Received 9 November 2010/Accepted 28 March 2011

The global transcriptional program of murine cytomegalovirus (MCMV), involving coding, noncoding, and antisense transcription, remains unknown. Here we report an oligonucleotide custom microarray platform capable of measuring both coding and noncoding transcription on a genome-wide scale. By profiling MCMV wild-type and immediate-early mutant strains in fibroblasts, we found rapid activation of the transcriptome by 6.5 h postinfection, with absolute dependency on *ie3*, but not *ie1* or *ie2*, for genomic programming of viral gene expression. Evidence is also presented to show, for the first time, genome-wide noncoding and bidirectional transcription at late stages of MCMV infection.

Murine cytomegalovirus (MCMV) is a ubiquitous betaherpesvirus with a 235-kbp genome transcribed in a classical cascade fashion (55). The genome sequence of MCMV has been available for some time (89), and yet a systematic study of temporal gene expression during MCMV infection has been lacking. Double-stranded PCR-based cDNA microarrays were used once previously (105) to validate the expression of a subset of predicted MCMV open reading frames (ORFs) (15) at a single time point (24 h postinfection [hpi]). More-advanced microarray technology based on oligonucleotide probes, affording increased specificity to distinguish RNA polarity, has not been reported. For human cytomegalovirus (HCMV), abundant antisense (AS) transcription has been observed (120), raising the possibility that aspects of the CMV life cycle are influenced or regulated by noncoding transcripts. For MCMV, small virus-encoded microRNAs (miRNAs) (19, 20, 33) and larger double-stranded RNAs (21, 110) have been reported to be transcribed from multiple loci; however, the frequency and abundance of noncoding transcripts throughout the MCMV genome have not yet been measured systematically on a genome-wide scale and at multiple stages of infection.

Here we have investigated the global transcriptional program of MCMV by constructing a microarray capable of measuring sense (S) and AS transcripts. Microarrays were designed using 55-mer oligonucleotide probes in sense and antisense orientations to each of the 170 viral ORFs predicted in the MCMV genome (89). One hundred ninety-two positive-control probes were designed against stably expressed mouse genes for normalization purposes, and 97 negative-control probes were designed against *Saccharomyces cerevisiae* sequences with no homology to mouse or MCMV genomes (for probe sequences, see Table S1 in the supplemental material). The 55-mer oligonucleotide probes were diluted to a concentration of 60 μM and inkjet printed (Arrayjet, United Kingdom) onto amino silane-coated glass slides, with each microarray consisting of six identical subarrays. Probes were printed in triplicate per array and have the capacity for developing a total of 18 measurements per probe per sample to ensure high technical replication. Target RNA was extracted from infected fibroblasts using PureLink RNA minikits with on-column DNase I treatment (Invitrogen, CA). Purified RNA (700 ng for each sample) was labeled for microarray analysis using the Agilent low-input fluorescent linear amplification protocol (Agilent, CA), with 3 μg of Cy5-labeled target cRNA hybridized per sample. Hybridized microarrays were washed and subsequently scanned using an Agilent (CA) G2505B scanner.

To perform a systematic analysis of genome-wide transcription in MCMV, we infected NIH 3T3 fibroblasts with the parental MCMV strain at a multiplicity of infection (MOI) of 1 and performed DNA microarray analysis on total RNA harvested from duplicate cultures at 0.5, 6.5, 24, and 48 hpi. Individual probe signals were background subtracted, median summarized, and log base 2 transformed to form raw data points (see Table S2 in the supplemental material). Raw data were quality controlled, and normalization between samples

TABLE 1. High-confidence MCMV microarray sense probes[a]

