# A Factor Analysis of Investment Behaviour for Small Investors in the Hong Kong Stock Market

# By Tai-Yuen HON<sup>†</sup>

**Abstract.** Hon (2012) found that small investors were overconfident and bought more stock during the buoyant market in the Hong Kong stock market. Small investors also exhibited herd behaviour. In this paper we extend his paper to identify and analyse the important factors that capture the behaviour of small investors in the Hong Kong stock market, especially during the financial crisis. Exploratory factor analysis is employed to analyse the data, we found that monitor investments is the second important factor and reference group is the most important factor.

Keywords. Factor analysis, Small investors, Stock market, Hong Kong. JEL. E22, G02, G10.

#### **1. Introduction**

Horizon construction of the study of behavioural financial market in the Hong Kong stock market. Small investors also exhibited herd behaviour. Exploratory factor factors and provide the the study of the study of

This paper is organised as follows: Section 2 reviews the related literature; Section 3 explains the methodology of the present study; Section 4 reports the research findings; and Section 5 provides the conclusion.

### 2. Literature Review

Although many personal and situational factors may influence the behaviour of small investors in the stock market, research on this topic is sparse. Previous studies found that interpersonal influence (Hoffmann & Broekhuizen, 2009), knowledge (Wang, 2009), and some other personal factors such as gender and personality traits (Durand et al., 2008) are crucial in explaining investment behavior. However, it is important to explore the psychological processes (such as perception, attitudes, learning, and motivation) that affect individual's decision

<sup>&</sup>lt;sup>†</sup> Hong Kong Shue Yan University, Department of Economics and Finance, Braemar Hill, North Point, Hong Kong. China.

<sup>🖹. 25707110 🗹.</sup> tyhon@hksyu.edu

regarding investment. For example, one's gender and educational level (i.e., individual factors) may affect his or her knowledge and orientation in investment, which then influences the risk perception, and finally his or her investment behaviour. Graham et al. (2009) noted that male investors, and investors with larger portfolios or more education, are more likely to perceive themselves as competent as are female investors, and investors with smaller portfolios or less education. Hoffmann & Post (2012) found that past returns positively impact investors' return expectations and risk tolerance, and negatively impact their risk perception. Besides, Korniotis & Kumar (2011) suggested that older peoplemake better investment choices as they gain more investmentknowledge and experience, or whether their investment skilldeteriorates with age is largely due to the adverse effects of cognitiveaging.

Obviously, the notion of risk tolerance is highly important for investor's assets allocations. The determinants of risk tolerance are central to the study of behavioural finance. Portfolio theory postulates that risk tolerance is a salient factor in portfolio construction and asset allocation. Risk tolerance, reflecting a person's attitude towards taking on risk, is a complex psychological concept. Jackson et al. (1972) contended that risk tolerance has four dimensions: financial, physical, social, and ethical. Hoffmann et al. (2011) showed how an investor's perceptions change, drive trading and risk-taking behaviour, and impact investment performance during the financial crisis of 2007-2009. They noted that revisions in return expectations and risk tolerance are positively, and revisions in risk perceptions are negatively, related to overall market developments. Successful investors had higher return expectations and lower risk tolerance, which led them to trade less, take less risk, and have lower buy-sell ratios. Hallahan et al. (2004) found that people's self-assessed risk tolerance and ProQuest risk tolerance score (RTS) generally accord, and there is considerable variation with a tendency for respondents to underestimate their risk tolerance. Wang & Hanna (1997) showed that risk tolerance increases with age when other variables have been controlled.

