2|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|}{(|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^2}. \quad (4.27)$$

$$(4.28)$$

All these integrals are convergent.

4.2 Final Bulk Answers in the Spinor Helicity Formalism

The expressions for the bulk action, and the radial integrals above in principle give us all the information we need about the boundary correlator. However, to extract some physics from this, it is convenient to choose various ‘‘helicities’’ for the stress-tensor and the currents and then write down the answer in the spinor-helicity formalism that was outlined above.

We only need to consider the following three choices of helicities:

1. Both currents, and the stress tensor have negative helicity.
2. The stress tensor and one current has negative helicity, but the other current has positive helicity.
3. The stress tensor has positive helicity, and the two currents have negative helicity.

All other possibilities can be obtained from these ones by permuting the two currents and/or using parity.

The use of the spinor-helicity formalism considerably simplifies the algebraic expressions involved in the answers. The reader who is interested in the algebra that enters this simplification should consult the accompanying Mathematica file [23]. Here, we simply present the final answers.

For the case where all the helicities are negative, we have the following expression.

$$\mathcal{K}_{\text{ads}}^{---}(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3) = -24\gamma \frac{\langle \lambda_2, \lambda_1 \rangle^2 \langle \lambda_3, \lambda_1 \rangle^2 |\mathbf{k}_1|}{g_4^2 E^4}, \quad (4.29)$$

where we have defined:

$$E \equiv |\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|. \quad (4.30)$$

It is natural for this expression (considered as an analytic function of E) to have a pole at $E = 0$, and in fact the residue at this pole is related to the four dimensional flat space amplitude of a graviton and two gluons as pointed out in Ref. [24]. We also note that the usual gravitational interaction does not contribute to this helicity combination at all, and the entire combination comes from the Weyl interaction.

When the stress tensor and the first current insertion are dotted with negative helicity polarization vectors and the second current is dotted with a positive helicity polarization vector, we find:

$$\mathcal{K}_{\text{ads}}^{--+} = - \frac{\langle \lambda_2, \lambda_1 \rangle^4 (|\mathbf{k}_2| + |\mathbf{k}_3| - |\mathbf{k}_1|)^2 (2|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)}{2 \langle \lambda_3, \lambda_2 \rangle^2 |\mathbf{k}_1|^2 g_4^2 E^2}. \quad (4.31)$$

In this case, we find that the Weyl interaction does not contribute to this helicity combination, whereas the usual gravitational interaction does.

Finally, we come to the the case where the stress-tensor has positive helicity and the two currents have negative helicity. For this correlator, we have:

$$\mathcal{K}_{\text{ads}}^{+--} = 0. \quad (4.32)$$

Neither the Weyl nor the gravitational interaction contribute to this helicity combination!

It is useful to check that these answers indeed have the expected behaviour under scaling. Recall that the stress tensor has dimension 3, and the two conserved currents have dimension 2 each. Fourier transforming the 3-position variables gives us a dimension of -9 , of which the momentum space δ -function that we have suppressed above soaks up -3 . So, we expect the net dimension in momentum space to be 1, which is true of all the expressions above.

The spinor helicity formalism only makes the Lorentz group on the boundary manifest. It is possible to check that these answers also satisfy the constraints of special conformal transformations as indicated in Ref. [18], but this is a slightly more involved calculation.

5 Matching the Answers

In this section, we will match the answers of the CFT computations of Sec. 3 (and Appendix A) with the AdS answers of Sec. 4. This will allow us to determine the values of physical parameters in the bulk, that would reproduce the free answers.

5.1 Scalars

$--+$ **Helicity** Let us start with (3.8), which we can write as:

$$\begin{aligned} \frac{1}{N_s} \mathcal{K}_s^{--+} &= \frac{\langle \lambda_2, \lambda_1 \rangle^4 (-|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^2}{32 \langle \lambda_3, \lambda_2 \rangle^2 |\mathbf{k}_1|^2 |\mathbf{k}_2| |\mathbf{k}_3| (|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^2} \\ &\times [(|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^2 (|\mathbf{k}_2| + |\mathbf{k}_3|) - 2 (2|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|) |\mathbf{k}_2| |\mathbf{k}_3|] \\ &= \frac{1}{N_s} \tilde{\mathcal{K}}_s^{--+} + \mathcal{C}_s^{--+}. \end{aligned} \quad (5.1)$$

Here,

$$\tilde{\mathcal{K}}_s^{--+} = -N_s \frac{\langle \lambda_2, \lambda_1 \rangle^4 (-|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^2 (2|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)}{\langle \lambda_3, \lambda_2 \rangle^2 16 |\mathbf{k}_1|^2 (|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^2}, \quad (5.2)$$

has exactly the same functional form as the answer obtained from the AdS calculation in (4.31) and we have defined:

$$\mathcal{C}_s^{--+} = \frac{\langle \lambda_2, \lambda_1 \rangle^4 (-|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^2 (|\mathbf{k}_2| + |\mathbf{k}_3|)}{32 \langle \lambda_3, \lambda_2 \rangle^2 |\mathbf{k}_1|^2 |\mathbf{k}_2| |\mathbf{k}_3|}. \quad (5.3)$$

We will now show that (5.3) is purely a contact term. In fact we can write

$$\mathcal{C}_s^{-- +} = \frac{1}{8} (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_2) (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_3) (|\mathbf{k}_2| + |\mathbf{k}_3|). \quad (5.4)$$

To check the equivalence of (5.4) and (5.3), we note that:

$$\begin{aligned} & \frac{-1}{8} (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_2) (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_3) (|\mathbf{k}_2| + |\mathbf{k}_3|) \\ &= \frac{-1}{32|\mathbf{k}_1|^2|\mathbf{k}_2||\mathbf{k}_3|} \langle \lambda_1, \lambda_2 \rangle^2 [\lambda_1, \bar{\lambda}_3]^2 (|\mathbf{k}_2| + |\mathbf{k}_3|) \\ &= \frac{1}{32|\mathbf{k}_1|^2|\mathbf{k}_2||\mathbf{k}_3|} \frac{\langle \lambda_1, \lambda_2 \rangle^4 \langle \bar{\lambda}_2, \bar{\lambda}_3 \rangle^2}{E^2} (|\mathbf{k}_2| + |\mathbf{k}_3|) \\ &= \frac{1}{32|\mathbf{k}_1|^2|\mathbf{k}_2||\mathbf{k}_3|} \frac{\langle \lambda_1, \lambda_2 \rangle^4}{\langle \lambda_2, \lambda_3 \rangle^2} (|\mathbf{k}_2| + |\mathbf{k}_3| - |\mathbf{k}_1|)^2 (|\mathbf{k}_2| + |\mathbf{k}_3|), \end{aligned} \quad (5.5)$$

where the last line is manifestly the same as (5.3).

However, we can write (5.4) as

$$\mathcal{C}_s^{-- +} = \frac{1}{32} e_{1i_1 j_1} \epsilon_{2i_2} \epsilon_{3i_3} [\eta^{i_1 i_2} \eta^{j_1 i_3} (|\mathbf{k}_2| + |\mathbf{k}_3|)]. \quad (5.6)$$

The term in the square brackets is the “bare” correlator, before contracting with the polarization vectors, and this is the term we should Fourier transform to position space. In position space, this is evidently a contact term.

The general rule is that a term that is “analytic” in two of the momenta yields a contact term when Fourier transformed to position space. In this case, we notice, for example, that after adding the overall momentum conserving delta function we have:

$$\int |\mathbf{k}_2| \delta(\mathbf{k}_2 + \mathbf{k}_3 + \mathbf{k}_1) e^{i \sum \mathbf{k}_m \cdot \mathbf{x}_m} \prod d^3 \mathbf{k}_m = (2\pi)^3 \delta(x_1 - x_3) \int |\mathbf{k}_2| e^{i \mathbf{k}_2 \cdot (\mathbf{x}_2 - \mathbf{x}_3)} d^3 \mathbf{k}_2. \quad (5.7)$$

Contact terms in correlators are very subtle since they depend on the precise definition of the correlator, and also on the regulator used to compute it. While they might have physical significance under some circumstances, in this paper, we will just drop these additional δ function terms and work with $\tilde{\mathcal{K}}_s^{-- +}$ instead of $\mathcal{K}_s^{-- +}$.

