**Abstract:** Liquid range of nanofluids is a crucial parameter as it intensively determines their application temperature scope. Meanwhile, improved thermal conductivity and stability are of great significances and comprise the main fundamental research topics of nanofluids. In this work, 2-butoxy-3,4-dihydropyran (DP), produced from a convenient one-pot three-component reaction in water, was employed as dual lipophilic brusher and metal nanoparticle anchor. It was found that DP was able to enhance the dispersing ability and thermal conductivity of SiO<sub>2</sub> nanoparticle filled deep eutectic solvent (DES) based nanofluids simultaneously. The key to the success of this protocol mainly relies on the electrophilic property and acetylacetonate moiety of DP, which ensures the formation of DP surficial modified and copper nanoparticle coated silica. Molecular dynamics simulation revealed that the hydrogen bonding effect between base solvent and alkane chain of nanoparticle was responsible for the enhanced affinity, which thus resulted in an improved stability. Viscosities of the nanofluids dropped within a certain range owing to the ruin of hydrogen bonding association among solvent molecules resulted by the hydrogen bonding effect between nanoparticle and solvent. Thermal conductivity of the copper modified silica filled DES nanofluids exhibits a maximum 13.6% enhancement, which demonstrated the advantages of this chemical covalent protocol. Additionally, study upon viscosity and convective heat transfer coefficient of the nanofluids with varies types of silica nanoparticle and DES base solvents indicated that a 24.9% heat transfer coefficient enhancement was gained that further revealed the superiority of this protocol.

**Key words:** Nanofluids; chemical modified silica; deep eutectic solvents; energy transportation.

## Introduction

Nanoscale materials and devices hold great potential for improved energy conservation, conversion, or harvesting. Heat transfer fluids, also known as working fluids, have a crucial role in thermal transport applications.<sup>1-3</sup> However, traditionally used working fluids, such as water, mineral oil or organic alcohol were heavily limited by their relatively poor thermal conductive performance.<sup>4</sup> In particular, with the rapid advances of electrical setup and continuous shrinkage of mechanic facilities, highly efficient heat removal has been becoming an urgent demand.<sup>5-7</sup> Nanofluid, which was first termed by Choi, mainly constituted by a nanofiller and a base solvent, was a good solution to the poor thermal conductivity of single phase working fluid.<sup>8-10</sup> Base solvent has a vital role in nanofluids since it determines the main thermophysical properties, eg. thermal conductivity, dragging coefficient, boiling point and melting point, etc. Moreover, it is the place for reserving nanoparticle, it highly impacts the dispersing ability and stability of the nanofluid system. Traditionally used base solvent can be generally classified into water, mineral oil and organic alcohol.<sup>11, 12</sup> As evidenced on their common inherent physical properties, they are quite limited by their relatively short liquid range, which will become invalid under complex temperature conditions or specific device requirements. Ionic liquid, emerging as a new base solvent alternative, has been gaining continuous interest due to less volatile, high boiling point and chemical stability. While, ionic liquid usually suffers from high cost, tedious preparation process and environmental issues.<sup>13-15</sup> Meanwhile, high temperature molten salt is another widely adopted base solvent system mainly works for the field of high temperature solar collector.<sup>16</sup> However, the high melting point of the salt is the main obstacle as it will inevitably cause the clogging of the flow system at a low temperature. Therefore, exploring a new base solvent system that could fulfil both wide liquid range and environmental benign requirement is an urgent topic that needs to be deeply studied.

Deep eutectic solvent (DES), which is mainly constituted by two or three simple chemicals through intermolecular hydrogen bonding effect, has attracted ample attention owing to its similar properties with traditionally used ionic liquids.<sup>17-20</sup> DES has been proven to possess high boiling point and less volatile. In addition, it contains vast, nonsymmetric ions that have low lattice energy and thus low melting points. Notably, compared with ionic liquid, it is much less costly and environmental friendly. So far, it has been widely adopted in catalysis, electrochemistry, material

