ARTICLE INFO

ABSTRACT

Laplace formulations are weak formulations of the Navier–Stokes equations commonly used in computational fluid dynamics. In these schemes, the viscous terms are given as a function of the Laplace diffusion operator only. Despite their popularity, recently, it has been proven that they violate a fundamental principle of continuum mechanics, the principle of objectivity. It is remarkable that such flaw has not being noticed before, neither detected in numerical experiments. In this work, a series of objectivity tests have been designed with the purpose of revealing such problem in real numerical experiments. Through the tests it is shown how, for slip boundaries or free-surfaces, Laplace formulations generate non-physical solutions which widely depart from the real fluid dynamics. These tests can be easily reproduced, not requiring complex simulation tools. Furthermore, they can be used as benchmarks to check consistency of developed or commercial software. The article is closed with a discussion of the mathematical aspects involved, including the issues of boundary conditions and objectivity.

1. Introduction

The Navier–Stokes (NS) equations are extensively used in fluid mechanics. They are typically presented, as partial differential equations (PDE), in the following format:

$$\rho \frac{\partial \boldsymbol{v}}{\partial t} + \rho \nabla \boldsymbol{v} \cdot \boldsymbol{v} + \nabla p - \mu \nabla^2 \boldsymbol{v} = 0, \qquad (1)$$

$$\nabla \cdot \boldsymbol{v} = 0, \qquad (2)$$

where ρ is the density, p the static pressure, $\boldsymbol{v}$ the velocity vector and μ the fluid viscosity. Such traditional PDE format is called the *Laplace format* because the viscous terms appear simply in the form of the *Laplace diffusion operator* ∇^2 applied to the velocity vector $\boldsymbol{v}$.

One important aspect of the Laplace diffusion operator is that it does not couple velocity components, as can be seen from its mathematical expression:

$$\nabla^2 \boldsymbol{v} = \begin{bmatrix} \nabla^2 u \\ \nabla^2 v \\ \nabla^2 w \end{bmatrix}. \qquad (3)$$

On the other hand, it is clear from Eq. (1) that the pressure and the convective terms do produce a coupling between velocity components. One naturally expects these features to be also present when solving numerically the Navier–Stokes equations.

In the case of modern numerical schemes based on integral forms (also called weak forms), there are two common approaches: either to use *Laplace formulations*, or to use *Divergence formulations* (see for example, [3,8,9,19,22,23,30,34,44–46,48]). Laplace formulations have been traditionally derived from the Laplace format given in Eqs. (1) and (2). In them, like in such PDE counterpart, the viscous terms depend only on the Laplace diffusion operator:

$$\mu \mathbb{L} \boldsymbol{v} = \text{weak form } [\mu \nabla^2 \boldsymbol{v}]. \qquad (4)$$

On the other hand, Divergence formulations are derived from the Divergence format of the Navier–Stokes equations (see Eqs. (6) and (7) below).

Despite the common use of both formulations, recently, Limache and Idelsohn [20] have shown that Laplace formulations violate a main axiom of continuum mechanics: the principle of objectivity (see [27,15]). In a following article [21], the proof was extended to cover also two-phase flows (i.e. discontinuities and the so called level set methods [22,48]). They also presented the first numerical examples showing the spurious effects of this violation. The examples required the use of the particle finite element method PFEM [16,17].

As it will be shown, the failure of Laplace formulations is caused by an over simplification of the boundary conditions. Simplificative

considerations are standard practice in physics. However, in this case, such unaccurate (but historically accepted) boundary treatment leads to an unforeseen consequence: the violation of a fundamental principle of continuum mechanics. Indeed, the detection of the failure and the understanding of the nature of the error did not come from noticing any problem on boundary conditions but came from noticing *Objectivity* issues. Objectivity played a key role in the discovery of the problem. First, when some numerical simulations showed a strange incapacity of pseudo-fluids (hypo-elastic) materials to achieve rotational motions. Second, when comparisons with the Divergence formulation, which is clearly objective, showed not a boundary condition problem but a volumetric term missed. This eventually lead to the demonstration that the error, made in Laplace formulations, was not simply another boundary condition approximation but, also, an error equivalent to the simulation of a *non-objective* fluid material. Furthermore, in order to emphasize the importance of objectivity, it should be mentioned that the tests presented in this article have been devised not by looking at boundary conditions but by trying to detect objectivity failures.

It is remarkable indeed that such objectivity flaw has not being noticed before, neither detected in numerical experiments, especially considering that Laplace formulations have been in use for several decades. The reason for this situation is probably because in many practical problems those formulations just give the correct physical response. The point made in this paper is that, surprisingly, in other circumstances they just do not. In the present work, it will be shown how a series of carefully devised numerical experiments, have the ability to reveal such problem showing the nonphysical solutions that can be produced by the use of Laplace formulations. Note that these objectivity tests can be easily reproduced, so any researcher working in flow simulation, or any user of CFD programs, can employ them as benchmarks to control consistency of any developed or commercial software.

A formal and careful derivation, applying strictly accurate physical boundary conditions, shows that the source of the problem lies in that Laplace formulations have a missing integral boundary term. The point made in the previous articles [20,21], and extended here to the case of slip boundary conditions, is that this missing term cannot be neglected and actually is extremely important. If one does take it into account, one arrives to a *corrected Laplace formulation* which is objective and, as a consequence, consistent. Unfortunately, the correction links velocity components and couples more strongly the momentum equations. Furthermore, the viscous terms cannot longer be written as a function of the Laplace diffusion operator only.

The article is structured in the following way. First, the Divergence format and the Laplace format, i.e., the two most common PDE formats of the Navier–Stokes equations are introduced. Then from these two formats, the two most commonly used weak formulations, the Divergence formulation and the Laplace formulation, are derived. Next, a series of simple flow experiments will be presented and simulated using the finite element method (FEM). The purpose of these tests is to evaluate if there are any differences between solutions obtained using either Divergence formulations or Laplace formulations. It will be seen that in many classical tests both approaches give the same results, as most people would expect. However, it will also be seen that, for the flow examples named *objectivity tests*, while the Divergence approach still produces correct physical answers, the Laplace scheme widely departs from the correct solution, producing non-physical results. The article is closed with a theoretical discussion explaining, from a mathematical point of view, many aspects observed in the numerical experiments, including the role of objectivity. In that section, the corrected Laplace formulation will be also presented, showing how existing code based on Laplace schemes can be fixed by adding an appropriate boundary correction term.

2. Navier–Stokes equations

The Navier–Stokes equations describe the dynamics of incompressible newtonian fluids. Such fluids are defined through their constitutive equation:

$$\boldsymbol{\sigma} = -p\boldsymbol{I} + \mu\nabla\boldsymbol{v} + \mu(\nabla\boldsymbol{v})^{\mathrm{T}}, \tag{5}$$

where $\boldsymbol{\sigma}$ is the Cauchy stress tensor and $\boldsymbol{I}$ the second order identity tensor. The so called *Divergence format* of the Navier–Stokes equations is obtained by inserting (5) into the equations of conservation of mass and momentum of continuum mechanics:

$$\rho\frac{\partial\boldsymbol{v}}{\partial t} + \rho(\nabla\boldsymbol{v})\cdot\boldsymbol{v} - \nabla\cdot(-p\boldsymbol{I} + \mu\nabla\boldsymbol{v} + \mu(\nabla\boldsymbol{v})^{\mathrm{T}}) = 0, \tag{6}$$

$$\nabla\cdot\boldsymbol{v} = 0, \tag{7}$$

One can recover the Navier–Stokes equations in the *Laplace format*, defined in Eqs. (1) and (2), by expanding the terms containing the Divergence operator in Eq. (6):

$$\nabla\cdot\boldsymbol{\sigma} = \nabla\cdot(-p\boldsymbol{I} + \mu\nabla\boldsymbol{v} + \mu(\nabla\boldsymbol{v})^{\mathrm{T}}) = -\nabla p + \mu\nabla^2\boldsymbol{v}. \tag{8}$$

Note that the term $(\nabla\boldsymbol{v})^{\mathrm{T}}$ produces no contribution because:

$$\nabla\cdot(\nabla\boldsymbol{v})^{\mathrm{T}} = \nabla(\nabla\cdot\boldsymbol{v}) = 0 \tag{9}$$

for incompressible flows. The Laplace format and the Divergence format are of course equivalent, they are just different ways of writing the same PDE (under the assumption of constant viscosity).