+ - - **Helicity** It turns out that the free answer (3.6) is entirely a contact term in this case! We note that

$$\begin{aligned}
& \frac{1}{4}(\boldsymbol{\epsilon}_1 \cdot \mathbf{k}_2)(\boldsymbol{\epsilon}_1 \cdot \mathbf{k}_3)(\boldsymbol{\epsilon}_2 \cdot \boldsymbol{\epsilon}_3)(|\mathbf{k}_2| + |\mathbf{k}_3|) \\
&= \frac{1}{32|\mathbf{k}_1|^2|\mathbf{k}_2||\mathbf{k}_3|} \langle \lambda_2, \lambda_3 \rangle^2 \langle \bar{\lambda}_1, \bar{\lambda}_2 \rangle \langle \bar{\lambda}_1, \bar{\lambda}_3 \rangle [\bar{\lambda}_1, \lambda_2] [\bar{\lambda}_1, \lambda_3] (|\mathbf{k}_2| + |\mathbf{k}_3|) \\
&= \frac{1}{32} \langle \lambda_2, \lambda_3 \rangle^4 (|\mathbf{k}_1| + |\mathbf{k}_3| - |\mathbf{k}_2|)^2 (|\mathbf{k}_1| + |\mathbf{k}_2| - |\mathbf{k}_3|)^2 (|\mathbf{k}_2| + |\mathbf{k}_3|) \\
&= \frac{1}{N_s} \mathcal{K}_s^{+--}.
\end{aligned} \tag{5.8}$$

This is consistent with the fact that both the Weyl interaction and the ordinary gravitational interaction yield 0 in the AdS calculation (4.32). For notational consistency, we can set:

$$\tilde{\mathcal{K}}_s^{+--} = 0, \quad \mathcal{C}_s^{+--} = \frac{1}{N_s} \mathcal{K}_s^{+--}. \tag{5.9}$$

- - - **Helicity** Turning finally to (3.7), we see that this expression can be written as:

$$\frac{1}{N_s} \mathcal{K}_s^{----} = \frac{1}{N_s} \tilde{\mathcal{K}}_s^{----} + \mathcal{C}_s^{----}, \tag{5.10}$$

where

$$\tilde{\mathcal{K}}_s^{----} = N_s \frac{\langle \lambda_2, \lambda_1 \rangle^2 \langle \lambda_3, \lambda_1 \rangle^2}{4} \left(\frac{|\mathbf{k}_1|}{(|\mathbf{k}_1| + |\mathbf{k}_2| + |\mathbf{k}_3|)^4} \right), \tag{5.11}$$

has exactly the same functional form as the AdS answer (4.29) and the contact term \mathcal{C}_s^{----} is:

$$\mathcal{C}_s^{----} = \frac{-1}{8} (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_2)(\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_3)(|\mathbf{k}_2| + |\mathbf{k}_3|). \tag{5.12}$$

5.1.1 Value of γ

Our final task is to find the value of γ for free-scalars. To make the normalization of the two-point functions drop out, we can simply consider the ratio:

$$\frac{\tilde{\mathcal{K}}_s^{----}}{\tilde{\mathcal{K}}_s^{----+}} = -12\gamma_s \frac{\mathcal{K}_{\text{ads}}^{----}}{\mathcal{K}_{\text{ads}}^{----+}}. \tag{5.13}$$

Since the two ratios above should be equal, we find that we should set:

$$\gamma_s = -\frac{1}{12}, \tag{5.14}$$

where we have added a subscript to distinguish it from the value for free-fermions that we will find below.

We end by pointing out a very interesting feature of the answers (4.29), (4.32) and (4.31): there is no term where the ordinary interaction and the Weyl interaction contribute simultaneously. If we had a term where the two interactions contributed simultaneously, we could have fixed γ by looking at the functional form of the answer. However, γ appears as a simple ratio of two answers and so one needs to be extremely careful in determining all the signs and numerical prefactors in the expressions for the various 3-point functions correctly.

5.1.2 Value of G_N

We can also set the value of G_N from our calculations. Although G_N does not appear in the three-point computations above, it does appear in the computation of the two-point function for the stress-tensor from the bulk using the action (B.22). If we write the results for the two point functions in Appendix A and Appendix B.5 as:

$$\begin{aligned} \epsilon_{1,i_1} \epsilon_{1,i_2} \epsilon_{2,i_3} \epsilon_{2,i_4} \langle T_s^{i_1 i_2}(\mathbf{k}) T_s^{i_3 i_4}(-\mathbf{k}) \rangle &= C_{T,s} |\mathbf{k}|^3 (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_2)^2, \\ \epsilon_{1,i_1} \epsilon_{2,i_2} \langle J_s^{i_1} J_s^{i_2} \rangle &= -C_{J,s} |\mathbf{k}| (\boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_2), \end{aligned} \quad (5.15)$$

then we should demand that the normalization independent quantities be equal:

$$\begin{aligned} \frac{1}{\sqrt{C_{T,s} C_{J,s}}} \tilde{\mathcal{K}}_s^{----} &= \frac{1}{\sqrt{C_{T,\text{ads}} C_{J,\text{ads}}}} \mathcal{K}_{\text{ads}}^{----}, \\ \frac{1}{\sqrt{C_{T,s} C_{J,s}}} \tilde{\mathcal{K}}_s^{--++} &= \frac{1}{\sqrt{C_{T,\text{ads}} C_{J,\text{ads}}}} \mathcal{K}_{\text{ads}}^{--++}. \end{aligned} \quad (5.16)$$

We have, from the results for two point functions:

$$\begin{aligned} C_{T,s} &= \frac{N_s}{128}, & C_{J,s} &= \frac{N_s}{16}, \\ C_{T,\text{ads}} &= \frac{1}{\pi G_{N,s}}, & C_{J,\text{ads}} &= \frac{1}{g_{4,s}^2}. \end{aligned} \quad (5.17)$$

This leads to the scalar contribution

$$\frac{1}{G_{N,s}} = \frac{\pi N_s}{512}. \quad (5.18)$$

Note that, with this choice, the quantities $C_{T,s}$ and $C_{T,\text{ads}}$ do not agree and this is a sign of the fact that, with our conventions, the stress-tensor of the bulk theory is normalized differently from that of the boundary theory. This, in turn, results from our choice of Z above (B.25). This choice was made to yield a particularly simple graviton bulk to boundary propagator, and to get $C_{T,s}$ to match with $C_{T,\text{ads}}$ we should have chosen $Z = \frac{-d}{4\pi G_N}$, which is twice the choice that we have made currently.

5.1.3 Value of g_4^2

Note that $g_{4,s}^2$ does not appear in the quantities (5.16) at all since it cancels between the three-point and the two-point functions. However, we can choose a value by demanding that the two-point functions of the currents be equal in the bulk and the boundary. Imposing:

$$C_{J,\text{ads}} = C_{J,s}, \quad (5.19)$$

we can set:

$$g_{4,s}^2 = \frac{16}{N_s}. \quad (5.20)$$

5.2 Fermions

The analysis for the fermionic answers is almost identical, so we will not repeat it in detail here. However, with a little work, (see the Mathematica file [21]) we find that we can write:

$$\begin{aligned} \frac{1}{N_f} \mathcal{K}_f^{---} &= \frac{1}{N_f} \tilde{\mathcal{K}}_f^{---} + \mathcal{C}_f^{---}, \\ \frac{1}{N_f} \mathcal{K}_f^{--+} &= \frac{1}{N_f} \tilde{\mathcal{K}}_f^{--+} + \mathcal{C}_f^{--+}, \\ \frac{1}{N_f} \mathcal{K}_f^{+--} &= \frac{1}{N_f} \tilde{\mathcal{K}}_f^{+--} + \mathcal{C}_f^{+--}, \end{aligned} \quad (5.21)$$

where

$$\tilde{\mathcal{K}}_f^{---} = -\tilde{\mathcal{K}}_s^{---}, \quad \tilde{\mathcal{K}}_f^{--+} = \tilde{\mathcal{K}}_s^{--+}, \quad \tilde{\mathcal{K}}_f^{+--} = \tilde{\mathcal{K}}_s^{+--} = 0, \quad (5.22)$$

and the analytic remainders are:

$$\mathcal{C}_f^{---} = \frac{1}{2} \mathcal{C}_s^{---}, \quad \mathcal{C}_f^{--+} = \frac{1}{2} \mathcal{C}_s^{--+}, \quad \mathcal{C}_f^{+--} = \frac{1}{2} \mathcal{C}_s^{+--}, \quad (5.23)$$

which are half those of the scalar-case above.

Thus, we immediately see that for free-fermions, we have

$$\gamma_f = -\gamma_s = \frac{1}{12}. \quad (5.24)$$

A standard computation of the fermion 2-point functions shows that as for the scalars, we now have

$$\begin{aligned} g_{4,f}^2 &= \frac{16}{N_f}, \\ \frac{1}{G_{N,f}} &= \frac{\pi N_f}{512}. \end{aligned} \quad (5.25)$$

Of course, the CFT only has a single G_N which is simply $1/G_N = 1/G_{N,f} + 1/G_{N,s}$ at this order in $1/N_F$.

5.3 Topological Current

To obtain the value of γ for the topological current, we do not need to do any additional work. The analysis for the topological current proceeds in the following sequence of steps:

1. First, we can ignore the third line of (3.15) which includes terms like η^{v2j1}, η^{v2i1} etc. since they are analytic in two of the momenta. This leaves us with the terms involving \mathcal{K}_s and \mathcal{K}_f .
2. Instead of contracting \mathcal{K}_f and \mathcal{K}_s with the polarization vectors ϵ_2 and ϵ_3 , we instead need to contract them with the vectors: $\epsilon_2 \times \mathbf{k}_2/|\mathbf{k}_2|$ and $\epsilon_3 \times \mathbf{k}_3/|\mathbf{k}_3|$.²
3. However, this returns the original polarization vectors, up to a sign that depends on the helicity. In particular

$$\epsilon_2 \times \mathbf{k}_2/|\mathbf{k}_2| = h_2 \epsilon_2, \tag{5.26}$$

where h_2 is the helicity of current 2. A similar formula holds for current 3.

4. Therefore we get the same amplitudes as earlier up to a sign that is 1 if both currents have the same helicity and -1 if the currents have opposite helicities.

This chain of argument immediately yields

$$\gamma_t = \frac{(N_s - N_f)}{12(N_s + N_f)}. \tag{5.27}$$

6 Position space correlators and energy flux

In this section, we provide an alternate route to fix the value of γ using the 3-point functions $\langle TJJ \rangle$ in position space. In particular, we will extend the calculation of energy flux in Ref. [6] to arbitrary spacetime dimensions d and by comparing it with the holographic results, we relate γ to the parameters in the 3-point correlator of a general CFT obtained by Osborn and Petkou [12]. The latter parameters are known for free CFTs, and so we will obtain an alternate derivation of the $N_F \rightarrow \infty$ limits of γ_s and γ_f , consistent with our previous results.