Unique probe ID[b]	ORF	Strand	MCMV name	HCMV name	Time on[c] (hpi)	Protein type	Annotation[d] (reference[s])	Virion association[e]
vMC132	m128 Ex3	C	ie2	US22 (GF2)	0.5	Immediate early	Spliced m128 (ie2) gene has sequence similarity to members of the US22 family of HCMV (77)	
vIE1rem	m123 Ex4	C	ie1	IE1	6.5	Immediate early	ie1 exon 4, with mRNA terminating at base 179544 (53-55); total length of Ex2 plus Ex3 plus Ex4 is 595 aa, total molecular size is 66.7 kDa	
vMC003	m03				6.5	Glycoprotein m02	Sequence variation and early transcriptional kinetics found in wild-type-derived MCMV isolates; m03-encoded protein could be found on cell surface (28)	
vMC004	m04		gp34		6.5	Glycoprotein m02	m04 gene product (gp34) forms a complex with MHC-I (51), which reaches the cell surface (46) and is required for Ly49P recognition of infected cells (57); m04/gp34 also antagonizes the effect of m152 (84)	
vMC006	m06		gp48		6.5	Glycoprotein m02	m06 gene product (gp48) downmodulates the levels of MHC-I proteins in infected cells (50) and binds to the ternary complex of assembled MHC-I with antigenic peptide in the ER, redirecting this complex to the lysosome for degradation; unbound gp48 is destroyed by the proteasome (18)	
vMC008	m08				6.5	Glycoprotein m02	Glycoprotein family m02	
vMC010	m10				6.5	Glycoprotein m02	Glycoprotein family m02	
vMC016	m16.2				6.5	Glycoprotein m02	Glycoprotein family m02, probe overlaps with newly predicted ORF m16.2 (105)	
vMC017	m17	C			6.5	Membrane glycoprotein		
vMC018	m18	C			6.5	Early	Highly antigenic early gene (44)	VAP
vMC027	m25.1	C		UL23 (GF2)	6.5	US22 family homolog	Mutant showed no obvious growth phenotype (75)	
vMC030	M28	C		UL28	6.5			
vMC037	m34.2			UL34	6.5		Reannotations of the MCMV genome have identified three putative M34-overlapping ORFs (m33.1, m34.1, and m34.2); this microarray probe overlaps with newly predicted ORF m34.2 (105); an M34 mutant virus which interrupted all three m34 ORFs had attenuated replication both in tissue culture and in SCID mice (10)	
vMC040	M36 Ex2	C		UL36 exon 2	6.5	US22 family homolog	Possible transcriptional regulator (89), implicated in blocking apoptosis via inhibition of caspase-8 (FLICE) activation (100); growth of M36 mutant was attenuated *in vitro* and *in vivo* (27); HCMV vICA/pUL36 protects cells from extrinsic apoptosis induced via death receptors in TNFR1, Fas/CD95, or Trail	
vMC041	M37	C		UL37	6.5	Glycoprotein	Glycoprotein, vMIA; M37 mutant is severely attenuated in growth and virulence *in vivo* (63); homolog of HCMV UL37 that inhibits mitochondrial megapore activation in a manner similar to members of the antiapoptotic Bcl family (37); may also be a transcriptional regulator (58)	
vMC045	m41	C			6.5		Putative antiapoptotic function (79)	
vMC046	m42	C			6.5	Putative glycoprotein		
vMC047	M43	C		UL43	6.5	US22 family homolog	Antiapoptotic (79), immunoregulatory gene that modulates T helper cell response (99); found to be nonessential for viral growth *in vitro* and *in vivo* and dispensable for virulence in killing SCID mice (117)	VAP
vMC049	M45	C		UL45 (RRL)	6.5	Ribonucleotide reductase	Antiapoptotic (17) homologue of the large subunit of ribonucleotide reductase (85); blocks NF-κB activation as a result of its inhibitory effect on RIP1 signaling (71, 109)	VAP
vMC055	m48.2	C			6.5	Capsid	Smallest capsid protein (14)	VAP
vMC061	M54	C	DNApol	UL54 (DNApol)	6.5	DNA polymerase	DNA polymerase delta subtype (59)	VAP
vMC064	M57	C		UL57 (MDBP)	6.5	DNA binding	Major ssDNA binding protein (3, 4)	VAP
vMC079	M80			UL80 (AP)	6.5	Assembly protein, protease	Assembly protein and protease (11, 69) that conserves the domain structure and cleavage sites present in HCMV UL80	VAP
vMC080	M82	C	pp71	UL82 (pp71)	6.5	Upper matrix phosphoprotein	Encodes a structural protein unique to the betaherpesvirus group, also known as pp71; same family as M83 (91)	VAP
vMC092	M94			UL94	6.5	Virion associated	Virion-associated, tegument/second envelopment protein (112)	VAP
vMC098	M99			UL99 (pp28)	6.5	Phosphoprotein	Encodes small structural phosphoprotein unique to the betaherpesvirus group, shown to be around 16 kDa in size and to be associated with the virion (30, 78)	VAP
vMC100	M102			UL102 (HP)	6.5	Helicase-primase	Part of the helicase-primase complex of three proteins (M70, M102, and M105) (70, 97)	VAP
vMC103	M105			UL105 (Hel)	6.5	DNA helicase	DNA helicase; part of the helicase-primase complex of three proteins (M70, M102, and M105) (70, 97)	VAP
vMC114	M118	C		UL118	6.5		Possible alternate splice to m119, as for HCMV UL118 (62, 88)	
vMC117	m119.2	C	sgg1		6.5		Exon 2 of M133 (sgg1) (61, 73)	
vMC136	m132 Ex2	C			6.5			

