5. CONCLUSION

## ABSTRACT

The spatial cycles hypothesis is investigated through the analytical method of ROXY index. Consideration is given to both "spatial centralization and decentralization phenomena" and "spatial concentration and deconcentration phenomena" of population in Japan; the former phenomena correspond to the intra-metropolitan redistribution processes of population, while the latter correspond to the inter-metropolitan redistribution processes of population. It may be laid down as a general rule that the empirical results of the study would reasonably support the basic conceptual framework of the spatial cycles hypothesis.

## KEY WORDS

Urban Systems, Centralization, Concentration,  
Metropolitan Analysis, ROXY Index, and Spatial Cycles.

The author is grateful to the participants of the Twenty-seventh European Congress of the Regional Science Association, Athens, Greece, August 25-28, 1987, for the helpful comments on an earlier draft of this paper, as well as to Ms. Masako Miyaoka for assistance in producing graphic charts. The supports for the research from the Kajima Foundation's Research Grant and Grant-in-Aid Scientific Research (B) of the Ministry of Education, Science and Culture, are also gratefully acknowledged.

## 1. INTRODUCTION

The characteristic of a nation's specific urban change has, in general, twin facets: (1) spatial centralization of population; and (2) spatial concentration of population. The former phenomena correspond to the agglomeration of population into centers, rather than into suburbs, of each metropolitan areas. The latter phenomena correspond to the agglomeration of population toward larger metropolitan areas from both smaller- and non-metropolitan areas. The spatial cycles hypothesis<sup>1)</sup>, however, implies that the characteristic of urban change in a nation also possesses another pair of facets: (1) decentralization of population within each metropolitan areas; and (2) deconcentration of population in a system of metropolitan areas. In the above context, the phenomena of the spatial centralization and decentralization of population should be recognized as the intra-metropolitan redistribution processes of population, while the phenomena of the spatial concentration and deconcentration of population should be recognized as the inter-metropolitan redistribution processes of population.

The primary objective of this paper is to investigate, based on the spatial cycles hypothesis and the ROXY index method<sup>2)</sup>, the staging of intra- and inter-metropolitan redistribution processes of population in Japan during the period of 1960 through 1985. For this purpose, we start with a discussion of the basic concepts of ROXY index in the next Section. In Section 3, the values of ROXY index for five consecutive five-year periods between 1960 and 1985, are calculated for four urbanized units. These four spatial units are Tokyo metropolitan area and its three major railway-line regions. Tokyo metropolitan area is the largest among the eighty-six metropolitan areas (FUCs)<sup>3)</sup> in Japan, and has its 143 component localities (*i.e.*, subareas). The first of the three major railway-line regions, on the other hand, is the Chuo Line region stretching westwards from the central business district (CBD) of Tokyo city. It consists of fifteen localities situated along the Chuo Line which is the busiest commuting railway line in Tokyo metropolitan area. The second one is the Takasaki Line region. It consists of eighteen localities situated along the Takasaki Line which is among the extremely busy major commuting railway lines in Tokyo metropolitan area. This region extends northwestwards from the CBD of Tokyo city. The third one is the Joban Line region stretching northeastwards from the CBD of Tokyo city along the Joban Line which is also quite a busy major commuting railway line in Tokyo metropolitan area. This region has fourteen component localities. In the same Section, we examine, based on the calculated values of ROXY index, the staging of intra-metropolitan urban changes for the four urbanized spatial units. We also try to compare the stage of spatial cycles among the three railway-line regions. In Section 4, we calculate the values of ROXY index for the Japanese urban system, and carry out an inter-metropolitan analysis on urban changes. Brief concluding remarks are pro-

ROXY INDEX ANALYSIS OF POPULATION CHANGES IN JAPAN FOR 1960-85 (Kawashima)  
vided in Section 5.

In our study we employ two sets of data. The first set is the population data for Tokyo metropolitan area (*i.e.*, Tokyo FUC) consisting of 143 component localities. The second set is the population data for the Japanese urban system composed of eighty-six metropolitan areas. Both data sets carry the information on the level of population in every five years from 1960 to 1985.

## 2. ROXY INDEX: DEFINITIONS AND IMPLICATIONS

The ROXY index for the period between year  $t$  and year  $t+1$  is generally defined as;

$$\left( \frac{\text{weighted average annual growth ratio}}{\text{simple average annual growth ratio}} - 1.0 \right) \times 10^4$$

Since we are interested in the spatial changes of population, the annual growth ratio appearing in this definitional formulation should be the population level in year  $t+1$  divided by the population level in year  $t$ .