In a CFT, we consider a thought experiment in which a localized disturbance or state is created by the insertion of a conserved vector current $(\epsilon \cdot \mathbf{J})$, where ϵ is a fixed, spatial polarization vector. We assume that this local disturbance injects a fixed energy E and the

²We need to be careful because we are in Lorentzian space, and the ordinary rules for the cross-product will take us from two vectors with lowered indices to a vector with a raised index.

system evolves in time. Now, we can place calorimeters at large distances and further study the anisotropic distribution of energy. In this experiment, a particular quantity, that is the energy flux escaping to the null infinity, will take a very simple form. If the direction of the null infinity is given by the unit vector \mathbf{n} , the energy flux collected by the calorimeter will be given by:

$$\langle \mathcal{E}(\mathbf{n}) \rangle = \frac{\langle 0 | (\boldsymbol{\epsilon}^* \cdot \mathbf{J}^\dagger) \mathcal{E}(\mathbf{n}) (\mathbf{J} \cdot \boldsymbol{\epsilon}) | 0 \rangle}{\langle 0 | (\boldsymbol{\epsilon}^* \cdot \mathbf{J}^\dagger) (\mathbf{J} \cdot \boldsymbol{\epsilon}) | 0 \rangle} \quad (6.1)$$

$$= \frac{E}{\Omega_d} \left[1 + \mathcal{A} \left(\frac{|\boldsymbol{\epsilon} \cdot \mathbf{n}|^2}{|\boldsymbol{\epsilon}|^2} - \frac{1}{d-1} \right) \right], \quad (6.2)$$

This form of the energy flux is completely fixed by the energy conservation and $O(d-1)$ symmetry of the construction. Here $\mathcal{E}(\mathbf{n})$ is the energy flux operator, to be introduced shortly in (6.3). The total energy injected by the perturbation is E and $\Omega_d = 2\pi^{\frac{d-1}{2}}/\Gamma(\frac{d-1}{2})$ is the area of the unit $(d-2)$ -sphere. Further, \mathcal{A} is a constant which characterizes the CFT. As pointed out after Eq. (1.6), the three point function $\langle TJJ \rangle$ in real space is completely determined by C_J , C_T and an additional constant. The coefficient \mathcal{A} is related to this additional constant and in holography, it is related to the coupling constant γ in (1.7). In this section, we will find \mathcal{A} through field theory and holographic calculations, and by comparing the results we will fix γ for free scalar and fermionic field theories. First, we will begin with the 3-point function $\langle TJJ \rangle$ in position space, which is specified by Osborn and Petkou [12], and calculate energy density (6.1) for CFTs.

6.1 \mathcal{A} in CFTs

To set up the calculations on field theory side, we work with Minkowski metric with ‘mostly positive’ signature. In our thought experiment, we place the calorimeter at large distance along x^1 direction and hence the unit vector $n^i = \delta_1^i$. To measure the energy along the null infinity, it is convenient to use the light-cone coordinates, which we define as $x^\pm = x^0 \pm x^1$. Then, the energy flux operator is given by [6, 14]

$$\mathcal{E}(\mathbf{x}_1, \mathbf{n}) = \int dx_1^- \left[\lim_{x_1^+ \rightarrow \infty} \left(\frac{x_1^+ - x_1^-}{2} \right)^{d-2} T_{--}(x_1^+, x_1^-) \right], \quad (6.3)$$

where T_{--} is the component of the stress energy tensor. Now to fix \mathcal{A} , it is sufficient to calculate the energy one point function for a state created by the operator $(\mathbf{J} \cdot \boldsymbol{\epsilon})$, which appears in the numerator of (6.1). So the calculation will boil down to using the expression for three point function $\langle J_i^\dagger(\mathbf{x}_2) T_{--}(\mathbf{x}_1, \mathbf{n}) J_j(\mathbf{x}_3) \rangle$ and performing various integrations. We can simplify these integrations by using symmetries of the construction. In the correlations $\langle J_i^\dagger(\mathbf{x}_2) T_{--}(\mathbf{x}_1, \mathbf{n}) J_j(\mathbf{x}_3) \rangle$, we can use translation invariance to set $\mathbf{x}_3 = 0$. By aligning the

calorimeter along $n^i = \delta_1^i$, we have also fixed $\mathbf{x}_1 = \{x_1^0, x_1^1, 0, \dots\}$. With these simplifications, we will only need to integrate over the coordinates $\mathbf{x}_2 = \mathbf{x} = \{x^0, x^1, x^2, \dots\}$. We further choose the spatial polarization vector ϵ to be $\epsilon = \{\epsilon^0, \epsilon^1, \epsilon^2, \epsilon^3, \dots\} = \{0, \cos \theta, \sin \theta, 0, \dots\}$. In this notation, we clearly have $|\epsilon \cdot \mathbf{n}| = \cos \theta$ and the numerator of (6.1) takes the following form

$$f(E) = \int dx^+ dx^- e^{iE\left(\frac{x^+ + x^-}{2}\right)} \int d^{d-2}x \times \int dx_1^- \left[\lim_{x_1^+ \rightarrow \infty} \left(\frac{x_1^+ - x_1^-}{2} \right)^{d-2} \epsilon^i \epsilon^j \langle J_i(\mathbf{x}) T_{--}(x_1^+, x_1^-) J_j(0) \rangle \right], \quad (6.4)$$

where now i, j will take the values $\{+, -, 2\}$. Now we use the three point correlator $\langle TJJ \rangle$ in position space to evaluate (6.4). As discussed in Ref. [12], using the conformal symmetry and Ward identities, the form of the three point functions in d -dimensional CFTs can be fixed to

$$\langle T_{ij}(\mathbf{x}_1) J_k(\mathbf{x}_2) J_l(\mathbf{x}_3) \rangle = \frac{t_{ijmn}(\mathbf{X}_{23}) g^{mp} g^{nq} I_{kp}(\mathbf{x}_{21}) I_{lq}(\mathbf{x}_{31})}{|\mathbf{x}_{12}|^d |\mathbf{x}_{13}|^d |\mathbf{x}_{23}|^{d-2}}, \quad (6.5)$$

where

$$\mathbf{x}_{12} = \mathbf{x}_1 - \mathbf{x}_2, \quad \mathbf{X}_{12} = \frac{\mathbf{x}_{13}}{|\mathbf{x}_{13}|^2} - \frac{\mathbf{x}_{23}}{|\mathbf{x}_{23}|^2} \text{ and } \hat{X}_i = \frac{X_i}{\sqrt{|\mathbf{X}|^2}}. \quad (6.6)$$

Further, we have

$$\begin{aligned} I_{ij}(\mathbf{x}) &= g_{ij} - 2 \frac{x_i x_j}{|\mathbf{x}|^2}, \\ t_{ijmn}(\mathbf{X}) &= \hat{a} h_{ij}^1(\hat{\mathbf{X}}) g_{mn} + \hat{b} h_{ij}^1(\hat{\mathbf{X}}) h_{mn}^1(\hat{\mathbf{X}}) + \hat{c} h_{ijmn}^2(\hat{\mathbf{X}}) + \hat{e} h_{ijmn}^3(\hat{\mathbf{X}}). \\ h_{ij}^1(\hat{\mathbf{X}}) &= \hat{X}_i \hat{X}_j - \frac{1}{d} g_{ij} \\ h_{ijmn}^2(\hat{\mathbf{X}}) &= \hat{X}_i \hat{X}_m g_{jn} + \{i \leftrightarrow j, m \leftrightarrow n\} \\ &\quad - \frac{4}{d} \hat{X}_i \hat{X}_j g_{mn} - \frac{4}{d} \hat{X}_m \hat{X}_n g_{ij} + \frac{4}{d^2} g_{ij} g_{mn}, \\ h_{ijmn}^3(\hat{\mathbf{X}}) &= g_{im} g_{jn} + g_{in} g_{jm} - \frac{2}{d} g_{ij} g_{mn}. \end{aligned} \quad (6.7)$$

In the above expression, $\{i \leftrightarrow j, m \leftrightarrow n\}$ represents three terms that we get by permuting the indices. Moreover in (6.7), all the coefficients with ‘hat’ are not independent and we have the following relations between them,

$$d \hat{a} - 2 \hat{b} + 2(d-2) \hat{c} = 0, \quad \hat{b} - d(d-2) \hat{e} = 0. \quad (6.9)$$

Now to evaluate (6.4), it is convenient to assume that the spacetime is even dimensional.