vMC141	m137	C			6.5	Putative glycoprotein		
vMC142	m138	C	Fcgr	fcr1	6.5	Glycoprotein	Encodes the 88-kDa Fc receptor glycoprotein (107); Fc receptor-specific (m138) deletion mutants show unexpected alterations in virulence and are attenuated in normal and immunosuppressed adult mice (31); m138 downmodulates the NKG2D ligands MULT-1, H60 (65), and RAE-1 epsilon (8)	
vMC146	m142	C		US26 (GF2)	6.5	US22 family homolog	Required to block PKR-mediated shutdown of cellular protein synthesis and associated antiviral response (21, 110)	
vMC151	m147	C			6.5	Possible membrane-spanning protein	Spliced gene m147.5 selectively targets CD86 expression on APCs (68)	VAP
vMC156	m152	C	gp40		6.5	Glycoprotein	m152 gene product (gp40) is a member of the MGP family that downmodulates MHC-I proteins in infected cells (50), disrupts export of MHC-I complexes from pre-Golgi compartments to the Golgi compartment via a luminal domain (122), and modulates NK cell response (inhibition), antigen presentation, and T cell response (40); viruses lacking gp40 show increased susceptibility to CTL killing in mice (43)	
vMC158	m154	C			6.5	Glycoprotein	Threonine-serine-rich glycoprotein of MGP family m145, some homology to EHV1 g(X) (106)	
vMC164	m160	C			6.5	Putative membrane glycoprotein		
vMC167	m163	C			6.5	Putative membrane glycoprotein		VAP
vMC168	m164	C	gp36.5		6.5	Putative membrane glycoprotein	MCMV viral carrier protein gp36.5 (64); m164-derived peptide 257-AGPPRYSR I-265 is presented by the MHC-I molecule D(d) (45)	
vMC170	m166	C			6.5	Putative membrane glycoprotein	Required for MCMV virulence in killing SCID mice and for optimal viral growth *in vivo* (121)	
vMC173	m169	C			6.5			
vIE3rem	M122 Ex5	C	ie3	UL122 (IE2)	24	Immediate early	ie3 exon 5, with mRNA terminating at base 177817 (76); total length of Ex2 plus Ex3 plus Ex5 is 611 aa, molecular size is 68.1 kDa	
vMC011	m11				24	Glycoprotein m02		
vMC013	m13				24	Glycoprotein m02		
vMC015	m15				24	Glycoprotein m02		
vMC020	m20	C			24		Reported irregularities in coding potential have suggested possible sequence errors in the 3′-proximal end (49)	
vMC023	M23	C		UL23 (GF2) P	24		US22 family homolog	
vMC026	M25			UL25 (GF1)	24	Tegument	UL25 family homologue (26, 32); encodes a component of the MCMV tegument (116)	VAP
vMC028	M26	C		UL26	24			
vMC029	M27	C		UL27	24		Plays important role in MCMV growth and virulence (2) and inhibits IFN-γ signaling (56) via selective binding and downregulation of Stat2 (123)	
vMC032	m29.1	C			24			
vMC033	m30				24			
vMC034	M31			UL31	24		Reported irregularities in coding potential have suggested possible sequence errors in the 3′-proximal end (49)	
vMC035	M32	C		UL32 (pp150)	24	Phosphoprotein (tegument)	Encodes large phosphoprotein homologous to HCMV tegument protein UL32 (pp150) (47, 48)	VAP
vMC038	M35			UL35 (GF1)	24	Virion associated	Virulence factor and HCMV UL25 family homologue (26, 32); M35 insertional mutant is defective in growth *in vivo* (103)	VAP
vMC039	M36 Ex1			UL36 exon 1	24		US22 family homolog	
vMC042	M38	C		UL38	24			
vMC050	m45.1	C			24			
vMC053	M48			UL48 (Teg)	24	Tegument	Large tegument protein (101)	VAP
vMC056	M49	C		UL49	24			
vMC057	M50	C		UL50	24	Nuclear export	Conserved herpesvirus protein that forms a complex essential for egress of nucleocapsids from the nucleus (94); M50/p35 inserts into the inner nuclear membrane and is aggregated by M53/p38 to form the capsid docking site (82)	
vMC059	M52			UL52	24			
vMC060	M53			UL53	24	Nuclear export	Conserved herpesvirus protein that forms a complex essential for egress of nucleocapsids from the nucleus (94); M50/p35 recruits cellular PKC for phosphorylation and dissolution of the nuclear lamina (82)	
vMC062	M55	C	gB	UL55 (gB)	24	Glycoprotein	Glycoprotein B (29, 87)	VAP
vMC063	M56	C		UL56 (NM)	24	Tegument	Tegument protein and homologue of HCMV terminase subunit and HSV ICP18.5 (13, 38)	VAP

Continued on following page

TABLE 1—*Continued*

Unique probe ID[b]	ORF	Strand	MCMV name	HCMV name	Time on[c] (hpi)	Protein type	Annotation[d] (reference[s])	Virion association[e]
vMC067	M69	C		UL69	24	Tegument	Tegument protein similar to HCMV transactivator UL69 (113), which in HCMV induces a G_1 block (42)	VAP
vMC071	M72	C		UL72 (dUTPase)	24	Putative dUTPase	Homology to HCMV UL72, a putative dUTPase enzyme required for nucleotide metabolism, replication, and/or repair (86)	VAP
vMC072	M73			UL73	24			
vMC077	M78			UL78	24	G protein-coupled receptor	G protein-coupled receptor homologue, same family as M33 (38); has subcellular trafficking properties (96); M78 mutants exhibit reduced replication in cultured cells as well as severe attenuation in the infected host (83)	
vMC078	M79	C		UL79	24			
vMC081	M83	C		UL83 (pp65)	24	Virion associated	Homologue of HCMV virion-associated factor with IFN repressor function (pp65) (1, 16, 74); M83 mutant has attenuated viral growth and virulence in SCID mice (119)	VAP
vMC083	M85	C		UL85	24	Capsid	Homologue of HCMV minor capsid protein (9)	VAP
vMC084	M86	C		UL86 (MCP)	24	Capsid	Homologue of HCMV major capsid protein (25)	VAP
vMC086	M88			UL88	24	Virion associated	Homologue of HCMV virion protein (9)	VAP
vMC091	M93			UL93	24			
vMC093	M89 Ex1	C		UL89	24			
vMC094	M95			UL95	24			
vMC095	M96			UL96	24			
vMC096	M97			UL97 (PK)	24	Phosphotransferase	Homologue of HCMV UL97 phosphotransferase gene, whose product phosphorylates ganciclovir in HCMV-infected cells (67, 102)	VAP
vMC097	M98			UL98 (DNase)	24	Exonuclease	Alkaline exonuclease (DNase) gene (89)	VAP
vMC099	M100	C	gM	UL100 (gM)	24	Glycoprotein	Glycoprotein M with seven hydrophobic stretches that are potential membrane-spanning regions (66, 93)	VAP
vMC101	M103	C		UL103	24			
vMC104	m106	C			24			
vMC105	m107				24			
vMC106	m108	C			24			
vMC107	M112 Ex1		e1	UL112	24	Early	Exon 1 of e1 (22); total e1 length is 330 aa, molecular size is 36.4 kDa; IE3 and the early M112/113 gene products colocalize and coimmunoprecipitate (104); neuron-specific activation of the e1 promoter observed in transgenic mice (7)	
vMC109	M114	C		UL114 (UNG)	24	Glycosylase	Uracil DNA glycosylase enzyme homolog (114) found in herpesviruses, required for nucleotide metabolism, replication, and/or repair	
vMC110	M115	C	gL	UL115 (gL)	24	Glycoprotein	M115 (gL) (52) contains five potential glycosylation sites, has significant amino acid similarity to gL homologs in HCMV and HHV-6, and has previously been shown to be glycosylated in virions (118)	
vMC115	m119				24			
vMC116	m119.1				24	Potential glycoprotein		
vMC119	m119.4				24		Predicted MCMV homologue of HCMV spliced ORF (89)	
vMC120	m119.5				24			
vMC121	m120	C			24			
vMC123	M122 Ex5	C	ie3	UL122 (IE2)	24	Immediate early	ie3 exon 5, with mRNA terminating at base 177817 (76); total length of Ex2 plus Ex3 plus Ex5 is 611 aa, molecular size is 68.1 kDa	
vMC127	m124				24		ORFs m124, m124.1, and m125 located within the enhancer region are nonessential for MCMV growth *in vitro* (6)	
vMC137	m132 Ex1	C	sgg1		24		Exon 2 of M133 (sgg1) (61, 73)	
vMC143	m139	C		US22 (GF2)	24		US22 family homolog	
vMC149	m145				24	Glycoprotein	Downmodulates expression of cellular MULT-1 (60) and is a member of MGP family m145	
vMC152	m148				24			
vMC159	m155				24	Glycoprotein	Member of MGP family m145 that modulates NK cell (inhibition) and T cell response and impedes an NKG2D ligand (H60) (41, 79)	
vMC163	m159	C			24	Putative membrane glycoprotein		
vMC165	m161	C			24	Putative glycoprotein	Putative membrane glycoprotein	
vMC172	m168				24			
vMC174	m170	C			24			
vMC005	m05				48	Glycoprotein m02		
vMC012	m12				48	Glycoprotein m02		
vMC014	m14				48	Glycoprotein m02		