**Table 1** ROXY Index for the Period between Year  $t$  and Year  $t+1$   
(Weighting Factor: Reversed Distance from Subarea to CBD,  
*i.e.*,  $d_{max} + d_{min} - d_i$ )

---

$$\text{ROXY Index} = \left( \frac{\text{weighted average growth ratio}}{\text{simple average growth ratio}} - 1.0 \right) \times 10^4$$

$$= \left[ \frac{\sum_{i=1}^n RD_i r_i^{t,t+1}}{\sum_{i=1}^n RD_i} \times \frac{n}{\sum_{i=1}^n r_i^{t,t+1}} - 1.0 \right] \times 10^4$$

$$= \frac{n \sum_{i=1}^n RD_i r_i^{t,t+1} - \sum_{i=1}^n RD_i \times \sum_{i=1}^n r_i^{t,t+1}}{\sum_{i=1}^n RD_i \times \sum_{i=1}^n r_i^{t,t+1}} \times 10^4$$

where

- $RD_i$  : Reversed distance from subarea  $i$  in a metropolitan area to its CBD which is defined as " $d_{max} + d_{min} - d_i$ "
- $d_i$  : Distance from subarea  $i$  in a metropolitan area to the CBD of the central city of the metropolitan area to which that subarea belongs
- $d_{max}$  : Maximum value of  $d_i$  ( $i = 1, 2, 3, \dots, n$ )
- $d_{min}$  : Minimum value of  $d_i$  ( $i = 1, 2, 3, \dots, n$ )
- $r_i^{t,t+1}$  : Population growth ratio of subarea  $i$  for the period between year  $t$  and year  $t+1$ , growth ratio being defined as the population level in year  $t+1$  divided by the population level in year  $t$
- $n$  : Number of subareas

The weighting factor which we use to calculate the value of ROXY index for our intra-metropolitan analysis is the “reversed distance.” For subarea  $i$  in the metropolitan area under investigation, the reversed distance is defined as;

the sum of “distance to the center of the metropolitan area from the subarea which is nearest to the center” and “distance to the metropolitan center from the subarea which is farthest from the center” subtracted by “distance to the metropolitan center from subarea  $i$ .<sup>4)</sup>

The ROXY index with the reversed distance as weighting factor, is mathematically presented in Table 1. Implications of the value of this kind of ROXY index are summarized in Table 2. As shown by this table, positive value of ROXY index for a specific period of time would imply that the centralization (or intra-metropolitan urbanization) of population is taking place during that period in the metropolitan area under investigation. If the positive value of ROXY index is increasing, unchanged, or decreasing over two adjacent periods, then the speed of population centralization is accelerating, stabilizing or decelerating respectively during those two periods. In case the value of ROXY index remains around zero during a specific period of time, the symmetric growth or decline of population<sup>5)</sup> is taking place in the metropolitan area during that period. In case the value of ROXY index for a specific period of time is negative, it would be implied that the decentralization (or suburbanization) of population is going on in the metropolitan area during that period. If the negative value of ROXY index is increasing, unchanged or decreasing over two adjacent periods, then the speed of suburbanization is decelerating, stabilizing or accelerating respectively.

For our inter-metropolitan analysis, meanwhile, we use the ROXY index for which the weighting factor is the population of each metropolitan area. Table 3 shows the mathematical formulation of this ROXY index, while Table 4 summarizes the implications of the value of this kind of ROXY index. As indicated by Table 4, positive value of ROXY index for a specific period of time would imply the concentration (or inter-metropolitan urbanization) of population during that period from smaller- and non-metropolitan areas to larger metropolitan areas. If the positive value of ROXY index is increasing, unchanged or decreasing over two adjacent periods, then the speed of population concentration in the system of metropolitan areas under investigation is accelerating, stabilizing or decelerating respectively. In case the value of ROXY index remains around zero during a specific period of time, the symmetric growth or decline of population<sup>6)</sup> in the system of metropolitan areas is taking place during that period. In case the value of ROXY index for a specific period of time is negative, then this would tell us that the deconcentration of population is taking place in the system of metropolitan

ROXY INDEX ANALYSIS OF POPULATION CHANGES IN JAPAN FOR 1960-85 (Kawashima)

**Table 2** Implications of ROXY Index for Intra-metropolitan Spatial Redistribution Processes of Population (Weighting Factor: Reversed Distance from Subarea to CBD, i.e.,  $d_{max} + d_{min} - d_i$ )

