### Abstract

The expressed sequence tags (ESTs) produced in the Forests project provide an invaluable opportunity to assess the *Eucalyptus* transcriptome. Besides providing information on the different proteins produced by this plant, it is possible to infer gene expression profiles because non-normalized cDNA libraries were used. The EST frequency from any gene is correlated to the transcript levels in the tissues from which the cDNA libraries were constructed. The goal of this work was to identify *Eucalyptus* genes that showed either differential expression pattern or were ubiquitously expressed in the tissues sampled in the Forests project. Six robust statistical tests and very restrictive rules were applied to gain confidence in the *in silico* data aiming to avoid false positives. Several genes with interesting expression profiles were identified and some of them were validated by RT-PCR.

**Key words:** transcriptome, *Eucalyptus*, tissue-specific, statistics, differential expression.

Received: May 28, 2004; Accepted: November 29, 2004.

### Introduction

Expressed sequence tags (ESTs) projects are a powerful strategy to discover genes and also to assess their expression profiles. The abundance of ESTs in a cDNA library reflects the expression levels in the tissues used to extract the RNA (Okubo *et al.*, 1992). The estimation of gene expression levels using the frequency of gene transcripts in non-normalized cDNA libraries has been done in several species, such as rice (Ewing *et al.*, 1999), *Medicago truncatula* (Journet *et al.*, 2002), sugarcane (Falco *et al.*, 2001) and *Schistosoma mansoni* (Franco *et al.*, 1997).

As in any genomic approach, gene expression profiling using EST counting produces a large amount of data. The use of robust statistical tests is essential in the identification of differentially expressed genes in EST projects. In the past few years several statistical approaches have been described (Audic and Claverie, 1997; Stekel *et al.*, 2000; Greller and Tobin, 1999; Romualdi *et al.*, 2001).

The extensive representation of the *Eucalyptus* transcriptome in the Forests database is a rich resource

for several studies, including the discovery of genes exhibiting tissue-specific or ubiquitous expression. This is, for example, a first step towards the cloning of promoters that can be used for biotechnological purposes. Most transgenic plants obtained so far use the 35S promoter, which is expressed in most cell types. In the majority of cases, the use of promoters with specific expression patterns is desirable either to avoid the waste of energy producing proteins of interest in cells that are not relevant or to avoid metabolic dysfunctions. A good example of this approach is the expression of a transcription factor under the control of a stress-inducible promoter in transgenic tomato plants (Lee *et al.*, 2003) which resulted in normal plants with increased tolerance to drought. In contrast, plants expressing the same gene under the control of the constitutive 35S promoter were also drought tolerant, but had a dwarf phenotype and reduced fruit set (Hsieh *et al.*, 2002).

In this work, we used an *in silico* approach to identify genes from *Eucalyptus* presenting differential expression in the tissues sampled in the Forests project. A set of six statistical tests was applied and several candidate genes were found. The *in silico* approach was validated by RT-PCR for selected genes and a searchable database containing all the results was built.

## Materials and Methods

### cDNA libraries and pools

EST data generated by the Forests consortium (<https://forests.esalq.usp.br/>) were taken from 18 libraries: BK1, CL1, CL2, FB1, LV2, LV3, RT3, RT6, SL1, SL4, SL5, SL6, SL7, SL8, ST2, ST6, ST7 and WD2 (see Table 1). Libraries representing the same organs or plant parts were grouped in eight pools: BK (only BK1), CL (CL1 and CL2), FB (FB1), LV (LV2 and LV3), RT (RT3, RT6), SL (SL1, SL4, SL5, SL6, SL7 and SL8), ST (ST2, ST6 and ST7) and WD (only WD2).

### Identification of gene expression patterns

To compare the expression level in different libraries, the data were normalized by the number of reads in each library. The IDEG.6 software (Romualdi *et al.*, 2001) was used to calculate the values of six different statistical tests aiming to identify differentially expressed genes in multiple tag sampling experiments. The AC, R and GT statistics (Audic and Claverie, 1997; Stekel *et al.*, 2000; Greller and Tobin, 1999), the Fisher's 2X2 exact test, the 2X2  $\chi^2$  test and general  $\chi^2$  test were applied on the Forests data. Three of these statistical tests (Fisher 2X2, 2X2  $\chi^2$  and AC) are pair wise tests and the estimated gene expression levels are compared between two libraries or pools. The other three are multicomparison statistical tests and allow the simultaneous comparison of all libraries or pools. The analyses were performed with scripts developed in the Perl programming language. A web-based searchable database is available at <https://ipe.cbmeq.unicamp.br>.