vMC043	m39	C		48		
vMC066	m59			48	Potential ORF located within the origin of replication (89)	
vMC073	m74	C	UL74 P	48	Putative glycoprotein	Functional homolog of HCMV gO, has key role in determining the entry pathway of MCMV (95)	VAP
vMC108	M113		UL113 P	48		Potential alternative splice to M112 Ex1 (e1) (22), as found for HCMV UL112/UL113 (115)	
vMC118	m119.3			48		Predicted MCMV homologue of HCMV spliced ORF	
vMC133	m129	C		48		m131/129 is a chemokine homolog and determinant of viral pathogenicity (35) and may modulate cytokine signaling (79)	

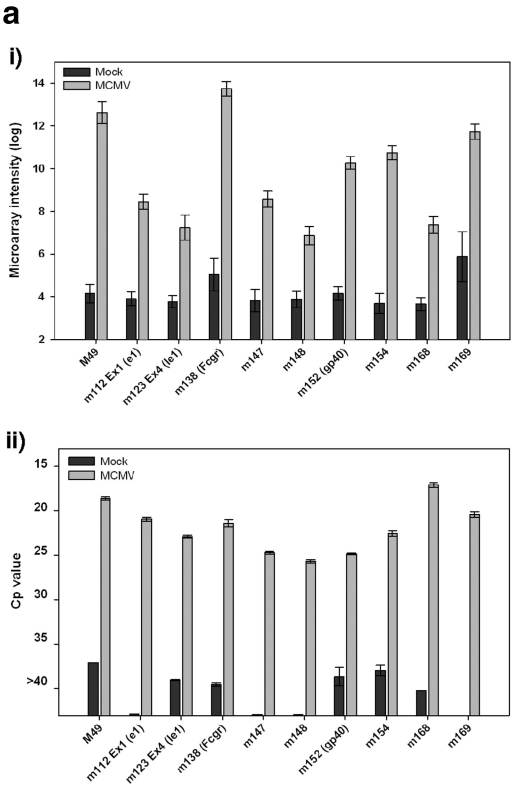
[a] Microarray probes for coding MCMV ORFs found to be significantly upregulated in MCMV-infected cells versus mock-infected cells to a high confidence level ($P \leq 0.05$ by empirical Bayes analysis).
[b] Probe ID, probe identifier.
[c] Time on, time detected.
[d] aa, amino acids; vICA, viral inhibitor of caspase-8 activation; vMIA, viral mitochondrial inhibitor of apoptosis; ER, endoplasmic reticulum; RIP1, receptor-interacting protein kinase 1; ssDNA, single-stranded DNA; PKR, protein kinase R; APCs, antigen-presenting cells; MGP, membrane glycoprotein; CTL, cytotoxic T lymphocyte; IFN-γ, gamma interferon; HHV-6, human herpesvirus 6.
[e] Virion-associated proteins (VAPs), based on reference 49.

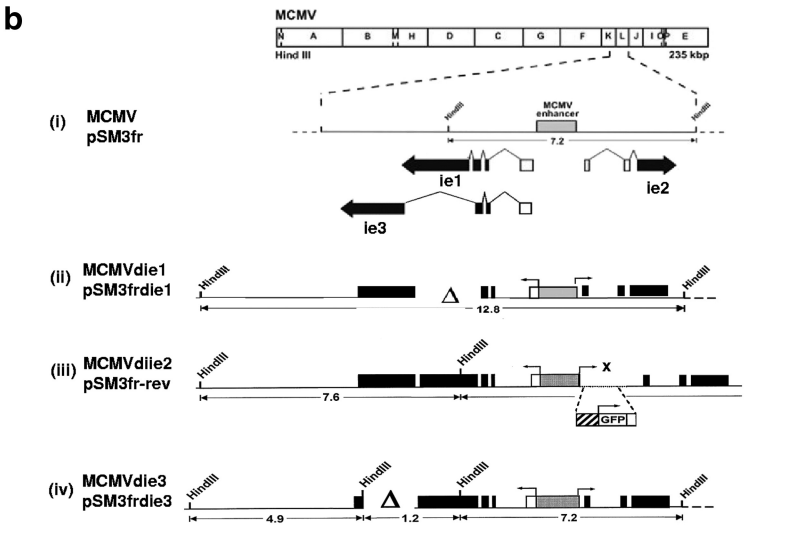
was performed based on a subset of 44 positive-control probes highly correlated across the data set (Pearson r of >0.90). Normalized expression data (see Table S3 in the supplemental material) were subjected to a statistically rigorous threshold detection methodology for providing on/off calls for each probe based on a receiver operating characteristic (ROC) (12). From these ROC analyses, we evaluated specificity levels corresponding to given sensitivities of 70%, 80%, and 90%. At a moderate sensitivity of 70%, we were able to obtain an average specificity of 93%, and this was chosen as affording an optimal balance between identifying true positives and excluding true negatives with stringency (for ROC plots, see Fig. S1 and S2 in the supplemental material). Accordingly, we detected 297 total probes having "on" calls and 163 probes for coding MCMV ORFs, making 87.6% of the MCMV genome detectable at 48 hpi (for a list of genes detected, see Table S4 in the supplemental material).