1  
2  
3 chemistry and so on.<sup>20, 21</sup> The research for its application as a working fluid and a base solvent of  
4 nanofluids for heat transportation has also been initiated.<sup>22-26</sup> Despite its superior thermophysical  
5 properties in terms of wide liquid range and accessibility, the stability issue of its based nanofluid  
6 is another problem that restricts its development. Adding a dispersant is a wide recognized protocol  
7 to address dispersing problem as it can inhibit the aggregation of nanoparticle. Whereas, it seems to  
8 be ineffective towards the DES base solvent system since the existence of dispersant, which usually  
9 composed by a cation and anion, will undoubtedly cause the interference of hydrogen bonding  
10 between the hydrogen donor and acceptor components and lead to the complexity of the whole  
11 solvent system.<sup>27, 28</sup> On the other hand, aging of dispersant would lead an irreversible damage of  
12 working efficiency of nanofluids during a long-term using.<sup>29, 30</sup> Decomposition of dispersant in  
13 some extreme condition, such as high temperature, would accelerate the failure process of the  
14 nanofluid. Further, the existence of dispersant in nanofluids also brings some negative influence to  
15 the performance of nanofluids, for instance, viscosity increase and thermal conductivity reduction.<sup>31</sup>  
16 Therefore, so far, a DES based nanofluid should face the problem of the absence of a dispersant. To  
17 alleviate this problem, a nanoparticle that has a good affinity with DES, such as coordination or  
18 hydrogen bonding effect, was recommended. However, this effect also brings some negative aspects  
19 to the behaviour of nanofluids, for example, our previous work revealed that the addition of Al<sub>2</sub>O<sub>3</sub>  
20 nanoparticle resulted in a decreasing of thermal conductivity of glycerol/chlorine DES nanofluids  
21 owing to the motion activity declining of glycerol molecule caused by the hydrogen bonding  
22 association with Al<sub>2</sub>O<sub>3</sub>.<sup>32</sup>

Covalently installing an organic chain on the surface of nanoparticle is an efficient way to improve the stability of nanofluids in particular for organic solvent based nanofluids owing to the affinity enhancement between nanoparticle and base solvent. Some relevant research can be found in literatures, for example, Lukehart et al. demonstrated the deaggregation of an oxidized ultradispersed diamond in dimethylsulfoxide (DMSO) followed by reacting with glycidol monomer to produce a covalent surface modified nanodiamond filled ethylene glycol (EG) based nanofluid.<sup>33</sup> The research results indicated that the covalent nanodiamond modification gave a 2-fold greater thermal conductivity than that of hydrogen-bonding interaction modification strategy at the similar concentration. Zhang et al. synthesized a graphene which possessed a similar molecular chain with

1  
2  
3 ionic liquid [HMIM]BF<sub>4</sub>, it was verified that the dispersion stability was greatly enhanced owing to  
4 the covalent modification.<sup>34</sup> The photo conversion performance of nanofluids was also enhanced as  
5 a consequence of the promising stability. Previously, we developed Lewis acid catalysis induced  
6 ring-opening reactions of 2-butoxy-3,4-dihydropyran (DP) with various of nucleophiles, among  
7 them, mercaptans quite stood out that it was able to react with DP with high regio-selectivity and  
8 yields.<sup>35-40</sup> Inspired by this reaction, we envision that DP deemed to be able to link onto the surface  
9 of SH containing silica with the aid of a Lewis acid. Moreover, owing to the coordination effect of  
10 acetylacetonate moiety in DP molecule, copper can be anchored on the surface of this modified  
11 silica with the purpose of thermal conductivity enhancement.

21 In this paper, in order to find a high thermal conductivity and stable DES based nanofluid system  
22 to address the short liquid range of traditional base solvent system based nanofluids (**Fig. 1**), a  
23 covalent modification and metal hybrid protocol on silica nanoparticle was investigated. SH  
24 containing silica nanoparticle was synthesized from TEOS and MPTMS through a sol-gel reaction  
25 with the aid of catalytic amount of *n*-hexadecylamine. The synthesized silica was subjected to react  
26 with DP under the catalysis of Lewis acid ZnCl<sub>2</sub>. The copper nanoparticle was evenly coated on the  
27 surface of silica thanks to the anchoring effect derived from the acetylacetonate group on the surface  
28 of silica moiety. The stability improvement mechanism behind was revealed by using molecular  
29 dynamic simulation approach. Nanofluids prepared from DP modified silica and DES were studied  
30 comprehensively regarding their stability and thermo-physical properties.

### 41 **Results and discussion**

42  
43 Our study commenced from the synthesis of DP derivative. 1-(Vinyloxy)butane, aqueous  
44 formaldehyde and acetylacetone were mixed and allowed to stir at 80 °C for 6 hours to complete  
45 the reaction in almost quantitative yields which were in good accordance with the results reported  
46 by Gu et al.<sup>41</sup> SH containing silica, SiO<sub>2</sub>-SH, synthesized from TEOS and MPTMS, some reaction  
47 parameters, including catalyst, solvent and reaction temperature etc., were applied to explore a  
48 uniform size distributed nanoparticle. After a careful study upon the synthetic parameters, the  
49 optimized reaction condition was determined to be 17.6 mol% of *n*-hexadecylamine as catalyst,  
50 H<sub>2</sub>O/EtOH 18/35 (*V/V*) as solvent, reacted at 50 °C for 20 h. DP decorated silica, which was named  
51 as SiO<sub>2</sub>-SH-DP, was then prepared by treating SiO<sub>2</sub>-SH with excess amount of DP under the  
52