The identification of library- and pool-specific genes was based upon two rules: A) the cluster must have reads from only one library or pool; B) all statistical tests must have a significance threshold of at least 0.05. Preferentially expressed genes were considered as those having reads from more than one library or pool. The library or pool with the highest number of reads must have statistically different results from all others, considering a 0.05 threshold. To identify ubiquitously expressed genes we considered only those clusters with at least one read from every library. In this case, all statistical tests must have non-significant results.

### Gene expression validation

The *in silico* expression pattern of selected ESTs was validated by reverse transcription-PCR (RT-PCR). Total RNA was extracted from leaf, stem, flower, fruit and root tissues of *Eucalyptus grandis* as described by Korimbocus *et al.*, (2002) with minor modifications. RNA was treated with DNase I at 37 °C for 15 min prior to use. Ten  $\mu$ g of total RNA was reverse transcribed using oligo (dT)<sub>20</sub> and Superscript II (Invitrogen, USA) according to the manufacturer's instructions. An aliquot of two  $\mu$ L from the

first-strand cDNA synthesis reaction was used for PCR amplification using gene-specific primers: 5' ACCACGAGC TCAAGGTCAAG 3' and 5' CTTCTCGTTCACACCCAC AA 3' (cluster EGEQFB1001C06.g), 5' TTTGGGGAA CAACTGGAGAG 3' and 5' CCATCAGAAACAGCAAAG CA 3' (EGEQRT3002E03.g), 5' TCTCTCGCCTTGTTG GTCTT 3' and 5' CTGGCCCTGGAACAGAGTTA 3' (EGACFB1015B10.g), 5' GGCATGTTCTGTGCATCA TC 3' and 5' ACCACCAGCACCTTTCCTTC 3' (EGA GLV2214H10.g), 5' CGTCTCAATTCAACGCACAC 3' and 5' CCTCCAGAACGAAGCATACC 3' (EGABST22 22G06.g), 5' AAGGGCTCGATAGGGATCAT 3' and 5' GCGTAGGACCCGATGAAGAT 3' (EGEPRT3362H 10.g), 5' GAACCTCCCCAGTAAATGC 3' and 5' GC CACACAGAGAGCCAAAGT 3' (EGABSL1082B12.g). Samples were heated to 94 °C for 3 min and the amplification was done for 30 and 35 cycles at 94 °C for 30 s, 65 °C for 45 s and 72 °C for 1 min, followed by a final extension at 72 °C for 10 min. Primers based on an EST encoding a glyceraldehyde-3-phosphate dehydrogenase (GAPDH) were used as an internal control for RNA integrity and equal loading. PCR products were electrophoresed on 1% agarose gels containing ethidium bromide and visualized under UV radiation.

## Results and Discussion

### *In silico* analyses

A total of 112,857 ESTs from the Forests project were used to infer gene expression patterns in several tissues from *Eucalyptus*. Expression profiles were evaluated considering either each library individually or eight pools where libraries from similar tissues/organs were grouped (Table 1).

We were interested in the identification of genes that were specifically or preferentially expressed in a particular library or pool, or in those expressed all over the *Eucalyptus* tissues sampled in the Forests project. A simple approach to identify such genes is to search for clusters containing reads that are exclusive or mainly present in a particular library. However, this approach does not have a statistical validation and will produce a high number of false positives.

To avoid false positives three statistical methods were used in pair wise comparison and another three to compare all samples at the same time. Only the genes that presented significant threshold ( $p < 0.05$ ) in all statistical tests were considered.

