# Conflict-Preserving Abstraction of Discrete Event Systems Using Annotated Automata 

Simon Ware . Robi Malik

the date of receipt and acceptance should be inserted later

#### Abstract

This paper proposes to enhance compositional verification of the nonblocking property of discrete event systems by introducing annotated automata. Annotations store nondeterministic branching information, which would otherwise be stored in extra states and transitions. This succinct representation makes it easier to simplify automata and enables new efficient means of abstraction, reducing the size of automata to be composed and thus the size of the synchronous product state space encountered in verification. The abstractions proposed are of polynomial complexity, and they have been successfully applied for nonblocking verification of the same set of large-scale industrial examples as used in related work.

## 1 Introduction

With the continuously increasing size and complexity of reactive systems software, the automatic verification of large reactive systems is and remains a challenging problem. This paper focuses on the verification of the nonblocking property, which is of great interest in supervisory control of discrete event systems [2,17]. Nonblocking is the question whether the composed behaviour of a set of automata is under all circumstances capable of reaching a terminal state.

The standard method to check whether a system is nonblocking involves the explicit composition of all the automata involved and the construction of the complete state space. This approach is limited by the well-known state-space explosion problem. Symbolic model checking has been used successfully to reduce the amount of memory required by representing the state space symbolically rather than enumerating it explicitly [3].

As an alternative, compositional verification tries to avoid constructing large state spaces by progressively composing automata and using abstraction to simplify intermediate results. This idea has been pursued with notable success in recent years. Automata can be simplified for nonblocking verification using observer projection $[6,16]$ or weak observation equivalence [19]. These well-known general-purpose abstractions are more restrictive than necessary for nonblocking verification. A possible alternative is to consider trajectory

[^0]nonblocking [11], while conflict equivalence is known to be the most general method of abstraction that preserves the nonblocking property in all contexts [12]. Conflict equivalence can be used to implement heuristic simplification rules, making it possible to verify discrete event systems models of industrial complexity [9].

This paper seeks to combine the advantages of bisimulation-based abstractions [19] with the benefits of conflict-preserving simplification [9]. Using annotations, certain aspects of the branching structure of nondeterministic automata can be unified. This makes it possible to overcome some limitations of the previous approach based on heuristics, and makes more aspects of conflict-preserving abstraction amenable to global reduction algorithms such as bisimulation.

This paper is an extended version of [20], including more detailed descriptions of annotated automata and full proofs of all results. Section 2 briefly introduces the needed terminology of languages, automata, and conflict equivalence. Then Section 3 presents annotated automata and the rules to construct and simplify them, which are explained using an example. Section 4 contains formal proofs of the correctness of the abstraction rules. Afterwards, Section 5 presents experimental results, and Section 6 adds some concluding remarks.

## 2 Preliminaries

### 2.1 Events and Traces

Event sequences and languages are a simple means to describe discrete system behaviours. Their basic building blocks are events, which are taken from a finite alphabet $\Sigma$. Two special events are used, the silent event $\tau$ and the termination event $\omega$. These are never included in an alphabet $\Sigma$ unless mentioned explicitly. For this, $\Sigma_{\tau}=\Sigma \cup\{\tau\}, \Sigma_{\omega}=\Sigma \cup\{\omega\}$, and $\Sigma_{\tau, \omega}=\Sigma \cup\{\tau, \omega\}$ are used.
$\Sigma^{*}$ denotes the set of all finite traces of the form $\sigma_{1} \sigma_{2} \cdots \sigma_{n}$ of events from $\Sigma$, including the empty trace $\varepsilon$. The concatenation of two traces $s, t \in \Sigma^{*}$ is written as $s t$. A subset $L \subseteq \Sigma^{*}$ is called a language. Given two alphabets $\Sigma_{1}$ and $\Sigma_{2} \subseteq \Sigma_{1}$, the natural projection $P: \Sigma_{1}^{*} \rightarrow \Sigma_{2}^{*}$ is the operation that deletes from traces over $\Sigma_{1}$ all events not in $\Sigma_{2}$.

### 2.2 Nondeterministic Automata

System behaviours are modelled using finite-state automata. Typically, system models are deterministic, but abstraction may result in nondeterminism.

Definition 1 A (nondeterministic) finite-state automaton is a 4-tuple $G=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}\right\rangle$ where $\Sigma$ is a finite alphabet of events, $Q$ is a finite set of states, $\rightarrow \subseteq Q \times \Sigma_{\tau, \omega} \times Q$ is the state transition relation, and $Q^{\circ} \subseteq Q$ is the set of initial states.

The transition relation is written in infix notation $x \xrightarrow{\sigma} y$, and is extended to traces in $\Sigma_{\tau, \omega}^{*}$ by letting $x \xrightarrow{\varepsilon} x$ for all $x \in Q$, and $x \xrightarrow{s \sigma} y$ if $x \xrightarrow{s} z \xrightarrow{\sigma} y$ for some $z \in Q$. For state sets $X, Y \subseteq Q$, the expression $X \xrightarrow{s} Y$ denotes the existence of $x \in X$ and $y \in Y$ such that $x \xrightarrow{s} y$. Furthermore, $x \rightarrow y$ denotes the existence of a trace $s \in \Sigma_{\omega}^{*}$ such that $x \xrightarrow{s} y$, and $x \xrightarrow{s}$ denotes the existence of a state $y \in Q$ such that $x \xrightarrow{s} y$. Finally, $G \xrightarrow{s}$ and $G \xrightarrow{s} X$ stand for $Q^{\circ} \xrightarrow{s}$ and $Q^{\circ} \xrightarrow{s} X$, respectively.

The transition relation must satisfy the additional requirement that, whenever $x \xrightarrow{\omega} y$, there does not exist any outgoing transition from $y$. That is, the termination event $\omega$ marks states (such as $x$ ) as terminal states. The traditional set of marked or terminal states of $G$ can be defined as $Q^{\omega}=\{x \in Q \mid x \xrightarrow{\omega}\}$. For the sake of graphical simplicity, states in $Q^{\omega}$ are shaded in the figures of this paper instead of explicitly showing $\omega$ transitions.

To support silent transitions, $x \stackrel{s}{\Rightarrow} y$, with $s \in \Sigma_{\omega}^{*}$, denotes the existence of a trace $t \in \Sigma_{\tau, \omega}^{*}$ such that $x \xrightarrow{t} y$ and $P(t)=s$. That is, $\xrightarrow{s}$ denotes a path with exactly the events in $s$, while $\stackrel{s}{\Rightarrow}$ denotes a path with an arbitrary number of $\tau$ shuffled with the events in $s$. Notations such as $X \stackrel{s}{\Rightarrow} Y$ for state sets, $x \Rightarrow y, G \stackrel{s}{\Rightarrow}$, etc., are defined analogously to $\rightarrow$. In addition, for a state $x \in Q$, the set of active or eligible events is $\operatorname{Elig}_{G}(x)=\left\{\sigma \in \Sigma_{\omega} \mid x \stackrel{\sigma}{\Rightarrow}\right\}$.

When two automata are running in parallel, lock-step synchronisation in the style of [10] is used.

Definition 2 Let $G_{1}=\left\langle\Sigma_{1}, Q_{1}, \rightarrow_{1}, Q_{1}^{\circ}\right\rangle$ and $G_{2}=\left\langle\Sigma_{2}, Q_{2}, \rightarrow_{2}, Q_{2}^{\circ}\right\rangle$ be two automata. The synchronous composition of $G_{1}$ and $G_{2}$ is

$$
\begin{equation*}
G_{1} \| G_{2}=\left\langle\Sigma_{1} \cup \Sigma_{2}, Q_{1} \times Q_{2}, \rightarrow, Q_{1}^{\circ} \times Q_{2}^{\circ}\right\rangle \tag{1}
\end{equation*}
$$

where

$$
\begin{aligned}
& (x, y) \xrightarrow[\rightarrow]{\sigma}\left(x^{\prime}, y^{\prime}\right) \text { if } \sigma \in\left(\Sigma_{1} \cap \Sigma_{2}\right) \cup\{\omega\}, x \xrightarrow[\rightarrow]{\sigma_{1}} x^{\prime}, y \xrightarrow{\sigma} 2 y^{\prime} ; \\
& (x, y) \xrightarrow[\rightarrow]{\boldsymbol{\sigma}}\left(x^{\prime}, y\right) \text { if } \sigma \in\left(\Sigma_{1} \backslash \Sigma_{2}\right) \cup\{\tau\}, x \xrightarrow[\rightarrow]{\sigma_{1}} x^{\prime} ; \\
& (x, y) \xrightarrow[\rightarrow]{\sigma}\left(x, y^{\prime}\right) \text { if } \sigma \in\left(\Sigma_{2} \backslash \Sigma_{1}\right) \cup\{\tau\}, y \xrightarrow[\rightarrow]{\boldsymbol{\sigma}_{2}} y^{\prime} .
\end{aligned}
$$

In synchronous composition, shared events (including $\omega$ ) must be executed by all automata synchronously, while other events (including $\tau$ ) are executed independently. In the notation of this paper,

$$
\begin{equation*}
G_{1} \| G_{2} \stackrel{s}{\Rightarrow}\left(x_{1}, x_{2}\right) \quad \text { if and only if } \quad G_{i} \xrightarrow{P_{i}(s)} x_{i} \quad \text { for } i=1,2, \tag{2}
\end{equation*}
$$

where $P_{i}: \Sigma \rightarrow \Sigma_{i}$ denotes the natural projection.

### 2.3 Conflict Equivalence

The key liveness property in supervisory control theory is the nonblocking property. An automaton is nonblocking if, from every reachable state, a terminal state can be reached; otherwise it is called blocking. When more than one automaton is involved, it also is common to use the terms nonconflicting and conflicting, respectively.

Definition 3 An automaton $G=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}\right\rangle$ is nonblocking if, for every state $x \in Q$ and every trace $s \in \Sigma^{*}$ such that $Q^{\circ} \stackrel{s}{\Rightarrow} x$, there exists a trace $t \in \Sigma^{*}$ such that $x \stackrel{t \Theta}{\Rightarrow}$. Two automata $G_{1}$ and $G_{2}$ are nonconflicting if $G_{1} \| G_{2}$ is nonblocking.

To reason about conflicts in a compositional way, a notion of conflict equivalence is developed in [12]. According to process-algebraic testing theory, two automata are considered as equivalent if they both respond in the same way to all tests of a certain type [4]. For conflict equivalence, a test is an arbitrary automaton, and the response is the observation whether the test composed with the automaton in question is nonblocking or not.

Definition 4 Two automata $G_{1}$ and $G_{2}$ are said to be conflict equivalent, written $G_{1} \simeq_{\text {conf }}$ $G_{2}$, if, for any automaton $T, G_{1} \| T$ is nonblocking if and only if $G_{2} \| T$ is nonblocking.

Conflict equivalence is the coarsest possible congruence with respect to synchronous composition that preserves nonblocking [12]. There are exponential algorithms to determine whether two given automata are conflict equivalent $[18,21]$. However, in general there is no unique minimal conflict equivalent representation of a given automaton [8].

When verifying whether a composed system of automata

$$
\begin{equation*}
G_{1}\left\|G_{2}\right\| \cdots \| G_{n} \tag{3}
\end{equation*}
$$

is nonblocking, the compositional method [9] avoids building the complete synchronous product immediately. Typically, some of the components $G_{i}$ have local events, i.e., events used only by $G_{i}$. These local events are abstracted using hiding, i.e., they are replaced by the silent event $\tau$. The resultant automaton can then be simplified in various ways, and $G_{i}$ is replaced by a typically smaller conflict equivalent automaton $G_{i}^{\prime}$. Once no further simplification is possible, a subsystem of automata $\left(G_{j}\right)_{j \in J}$ is selected and replaced by its synchronous composition, and the procedure starts over.

## 3 Annotated Automata

This section shows how annotations are used to bring automata in a more regular form to make simplification with respect to conflict equivalence more effective. Using the running example in Fig. 1, methods to construct an annotated automaton are described in 3.1 and 3.2, and three abstraction rules to simplify annotated automata are presented in 3.3-3.5. In 3.6, the complete abstraction procedure to simplify automata using annotations is presented. Proofs of the propositions stated in this section can be found in Section 4.

### 3.1 Annotation

The states in a nondeterministic automaton carry several implicit requirements characterising their blocking or nonblocking behaviour in composition with other automata. For illustration, consider state $q_{0}$ in automaton $G$ in Fig. 1. Its eligible event set is $\operatorname{Elig}_{G}\left(q_{0}\right)=$ $\{\alpha, \beta, \gamma\}$; note that $\beta$ is included because of the silent transition to $q_{4}$. Blocking will occur if state $q_{0}$ is composed with a state that does not enable at least one of the events $\alpha, \beta$, or $\gamma$. Moreover, due to the silent transitions to states $q_{3}$ and $q_{4}$, any state composed with $q_{0}$ also needs to enable at least one event from their sets of eligible events, $\operatorname{Elig}_{G}\left(q_{4}\right)=\{\alpha, \beta\}$ and $\operatorname{Elig}_{G}\left(q_{3}\right)=\{\alpha\}$. In order to capture these nonblocking requirements in a more concise manner, the three eligible event sets are associated with state $q_{0}$ as annotations.