1  
2  
3 catalysis of 20 mol% of  $\text{ZnCl}_2$ . The final copper coated silica nanoparticle,  $\text{SiO}_2\text{-SH-DP-Cu}$ , was  
4  
5 obtained by treating  $\text{SiO}_2\text{-SH-DP}$  with  $\text{Cu}(\text{acac})_2$  and  $\text{NaBH}_4$  sequentially (**Fig. 2**). To facilitate  
6  
7 reading and understanding, the name of different silica nanoparticle was listed and explained in  
8  
9 table 1. After synthesis of the chemical modified silica nanoparticle, some analyses with respect to  
10  
11 the above mentioned three different kinds of materials were conducted. As shown in **Fig. 3a-c**, SEM  
12  
13 images show that the morphology of the as-prepared chemical modified silica displays a uniform  
14  
15 size distribution with a sphere like shape. TEM images (**Fig. 3d-e**) further proved that the  
16  
17 morphology of the obtained materials is a uniform sphere structure with an average diameter of  
18  
19 around 300 nm. It should be mentioned that the surface of the prepared  $\text{SiO}_2\text{-SH}$  material is quite  
20  
21 smooth without observation of nanoporous structure. The morphology of DP modified  $\text{SiO}_2\text{-SH}$   
22  
23 shows no significant change after fixing with organic linker that neither nanoparticle aggregation  
24  
25 nor broken of the nanoparticle is observed from the TEM image (**Fig. 3h**). What's more, the surface  
26  
27 of the silica nanoparticle is seemly smoother than that of  $\text{SiO}_2\text{-SH}$  owing to the existence of the  
28  
29 organic chain derived from DP. Interestingly, the surface of the silica becomes rough after coating  
30  
31 with Cu nanoparticle as evidenced in **Fig. 3i**, which clearly demonstrates the existence of Cu on the  
32  
33 surface of DP modified silica. Meanwhile, diameter of the  $\text{SiO}_2\text{-SH-DP-Cu}$  increases a little bit due  
34  
35 to the contribution of Cu layer. Moreover, there is no observation of nanoparticle destruction or  
36  
37 aggregation after a blending with copper acetate and reduction treatment. Moreover, EDS mapping  
38  
39 further evidences that Cu and other elements were uniformly distributed on the surface of  $\text{SiO}_2\text{-SH-}$   
40  
41  $\text{DP-Cu}$  (**Fig. 3j**).

42  
43 XRD spectra of the above mentioned three different types of silica samples were tested. As shown  
44  
45 in **Fig. 4a**, all of the silica samples display a typical  $\text{SiO}_2$  peak appeared at  $2\theta=22.5^\circ$ , which illustrates  
46  
47 the main component of the sample is still  $\text{SiO}_2$ . While, we did not find the response of copper from  
48  
49 the spectra of  $\text{SiO}_2\text{-SH-DP-Cu}$ , probably due to the relatively low concentration of Cu in the sample.  
50  
51 FT-IR spectra of the prepared samples in **Fig. 4b** proves the successful covalently bonding of DP  
52  
53 on the surface of  $\text{SiO}_2\text{-SH}$  since the observation of peak in  $1750\text{ cm}^{-1}$ , which is attributed to the  
54  
55 carbonyl group of ring-opening structure of DP. The adsorption peak in the range of  $1700\text{-}1750$   
56  
57  $\text{cm}^{-1}$  becomes boarder when loaded Cu on the surface of  $\text{SiO}_2\text{-SH-DP}$ , which reveals the  
58  
59 coordination effect of Cu on carbonyl group, and this phenomenon is quite in agreement with the  
60

1  
2  
3 literature result.<sup>42</sup> <sup>13</sup>C MAS NMR was also conducted to prove the covalent bond formation between  
4 SiO<sub>2</sub> and DP. As shown in **Fig. 4c**, the appearance of peak at 203.1 ppm is assigned to the carbonyl  
5 group of SiO<sub>2</sub>-SH-DP, accompanied by the appearance of a characteristic band of a carbonyl group  
6 at 1700 cm<sup>-1</sup> in FT-IR spectra, constitute a strong evidence of the nondestructive tethering of an  
7 acetylacetonate fragment on the surface of SiO<sub>2</sub>-SH. Furthermore, TGA curves also provide an  
8 indirect evidence to support the covalently formation of the SiO<sub>2</sub>-SH-DP that a sharp weight loss  
9 happened at a temperature higher than 350 °C, which can be explained by the decomposition of  
10 organic fragment on SiO<sub>2</sub>-SH-DP. Interestingly, the total weight loss of SiO<sub>2</sub>-SH-DP-Cu is  
11 decreased by 9% compared to SiO<sub>2</sub>-SH-DP, we ascribed the reason to the shielding effect of the  
12 copper shell on the surface of SiO<sub>2</sub>-SH-DP and the weight incremental influence which given by  
13 copper nanoparticle. XPS analysis with respect to the silica nanoparticle was also conducted. In the  
14 XPS pattern of the C 1s region, contributions of C-O (287.6 eV), C-C (285.1 eV), and C=C (284.2  
15 eV) bonds can all be found in the sample of SiO<sub>2</sub>-SH, which corresponds to the alkane chain in the  
16 chemical modified silica (**Fig. 4e**). After covalently reacted with DP, a new peak in 287.6 eV, which  
17 can be ascribed to the C=O, is observed in the XPS pattern (**Fig. 4g**). On the other hand, there is no  
18 observation of Cu peaks in the XPS spectra of SiO<sub>2</sub>-SH, while, peaks at 732.5, 952.3 eV is found in  
19 SiO<sub>2</sub>-SH-DP-Cu, proves the existence of Cu (**Fig. 4f and 4h**). Along with the Cu 2p response, the  
20 XPS data constituted a solid evidence that DP is linked on the skeleton of silica and Cu is also a key  
21 component in SiO<sub>2</sub>-SH-DP-Cu.