As the fluid moves in a domain Ω, the NS equations (written either in Divergence or Laplace formats) have to be solved subject to appropriate *physical boundary conditions*, prescribing either the velocity or external surface forces (tractions) at the boundary surfaces Γ of Ω. Then, one can account for three possible types of boundary conditions: no-slip, slip, and free-surface conditions. For simplicity and clarity, it will be assumed here that the traction conditions are homogeneous, i.e. the fluid suffers no external tractions.

2.1. No-slip boundary conditions

At no-slip boundaries $\Gamma_{\text{no-slip}}$, all the flow velocity components are imposed:

$$\boldsymbol{v} = \bar{\boldsymbol{v}} \quad \text{on} \quad \Gamma_{\text{no-slip}}. \tag{10}$$

2.2. Slip boundary conditions

At slip boundaries Γ_{slip}, the normal velocity component v_n vanishes and there are not tangential stresses. This means:

$$\left.\begin{array}{l} v_n = \boldsymbol{v}\cdot\boldsymbol{n} = 0 \\ (\boldsymbol{\sigma}\cdot\boldsymbol{n})\cdot\boldsymbol{t} = 0 \quad \forall\boldsymbol{t}\in\{\boldsymbol{n}^{\perp}\} \end{array}\right\} \quad \text{on} \quad \Gamma_{\text{slip}}, \tag{11}$$

where $\boldsymbol{n}$ is the unit vector normal to the boundary surface Γ and $\boldsymbol{t}$ is any of the unit vectors tangent to the surface.

2.3. Free-surface boundary conditions

At free-surfaces Γ_{fs}, the velocity components are let free and zero tractions are imposed:

$$\boldsymbol{\sigma}\cdot\boldsymbol{n} = 0 \quad \text{on} \quad \Gamma_{\text{fs}}. \tag{12}$$

or equivalently:

$$\left.\begin{array}{l} (\boldsymbol{\sigma}\cdot\boldsymbol{n})\cdot\boldsymbol{n} = 0 \\ (\boldsymbol{\sigma}\cdot\boldsymbol{n})\cdot\boldsymbol{t} = 0 \quad \forall\boldsymbol{t}\in\{\boldsymbol{n}^{\perp}\} \end{array}\right\} \quad \text{on} \quad \Gamma_{\text{fs}}. \tag{13}$$

Remark 1. A normal traction condition must exist in order to fix the pressure, then for the cases of domains with no free-surfaces, the internal pressure p must be fixed at some point $\boldsymbol{x}_0$ on the surface, i.e., for such cases the condition $p = 0$ for $\boldsymbol{x}_0 \in \Gamma$ will be used.

Next, the two most commonly used weak/variational formulations will be derived using a FEM-like approach. The first one will be obtained (using classical arguments) from the Laplace format (1) and (2) and will lead to the Laplace formulation. The second will be derived starting from the Divergence format (6) and (7) leading to the Divergence formulation. After presenting them in Sections 3–5, their behavior will be compared via a series of simple flow tests in Section 6.

3. Laplace formulations for fully-imposed domains

Laplace formulations are weak formulations of the NS equations initially derived for applications dealing with flows in fully-imposed domains, i.e., when $\Gamma = \Gamma_{\text{no-slip}}$. They can be obtained in a straightforward manner from the Laplace format Eqs. (1) and (2), as shown below. Integration of the scalar product of Eq. (1) with a vector $\boldsymbol{w}$ of admissible weighting functions over the fluid domain Ω yields:

$$\int_\Omega \boldsymbol{w} \cdot \rho \left[\frac{\partial \boldsymbol{v}}{\partial t} + \nabla \boldsymbol{v} \cdot \boldsymbol{v}\right] d\Omega + \int_\Omega \boldsymbol{w} \cdot \nabla p \, d\Omega - \int_\Omega \boldsymbol{w} \cdot \mu \nabla^2 \boldsymbol{v} \, d\Omega = 0. \tag{14}$$

Integrating by parts, both, the pressure and the Laplace terms in Eq. (14), leads to:

$$\int_\Omega \boldsymbol{w} \cdot \rho \left[\frac{\partial \boldsymbol{v}}{\partial t} + \nabla \boldsymbol{v} \cdot \boldsymbol{v}\right] d\Omega - \underbrace{\int_\Omega p \nabla \cdot \boldsymbol{w} \, d\Omega}_{\text{pressure grad. term}} + \underbrace{\int_\Omega \nabla \boldsymbol{w} : \mu \nabla \boldsymbol{v} \, d\Omega}_{\text{Laplace term}} +$$
$$- \underbrace{\int_\Gamma \boldsymbol{w} \cdot (-p\boldsymbol{I} + \mu \nabla \boldsymbol{v}) \cdot \boldsymbol{n} \, d\Gamma}_{\text{Laplace natural boundary term}} = 0. \tag{15}$$

Since $\Gamma = \Gamma_{\text{no-slip}}$, the boundary integral in Eq. (15) is zero because, in such a case, $\boldsymbol{w}$ vanishes everywhere on the boundary. Using this property and performing a similar variational procedure on the continuity Eq. (2) with an admissible weighting function q, one gets the general expression defining Laplace formulations:

$$\underbrace{\int_\Omega \boldsymbol{w} \cdot \rho \left[\frac{\partial \boldsymbol{v}}{\partial t} + \nabla \boldsymbol{v} \cdot \boldsymbol{v}\right] d\Omega}_{\mathbb{M}\frac{d\boldsymbol{v}}{dt} + \mathbb{C}(\boldsymbol{v})} - \underbrace{\int_\Omega p \nabla \cdot \boldsymbol{w} \, d\Omega}_{-\mathbb{G}p} + \underbrace{\int_\Omega \nabla \boldsymbol{w} : \mu \nabla \boldsymbol{v} \, d\Omega}_{-\mu \mathbb{L}\boldsymbol{v}} = 0, \tag{16}$$

$$\underbrace{\int_\Omega q \nabla \cdot \boldsymbol{v} \, d\Omega}_{\mathbb{D}\boldsymbol{v}} = 0. \tag{17}$$

Using the symbolic operators defined below the underbraces in Eqs. (16) and (17), one can write the Laplace formulation simply as:

$$\mathbb{M}\left(\frac{d\boldsymbol{v}}{dt}\right) + \mathbb{C}(\boldsymbol{v}) + \mathbb{G}(p) - \mu \mathbb{L}(\boldsymbol{v}) = 0,$$
$$\mathbb{D}(\boldsymbol{v}) = 0. \tag{18}$$

Note that the Laplace diffusion operator term has been denoted with the symbol $\mu \mathbb{L}$.

4. Divergence formulation for fully-imposed domains

To get the Divergence formulation for the case of fully-imposed domains ($\Gamma = \Gamma_{\text{no-slip}}$) we start from the Divergence format (6) and (7) instead of the Laplace format. Integrating the scalar product of Eq. (6) with a vector $\boldsymbol{w}$ of *admissible* weighting functions over the fluid domain Ω one gets:

$$\int_\Omega \boldsymbol{w} \cdot \rho \left[\frac{\partial \boldsymbol{v}}{\partial t} + \nabla \boldsymbol{v} \cdot \boldsymbol{v}\right] d\Omega - \int_\Omega \boldsymbol{w} \cdot \nabla \cdot (-p\boldsymbol{I} + \mu \nabla \boldsymbol{v} + \mu (\nabla \boldsymbol{v})^{\text{T}}) \, d\Omega = 0. \tag{19}$$

Integration by parts (Green's Theorem) of the stress terms leads to:

$$\int_\Omega \boldsymbol{w} \cdot \rho \left[\frac{\partial \boldsymbol{v}}{\partial t} + \nabla \boldsymbol{v} \cdot \boldsymbol{v}\right] d\Omega - \underbrace{\int_\Omega p \nabla \cdot \boldsymbol{w} \, d\Omega}_{\text{pressure grad. term}} + \underbrace{\int_\Omega \nabla \boldsymbol{w} : \mu \nabla \boldsymbol{v} \, d\Omega}_{\text{Laplace term}}$$
$$+ \underbrace{\int_\Omega \nabla \boldsymbol{w} : \mu (\nabla \boldsymbol{v})^{\text{T}} \, d\Omega}_{\text{vel. grad. symmetrization term}} - \underbrace{\int_\Gamma \boldsymbol{w} \cdot (-p\boldsymbol{I} + \mu \nabla \boldsymbol{v} + \mu (\nabla \boldsymbol{v})^{\text{T}}) \cdot \boldsymbol{n} \, d\Gamma}_{\text{Divergence natural boundary term}} = 0. \tag{20}$$