Definition 5 An annotated automaton is a 5 -tuple $A=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}, A n n\right\rangle$ such that $\langle\Sigma, Q$, $\left.\rightarrow, Q^{\circ}\right\rangle$ is an ordinary automaton without $\tau$-transitions, and Ann $\subseteq Q \times 2^{\Sigma_{\omega}}$ is the annotation relation, which satisfies the following conditions:
(i) for every $x \in Q$, there exists $a \subseteq \Sigma_{\omega}$ such that $(x, a) \in A n n$;
(ii) for every $(x, a) \in A n n$, it holds that $a \subseteq \operatorname{Elig}_{A}(x)$.

An annotation is a set of events $a \subseteq \Sigma_{\omega}$ associated with a state $x \in Q$. The intended meaning of $(x, a) \in A n n$ is that, if the automaton is in state $x$, at least one of the events in $a$ must be enabled in the synchronous composition of the entire system in order to avert blocking. The empty set of events can also serve as an annotation, which is used to characterise

Fig. 1 Simplification of automaton $G$ using annotations gives $G \simeq_{\text {conf }} U^{\prime \prime}$.
deadlock states. Annotations are similar to ready sets [15] or the complements of failure sets [10], but they can only be used to partially characterise conflict equivalence.

The two requirements (i) and (ii) ensure that annotations capture the idea of nonblocking requirements correctly. Each state must have at least one annotation, and all annotations must be subsets of the eligible event set of their state. When annotating automata in practice, every state can be associated with its own eligible event set as an annotation, and this "maximal" annotation does not need to be stored explicitly in an annotated automaton as it can be inferred from the transitions.

The following definition shows how to transform an arbitrary nondeterministic automaton into an annotated automaton, replacing silent $(\tau)$ transitions by annotations to represent the associated nonblocking requirements.

Definition 6 Let $G=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}\right\rangle$ be an automaton. The annotated form of $G$ is

$$
\begin{equation*}
\mathscr{A}(G)=\left\langle\Sigma, Q, \rightarrow_{A}, Q^{\circ}, A n n\right\rangle, \tag{4}
\end{equation*}
$$

where

$$
\begin{align*}
\rightarrow_{A} & =\left\{(x, \sigma, y) \in Q \times \Sigma_{\omega} \times Q \mid x \stackrel{\varepsilon}{\Rightarrow} z \stackrel{\sigma}{\rightarrow} y \text { for some } z \in Q\right\} ;  \tag{5}\\
\text { Ann } & =\left\{\left(x, \operatorname{Elig}_{G}(y)\right) \mid x \stackrel{\varepsilon}{\Rightarrow} y\right\} . \tag{6}
\end{align*}
$$

The annotated form clearly satisfies the two conditions (i) and (ii) in Def. 5, because $\left(x, \operatorname{Elig}_{G}(x)\right) \in \operatorname{Ann}$ for every $x \in Q$, and $x \stackrel{\varepsilon}{\Rightarrow} y$ implies $\operatorname{Elig}_{G}(y) \subseteq \operatorname{Elig}_{G}(x)$.

The annotated form is obtained from the original automaton by replacing all silent transitions by the transitions originating from the silent successor states: if state $z$ can be reached silently from state $x$, then all transitions originating from $z$ are copied to $x$. Due to this removal of silent transitions, some states may become unreachable and then can be removed. To retain the nonblocking conditions associated with the originally silently reached states, their eligible event sets are added as annotations to the start states of the removed transitions.

Example 1 Fig. 1 shows an automaton $G$ and its annotated form $\mathscr{A}(G)$. As each state can be reached from itself after 0 silent transitions, it is associated with its own eligible event set as an annotation. The state $q_{0}$ collects all the outgoing transitions of $q_{3}$ and $q_{4}$, because it is connected to these two states by silent transitions, and annotations are added to $q_{0}$ for each of these two states. Similarly, $q_{1}$ has all the outgoing transitions and the annotation $\{\alpha\}$ of $q_{6}$. The states $q_{3}, q_{4}$, and $q_{6}$ have been deleted because they become unreachable after the removal of silent transitions.

Complexity The annotated form $\mathscr{A}(G)$ of $G=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}\right\rangle$ has $|Q|$ states, up to $|Q|^{2}\left|\Sigma_{\omega}\right|$ transitions, and up to $|Q|^{2}$ annotations. Thus, its size is bounded by $O\left(|Q|^{2}|\Sigma|\right)$. The time complexity to construct $\mathscr{A}(G)$ is dominated by the computation of the transitive closure of the silent transitions, i.e., $O\left(|Q|^{3}\right)$ [14].

Annotation removes information, and it may well happen that two different automata have equal annotated forms. The following proposition shows that this can only happen if the two original automata are conflict equivalent, so the annotation procedure does indeed yield a standardised form with respect to conflict equivalence.

Proposition 1 Let $G$ and $H$ be two automata such that $\mathscr{A}(G)=\mathscr{A}(H)$. Then $G \simeq_{\text {conf }} H$.
Conversely, it is not true that two conflict equivalent automata have the same annotated forms. Annotations cannot be used to characterise conflict equivalence. This is due to the fact that failures equivalence [10] does not imply conflict equivalence, and the same counterexample as given in [12] applies.

### 3.2 Unannotation

The annotation procedure can be reversed to obtain an ordinary automaton from a given annotated automaton. The reverse operation is called unannotation and is characterised by the following definition.

Definition 7 Let $A=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}\right.$, Ann $\rangle$ be an annotated automaton. An unannotated form of $A$ is any automaton $U=\left\langle\Sigma, Q_{U}, \rightarrow_{U}, Q^{\circ}\right\rangle$ such that the following properties hold.
(i) $Q_{U}=Q \cup A n n$;
(ii) $x \xrightarrow{\tau} U(x, a)$ for all $(x, a) \in A n n$, and these are the only $\tau$-transitions in $U$;
(iii) If $x, y \in Q$, then $x \stackrel{\sigma}{\rightarrow}_{U} y$ if and only if $x \xrightarrow{\sigma} y$.
(iv) If $(x, a) \in A n n$ and $\sigma \in a$, then $(x, a) \xrightarrow[\rightarrow]{\sigma}_{U}$;
(v) If $(x, a) \xrightarrow{\sigma} U y$, then $\sigma \in a$ and $x \xrightarrow{\sigma} y$.

The state space of an unannotated form consists of all the original states of the annotated automaton plus an additional so-called annotation state for each annotation (i), which is linked to its original state by a silent transition (ii). Furthermore, the unannotated form contains all the transitions of the annotated automaton (iii). In addition, the annotation states must have outgoing transitions for each event in their respective annotation (iv), and these transitions must lead to some successor state reached by the same event from the corresponding original state (v).

Given an annotated automaton $A$, an unannotated form can be constructed by including the states and transitions according to (i), (ii), and (iii), and by arbitrarily choosing for each annotation state $(x, a)$ and each event $\sigma \in a$ a transition $x \xrightarrow{\sigma} y$, and then including the transition $(x, a) \xrightarrow{\sigma} y$ in the unannotated form. There are several possibilities to choose transitions satisfying points (iv) and (v), but the ambiguity does not cause problems with conflict-preserving abstraction.

Proposition 2 Let $A$ be an annotated automaton, and let $U_{1}$ and $U_{2}$ be unannotated forms of $A$. Then $U_{1} \simeq_{\text {conf }} U_{2}$.

This result confirms that unannotated forms are well-defined up to conflict equivalence, so the ambiguity in Def. 7 does not affect the nonblocking property and can be exploited to minimise unannotated forms.

Example 2 In Fig. 1, automaton $U$ is an unannotated form of the annotated automaton $A^{\prime \prime}$. The three annotations in $A^{\prime \prime}$ have been replaced by annotation states $\left(q_{7},\{\omega\}\right)\left(q_{8},\{\alpha\}\right)$, and $\left(q_{0125},\{\alpha\}\right)$. Note that the transition $\left(q_{0125},\{\alpha\}\right) \xrightarrow{\alpha} q_{0125}$ is not included in $U$, although it could be inherited from $q_{0125}$.

Complexity Given $G=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}\right\rangle$, an unannotated form of $\mathscr{A}(G)$ has up to $|Q|+$ $|A n n| \leq|Q|+|Q|^{2}$ states and up to $|\rightarrow|+|A n n|+|A n n|\left|\Sigma_{\omega}\right| \leq|Q|^{2}\left|\Sigma_{\omega}\right|$ transitions. Its space complexity is $O\left(|Q|^{2}|\Sigma|\right)$, and this is also the time complexity to construct it from an annotated automaton. This worst-case is unusual in practice-in the experiments in Section 5, the number of states after unannotation is almost always less than it was before annotation.

The following result confirms that unannotation is a reverse operation of the annotation procedure, up to conflict equivalence. Conflict equivalence is preserved by annotation and subsequent unannotation.

Proposition 3 Let $G$ be an automaton, and let $U$ be an unannotated form of $\mathscr{A}(G)$. Then $U \simeq_{\text {conf }} G$.

In the following sections, different methods are presented to simplify annotated automata. The simplification needs to be carried out in a conflict-preserving way, and this requires an appropriate notion of conflict equivalence of annotated automata. The following definition is justified by Prop. 2 and 3, and by the fact that every annotated automaton has an unannotated form.

Definition 8 Two annotated automata $A_{1}$ and $A_{2}$ are conflict equivalent, written $A_{1} \simeq_{\text {conf }} A_{2}$, if for every unannotated form $U_{1}$ of $A_{1}$ and for every unannotated form $U_{2}$ of $A_{2}$ it holds that $U_{1} \simeq_{\text {conf }} U_{2}$.

### 3.3 Subsumption

Annotations are sets of events that must be enabled to avert blocking. More precisely, when a state is entered, at least one of the events in each of its annotations needs to be enabled in order to avert blocking. This leads to the observation that certain annotations are redundant. For example, if a state has both the annotations $\{\alpha\}$ and $\{\alpha, \beta\}$, then the latter is implied by the former. The state already requires event $\alpha$ to be enabled, so the fact that $\alpha$ or $\beta$ needs to be enabled adds no additional information. The annotation $\{\alpha, \beta\}$, being a superset of $\{\alpha\}$, is said to be covered or subsumed by $\{\alpha\}$, and subsumed annotations can be removed without affecting conflict equivalence.

This gives rise to the following subsumption rule: if an annotated automaton contains annotations $(x, a)$ and $(x, b)$ such that $a \varsubsetneqq b$, then the annotation $(x, b)$ can be removed. The removal of subsumed annotations from an annotated automaton preserves conditions (i) and (ii) in Def. 5, because no annotations are added and annotations can only be removed from states that have more than one annotation.

Example 3 In state $q_{0}$ of automaton $\mathscr{A}(G)$ in Fig. 1, the annotation $\{\alpha\}$ subsumes $\{\alpha, \beta\}$ and $\{\alpha, \beta, \gamma\}$, and the annotation $\{\alpha\}$ in state $q_{1}$ subsumes $\{\alpha, \beta, \gamma\}$. The subsumed annotations are struck out in the figure.

Proposition 4 Let $A=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}, A n n\right\rangle$ and $A_{\text {sub }}=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}, A n n_{\text {sub }}\right\rangle$ be two annotated automata such that $A n n_{\text {sub }} \subseteq A n n$ and for all $(x, a) \in A n n$ there exists $a_{\text {sub }} \subseteq a$ such that $\left(x, a_{\text {sub }}\right) \in A n n_{\text {sub }}$. Then $A \simeq_{\text {conf }} A_{\text {sub }}$.

Complexity The annotated form $\mathscr{A}(G)$ of $G=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}\right\rangle$ has up to $|Q|$ annotations per state, which gives $O\left(|Q|^{2}\right)$ subsumption tests per state, and the cost of each test is $O(|\Sigma|)$. So the worst-case time complexity of the subsumption test for $\mathscr{A}(G)$ is $O\left(|Q|^{3}|\Sigma|\right)$. This makes subsumption one of the most expensive of the abstractions presented here, but experimental results show that it is worthwhile. The subsumption test is best done immediately while constructing annotated automata or introducing annotations, considerably reducing memory requirements.

### 3.4 Incoming Equivalence

Incoming equivalence [9] identifies two states as equivalent if they have exactly the same incoming transitions. The concept is extended to annotated automata as follows.

Definition 9 Let $A=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}, A n n\right\rangle$ be an annotated automaton. The incoming equivalence relation $\sim_{\text {inc }} \subseteq Q \times Q$ is defined such that $x \sim_{\text {inc }} y$ if and only if the following conditions hold.