This assumption will allow us to use the residue theorem to evaluate certain integrals when we are doing the calculation for arbitrary d . However, our final results are insensitive to the parity of the spacetime dimension and in the end, we can analytically continue the results to odd spacetime dimensions. Now for even d , we go through the following steps to compute (6.4):

- First we use (6.5) to find the form of $\langle J_i(\mathbf{x})T_{--}(\mathbf{x}_1)J_j(0) \rangle$.
- We take the limit $x_1^+ \rightarrow \infty$ to get

$$K_{i--j} = \lim_{x_1^+ \rightarrow \infty} \left(\frac{x_1^+ - x_1^-}{2} \right)^{d-2} \langle J_i(\mathbf{x})T_{--}(\mathbf{x}_1)J_j(0) \rangle \quad (6.10)$$

- Next, we integrate over x_1^- . For that, we time order the operators using following $i\epsilon$ prescription: $x_1^0 \rightarrow x_1^0 - i\epsilon$ and $x^0 \rightarrow x^0 - 2i\epsilon$.
- We use standard results to integrate over the $(d-2)$ spatial dimensions orthogonal to x^\pm . While going through this step for different i, j in (6.4), we will find that some of the integrals are divergent. This is just an artifact of performing the integrations along the directions orthogonal to x^\pm , before integrating over x^\pm . We do so to simplify the integrations for arbitrary d and to fix these spurious divergences, we use the techniques of dimensional regularization. At this step, we perform the integration over $(d-2-\kappa)$ spatial dimensions instead of $(d-2)$, and in the final result we will take the limit $\kappa \rightarrow 0$. So here, we actually calculate

$$\int d^{d-2-\kappa}x \int dx_1^- K_{i--j}. \quad (6.11)$$

- Now we perform the integration over x^- and x^+ :

$$\int dx^- dx^+ e^{i\frac{E}{2}x^-} e^{i\frac{E}{2}x^+} \int d^{d-2-\kappa}x \int dx_1^- K_{i--j}. \quad (6.12)$$

In the contour integrations at this step, we close the loop from above because only then the integrations will converge.

- Finally, we take the limit $\kappa \rightarrow 0$ to get a finite result:

$$Q_{i--j} = \lim_{\kappa \rightarrow 0} \int dx^- dx^+ e^{i\frac{E}{2}x^-} e^{i\frac{E}{2}x^+} \int d^{d-2-\kappa}x \int dx_1^- K_{i--j}. \quad (6.13)$$

We repeat the above steps for all the values of i and j in (6.4). Details of these calculations can be found in attached Mathematica program [25] and we find that

$$\begin{aligned}
Q_{-----} &= \frac{(d-2)\left((d+1)(2d\hat{a} + (d-2)\hat{b} + 4(d-2)\hat{c}) + 2d(d+2)\hat{e}\right)\pi^{\frac{d}{2}+2}}{2^{d-1}(d+2)\Gamma\left(\frac{d+2}{2}\right)^3} \left(\frac{E}{2}\right)^{d-1}, \\
Q_{----+} &= -\frac{d\left((d-2)(d+1)\hat{b} + d(d\hat{a} + 2(d-2)\hat{c})\right)\pi^{\frac{d}{2}+2}}{2^d\Gamma\left(\frac{d}{2}+2\right)\Gamma\left(\frac{d}{2}+1\right)^2} \left(\frac{E}{2}\right)^{d-1}, \\
Q_{---2} &= 0, \\
Q_{+----} &= -\frac{\left((d\hat{a} + 2(d-2)\hat{c})\Gamma\left(\frac{d}{2}-1\right)\Gamma\left(\frac{d}{2}+1\right) + (d+1)\hat{b}\Gamma\left(\frac{d}{2}\right)^2\right)\pi^{\frac{d}{2}+2}}{2^{d-2}\Gamma\left(\frac{d}{2}-1\right)\Gamma\left(\frac{d}{2}+2\right)\Gamma\left(\frac{d}{2}\right)^2\Gamma\left(\frac{d}{2}+1\right)} \left(\frac{E}{2}\right)^{d-1}, \\
Q_{+---+} &= \frac{d(d-1)\hat{b}\pi^{\frac{d}{2}+2}}{2^{d-1}\Gamma\left(\frac{d}{2}+1\right)^3} \left(\frac{E}{2}\right)^{d-1}, \\
Q_{+--2} &= 0, \\
Q_{2---} &= 0, \\
Q_{2--+} &= 0, \\
Q_{2--2} &= -\frac{(d\hat{a} - 4\hat{c})\pi^{\frac{d}{2}+2}}{2^{d-3}\Gamma\left(\frac{d}{2}\right)\Gamma\left(\frac{d}{2}+1\right)^2} \left(\frac{E}{2}\right)^{d-1}.
\end{aligned}$$

Using these values for Q_{ijkl} and relations (6.9) in (6.4), we find that the energy flux for arbitrary d becomes

$$\langle \mathcal{E}(\mathbf{n}) \rangle = \frac{E}{\Omega_d} \left(1 - \frac{(d-1)(d(d-2)\hat{e} - \hat{c})}{(d-2)(\hat{e} + \hat{c})} \left(\cos^2 \theta - \frac{1}{d-1} \right) \right). \quad (6.14)$$

Note that the two point function in the denominator of (6.1) does not have any angular dependence, and it fixes the normalization of higher point functions. Now, we can easily read off the value of \mathcal{A} from (6.14) and also find it to be consistent with results for $d = 4$ in Ref. [6].

In Ref. [12], Osborn and Petkou have further studied the position three-point functions for the specific conformal field theory (1.1). By calculating the collinear three point functions $\langle TJJ \rangle$ for free scalar and free fermions, they have found the ratio of the coefficients \hat{c} and \hat{e} to be

$$\left(\frac{\hat{e}}{\hat{c}}\right)_s = \frac{1}{d-2} \quad \text{and} \quad \left(\frac{\hat{e}}{\hat{c}}\right)_f = 0. \quad (6.15)$$

These can be further used to find the value of \mathcal{A} in scalar and fermionic conformal field theories to be

$$\mathcal{A}_s = d-1 \quad \text{and} \quad \mathcal{A}_f = -\frac{d-1}{d-2}. \quad (6.16)$$

In the next section, we show how \mathcal{A} is related to the coupling constant γ in action (1.7) for $d = 3$. Then, these results are compared with the CFT results (6.16) to fix γ for free field theories.

6.2 \mathcal{A} from holography and matching the results

The holographic computation of \mathcal{A} for $d = 4$ was first done in Ref. [6] and then was extended to $d = 3$ in Ref. [4]. These calculations can be easily generalized to arbitrary dimensions and we find that

$$\mathcal{A} = -4d(d-1)\gamma. \quad (6.17)$$

A quick overview of the holographic computation is as follows. According to the AdS/CFT dictionary, the computation of expectation value of energy flux in the boundary theory, for a state created by a conserved vector current, boils down to calculating the three point function between two photons and a graviton. To compute such a three point function in the bulk gravity (1.7), we need to introduce appropriate metric fluctuations and two gauge field perturbations in the $(d+1)$ -dimensional AdS background. These fluctuations couple to the stress-energy tensor and vector current insertions T_{ij} and J_i on the boundary and one needs to evaluate their on-shell contribution for the action (1.7), as was done in Section 4. The bulk action has two terms. We find that the first term only contributes to the angle independent component of (6.2) and the second term introduces the anisotropy in the flux distribution. Hence, merely by comparing the contributions from both of the terms, we can easily extract the coefficient \mathcal{A} . For more details of this calculation, interested readers can refer to Appendix D of Refs. [6] and [15].

Now we match the field theory and holographic calculations from Eqs. (6.16) and (6.17) for $d = 3$ to find following values of γ for free scalars and fermions

$$\gamma_s = -\frac{1}{12} \quad \text{and} \quad \gamma_f = \frac{1}{12}, \quad (6.18)$$

which indeed are consistent with the momentum space calculations in (5.14) and (5.24) in the limit $N_F = \infty$.

7 Conclusions

The primary results of this paper are the values of γ in Eq. (1.8) for the conserved currents of the 2+1 dimensional CFTs defined in (1.1). Here γ is defined as a parameter controlling the structure of the zero temperature three-point correlator $\langle TJJ \rangle$ between the stress-energy tensor and the conserved current. Osborn and Petkou [12] specified the general form of the $\langle TJJ \rangle$ correlator, and γ was exactly connected to their parameterization in Section 6. However, γ also appears in the holographic representation of the CFT on AdS₄, and is the

coupling constant determining a four-derivative term in a gradient expansion of the effective action: see Eq. (1.7). The latter connection endows γ with much greater physical importance: it determines the structure of a variety of dynamical properties of charge transport at non-zero temperatures, both equilibrium and non-equilibrium. The holographic formulation also leads to the bound $|\gamma| \leq 1/12$ [4].

The action (1.7) was derived in Ref. [4] as the most general 4-derivative holographic theory expressed in terms of the gauge flux $F_{\mu\nu}$ and the metric tensor. We can also consider augmenting this action by other fields, which are holographic duals of other primary operators of the CFT [7, 26]. The most important of these is the “mass” term $|z_a|^2$ in (1.1), which tunes the CFT away from the critical point at $T = 0$. Here we are assuming we are at the CFT critical point at $T = 0$, and so such a relevant perturbation is not present in the underlying theory at $T = 0$; the structure of the interactions in the CFT ensures that there is no change in $\langle |z_a|^2 \rangle$ at $T > 0$ [27]. In the holographic theory, $|z_a|^2$ is represented by a scalar dilaton field, Φ . This can influence charge transport by an additional term $\sim \Phi F_{\mu\nu} F^{\mu\nu}$ in (1.7). Such a Φ does not have an expectation value in the AdS₄ theory at $T = 0$, and will not acquire one at $T > 0$ in the absence of external sources. In the linear response computation of the conductivity from such an augmented action, the $\sim \Phi F_{\mu\nu} F^{\mu\nu}$ term only influences the conductivity at the one-loop level in the bulk theory, so need not be included in our tree-level treatment of the effective theory (1.7). Thus γ remains as the crucial coupling determining the structure of the charge transport properties of the CFT, as was noted recently [7].