(i)	(ii)	(iii)	(iv)
Value of ROXY Index	Intra-metropolitan Spatial Redistribution Pattern of Population Shares	Direction of Changes in Value of ROXY Index	Speed of Spatial Redistribution of Population
ROXY > 0	Centralization of Population (Agglomeration of Population)	 (1) Accelerating (2) Stabilizing (3) Decelerating	(1) Accelerating (2) Stabilizing (3) Decelerating
ROXY = 0	Symmetric Growth or Decline of Population (viz. BGD, BSGD or CSGD of Population)	 0.0 → 0.0	Can not be specified
ROXY < 0	Decentralization of Population (Dispersion or Suburbanization of Population)	 (1) Decelerating (2) Stabilizing (3) Accelerating	(1) Decelerating (2) Stabilizing (3) Accelerating

(Note)

1.  $d_i$  : Distance from subarea  $i$  in a metropolitan area to the CBD of its central city to which that subarea belongs
2.  $d_{max}$  : Maximum value of  $d_i$  for the metropolitan area
3.  $d_{min}$  : Minimum value of  $d_i$  for the metropolitan area
4. BGD : Balanced Growth or Decline (Namely, the growth rate curve is nearly flat, reflecting the constant share of population over different distance-zone groups of subareas in a metropolitan area.)
5. BSGD : Bell-Shaped Growth or Decline (Namely, the growth rate curve is bell-shaped, reflecting the "medianization" of population over distance-zone groups of subareas. This "medianization" means increase in population share by middle distance-zone group of subareas and, at the same time, decrease in population share by near and far distance-zone groups of subareas.)
6. CSGD : Cup-Shaped Growth or Decline (Namely, the growth rate curve is cup-shaped, reflecting the "bipolarization" of population over distance-zone groups of subareas. This "bipolarization" means increase in population share by near and far distance-zone groups of subareas and, at the same time, decrease in population share by middle distance-zone group of subareas.)
7. In this table, special attention should be paid to that, if we use  $d_i$  (the distance from subarea  $i$  in a metropolitan area to the CBD of its central city to which that subarea belongs) as weighting factor, then positive value of ROXY index would imply the intra-metropolitan decentralization phenomena (suburbanization phenomena) of population while negative value of ROXY index would imply the intra-metropolitan centralization phenomena (i.e., intra-metropolitan urbanization phenomena) of population.

**Table 3** ROXY Index for the Period between Year  $t$  and Year  $t+1$   
(Weighting Factor: Population of Metropolitan Area)

$$\text{ROXY Index} = \left( \frac{\text{weighted average growth ratio}}{\text{simple average growth ratio}} - 1.0 \right) \times 10^4$$

where

Weighted average growth ratio:

$$\sum_{i=1}^n X_{i,t+1} / \sum_{i=1}^n X_{i,t}$$

Simple average growth ratio:

$$\sum_{i=1}^n (X_{i,t+1}/X_{i,t}) \times \frac{1}{n}$$

$X_{i,t}$ : Population level of metropolitan area  $i$  in year  $t$

$n$  : Number of metropolitan areas

**Table 4** Implications of ROXY Index for Inter-metropolitan Spatial Redistribution Processes of Population (Weighting Factor: Population of Metropolitan Area)

(i)	(ii)	(iii)	(iv)
Value of ROXY Index	Inter-metropolitan Spatial Redistribution Pattern of Population Shares	Direction of Changes in Value of ROXY Index	Speed of Spatial Redistribution of Population
ROXY > 0	Concentration of Population (Agglomeration of Population)	→ (1) → (2) → (3)	(1) Accelerating (2) Stabilizing (3) Decelerating
ROXY = 0	Symmetric Growth or Decline of Population (viz. BGD, BSGD or CSGD of Population)	0.0 → 0.0	Can not be specified
ROXY < 0	Deconcentration of Population (Dispersion of Population)	→ (1) → (2) → (3)	(1) Decelerating (2) Stabilizing (3) Accelerating

(Note)

1. BGD : Balanced Growth or Decline (Namely, the growth rate curve is nearly flat, reflecting the constant share of population over different population-size groups of metropolitan areas.)
2. BSGD : Bell-Shaped Growth or Decline (Namely, the growth rate curve is bell-shaped, reflecting the "medianization" of population over population-size groups. This "medianization" means increase in population share by medium population-size group of metropolitan areas and, at the same time, decrease in population share by small and large population-size groups of metropolitan areas.)
3. CSGD : Cup-Shaped Growth or Decline (Namely, the growth rate curve is cup-shaped, reflecting the "bipolarization" of population over population-size groups. This "bipolarization" means increase in population share by small and large population-size groups of metropolitan areas and, at the same time, decrease in population share by medium population-size group of metropolitan areas.)