- $x \in Q^{\circ}$ if and only if $y \in Q^{\circ}$;
- For all states $z \in Q$ and all events $\sigma \in \Sigma_{\omega}$, it holds that $z \xrightarrow{\sigma} x$ if and only if $z \xrightarrow{\sigma} y$.

In [9], incoming equivalence is used as a restriction to make certain simplification rules applicable. Due to the improved regularity achieved by annotations, all incoming equivalent states in an annotated automaton can be merged. This merging is done using the standard automaton quotient, with the addition that, when merging several states into one, the resultant state receives the annotations of all original states.

Definition 10 Let $A=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}\right.$, Ann $\rangle$ be an annotated automaton, and let $\sim \subseteq Q \times Q$ be an equivalence relation. The quotient automaton of $A$ modulo $\sim$ is $A / \sim=\langle\Sigma, Q / \sim, \rightarrow / \sim$, $\left.\tilde{Q}^{\circ}, \tilde{A} n n\right\rangle$, where

$$
\begin{align*}
\rightarrow / \sim & =\{([x], \sigma,[y]) \mid x \xrightarrow{\sigma} y\} ;  \tag{7}\\
\tilde{Q}^{\circ} & =\left\{[x] \mid x \in Q^{\circ}\right\} ;  \tag{8}\\
\tilde{A} n n & =\left\{([x], a) \mid x \in Q \text { and there exists } x^{\prime} \sim x \text { such that }\left(x^{\prime}, a\right) \in \operatorname{Ann}\right\} . \tag{9}
\end{align*}
$$

Here, $[x]=\left\{x^{\prime} \in Q \mid x^{\prime} \sim x\right\}$ denotes the equivalence class of $x \in Q$ with respect to $\sim$, and $Q / \sim=\{[x] \mid x \in Q\}$ is the set of equivalence classes modulo $\sim$.

It is easily confirmed that the quotient $A / \sim$ of an annotated automaton $A$ satisfies conditions (i) and (ii) in Def. 5, because every merged state receives annotations from all its original states, and the eligible events sets are increased when merging.

Proposition 5 Let $A=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}, A n n\right\rangle$ be an annotated automaton. Then $A \simeq_{\text {conf }} A / \sim_{\text {inc }}$.
The merging of incoming equivalent states can be considered as a generalisation of the silent continuation rule [9]. An annotation symbolises a silent transition to an implicit state. When incoming equivalent states are merged, the nondeterministic decisions of the predecessor states are deferred by one step, expressed by the merged annotations.

Example 4 The annotated automaton $A^{\prime}$ in Fig. 1 is the result of using incoming equivalence to simplify $\mathscr{A}(G)$. States $q_{2}$ and $q_{5}$ are incoming equivalent and have been merged. The resultant state $q_{25}$ receives the annotations $\{\alpha\}$ and $\{\alpha, \beta, \gamma\}$, but only $\{\alpha\}$ remains because of subsumption.

Complexity The complexity of partitioning an automaton based on incoming equivalence is $O\left(|Q|^{2}|\Sigma|\right)$. Two states are equivalent if they have equal sets of incoming transitions, which can be determined efficiently using hash codes. Hash codes can be set up in a single pass over all transitions of the automaton, of which there are up to $|Q|^{2}\left|\Sigma_{\omega}\right|$, and the construction of the simplified automaton is achieved by another loop over all transitions, in the same complexity [9]. However, the merging of some states may make other states incoming equivalent, so the abstraction should be repeated to ensure a minimal result. The maximum number of iterations is $|Q|$, as each merge except the last reduces the number of states, so the complexity to obtain a minimal abstraction by incoming equivalence is $O\left(|Q|^{3}|\Sigma|\right)$.

### 3.5 Bisimulation

Bisimulation and observation equivalence [13] are general tools that have been used with considerable success to simplify automata during nonblocking verification [9, 19]. Bisimulation can also be applied to annotated automata, with the added restriction that bisimilar states must have the same annotations. Nevertheless, the removal of silent transitions can transform several conflict equivalent transition structures into the same annotated states, even if they are not originally observation equivalent. So bisimulation on the annotated automaton can be more effective, particularly after the removal of subsumed annotations.

Definition 11 Let $A_{1}=\left\langle\Sigma, Q_{1}, \rightarrow_{1}, Q_{1}^{\circ}, A n n_{1}\right\rangle$ and $A_{2}=\left\langle\Sigma, Q_{2}, \rightarrow_{2}, Q_{2}^{\circ}\right.$,Ann $\left.n_{2}\right\rangle$ be two annotated automata. A relation $\approx \subseteq Q_{1} \times Q_{2}$ is called a bisimulation between $A_{1}$ and $A_{2}$, if the following conditions hold for all states $x_{1} \in Q_{1}$ and $x_{2} \in Q_{2}$ such that $x_{1} \approx x_{2}$.

- For all $\sigma \in \Sigma_{\omega}$, if $x_{1} \xrightarrow{\sigma} y_{1}$ then there exists $y_{2} \in Q_{2}$ such that $y_{1} \approx y_{2}$ and $x_{2} \xrightarrow{\sigma} y_{2}$.
- For all $\sigma \in \Sigma_{\omega}$, if $x_{2} \xrightarrow{\sigma} y_{2}$ then there exists $y_{1} \in Q_{1}$ such that $y_{1} \approx y_{2}$ and $x_{1} \xrightarrow{\sigma} y_{1}$.
- For all $a \subseteq \Sigma_{\omega}$, it holds that $\left(x_{1}, a\right) \in A n n_{1}$ if and only if $\left(x_{2}, a\right) \in A n n_{2}$.
$A_{1}$ and $A_{2}$ are bisimulation equivalent or bisimilar, written $A_{1} \approx A_{2}$, if there exists a bisimulation $\approx$ between $A_{1}$ and $A_{2}$ such that, for every initial state $x_{1}^{\circ} \in Q_{1}^{\circ}$ there exists an initial state $x_{2}^{\circ} \in Q_{2}^{\circ}$ such that $x_{1}^{\circ} \approx x_{2}^{\circ}$, and vice versa.

It is easily confirmed that conditions (i) and (ii) in Def. 5 are preserved under bisimilarity of annotated automata. This is because bisimilar states always have the same sets of annotations and eligible events.

Example 5 Automaton $A^{\prime \prime}$ in Fig. 1 is bisimilar to $A^{\prime}$. States $q_{0}, q_{1}$, and $q_{25}$ have been merged due to the fact that they have the same annotations and equivalent outgoing transitions. Note that this only becomes possible after annotation, subsumption, and incoming equivalence.

Proposition 6 Let $A_{1}$ and $A_{2}$ be annotated automata such that $A_{1} \approx A_{2}$. Then $A_{1} \simeq_{\text {conf }} A_{2}$.
Complexity Given an annotated automaton, a coarsest bisimulation relation can be found in time complexity $O(|\rightarrow| \log |Q|)$ using the algorithm in [7]. The annotated form of $G=$ $\left\langle\Sigma, Q, \rightarrow, Q^{\circ}\right\rangle$ has $O\left(|Q|^{2}|\Sigma|\right)$ transitions, giving $O\left(|Q|^{2}|\Sigma| \log |Q|\right)$ time complexity for its simplification. An initial partition based on annotations can be established with lower time complexity.

### 3.6 Abstraction Procedure

This section explains how the above results can be used to minimise a given automaton with respect to conflict equivalence. Given an automaton $G$, the task is to compute a hopefully smaller abstraction $G^{\prime}$ conflict equivalent to $G$.

Given the complexity of the annotation procedure, it is advisable to reduce the size of the input automaton $G$ using some standard means before constructing an annotated form. While not necessarily optimal for conflict equivalence, bisimulation or observation equivalence [13] can be computed efficiently and are known to achieve significant reduction, as is the removal of blocking states [9].

After simplification of the input automaton, the next step is to compute its annotated form $\mathscr{A}(G)$, which then is simplified in several steps. While constructing the annotated form, annotations can be checked for subsumption on the fly, suppressing the generation of any redundant annotations. The resulting annotated form is next simplified by merging incoming equivalent states, again checking for subsumption and removing annotations that become redundant. Then the result is minimised according to bisimulation equivalence.

After simplifying the annotated automaton, it is unannotated to obtain an ordinary automaton that is conflict equivalent to the input. There are different ways to construct an unannotated form that satisfies the conditions of Def. 7, as there is considerable leeway in how outgoing transitions from annotation states can be chosen, and by making clever choices, the new annotation states can become bisimilar to original states or other annotation states, making it possible to further simplify the result.

An example of the abstraction procedure is shown in Fig. 1. Automaton $G$ is first annotated to obtain $\mathscr{A}(G)$, with subsumption being tested on the fly to suppress some annotations struck out in the figure. Next incoming equivalence leads to the abstraction $A^{\prime}$, with another annotation being suppressed due to subsumption as discussed in example 4, and the result is further simplified using bisimulation, giving $A^{\prime \prime}$.

Since the annotated automaton cannot be simplified further, it is replaced by its unannotated form $U$. As explained in example 2, the transition $\left(q_{0125},\{\alpha\}\right) \xrightarrow{\alpha} q_{0125}$ is not included in $U$. This choice makes the states $q_{8},\left(q_{8},\{\alpha\}\right)$, and $\left(q_{0125},\{\alpha\}\right)$ observation equivalent [13], so they can be merged in addition to states $q_{7}$ and $\left(q_{7},\{\omega\}\right)$. This results in the observation equivalent abstraction $U^{\prime}$. Furthermore, the transition $q_{0125} \xrightarrow{\alpha} q_{8}$ is redundant according to observation equivalence [5] and can be removed, giving the final result $U^{\prime \prime}$.

The abstraction steps in Fig. 1 can be justified by the propositions given in the previous sections. Note that, for every annotated automaton, there exists an unannotated form although it does not always have to be constructed explicitly. Let $V$ and $V^{\prime}$ be unannotated forms of $\mathscr{A}(G)$ and $A^{\prime}$, respectively. Then $G \simeq_{\text {conf }} V$ by Prop. 3 and $V \simeq_{\text {conf }} V^{\prime} \simeq_{\text {conf }} U$ by Prop. 4-6. Furthermore, $U$ is observation equivalent to $U^{\prime}$ and $U^{\prime \prime}$, which implies $U \simeq_{\operatorname{conf}} U^{\prime \prime}$ according to [12]. Thus,

$$
\begin{equation*}
G \simeq_{\text {conf }} V \simeq_{\text {conf }} V^{\prime} \simeq_{\text {conf }} U \simeq_{\text {conf }} U^{\prime} \simeq_{\text {conf }} U^{\prime \prime} . \tag{10}
\end{equation*}
$$

Overall, the automaton $G$ with nine states and 25 transitions is simplified to the conflictequivalent automaton $U^{\prime \prime}$ with three states and seven transitions.

## 4 Formal Proofs

This section contains formal proofs of the propositions stated in the previous section. The properties of annotated automata and unannotated automata are established in Section 4.1 and 4.2, and these results are used in Section 4.3-4.5 to confirm the correctness of the abstraction rules.

### 4.1 Annotation

The main result about annotated forms is Prop. 1 in Section 3.1, which states that automata with equal annotated forms are conflict equivalent. Its proof depends on two lemmas that describe the relationship between paths in an automaton and its annotated form.

Lemma 7 Let $G=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}\right\rangle$ be an automaton, and let $\mathscr{A}(G)=\left\langle\Sigma, Q, \rightarrow_{A}, Q^{\circ}, A n n\right\rangle$ be its annotated form. For all traces $s \in \Sigma^{*}$ and all events $\sigma \in \Sigma$, the annotated form has a path $x \xrightarrow{s \sigma} z$ if and only if there exists a path $x \stackrel{s}{\Rightarrow} y \xrightarrow{\sigma} z$ in $G$, for some $y \in Q$.