To account for experimental variation, statistical testing (empirical Bayes moderated t test) was applied between mock-infected and infected groups to identify differential expression of only the most highly significant MCMV ORFs. By use of this more stringent approach, 119 ORFs were found to be significantly activated to a confidence level of $P \leq 0.05$ above mock-infected levels at all time points (Table 1). These included the DNA polymerase subunit M54 (59), known inhibitors of major histocompatibility complex class I (MHC-I) surface expression m04 (gp34) (51) and m06 (gp48) (90), and the Fc receptor m138 (108). After a single round of replication at 24 hpi, a total of 111 MCMV ORFs were detected at the high significance level. To further validate these findings, a subset of MCMV ORFs were subjected to quantitative reverse transcription-PCR (qRT-PCR) analysis (for primer sequences, see File S1 in the supplemental material), and in agreement with the microarray results, each test case showed that ORF expression was also detectable by qRT-PCR (Fig. 1a).

As previously noted for HCMV microarray analysis, there is no overt positional bias toward expression of coding ORFs based on genomic location that could be linked to the patterns of gene expression observed during infection. MCMV ORFs were annotated based on Rawlinson et al. (89) and updated with details from additional publications wherever possible. MCMV ORFs from recent predictions (15, 105) were aligned against 55-mer probe sequences, identifying five probes overlapping with newly predicted ORFs (m107-m107.2, m16-m16.2, m22-m22.1, M34-m34.2, and M58-m58.1), which were reannotated accordingly.

As a result of the statistical cutoff ($P \leq 0.05$), MCMV probes for ORFs M44, M70, M75, m135, m143, m144, m153, and m157 failed to be included, although these genes have been reported to be expressed in previous MCMV studies or are homologues of HCMV genes reported to be expressed (21, 29, 34, 79, 80, 89, 92, 110, 118). It is most likely that the specific probes for these genes exhibit false-negative results. Nevertheless, in this study, we aimed to purposefully avoid false positives at the sacrifice of capturing a modest level of false negatives. For this reason, we also did not detect *ie1* or *ie3* expression until 24 hpi based on the statistical cutoff; however, these genes are detectable as early as 0.5 hpi and 2.5 hpi by use of a more sensitive qRT-PCR approach (see Fig. S3 in the supplemental material).





c

	Titre (PFU/ml)	Genomes per ml in viral stocks	Genomes per PFU in viral stocks
MCMV	6.8×10^6	$2.2 \pm 0.3 \times 10^7$	166.2 ± 3.4
MCMVdie1	3.0×10^6	$1.7 \pm 0.8 \times 10^7$	283.3 ± 137.9
MCMVdiie2	1.3×10^7	$4.4 \pm 0.8 \times 10^7$	146.7 ± 18.8
MCMVdie3	1.1×10^7	$4.0 \pm 0.2 \times 10^7$	183.2 ± 2.4

FIG. 1. MCMV ORF detection and characterization of MCMV IE deletion mutant strains. (a) (Panel i) Microarray signals for 10 MCMV ORFs in mock- and MCMV-infected cells. (Panel ii) qRT-PCR validation of the 10 MCMV ORFs at 24 hpi. The *y* axis represents crossing point (Cp) values from qPCR amplification curves, with low Cp values indicating high transcript abundance. Error bars represent standard errors of the mean. (b) Schematic representations of recombinant MCMV IE deletion mutants. The map of the parental MCMV genome is shown at the top, with structures of the *ie1*, *ie2*, and *ie3* transcripts below. Coding exons are shown in black, with arrows indicating the directions of transcription, and white triangles represent deleted loci. The gray box marks the MCMV *ie1*/*ie3* promoter enhancer (MIEP). (Line iii) The MCMVdie3 revertant strain was renamed MCMVdiie2 in this study, as the HCMV MIEP is inserted between two HpaI sites spanning the transcription start site of the *ie2* gene, disrupting *ie2* expression (marked with ×). GFP, green fluorescent protein. (c) Viral titers and genome particle/PFU equivalences of the four MCMV strains, as determined by qPCR.

To gain further insight into the transcriptional programming of MCMV, we next sought to profile gene expression from three well-characterized MCMV mutants (5, 23, 36, 72) alongside the parental MCMV strain (111) (for schematics of strains, see Fig. 1b). To characterize the mutant strains before microarray analysis, we sought to (i) determine equivalent infectious doses at the genomic level by measuring genome/PFU ratio for each stock, (ii) ensure that generating the *ie3* deletion mutant (MCMVdie3) in a complementing cell line did not drastically alter the infectious-particle ratio, (iii) ensure that viral growth phenotypes were consistent with those previously published (5, 36, 72), and (iv) ensure that no viral transcription was occurring from deleted loci. On the basis of quantitative PCR (qPCR), we detected equivalent numbers of MCMV genome copies per PFU for each viral strain (Fig. 1c), using as a calibrator a reference plasmid containing the m115 (gL) gene (nucleotides [nt] 166387 to 167208; GenBank accession no. NC_004065) (for a detailed account of this approach, see reference 98). Equivalent numbers of MCMV genomes were also found at 2 hpi inside cells infected with different MCMV strains (data not shown). Multistep growth curves confirmed viral growth phenotypes (see Fig. S4 in the supplemental material), and qRT-PCR (Qiagen 1-step kit; Germany) confirmed that transcription was not detectable from the respective deleted loci for *ie1*, *ie2*, and *ie3* (data not shown). These data show that the four MCMV strains are experimentally comparable for downstream gene expression analysis.