As in the case of the Laplace formulation, the boundary term in Eq. (20) is zero because, for $\Gamma = \Gamma_{\text{no-slip}}$, $\boldsymbol{w}$ vanishes everywhere on the boundary. Using this property and the variational form of the continuity Eq. (7), one gets the general expression defining Divergence formulations:

$$\underbrace{\int_\Omega \boldsymbol{w} \cdot \rho \left[\frac{\partial \boldsymbol{v}}{\partial t} + \nabla \boldsymbol{v} \cdot \boldsymbol{v}\right] d\Omega}_{\mathbb{M}\frac{d\boldsymbol{v}}{dt} + \mathbb{C}(\boldsymbol{v})} - \underbrace{\int_\Omega p \nabla \cdot \boldsymbol{w} \, d\Omega}_{-\mathbb{G}p} + \underbrace{\int_\Omega \nabla \boldsymbol{w} : \mu \nabla \boldsymbol{v} \, d\Omega}_{-\mu \mathbb{L}\boldsymbol{v}}$$
$$+ \underbrace{\int_\Omega \nabla \boldsymbol{w} : \mu (\nabla \boldsymbol{v})^{\text{T}} \, d\Omega}_{-\mu \mathbb{T}\boldsymbol{v}} = 0, \tag{21}$$

$$\underbrace{\int_\Omega q \nabla \cdot \boldsymbol{v} \, d\Omega}_{\mathbb{D}\boldsymbol{v}} = 0. \tag{22}$$

Using the same symbolic operators defined in Eqs. (16) and (17) (and repeated below the underbraces in Eqs. (21) and (22), one can write the Divergence formulation simply as:

$$\mathbb{M}\left(\frac{d\boldsymbol{v}}{dt}\right) + \mathbb{C}(\boldsymbol{v}) + \mathbb{G}(p) - \mu \mathbb{L}(\boldsymbol{v}) - \mu \mathbb{T}(\boldsymbol{v}) = 0,$$
$$\mathbb{D}(\boldsymbol{v}) = 0. \tag{23}$$

Note however that a new operator $\mathbb{T}$:

$$\mu \mathbb{T}(\boldsymbol{v}) = -\int_\Omega \nabla \boldsymbol{w} : \mu (\nabla \boldsymbol{v})^{\text{T}} \, d\Omega \tag{24}$$

coming from the symmetrization term $(\nabla \boldsymbol{v})^{\text{T}}$ had to be defined.

5. Laplace and Divergence formulations on more general boundary conditions

Until now, we have presented two weak formulations of the NS equations the so called Laplace and Divergence formulations, both were restricted to the particular case of no-slip boundary condition ($\Gamma = \Gamma_{\text{no-slip}}$). In that context, they are completely equivalent (except by the assumed condition of local incompressibility of the Laplace format). In this section, extensions to consider boundaries of any type: no-slip, slip and free-surfaces or any combination of them are discussed. Related issues about the boundary conditions associated with the Divergence and Laplace forms were addressed in [40,41].

In order to explain the underlying concepts as simple as possible, we introduce the following mathematical property:

Weak form property: Due to the admissibility properties of $\boldsymbol{w}$ (components of $\boldsymbol{w}$ vanish where corresponding components of $\boldsymbol{v}$ are

imposed) and the homogenous physical boundary conditions given in Eqs. (11) and (12), the following boundary term always vanishes:

$$\int_{\Gamma} \boldsymbol{w} \cdot \overbrace{(-p\boldsymbol{I} + \mu\nabla\boldsymbol{v} + \mu(\nabla\boldsymbol{v})^{\mathrm{T}})}^{\sigma} \cdot \boldsymbol{n}\, \mathrm{d}\Gamma = 0 \qquad (25)$$

for

$$\left.\begin{array}{c} \text{no-slip} \\ \text{slip} \\ \text{free-surface} \end{array}\right\} \text{boundaries}$$

or for any boundary formed by any combination of them.

The weak form property just introduced permits us to affirm that the Divergence formulation, shown in symbolic form in Eq. (23) and repeated here:

$$\mathbb{M}\left(\frac{\mathrm{d}\boldsymbol{v}}{\mathrm{d}t}\right) + \mathbb{C}(\boldsymbol{v}) + \mathbb{G}(p) - \mu\mathbb{L}(\boldsymbol{v}) - \mu\mathbb{T}(\boldsymbol{v}) = 0,$$
$$\mathbb{D}(\boldsymbol{v}) = 0. \qquad (26)$$

is valid not only for the case of no-slip boundaries, but also for any type of physical boundary condition. This affirmation can be proved in a straightforward way using that, when the general boundary conditions are imposed through Eq. (25), the contribution of the boundary term of Eq. (20) is still null. Thus, neither a special modification of Eqs. (21) and (22) nor particular considerations about the physics of the problem are required.

In the Laplace formulation the previous statement is not true. A careful examination shows that (to the authors' surprise), in the Laplace approach, the natural boundary term (that emerged from integration by parts) in Eq. (15) is not strictly equal to the general boundary condition expressed in (25). Furthermore, there is no a rigorous mathematical foundation assuring that the boundary term of Eq. (15) vanishes identically for the other (i.e. slip and free-surfaces) boundary conditions considered in the paper. Despite what has just been said, either by an oversight or by some type of empirical assumption, it is still a standard practice to not consider such natural surface contribution. In words, this means that the Laplace formulation, shown in symbolic form in Eq. (18), and repeated here:

$$\mathbb{M}\left(\frac{\mathrm{d}\boldsymbol{v}}{\mathrm{d}t}\right) + \mathbb{C}(\boldsymbol{v}) + \mathbb{G}(p) - \mu\mathbb{L}(\boldsymbol{v}) = 0,$$
$$\mathbb{D}(\boldsymbol{v}) = 0. \qquad (27)$$

is commonly used in general boundary conditions.

Furthermore, such unchanged form has gained popularity in the computational scientific community for general applications and also has been used as the underlying formulation for subsequent developments (projection methods, fractional-steps algorithms). With respect to this last point, we should mention that, although a number of stabilized fractional-step formulations for different velocity–pressure interpolations have been proposed based on Divergence formulations (see, for example, [38,39,42]), Laplace formulations are what we see most of the time in fractional-step algorithms. Similarly, Laplace formulations are what we see most often in pressure-projection methods.

As a conclusion of the Section we say that both formulations, the Divergence and the Laplace ones, have been widely adopted. It is not rare to see research articles where both forms are presented and discussed in parallel (see for example [14]). Besides, from the point of view of the numerical implementation, most commercial codes and open-source codes [7,11,28,29,37] are based on one or the other.

6. Numerical tests: the revealing of non-physical solutions generated by Laplace formulations

Recently in [20] and [21], a theoretical evidence demonstrating that Laplace formulations have a potentially severe inconsistency, has emerged. Based on that evidence, in this section a series of carefully designed simple flow tests are presented. The idea behind these tests is to see if we can capture, in real numerical experiments, the failure of the Laplace approach. For this purpose, such formulation is compared in parallel with the Divergence one. It is shown that in some of these experiments, the Laplace scheme coincides with the Divergence approach giving both correct physical answers. However in other tests, named objectivity tests, non-physical solutions are indeed detected. We will delay to Section 7 any theoretical discussion, where we will also explain how the numerical failures can be attributable to the non-objectivity of the formulation.

The first two tests presented in this section are based on the classical *square cavity* problem. The two following ones are based on the study of *annular cavity* flows. Both of these tests have proved to be extremely useful for the purpose of this work. After these examples, other three valuable numerical tests will be shown. The simulations that are presented here have been obtained using the open-source PETSc-FEM library [29]. Its monolithic Navier–Stokes module was modified to solve the FEM equations corresponding either to Laplace formulations or to Divergence formulations. In all the examples, mixed $(\boldsymbol{v}, p)$ linear elements equipped with standard SUPG-PSPG [5,43] stabilization terms were used. The solutions obtained using the Laplace formulation and the Divergence one are denoted by $S_{\mathrm{Lap}} = \{\boldsymbol{v}_{\mathrm{Lap}}, p_{\mathrm{Lap}}\}$ and by $S_{\mathrm{Div}} = \{\boldsymbol{v}_{\mathrm{Div}}, p_{\mathrm{Div}}\}$, respectively.