Proof The claim is proved by induction on $|s|$.
In the base case, $s=\varepsilon$, the claim follows directly from the definition (5).
For the inductive step, let $s=t \sigma^{\prime}$. Then note,

$$
\begin{equation*}
x \xrightarrow[\rightarrow]{s \sigma}_{A} z \quad \Longleftrightarrow \quad x{\xrightarrow{t \sigma^{\prime} \sigma} A}_{A} \quad \Longleftrightarrow \quad x{\xrightarrow[\rightarrow]{t \sigma^{\prime}}}_{A} y \xrightarrow{\sigma}_{A} z \quad \text { for some } y \in Q . \tag{11}
\end{equation*}
$$

By inductive assumption, $x \xrightarrow{t \sigma^{\prime}} y$ holds if and only if $x \stackrel{s}{\Rightarrow} y^{\prime} \xrightarrow{\sigma^{\prime}} y$ for some $y^{\prime} \in Q$, and by (5) $y \stackrel{\sigma}{\rightarrow}_{A} z$ holds if and only if $y \stackrel{\varepsilon}{\Rightarrow} z^{\prime} \xrightarrow{\sigma} z$ for some $z^{\prime} \in Q$. Thus, (11) becomes equivalent to,

$$
x \stackrel{s}{\Rightarrow} y^{\prime} \xrightarrow{\sigma^{\prime}} y \stackrel{\varepsilon}{\Rightarrow} z^{\prime} \xrightarrow{\sigma} z \quad \text { for some } y^{\prime}, z^{\prime} \in Q \quad \Longleftrightarrow \quad x \stackrel{s \sigma^{\prime}}{\Rightarrow} z^{\prime} \xrightarrow{\sigma} z \quad \text { for some } z^{\prime} \in Q .
$$

Lemma 8 Let $G=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}\right\rangle$ be an automaton, and let $\mathscr{A}(G)=\left\langle\Sigma, Q, \rightarrow_{A}, Q^{\circ}\right.$, Ann $\rangle$ be its annotated form. Also let $x, z \in Q$ and $s \in \Sigma^{*}$.
(i) If $x \stackrel{s}{\Rightarrow} z$, then there exists $z^{\prime} \in Q$ such that $x \stackrel{s}{\Rightarrow}_{A} z^{\prime}$ and $\left(z^{\prime}, \operatorname{Elig}_{G}(z)\right) \in$ Ann.
(ii) If $x \xrightarrow{s}_{A} z$ and $(z, a) \in A n n$, then there exists $z^{\prime} \in Q$ such that $x \stackrel{s}{\Rightarrow} z^{\prime}$ and $\operatorname{Elig}_{G}\left(z^{\prime}\right)=a$.

Proof (i) Let $x \stackrel{s}{\Rightarrow} z$. If $s=\varepsilon$ then $x \stackrel{\varepsilon}{\Rightarrow} z$, so $x \stackrel{\varepsilon}{\rightarrow}_{A} x$ with $\left(x\right.$, Elig $\left._{G}(z)\right) \in$ Ann by Def. 6 (6). Otherwise, $s=t \sigma$ and thus $x \stackrel{t}{\Rightarrow} y \xrightarrow{\sigma} z^{\prime} \stackrel{\varepsilon}{\Rightarrow} z$ for some $y, z^{\prime} \in Q$. By Lemma 7, it follows that $x \stackrel{t \sigma}{\Rightarrow}_{A} z^{\prime}$, and $\left(z^{\prime}, \operatorname{Elig}_{G}(z)\right) \in$ Ann since $z^{\prime} \stackrel{\varepsilon}{\Rightarrow} z$.
(ii) Let $x \xrightarrow{s}_{A} z$ and $(z, a) \in$ Ann. By Def. 6 (6), there exists $z^{\prime} \in Q$ such that $z \stackrel{\varepsilon}{\Rightarrow} z^{\prime}$ and $\operatorname{Elig}_{G}\left(z^{\prime}\right)=a$. If $s=\varepsilon$ then $x=z \stackrel{\varepsilon}{\Rightarrow} z^{\prime}$ with $\operatorname{Elig}_{G}\left(z^{\prime}\right)=a$. Otherwise, $s=t \sigma$ and by Lemma 7, there exists $y \in Q$ such that $x \stackrel{t}{\Rightarrow} y \stackrel{\sigma}{\rightarrow} z$. Then $x \stackrel{s}{\Rightarrow} z \stackrel{\varepsilon}{\Rightarrow} z^{\prime}$ with $\operatorname{Elig}_{G}\left(z^{\prime}\right)=a$.

Given these results, it is now possible to prove Prop. 1, the main result about annotated forms introduced in Section 3.1.

Proposition 1 Let $G$ and $H$ be two automata such that $\mathscr{A}(G)=\mathscr{A}(H)$. Then $G \simeq_{\text {conf }} H$.
Proof Let $G=\left\langle\Sigma, Q_{G}, \rightarrow_{G}, Q_{G}^{\circ}\right\rangle$ and $H=\left\langle\Sigma, Q_{H}, \rightarrow_{H}, Q_{H}^{\circ}\right\rangle$, and let $T=\left\langle\Sigma_{T}, Q_{T}, \rightarrow_{T}, Q_{T}^{\circ}\right\rangle$ be an arbitrary automaton.

Assume that $G \| T$ is nonblocking. It is enough to show that this implies that $H \| T$ is nonblocking. Therefore, let $s \in\left(\Sigma \cup \Sigma_{T}\right)^{*}$ such that $H \| T \stackrel{s}{\Rightarrow}\left(x_{H}, x_{T}\right)$. Then $H \xrightarrow{P(s)} x_{H}$ according to (2), where $P: \Sigma \cup \Sigma_{T} \rightarrow \Sigma$ denotes the natural projection, and by Lemma 8 (i), there exists a state $x_{A} \in Q_{H}$ such that $\mathscr{A}(G)=\mathscr{A}(H) \xrightarrow{P(s)} x_{A}$ and $\left(x_{A}, \operatorname{Elig}_{H}\left(x_{H}\right)\right) \in A n n_{H}=$ $A n n_{G}$. By Lemma 8 (ii), there also exists a state $x_{G} \in Q_{G}$ such that $G \stackrel{P(s)}{\Longrightarrow} x_{G}$ and $\operatorname{Elig}_{G}\left(x_{G}\right)=$ $\operatorname{Elig}_{H}\left(x_{H}\right)$. Thus, $G \| T \stackrel{s}{\Rightarrow}\left(x_{G}, x_{T}\right)$.

As $G \| T$ is nonblocking, there exists a trace $t \in\left(\Sigma \cup \Sigma_{T}\right)^{*}$ such that $\left(x_{G}, x_{T}\right) \stackrel{t \oplus}{\Rightarrow}$. Clearly, $t \omega=u \sigma v$ for some $u \in\left(\Sigma_{T} \backslash \Sigma\right)^{*}, \sigma \in \Sigma_{\omega}$, and $v \in\left(\Sigma_{\omega} \cup \Sigma_{T}\right)^{*}$. Then $x_{G} \stackrel{u}{\Rightarrow}_{G} x_{G}{ }_{\rightarrow}^{\sigma}$, i.e., $\sigma \in \operatorname{Elig}_{G}\left(x_{G}\right)=\operatorname{Elig}_{H}\left(x_{H}\right)$. If $\sigma=\omega$, then clearly $H \| T \stackrel{s}{\Rightarrow}\left(x_{H}, x_{T}\right) \stackrel{u \varrho}{\Rightarrow}$, which is enough to show that $H \| T$ is nonblocking. Otherwise, if $\sigma \in \Sigma$, let $y_{H} \in Q_{H}$ such that $H \stackrel{P(s)}{\Longrightarrow} x_{H} \xrightarrow{\sigma} y_{H}$. By Lemma 7, this implies $\mathscr{A}(G)=\mathscr{A}(H) \xrightarrow{P(s) \sigma} y_{H}$ and $G \xrightarrow{P(s) \sigma} y_{H}$. Since $u \in\left(\Sigma_{T} \backslash \Sigma\right)^{*}$, it
also follows that $G \| T \stackrel{\text { su }}{\Longrightarrow}\left(y_{H}, y_{T}\right)$ for some state $y_{T}$ of $T$. Since $G \| T$ is nonblocking, there exists a trace $w \in\left(\Sigma \cup \Sigma_{T}\right)^{*}$ such that $\left(y_{H}, y_{T}\right) \stackrel{w \omega}{\Rightarrow}$. Therefore,

$$
\begin{equation*}
H \| T \stackrel{s}{\Rightarrow}\left(x_{H}, x_{T}\right) \stackrel{u \sigma}{\Rightarrow}\left(y_{H}, y_{T}\right) \stackrel{w \omega}{\Rightarrow} . \tag{12}
\end{equation*}
$$

Since ( $x_{H}, x_{T}$ ) was chosen arbitrarily, it follows that $H \| T$ is nonblocking.

### 4.2 Unannotation

This section proves two key results about unannotation. Unannotated forms are equal with respect to conflict equivalence (Prop. 2), and conflict equivalence is preserved when annotating and unannotating again (Prop. 3).

These results depend on the relationship between traces in an annotated automaton and its unannotated forms, which are first established. Lemma 9 shows that every nonempty path of an annotated automaton corresponds to an equivalent path of its unannotated form. Lemma 10 lifts this result to all paths of an unannotated form, considering separately the cases of original and annotation end states.

Lemma 9 Let $A=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}, A n n\right\rangle$ be an annotated automaton, and let $U=\left\langle\Sigma, Q_{U}, \rightarrow_{U}\right.$, $\left.Q^{\circ}\right\rangle$ be an unannotated form of $A$. For all traces $s \in \Sigma^{*}$, all events $\sigma \in \Sigma$, and all states $x \in Q$, it holds that $x \xrightarrow{s \sigma} z$ if and only if $x \stackrel{s}{\Rightarrow}_{U} y \xrightarrow{\sigma} U$ for some $y \in Q_{U}$.

Proof The claim is proved by induction on $|s|$.
First consider the base case $s=\varepsilon$. If $x \xrightarrow{\sigma} z$, it follows directly from Def. 7 (iii) that $x \xrightarrow{{\underset{\sigma}{U}}_{U}} z$. Conversely, if $x \stackrel{\varepsilon}{\Rightarrow}_{U} y \xrightarrow{\sigma}_{U} z$, then by Def. 7 (ii) either $x=y$ or $x \xrightarrow{\tau}_{U} y$. If $x=y \stackrel{\sigma}{G}_{U} z$, then $x \xrightarrow{\sigma} z$ by Def. 7 (iii). If $x \xrightarrow{\tau} U y$, then $y=(x, a) \in$ Ann by Def. 7 (ii), and $(x, a)=y \xrightarrow{\sigma} U z$ implies $x \xrightarrow{\sigma} z$ by Def. 7 (v).

For the inductive step, let $s=t \sigma^{\prime}$, and first assume $x \xrightarrow{t \sigma^{\prime}} y \xrightarrow{\sigma} z$. By inductive assumption, it follows that $x \stackrel{t \sigma^{\prime}}{\Rightarrow} y$, and by Def. 7 (iii) it holds that $y \stackrel{\sigma}{\rightarrow}_{U} z$. This implies $x \stackrel{t \sigma^{\prime}}{\Rightarrow} y \stackrel{\sigma}{\rightarrow} U$. Conversely, assume that $x{\stackrel{t \sigma^{\prime}}{\Rightarrow}}_{U} y \xrightarrow{\sigma}$, i.e.,

$$
\begin{equation*}
x \stackrel{t}{\Rightarrow}_{U} x^{\prime} \stackrel{\sigma}{\rightarrow}_{U} y^{\prime} \stackrel{\varepsilon}{\Rightarrow}_{U} y \stackrel{\sigma}{\rightarrow}_{U} z . \tag{13}
\end{equation*}
$$

Then $x \xrightarrow{t \sigma^{\prime}} y^{\prime}$ by inductive assumption, and by Def. 7 (ii), it either holds that $y^{\prime}=y$, and thus $y^{\prime} \xrightarrow{\sigma}_{U} z$, which implies $y^{\prime} \xrightarrow{\sigma} z$ by Def. 7 (iii); or there is an annotation $\left(y^{\prime}, a\right) \in$ Ann such that $y=\left(y^{\prime}, a\right)$, i.e., $\left(y^{\prime}, a\right) \xrightarrow{\sigma}_{U} z$ and thus $y^{\prime} \xrightarrow{\sigma} z$ by Def. 7 (v). In both cases, $x \xrightarrow{t \sigma^{\prime}} y^{\prime} \xrightarrow{\sigma} z$, i.e., $x \xrightarrow{s \sigma} z$.

Lemma 10 Let $A=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}, A n n\right\rangle$ be an annotated automaton, and let $U=\left\langle\Sigma, Q_{U}\right.$, $\left.\rightarrow_{U}, Q^{\circ}\right\rangle$ be an unannotated form of $A$.
(i) For all traces $s \in \Sigma^{*}$ and all states $x \in Q$, it holds that $A \xrightarrow{s} x$ if and only if $U \stackrel{s}{\Rightarrow} x$.
(ii) For all traces $s \in \Sigma^{*}$ and all annotations $(x, a) \in A n n$, it holds that $A \xrightarrow{s} x$ if and only if $U \stackrel{s}{\Rightarrow}(x, a)$.

Proof (i) Firstly, if $s=\varepsilon$, then $A \xrightarrow{\varepsilon} x$ implies $x \in Q^{\circ}$ and thus $U \stackrel{\varepsilon}{\Rightarrow} x$, and conversely $U \stackrel{\varepsilon}{\Rightarrow} x$ with $x \in Q$ implies $x \in Q^{\circ}$ by Def. 7 (ii) and thus $A \xrightarrow{\varepsilon} x$. Secondly, if $s=t \sigma$, the claim follows immediately from Lemma 9.
(ii) Let $(x, a) \in$ Ann. Then $x \xrightarrow{\tau}_{U}(x, a)$ by Def. 7 (ii), and this is the only way how $(x, a)$ can be reached in $U$. Then the claim follows from (i), because $x \in Q$ and thus $A \xrightarrow{s} x$ if and only if $U \stackrel{s}{\Rightarrow} x \xrightarrow{\tau}(x, a)$.