ROXY INDEX ANALYSIS OF POPULATION CHANGES IN JAPAN FOR 1960-85 (Kawashima) areas during that period. If the negative value of ROXY index is increasing, unchanged or decreasing over two adjacent periods, then the speed of inter-metropolitan deconcentration of population is decelerating, stabilizing or accelerating respectively.

### 3. CHANGE IN VALUES OF ROXY INDEX: INTRAMETROPOLITAN ANALYSIS

Table 5 furnishes the value of ROXY index for Tokyo FUC and its three major railway-line regions<sup>7)</sup>. From this table, we can draw Figure 1 diagrammatically showing the change in the value of ROXY index. Table 5 shows that the ROXY index for Tokyo FUC decreased continuously from 44.00 for the 1960-65 period to -35.80 for 1975-80, with the positive sign turning negative towards the end of the 1960s. It then began to increase to -24.61 for the 1980-85 period. This would imply, according to Table 2, that the phenomena of the centralization of population were observed in Tokyo FUC until the end of the 1960s, with the speed of centralization decelerating. After that Tokyo FUC entered the suburbanization stage, with the speed of suburbanization accelerating until the end of the 1970s. In the early 1980s, however, the speed of suburbanization began to decelerate.

For the Chuo Line region, the ROXY index remained negative throughout the whole twenty-five year period of 1960 through 1985, but it increased continuously from -193.09 for the 1960-65 period to -43.59 for 1980-85. This would imply that the Chuo Line region was being deceleratingly suburbanized in the past quarter century.

For the Takasaki Line region, the ROXY index decreased from -46.98 for the 1960-65 period to -101.98 for 1965-70. It then began to increase to have the value of -44.38 for 1980-85. This would imply that the Takasaki Line region was being acceleratingly suburbanized until the late 1960s. After that, the speed of suburbanization was being decelerated continuously in this region.

For the Joban Line region, the ROXY index decreased from -51.12 for the 1960-65 period to -143.50 for 1970-75. It then began to increase to -124.60 for 1975-80 and to -77.24 for 1980-85. It would imply that the accelerating suburbanization was taking place until the middle of the 1970s. After that, the speed of suburbanization process started decelerating in this region.

From Table 5, we now construct Table 6 which shows the marginal values of ROXY index for each five-year period. Based on Table 6, we can produce Figure 2. This figure transforms the aforementioned "spatial cycles implications" into a scheme of "visual paradigm of spatial cycles" which is conceived in terms of the two-dimensional plane with the value of ROXY index along the horizontal axis and marginal value of ROXY index along the vertical axis<sup>8)</sup>. The essence of what this

**Table 5** ROXY Index for Tokyo FUC and Its Three Railway-line Regions

(Weighting Factor: Reversed Distance to CBD)

**Figure 3** Implications of Circular Diagram for Spatial Cycles

visual paradigm of spatial cycles would tell us, can be presented through the circular diagram shown in Figure 3<sup>9)</sup>. Referring to Figure 3, Figure 2 enables us to perceive visually that among the three major railway-line regions in Tokyo FUC the Chuo Line region had been always at the most advanced stage along the circular path in the spatial cycles scheme since 1960, followed by the Takasaki Line region, and then by the Joban Line region. Figure 2 would also draw us to perceive casually that the Chuo Line region will perhaps be the first one among the three major railway-line regions to enter the accelerating centralization stage (*i.e.*, recentralization stage) in the foreseeable future, from the present decelerating suburbanization stage.

#### 4. CHANGE IN VALUES OF ROXY INDEX: INTER-METROPOLITAN ANALYSIS

Table 7 furnishes the value of ROXY index for the Japanese metropolitan system of eighty-six FUCs. From this table, we can draw Figure 4 which diagrammatically shows the change in the value of ROXY index. Table 7 indicates that the ROXY index for the Japanese metropolitan system remained positive throughout the twenty five years since 1960, but that it decreased continuously from 118.05 for the 1960–65 period to 0.74 for 1975–80. It then increased to 17.57 for the 1980–85. This would imply, according to Table 4, that before 1980 the population had been always agglomerating to larger metropolitan areas, with the speed of concentration decelerating. However, during the 1980–85 period, the population concentration became somewhat reaccelerated.