With the chemical modified silica nanoparticle in hand, we initiated the study on its performance  
in nanofluids in terms of stability and some thermo-physical properties. In this work, we chose two  
representative DESs, glycerol (GL)/chlorine chloride (ChCl) and EG/ ChCl. As is well known, GL  
is a kind of green solvent which was mainly produced as a by-product of biodiesel. As the rapid  
expansion of biodiesel demand caused by shortage of fossil resource, a significant glut of global GL  
market is under continuous growing.<sup>43</sup> Thus, utilization GL, in particular for high value-added using  
has been becoming a bottleneck of the advance of biodiesel industry.<sup>44,45</sup> Meanwhile, as a matter of  
fact, EG is a good alcohol type working fluid that has been widely adopted in both academia and  
industry owing to its low cost, accessibility and chemical stability.<sup>46</sup> Especially, the mixture of 40-  
50 vol% EG in water has been well recognized to be used as a coolant due to its low freezing point.<sup>47,</sup>

<sup>48</sup> In addition, ChCl is also a bio-degradable chemical that was usually used as an animal food additive. Despite GL/ChCl and EG/ChCl DESs have been studied towards as base solvents of nanofluids, they usually restricted by poor stability and thermal conductivity.<sup>32, 49</sup> Therefore, nanoparticle that can be dispersed in DES with superior stability and thermal conductivity would be highly desirable. To verify the feasibility of the prepared silica nanoparticle, GL/ChCl DES based nanofluids were fabricated. Thermal conductivity of the nanofluids was firstly considered. To ease the influence of the testing uncertainties, thermal conductivity in a certain condition was tested for ten times, data described in following text was the average of the testing results. As shown in **Fig. 5a** and **5b**, thermal conductivity of GL/ChCl DES was observed to possess a maximum enhancement of 2.0% after dispersing 1.0 wt% of SiO<sub>2</sub>-SH-DP-Cu nanoparticle, while SiO<sub>2</sub>-SH and SiO<sub>2</sub>-SH-DP dispersed nanofluids display only comparable thermal conductivity enhancement, clearly indicates the thermal conductive enhancement effect of copper decorated silica nanoparticle. Similar results can be observed in the case of EG/ChCl DES based nanofluids that silica containing copper exhibited an enhancement approximate 5.0%, while, the rest of other two silica nanoparticles show only 1.0-2.0% enhancement (**Fig. 5c** and **5d**). Further, thermal conductivity of GL/ChCl based nanofluids with different amount of SiO<sub>2</sub>-SH-DP-Cu nanoparticle filler was studied. As it is seen in **Fig. 5e** and **5f**, thermal conductivity is increased significantly with the rising amount of nanofiller, 12.5% of thermal conductivity enhancement is observed when 5.0 wt% of nanoparticle was filled in the base solvent. On the other hand, SiO<sub>2</sub>-SH-DP-Cu nanoparticle filled EG/ChCl also displays a remarkable 13.6% of thermal conductivity enhancement after blending 5.0 wt% of nanoparticle in the based DES. Comparing with the reported results summarized in table 2, nanofluids prepared by using this kind of hybrid silica composite displays an obvious superiority in terms of thermal conductivity. Moreover, to the best of our knowledge, this is the first example which adopts a silica into fabrication a DES based nanofluid. It is worth noting that these nanofluids exhibit promising stability that it can kept at ambient temperature for 15 days without observation of obvious precipitation thanks to the alkane chain on the surface of silica. Zeta potential value, the gravity settlement observation results as well as TEM images at different standing time were shown in the supporting information (SI) (**Fig. S1**).