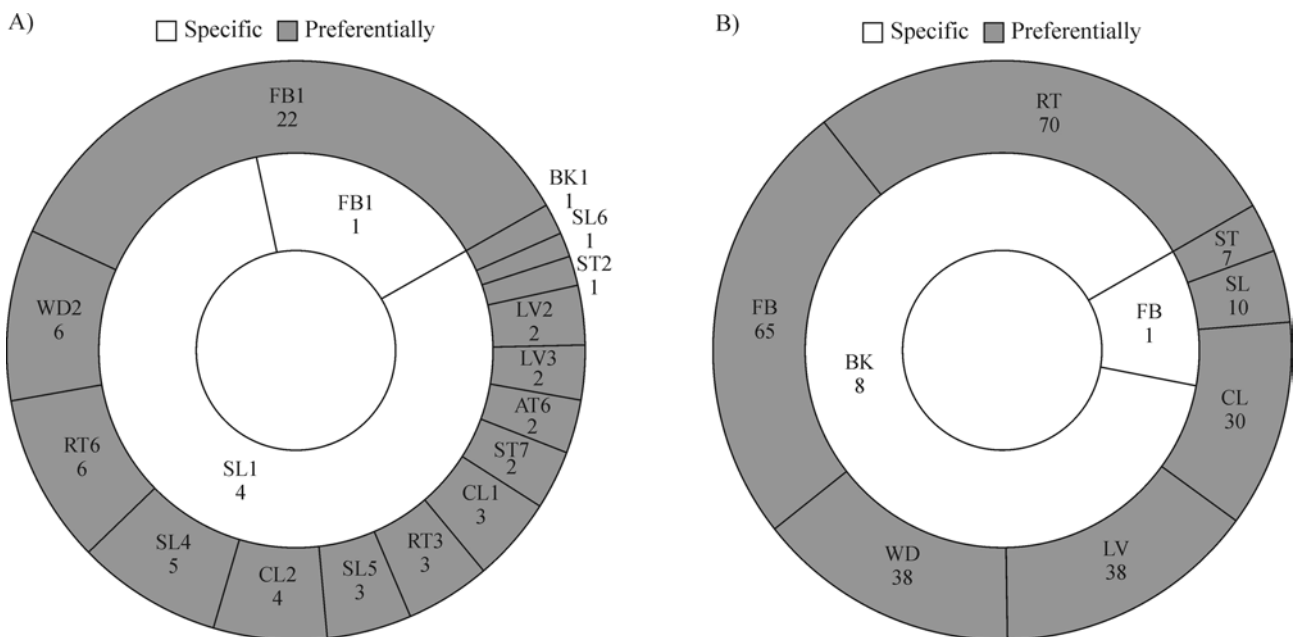

Five clusters were specific to a single library, while 63 were preferentially expressed in a particular library (Figure 1A). A total of nine clusters was found to be specific to a single pool (Figure 1B), and one cluster, EGE QFB1201B08.g, was selected as specific in both library and pool analyses. The number of preferential clusters found in the pool analyses was much higher: 258. This difference may reflect the fact that several libraries represent

**Table 1** - Description of the FOREST libraries and *in silico* pools.

Library	Pool	ESTs (library)	ESTs (pool)	Description		
BK1	BK	1,052	1,052	Bark and sapwood from 7-8 year-old trees		
CL1	CL	9,998	12,533	<i>E. grandis</i> calli grown in the dark

FB1	FB	12,275	12,275	Young and mature buds and flowers		
LV2	LV	7,352	11,693	Leaves from plants at different stages of development: 8, 26 months and 8 years		
LV3		4,341		Leaves from 8-month-old plants infested by <i>Thyrinteina arnobia</i>		
RT3	RT	13,252	20,129	Roots from seedlings		
RT6		6,877		Roots from cold stress-treated seedlings		
SL1	SL	6,182	27,437	<i>E. grandis</i> seedlings grown in the dark and exposed to light for three hours		
SL4		6,718		<i>E. globulus</i> seedlings grown in the dark		
SL5		7,165		<i>E. saligna</i> seedlings grown in the dark		
SL6		1,217		<i>E. urophylla</i> seedlings grown in the dark		
SL7		4,120		<i>E. grandis</i> seedlings grown in the dark		
SL8		2,035		<i>E. camaldulensis</i> seedlings grown in the dark		
ST2		ST		11,032	26,318	Stem from drought-stressed seedlings (small DNA inserts)
ST6				12,558		Stem from drought-stressed seedlings (large DNA inserts)
ST7	2,728		Stem from cold-stressed seedlings			
WD2	WD	10,224	10,224	Sapwood and heartwood from 7-8 year-old trees		

the same tissues/organs taken from different species or grown in slightly different conditions. On the other hand, the small number of genes specific to a library or pool indicates that most genes are expressed in more than one cell type. It is worth noting that the four genes considered specific to the SL1 library were not considered specific to the