The result that two unannotated forms of the same annotated automaton are conflict equivalent now becomes a consequence of Lemmas 9 and 10 .

Proposition 2 Let $A$ be an annotated automaton, and let $U_{1}$ and $U_{2}$ be unannotated forms of $A$. Then $U_{1} \simeq_{\text {conf }} U_{2}$.

Proof Let $A=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}, A n n\right\rangle$, and let $U_{i}=\left\langle\Sigma, Q \cup A n n, \rightarrow_{i}, Q^{\circ}\right\rangle$ for $i=1,2$ be unannotated forms of $A$. Furthermore, let $T=\left\langle\Sigma_{T}, Q_{T}, \rightarrow_{T}, Q_{T}^{\circ}\right\rangle$ be an arbitrary automaton such that $U_{1} \| T$ is nonblocking. It is enough to show that this implies that $U_{2} \| T$ is nonblocking. Therefore, let $s \in\left(\Sigma \cup \Sigma_{T}\right)^{*}$ such that $U_{2} \| T \stackrel{s}{\Rightarrow}\left(x, x_{T}\right)$, and consider two cases.

Case 1: $x=\left(x_{a}, a\right) \in$ Ann. Then $U_{2} \xrightarrow{P(s)}\left(x_{a}, a\right)$, which implies $A \xrightarrow{P(s)} x_{a}$ and $U_{1} \xrightarrow{P(s)}$ ( $\left.x_{a}, a\right)$ by Lemma 10 (ii). Thus $U_{1} \| T \stackrel{s}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}\right)$, and since $U_{1} \| T$ is nonblocking, there exists $t \in \Sigma^{*}$ such that $U_{1} \| T \stackrel{s}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}\right) \stackrel{t \omega}{\Rightarrow}$. Write $t \omega=u \sigma v$ with $u \in\left(\Sigma_{T} \backslash \Sigma\right)^{*}$, $\sigma \in \Sigma_{\omega}$, and $v \in\left(\Sigma_{\omega} \cup \Sigma_{T}\right)^{*}$. Then $\left.U_{1} \| T \stackrel{\stackrel{y}{\Rightarrow}}{( }\left(x_{a}, a\right), x_{T}\right) \stackrel{\mu}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}^{\prime}\right) \xrightarrow{\sigma}\left(y_{1}, y_{T}\right)$, so $\sigma \in \operatorname{Elig}_{U_{1}}\left(\left(x_{a}, a\right)\right)=a=\operatorname{Elig}_{U_{2}}\left(\left(x_{a}, a\right)\right)$ by Def. 7 (iv) and (v), and thus $\left(x_{a}, a\right) \xrightarrow{\sigma}_{2} y_{2}$ for
 $U_{2} \| T \stackrel{s}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}\right) \stackrel{u \oplus}{\Rightarrow}$, which is enough to show that $U_{2} \| T$ is nonblocking. Otherwise, $U_{2} \| T \stackrel{\text { suढ }}{\Longrightarrow}\left(y_{2}, y_{T}\right)$ with $s u \sigma \in\left(\Sigma \cup \Sigma_{T}\right)^{*}$ and $y_{2} \in Q$, and the proof continues as in Case 2.

Case 2: $x \in Q$. Then $U_{2} \xrightarrow{P(s)} x$ implies $A \xrightarrow{P(s)} x$ and $U_{1} \xrightarrow{P(s)} x$ by Lemma 10 (i). Thus $U_{1} \| T \stackrel{s}{\Rightarrow}\left(x, x_{T}\right)$, and since $U_{1} \| T$ is nonblocking, there exists $w \in \Sigma^{*}$ such that $U_{1} \| T \stackrel{s}{\Rightarrow}$ $\left(x, x_{T}\right) \stackrel{w \omega}{\Rightarrow}\left(y, y_{T}\right)$ where $y \in Q$. Therefore $x \xrightarrow{P(w) \omega} 1 y$, which implies $x \xrightarrow{P(w) \omega} y$ and $x \xrightarrow{P(w) \omega}{ }_{2} y$ by Lemma 9. Then $U_{2} \| T \stackrel{\stackrel{s}{\Rightarrow}}{\Rightarrow}\left(x, x_{T}\right) \stackrel{w \omega}{\Rightarrow}$, and since $\left(x, x_{T}\right)$ was chosen arbitrarily, it follows that $U_{2} \| T$ is nonblocking.

The second main result about unannotation is that conflict equivalence is preserved when annotation is followed by unannotation. To prove this, it is helpful to first establish a lemma about annotations, namely that the annotated form of an automaton is equal to the annotated form of its unannotation. Due to the way how annotated forms are defined in this paper, Lemma 11 only applies to annotated forms of an ordinary automaton $G$, not to arbitrary annotated automata.

Lemma 11 Let $G$ be an automaton, and let $U$ be an unannotated form of $\mathscr{A}(G)$. Then $\mathscr{A}(U)=\mathscr{A}(G)$.

Proof Let $\mathscr{A}(G)=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}\right.$, Ann $\rangle$, let $U=\left\langle\Sigma, Q_{U}, \rightarrow_{U}, Q^{\circ}\right\rangle$ be an unannotated form of $\mathscr{A}(G)$, and let $\mathscr{A}(U)=\left\langle\Sigma, Q_{U}, \rightarrow_{\mathscr{A}(U)}, Q^{\circ}, A n n_{\mathscr{A}(U)}\right\rangle$. It will be shown that the reachable parts of $\mathscr{A}(G)$ and $\mathscr{A}(U)$ are equal, i.e., that $\rightarrow=\rightarrow \mathscr{A}(U) \mid Q$ and $A n n=A n n_{\mathscr{A}(U) \mid Q}$, where $\rightarrow_{\mathscr{A}(U) \mid Q}=\rightarrow_{\mathscr{A}(U)} \cap\left(Q \times \Sigma_{\omega} \times Q_{U}\right)$ and $A n n_{\mathscr{A}(U) \mid Q}=A^{\prime n} n_{\mathscr{A}(U)} \cap\left(Q \times 2^{\Sigma_{\omega}}\right)$.

First, let $x \xrightarrow{\sigma} y$. Then $x \in Q$ and $x \stackrel{\sigma}{\rightarrow}_{U} y$ by Def. 7 (iii), and $x \xrightarrow{\sigma}_{\mathscr{A}(U)} y$ by Def. 6 (5),

Conversely, let $x \xrightarrow[\rightarrow]{\sigma} \mathscr{A}_{(U) \mid Q} y$. Then $x \in Q$ and $x \stackrel{\varepsilon}{\Rightarrow}_{U} z \stackrel{\sigma}{\rightarrow}_{U} y$ for some $z \in Q_{U}$ by Def. 6 (5). By Def. 7 (ii), this means that either $x=z$, which implies $x \xrightarrow{\sigma} U y$ and $x \xrightarrow{\sigma} y$ by Def. 7 (iii), or $z=(x, a) \xrightarrow{\sigma} U y$, which implies $x \xrightarrow{\sigma} y$ by Def. 7 (v).

Second, let $(x, a) \in A n n$. Then $x \in Q$ and $x \xrightarrow{\tau} U(x, a)$ by Def. 7 (ii) and $\operatorname{Elig}_{U}((x, a))=a$ by Def. 7 (iv) and (v). By Def. 6 (6), it follows that $(x, a)=\left(x, \operatorname{Elig}_{U}((x, a))\right) \in \operatorname{Ann}_{\mathscr{A}(U) \mid Q}$.

Conversely, let $(x, a) \in A n n_{\mathscr{A}(U) \mid Q}$. Then $x \in Q$, and by Def. 6 (6), there exists $y \in Q_{U}$ such that $x \stackrel{\varepsilon}{\Rightarrow}_{U} y$ and $\operatorname{Elig}_{U}(y)=a$. Here, $x \stackrel{\varepsilon}{\Rightarrow}_{U} y$ means that either $x=y$ or $x \xrightarrow{\tau}_{U} y$.

In the case $x=y$, note that $y=x \in Q$, and $\operatorname{Elig}_{U}(y)=\operatorname{Elig}_{A}(y) \cup \bigcup_{(z, a) \in \operatorname{Ann}} a=\operatorname{Elig}_{A}(y)$ by Def. 5 (ii), and $\operatorname{Elig}_{A}(y)=\operatorname{Elig}_{G}(y)$ by Def. 6 (5). Therefore, $(x, a)=\left(y, \operatorname{Elig}_{U}(y)\right)=$ $\left(y, \operatorname{Elig}_{A}(y)\right)=\left(y, \operatorname{Elig}_{G}(y)\right) \in \operatorname{Ann}$.

In the case $x \xrightarrow{\tau} U y$, note that $y \in A n n$ by Def. 7 (ii). Then it follows from $\operatorname{Elig}_{U}(y)=a$ by Def. 7 (iv) and (v) that $(x, a)=y \in$ Ann.

Proposition 3 Let $G$ be an automaton, and let $U$ be an unannotated form of $\mathscr{A}(G)$. Then $U \simeq_{\text {conf }} G$.

Proof By Lemma 11, it holds that $\mathscr{A}(U)=\mathscr{A}(G)$, which implies $U \simeq_{\text {conf }} G$ by Prop. 1.

### 4.3 Subsumption

This section contains the proof of Prop. 4 introduced in 3.3, which says that conflict equivalence of annotated automata is preserved under subsumption of annotations. Although lengthy, the proof can be done using the properties of the paths of unannotated forms established in 4.2.

Proposition 4 Let $A=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}, A n n\right\rangle$ and $A_{\text {sub }}=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}, A n n_{\text {sub }}\right\rangle$ be two annotated automata such that $A n n_{\text {sub }} \subseteq A n n$ and for all $(x, a) \in A n n$ there exists $a_{\text {sub }} \subseteq a$ such that $\left(x, a_{\text {sub }}\right) \in A n n_{\text {sub }}$. Then $A \simeq_{\text {conf }} A_{\text {sub }}$.

Proof Let $U=\left\langle\Sigma, Q \cup A n n, \rightarrow_{U}, Q^{\circ}\right\rangle$ and $U_{\text {sub }}=\left\langle\Sigma, Q \cup A n n_{\text {sub }}, \rightarrow_{U, \text { sub }}, Q^{\circ}\right\rangle$ be unannotated forms of $A$ and $A_{\text {sub }}$, respectively. It is to be shown that $U \simeq_{\text {conf }} U_{\text {sub }}$. Therefore, let $T=$ $\left\langle\Sigma_{T}, Q_{T}, \rightarrow_{T}, Q_{T}^{\circ}\right\rangle$ be an arbitrary automaton.

First, assume that $U \| T$ is nonblocking, and let $s \in\left(\Sigma \cup \Sigma_{T}\right)^{*}$ such that $U_{\text {sub }} \| T \stackrel{s}{\Rightarrow}$ $\left(x, x_{T}\right)$. Then $U_{\text {sub }} \stackrel{P(s)}{\Longrightarrow} x \in Q \cup A n n_{\text {sub }}$. Consider two cases.

Case 1: $x=\left(x_{a}, a\right) \in A n n_{\text {sub }}$. From $U_{\text {sub }} \xrightarrow{P(s)} x=\left(x_{a}, a\right)$, it follows that $A_{\text {sub }} \xrightarrow{P(s)} x_{a}$ by Lemma 10 (ii), which implies $A \xrightarrow{P(s)} x_{a}$ because $A$ and $A_{\text {sub }}$ have the same transition relations. Furthermore, since $\left(x_{a}, a\right) \in A n n_{\text {sub }} \subseteq A n n$, it follows by Lemma 10 (ii) that $U \xrightarrow{P(s)}$ $\left(x_{a}, a\right)$. This implies $U \| T \stackrel{s}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}\right)$, and since $U \| T$ is nonblocking, there exists $t \in \Sigma^{*}$ such that $U \| T \stackrel{s}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}\right) \stackrel{t \omega}{\Rightarrow}$. Write $t \omega=u \sigma v$ with $u \in\left(\Sigma_{T} \backslash \Sigma\right)^{*}, \sigma \in \Sigma_{\omega}$, and $v \in$ $\left(\Sigma_{\omega} \cup \Sigma_{T}\right)^{*}$. Then $U \| T \stackrel{s}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}\right) \stackrel{\mu}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}^{\prime}\right) \xrightarrow{\sigma}\left(y, y_{T}\right)$, so $\sigma \in \operatorname{Elig}_{U}\left(\left(x_{a}, a\right)\right)=$ $a=\operatorname{Elig}_{U_{\text {sub }}}\left(\left(x_{a}, a\right)\right)$ by Def. 7 (iv) and (v), and $\left(x_{a}, a\right) \stackrel{\sigma}{\rightarrow}_{U, \text { sub }} y_{\text {sub }}$ for some $y_{\text {sub }} \in Q$. If $\sigma=\omega$, then clearly $U_{\text {sub }} \| T \stackrel{s}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}\right) \stackrel{u \omega}{\Rightarrow}$, which is enough to show that $U_{\text {sub }} \| T$ is nonblocking. Otherwise, $U_{\text {sub }} \| T \stackrel{\text { suб }}{\Longrightarrow}\left(y_{\text {sub }}, y_{T}\right)$ with $s u \sigma \in\left(\Sigma \cup \Sigma_{T}\right)^{*}$ and $y_{\text {sub }} \in Q$, and the proof continues as in Case 2.