As argued by Shefrin (2000), the financial community ignores the psychology of investing at its own peril. Beyond greed and fear illuminate behavioural finance for today's investors. Behavioural finance can help practitioners to recognize and avoid bias and error in their decisions, as well as to modify and improve their overall investment strategies. Tversky & Kahneman (1974) defined availability as the situation which people assess the frequency or probability of an event by the ease with which instances can be brought to mind. Generally speaking, availability is the degree to which information is readily available. Availability bias exists when the investors wrongly weight the importance or relies upon available information for decision making without examining other alternatives (Sewell, 2010). Singh (2012) pointed out that individual investors can benefit by increasing awareness of the various human biases and the high costs they impose on their portfolio. Law (2010) argued that traditional risk disclosure requirements, known as financial risk disclosure, cannot sufficiently protect retail investors from cognitive and psychological biases. Kannadhasan (2006) reported that an optimum investment plays an active role and is a significant consideration. There is suggestive evidence that the experience of the investor has an explanatory role in this regard with less experienced investors being prone to extrapolation (i.e., representativeness), while more experienced investors commit the gambler fallacy, which is misconception of chance. Tversky & Kahneman (1971) defined gambler's fallacy as a misconception of the fairness of the law of chance. Under gambler's fallacy, people apply small samples as well as to large samples.

### 3. Data and Method

The data for the present study were collected from small investors in Hong Kong through a survey questionnaire. The main purpose of the survey is to collect their opinions, investment behaviour, and financial decision-making behaviour in the stock market. The survey was conducted between October and November 2008. The snowball method was adopted to select individuals aged 18 or above in Hong Kong population. A group of undergraduate students helped to distribute 1,200 questionnaires to the respondents. Finally, there were 1,199 selected respondents who completed and returned the questionnaires and this represents a response rate of 99.92 per cent.Before we begin using the survey dataset for factor analysis, we need to ensure the survey results are reliable enough. According to Carmines & Zeller (1987), reliability focuses on the extent to which the empirical indicator provides consistent results across repeated measurements. In testing the applicability of survey results, we used the Cronbach alpha (Cronbach, 1947; Cronbach & Shavelson, 2004) to test the reliability. Also, we use the coefficient of variation for comparing the reliability and precision of the results of our survey (Bruton, 2000) which are subject to sample error and non-sampling error. It should be noted that the measure used to assess the statistical significance of the item was the coefficient of variation (CV), which expresses the ratio of the standard error to

the arithmetic mean  $C.V. = \frac{S_{\overline{X}}}{|\overline{X}|}$ . The CVs for each of questionnaire items have

been shown in the table 1. Taking a look at these CVs, we can find the maximum and minimum value is 1.91% and 0.99% respectively with mean 2.73%. Accordingly, it was considered the consensus had been achieved when the level of item was on the statistically significant (that is  $CV \le 5\%$ )

Factor analysis is employed to identify the key factors that affect the behaviour of small investors in the Hong Kong stock market. We make the factor structure more interpretable. The initial extracted factor matrix must be rotated before the final factor solution is achieved. Bartlett's test of sphericity and Kaiser-Meyer-Olkin measure of sampling adequacy are both tests that can be used to determine the factorability of the matrix as a whole. If Bartlett's test of sphericity is large and significant and the Kaiser-Meyer-Olkin measure is greater than 0.6, then factorability is assumed. If the sums of squares of the loadings on the extracted factors are no longer dropping but are remaining at a low and rather uniform level, factor extraction may be reasonably terminated. Cattell's (1966) Scree test is based on this principle. SPSS use a default option of extracting all principal factors with eigenvalues of 1.0 or more (i.e., the Kaiser-Guttman rule). The main thing to consider in deciding when to stop factoring is that it is better to err on the side of extracting too many factors rather than too few. One of the most commonly used is Cronbach's coefficient  $\alpha$ , which is based on the average correlation of items within a reliability test if the items are standardised. Cronbach's coefficient  $\alpha$  can be interpreted as a correlation coefficient; it ranges in value from 0 to 1. However, content validity refers to the representativeness and comprehensiveness of the items used to create the scale. It is assessed by examining the process through which the scale items are generated (Straub 1989; Woobock & Kim 2002). In this research, the definitions of behavioural finance were initially proposed based on reviews of Tversky & Kahneman (1971, 1974). Previous studies on behavioural finance and other disciplines were comprehensively reviewed to develop the measurement items. On the other hand, construct validity examines the extent to which a scale measures a theoretical variable of interest. There are many different aspects of construct validity that have been proposed in psychometric literature

(Bagozzi et al. 1991; Straub 1989). To test construct validity, factor analysis with varimax rotation were performed. For convergent validity, the corrected item-to total correlation (that is, the correction of each item to the sum of the remaining items) is appropriate.