In the same way as we have done for four urbanized spatial units, from Table 7 we can construct Table 8 showing the marginal values of ROXY index. Based on

**Table 7** ROXY Index for Japanese Metropolitan System of 86 FUCs  
(Weighting Factor: Population of Metropolitan Area)

Number of FUCs	Period				
	1960-65	1965-70	1970-75	1975-80	1980-85
86	118.05	85.71	40.06	0.74	17.57

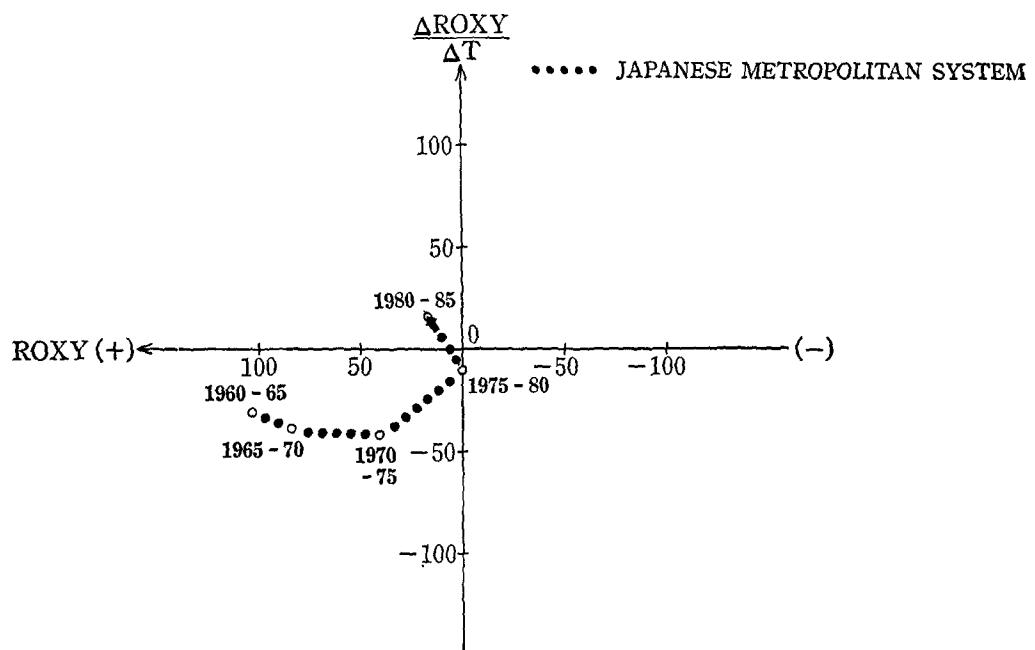

Figure 5 ROXY Index and Its Marginal Change  
(Weighting Factor: Population of Metropolitan Area)

## ROXY INDEX ANALYSIS OF POPULATION CHANGES IN JAPAN FOR 1960-85 (Kawashima)

this table, we can produce Figure 5 which transforms the spatial cycles implications discussed above for the Japanese metropolitan system, into a visual paradigm of spatial cycles. Referring to interpretations analogous to those provided by Figure 3 for the visual paradigm of spatial cycles, Figure 5 addresses us at least three possibilities. One is that the Japanese metropolitan system already got into the reconcentration stage for the 1980-85 period and would remain in that stage for a while, skipping both accelerating and decelerating deconcentration stages. The second possibility is that the abrupt sharp reverse turn of the curve for the 1980-85 period would not necessarily indicate the actual basic trend of spatial cycle movement of the Japanese metropolitan system but that the abrupt turn had better be considered as showing merely a short-term tendency. The third possibility is that the application of spatial cycles hypothesis to the analysis of population changes in the Japanese system of metropolitan areas would not be appropriate. The results of the next population census of Japan which will take place in 1990 will possibly provide us with some answers to this argument.

## 5. CONCLUSION

This paper has tried to investigate how the spatial cycles hypothesis and the method of ROXY index can work together for getting a better insight into the dynamic characteristics of urban changes: urban changes in terms of both intra- and inter-metropolitan redistribution processes of population. It seems to have been demonstrated that the analytical approach employed in this paper would be useful to a reasonable extent for the study of spatial redistribution processes though it should be clearly kept in mind that our approach still has to be further improved in many aspects.

### NOTES

- 1) The spatial cycles hypothesis argues that the life-cycle of metropolitan areas recurrently follows four successive metamorphous stages; (1) urbanization stage, (2) suburbanization stage, (3) disurbanization stage, and (4) reurbanization stage. The basic framework of the spatial cycles hypothesis was originally conceived by Klaassen and Paelinck (1979), and was well discussed, for example, by Klaassen et al. (1981).
- 2) See Kawashima (1982) for the initial application of ROXY index, and Kawashima (1985) for a detailed discussion on the definitional aspects of ROXY index. See also Kawashima (1986a, b and c) for the application of ROXY index method to the analyses of intra-metropolitan redistribution processes of population in Japan, and Kawashima (1987) for the application of ROXY index method to the analysis of inter-metropolitan redistribution processes of population in Japan as compared with those in the U.S.
- 3) These eighty-six metropolitan areas are called Functional Urban Cores (FUCs), and are the Japanese version of Standard Metropolitan Statistical Areas (SMSAs) in the