6.1. Test 1: the lid-driven square-cavity

The lid-driven square-cavity is a classical test of computational fluid dynamics to assess the performance of numerical codes (see for example: [49,10,47,33,6,1]). It consists of a two-dimensional square domain filled with an incompressible fluid. The left, right and bottom boundaries are formed by no-slip fixed walls, while the upper boundary is formed by a no-slip moving wall which has an imposed horizontal velocity $U = 1$. The length of the walls is chosen to be $L = 1$. The two upper corners are maintained fixed. The case is shown in Fig. 1.

The purpose is to check if the same steady solution is obtained using either the Laplace or the Divergence approach. The mesh is formed by 100×100 quadrangular elements. The Reynolds number is set to $Re = 1$, so as to test the case where viscous terms and convective (inertial) terms are equally important. The pressure is set to zero at the bottom right corner. The numerical results are shown in Figs. 1 and 2. The resulting streamlines using the Laplace formulation are displayed in Fig. 1 (a similar plot is recovered if the

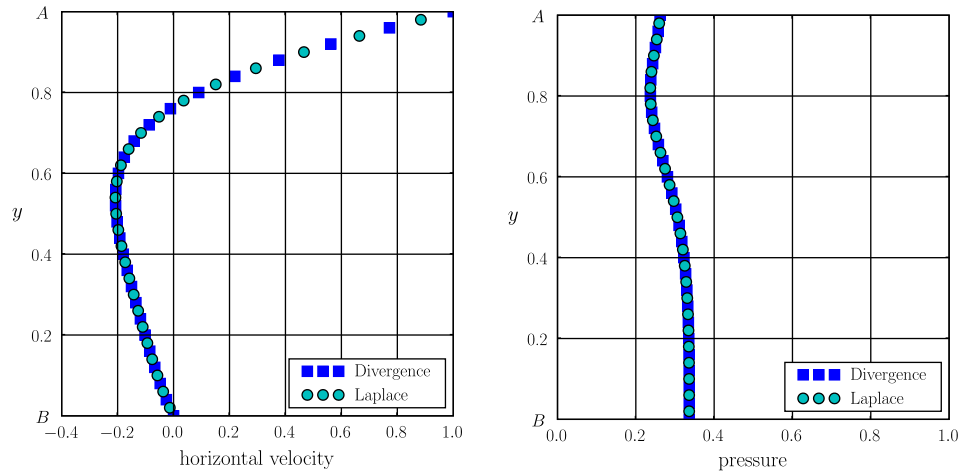

Fig. 1. The lid-driven square-cavity problem.

Fig. 2. The lid-driven square-cavity problem: horizontal velocity and pressure profiles (u, p) along line AB of Fig. 1.

Divergence formulation is used). The left plot of Fig. 2 shows the horizontal velocity u profile along the line AB of Fig. 1. From the plot it can be seen that the same velocity profile is obtained in both approaches. Observe that the horizontal velocity becomes $u = U = 1$ at the upper wall and zero at the lower wall. The vortex center is located at about $y \approx 0.75$. This position approximately corresponds to the intersection of the velocity profile with the vertical line $u = 0$. The maximum absolute error in velocities, $e_{\max} = \max(\|\mathbf{v}_{\mathrm{Div}} - \mathbf{v}_{\mathrm{Lap}}\|)$, is about 0.02 and occurs near the upper corners. Such value corresponds to a relative error of less than 2% with respect to the reference velocity U. The difference decreases several orders of magnitude away from the corners. For example along the line AB, the velocity's maximum relative error is of only 0.004%. Note from the plot on the right of Fig. 2 that the pressure values also match well; along the line AB the pressure's maximum absolute error is 0.001.

6.2. Test 2: the slippery square-cavity

A good idea to check both formulations under slip boundary conditions is to modify the standard lid-driven square-cavity, defined in test 1, by changing the no-slip condition to a slip condition in the three non-driven walls (i.e. the left, right and bottom walls). In Figs. 3 and 4, the obtained numerical results are shown. The streamlines corresponding to the solution obtained using the Divergence formulation are displayed in Fig. 3 (a similar plot can be recovered for the Laplace one).

Fig. 4 shows plots of the horizontal velocity u and the pressure, along the line AB of Fig. 3. It can be seen that the same velocity and pressure profiles are obtained for both formulations. Note from the left plot that, because of the slip condition, the velocities on the non-driven walls are non-zero now (see velocity u at point B).
The vortex center moves down to about $y \approx 0.68$, corresponding to the intersection of the velocity profile with the vertical line $u = 0$. Again, the maximum relative error in velocities, $e_{\max} = \max(\|\mathbf{v}_{\mathrm{Div}} - \mathbf{v}_{\mathrm{Lap}}\|)$, in all the domain is less than 2% with respect to the reference velocity U and occurs near the upper corners. As in the test 1, these differences can be attributed to the flow singularity occurring near these two areas. In the other regions of the domain, $\mathbf{v}_{\mathrm{Div}}$ and $\mathbf{v}_{\mathrm{Lap}}$ coincide quite well, as the left plot of Fig. 4 shows. Note, from the right plot of the same figure, that the pressure values also match well. Along the observation line AB, the velocity's absolute error is of only 0.00001 and the pressure's absolute error is of only 0.0003. Nothing wrong is found in this test with the Laplace formulation, it matches the Divergence solution.

6.3. The annular-cavity: A general analytical solution

In Sections 6.1 and 6.2 it has been shown that the two first attempts to detect the non-objectivity of Laplace formulations failed: running the well-known and commonly used square-cavity test does not show any really appreciable discrepancy between Laplace and Divergence solutions. Is the error in Laplace formulations so small and negligible to just really be appreciable in extreme cases with free-surfaces as the ones shown in [21]? Are there no simpler tests that could clearly show the effects of the violation of objectivity and that be simple enough so that any researcher working in numerical simulations of fluids could replicate? This topic is addressed in what follows.

Flows between cylinders are commonly used for studies of viscometry, hydrodynamic stability, lubrication and bifurcation theory, etc. (see for example: [4,35,24,25]). Among these different types of flows, here, the case of flows in the annular cavity is considered. The *annular-cavity* problem consists of the study of 2D flows (fluid motion in the axial direction is assumed zero) between two coaxial cylindrical walls, as shown in Fig. 5. The internal cylinder has a radius r_A and the external cylinder a radius r_B, both can be arbitrary. These series of tests have two fundamental properties. First, one can easily set up different boundary conditions to the walls, such as imposing different angular velocities together with slip or no-slip conditions. Second, analytical solutions can be derived for all these different types of boundary conditions.

Let us obtain the general analytical solution of the Navier–Stokes Equations for the case of two-dimensional steady laminar flows around two coaxial cylinders of arbitrary radius, r_A and r_B, respectively. In polar coordinates (r, θ) the 2D steady Navier–Stokes Eqs. (1) and (2) can be written as:

**Fig. 3.** The slippery square-cavity problem.

Fig. 4. The slippery square-cavity problem: horizontal velocity and pressure profiles (u, p) along line AB of Fig. 3.

$$\rho a_r = -\frac{\partial p}{\partial r} + 2\mu \left[\frac{1}{r}\frac{\partial(rG_{rr})}{\partial r} + \frac{1}{r}\frac{\partial G_{r\theta}}{\partial \theta} - \frac{1}{r}G_{\theta\theta}\right], \quad (28)$$

$$\rho a_\theta = -\frac{1}{r}\frac{\partial p}{\partial \theta} + 2\mu \left[\frac{1}{r}\frac{\partial G_{\theta\theta}}{\partial \theta} + \frac{1}{r}\frac{\partial(rG_{\theta r})}{\partial r} + \frac{1}{r}G_{r\theta}\right], \quad (29)$$

$$\nabla \cdot \boldsymbol{v} = \frac{1}{r}\frac{\partial(rv_r)}{\partial r} + \frac{1}{r}\frac{\partial v_\theta}{\partial \theta} = 0, \quad (30)$$

where the velocity, the acceleration $\boldsymbol{a}$ and the tensor gradient are given by:

$$\boldsymbol{v} = \begin{bmatrix} v_r \\ v_\theta \end{bmatrix} = v_r \boldsymbol{e}_r + v_\theta \boldsymbol{e}_\theta, \quad (31)$$

$$\boldsymbol{a} = \begin{bmatrix} a_r \\ a_\theta \end{bmatrix} = \begin{bmatrix} v_r \frac{\partial v_r}{\partial r} + \frac{v_\theta}{r}\frac{\partial v_r}{\partial \theta} - \frac{1}{r}v_\theta^2 \\ v_r \frac{\partial v_\theta}{\partial r} + \frac{v_\theta}{r}\frac{\partial v_\theta}{\partial \theta} + \frac{1}{r}v_\theta v_r \end{bmatrix}, \quad (32)$$

$$\nabla \boldsymbol{v} = \begin{bmatrix} G_{rr} & G_{r\theta} \\ G_{\theta r} & G_{\theta\theta} \end{bmatrix} = \begin{bmatrix} \frac{\partial v_r}{\partial r} & \frac{1}{r}\frac{\partial v_r}{\partial \theta} - \frac{v_\theta}{r} \\ \frac{\partial v_\theta}{\partial r} & \frac{1}{r}\frac{\partial v_\theta}{\partial \theta} + \frac{v_r}{r} \end{bmatrix}. \quad (33)$$