# 4. Results

The coefficient of variation (CV) of the estimates of the main items in the survey questionnaire and the profile of the respondents is reported in Table 1.

The majority of the respondents were under the age of 50 (85.6%), and only 14.4% were aged 51 or above. The median income was \$12,034. 37.4% of the respondents monitored their investments with a short-term investment horizon the

same today compared with the period before the market decline at the end of October 2007.Also, 47.2% of the respondents monitored their investments with a long-term investments horizon the same today compared with the period before the market decline at the end of October 2007. These group may have superiority in strategy formulation in decision making than those who responded "Yes". These groups of small investors were overconfident.In view of the above demographic profile of the respondents, we believe that they are representative of small investors in Hong Kong.

 Table 2: Descriptive statistics

The importance of various items on the behaviour of small investors when they invested on stock market is presented in Table 2. All the items are statistically significant with high mean values. To identify the underlying dimensions of the items, which are perceived to be important by the respondents, the 10 items were then factor analysed. Initial visual assessment of the correlation matrix indicated considerable degree of inter-factor correlation (see Table 3). In addition, from the factor correlation matrix, the Barlett test of Sphericity ( $\rho < 0.000$ ) and the Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy index (with a value of 0.546) confirm the appropriateness of the data for exploratory factor analysis.

Item name (see also Table3) 1.Reference group affects investment decision today, 2. Reference group affected past investment decision, 3.Monitor short-term investments, 4. Monitor long-term investments, 5.Age, 6. Personal income, 7. Forecasting the future market development, 8. Announcements from companies, 9. Factor for bear market, 10.Reason for investment failure

Given that our aim was to identify the minimum number of factors that would account for the maximum portion of variance of original items, the principal component analysis was selected (Nunnally, 1978) to reduce the number of factors with an eigenvalue greater than 1. A cumulative percentage of variance explained being greater than 50% is the criteria used in determining the number of factors. On the basis of the criteria, five factors were extracted (see Table 4).

Item	Item name	Commu	Factor	Eigen	Per cent	Cumulat
		nality	(Compo	value	of	ive per
			nent)		variance	cent
1	Reference group affects investment	0.813	1	1.877	18.768	18.768
	decision today					
2	Reference group affected past	0.811	2	1.545	15.451	34.219
	investment decision					
3	Monitor short-term investments	0.716	3	1.268	12.678	46.897
4	Monitor long-term investments	0.704	4	1.052	10.520	57.417
5	Age	0.720	5	1.013	10.130	67.547
6	Personal income	0.700				
7	Forecasting the future market	0.786				
	development					
8	Announcements from companies	0.513				
9	Factor for bear market	0.534				
10	Reason for investment failure	0.459				

Table 4: Principal component analysis

The five factors, collectively, accounted for a satisfactory 67.547% of the variance. Communality values in between 1.0 and 0 indicate partial overlapping between the items and the factors in what they measure. Furthermore, the communality column, provides further evidence of the overall significance, albeit, moderate, of the solution. The underlying rationale for the Scree test is based on the fact that within a set of items, a limited number of factors are measured more precisely than the others. By graphing the eigenvalues, we found that the smaller factors form a straight line sloping downward. The dominant factors will fall above the line. Figure 1 demonstrates a five-factor solution is obtained.

Figure 1: Scree plot

			Factor				
Item	А	В	С	D	Е	Item name	Factor
1	0.900					Reference group affects	А
						investment decision today	
2	0.898					Reference group affected past	А
						investment decision

10					0.651	Reason for investment failure	Е

Table 5: Varimax-rotate	ed principal	component	loadings
-------------------------	--------------	-----------	----------