Case 2: $x \in Q$. From $U_{\text {sub }} \xrightarrow{P(s)} x$, it follows that $A_{\text {sub }} \xrightarrow{P(s)} x$ by Lemma 10 (i), which implies $A \xrightarrow{P(s)} x$ because $A$ and $A_{\text {sub }}$ have the same transition relations, which implies $U \xrightarrow{P(s)} x$ again by Lemma 10 (i). Then $U \| T \stackrel{s}{\Rightarrow}\left(x, x_{T}\right)$, and since $U \| T$ is nonblocking, there exists $w \in \Sigma^{*}$ such that $U \| T \stackrel{s}{\Rightarrow}\left(x, x_{T}\right) \stackrel{w \omega}{\Longrightarrow}\left(z, z_{T}\right)$. This means $x \stackrel{P(w) \omega}{ }_{U} z$, which implies $x \xrightarrow{P(w) \omega} z$ by Lemma 9, which implies $x \xrightarrow{P(w) \omega}$ sub $z$ because $A$ and $A_{\text {sub }}$ have the same transition relations, which implies $x \xrightarrow{P(w) \omega} U$,sub $z$ again by Lemma 9 . Thus, $U_{\text {sub }} \| T \stackrel{s}{\Rightarrow}\left(x, x_{T}\right) \stackrel{w \omega}{\Rightarrow}$, and since $\left(x, x_{T}\right)$ was chosen arbitrarily, it follows that $U_{\text {sub }} \| T$ is nonblocking.

Conversely, assume that $U_{\text {sub }} \| T$ is nonblocking, and let $s \in\left(\Sigma \cup \Sigma_{T}\right)^{*}$ such that $U \| T \stackrel{s}{\Rightarrow}$ $\left(x, x_{T}\right)$. Then $U \xrightarrow{P(s)} x \in Q \cup A n n$. Consider two cases.

Case 1: $x=\left(x_{a}, a\right) \in$ Ann. By assumption there exists $a_{\text {sub }} \subseteq a$ such that $\left(x_{a}, a_{\text {sub }}\right) \in$ $A n n_{\text {sub }}$. From $U \xrightarrow{P(s)} x=\left(x_{a}, a\right)$, it follows that $A \xrightarrow{P(s)} x_{a}$ by Lemma 10 (ii), which implies $A_{\text {sub }} \xrightarrow{P(s)} x_{a}$ because $A$ and $A_{\text {sub }}$ have the same transition relations. Therefore, $U_{\text {sub }} \xrightarrow{P(s)} x_{a} \xrightarrow{\tau}$ $\left(x_{a}, a_{\text {sub }}\right)$ by Lemma 10 (i) and by Def. 7 (ii). Thus, $U_{\text {sub }} \| T \stackrel{S}{\Rightarrow}\left(\left(x_{a}, a_{\text {sub }}\right), x_{T}\right)$, and since $U_{\text {sub }} \| T$ is nonblocking, there exists $t \in \Sigma^{*}$ such that $U_{\text {sub }} \| T \stackrel{s}{\Rightarrow}\left(\left(x_{a}, a_{\text {sub }}\right), x_{T}\right) \stackrel{t \oplus}{\Rightarrow}$. Write $t \omega=u \sigma v$ with $u \in\left(\Sigma_{T} \backslash \Sigma\right)^{*}, \sigma \in \Sigma_{\omega}$, and $v \in\left(\Sigma_{\omega} \cup \Sigma_{T}\right)^{*}$. Then $U_{\text {sub }} \| T \stackrel{s}{\Rightarrow}\left(\left(x_{a}, a_{\text {sub }}\right), x_{T}\right) \stackrel{u}{\Rightarrow}$ $\left(\left(x_{a}, a_{\text {sub }}\right), x_{T}^{\prime}\right) \xrightarrow{\sigma}\left(y_{\text {sub }}, y_{T}\right)$, i.e., $\sigma \in \operatorname{Elig}_{U_{\text {sub }}}\left(\left(x_{a}, a_{\text {sub }}\right)\right)=a_{\text {sub }} \subseteq a=\operatorname{Elig}_{U}\left(\left(x_{a}, a\right)\right)$ by Def. 7 (iv) and (v), and $\left(x_{a}, a\right) \xrightarrow{\sigma}{ }_{U} y$ for some $y \in Q$. If $\sigma=\omega$, then clearly $U \| T \stackrel{s}{\Rightarrow}$ $\left(\left(x_{a}, a\right), x_{T}\right) \stackrel{u \omega}{\Rightarrow}$, which is enough to show that $U \| T$ is nonblocking. Otherwise, $U \| T \stackrel{\text { su厅 }}{\Longrightarrow}$ $\left(y, y_{T}\right)$ with $s u \sigma \in\left(\Sigma \cup \Sigma_{T}\right)^{*}$ and $y \in Q$, and the proof continues as in Case 2.

Case 2: $x \in Q$. From $U \xrightarrow{P(s)} x$, it follows that $A \xrightarrow{P(s)} x$ by Lemma 10 (i), which implies $A_{\text {sub }} \xrightarrow{P(s)} x$ because $A$ and $A_{\text {sub }}$ have the same transition relations, which implies $U_{\text {sub }} \xrightarrow{P(s)} x$ again by Lemma 10 (i). Then $U_{\text {sub }} \| T \stackrel{s}{\Rightarrow}\left(x, x_{T}\right)$, and since $U_{\text {sub }} \| T$ is nonblocking, there exists $w \in \Sigma^{*}$ such that $U_{\text {sub }} \| T \stackrel{s}{\Rightarrow}\left(x, x_{T}\right) \stackrel{w \omega}{\Rightarrow}\left(z, z_{T}\right)$. This means $x \xrightarrow{P(w) \omega} U$, sub $z$, which by Lemma 9 implies $x \xrightarrow{P(w) \omega} z$, both in $A$ and $A_{\text {sub }}$, and $x \xrightarrow{P(w) \omega} U$. Thus, $U \| T \stackrel{s}{\Rightarrow}\left(x, x_{T}\right) \xrightarrow{w \omega}$, and since ( $x, x_{T}$ ) was chosen arbitrarily, it follows that $U \| T$ is nonblocking.

### 4.4 Incoming Equivalence

To prove the correctness of abstractions based on automaton quotients, such as the incoming equivalence abstraction, the relationship between the traces in an automaton $A$ and its quotient $A / \sim$ needs to be established. It is well-known that every trace in $A$ also has a corresponding trace in $A / \sim$. The following Lemma 12 is quoted from [9] and holds for every equivalence relation. Conversely, not every path in a quotient automaton exists in the original automaton, but Lemma 13 shows how such a path can be obtained if the quotient is constructed using incoming equivalence.

Lemma 12 Let $A=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}, A n n\right\rangle$ be an annotated automaton, and let $\sim \subseteq Q \times Q$ be an equivalence relation. Then, for all states $x, y \in Q$ and all traces $s \in \Sigma^{*}$ such that $x \xrightarrow{s} y$ in $A$, it holds that $[x] \xrightarrow{s}[y]$ in $A / \sim$.

Proof Let $x \xrightarrow{s} y$ in $A$ with $s=\sigma_{1} \ldots \sigma_{n}$. Then there exist states $x_{0}, \ldots, x_{n} \in Q$ such that

$$
\begin{equation*}
x=x_{0} \xrightarrow{\sigma_{1}} x_{1} \xrightarrow{\sigma_{2}} \cdots \xrightarrow{\sigma_{n}} x_{n}=y . \tag{14}
\end{equation*}
$$

By Def. 10, it holds that $\left[x_{k-1}\right] \xrightarrow{\sigma_{k}}\left[x_{k}\right]$ for each $k=1, \ldots, n$, which implies $[x] \xrightarrow{s}[y]$ in $A / \sim$.

Lemma 13 Let $A=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}, A n n\right\rangle$ be an annotated automaton, and let $\tilde{x}, \tilde{z} \in Q / \sim_{\text {inc }}$ be two states of $A / \sim_{\text {inc }}$.
(i) For all $s \in \Sigma^{*}$ and all $\sigma \in \Sigma$ such that $\tilde{x} \xrightarrow{s \sigma} \tilde{z}$, there exists $x \in \tilde{x}$ such that for all $z^{\prime} \in \tilde{z}$ it holds that $x \xrightarrow{s \sigma} z^{\prime}$.
(ii) For all $s \in \Sigma^{*}$ such that $A / \sim_{\text {inc }} \xrightarrow{s} \tilde{z}$ and for all $z^{\prime} \in \tilde{z}$, it holds that $A \xrightarrow{s} z^{\prime}$.

Proof (i) The claim is proved by induction on $|s|$.
Base case: $s=\varepsilon$. As $\tilde{x} \xrightarrow{\sigma} \tilde{z}$, there must exist $x \in \tilde{x}$ and $z \in \tilde{z}$ such that $x \xrightarrow{\sigma} z$. Let $z^{\prime} \in \tilde{z}$. Then $z \sim_{\text {inc }} z^{\prime}$, and it follows from Def. 9 that $x \xrightarrow{\sigma} z^{\prime}$.

Inductive step: $s=t \sigma$. Assume that $\tilde{x} \xrightarrow{t} \tilde{y} \xrightarrow{\sigma} \tilde{z}$. Then there are states $y \in \tilde{y}$ and $z \in \tilde{z}$ such that $y \xrightarrow{\sigma} z$. By inductive assumption, there exists a state $x \in \tilde{x}$ such that $x \xrightarrow{t} y$. Let $z^{\prime} \in \tilde{z}$. Then $z \sim_{\text {inc }} z^{\prime}$, and it follows from Def. 9 that $x \xrightarrow{t} y \xrightarrow{\sigma} z^{\prime}$.
(ii) Let $\tilde{Q}^{\circ}=\left\{\left[x^{\circ}\right] \mid x^{\circ} \in Q^{\circ}\right\}$ be the set of initial states of $A / \sim_{\text {inc }}$.

If $s=\varepsilon$, then $\tilde{z} \in \tilde{Q}^{\circ}$ and thus $\tilde{z}=\left[x^{\circ}\right]$ for some $x^{\circ} \in Q^{\circ}$, which implies $x^{\circ} \in \tilde{z}$. Let $z^{\prime} \in \tilde{z}$. Then $x^{\circ} \sim_{\text {inc }} z^{\prime}$, which implies $z^{\prime} \in Q^{\circ}$ by Def. 9 and thus $A \xrightarrow{\varepsilon} z^{\prime}$.

Otherwise $s=t \sigma$ for some $t \in \Sigma^{*}$ and $\sigma \in \Sigma$, and there exists $\tilde{x} \in \tilde{Q}^{\circ}$ such that $\tilde{x} \xrightarrow{t \sigma} \tilde{z}$. Let $z^{\prime} \in \tilde{z}$. It follows from (i) that there exists $x \in \tilde{x}$ such that $x \xrightarrow{t \sigma} z^{\prime}$. Since $\tilde{x} \in \tilde{Q}^{\circ}$, there exists $x^{\circ} \in \tilde{x}$ such that $x^{\circ} \in Q^{\circ}$. Then $x^{\circ} \sim_{\text {inc }} x$ implies $x \in Q^{\circ}$ and thus $A \xrightarrow{t \sigma} z^{\prime}$.

Using the above two lemmas and the properties of the paths of unannotated forms established in Section 4.2, the proof of Prop. 5 proceeds using similar ideas to that of the Active Events Rule [9].

Proposition 5 Let $A=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}, A n n\right\rangle$ be an annotated automaton. Then $A \simeq_{\text {conf }} A / \sim_{\text {inc }}$.
Proof Let $U=\left\langle\tilde{\tilde{A}}, Q \cup A n n, \rightarrow_{U}, Q^{\circ}\right\rangle$ and $\tilde{U}=\left\langle\Sigma, Q / \sim_{\text {inc }} \cup \tilde{A} n n, \rightarrow_{\tilde{U}}, \tilde{Q}^{\circ}\right\rangle$ be unannotated forms of $A$ and $\tilde{A}=A / \sim_{\text {inc }}$, respectively. It is to be shown that $U \simeq_{\text {conf }} \tilde{U}$. Therefore, let $T=\left\langle\Sigma_{T}, Q_{T}, \rightarrow_{T}, Q_{T}^{\circ}\right\rangle$ be an arbitrary automaton.