By symmetry, it can be assumed that the flow fields do not depend on θ, i.e.:

$$v_r = v_r(r); \quad v_\theta = v_\theta(r); \quad p = p(r). \quad (34)$$

Inserting Eq. (34) into the continuity Eq. (30) and using the condition of non-permeable cylinder walls, we get that:

$$v_r = 0 \quad \text{in all the domain}. \quad (35)$$

Taking into account (34) and (35), the tensor gradient reduces to:

$$\nabla \boldsymbol{v} = \begin{bmatrix} G_{rr} & G_{r\theta} \\ G_{\theta r} & G_{\theta\theta} \end{bmatrix} = \begin{bmatrix} 0 & -\frac{v_\theta}{r} \\ \frac{\partial v_\theta}{\partial r} & 0 \end{bmatrix} \quad (36)$$

and the momentum equations simplify to:

$$-\frac{\rho}{r}v_\theta^2 = -\frac{\partial p}{\partial r}, \quad (37)$$

$$0 = 2\mu \left[\frac{\partial^2 v_\theta}{\partial r^2} + \frac{1}{r}\frac{\partial v_\theta}{\partial r} - \frac{v_\theta}{r^2}\right]. \quad (38)$$

Solving Eq. (38) for v_θ and Eq. (37) for p, the general solution for the flow is obtained:

$$v_r = 0; \quad v_\theta = \frac{a}{r} + br, \quad (39)$$

$$p = \rho \left[-\frac{a^2}{2r^2} + 2ab\ln(r) + \frac{1}{2}b^2 r^2\right] + p_0, \quad (40)$$

where a, b and p_0 are constants to be determined by boundary conditions. Observe that the general solution is independent of the viscosity μ, i.e. all steady flow solutions are independent of the Reynolds number.

6.4. Test 3: the fully-driven annular-cavity

Now let us obtain the particular solutions corresponding to fully-driven flows in the annular cavity. These solutions correspond to the case when both cylinders are rotating with arbitrary angular velocities ω_A and ω_B, and their walls are no-slip walls, as shown in Fig. 6. Then, the following boundary conditions apply:

$$v_\theta(r_A) = V_A = \omega_A r_A; \quad v_\theta(r_B) = V_B = \omega_B r_B; \quad p(r_A) = 0. \quad (41)$$

Remark 2. The fully-driven annular-cavity problem presented in this section can be seen as the 2D case of the renowned Taylor-Couette flow [36,26].

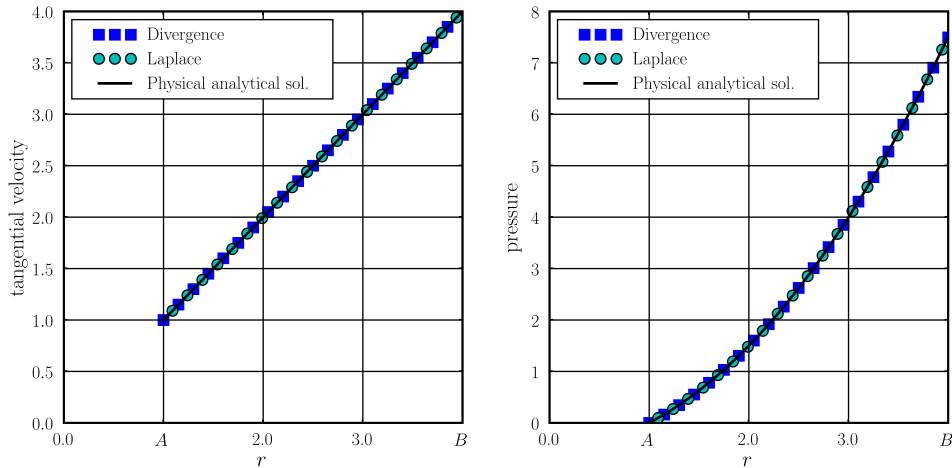

Fig. 5. The annular-cavity problem.

Fig. 6. The fully-driven annular-cavity problem.

Fig. 7. The fully-driven annular-cavity problem: tangential velocity and pressure profiles (v_θ, p) along the radial coordinate r.

Inserting Eq. (41) into Eqs. (39) and (40), it can be shown that the general solution for the fully-driven cavity is given by:

$$a = -\frac{r_B^2 r_A^2}{(r_B^2 - r_A^2)}(\omega_B - \omega_A); \quad b = \frac{\omega_B r_B^2 - \omega_A r_A^2}{(r_B^2 - r_A^2)}. \tag{42}$$

When both cylinders rotate with the same angular velocity $\omega = \omega_B = \omega_A$, a becomes zero, and the flow solution is given by:

$$v_r = 0; \quad v_\theta = \omega r; \quad p = \rho\left[\frac{1}{2}\omega^2 r^2 - \frac{1}{2}\omega^2 r_A^2\right]. \tag{43}$$

Then in the case of two co-rotating cylinders, the velocity field corresponds to a *rigid* motion and v_θ varies linearly with r. In this case, the pressure is zero on the surface of the internal cylinder A and increases quadratically with r. The increase in pressure is an effect of the centrifugal force acting on the fluid.

With the analytical solution (43) at hand, numerical simulations were done to see if differences between Divergence and Laplace formulations can be detected. Figs. 6 and 7 show the numerical results obtained for the case where $r_A = 1$, $r_B = 4$ and $\omega = \omega_B = \omega_A = 1$. In Fig. 6, the obtained streamlines for the Divergence case are displayed. A similar plot can be recovered for the Laplace case. From Fig. 7, one can see that both solutions behave equally well matching the analytical solution.

6.5. Objectivity test 1: the slippery annular-cavity

In this section, the results corresponding to slippery annular-cavity flow problems are presented. These particular flows are obtained when the internal cylinder is formed by a no-slip wall that is rotating with an arbitrary angular velocity ω_A, while the external cylinder is formed by a slip wall. The case is shown in Fig. 8 and corresponds to the following boundary conditions:

$$v_\theta(r_A) = V_A = \omega_A r_A; \quad [\mathbf{e}_\theta \cdot (\boldsymbol{\sigma} \cdot \mathbf{e}_r)]_{r=r_B} = 0; \quad p(r_A) = 0, \tag{44}$$

where the second equation corresponds to the slip condition on the external cylinder B. The analytical solution for this type of flows can be obtained using Eqs. (5) and (36). The slip condition becomes:

$$\left[\frac{\partial v_\theta}{\partial r} - \frac{v_\theta}{r}\right]_{r=r_B} = 0, \tag{45}$$

which in terms of the general solution (39) means:

$$-\frac{a}{r^2} + b - \frac{a}{r^2} - b = 0 \Rightarrow a = 0. \tag{46}$$

Then, the closed-form expression for the case of slippery annular-cavity flows is:

$$v_r = 0; \quad v_\theta = \omega_A r; \quad p = \rho\left[\frac{1}{2}\omega_A^2 r^2 - \frac{1}{2}\omega_A^2 r_A^2\right], \tag{47}$$

Comparison of Eqs. (43) and (47) tell us that the slippery annular-cavity and the fully-driven annular-cavity with co-rotating cylinders ($\omega = \omega_B = \omega_A$) gives the same steady flow solution: a rigid motion of the fluid. Observe again that this behavior is independent of the Reynolds number.