In Refs. [4, 7], it was shown that γ determined the structure of the universal frequency dependence of the conductivity $\sigma(\omega)$ at non-zero temperatures. For $0 < \gamma \leq 1/12$, it was found that there was a Drude-like peak at $\omega = 0$, followed by an eventual saturation at a constant at large ω . Such a structure appears physically reasonable from our present computation of $\gamma = 1/12$ for the free-fermion theory with $N_s = 0$: the free fermion theory has a delta function at zero frequency [28], and it is expected that this will be broadened to a Drude peak upon including interactions.

In the complementary range $-1/12 \leq \gamma < 0$, it was found [4, 7] that $\sigma(\omega)$ had a ‘dip’ at $\omega = 0$, rather than a peak. The value $\gamma = -1/12$ is obtained for the free scalar theory with $N_f = 0$. We can understand this dip if we interpret the scalar field in (1.1) as representing a *vortex* degree of freedom near *e.g.* a superfluid-insulator quantum phase transition [28]. Particle-vortex duality maps the conductivity to its inverse, and the inverse conductivity then has a Drude-like peak at $\omega = 0$. Further evidence for this interpretation comes from our computation of $\gamma_t = 1/12$ obtained with $N_f = 0$ for the topological current of (1.1). Under particle-vortex duality, the charged particle current in the dual theory maps to the topological current of (1.1), and so this also implies a peak in $\sigma(\omega)$ for the charged particle current.

It would be interesting to compute other dynamical consequences of the value of γ . In a

recent work [7], it was shown that γ crucially determined the structure of the poles and zeros of the complex conductivity in the lower-half of the complex frequency plane. These poles and zeros are associated with quasinormal modes of the holographic theory, and they are expected to be central to an understanding of the thermal dynamics of the CFT. Combined with more precise computations of the value of γ by the methods of the present paper, these connections open up the possibility of precise predictions for the dynamics of the strongly-interacting condensed matter systems.

A Review of the CFT two-point correlators $\langle JJ \rangle$ and $\langle TT \rangle$

In this appendix, we derive the current and stress-tensor two-point functions given in Eq. (1.5, 1.6) and compute C_J and C_T for the free theory. In momentum space, the two point function for currents and for the stress-tensor is just given by two bubble diagrams: one with two scalar boson propagators and the other with two fermion propagators, respectively. The scalar boson contribution to the current-current correlator reads:

$$\epsilon_{1,i_1} \epsilon_{2,i_2} \langle J_s^{i_1}(-\mathbf{k}) J_s^{i_2}(\mathbf{k}) \rangle = 4N_s \epsilon_1^{i_1} \epsilon_2^{i_2} \int \frac{P_{i_1} P_{i_2}}{P^2(\mathbf{P} + \mathbf{k})^2} \frac{d^3 P}{8\pi^3}. \quad (\text{A.1})$$

Using the identity

$$\int \frac{P_{i_1} P_{i_2}}{P^2(\mathbf{P} + \mathbf{k})^2} \frac{d^3 P}{8\pi^3} = \left(3 \frac{k_{i_1} k_{i_2}}{|\mathbf{k}|^2} - \eta_{i_1 i_2} \right) \frac{|\mathbf{k}|}{64}, \quad (\text{A.2})$$

one obtains

$$\epsilon_{1,i_1} \epsilon_{2,i_2} \langle J_s^{i_1} J_s^{i_2} \rangle = -N_s \frac{|\mathbf{k}|}{16} \boldsymbol{\epsilon}_1 \cdot \boldsymbol{\epsilon}_2, \quad (\text{A.3})$$

in agreement with the uncontracted expression in (1.5). This yields $C_{J,s} = N_s/16$ for the complex scalars. The calculation for free Dirac fermions is similar and one obtains $C_{J,f} = N_f/16$.

For the two point function of the stress-tensor, the scalar boson bubble can be integrated using the identity

$$\int \frac{d^3P}{8\pi^3} \frac{P_{i_1} P_{i_2} P_{i_3} P_{i_4}}{P^2(\mathbf{P} + \mathbf{k})^2} = (\eta_{i_1 i_2} \eta_{i_3 i_4} + 2 \text{ terms}) \frac{|\mathbf{k}|^3}{1024} - \left(\frac{k_{i_1} k_{i_2}}{|\mathbf{k}|^2} \eta_{i_3 i_4} + 5 \text{ terms} \right) \frac{5|\mathbf{k}|^3}{1024} + \frac{35 k_{i_1} k_{i_2} k_{i_3} k_{i_4}}{1024 |\mathbf{k}|}, \quad (\text{A.4})$$

resulting in the expression

$$\epsilon_{1,i_1} \epsilon_{1,i_2} \epsilon_{2,i_3} \epsilon_{2,i_4} \langle T_s^{i_1 i_2}(\mathbf{k}) T_s^{i_3 i_4}(-\mathbf{k}) \rangle = \frac{N_s}{256} 2(\epsilon_1 \cdot \epsilon_2)^2 |\mathbf{k}|^3. \quad (\text{A.5})$$

Note that this agrees with (1.6) with $C_{T,s} = N_s/128$. An identical computation for the two point function of the stress-tensor for free Dirac fermions gives $C_{T,f} = N_f/128$.

These quantities enable us to fix the values of certain coupling constants in the gravity theory in Section 5.

B AdS/CFT Correlators and Two Point Functions

This appendix provides background on the methods of gauge-gravity duality for readers who are condensed matter physicists.

The AdS/CFT conjecture states that theories of quantum gravity on $d + 1$ dimensional anti-de Sitter space (denoted AdS_{d+1}), are dual to d -dimensional conformal field theories that live on the “boundary” of AdS. The theory in AdS_{d+1} is called the “bulk theory” and the theory on the boundary is called the “boundary theory.” In the version of the correspondence that we will be using here, the bulk theory will live on the “Poincare patch” of AdS_{d+1} (the metric for this patch was already described above), while the boundary theory will live on $R^{d-1,1}$.

More precisely, the conjecture states that each “field” in the bulk corresponds to an operator on the boundary; second, if we do the path integral in the bulk theory with asymptotic boundary conditions fixed for these fields, then this equals the generating functional of the boundary theory with sources turned on for the corresponding operators.

Such an approach makes sense as long as we can distinguish individual fields in the bulk, and there is a corresponding decomposition of the spectrum of operators in the boundary theory in terms of single and double trace operators. This decomposition is possible for

theories with a large- N expansion, and it is in this regime that the AdS/CFT conjecture has been widely tested.

We now describe this conjecture quantitatively and explain how it may be used to calculate and compare correlation functions.

B.1 Prescription

In this section, we describe the prescription for computing correlation functions in AdS/CFT. This follows Ref. [2] with some refinements that were made in Ref. [29]. (See Ref. [30] for a review.)

A scalar field of mass-squared m^2 in the bulk is dual to an operator of dimension $\Delta = \frac{d}{2} + \sqrt{\left(\frac{d}{2}\right)^2 + m^2}$ on the boundary. If we solve the equations of motion for a free field of this mass we find, that near the boundary, we can have $\phi \sim z^{d-\Delta}$ and $\phi \sim z^\Delta$. The solution that grows at the boundary is called the “non-normalizable” solution, while the other one is called the “normalizable” solution. If we work in Euclidean AdS, then fixing the coefficient of the non-normalizable mode, and demanding regularity in the interior automatically fixes the normalizable mode also. In Lorentzian AdS, the normalizable mode can be set independently for time-like momenta, but below we will consider those solutions that come from a continuation of the Euclidean solutions.

The original prescription for correlation functions [2] was given for massless fields. For massive fields, we need to be careful about regularization because the non-normalizable mode diverges as we approach the boundary. So, we will cut the AdS space off at $z = \epsilon$, and consider doing the bulk path integral with the following regularized boundary condition for the scalar field as we approach the boundary:

$$\phi(\mathbf{x}, z) \xrightarrow{z \rightarrow \epsilon} \epsilon^{d-\Delta} \phi_0(\mathbf{x}). \quad (\text{B.1})$$

The idea is to work with this boundary condition and extract the finite part in ϵ at the end of the calculation. Then, the AdS/CFT prescription is that:

$$\int e^{-S} \mathcal{D}\phi \Big|_{\text{bound}} = \langle e^{\int \phi_0(\mathbf{x}) O(\mathbf{x}) d^d \mathbf{x}} \rangle_{\text{CFT}}. \quad (\text{B.2})$$

Here the left hand side is short hand for the path integral in the bulk done with the boundary conditions (B.1) while the right hand side is an expectation value in the conformal field theory. Although, to lighten the notation, we have chosen a particular coordinate system to represent the boundary conditions (B.1), the prescription is independent of this choice.

The original conjecture (B.2) was made in specific contexts: for example, one of the best studied examples of the AdS/CFT duality is when the bulk theory is type IIB string theory

on $\text{AdS}_5 \times S^5$ and the boundary theory is $\mathcal{N} = 4$ super-Yang-Mills theory. Several other examples are known.

However, where correlation functions are concerned, the prescription (B.2) may be examined just as well within effective field theory. This means that we take some effective field theory in the bulk and compute the left hand side of (B.2) at tree-level in the bulk. This computation can be used to *define* a generating functional in a CFT to leading order in $\frac{1}{N}$.³ This is because one can show that the quantity obtained this way satisfies all the constraints of conformal invariance and the operator product expansion (OPE) to leading order in $\frac{1}{N}$ in the boundary theory.