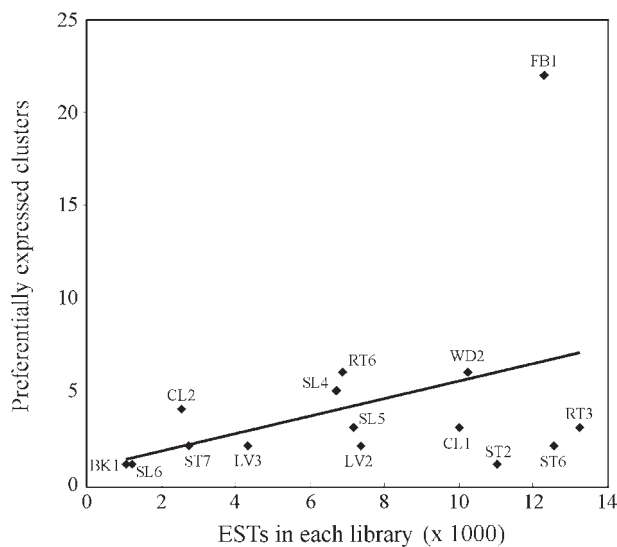

SL pool (Figure 1). This can be understood if we take into account that pools are made from libraries, and consequently the number of elements in each pool is much higher than the number found in each library. So the frequency of ESTs in any particular cluster might drop to a level closer to values expected by chance. As a consequence, the number

**Figure 1** - Distribution of genes with specific or preferential expression in libraries or pools. Six statistical tests were applied to the Forest ESTs and the number of genes with specific or preferential expression in all tests is shown in the inner and outer circles, respectively, for the analysis with libraries (A) or pools of libraries (B). Library and pool names are shown in three and two-character code, respectively, as described in Table 1.

of genes with significant statistical differences in the analysis of pools is smaller compared with the analysis of libraries.

The number of reads in each library ranged from 1052 (BK1) to 13,252 (RT3) and had no clear correlation with the number of genes with differential expression pattern (Figure 2). This result prompted us to speculate that above a certain threshold of ESTs per library, no significant change in the number of differentially expressed genes is observed. A striking difference was observed for FB1 library, corresponding to flowers, flower buds and fruits, which had the highest number of differentially expressed genes. The pres-

**Figure 2** - Distribution of *Eucalyptus* genes with preferential expression. Each point represents the number of genes with preferential expression in each cDNA library. Libraries are indicated by a three-character code, as described in Table 1. The line represents the regression of the data.

ence of a high number of genes preferentially expressed in flower tissues was also observed *in silico* in sugarcane (Figueiredo *et al.*, 2001), indicating that this organ has special features that require a wide range of protein functions.

The library- and/or pool-specific genes are shown in Table 2. No predominance of any particular protein class could be observed, except for two cytochrome P450. It is interesting to note that five genes encode proteins with unknown function. The normalized expression levels of most clusters (considering the number of ESTs at 10,000) were around 19 and a few clusters had 6-8 ESTs per 10,000 ESTs. The highest value was observed for cluster EGEQFB1201B08.g, with a normalized expression of 43. This gene encodes a protein with high similarity to two cytochrome P450-dependent enzymes that were induced by wounding in peas (Frank *et al.*, 1996) and by elicitors in soybeans (Schopfer and Ebel, 1998), making the gene an attractive target for further studies. Moreover, the expression value based in EST counting can be used to infer the strength of the corresponding promoters. However, it is worth noting that some genes may be subject to posttranscriptional regulation, altering mRNA stability, for example, which would mask the results. In the case of genes with low expression levels, a strategy to increase the transcriptional activity without losing the expression pattern is to use multiple copies of the promoter, as observed in the stress inducible HAV22 promoter from barley (Lee *et al.*, 2003).

Due to the high number of genes that had preferential expression in libraries or pools, only the most expressed ones (per library or pool) are shown (Table 3). The range of normalized expression varied from 5 to 31 (mean of 11) in libraries and from 1.8 to 31 (mean 4.24) in pools. No predominance of any type of protein could be observed. Sur-

**Table 2** - Library- and pool-specific clusters. The number of ESTs in each cluster and the normalized expression (corrected for 10,000 ESTs per library) are indicated. The best hit protein was identified by Blast using a threshold E-values of  $\leq e^{-5}$  (Altschul *et al.*, 1997). The p-value indicates the highest threshold observed in the different statistical tests.