Moreover, viscosity of the nanofluids was tested since pump power input in real application has

1  
2  
3 a great dependence on it, which thus deeply associates with the energy consumption. As it is  
4 displayed in **Fig. 6a**, the addition of 1.0 wt% chemical decorated SiO<sub>2</sub> nanofillers results in a slight  
5 viscosity decrease in GL/ChCl DES base solvent, the same phenomenon can be observed in  
6 EG/ChCl based solvent system. These uncommon experimental results demonstrated that the  
7 addition of nanoparticle could offer a positive effect on the decrease of viscosity. It is well  
8 recognized that viscosity of liquid is mainly determined by the interaction between the molecules.<sup>50</sup>

<sup>51</sup> The decreasing of viscosity was mainly beneficial from interaction between nanoparticles and base solvent, which was mainly constituted by hydrogen bonding effect, thus the hydrogen bonding effect among base solvent molecule, a hydrogen donor component, would be partially ruined. Therefore we assumed that this interrupting effect that caused by the participation of nanoparticle was responsible for the decreasing of relative viscosity.

Viscosities of nanofluids with different mass fraction of nanofiller were then subjected to test. As shown in **Fig. 6c**, viscosities of nanofluids lies below GL/ChCl base solvent when 1.0 wt%, 2.0 wt% and 3.0 wt% of SiO<sub>2</sub>-SH-DP-Cu were used as nanofiller, and the lowest viscosity value is found in the case of 3.0 wt% nanofluids. While the viscosities increase to some degree when the mass fraction of nanoparticle is more than 3.0 %. This result indicated that the shearing effect between nanofiller, which would lead to viscosity increase, has overwhelmed the intermolecular hydrogen bonding effect between nanofiller and base solvent. Therefore, viscosity of the whole nanofluids system was raised. The similar phenomenon was found in EG/ChCl DES based nanofluids, viscosity of nanofluids exhibited an decreasing trend in the initial stage, but rising up after dispersing a mass fraction of nanoparticle more than 2.0% (**Fig. 6d**). Notably, the hydrogen bonding interrupting effect in EG/ChCl DES system which caused by nanoparticle was weaker than that of GL/ChCl owing to its relatively low hydrogen bonding concentration. Therefore, viscosity enhancement phenomenon derived from nanoparticle becomes a dominating factor to impact the performance of the base solvent for EG/ChCl DES system. It should be noted that this uncommon phenomenon has actually been unveiled in literatures, in particular for those solvent system involving fertile intermolecular hydrogen bonding.<sup>51</sup>

After knowing the static characteristics of the as-prepared copper silica hybrid nanoparticle, the convective heat transfer coefficient  $h$  was submitted to study with the aim at understanding the flow

convective performance of the nanofluids. **Fig. 7a** is a schematic diagram of the experimental setup for testing the heat transfer performance of nanofluids, it is constituted by a nanofluids reservoir equipped with a magnetic stirrer, two pumps, a heat transfer test section, a water bath which served as low temperature regulation unit, a flow meter, a tubular heat exchanger and a data acquisition system. Before the  $h$  testing experiment, some factors that related thermophysical properties were calculated. At the first, the density of nanofluids can be calculated as eqn (1) <sup>52</sup>,

$$\rho_{nf} = (1 - \varphi)\rho_{bf} + \varphi\rho_{Particle} \quad (1)$$

where  $\rho_{nf}$ ,  $\rho_{bf}$  and  $\rho_p$  refer to the density of nanofluid, base fluid and nanoparticle, respectively.  $\varphi$  is volumetric fraction of nanoparticles. Assuming that the nanoparticle and the base solvent are in thermal equilibrium, the specific heat capacity of this type mixture can be obtained by eqn (2) <sup>52</sup>,

$$c_{p,nf} = \frac{\rho_p}{\rho_{nf}}c_{p,Particle} + (1 - \varphi)\frac{\rho_{bf}}{\rho_{nf}}c_{p,bf} \quad (2)$$

Where  $c_{p,nf}$  represents the specific heat capacity of nanofluid,  $c_{p,Particle}$  is the specific heat capacity of nanoparticle, and  $c_{p,bf}$  is assigned to specific heat capacity of base fluid. Then the specific heat capacity of nanofluids can be calculated as eqn (3),

$$c_{p,nf} = \frac{\varphi\rho_p c_{p,Particle} + (1 - \varphi)\rho_{bf}c_{p,bf}}{(1 - \varphi)\rho_{bf} + \varphi\rho_p} \quad (3)$$

The average heat transfer rate of working fluids in the  $Q_{nf}$  can be calculated as:

$$Q_{nf} = q_v\rho_{nf}c_{p,nf}(t_{out} - t_{in}) \quad (4)$$

where  $q_v$  is the volumetric flow rate of nanofluids,  $t_{out}$  and  $t_{in}$  are the output and input temperature of nanofluids respectively, and it can be converted to mass flow rate after multiplying the density of nanofluids, thus  $Q_{nf}$  can be calculated as eqn (5):

$$Q_{nf} = q_{mf}c_{p,nf}(t_{out} - t_{in}) \quad (5)$$

Eqn (9) is used to verify the inner temperature of flow pipeline, where  $\lambda$  refers to thermal conductivity of copper,  $t_{w,o}$  and  $t_{w,i}$  are the outside and inner temperature of tube respectively,  $U$  and  $I$  represent the electricity voltage and current displayed in the controller.