Based on previous virologic characterization of these MCMV immediate-early (IE) mutants, we expected to observe different gene expression profiles for the MCMV strains. For example, given that removal of the *ie2* gene causes no reported change in phenotype (45), we anticipated few gene expression changes in the MCMVdiie2 strain relative to the parental MCMV strain. Alternatively, given that *ie3* has an indispensable regulatory function and is essential for viral growth (5), we expected little or no viral gene expression to be detectable from the MCMVdie3 strain. However, for the *ie1* deletion mutant (MCMVdie1), the expectation was less clear, given that this strain has wild-type growth characteristics and yet the IE1 protein is well known to have transcriptional regulatory activity (24, 39, 76) and is further known to interact with cellular host factors (81, 104). In order to profile the gene expression of each mutant strain, we infected NIH 3T3 fibroblasts in parallel at an MOI of 1 and harvested total RNA for microarray anal-

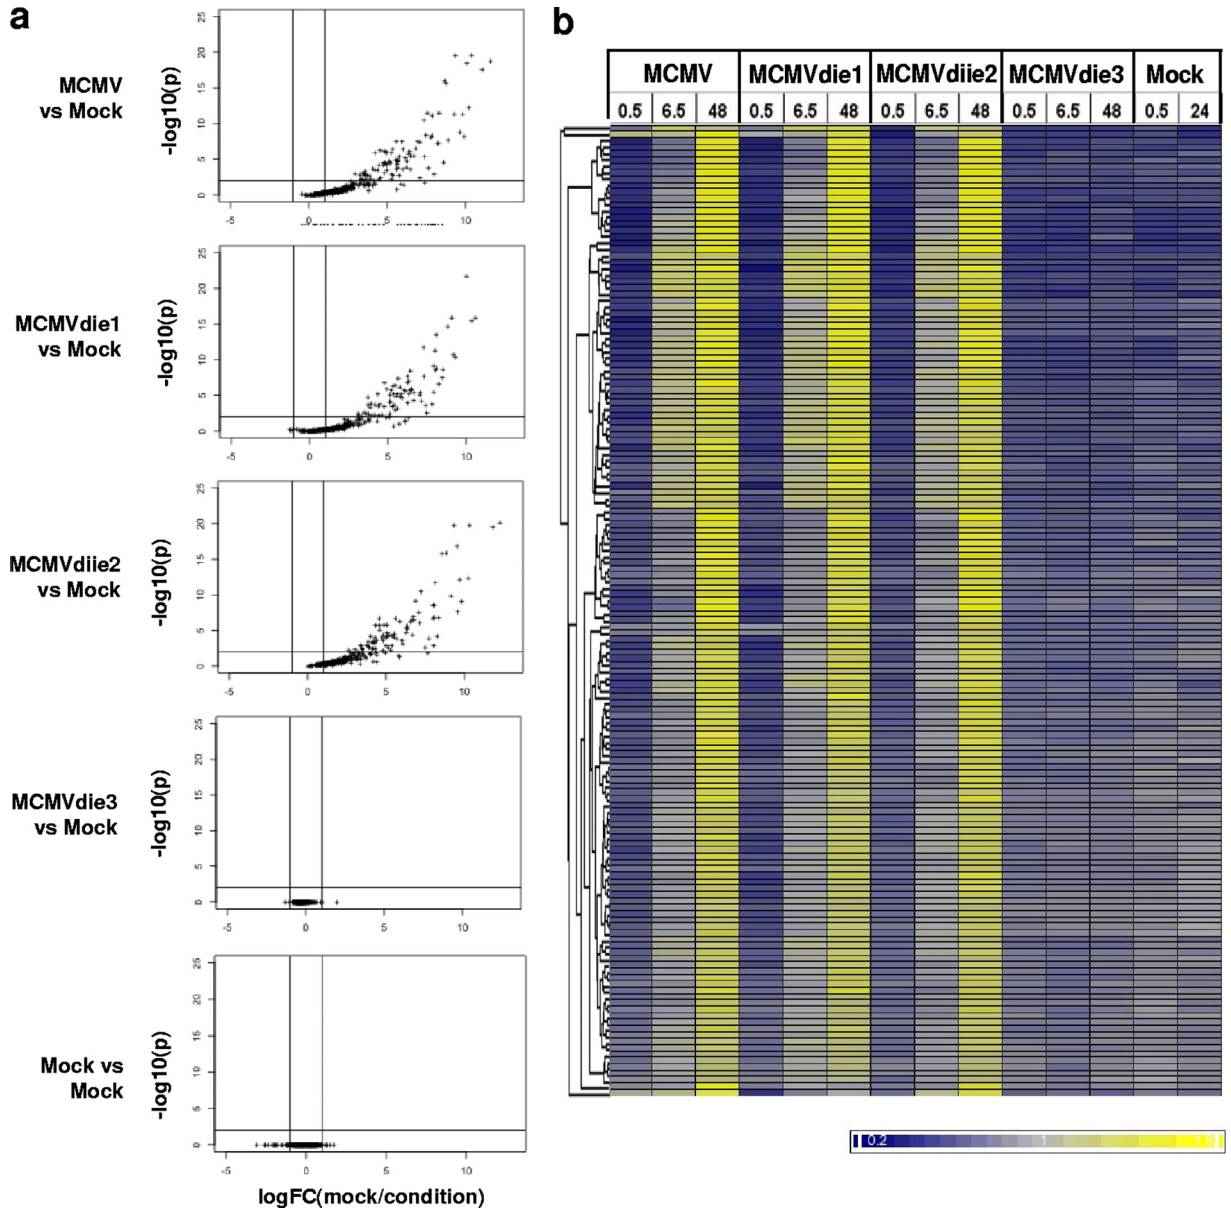


FIG. 2. Gene expression program of MCMV, MCMVdie1, MCMVdiie2, and MCMVdie3. (a) Volcano plots comparing microarray signals from mock-infected and infected samples at 48 hpi, using *P* value (*y* axis) and fold change (FC) (*x* axis) comparisons derived from empirical Bayes testing, with two biological replicates per group. (b) Hierarchical clustering of high-confidence MCMV probes, with each row representing a single probe normalized to its mean value across the data set to show relative expression. Yellow indicates increased expression and blue indicates decreased expression relative to the mean. Genes clustered based on the similarity of their expression profiles across the data set, with similar genes connected at the hierarchical tree on the left. Data represent mean values from two biological replicates. Numerical values at top indicate hours postinfection.

ysis at 0.5, 6.5, and 48 hpi, along with that of mock-infected cells.

Figure 2 shows the comparative activation of viral transcriptomes among the four MCMV strains at 48 hpi and indicates that the transcriptomes of MCMVdie1 and MCMVdiie2 are activated with profiles of viral gene expression very similar to that of the parental MCMV strain over the 48-h period (Fig. 2a). Similar numbers (within 10%) of MCMV probes were detectable from MCMVdie1 (103 ORFs), MCMVdiie2 (114 ORFs), and the parental strain (113 ORFs) at 48 hpi. The degree of similarity in expression profiles among the MCMVdie1, MCMVdiie2, and parental MCMV strains suggests that *ie1* and *ie2* have a redundant or negligible transcriptional regulatory role in controlling downstream MCMV gene expression during fibroblast infection. Hierarchical clustering (Fig. 2b) further indicates few, if any, differences in the global gene expression profiles of MCMVdie1 and MCMVdiie2 compared to that of the parental MCMV strain. These results could point to a redundant role for the *ie1* and *ie2* genes in controlling downstream viral gene expression or, alternatively, a lack of