Cluster	Library or pool	ESTs	Normalized expression	Best hit protein	p-value

prisingly, one cluster encoding a putative ubiquitin (EGCART6008F08.g) preferentially expressed in roots was found.

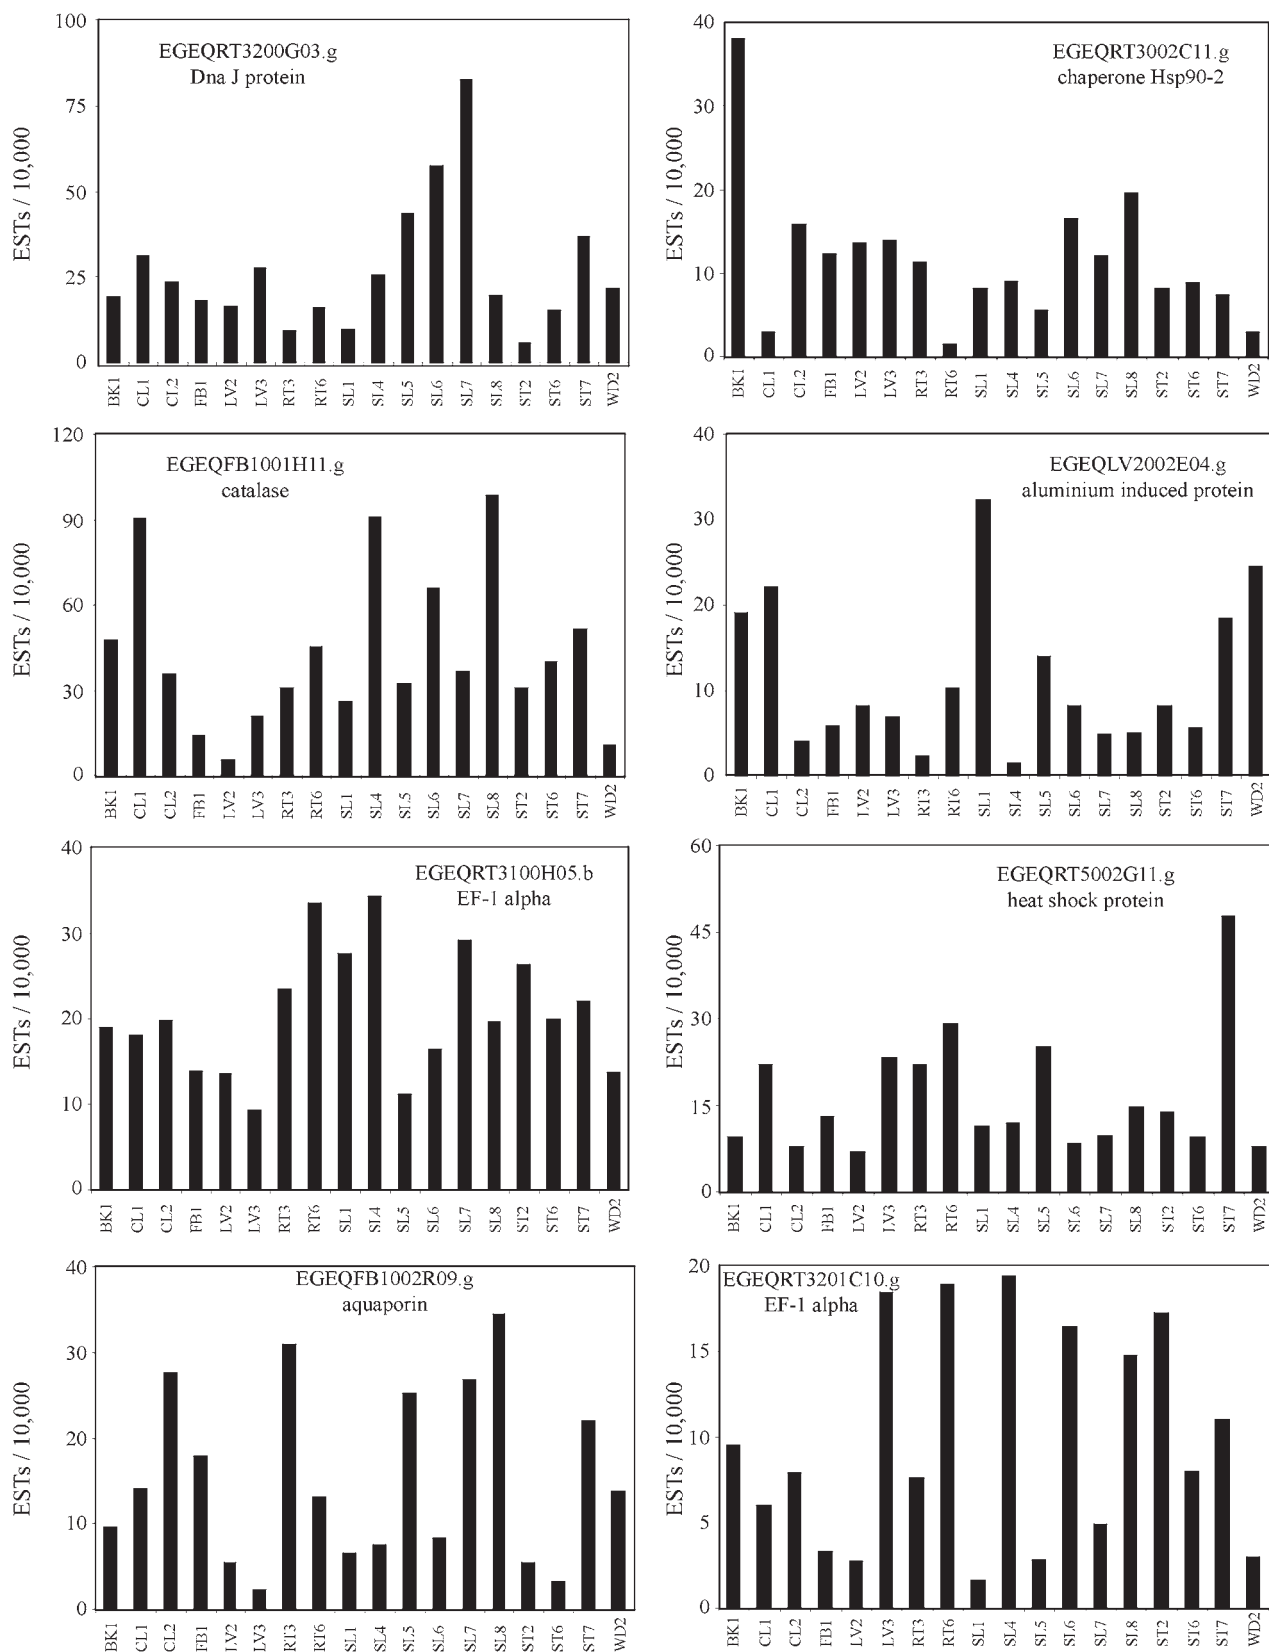

Genes that are expressed in most tissues are good targets to clone ubiquitous promoters that can be useful in some applications. The selection of ubiquitous candidates was based in two assumptions: the cluster must have reads in every library and no significant statistical difference should be detected among any comparison. Eight clusters were in agreement with these conditions (Table 4). The *in silico* expression pattern of these genes is shown in Figure 3. Two of them, EGEQRT3100H05.b and EGEQRT3201C10.g, encode proteins with similarity to the alpha subunit of the translation elongation factor 1, which is encoded by well-known ubiquitously expressed genes.

**Table 4** - Ubiquitously expressed clusters. The best hit protein was identified by Blast using a threshold E-values of  $\leq e^{-5}$  (Altshul *et al.*, 1997).