Having established that the analysis has provided a stable solution, examination of the varimax-rotated principal component loading was performed (see Table 5). The cumulative factors revealed that the first factor accounts for 18.768% of the variance. The second factor accounts for 34.219% of the variance. The third factor accounts for 46.897% of the variance. The fourth factor accounts for 57.417% of the variance. Finally, the fifth factor accounts for 67.547% of the variance. After the rotation, there are no negative loadings on any consequence on factor A, factor B, factor C, factor D or factor E. We found five factors affecting the behaviour of small investors in the Hong Kongstock marketas follows: factor A might be interpreted as reference groupwhich includescommentators' recommendations from newspapers/TV/magazines, relatives/friends, Internet, investment consultants, and companies' annual reports; factor B as monitor investments which includesmonitor short-term and long-term investments; factor C as personal background which includesage, personal income; factor D as reaction to announcements which includes announcements and other information from companies, forecasting the future market developmentand factor E as cognitive style which includes factor for bear market and reason for investment failure. The specific name given to each factor is designed to reflect an item or notion that conceptually relates to the rest of the items under a particular factor.

 Table 6: Internal consistency and related decisions of first structure

Factors and items	Corrected item- total correlation	α value	Decision	
Factor A (Reference Group)				
Reference group affects investment decision today	0.6155	0.7619	Retained	
Reference group affected past investment decision	0.6155			
Factor B (Monitor Investments)				
Monitor short-term investments	0.4436	0.6145	Retained	
Monitor long-term investments	0.4436			
Factor C (Personal Background)				
Age	0.3149	0.4370	Eliminated	
Personal income	0.3149			
Factor D (Reaction to announcements)				
Forecasting the future market development	0.2060	0.3380	Eliminated	
Announcements from companies	0.2060			
Factor E (Cognitive Style)				
Factor for bear market	0.0214	0.0410	Eliminated	
Reason for investment failure	0.0214			

The reliability test is reported in Table 6. At this point only initial of internal reliability of the expected factors was performed in the form of Cronbach's coefficient  $\alpha$ . For the purposes of this study, the cut-off value adopted was 0.5 (Nunnally, 1978) and the acceptable benchmark level of item-to-total correlation was set above 0.3. Corrected item-total correlation gives the Pearson correlation coefficient between the score on the individual item and the sum of score on the remaining items. Following the decision relating to the internal reliability, the factors were re-specified. This was undertaken to further reduce the number of factors. The internal reliability of the first structure was tested and the decision results provide evidence as to the weakness of the structure since two factors (factor A and B) exceeded the adopted criteria. It is found that factor A contains two items and relates to "reference group". Factor B is made up of two items and refers to "monitor investments". The derived scales appear to possess moderate to weak internal consistency. So, we eliminated among factors C, D and E (see Table 7).

Items	Number of item	Corrected item-total correlation	α value
Factor A (Reference Group)		0 (1 5 5	0 = (10
Reference group affects investment decision today	2	0.6155	0.7619
Reference group affected past investment decision		0.6155	
Factor B (Monitor Investments)			
Monitor short-term investments	2	0.4436	0.6145
Monitor long-term investments		0.4436	

 Table 7: Internal consistency of final revised structure

To examine possible differences in the perceived importance of five factors, our analyses indicate that out of four criteria (i.e., rotated principal component loadings, scree test, KMO and Bartlett's test, reliability test) examined, only two factors (reference group and monitor investments) are significant. Based on these results, monitor investmentsis the second important factor and reference group is the most important factor.

### 5. Conclusion

The primary objective is to identify and analyse the important factors that capture the behaviour of small investors in the Hong Kong stock market. Using factor analysis, we identify five factors that capture the behaviour of small investors in the Hong Kong stock market. The factors are reference group, monitor investments, personal background, reaction to announcements and cognitive style. The factor of reference group includes commentators' recommendations from newspapers/TV/magazines, relatives/friends, Internet, investment consultants, companies' annual reports; the factor of monitor investments includes monitor short-term and long-term investments; the factor of personal background includes age and personal income; the factor of reaction to announcements includes announcements and other information from companies, forecasting the future market development and the factor of cognitive style includes factor for bear market and reason for investment failure. In order to examine possible differences in the perceived importance of the five factors, our analysis indicate that out of four criteria (including rotated principal component loadings, scree test, KMO and

Bartlett's test, and reliability test) examined, only two factors (i.e., reference group, monitor investments) stand out to be significant. Accordingly, it can be concluded that monitor investments the second important factor and reference group is the most important factor