TABLE 2. High-confidence MCMV microarray antisense probes[a]

Unique probe ID[b]	ORF	Time on[c] (hpi)	Details of cDNA cloning validation	Sense probe[d]

[a] Microarray probes for antisense transcripts found to be significantly upregulated in MCMV-infected cells versus mock-infected cells to a high confidence level ($P \leq 0.05$ by empirical Bayes analysis).
[b] Probe ID, probe identifier.
[c] Time on, time detected.
[d] AS probes with significant signal also found from the corresponding sense probes are marked with an "S."

sensitivity in controlling the viral genomic program in fully permissive fibroblasts.

In marked contrast to the *ie1* and *ie2* mutant strains, MCMVdie3 exhibited an undetectable level of viral gene expression, suggesting that *ie3* acts as a global *trans*-activator of downstream MCMV gene expression, as indicated by previous studies (5). To further examine the transcriptional status of MCMVdie3 using a more sensitive approach, IE and downstream MCMV genes were measured using qRT-PCR in MCMVdie3-infected cells both in the presence and in the absence of 50 μg/ml cycloheximide (C7698; Sigma, United Kingdom) at 2.5 hpi. These experiments confirmed that IE kinetic class genes were expressed in MCMVdie3 but that genes beyond the IE region were not (see Fig. S5 in the supplemental material).

The design of the MCMV microarray platform enables selective detection of transcripts originating from both strands of the viral genome by having probes designed in sense (S) and antisense (AS) orientations to each MCMV ORF. At 24 hpi, we detected antisense transcripts from 23 AS loci, five of which (m104as, M113as, m147as, m163as, and m168as) have overlapping ORFs on the opposite strand of the genome, indicating known or predicted regions of bidirectional transcription based on prior annotation (105). Three other loci were found to have neighboring but nonoverlapping ORFs in their vicinity (M57as, m74as, and M88as). An additional 15 MCMV AS probes detected at 24 hpi were found to have no overlapping or nearby ORFs located on the opposite strand, indicating previously unknown noncoding transcripts derived from regions outside MCMV ORFs (m04as, m05as, m06as, m07as, m09as, m13as, m41as, M47as, M50as, M87as, M102as, M115as, m119.2as, m124as, and m145as). At 48 hpi, an additional eight antisense probes were detectable, but all have overlapping or nearby ORFs on the opposite strand of the genome (M48as, m69.1as, M89as, M94as, m108as, m119.3as, m132as, and m144as). In total, evidence of antisense transcription was detected from 35 loci over the four time points as measured by microarray analysis (Table 2 and Fig. 3). Twenty-six of these loci were also