Now let us turn to the stress-tensor and conserved currents. The graviton in the bulk is dual to the stress tensor on the boundary, and a gauge field is dual to conserved currents. Now, consider doing the bulk path integral with the following boundary conditions for the metric and the gauge fields:

$$\begin{aligned} g_{zz}(\mathbf{x}, z) &\xrightarrow{z \rightarrow 0} \frac{1}{z^2}; g_{zi}(\mathbf{x}, z) \xrightarrow{z \rightarrow 0} 0; g_{ij}(\mathbf{x}, z) \xrightarrow{z \rightarrow 0} \frac{1}{z^2} (\eta_{ij} + \chi_{ij}(\mathbf{x})), \\ A_z(\mathbf{x}, z) &\xrightarrow{z \rightarrow 0} 0; A_i(\mathbf{x}, z) \xrightarrow{z \rightarrow 0} \mathbb{V}_i(\mathbf{x}). \end{aligned} \tag{B.3}$$

Then the bulk path integral with these boundary conditions is conjectured to be the same as the following generating functional of the conformal field theory:

$$\langle e^{\int [\chi_{ij}(\mathbf{x}) T^{ij}(\mathbf{x}) + \mathbb{V}_i(\mathbf{x}) j^i(\mathbf{x})] d^d \mathbf{x}} \rangle.$$

B.2 Scalar Two Point Function

The simplest setting in which we can test these ideas is to evaluate two-point functions. Consider a free massive scalar with action:

$$S_{\text{bulk}} = -\frac{1}{2} \int \sqrt{-g} [(\partial_\mu \phi)^2 + m^2 \phi^2]. \tag{B.4}$$

At leading order we can evaluate the left hand side of (B.2) in the saddle point approximation. Let us also take

$$\phi_0(\mathbf{x}) = \lambda_1 e^{i\mathbf{k}_1 \cdot \mathbf{x}} + \lambda_2 e^{i\mathbf{k}_2 \cdot \mathbf{x}}. \tag{B.5}$$

We need to find a solution of the equations of motion:

$$(\square - m^2)\phi = 0, \tag{B.6}$$

³As we mentioned above, the prescription (B.2) makes sense when we have a perturbative parameter that allows us to differentiate between single and double trace operators, and we are using N as a short-hand for this parameter here.

that respects (B.1).

In fact, it is rather subtle to write down such a solution. The authors of Ref. [29] showed that the correct method is to write down the following solution:

$$\phi(\mathbf{x}, z) = \epsilon^{d-\Delta} \left[\lambda_1 \frac{(|\mathbf{k}_1|z)^{\frac{d}{2}} K_{\Delta-\frac{d}{2}}(|\mathbf{k}_1|z)}{(|\mathbf{k}_1|\epsilon)^{\frac{d}{2}} K_{\Delta-\frac{d}{2}}(|\mathbf{k}_1|\epsilon)} e^{i\mathbf{k}_1 \cdot \mathbf{x}} + \lambda_2 \frac{(|\mathbf{k}_2|z)^{\frac{d}{2}} K_{\Delta-\frac{d}{2}}(|\mathbf{k}_2|z)}{(|\mathbf{k}_2|\epsilon)^{\frac{d}{2}} K_{\Delta-\frac{d}{2}}(|\mathbf{k}_2|\epsilon)} e^{i\mathbf{k}_2 \cdot \mathbf{x}} \right], \quad (\text{B.7})$$

where K is the modified Bessel function. Here we have defined $|\mathbf{k}_m|$ to be taken in the Lorentzian metric, with a mostly positive signature i.e the boundary metric is defined to be $\text{diag}(-1, 1, 1 \dots 1)$. For timelike \mathbf{k} , we should take its norm to have a negative imaginary part; this continues the modified Bessel function K to a Hankel function $H^{(1)}$.

We can superpose solutions of different momenta, so that the sum has delta function support at a given point; such a solution is called a ‘‘bulk to boundary’’ propagator. If we Fourier transform the bulk to boundary propagator, we will get a solution of the sort above.

It is very tempting to expand (B.7) in powers of ϵ so that we have:

$$\begin{aligned} \phi(\mathbf{x}, z) &= \frac{2^{\frac{1}{2}(d-2\Delta)+1}}{\Gamma(-\frac{d}{2} + \Delta)} \left[\lambda_1 |\mathbf{k}_1|^{\Delta-\frac{d}{2}} z^{\frac{d}{2}} K_{\Delta-\frac{d}{2}}(|\mathbf{k}_1|z) e^{i\mathbf{k}_1 \cdot \mathbf{x}} + \lambda_2 |\mathbf{k}_2|^{\Delta-\frac{d}{2}} z^{\frac{d}{2}} K_{\Delta-\frac{d}{2}}(|\mathbf{k}_2|z) \right] \\ &+ \mathcal{O}(\epsilon^{2\Delta-d}) + \mathcal{O}(\epsilon). \end{aligned} \quad (\text{B.8})$$

However, as was shown in Ref. [29], we *cannot* discard the subleading terms in ϵ at this stage because there is a second divergence when we evaluate the on-shell action and these subleading terms then contribute at $\mathcal{O}(\epsilon^0)$ in the final answer.

Now, let us compute the two point function using the prescription above. The on-shell action is divergent if we take $\epsilon \rightarrow 0$, so we should do the calculation with ϵ kept finite and extract the ϵ^0 term at the end.

On the solution (B.7), the on-shell action is simply:

$$S_{\text{on-shell}} = \frac{-1}{2} \int \sqrt{-g} z^2 \phi \frac{\partial \phi}{\partial z} d^d x \Big|_{z=\epsilon}. \quad (\text{B.9})$$

A short calculation shows that the ϵ^0 term on the right hand side of (B.9) that is bilinear in λ_1 and λ_2 is:

$$\frac{\partial^2 S_{\text{on-shell}}}{\partial \lambda_1 \partial \lambda_2} = -(2\Delta - d) \frac{\Gamma(\frac{d}{2} + 1 - \Delta)}{\Gamma(\Delta - \frac{d}{2} + 1)} \left(\frac{|\mathbf{k}_1|}{2} \right)^{2\Delta-d} \delta(\mathbf{k}_1 + \mathbf{k}_2) + \dots, \quad (\text{B.10})$$

where the \dots are higher and lower order terms in ϵ . The terms that are divergent as $\epsilon \rightarrow 0$, are analytic in the momentum, and so they can be removed by local counterterms.

From the prescription, (B.2), we can see that this is also the two point function of the operator O in the conformal field theory:

$$\langle O(\mathbf{k}_1)O(\mathbf{k}_2) \rangle = C_\Delta |\mathbf{k}_1|^{2\Delta-d} \delta(\mathbf{k}_1 + \mathbf{k}_2), \quad (\text{B.11})$$

where C_Δ is the numerical constant in (B.10). In fact, this is precisely what one expects from conformal invariance, for a primary operator of dimension Δ .

B.3 An Alternate Prescription

For the stress-tensor, and even for scalar fields, at leading order in $\frac{1}{N}$ (i.e at tree level in the bulk), it is often convenient to replace the prescription (B.2) with an equivalent prescription[31]. This prescription simply states that if we write the metric as:

$$g_{\mu\nu} = g_{\mu\nu}^{\text{AdS}} + h_{\mu\nu}, \quad (\text{B.12})$$

where $g_{\mu\nu}^{\text{AdS}}$ is the metric (4.1), and consider field configurations that satisfy the asymptotic conditions (B.1) then:

$$\langle T_{i_1 j_1}(\mathbf{x}_1) \dots T_{i_n j_n}(\mathbf{x}_n) \rangle_{\text{boundary}} = Z^n \lim_{z_i \rightarrow 0} z_1^{2-d} \dots z_n^{2-d} \langle h_{i_1 j_1}(\mathbf{x}_1, z_1) \dots h_{i_n j_n}(\mathbf{x}_n, z_n) \rangle_{\text{bulk}}. \quad (\text{B.13})$$

This is the statement that: *boundary correlators are just boundary values of bulk Green's functions*. Here Z is a wave-function renormalization factor. At tree-level in the bulk, this factor is just a constant as we will see below, and so we have written Z^n rather than writing separate factors for each insertion. Z just fixes the overall normalization of operators and so, at tree-level, it is not physically relevant but we will retain it for later convenience. For scalar operators, the analogous prescription is:

$$\langle O(\mathbf{x}_1) \dots O(\mathbf{x}_n) \rangle_{\text{boundary}} = Z^n \lim_{z \rightarrow 0} z_1^{-\Delta} \dots z_n^{-\Delta} \langle \phi(\mathbf{x}_1, z_1) \dots \phi(\mathbf{x}_n, z_n) \rangle_{\text{bulk}}. \quad (\text{B.14})$$

This is the prescription that we will use to evaluate two point functions.