First, assume that $U \| T$ is nonblocking, and let $s \in\left(\Sigma \cup \Sigma_{T}\right)^{*}$ such that $\tilde{U} \| T \stackrel{s}{\Rightarrow}\left(\tilde{x}, x_{T}\right)$. Then $\tilde{U} \xrightarrow{P(s)} \tilde{x} \in Q / \sim_{\text {inc }} \cup \tilde{A} n n$. Consider two cases.

Case 1: $\tilde{x}=\left(\tilde{x}_{a}, a\right) \in \tilde{A} n n$. Then there exists $x_{a} \in \tilde{x}_{a}$ such that $\left(x_{a}, a\right) \in$ Ann. From $\tilde{U} \xrightarrow{P(s)} \tilde{x}=\left(\tilde{x}_{a}, a\right)$, it follows that $\tilde{A} \xrightarrow{P(s)} \tilde{x}_{a}$ by Lemma 10 (ii), which implies $A \xrightarrow{P(s)} x_{a}$ by Lemma 13 (ii), and $U \xrightarrow{P(s)}\left(x_{a}, a\right)$ again by Lemma 10 (ii). Thus, $U \| T \stackrel{s}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}\right)$, and since $U \| T$ is nonblocking, there exists $t \in \Sigma^{*}$ such that $U \| T \stackrel{s}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}\right) \stackrel{t \Theta}{\Rightarrow}$. Write $t \omega=u \sigma v$ with $u \in\left(\Sigma_{T} \backslash \Sigma\right)^{*}, \sigma \in \Sigma_{\omega}$, and $v \in\left(\Sigma_{\omega} \cup \Sigma_{T}\right)^{*}$. Then $U \| T \stackrel{s}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}\right) \stackrel{u}{\Rightarrow}$ $\left(\left(x_{a}, a\right), x_{T}^{\prime}\right) \xrightarrow{\sigma}\left(y, y_{T}\right)$, i.e., $\sigma \in \operatorname{Elig}_{U}\left(\left(x_{a}, a\right)\right)=a=\operatorname{Elig}_{\tilde{U}}\left(\left(\tilde{x}_{a}, a\right)\right)$ by Def. 7 (iv) and (v), and $\left(\tilde{x}_{a}, a\right) \xrightarrow{\sigma}_{\tilde{U}} \tilde{y}$ for some $\tilde{y} \in Q / \sim_{\text {inc }}$. If $\sigma=\omega$, then clearly $\tilde{U} \| T \stackrel{s}{\Rightarrow}\left(\left(\tilde{x}_{a}, a\right), x_{T}\right) \stackrel{u}{\Rightarrow}$ $\left(\left(\tilde{x}_{a}, a\right), x_{T}^{\prime}\right) \stackrel{\omega}{\Rightarrow}$, which is enough to show that $\tilde{U} \| T$ is nonblocking. Otherwise, $\tilde{U} \| T \stackrel{s}{\Rightarrow}$ $\left(\left(\tilde{x}_{a}, a\right), x_{T}\right) \stackrel{\mu}{\Rightarrow}\left(\left(\tilde{x}_{a}, a\right), x_{T}^{\prime}\right) \xrightarrow{\sigma}\left(\tilde{y}, y_{T}\right)$ with $s u \sigma \in\left(\Sigma \cup \Sigma_{T}\right)^{*}$ and $\tilde{y} \in Q / \sim_{\text {inc }}$, and the proof continues as in Case 2.

Case 2: $\tilde{x} \in Q / \sim_{\text {inc. }}$. Then $\tilde{A} \xrightarrow{P(s)} \tilde{x}$ by Lemma 10 (i). Then let $x \in \tilde{x}$, and it follows from Lemma 13 (ii) that $A \xrightarrow{P(s)} x$, which implies $U \xrightarrow{P(s)} x$ again by Lemma 10 (i). Thus,
$U \| T \xrightarrow{P(s)}\left(x, x_{T}\right)$, and since $U \| T$ is nonblocking, there exists $w \in \Sigma^{*}$ such that $U \| T \xrightarrow{P(s)}$ $\left(x, x_{T}\right) \stackrel{w \omega}{\Longrightarrow}\left(z, z_{T}\right)$. Then $x \xrightarrow{P(w) \omega} U z$, with $z \in Q$ by Def. 7. This implies $x \xrightarrow{P(w) \omega} z$ by Lemma 9 , and thus $[x] \xrightarrow{P(w) \omega}[z]$ in $A / \sim_{\text {inc }}$ by Lemma 12, which implies $\tilde{x}=[x] \xrightarrow{P(w) \omega} \tilde{U}[z]$ again by Lemma 9. Thus, $\tilde{U} \| T \stackrel{s}{\Rightarrow}\left(\tilde{x}, x_{T}\right) \stackrel{w \omega}{\Rightarrow}$, and since $\left(\tilde{x}, x_{T}\right)$ was chosen arbitrarily, it follows that $\tilde{U} \| T$ is nonblocking.

Conversely, assume that $\tilde{U} \| T$ is nonblocking, and let $s \in\left(\Sigma \cup \Sigma_{T}\right)^{*}$ such that $U \| T \stackrel{s}{\Rightarrow}$ $\left(x, x_{T}\right)$. Then $U \xrightarrow{P(s)} x \in Q \cup A n n$. Consider two cases.

Case 1: $x=\left(x_{a}, a\right) \in A n n$. From $U \xrightarrow{P(s)}\left(x_{a}, a\right)$, it follows that $A \xrightarrow{P(s)} x_{a}$ by Lemma 10 (ii), which implies $\tilde{A} \xrightarrow{P(s)}\left[x_{a}\right]$ by Lemma 12. Note that $\left(\left[x_{a}\right], a\right) \in \tilde{A} n n$ and thus $\tilde{U} \xrightarrow{P(s)}\left(\left[x_{a}\right], a\right)$ again by Lemma 10 (ii). Thus, $\tilde{U} \| T \stackrel{s}{\Rightarrow}\left(\left(\left[x_{a}\right], a\right), x_{T}\right)$, and since $\tilde{U} \| T$ is nonblocking, there exists $t \in \Sigma^{*}$ such that $\tilde{U} \| T \stackrel{s}{\Rightarrow}\left(\left(\left[x_{a}\right], a\right), x_{T}\right) \stackrel{t \omega}{\Rightarrow}$. Write $t \omega=u \sigma v$ with $u \in\left(\Sigma_{T} \backslash \Sigma\right)^{*}$, $\sigma \in \Sigma_{\omega}$, and $v \in\left(\Sigma_{\omega} \cup \Sigma_{T}\right)^{*}$. Then $\tilde{U} \| T \stackrel{s}{\Rightarrow}\left(\left(\left[x_{a}\right], a\right), x_{T}\right) \stackrel{u}{\Rightarrow}\left(\left(\left[x_{a}\right], a\right), x_{T}^{\prime}\right) \xrightarrow{\sigma}\left(\tilde{y}, y_{T}\right)$, i.e., $\sigma \in \operatorname{Elig}_{\tilde{U}}\left(\left(\left[x_{a}\right], a\right)\right)=a=\operatorname{Elig}_{U}\left(\left(x_{a}, a\right)\right)$ by Def. 7 (iv) and (v), and $\left(x_{a}, a\right) \xrightarrow{\sigma}_{U} y$ for some $y \in Q$. Thus $U \| T \stackrel{s}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}\right) \stackrel{u}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}^{\prime}\right) \xrightarrow{\sigma}\left(y, y_{T}\right)$ with $y \in Q$. If $\sigma=\omega$, then clearly $U \| T \stackrel{s}{\Rightarrow}\left(\left(x_{a}, a\right), x_{T}\right) \stackrel{u \omega}{\Rightarrow}$, which is enough to show that $U \| T$ is nonblocking. Otherwise, $U \| T \stackrel{\text { suढ }}{\Longrightarrow}\left(y, y_{T}\right)$ with $s u \sigma \in\left(\Sigma \cup \Sigma_{T}\right)^{*}$ and $y \in Q$, and the proof continues as in Case 2.

Case 2: $x \in Q$. Then $A \xrightarrow{P(s)} x$ by Lemma 10 (i), which implies $\tilde{A} \xrightarrow{P(s)}[x]$ by Lemma 12. By Def. 5, there exists $a \subseteq \operatorname{Elig}_{A}(x)$ such that $(x, a) \in \operatorname{Ann}$. Then $([x], a) \in \tilde{A} n n$, and $\tilde{U} \xrightarrow{P(s)}$ ( $[x], a$ ) by Lemma 10 (ii). Thus, $\tilde{U} \| T \stackrel{s}{\Rightarrow}\left(([x], a), x_{T}\right)$, and since $\tilde{U} \| T$ is nonblocking, there exists $t \in \Sigma^{*}$ such that $\tilde{U} \| T \stackrel{s}{\Rightarrow}\left(([x], a), x_{T}\right) \stackrel{t \omega}{\Rightarrow}$. Write $t \omega=u \sigma v$ with $u \in\left(\Sigma_{T} \backslash \Sigma\right)^{*}$, $\sigma \in \Sigma_{\omega}$, and $v \in\left(\Sigma_{\omega} \cup \Sigma_{T}\right)^{*}$. Then $\tilde{U} \| T \stackrel{s}{\Rightarrow}\left(([x], a), x_{T}\right) \stackrel{\mu}{\Rightarrow}\left(([x], a), x_{T}^{\prime}\right) \xrightarrow{\sigma}\left(\tilde{y}, y_{T}\right)$. Clearly, $\sigma \in \operatorname{Elig}_{\tilde{U}}(([x], a))=a \subseteq \operatorname{Elig}_{A}(x)=\operatorname{Elig}_{U}(x)$ by Def. 7 (iii) and (v). If $\sigma=\omega$, it already
 that $x \xrightarrow{\sigma} y$ for some $y \in Q$. Then $\tilde{A} \xrightarrow{P(s)}[x] \xrightarrow{\sigma}[y]$ by Def. 10 and $\tilde{U} \xrightarrow{P(s) \sigma}[y]$ by Lemma 10 (i). Therefore $\tilde{U} \| T \stackrel{\text { sü }}{\Longrightarrow}\left([y], y_{T}\right)$, and since $\tilde{U} \| T$ is nonblocking, there exists $w \in \Sigma^{*}$ such that $\tilde{U} \| T \xrightarrow{\text { suб }}\left([y], y_{T}\right) \stackrel{w \omega}{\Longrightarrow}$. Then $[y] \stackrel{P(w) \omega}{\Longrightarrow} \tilde{U}$, and by Lemma 13 (i) there exists $y^{\prime} \in[y]$ such that $y^{\prime} \xrightarrow{P(w) \omega}{ }_{U}$. Thus $x \xrightarrow{\sigma} y \sim_{\text {inc }} y^{\prime}$, which implies $x \xrightarrow{\sigma} y^{\prime}$ by Def. 9 , and $x \xrightarrow{\sigma}_{U} y^{\prime}$ by Def. 7 (iii). Thus, $U \| T \stackrel{s}{\Rightarrow}\left(x, x_{T}\right) \stackrel{u \sigma}{\Rightarrow}\left(y^{\prime}, y_{T}\right) \stackrel{w \omega}{\Rightarrow}$, and since $\left(x, x_{T}\right)$ was chosen arbitrarily, it follows that $U \| T$ is nonblocking.

### 4.5 Bisimulation

This section contains the proof of Prop. 6 introduced in 3.5, which states that conflict equivalence is preserved under bisimulation of annotated automata. This is best proved by showing that the unannotated forms of bisimilar annotated automata are bisimilar. For this purpose, the following standard definition of bisimulation for ordinary automata is used [13].

Definition 12 Let $G_{1}=\left\langle\Sigma, Q_{1}, \rightarrow_{1}, Q_{1}^{\circ}\right\rangle$ and $G_{2}=\left\langle\Sigma, Q_{2}, \rightarrow_{2}, Q_{2}^{\circ}\right\rangle$ be two automata. A relation $\approx \subseteq Q_{1} \times Q_{2}$ is called a bisimulation between $G_{1}$ and $G_{2}$, if the following conditions hold for all states $x_{1} \in Q_{1}$ and $x_{2} \in Q_{2}$ such that $x_{1} \approx x_{2}$.
(i) For all $\sigma \in \Sigma_{\tau, \omega}$, if $x_{1} \xrightarrow{\sigma} y_{1}$ then there exists $y_{2} \in Q_{2}$ such that $y_{1} \approx y_{2}$ and $x_{2} \xrightarrow{\sigma} y_{2}$.
(ii) For all $\sigma \in \Sigma_{\tau, \omega}$, if $x_{2} \xrightarrow{\sigma} y_{2}$ then there exists $y_{1} \in Q_{1}$ such that $y_{1} \approx y_{2}$ and $x_{1} \xrightarrow{\sigma} y_{1}$.
$G_{1}$ and $G_{2}$ are bisimulation equivalent or bisimilar, written $G_{1} \approx G_{2}$, if there exists a bisimulation $\approx$ between $G_{1}$ and $G_{2}$ such that, for every initial state $x_{1}^{\circ} \in Q_{1}^{\circ}$ there exists an initial state $x_{2}^{\circ} \in Q_{2}^{\circ}$ such that $x_{1}^{\circ} \approx x_{2}^{\circ}$, and vice versa.