3. Calculation of the Marginal Change in the Value of ROXY Index:

For the period 1960-65;

$$ROXY(1965-70) - ROXY(1960-65)$$

For the periods 1965-70, 1970-75, and 1975-80 respectively;

$$\{ROXY(1970-75) - ROXY(1960-65)\}/2$$

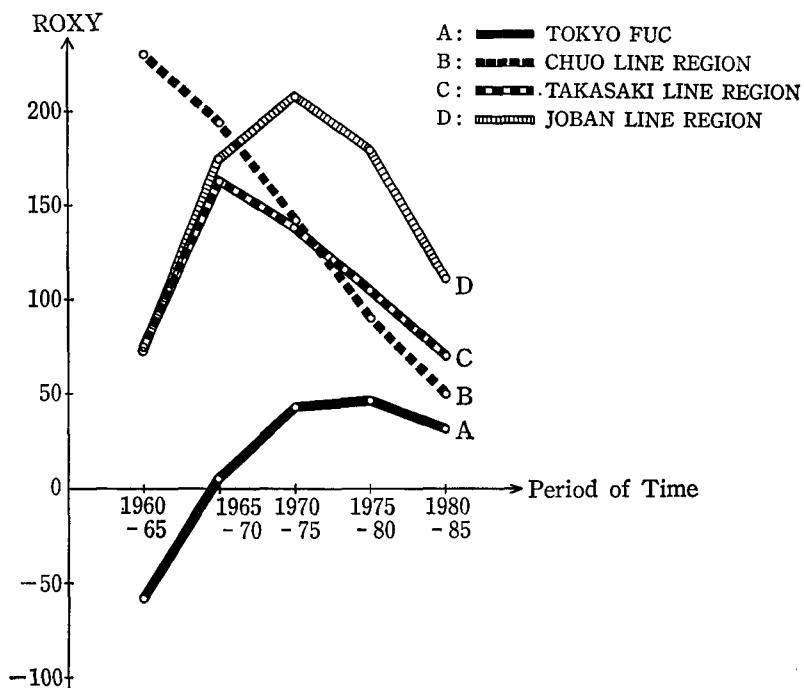

$$\{ROXY(1975-80) - ROXY(1965-70)\}/2$$

$$\{ROXY(1980-85) - ROXY(1970-75)\}/2$$

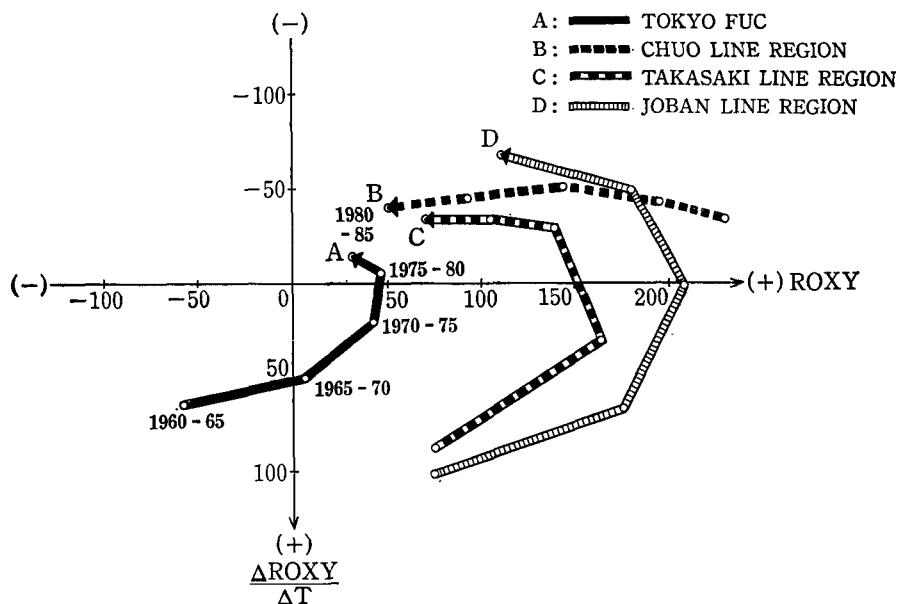

For the period 1980-85;

$$ROXY(1980-85) - ROXY(1975-80)$$

ROXY INDEX ANALYSIS OF POPULATION CHANGES IN JAPAN FOR 1960-85 (Kawashima)