Next, the numerical results obtained for the case $r_A = 1$, $r_B = 4$ and $\omega_A = 1$ are shown in Fig. 9. According to Eq. (47) a linearly increasing tangential velocity and a quadratic variation of pressure should be obtained. In particular for the velocity we expect to get the value $v_\theta(r_B) = 4.0$ on the external cylinder. From the results shown in Fig. 9 one can clearly see that, while the Divergence scheme still matches the analytical solution, the Laplace formulation gives a completely wrong answer. Note the loss of physical meaning of the Laplace solution: the tangential velocity starts at the imposed velocity on the inner cylinder $V_A = 1$, but instead of increasing linearly with the distance from the origin r, it continually decreases to a value $v_\theta(r_B) \approx 0.47$. A similar phenomenon can be observed for the pressure: the expected quadratic increase due to the centrifugal force is not recovered. This simple objectivity test shows the severe consequences of the violation of objectivity. Some more tests are presented next.

6.6. Objectivity test 2: the slippery semicircular-cavity

The lid-driven semicircular-cavity is another test of computational fluid dynamics used as benchmark of numerical schemes

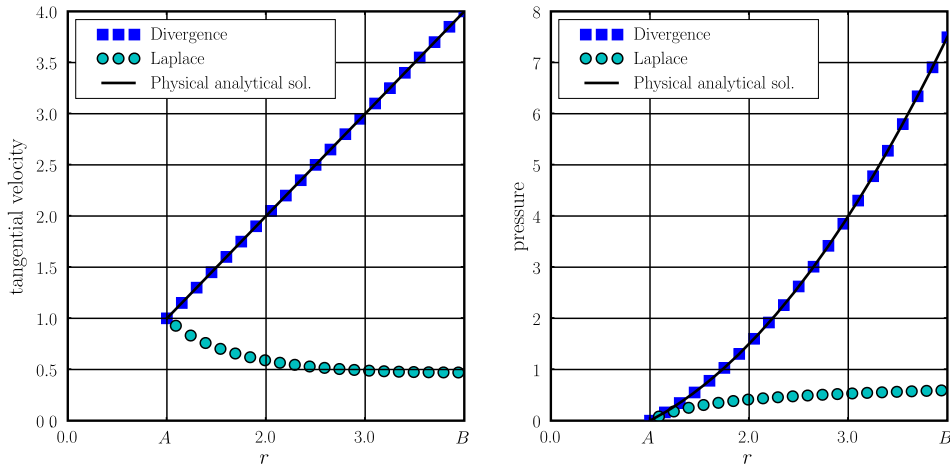

Fig. 8. The slippery annular-cavity problem.

Fig. 9. The slippery annular-cavity problem: tangential velocity and pressure profiles (v_θ, p) along the radial coordinate r.

and in the context of studies of bifurcation theory [12,18]. It consists of a 2D semicircular domain filled with an incompressible fluid. In the standard test the semicircular boundary is formed by a fixed no-slip wall, while the upper rectilinear boundary, i.e the lid, is formed by a moving wall which has an imposed horizontal velocity $U = 1$. The radius of the semicircular wall is chosen to be $r_B = 1$. The two upper corners are maintained fixed. When this classical test is numerically solved, S_{Lap} and S_{Div} agree in the same way as the previously discussed fully-driven cases (square-cavity and annular-cavity).

For the purpose of detecting the failure of Laplace formulations, the standard test is modified by changing the no-slip condition, on the semicircular wall, to a slip condition, as depicted in Fig. 10. The

Fig. 10. The slippery semicircular-cavity problem.

numerical values of the horizontal velocity u along the line AB are shown in the left plot of Fig. 11. Observe that, although both solutions match the prescribed condition $u_{Lap} = u_{Div} = 1$ on the upper boundary, the velocity profile along the line is different. One remarkable property of the Laplace scheme is that the gradient of the velocity field tends to zero near the slip wall. Note that different pressure profiles are obtained too (see right plot of Fig. 11).

6.7. Objectivity test 3: flow around a slippery cylinder

The case of steady uniform flow around a no-slip cylinder is a classical problem used as benchmark for numerical simulations. We modify the original test by configuring the cylinder with slip walls instead of no-slip walls. The numerical results, for a Reynolds number $Re = 1$ and an incident horizontal velocity $V = 1$, are shown in Figs. 12 and 13. In Fig. 12, the resulting streamlines for both formulations are presented, giving similar results. However, when the velocity V and pressure profiles along the upper semicircular arc ABC are plotted, severe discrepancies are observed (see Fig. 13). The most notable difference is that the flow accelerates more in the Laplace solution, reaching a maximum speed of about 1 instead of the value close to 0.6 obtained when the Divergence formulation is employed. Note that for this case the effect of non-objectivity is similar as if an external force would be helping the flow to move along the cylinder.

(a) Divergence Form   (b) Laplacian Form

**Fig. 12.** Flow around a slippery cylinder.

Fig. 13. Flow around a slippery cylinder: velocity profiles and pressure profiles ($\|\mathbf{v}\|$, p) along the semicircular arc ABC shown in Fig. 12.

6.8. Objectivity test 4: a free-surface sloshing test

The last test presented is the sloshing problem, i.e., a problem with free-surfaces, depicted in Fig. 14. It consists of a tank filled with liquid at rest such that, at time $t = 0$, its free-surface is configured so as to have a sinusoidal shape perturbation. As a consequence of the perturbation, the free-surface of the liquid moves in an oscillatory motion [2,32]. For small amplitudes an analytical solution can be obtained [31].

Following the same configuration set-up defined in [2], the problem is run using both formulations. The obtained results, for the motion of the fluid particle A on the free-surface, are displayed in Fig. 15. Note that the Divergence scheme agrees quite well with

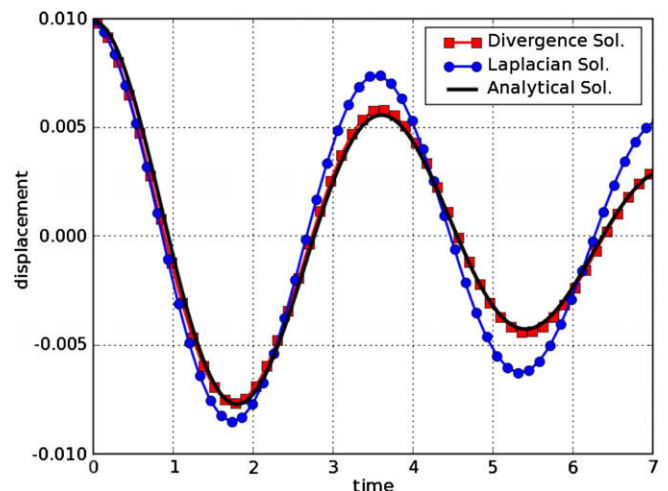

Fig. 14. Sloshing tank problem.

Fig. 15. Sloshing tank problem: time evolution of the fluid particle located at point A on the free surface, as depicted in Fig. 14.

the analytical solution while the Laplace approach notably differs from it, having a slightly higher frequency and a much smaller damping.

7. Discussion of results

In the previous section a number of tests were presented. Among them, the named objectivity tests reveal a series of non-physical solutions obtained when Laplace formulations are used.

7.1. A correct approach: the corrected Laplace formulation

After seen the numerical solutions obtained by Laplace formulations, we do not want the reader to fall into the conclusion that starting from the Laplace format (1) and (2) of the NS equations is definitely wrong. Although we recommend the Divergence approach because is more general, a correct formulation can indeed be obtained from the Laplace approach. This is shown in this section. We have named the correct approach: *corrected Laplace formulation*, to make it clear that it is the counterpart of the Laplace formulation and to emphasize that it is *not the standard* or classical approach.