B.4 Scalar Two Point Function Rederived

To get a feel for this prescription, let us re-derive the result above for the two point function of scalar operators. The scalar two-point Green's function in the bulk is given by Ref. [32]:

$$\begin{aligned} G(\mathbf{x}, z, \mathbf{x}', z') &= \int \frac{d^d \mathbf{k}}{(2\pi)^d} G_{\mathbf{k}}(z, z') e^{-i\mathbf{k} \cdot (\mathbf{x} - \mathbf{x}')} \\ &= - \int \frac{d^d \mathbf{k}}{(2\pi)^d} \frac{dp^2}{2} \frac{e^{i\mathbf{k} \cdot (\mathbf{x} - \mathbf{x}')} z^{\frac{d}{2}} J_{\Delta - \frac{d}{2}}(pz) J_{\Delta - \frac{d}{2}}(pz') (z')^{\frac{d}{2}}}{(\mathbf{k}^2 + p^2 - i\epsilon)}. \end{aligned} \quad (\text{B.15})$$

We can check that this Green's function obeys:⁴

$$(\square - m^2)G(\mathbf{x}, z, \mathbf{x}', z') = \frac{1}{\sqrt{-g}}\delta(\mathbf{x} - \mathbf{x}')\delta(z - z'). \quad (\text{B.16})$$

In Fourier space, the relation (B.16) is simply:

$$z^{d+1}\frac{\partial}{\partial z}z^{1-d}\frac{\partial G_k(z, z')}{\partial z} - m^2G_k(z, z') - z^2k^2G_k(z, z') = \delta(z - z')z^{d+1}. \quad (\text{B.17})$$

We can verify that this is satisfied by virtue of the identity:

$$\int pJ_\nu(pz)J_\nu(pz')dp = z^{-1}\delta(z - z'). \quad (\text{B.18})$$

After doing the p integral and transforming to momentum space, we find that the two point Green function can be written:

$$G(\mathbf{k}, z_1, z_2) = -(z_1z_2)^{\frac{d}{2}}I_{\Delta-\frac{d}{2}}(|\mathbf{k}|z^<)K_{\Delta-\frac{d}{2}}(|\mathbf{k}|z^>), \quad (\text{B.19})$$

where $z^< = \min(z_1, z_2)$ and $z^> = \max(z_1, z_2)$.⁵

With this choice, when we now take the limit where one point goes to the boundary, and also take $Z = -(2\Delta - d)$, we find:

$$Z \lim_{z_1 \rightarrow 0} z_1^{-\Delta} G(\mathbf{k}, z_1, z_2) = \frac{2^{\frac{1}{2}(d-2\Delta)+1}}{\Gamma(-\frac{d}{2} + \Delta)} |\mathbf{k}|^{\Delta-\frac{d}{2}} z_2^{\frac{d}{2}} K_{\Delta-\frac{d}{2}}(|\mathbf{k}|z_2). \quad (\text{B.20})$$

Note that this matches the “naive” bulk to boundary propagator of (B.8). We could also use a different value of Z provided that, in calculating higher point functions, we consistently use the bulk to boundary propagator that comes from taking the limit above. When we take both points to the boundary, we recover the two point function of the boundary operator.

$$\begin{aligned} \langle O(\mathbf{k})O(-\mathbf{k}) \rangle &= Z^2 \lim_{z_2 \rightarrow 0} z_2^{-\Delta} \lim_{z_1 \rightarrow 0} z_1^{-\Delta} G(\mathbf{k}, z_1, z_2) \\ &= -(2\Delta - d) \frac{\Gamma(\frac{d}{2} + 1 - \Delta)}{\Gamma(\Delta - \frac{d}{2} + 1)} \left(\frac{|\mathbf{k}_1|}{2} \right)^{2\Delta-d} \delta(\mathbf{k}_1 + \mathbf{k}_2) + \dots \end{aligned} \quad (\text{B.21})$$

Here, once again, as we take $z_2 \rightarrow 0$, we find a divergent term that is analytic in the momenta and so a delta function in position space. This is indicated by the \dots , which are unimportant.

Note that this prescription is somewhat more straightforward than evaluating the on-shell

⁴Note that Ref. [32] defines the Green's function with an additional minus sign on the right hand side.

⁵We have written this as a function of one momentum, rather than two, because the two momenta are forced to be equal by momentum conservation.

action, since we don't have to worry about the subleading terms in ϵ in imposing (B.1) and so we will use it for the stress tensor and conserved currents.

B.5 Two Point Function of the Stress Tensor and Currents

To evaluate the two point function of the stress-tensor using AdS/CFT, we simply need to evaluate the two point function of the metric fluctuation in AdS. We will consider the Hilbert-Einstein action:

$$S_{\text{grav}} = \frac{-1}{16\pi G_N} \int \sqrt{-g} (R - 2\Lambda), \quad (\text{B.22})$$

where Λ is the cosmological constant. We now expand the metric out as:

$$g_{\mu\nu} = g_{\mu\nu}^{\text{ads}} + h_{\mu\nu}. \quad (\text{B.23})$$

The propagator, in the gauge where we set $h_{zi} = h_{zz} = 0$ is easily evaluated and found to be [33]:

$$\begin{aligned} G_{ij,kl}^{\text{grav}}(\mathbf{k}, z_1, z_2) \\ = 8\pi G_N \int \left[\frac{z_1^{\frac{d}{2}-2} J_{\frac{d}{2}}(pz_1) J_{\frac{d}{2}}(pz_2) (z_2)^{\frac{d}{2}-2}}{(\mathbf{k}^2 + p^2 - i\epsilon)} \frac{1}{2} \left(\mathcal{T}_{ik} \mathcal{T}_{jl} + \mathcal{T}_{il} \mathcal{T}_{jk} - \frac{2\mathcal{T}_{ij} \mathcal{T}_{kl}}{d-1} \right) \right] \frac{-dp^2}{2}, \end{aligned} \quad (\text{B.24})$$

where $\mathcal{T}_{ij} = \eta_{ij} + k_i k_j / p^2$.

First let us take the limit $z_1 \rightarrow 0$, and take Z in (B.13) to be $Z = -\frac{d}{8\pi G_N}$. With this, we see that when we take $z_1 \rightarrow 0$:

$$Z \lim_{z_1 \rightarrow 0} z_1^{2-d} G_{ij,kl}^{\text{grav}}(\mathbf{k}, z_1, z_2) = \frac{1}{2} \left(\tilde{\mathcal{T}}_{ik} \tilde{\mathcal{T}}_{jl} + \tilde{\mathcal{T}}_{il} \tilde{\mathcal{T}}_{jk} - \frac{2\tilde{\mathcal{T}}_{ij} \tilde{\mathcal{T}}_{kl}}{d-1} \right) \left[\frac{2^{-\frac{d}{2}+1}}{\Gamma(\frac{d}{2})} |\mathbf{k}|^{\frac{d}{2}} z_2^{\frac{d}{2}-2} K_{\frac{d}{2}}(|\mathbf{k}|z_2) \right], \quad (\text{B.25})$$

where $\tilde{\mathcal{T}}_{ij} = \eta_{ij} - k_i k_j / |\mathbf{k}|^2$.

For $d = 3$, which is the case that we are interested in, this takes on a very simple form:

$$Z \lim_{z_1 \rightarrow 0} z_1^{2-d} G_{ij,kl}^{\text{grav}}(\mathbf{k}, z_1, z_2) = \frac{1}{2z_2^2} \left(\tilde{\mathcal{T}}_{ik} \tilde{\mathcal{T}}_{jl} + \tilde{\mathcal{T}}_{il} \tilde{\mathcal{T}}_{jk} - \tilde{\mathcal{T}}_{ij} \tilde{\mathcal{T}}_{kl} \right) e^{-|\mathbf{k}|z_2} (1 + |\mathbf{k}|z_2). \quad (\text{B.26})$$

This is the bulk to boundary propagator that we will use below.

Taking the limit as $z_2 \rightarrow 0$, we now find that:

$$\langle T_{ij}(\mathbf{k}) T_{kl}(-\mathbf{k}) \rangle = -\frac{1}{8\pi G_N} |\mathbf{k}|^d \frac{\Gamma(1-\frac{d}{2})}{\Gamma(\frac{d}{2}+1)} \frac{d}{2} \left(\tilde{\mathcal{T}}_{ik} \tilde{\mathcal{T}}_{jl} + \tilde{\mathcal{T}}_{il} \tilde{\mathcal{T}}_{jk} - \frac{2\tilde{\mathcal{T}}_{ij} \tilde{\mathcal{T}}_{kl}}{d-1} \right). \quad (\text{B.27})$$

Let us now specialize to the case where $d = 3$. We now have:

$$\langle T_{ij}(\mathbf{k})T_{kl}(-\mathbf{k}) \rangle = \frac{4}{8\pi G_N} |\mathbf{k}|^3 \left(\tilde{\mathcal{T}}_{ik}\tilde{\mathcal{T}}_{jl} + \tilde{\mathcal{T}}_{il}\tilde{\mathcal{T}}_{jk} - \tilde{\mathcal{T}}_{ij}\tilde{\mathcal{T}}_{kl} \right), \quad \text{for } d = 3. \quad (\text{B.28})$$

This matches with the answer obtained from the CFT in (1.6).

