TABLE 2 -- EFFECT OF ADDED ELECTROLYTES ON THE RATES OF SOLVOLYSIS IN AQUEOUS ALCOHOLS

are as follows: t-butyl: 0.1M NaBr, +82.5, 0.1M LiClO<sub>4</sub>, +74.3; Et<sub>3</sub>CCl: 0.1*M* NaBr, +54.2, 0.1*M* LiClO<sub>4</sub>, +65.1%. The salts will exist mainly as ion pairs and this will lead to (a) reduced effect on the initial state, (b) reduced ionic atmosphere effect, and (c) stabilization of the transition state due to dipole-dipole interaction<sup>15</sup>.

The rate data in aqueous alcoholic solvents (Table 2) can be interpreted in terms of the ionic atmosphere effect, salt-induced medium effect, and solvent structure-induced ion-pairing effect. The effect of first factor should be larger while that of the other two should be smaller with decrease in water content of the medium.

## Estimation of $pK_{BH^+}$ of Some Mesoionic Thiones

### P. B. TALUKDAR & A. CHAKRABORTY

Research & Development Division East India Pharmaceutical Works Ltd, Calcutta 700061

Received 16 September 1975; accepted 25 October 1975

Apparent second order rate constants  $(k'_2)$  for the reactions between mesoionic thiones and chloroacetate are determined in 50% ( $\nu/\nu$ ) buffer-methanol mixture at pH = 3.40, temp. = 30° and  $\mu = 0.1$ . These were in turn used for estimating  $pK_{BH^+}$  values with the help of a regression equation log  $k_{2}^{\prime}=2.3322+0.7745$  (pKBH+). Calculated data are in accord with the experimental values.

 $\mathbf{E}_{\mathrm{to}\ \mathrm{determine}\ p\mathbf{K}_{\mathrm{BH}^{*}}}^{\mathrm{ARLIER}\ \mathrm{we}\ \mathrm{described^{1}}\ \mathrm{a}\ \mathrm{kinetic}\ \mathrm{approach}\ \mathrm{mesoionic\ thiones}}$ using the following regression equation,

$$\log k_2' = 2.3322 + 0.7745(\phi K_{BH^+}) \qquad \dots (1)$$

where r = 0.989, std dev. = 0.108 and  $k'_2$  is the apparent second order rate constant for reactions with chloroacetic acid. It was also suggested that this equation might be profitably utilized to predict the  $pK_{BH^+}$  of other mesoionic thiones which are not amenable to direct experimental conditions for  $pK_{BH^+}$  determinations. As  $pK_{BH^+}$  reflects an important intrinsic property of a system and only a limited number of compounds have been examined so far<sup>2</sup>, it was decided to examine the scope and validity of Eq. (1) in the light of additional experimental data with other mesoionic compounds recently reported by us<sup>3,4</sup>.

†Values obtained by direct determination as per ref. 1.

The  $pK_{\rm BH^+}$  values of mesoionic thiones, viz. 1,3,4thiadiazolo[3,2-a]quinolinium-5-thione<sup>3</sup> (I), 1-alkyl-1,3,4-triazolo[3,2-a]quinolinium-5-thione<sup>3</sup> (II, alkyl = Me, *n*-Pr and *n*-Bu), 1,3,4-thiadiazolo[2,3-a]isoquinolinium-5-thione<sup>3</sup> (III), 1-*n*-Bu-1,3,4-triazolo[2, 3-*a*]isoquinolinium-5-thione<sup>3</sup> (IV) and 1-substituted 3-methyl-2,4-diphenylimidazolium-5-thione<sup>4</sup> (V, R = Me and p-Me Ph) presented in Table 1 lead to the following conclusions:

(i) Calculated rate constants  $(k'_2)$  cover a significantly wide range as expected<sup>2</sup> for compounds of diverse structural type, and this difference is also adequately reflected in the estimated  $pK_{\rm BH+}$  values from Eq. 1. This is also in accord with observed slope (= 0.7745), and confirms the use-fulness of our findings.

(ii) Tricyclic systems (I, II, III and IV), as anticipated, are weaker bases than the monocyclic imidazoles (V) indicating appreciable intranucleous conjugation in I to IV. Stronger basicity of imidazole derivatives is a well-known fact.