The correct formulation valid for the three types of boundary conditions (no-slip, slip or free-surfaces or for any boundary that is a combination of them) can be obtained by taking into account the natural boundary integral of Eq. (15) (which was neglected in the derivation of the Laplace formulation in Section 5). Such boundary integral can be rewritten as:

$$\underbrace{\int_\Gamma \boldsymbol{w} \cdot (-p\boldsymbol{I} + \mu\nabla\boldsymbol{v}) \cdot \boldsymbol{n}\, d\Gamma}_{\text{natural boundary term}} = \int_\Gamma \boldsymbol{w} \cdot \underbrace{(-p\boldsymbol{I} + \mu\nabla\boldsymbol{v} + \mu(\nabla\boldsymbol{v})^T)}_{\sigma} \cdot \boldsymbol{n}\, d\Gamma$$
$$- \int_\Gamma \boldsymbol{w} \cdot \left(\mu(\nabla\boldsymbol{v})^T\right) \cdot \boldsymbol{n}\, d\Gamma. \tag{48}$$

Then, after imposing the physical boundary conditions through the weak form property given in Eq. (25), we get that the corrected Laplace formulation is given by:

$$\int_\Omega \boldsymbol{w} \cdot \rho\left[\frac{\partial\boldsymbol{v}}{\partial t} + \nabla\boldsymbol{v} \cdot \boldsymbol{v}\right] d\Omega - \underbrace{\int_\Omega p\nabla \cdot \boldsymbol{w}\, d\Omega}_{\text{pressure grad. term}} + \underbrace{\int_\Omega \nabla\boldsymbol{w} : \mu\nabla\boldsymbol{v}\, d\Omega}_{\text{Laplace term}}$$
$$+ \underbrace{\int_\Gamma \boldsymbol{w} \cdot (\mu(\nabla\boldsymbol{v})^T) \cdot \boldsymbol{n}\, d\Gamma}_{\text{additional boundary term}} = 0. \tag{49}$$

If we define the symbolic operator $\mathbb{V}$:

$$\mu\mathbb{V}(\boldsymbol{v}) = -\int_\Gamma \boldsymbol{w} \cdot (\mu(\nabla\boldsymbol{v})^T) \cdot \boldsymbol{n}\, d\Gamma = 0 \tag{50}$$

and use the operators defined in Section 3, we can write the corrected Laplace formulation in symbolic form as:

$$\mathbb{M}\left(\frac{d\boldsymbol{v}}{dt}\right) + \mathbb{C}(\boldsymbol{v}) + \mathbb{G}(p) - \mu\mathbb{L}(\boldsymbol{v}) - \mu\mathbb{V}(\boldsymbol{v}) = 0,$$
$$\mathbb{D}(\boldsymbol{v}) = 0. \tag{51}$$

Note that the corrected Laplace formulation does not longer have the property that the viscous terms are given as function of the Laplace diffusion operator only.

To see the numerical behavior of the corrected formulation, we implemented the scheme into PETSc-FEM (by adding the additional boundary term to the existent Laplace module) and re-run the tests of Section 6. In Figs. 16 and 17, we show as an example, the results corresponding to the cases of the slippery annular-cavity and of the flow around a slippery cylinder (Sections 6.5 and 6.7, respectively). As can be seen from these figures, now, the corrected Laplace scheme gives right physical responses. Note that such solutions also match the ones of the Divergence approach.

The agreement between the corrected Laplace and the Divergence formulations can, indeed, be proved mathematically in the continuum from the following operator equality (derived using integration by parts and the incompressibility equation):

$$\mu\mathbb{V}(\boldsymbol{v}) = -\int_\Gamma \boldsymbol{w} \cdot (\mu(\nabla\boldsymbol{v})^T) \cdot \boldsymbol{n}\, d\Gamma = -\int_\Omega \nabla\boldsymbol{w} : \mu(\nabla\boldsymbol{v})^T\, d\Omega = \mu\mathbb{T}(\boldsymbol{v}). \tag{52}$$

7.2. The failure of Laplace formulations from the point of view of objectivity

Comparison of the Laplace formulation given in Eq. (27) with the corrected formulation given in Eq. (51), clearly reflects the point of view that the failure of the standard approach lies in an inappropriate management of boundary conditions. Not imposing the real physical conditions caused the absence of a integral boundary term. As shown in the numerical tests, the missing of such term produces severely distorted non-physical solutions.

However, we want to emphasize that the failure of the Laplace formulation was not detected by realizing that there was a problem with the imposed boundary conditions. After all, the use of

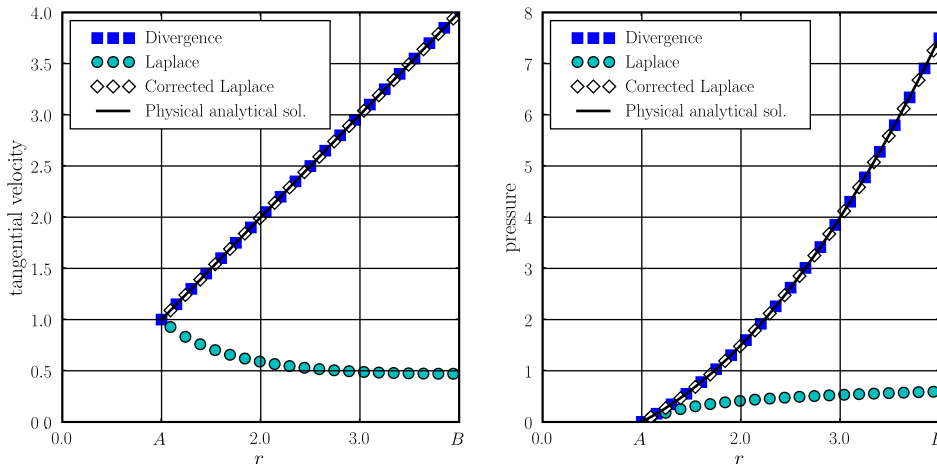

Fig. 16. The slippery annular-cavity problem. Solutions obtained with the three formulations: Divergence, Laplace and corrected Laplace.
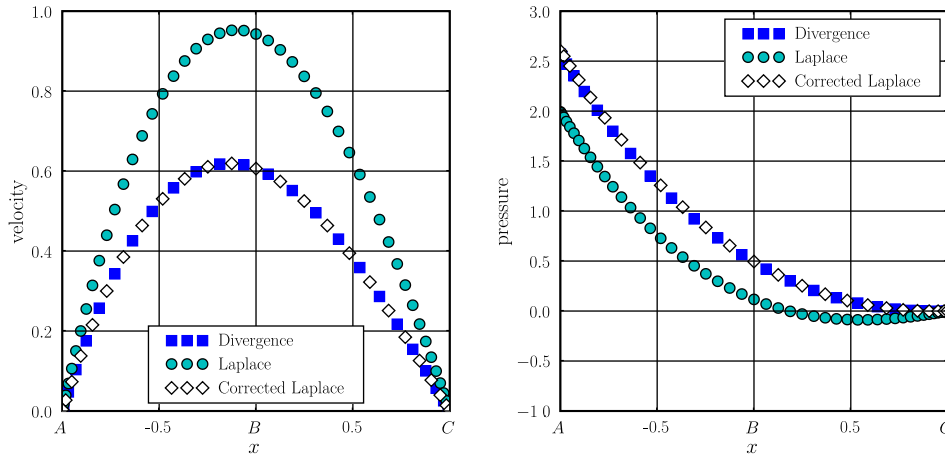

Fig. 17. Flow around a slippery cylinder. Solutions obtained with the three formulations: Divergence, Laplace and corrected Laplace.

approximate boundary conditions is very common in physics and computational fluid mechanics. Actually, the discovery of the failure came by noticing that the Divergence formulation was able to give correct physical responses where the Laplace one did not. This provided an alternative point of view which shows that the non-physical responses of the Laplace formulation can be explained as caused by its lack of objectivity.

As mentioned above, such *objective* point of view surges from the comparison of the Laplace formulation (27) with the Divergence formulation (26). Since the Divergence gives corrects physical answers, the comparison leads to the conclusion that the failure of the Laplace formulation can be seen as caused by a missing volume integral:

$$\mu \mathbb{T}(\boldsymbol{v}) = -\int_{\Omega} \nabla \boldsymbol{w} : \mu(\nabla \boldsymbol{v})^{\mathrm{T}} \, \mathrm{d}\Omega. \tag{53}$$

The observation that this volume integral comes from the symmetrization of the velocity gradient in the constitutive Eq. (5), was the key factor for the demonstration that Laplace formulations are non-objective [20,21]. In particular, it can be rigorously proved that such type of formulation does not model anymore the correct fluid material given by Eq. (5), but instead it models a non-objective material whose constitutive equation is given by:

$$\tilde{\boldsymbol{\sigma}} = -p\boldsymbol{I} + \mu\nabla\boldsymbol{v}. \tag{54}$$

If this equivalent point of view is adopted, then the non-physical solutions obtained with Laplace formulations can be seen as a natural manifestation of the non-objectivity of the simulated material defined in Eq. (54). We want to remark, again, that the numerical tests were designed to get such manifestation in the whole fluid domain and not by paying particular attention to boundary effects.

In Section 6.5, it was observed that Laplace formulations give a severely incorrect answer for the case of slippery annular-cavity tests. As pointed out in the previous paragraph, using such type of formulations is equivalent to simulate a non-objective fluid material which does not have the symmetrization of the stress tensor. It is possible, indeed, to get the analytical solution that describe the behavior of this non-physical fluid.