**Figure N-1** Value of ROXY Index (Weighting Factor: Distance to CBD)

**Figure N-2** ROXY Index and Its Marginal Change  
(Weighting Factor: Distance to CBD)

**Table N-3** ROXY Index for Tokyo FUC and Its Three Railway-line Regions  
(Weighting Factor: Inverse of Distance to CBD)

Spatial Unit	Number of Localities	Period				
		1960-65	1965-70	1970-75	1975-80	1980-85
Tokyo FUC	143	-213.31	-263.45	-237.20	-157.36	-93.63
Chuo Line Region	15	-524.46	-397.43	-262.43	-133.54	-82.90
Takasaki Line Region	18	-478.59	-482.87	-339.66	-187.79	-116.80
Joban Line Region	14	-421.70	-452.21	-395.12	-289.10	-162.79

**Table N-4** Value of ROXY Index and Its Marginal Change for Tokyo FUC and Three Railway-line Regions  
(Weighting Factor: Inverse of Distance to CBD)

Spatial Unit	1960-65		1965-70		1970-75		1975-80		1980-85	
	ROXY	$\Delta\text{ROXY}/\Delta T$								
Tokyo FUC	-213.31	-50.14	-263.45	-11.95	-237.20	53.05	-157.36	71.79	-93.63	63.73
Chuo Line Region	-524.46	127.03	-397.43	131.02	-262.43	131.95	-133.54	89.77	-82.90	50.64
Takasaki Line Region	-478.59	-4.28	-482.87	69.47	-339.66	147.49	-187.79	111.43	-116.80	71.09
Joban Line Region	-421.70	-30.51	-452.21	13.29	-395.12	81.56	-289.10	116.17	-162.79	126.31

(Note) 1.  $\Delta T$ : Five Years

2.  $\Delta\text{ROXY}/\Delta T$ : Marginal Change in the Value of ROXY Index

3. Calculation of the Marginal Change in the Value of ROXY Index:

For the period 1960-65;

$$\text{ROXY}(1965-70) - \text{ROXY}(1960-65)$$

For the periods 1965-70, 1970-75, and 1975-80 respectively;

$$\{\text{ROXY}(1970-75) - \text{ROXY}(1960-65)\}/2$$

$$\{\text{ROXY}(1975-80) - \text{ROXY}(1965-70)\}/2$$

$$\{\text{ROXY}(1980-85) - \text{ROXY}(1970-75)\}/2$$

For the period 1980-85;

$$\text{ROXY}(1980-85) - \text{ROXY}(1975-80)$$

ROXY INDEX ANALYSIS OF POPULATION CHANGES IN JAPAN FOR 1960-85 (Kawashima)

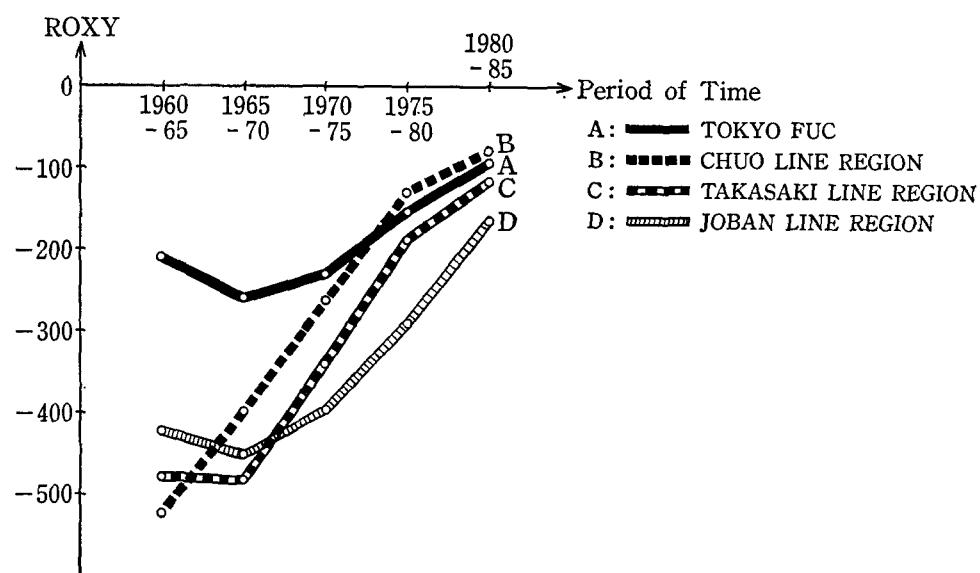

Figure N-3 ROXY Index (Weighting Factor: Inverse of Distance to CBD)