$$\phi = \frac{2\pi\lambda(t_{w,o} - t_{w,i})}{\ln\frac{d_o}{d_i}} = UI \quad (6)$$

$t_{w,i}$  can be obtained according to eqn (6), thus, the average convective heat transfer coefficient  $h$  can be calculated using the Newton cooling eqn (7), where  $t_f$  is the average temperature of nanofluids

in the testing tube and it is the mean value of output and input temperature of nanofluids (eqn (8)).

$$h = \frac{Q_{nf}}{\pi d_i (t_{w,i} - t_f)} \quad (7)$$

$$t_f = \frac{t_{out} + t_{in}}{2} \quad (8)$$

$$Re = \frac{ud_i}{\nu} = \frac{\rho_{nf} d_i}{\mu} \cdot u = \frac{\rho_{nf} d_i}{\mu} \cdot \frac{q_v}{\frac{\pi}{4} d_i^2} \quad (9)$$

According to the above equations, thermo-physical properties of different types silica filled EG/ChCl DES based nanofluids were shown in table 3. To facilitate the comparison among different nanofluids and base solvents, we fixed the base solvent of nanofluids at EG/ChCl = 3:1, the mass fraction of nanoparticle at 1.0%. As it is presented in **Fig. 7b** the convective heat transfer coefficients of nanofluids are much higher than that of base solvent regardless of Reynolds number. In the low Reynold number range, SiO<sub>2</sub>-SH displays the optimum convective heat transfer performance mainly due to the relatively smaller size of the SiO<sub>2</sub>-SH compared with the other two chemical modified, for which, a more dynamic Brownian motion could be theoretically expected. While, as the increase of Reynold number, SiO<sub>2</sub>-SH-DP-Cu filled nanofluids affords the superior convective heat transfer coefficient over the rest of two kinds of nanofluids that a 24.9% heat transfer coefficient enhancement was obtained compared with that of base solvent at a Reynolds number of 1400. This phenomenon further proves that the chemical modified silica nanoparticles filled nanofluids not only displays a better thermo-physical performance regarding static state, but also the convective heat transfer in a dynamic condition is beneficial from the existence of Cu on the surface of silica owing to the thermal conductivity enhancement effect.

In order to understand the deep mechanism responsible for the stability improvement of SiO<sub>2</sub>-SH-DP in glycerol, a molecular dynamic simulation was conducted by using SiO<sub>2</sub> nanoparticle as a comparison sample. The molecular dynamic simulations method was demonstrated in supporting information (SI). As it is shown in **Fig. 8a** and **8b**, interface interactions between SiO<sub>2</sub>, SiO<sub>2</sub>-SH-DP and glycerol molecule were taken into account, the bottom part stands for the surface of nanoparticle and the upper dispersing molecule represents the solvent of GL. The number of vicinal oxygen atom on the surface of nanoparticles as a function of radial distribution was plotted in **Fig. 8c**, the area blow the curve thus means the coordinate effect of GL on the vicinal of SiO<sub>2</sub> nanoparticles, it is obvious that the coordination effect between liquid and solid interface becomes

1  
2  
3 stronger after covalent modification of alkane chain, which clearly proves that affinity between  
4 nanoparticle and solvent is improved owing to the existence of alkane chain. In addition, the  
5 diffusion coefficient significantly decreases after decorating with the alkane chain (table 4), which  
6 also supports the assumption that interaction between SiO<sub>2</sub>-SH-DP and glycerol was enhanced  
7 compared with that of SiO<sub>2</sub> and glycerol molecule. Hydrogen bond lifetime analysis regarding  
8 glycerol molecule provides another evidence to the interaction between solid and liquid phase since  
9 it increases from 539.563 fs to 541.798 fs after alkane modification which means that the alkane  
10 chain renders the increment of hydrogen bond interaction thanks to the contribution of interaction  
11 between nanoparticle and solvent molecule. Hence, all of the data obtained from molecular dynamic  
12 simulation could support our hypothesis that the affinity of SiO<sub>2</sub> and glycerol was much improved  
13 due to grafting of alkane chain on its surface, which in turn resulted in the enhancement of stability  
14 of the as-prepared nanofluids.