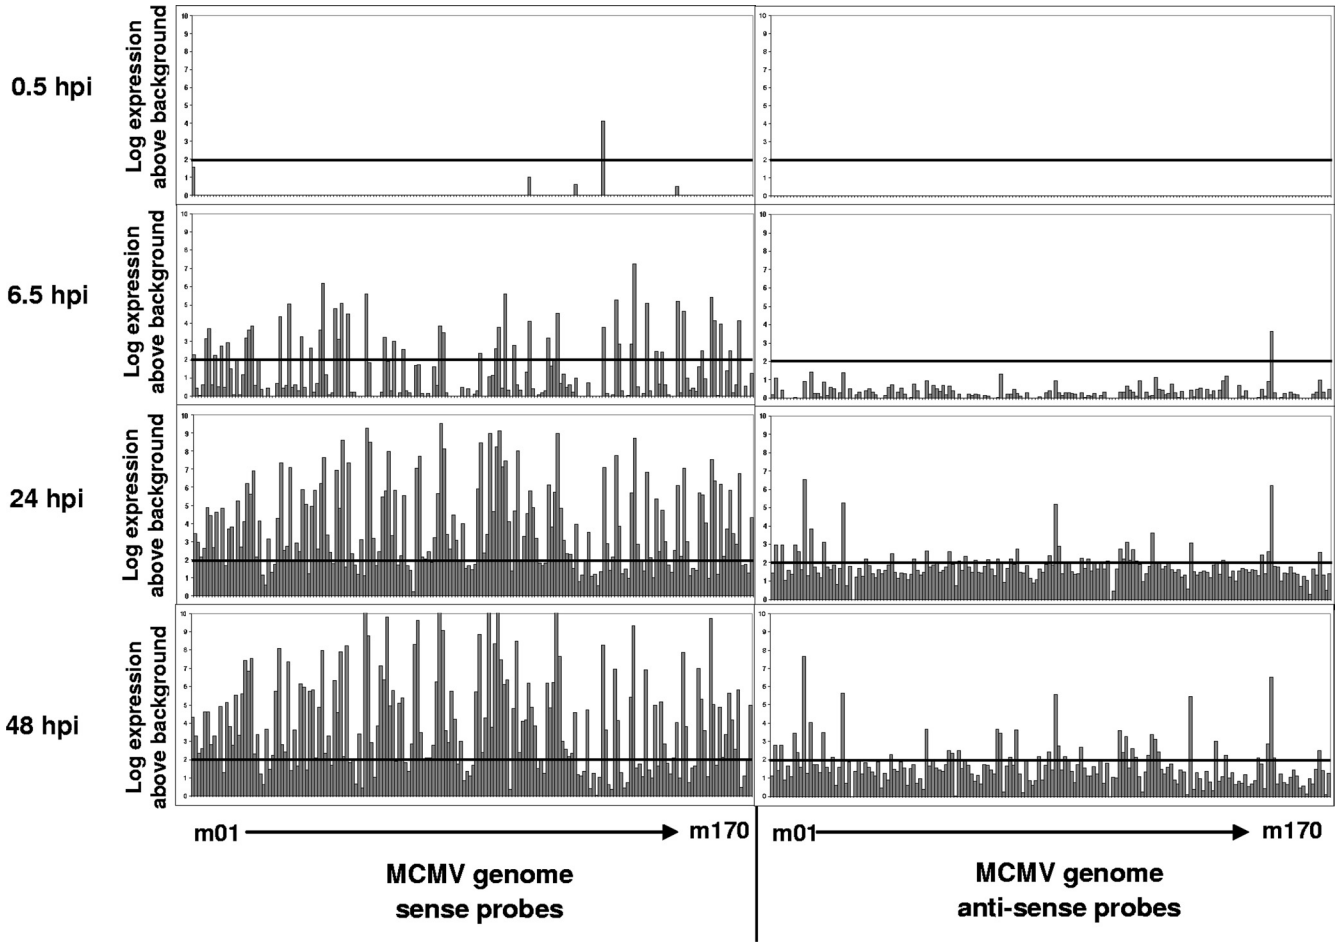

FIG. 3. MCMV genome activation measured by microarray analysis and qRT-PCR. Transcript abundance of ORFs expressed from the parental MCMV strain was measured using oligonucleotide microarrays at 0.5, 6.5, 24, and 48 hpi in NIH 3T3 cells at an MOI of 1. Histograms represent mean values from two replicate samples after background (mock infection) subtraction. Transcripts are arranged in order from left to right according to ORF names ranging from m01 to m170, with sense probes shown on the left and antisense probes on the right. All raw data are available in the supplemental material.

found to have significant signal from the corresponding sense (S) probe, indicating a potential site of bidirectional transcription. A trend toward antisense transcription occurring more frequently at the terminal ends of the MCMV genome is also noted (Fig. 3).

In order to independently validate AS transcripts identified by microarray analysis, we generated cDNA libraries from MCMV-infected fibroblasts pooled from 4, 8, and 12 hpi (IE library), 16, 24, and 32 hpi (E library), or 40, 60, 80, and 100 hpi (L library). cDNA libraries were generated as described previously for HCMV (120). cDNA clones overlapping AS microarray regions were found at m04as, m74as, M94as (none of which have overlapping ORFs on the opposite strand of the genome), and m148as (which has the m147 ORF on the opposite strand of the genome) (for validated AS transcripts, see Table 2). We also found one large cDNA clone that overlapped three MCMV ORFs (m119.2, m119.3, and m119.4), two of which had potential AS regions identified by microarray probes (m119.2 and m119.3). Four additional AS cDNA clones were found to overlap AS regions not identified by microarray analysis (m19as, M72as, m149as, and m151as). These experiments thus reveal for the first time that antisense transcription occurs frequently throughout the MCMV genome, an observation that will likely seed further studies.

This work was supported by Wellcome Trust Programme grant no. WT 066784/Z/02/Z (to P.G.), Unity through Knowledge Fund grant no. UKF 08/07 (to J.T.), and Ministerio de Educación y Ciencia grant no. SAF 2008 00382 (to A.A.). qPCR data were obtained in the Kinetic Parameter Facility of The Centre for Systems Biology at Edinburgh, which is a Centre for Integrative Systems Biology (CISB) funded by BBSRC and EPSRC BB/D019621/1 (P.G.).

We kindly thank Ulrich Koszinowski for his comments and input on the manuscript. We also thank Daniel Foster and Fátima García del Rey for their technical input, Stipan Jonjic for his support in generating cDNA libraries, and Chitrangada Das Mukhopdhyay for bioinformatics analysis of MCMV cDNA clones.