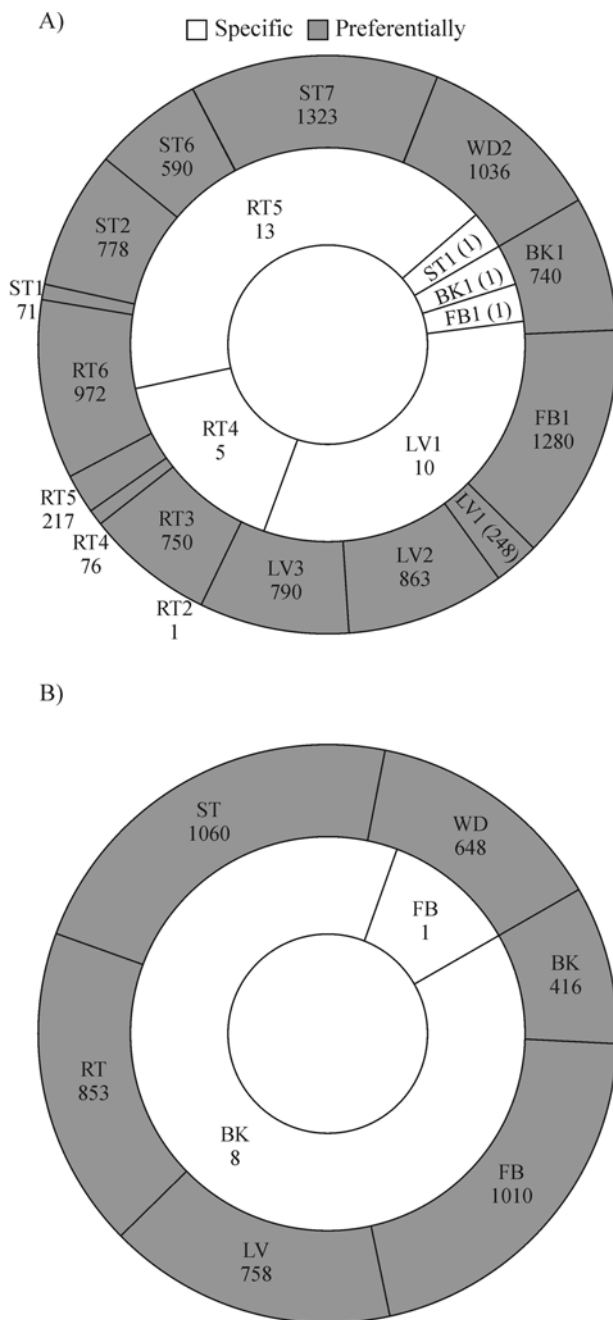

Cluster	Best hit protein
EGEQFB1001H11.g	catalase
EGEQFB1002E09.g	aquaporin
EGEQLV2002E04.g	aluminum induced protein
EGEQRT3002C11.g	chaperone Hsp90-2
EGEQRT3100H05.b	EF-1 alpha
EGEQRT3200G03.g	DnaJ protein
EGEQRT3201C10.g	EF-1 alpha
EGEQRT5002G11.g	heat shock protein

In these *in silico* analyses, multiple statistical tests and very restrictive rules were applied to avoid false positives. We are aware that many false negatives will be present, leaving open the possibility that several other genes represented in the Forests database probably have interesting expression patterns when less restrictive parameters are applied. That was the case when libraries CL (callus) and SL (seedlings) were not considered in the analyses and the same rules as described above were applied. Since both libraries are a mixture of tissues, they are redundant to other cDNA libraries. The consequence is that several genes specific or preferentially expressed in a library made from a particular tissue or organ would not be considered in the analyses if they were also found in CL or SL libraries.

The effects of ignoring these two libraries were clear: the number of genes specifically or preferentially expressed in one library increased from 5 to 31 and from 63 to 9,735, respectively (Figure 4). The genes specific to a particular pool were unchanged, whereas the total number of genes preferentially expressed in a particular pool increased to 4,745. The description of these genes can be found in the supplementary material web page at <http://ipe.cbmeg.unicamp.br/pub/sup/>. These findings indicate that for any particular goal, it is important to carefully set the parameters to assess the genes with useful expression patterns. Considering that all the data from this work is stored in a searchable, web-based database, any particular task can be easily done.

**Figure 3** - *In silico* expression profile of ubiquitous clusters. The EST frequency was normalized by the number of reads in each library and corrected to 10,000 ESTs. Libraries are indicated by a three-character code, as described in Table 1. The cluster name and the annotation based in the Blast hits are shown for each gene.

**Figure 4** - Distribution of genes with specific or preferential expression in libraries or pools when calli and seedlings libraries and pools were not considered. Six statistical tests were applied to the Forest ESTs and the number of genes with specific or preferential expression in all tests is shown in the inner and outer circles, respectively, for the analysis with libraries (A) or pools of libraries (B). Library and pool names are shown in three- and two-character code, respectively, as described in Table 1.

#### Validation of the *in silico* expression pattern

The expression profile of selected genes was evaluated by semi-quantitative RT-PCR using total RNA extracted from leaf (organ used in LV libraries), stem (ST libraries), flower and fruit (both in the FB1 library, that also

had flower buds) and root tissues (RT libraries) of *Eucalyptus grandis*.