(iii) Compounds I and III are isomeric, but the effect of position of sulphur (endo) on their  $pK_{\rm BH+}$  values is only marginal. The insertion of = NR fragment in lieu of the endo-S generally raises the  $pK_{\rm BH+}$  values, and the difference is conspicuous in the case of II. Similar trend in other mesoionic systems has been recorded earlier by us<sup>2</sup>. (iv) In support of our estimated  $pK_{\rm BH+}$  values

(iv) In support of our estimated  $pK_{\rm BH^+}$  values derived from Eq. 1, these were directly determined for II (R=*n*-Pr) and III on account of better stabilities of the tricyclic systems under the experimental condition. Agreement between the two sets (Table 1) is indeed quite satisfactory, and the observed difference falls within the estimated standard deviation ( $\pm 0.108$ ) justifying the utility of Eq. 1.

deviation  $(\pm 0.108)$  justifying the utility of Eq. 1. The mesoionic compounds (I-V) used were prepared by the literature method<sup>3,4</sup>.

The dried samples were stored in the desiccator prior to their use. Imidazoles (V) tend to decompose slowly on storage at room temperature and freshly made samples were used for our work. Other reagents, viz. methanol, KCl, chloroacetic acid,  $H_2SO_4$ , NaOH, etc., were of AR grade. All spectrophotometric measurements were made with either Hilger UVspec or recording spectrophotometer in 1 cm quartz cells. pH measurements were made on a Philips pH meter, model PR9405L.

Kinetic runs — Rate measurements were carried out spectrophotometrically under *pseudo* first order conditions at appropriate wavelength (Table 1) determined previously by separate experiments in aq. methanol (50% v/v). In all cases the rate constants ( $k_{obs}$ ) were obtained from duplicate runs in methanol-buffer (chloroacetate) mixtures (at pH = 3.40, temp.= 30° and  $\mu = 0.1M$ ) where the [chloroacetic acid] varried from 10<sup>2</sup> to 10<sup>3</sup> moles litre<sup>-1</sup> over the [substrate]. Values of  $k'_2$  were derived by dividing  $k_{obs}$  with the total molar concentration of the buffer in the reaction medium. Other experimental details and calculations were the same as before<sup>1</sup>.

Determination of  $pK_{\rm BH^+}$  — Experimental details for  $pK_{\rm BH^+}$  determination have been reported earlier<sup>2</sup>.  $pK_{\rm BH^+}$  (25°C) values obtained for the two stable systems in 50% v/v aq. methanol determined at 355 nm (II, R = n-Pr, isosbestic point, 325±2 nm) and at 375 nm (III, isosbestic point 340±2 nm) are also recorded in Table 1.

# Succinimide Complexes of Cu(II), Ni(II), Co(II), Fe(II) & Hg(II)

### C. L. SHARMA & SAVITA SHARMA

Department of Chemistry, University of Roorkee, Roorkee

### Received 7 April 1975; accepted 18 September 1975

Stability constants of succinimide complexes of Fe(II), Co(II), Ni(II), Cu(II) and Hg(II) have been determined and are found to be  $3 \cdot 10$ ,  $6 \cdot 28$ ,  $3 \cdot 30$ ,  $6 \cdot 44$  and  $6 \cdot 88$  respectively. The solid complexes are non-electrolytes in nitrobenzene and show IR bands due to coordinated hydroxo groups.

M<sup>ETAL-LIGAND</sup> stability constants of Cu(II), Ni(II), Co(II), Fe(II) and Hg(II) complexes with succinimide have been determined in aqueous medium using Bjerrum's pH titration technique.

Succinimide (BDH) was recrystallized from ethanol. CuCl<sub>2</sub>.2H<sub>2</sub>O; NiSO<sub>4</sub>.6H<sub>2</sub>O; Co(NO<sub>3</sub>)<sub>2</sub>.6H<sub>2</sub>O; FeSO<sub>4</sub>. 7H<sub>2</sub>O and HgCl<sub>2</sub> were of AR grade. Carbonate-free KOH was prepared by the method of Davies and Nancollas<sup>1</sup>. All the solutions were prepared in doubly distilled water. Physical measurements were carried out as described earlier<sup>2</sup>.

The solid 1:1 and 1:2 metal complexes were prepared by mixing the reactants containing a little excess of succinimide over the calculated amount and adjusting the pH to 8.5, 5.8, 7.0, 9.0 and 8.5 in the case of Ni(II), Hg(II), Fe(II), Cu(II) and Co(II) complexes respectively by the addition of KOH. The resulting solutions were heated to  $\approx 40^{\circ}$  and ethanol added until the precipitates were formed. The precipitates were filtered, washed with 50%