Similarly, we can obtain the two point function of currents in the Maxwellian theory in the bulk. (For this, we set $\gamma = 0$, for the moment.) We start with the Maxwell action:

$$S_{\text{gauge}} = \frac{-1}{4g_4^2} \int \sqrt{-g} F_{\mu\nu} F^{\mu\nu}. \quad (\text{B.29})$$

The bulk to bulk propagator of currents in ‘‘axial gauge’’ (where we set the z component of the gauge field to 0) is given by:

$$G_{ij}^{\text{axial,ab}}(\mathbf{k}, z_1, z_2) = g_4^2 \int \frac{-dp^2}{2(2\pi)^d} \left[\frac{(z_1 z_2)^{\nu_1} J_{\nu_1}(pz_1) J_{\nu_1}(pz_2) \mathcal{T}_{ij} \delta^{ab}}{(\mathbf{k}^2 + p^2 - i\epsilon)} \right], \quad (\text{B.30})$$

with $\nu_1 = \frac{d}{2} - 1$. Repeating the process above and now taking $Z = \frac{2-d}{g_4^2}$, we find that when $z_1 \rightarrow 0$, we get:

$$Z \lim_{z_1 \rightarrow 0} z_1^{1-d} G_{ij}^{\text{axial}}(\mathbf{k}, z_1, z_2) = \frac{2^{\frac{1}{2}(2-d)+1}}{\Gamma(\frac{d}{2}-1)} |\mathbf{k}|^{\frac{d}{2}-1} z_2^{\frac{d}{2}-1} K_{\frac{d}{2}-1}(|\mathbf{k}|z_2) \tilde{\mathcal{T}}_{ij}. \quad (\text{B.31})$$

For $d = 3$, we simply have

$$Z \lim_{z_1 \rightarrow 0} z_1^{1-d} G_{ij}^{\text{axial}}(\mathbf{k}, z_1, z_2) = \tilde{\mathcal{T}}_{ij} e^{-|\mathbf{k}|z_2}, \quad \text{for } d = 3. \quad (\text{B.32})$$

The two point function of currents is given by:

$$\langle j_i(\mathbf{k})j_j(-\mathbf{k}) \rangle = \frac{1}{g_4^2} (2-d) \frac{\Gamma(2-\frac{d}{2})}{\Gamma(\frac{d}{2})} \left(\frac{|\mathbf{k}_1|}{2} \right)^{d-2} \tilde{\mathcal{T}}_{ij}. \quad (\text{B.33})$$

For $d = 3$, we have the remarkably simple expression

$$\langle j_i(\mathbf{k})j_j(-\mathbf{k}) \rangle = -\frac{1}{g_4^2} |\mathbf{k}_1| \tilde{\mathcal{T}}_{ij}, \quad (\text{B.34})$$

which agrees with (1.5), and fixes $C_J = 1/g_4^2$.

C Spinor Helicity Formalism

In this appendix, we review the spinor helicity formalism for correlation functions in 3 dimensional conformal field theories that was described briefly in section 2. The spinor helicity formalism adapted to 3-dimensional Lorentzian CFTs is also described in section 2 of Ref. [22].

In our conventions, the boundary metric is Lorentzian and mostly positive. This means that for two boundary vectors:

$$\mathbf{k} \cdot \mathbf{k} = (k_1)^2 + (k_2)^2 - (k_0)^2. \quad (\text{C.1})$$

We use bold-face for vectors but not their components. We use i, j etc. for boundary spacetime indices and μ, ν etc. for bulk spacetime indices. We use m, n etc. to index particle-number. Finally, the components of a momentum vector come with a naturally lowered index.

Our σ matrix conventions are the following

$$\begin{aligned} \sigma_{\alpha\dot{\alpha}}^0 &= \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, & \sigma_{\alpha\dot{\alpha}}^1 &= \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \\ \sigma_{\alpha\dot{\alpha}}^2 &= \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, & \sigma_{\alpha\dot{\alpha}}^3 &= \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \end{aligned} \quad (\text{C.2})$$

Given a three momentum $\mathbf{k} = (k_0, k_1, k_2)$, as we described in section 2, we convert it into spinors using

$$k_{\alpha\dot{\alpha}} = k_0\sigma_{\alpha\dot{\alpha}}^0 + k_1\sigma_{\alpha\dot{\alpha}}^1 + k_2\sigma_{\alpha\dot{\alpha}}^2 + i|\mathbf{k}|\sigma_{\alpha\dot{\alpha}}^3 = \lambda_\alpha\bar{\lambda}_{\dot{\alpha}}, \quad (\text{C.3})$$

where

$$|\mathbf{k}| \equiv \sqrt{\mathbf{k} \cdot \mathbf{k}} = \sqrt{k_1^2 + k_2^2 - k_0^2}. \quad (\text{C.4})$$

If \mathbf{k} is spacelike to start with, then the σ^3 component will be imaginary.

In components, we have the following expressions for the spinors

$$\begin{aligned} \lambda &= \left(\sqrt{k_0 + i|\mathbf{k}|}, \frac{k_1 + ik_2}{\sqrt{k_0 + i|\mathbf{k}|}} \right), \\ \bar{\lambda} &= \left(\sqrt{k_0 + i|\mathbf{k}|}, \frac{k_1 - ik_2}{\sqrt{k_0 + i|\mathbf{k}|}} \right). \end{aligned} \quad (\text{C.5})$$

We have the freedom to rescale the spinors by any complex number: $\lambda \rightarrow \alpha\lambda$, $\bar{\lambda} \rightarrow \frac{1}{\alpha}\bar{\lambda}$ without changing the momentum. If we do this for spinors corresponding to an external particle, then this rescales the polarization vectors and amplitudes pick up a simple phase.

We can raise and lower spinor indices using the ϵ tensor. We choose the ϵ tensor to be

$i\sigma_2$ for both the dotted and the undotted indices. This means that

$$\epsilon^{01} = 1 = -\epsilon^{10}, \quad (\text{C.6})$$

and spinor dot products are defined via

$$\langle \lambda_1, \lambda_2 \rangle = \epsilon^{\alpha\beta} \lambda_{1\alpha} \lambda_{2\beta} = \lambda_{1\alpha} \lambda_2^\alpha, \quad \langle \bar{\lambda}_1, \bar{\lambda}_2 \rangle = \epsilon^{\dot{\alpha}\dot{\beta}} \bar{\lambda}_{1\dot{\alpha}} \bar{\lambda}_{2\dot{\beta}} = \bar{\lambda}_{1\dot{\alpha}} \bar{\lambda}_2^{\dot{\alpha}}. \quad (\text{C.7})$$

In the case of four-dimensional flat-space scattering amplitudes, all expressions can be written in terms of the two kinds of dot products above. However, in our case, we should expect our expressions for CFT_3 correlators to only have a manifest $SO(2,1)$ invariance. This means that we might have mixed products between dotted and undotted indices. Such a mixed product extracts the z -component of vector and is performed by contracting with σ^3

$$2i|\mathbf{k}| = (\sigma^3)^{\alpha\dot{\alpha}} k_{\alpha\dot{\alpha}} \equiv [\lambda, \bar{\lambda}]. \quad (\text{C.8})$$

The reader should note that we use square brackets only for this mixed product; products of both left and right handed spinors are denoted by angular brackets. Second, we note that this mixed dot product is symmetric:

$$[\lambda, \bar{\lambda}] = [\bar{\lambda}, \lambda]. \quad (\text{C.9})$$

When we take the dot products of two 3-momenta, we have

$$\begin{aligned} \mathbf{k} \cdot \mathbf{q} &\equiv (k_1 q_1 + k_2 q_2 - k_0 q_0) \\ &= -\frac{1}{2} \left(\langle \lambda_k, \lambda_q \rangle \langle \bar{\lambda}_k, \bar{\lambda}_q \rangle + \frac{1}{2} [\lambda_k, \bar{\lambda}_k] [\lambda_q, \bar{\lambda}_q] \right). \end{aligned} \quad (\text{C.10})$$

Another fact to keep in mind is that

$$\begin{aligned} \mathbf{k}_1 + \mathbf{k}_2 &= \mathbf{k}_3 \\ \Rightarrow \lambda_1 \bar{\lambda}_1 + \lambda_2 \bar{\lambda}_2 &= \lambda_3 \bar{\lambda}_3 + \frac{1}{2} ([\lambda_1, \bar{\lambda}_1] + [\lambda_2, \bar{\lambda}_2] - [\lambda_3, \bar{\lambda}_3]) \sigma^3. \end{aligned} \quad (\text{C.11})$$

We also need a way to convert dotted to undotted indices. We write

$$\lambda_{\dot{\alpha}}^\dagger = \sigma_{\alpha\dot{\alpha}}^3 \lambda^\alpha, \quad \bar{\lambda}_\alpha^\dagger = \sigma_{\alpha\dot{\alpha}}^3 \bar{\lambda}^{\dot{\alpha}}. \quad (\text{C.12})$$

This has the property that

$$\langle \mu, \lambda^\dagger \rangle = [\mu, \lambda], \quad (\text{C.13})$$

where the quantity on the right hand side is defined in (C.8).

With all this, we can write down polarization vectors for conserved currents. The polarization vectors for a momentum vector \mathbf{k} associated with spinors $\lambda, \bar{\lambda}$ are given by

$$\begin{aligned}\epsilon_{\alpha\dot{\alpha}}^+ &= 2 \frac{\bar{\lambda}_\alpha^\dagger \bar{\lambda}_{\dot{\alpha}}}{[\lambda, \bar{\lambda}]} = \frac{\bar{\lambda}_\alpha^\dagger \bar{\lambda}_{\dot{\alpha}}}{i|\mathbf{k}|}, \\ \epsilon_{\alpha\dot{\alpha}}^- &= 2 \frac{\lambda_\alpha \lambda_{\dot{\alpha}}^\dagger}{[\lambda, \bar{\lambda}]} = \frac{\lambda_\alpha \lambda_{\dot{\alpha}}^\dagger}{i|\mathbf{k}|}.\end{aligned}\tag{C.14}$$

These vectors are normalized so that

$$\epsilon^+ \cdot \epsilon^+ = \epsilon^- \cdot \epsilon^- = 0, \quad \epsilon^+ \cdot \epsilon^- = 2.\tag{C.15}$$

Polarization tensors for the stress tensor are just outer-products of these vectors with themselves:

$$e_{ij}^\pm = \epsilon_i^\pm \epsilon_j^\pm.\tag{C.16}$$