## 29 **Conclusions**

30  
31 A chemically decorated silica filled DES based nanofluid that could fulfill both thermal conductivity  
32 enhancement and static stability was fabricated by rendering DP derivative as a covalently linker  
33 with the aid of catalytic amount of Lewis acid. DP was employed as dual alkane brush and metal  
34 nanoparticle anchor to ensure the superior performance of SiO<sub>2</sub>-SH-DP-Cu in DES base solvent  
35 system. This work represent the concept of sustainability well since the main raw material, DP, is  
36 made from a convenient three-component reaction in water, and DESs are also produced from  
37 environmental benign solvents and chemicals. Moreover, the synthesized nanofluids were applied  
38 into energy transfer. 12.5% and 13.6% thermal conductivity were achieved in GL/ChCl and  
39 EG/ChCl DES system respectively with a promising stability. The mechanism responsible for  
40 stability enhancement was evidenced by a molecular dynamic simulation that the intermolecular  
41 hydrogen bonding effect between base solvent and nanoparticle has an important role. Given the  
42 wide liquid range, high static thermal conductivity and convective heat transfer efficiency,  
43 nanofluids developed in this article bearing a great potential for further thermal management and  
44 energy harvesting application field.

## Experimental section

### Materials

Unless otherwise noted, the reagents were used as received without further purification. Pure anhydrous glycerol (99.8%) and (3-mercaptopropyl)trimethoxysilane (99.0%) were purchased from Shanghai Aladdin Bio-Chem Technology Co., Ltd. Choline chloride, EG (99.8%), tetraethyl orthosilicate (TEOS) were purchased from National Medicines Corporation Ltd. China. SiC and Fe<sub>3</sub>O<sub>4</sub> were purchased from Nanjing Xianfeng Nanotechnology Company. *n*-Hexadecylamine was purchased from Tokyo Chemical industry Co., Ltd (TCI), Japan. Cupric acetylacetonate was purchased from Sigma-Aldrich Company.

FT-IR spectra were recorded using a Bruker VERTEX 70 FT-IR as KBr discs. Thermal gravimetric analysis (TGA) was carried out on a TA SDT Q600 instrument under a nitrogen atmosphere by heating from room temperature to 800 °C at a rate of 10 °C min<sup>-1</sup>. X-ray diffraction (XRD) patterns were recorded on a diffractometer (Smartlab, Rigaku) with Ni-filtered CuK  $\alpha$  radiation ( $k = 0.154$  nm) at a tube current of 30 mA and a generator voltage of 40 kV. Scanning was performed at a speed of 8 °C min<sup>-1</sup>, from 0 to 80° of  $2\theta$ . The viscosities of nanofluids were measured by digital rotary viscometer (NDJ-79B, Shanghai changji geological instrument Co.LTD, China). The thermal conductivities were measured by a Xiotech TC3000L liquid thermal conductivity analyzer, the testing temperature was adjusted and controlled by a water bath and an insulated chamber. X-ray photoelectron spectra (XPS) were recorded on a SHIMADZU-Kratos AXIS-ULTRA DLD-600W X-ray photoelectron spectrometer at a base pressure of  $2 \times 10^{-9}$  Pa in the analysis chamber using Al K $\alpha$  radiation. Scanning electron microscopy (SEM) images were recorded using a FEI Sirion 200 field-emission scanning electron microscope operating at 10 kV. Transmission electron microscopy (TEM) were recorded using a FEI Tecnai G2 F20 equipped with an X-ray energy dispersive spectroscopy (EDS).

### Uncertainty analysis

Uncertainty analysis is taken into account. Due to the uncertainty of the data acquisition device and thermocouples, the temperature measurement error range for each measuring point is  $\pm 0.5$  °C. The accuracy of rotary viscometer is  $\pm 3\%$  at a working temperature from 0 to 100 °C. The thermal

1  
2  
3 conductivity analyser has an accuracy of  $\pm 3\%$  at a working temperature from  $-200$  to  $150$  °C.  
4

#### 5 **Preparation of SiO<sub>2</sub>-SH**

6  
7 To a 250 ml round bottom flask, *n*-hexadecylamine (3.31 mmol, 0.8 g) was dissolved at room  
8 temperature in an aqueous mixture of water (18 mL) and ethanol (21 mL). Then, tetraethoxysilane  
9 (TEOS, 0.039mol, 4.15 g) and (3-mercaptopropyl)trimethoxysilane (MPTMS, 1.97 g, 0.01 mol)  
10 were premixed in ethanol (14 mL) and simultaneously dropped in the reaction mixture through a  
11 dropping funnel at a 50 °C reaction temperature. The mixture was allowed to stir for another 20 h.  
12  
13 After completion of the reaction, the resulting mixture was subjected to filtration to obtain a white  
14 powder raw silica material. The final SiO<sub>2</sub>-SH nanomaterial (1.89 g) was gained after a soxhlet  
15 washing with methanol as solvent for 48 h and drying in a 60 °C oven for 18 h.  
16  
17