Although unannotated forms have been shown to be unique up to conflict equivalence in Prop. 2, two unannotated forms of the same annotated automaton are not necessarily bisimilar. To prove the result about bisimulation, a unique unannotated form is needed.

Definition 13 Let $A=\left\langle\Sigma, Q, \rightarrow, Q^{\circ}, A n n\right\rangle$ be an annotated automaton. The standard unannotation of $A$ is $\mathscr{U}(A)=\left\langle\Sigma, Q_{U}, \rightarrow_{U}, Q^{\circ}\right\rangle$ where $Q_{U}=Q \cup A n n$ and

$$
\begin{align*}
\rightarrow_{U}= & \rightarrow \cup\{(x, \tau,(x, a)) \in Q \times\{\tau\} \times A n n\} \cup \\
& \left\{((x, a), \sigma, y) \in A n n \times \Sigma_{\omega} \times Q \mid \sigma \in a \text { and } x \xrightarrow{\sigma} y\right\} \tag{15}
\end{align*}
$$

The standard unannotation resolves the ambiguity in points (iv) and (v) of Def. 7 by simply including all possible transitions for every annotation state. This ensures uniqueness at the expense of minimality. It is easy to confirm that, for every annotated automaton $A$, the standard unannotation $\mathscr{U}(A)$ is indeed an unannotated form of $A$.

The standard unannotations of bisimilar automata can be shown to be bisimilar, and this is enough to complete the proof of Prop. 6.
Lemma 14 Let $A_{1}=\left\langle\Sigma, Q_{1}, \rightarrow_{1}, Q_{1}^{\circ}, A n n_{1}\right\rangle$ and $A_{2}=\left\langle\Sigma, Q_{2}, \rightarrow_{2}, Q_{2}^{\circ}, A n n_{2}\right\rangle$ be two annotated automata such that $A_{1} \approx A_{2}$. Then $\mathscr{U}\left(A_{1}\right) \approx \mathscr{U}\left(A_{2}\right)$.
Proof Let $\mathscr{U}\left(A_{i}\right)=\left\langle\Sigma, Q_{U, i}, \rightarrow_{U, i}, Q_{i}^{\circ}\right\rangle$ where $Q_{U, i}=Q_{i} \cup A n n_{i}$ for $i=1,2$, and let $\approx$ be a bisimulation between $A_{1}$ and $A_{2}$. Consider the relation $\approx_{U} \subseteq Q_{U, 1} \times Q_{U, 2}$ such that $x_{1} \approx_{U} x_{2}$ if and only if one of the following two conditions holds:
$x_{1} \in Q_{1}, x_{2} \in Q_{2}$, and $x_{1} \approx x_{2} \quad$ or
there exists $a \subseteq \Sigma_{\omega}$ such that $x_{1}=\left(x_{1}^{\prime}, a\right) \in A n n_{1}, x_{2}=\left(x_{2}^{\prime}, a\right) \in A n n_{2}$, and $x_{1}^{\prime} \approx x_{2}^{\prime}$.
It is to be shown that $\approx_{U}$ is a bisimulation between $\mathscr{U}\left(A_{1}\right)$ and $\mathscr{U}\left(A_{2}\right)$. To see (i) in Def. 12, let $x_{1} \approx_{U} x_{2}$ and $x_{1} \xrightarrow{\sigma}_{U, 1} y_{1}$ for some $\sigma \in \Sigma_{\tau, \omega}$. Then either (16) or (17) holds.

If (16) holds, then $x_{1} \approx x_{2}$ with $x_{1} \in Q_{1}$ and $x_{2} \in Q_{2}$. Then either $y_{1} \in Q_{1}$ or $y_{1} \in A n n_{1}$. If $y_{1} \in Q_{1}$, then it follows from $x_{1} \xrightarrow{\sigma}_{U, 1} y_{1}$ that $x_{1} \xrightarrow{\sigma}_{1} y_{1}$ by Def. 13. Since $x_{1} \approx x_{2}$, by Def. 11 there exists $y_{2} \in Q_{2}$ such that $x_{2}{\underset{\sim}{\sigma}}_{2} y_{2}$ and $y_{1} \approx y_{2}$. Again by Def. 13, this implies $x_{2} \xrightarrow{\sigma}_{U, 2} y_{2}$, and $y_{1} \approx_{U} y_{2}$ according to (16). If on the other hand $y_{1} \in A n n_{1}$, then $\sigma=\tau$ and $y_{1}=\left(x_{1}, a\right)$ for some $a \subseteq \Sigma_{\omega}$ by Def. 7. Since $x_{1} \approx x_{2}$ and $\left(x_{1}, a\right)=y_{1} \in A n n_{1}$, it follows from Def. 11 that $\left(x_{2}, a\right) \in A n n_{2}$. Then $x_{2} \xrightarrow{\tau}{ }_{U, 2}\left(x_{2}, a\right)$ by Def. 13 and $y_{1}=\left(x_{1}, a\right) \approx_{U}\left(x_{2}, a\right)$ by (17).

If (17) holds, then $x_{1}=\left(x_{1}^{\prime}, a\right) \in A n n_{1}$ and $x_{2}=\left(x_{2}^{\prime}, a\right) \in A_{2} n_{2}$ for some $a \subseteq \Sigma_{\omega}$, and $x_{1}^{\prime} \approx x_{2}^{\prime}$. Then it follows from $\left(x_{1}^{\prime}, a\right) \xrightarrow[\rightarrow]{\sigma}_{U, 1} y_{1}$ by Def. 13 that $\sigma \in a, y_{1} \in Q_{1}$, and $x_{1}^{\prime} \xrightarrow{\sigma}_{1} y_{1}$. Since $x_{1}^{\prime} \approx x_{2}^{\prime}$, there exists $y_{2} \in Q_{2}$ such that $x_{2}^{\prime} \xrightarrow{\sigma}_{2} y_{2}$ and $y_{1} \approx y_{2}$. Then $\left(x_{2}^{\prime}, a\right) \xrightarrow{\sigma}_{U, 2} y_{2}$ by Def. 13 since $\sigma \in a$, and $y_{1} \approx_{U} y_{2}$ by (16) since $y_{1} \approx y_{2}$.

This shows (i) in Def. 12. The proof of (ii) is symmetric, and the condition on the initial states follows since $A_{1} \approx A_{2}$ and $A_{i}$ and $\mathscr{U}\left(A_{i}\right)$ have the same initial states.
Proposition 6 Let $A_{1}$ and $A_{2}$ be annotated automata such that $A_{1} \approx A_{2}$. Then $A_{1} \simeq_{\text {conf }} A_{2}$.
Proof Let $U_{1}$ be an unannotated form of $A_{1}$, and let $U_{2}$ be an unannotated form of $A_{2}$. Then $U_{1} \simeq_{\text {conf }} \mathscr{U}\left(A_{1}\right) \approx \mathscr{U}\left(A_{2}\right) \simeq_{\text {conf }} U_{2}$ by Prop. 2 and Lemma 14 . The claim follows from results in [12], according to which bisimilar automata are conflict equivalent.

## 5 Experimental Results

A conflict checker using annotated automata has been implemented in the DES software tool Supremica [1] and tested on the same set of industrial-scale and parametrised models as used previously in [9]. All these problems have been solved successfully, and the results are shown in Table 1.

After simplifying each individual component in a composed system such as (3), the algorithm selects a candidate set of automata for composition using strategies described in [9]. After synchronous composition and hiding of local events, the result is first simplified using observation equivalence and by removing obvious certain conflicts [9]. Then the annotated form is constructed and simplified using incoming equivalence and bisimulation. Subsumption is used during each of these steps. Finally, an unannotated form is obtained and further simplified by removing states with only silent outgoing transitions.

The Annotating Method described above has been compared to the Heuristic Method described in [9]. The heuristic compositional conflict checker of [9] selects and composes candidate sets of automata in the same way as the annotating method, but it uses a more straightforward set of abstraction rules to simplify automata. In addition to the Certain Conflicts Rule and observation equivalence, which are part of the preprocessing steps in the Annotating Method, the Heuristic Method also uses the Active Events Rule, the Silent Continuation Rule, the Only Silent Incoming Rule, and the Only Silent Outgoing Rule [9]. All these rules are directly applied to the transitions of an automaton, without computing an annotated form. This makes the rules simpler to apply, but they also have somewhat weaker abstraction potential, as it can be shown that all abstractions obtained using the above mentioned rules and more can in principle be achieved by simplifying an annotated automaton.

To make the Annotating and Heuristic Method comparable, they have been modified to ensure that both implementations select and compose the same automata in the same order, regardless of possible differences in the intermediate results. This is done to compare the effects of the different simplification methods, as opposed to comparing different choices of automata for composition (which often lead to dramatic changes). However, the chosen order of composition is no longer optimal, which explains the difference between the results in Table 1 and [9].

Table 1 shows the experimental results for nonblocking verification of 14 large models of industrial-scale applications and 9 very large parametrised models. Please refer to [9] for a more detailed description of the models. The table shows the number of reachable states of the synchronous product of each model (Size), and the number of states of the largest automaton encountered during compositional verification (Peak States), the cumulative number of states constructed during verification (Total States), and the total verification time in seconds, for both the Annotating Method and the Heuristic Method,

All experiments were run on a standard laptop computer with a 2 GHz microprocessor and 4 GB of RAM, and controlled by state limits. If during abstraction some synchronous product has more than 10,000 states, its construction is aborted and another set of automata is composed instead. If no suitable set of automata for composition can be identified, a final attempt is made to construct and check the full synchronous product of all remaining automata whether it is nonblocking. If this attempt runs out of memory, the run is aborted and the corresponding table entries are left blank.

The annotating conflict checker performs much better than the heuristic method for the parametrised dining philosophers and tree arbiter problems, which cannot be solved by the heuristic method using the given state limits and candidate selection strategy. For the industrial applications, the two methods yield similar results, with the Annotating Method

Table 1 Experimental results

|  | Size | Annotating |  |  | Heuristic |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

producing a smaller peak number of states in 5 cases, and the Heuristic Method producing a smaller peak number of states in 4 cases. The difference is particularly notable for the $A G V$ and ftechnik models, where the annotating method results in larger automata. This seems to be caused by the annotating and unannotating steps, which may change the structure of an automaton in such a way that certain states are no longer observation equivalent. The more regular parametrised examples do not suffer from this issue, and the Annotating Method works better here.

Table 2 shows some information on the effectiveness of the individual steps taken by the annotating method. First, it shows for each model the total number of annotations created and removed by subsumption. Next, it shows the total number of states removed as unreachable after annotation (Ann.), the number of states removed by merging incoming equivalent $\left(\sim_{\text {inc }}\right)$ and bisimilar $(\approx)$ states, and the number of states added back in when constructing unannotated forms (Unann.). Note that $\approx$ refers to simplification of annotated automata and is in addition to observation equivalence simplification, which is performed on all automata before annotating.

In most cases, annotating helps to remove substantially more states than need to be added back during unannotation. The data clearly shows the importance of the subsumption step, which is performed directly while constructing the annotated form. While merging incoming equivalent and bisimilar states seems to have a limited effect for most industrial models, it has a marked effect for some of the more regular models in the dining philosophers and arbiter series.

Table 2 Rule Usage

|  | Annotations |  | States |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |

## 6 Conclusions

This paper shows how annotations can be used for compositional nonblocking verification. Methods to construct annotated automata and to compute abstractions are presented, and their correctness is proved formally. Experimental results show that the performance of nonblocking verification using annotations is comparable to existing methods of simplifying automata with respect to conflict equivalence.

In addition, annotations lead to an improved structure and more regular nondeterministic automata, and help to better understand the nature and possibilities of conflict-preserving abstractions. So far, three simplification rules for annotated automata have been implemented, and it is already known that the framework allows for other more powerful ways of conflictpreserving abstraction.

In the future, the authors would like to the investigate identification of implicit transitions with respect to conflict equivalence and their selective introduction to aid bisimulation reduction of annotated automata. Another topic of future work is the investigation of alternatives to the unannotation procedure, to avoid the construction of additional states by verifying nonblocking using only annotated automata.