According to the *in silico* tests, the cluster EGACFB 1015B10.g had preferential expression in the FB library and the FB pool. The expression profile found by RT-PCR confirmed the *in silico* data, and the corresponding transcripts were detected only in flower buds (Figure 5A). Curiously, this gene was not expressed in fruits, an organ that was also sampled in the FB library. This gene encodes a putative protein that probably represents a novel *Eucalyptus* gene since it presented no similarity to database entries.

Cluster EGEPT3362H10.g encodes a polypeptide with high similarity to TIPs (tonoplast intrinsic proteins) and had reads both in RT and SL pools. Although in these two pools an identical estimated expression level of the *Eucalyptus TIP* gene was observed, a homologous gene from maize presents a root-specific expression (Lopez *et al.*, 2004). Based on this finding, we decided to check whether the *TIP* gene corresponded to a false negative in the *in silico* analyses. The RT-PCR evaluation showed that *TIP* transcripts were detected only in roots, confirming our suspicion (Figure 5A). As stated above, since the *in silico* approach was designed to prevent false positives, a large number of false negatives should be expected. This highlights the hypothesis that several genes not considered as specific or preferential in this study may have interesting expression patterns.

The deduced protein from cluster EGEQT3002 E03.g had significant similarity to BOR1, an efflux-type boron transporter for xylem loading in *Arabidopsis thaliana* (Takano *et al.*, 2002). The *Eucalyptus BOR1* gene presented four reads from the RT pool and one read from the CL pool (data not shown). By simple EST counting, this cluster might be considered as preferentially expressed in roots although our statistical tests did not support this inference. In agreement with the statistical test, the RT-PCR assay supported the hypothesis that this gene was not preferentially expressed in roots. Although expressed in roots, similar levels of transcripts were also observed in other organs (Figure 5A) as reported for the *A. thaliana BOR1* gene, which is expressed in roots and shoots (Takano *et al.*, 2002). The possible expression of the *Eucalyptus BOR-1* in undifferentiated tissues could therefore explain the observed expression pattern.

Cluster EGABSL1082B12.g also displayed no specific or preferential expression in the RT-PCR assay (Figure 5A). This cluster, encoding a putative protein, was enriched in reads from pool SL but was not granted by the statistical tests. This was also the case for the other two clusters, EGAGLV2214H10.g, enriched in reads from pool LV and encoding an homologue of the pea Cytochrome B6-F complex iron-sulfur subunit (Salter *et al.*, 1992), and EGABST2222G06.g, enriched in reads from pool BK and encoding a protein with high identity to beta-carotene hydroxylases from *Citrus unshiu* (Kim *et al.*, 2001) (data

**Figure 5** - RT-PCR validation of candidate clusters. RT-PCR was performed with specific primers using RNA from the organs indicated above each lane and the products were separated in a 1% agarose gel containing ethidium bromide. A) Candidate genes with possible organ-specific or -preferential expression, encoding the following proteins. The deduced protein was named according to the best Blast hit: No hits, without homology in the database (cluster EGACFB1015B10.g); TIP (EGEPRT3362H10.g), BOR1 (EGEQRT3002E03.g) and a Putative protein (EGABSL1082B12.g). B) GAPDH control (EGEQFB1001C06.g). Numbers at the bottom of each panel indicate the number of reaction cycles.

not shown). These results reinforce our view that the use of multiple statistical tests is a good strategy to prevent false positives.

The EGEQFB1001C06.g cluster encodes a glyceraldehyde-3-phosphate dehydrogenase (GAPDH). Genes encoding these proteins are widely used as control in gene expression studies because they are ubiquitously and constitutively expressed. However, the *Eucalyptus* GAPDH gene did not pass in the *in silico* tests because it has no reads in the BK pool. When this pool was not included in the analyses, this cluster was considered ubiquitous. The expression pattern deduced from the RT-PCR assay confirmed the expression in all organs at similar levels (Figure 5B), indicating that the *Eucalyptus* GAPDH gene is indeed ubiquitously expressed.

## Outlook for the Future

The *in silico* analysis presented here constitutes a valuable tool for predicting expression patterns for a large number of ESTs. We hope this bioinformatics tool will be of great help to many studies, especially those targeting promoter identification and cloning.