From the definition of the non-objective stress tensor in Eq. (54) and the equations of conservation of mass and momentum, it can be seen that such non-objective fluid still satisfies the incompressible NS Eqs. (1) and (2). As a consequence, for the slippery annular-cavity, its response can be obtained by solving the NS equations but with an erroneous traction boundary condition:

$$v_{\theta}(r_{\mathrm{A}}) = \omega_{\mathrm{A}} r_{\mathrm{A}}; \quad \left[\boldsymbol{e}_{\theta} \cdot \underbrace{(-p\boldsymbol{I} + \mu\nabla\boldsymbol{v})}_{\tilde{\sigma}} \cdot \boldsymbol{e}_{\mathrm{r}} \right]_{r=r_{\mathrm{B}}} = 0; \quad p(r_{\mathrm{A}}) = 0. \tag{55}$$

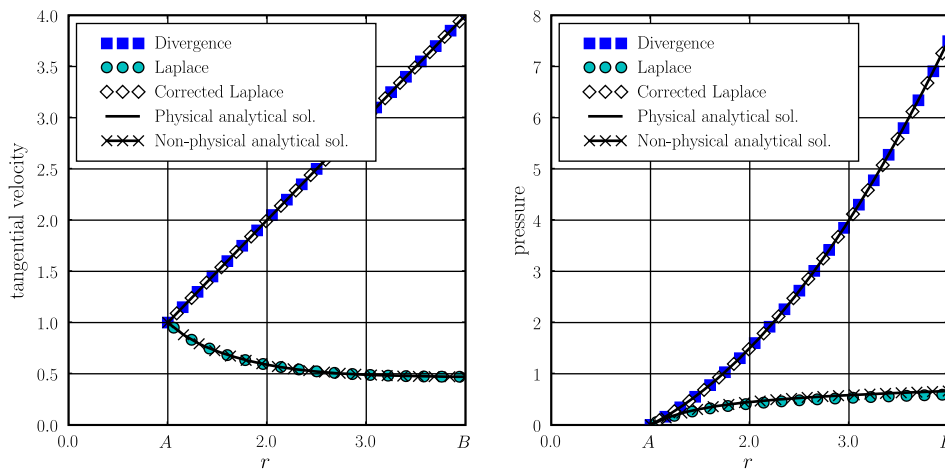

Fig. 18. The slippery annular-cavity problem. The non-physical analytical solution corresponding to the non-objective fluid material defined in Eq. (54) is included.

Using Eq. (36), the erroneous traction condition becomes:

$$\left[\frac{\partial v_\theta}{\partial r}\right]_{r=r_B} = 0. \tag{56}$$

Then, inserting Eqs. (55) and (56) into Eqs. (39) and (40), one can get the analytical solutions that corresponds to the non-physical fluid material defined by the Laplace approach:

$$a = \frac{\omega_A r_B^2 r_A^2}{(r_B^2 + r_A^2)}; \quad b = \frac{\omega_A r_A^2}{(r_B^2 + r_A^2)}, \tag{57}$$

so:

$$v_r = 0; \quad v_\theta = \frac{\omega_A r_B^2 r_A^2}{(r_B^2 + r_A^2)}\frac{1}{r} + \frac{\omega_A r_A^2}{(r_B^2 + r_A^2)}r. \tag{58}$$

In Fig. 18, Fig. 16 has been plotted again but adding the curve for the analytical solutions given by (57) and (58). From the new plot it is clear that the numerical solutions obtained by Laplace formulations match the analytical solutions of the non-objective fluid material.

The proof that the material being simulated is given by (54) is general and applies to the three types of boundary conditions (no-slip, slip and free-surfaces). Now, when the fluid is fully bounded by non-slip walls, i.e. $\Gamma = \Gamma_{\text{no-slip}}$, such a non-objective material cannot be distinguished from the correct one. Mathematically, this can be seen by noting that, under the no-slip condition, the corrective term vanishes:

$$[\mu\mathbb{V}(\boldsymbol{v})]_{\Gamma_{\text{no-slip}}} = 0. \tag{59}$$

Numerically, this phenomenon can be observed in tests 1 and 3 of Section 6 where both, the Laplace and the Divergence, formulations match. In other flow situations, with boundaries having slip walls or free-surfaces, one should expect to detect a difference. This is what happens in the objectivity tests.

However, the reader may ask why, in the slippery square-cavity, where a slip condition was used, both approaches gave the same result. The answer to this requires to put more attention to the integrand of the missing boundary term (50). Splitting the admissible test functions, into surface's normal and tangential coordinates

$$\boldsymbol{w} = w_t\boldsymbol{t} + w_n\boldsymbol{n} \tag{60}$$

and making use that the normal component of the test function is zero, because normal velocities are set to zero ($\boldsymbol{v}\cdot\boldsymbol{n} = 0$), one gets that:

$$[\mu\mathbb{V}(\boldsymbol{v})]_{\Gamma_{\text{slip}}} = -\int_{\Gamma_{\text{slip}}} \mu\boldsymbol{w}\cdot(\nabla\boldsymbol{v})^{\text{T}}\cdot\boldsymbol{n}\,\mathrm{d}\Gamma$$
$$= -\int_{\Gamma_{\text{slip}}} \mu w_t\frac{\partial v_j}{\partial x_t}n_j\,\mathrm{d}\Gamma. \tag{61}$$

Using the chain rule in the last two terms of the integrand, we get that:

$$[\mu\mathbb{V}(\boldsymbol{v})]_{\Gamma_{\text{slip}}} = -\int_{\Gamma_{\text{slip}}} \mu w_t\left(\frac{\partial(v_j n_j)}{\partial x_t} - v_j\frac{\partial n_j}{\partial x_t}\right)\mathrm{d}\Gamma. \tag{62}$$

Now, the first term inside the parenthesis is zero, because $\boldsymbol{v}\cdot\boldsymbol{n} = 0$ along the surface's tangential direction:

$$\frac{\partial(v_j n_j)}{\partial x_t} = \frac{\partial(\boldsymbol{v}\cdot\boldsymbol{n})}{\partial x_t} = 0.$$

So we get that:

$$[\mu\mathbb{V}(\boldsymbol{v})]_{\Gamma_{\text{slip}}} = \int_{\Gamma_{\text{slip}}} \mu w_t\left(v_j\frac{\partial n_j}{\partial x_t}\right)\mathrm{d}\Gamma. \tag{63}$$

Now by definition the $\frac{\partial n_j}{\partial x_t}$ term is inversely proportional to the radius of curvature R_{slip} of the slip wall, then we have:

$$[\text{missing term}]_{\Gamma_{\text{slip}}} \propto \frac{1}{R_{\text{slip}}}. \tag{64}$$

Then for straight walls, $R_{\text{slip}} \to \infty$ and the missing term vanishes again. This explains why in the case of the slippery square-cavity both formulations give quite similar results.

Eqs. (59) and (64) explain also why the phenomenon of violation of objectivity has been undetected in many standard flow problems.

Finally, it is worth to mention that the results obtained for the sloshing tank problem prove that Laplace formulations cannot even be used in problems dealing with small perturbations.

8. Conclusions

In this article, a number of easily reproducible numerical tests has been presented. Running them with numerical schemes based on Laplace formulations reveal that such formulations produce severely distorted non-physical solutions. Stated in different words, these tests can make visible the non-objectivity of such formulations. Here, it is shown that although Laplace formulations give correct results in the case of fully-imposed (no-slip) domains, they yield non-physical behavior in problems dealing with flows around slip walls and flows with free surfaces.

The results obtained here are a useful reminder that boundary terms and boundary conditions should always be treated with special care.

Note, that there might be several numerical programs based on Laplace forms available to researchers and engineers, who might be unaware of the flaw of these formulations. Special attention should be given to schemes based on fractional-step or projection methods (see the reviews by Guermond et al. [13,14] for a description of such techniques).

It should be emphasized that Laplace formulations can be corrected so as to recover objectivity by adding the missing integral boundary term discussed in Section 7. However, this corrected Laplace formulation is not longer strictly diffusive because, due to the corrective term, the viscous forces do not come exclusively from the Laplace's diffusion operator. Note also that the additional term produces a coupling between velocity components, with this, a computational advantage of Laplace formulations is lost.

The proposed objectivity tests can be used as benchmark tools to check if CFD programs are formulated properly. The numerical experiments presented in Sections 6 and 7, based on annular-cavity flow problems, are equipped with analytical solutions which can be useful to assess correctness and consistency of numerical schemes implemented in open-source codes and commercial software with a minimum of effort.