#### 18 **Preparation of SiO<sub>2</sub>-SH-DP**

19  
20 To a 100 mL round bottom flask, SiO<sub>2</sub>-SH (2.0) was mixed with DP (4.0 mmol, 0.85 g) and ZnCl<sub>2</sub>  
21 (0.8 mmol, 0.109 g) in acetonitrile (20 mL). The mixture was heated to 80 °C and stirred at that  
22 temperature for 10 h. After the completion of reaction, the mixture was then undergone a filtration  
23 and ethanol washing for three times. SiO<sub>2</sub>-SH-DP (2.42 mg) was obtained as a white powder after  
24 drying for 18 h in a 60 °C oven.  
25  
26

#### 27 **Preparation of SiO<sub>2</sub>-SH-DP-Cu**

28  
29 To a 100mL round bottom flask, SiO<sub>2</sub>-SH-DP (0.5 g) was mixed with Cu(acac)<sub>2</sub> (0.2 mmol, 52.0  
30 mg) in ethanol (20 mL). The mixture was heated to 70 °C and stirred at that temperature for 24 h.  
31 NaBH<sub>4</sub> (6.873 mmol, 260 mg) was added into the reaction in one portion, the solution was continued  
32 to stir at the same temperature for another 24 h. SiO<sub>2</sub>-SH-DP-Cu (349.8 mg) was obtained as a white  
33 powder after drying for 18 h in a 60 °C oven.  
34  
35

#### 36 **Preparation of GL/ChCl DES<sup>32</sup>**

37  
38 The reaction was conducted in a 500 mL round bottom flask with a magnetic stirrer. GL (150 g,  
39 1.63 mol) was mixed with ChCl (75.5 g, 0.54 mol). The mixture was heated to 100 °C and allowed  
40 to stir for 1 h. GL/ChCl DES was obtained after cooling the mixture to room temperature. Unless  
41 otherwise noted the mole ratio of GL to ChCl and GC to ChCl was 3:1 in this paper.  
42  
43

#### 44 **A typical preparation procedure of nanofluids**

45  
46 The reaction was conducted in a 50 mL glass sealed tube with a magnetic stirrer. GL/ChCl DES

(100 mL) was mixed with silica nanoparticle (varied according to the mass fraction of the nanofiller), the mixture was then heated to 80 °C and allowed to stir for 2 h. After reaction, the mixture was cooled to room temperature. Subsequently, the solution was subjected to sonication (53 KHz) for 2 h to obtain the final nanofluid.

**Fig. 8** Molecule model description of (a) SiO<sub>2</sub>/glycerol system, (b) SiO<sub>2</sub>-SH-DP/glycerol system, (c) the number of vicinal oxygen atom on the surface of nanoparticles as a function of radial distribution.

**Table 1** Summary of silica nanoparticles in this work.

Sample name	Preparation procedure
SiO <sub>2</sub> -SH	Made from TEOS and MPTMS through a base mediated sol-gel method
SiO <sub>2</sub> -SH-DP	Treated SiO <sub>2</sub> -SH with DP under the catalysis of Lewis acid
SiO <sub>2</sub> -SH-DP-Cu	Treated SiO <sub>2</sub> -SH-DP with Cu(acac) <sub>2</sub> and followed by NaBH <sub>4</sub> reduction

**Table 2** Some reported results on the thermal conductivity performance of silica filled nanofluids.

Base solvent	Author	Fraction of silica	Thermal conductivity enhancement (%)	Reference
Water	Hwang et al.	1.0 vol%	3.0	53
Water	Iqbal et al.	1.0 vol%	6.0	54
Water	Yan et al.	5.0 wt%	6.8	55

Ethanol	Mohammad et al.	0.44 vol%	6.0	59
GL	Akilu et al.	2.0 vol%	6.1	60
Water	Guo et al.	0.5 vol%	1.0	61
EG	Guo et al.	1.0 vol%	3.4	61

**Table 3** Some related thermo-physical parameters of EG/ChCl based nanofluids.

Nanoparticle	Density (Kg/m <sup>3</sup> )	Specific heat	Viscosity (mPa·s)
--------------	------------------------------	---------------	-------------------

capacity			
(J/(Kg·K))			
--	1086.4	2.504	24.2
SiO <sub>2</sub> -SH	1083.5	2.503	24.7
SiO <sub>2</sub> -SH-DP	1076.8	2.504	23.4
SiO <sub>2</sub> -SH-DP-Cu	1081.0	2.504	21.8

**Table 4** The diffusion coefficient and lifetime of SiO<sub>2</sub>/glycerol heterogeneous system.

Heterogeneous system	Diffusion coefficient ( $\times 10^{-12} \text{ m}^{-1} \cdot \text{s}^{-1}$ )	Lifetime of hydrogen bond (fs)
SiO <sub>2</sub> /Glycerol	3.32975	539.563
SiO <sub>2</sub> -SH-DP/Glycerol	1.86119	541.798

**For Table of Contents Use Only**

A chemically decorated silica filled DES based nanofluid that could fulfill both thermal conductivity enhancement and static stability was fabricated.