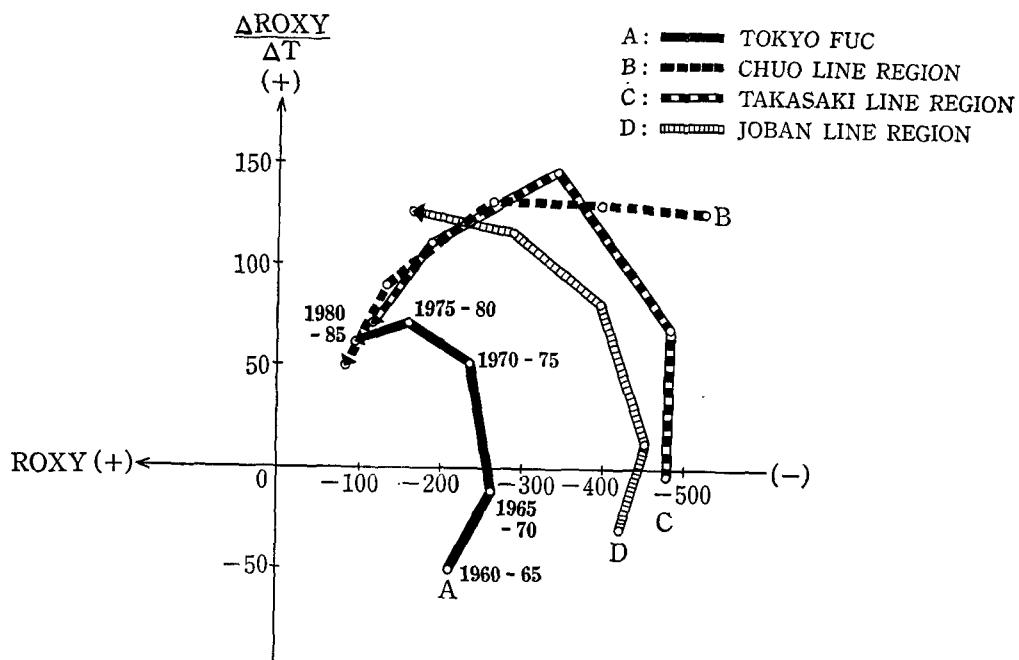

Figure N-4 ROXY Index and Its Marginal Change  
(Weighting Factor: Inverse of Distance to CBD)

U.S. For the details of the delineation of FUCs, see Kawashima (1982).

4) Among other possible alternative variables to be used as weighting factor for the intra-metropolitan analysis are: (1) distance to the metropolitan center from subarea  $i$ , and (2) inverse of distance to the metropolitan center from subarea  $i$ . Though the former variable was previously used as weighting factor in Kawashima (1986a, b and c), we employ in the present study "reversed distance" as weighting factor so that the positive or negative value of ROXY index would indicate the population agglomeration or dispersion respectively. This correspondence between the sign of ROXY index and population agglomeration/dispersion phenomena can be consistent with that shown in Table 4 for the inter-metropolitan analysis. The latter variable (inverse of distance), in the meantime, can also keep the consistent with the contents of Table 4. However, the author decided not to employ it as a weighting factor since the weight will turn out to be unreasonably large if the value of the distance is extremely small.

5) Symmetric growth or decline of population would primarily represent, as described by notes 4, 5 and 6 of Table 2, (1) balanced growth or decline, (2) bell-shaped growth or decline, or (3) cup-shaped growth or decline.

6) Detailed explanations of symmetric growth or decline of population in a system of metropolitan areas, are furnished by notes 1, 2 and 3 of Table 4.

7) The values of ROXY index shown in this Table and Tables N-1 and N-2 as well, have been calculated based on Tables A-1 through A-4. Meanwhile, the values of ROXY index were previously analyzed for Tokyo FUC and its three major railway-line regions by Kawashima (1986s). In that analysis, he used the data for Tokyo FUC with 121 localities instead of 143 localities and employed distance instead of reversed distance as weighting factor. The increase in the number of component localities of Tokyo FUC in the present paper is consequent upon the disaggregation of Tokyo city, which served as one spatial entity in the author's 1986 paper, into twenty-three smaller spatial units (*i.e.*, special wards).

8) For the purpose of reference, the marginal value of ROXY index and the visual paradigm of spatial cycles are shown by Tables N-1 and N-2 and Figures N-1 and N-2 for ROXY index with the weighting factor of distance to CBD, and by Tables N-3 and N-4 and Figures N-3 and N-4 for ROXY index with the weighting factor of inverse of distance to CBD.

9) See Kawashima (1986b) for a more detailed discussion on the circular diagram framework though it should be noted that in that paper the lower portion of the vertical axis in the circular diagram presents positive values and that its upper portion presents negative values.
