Abstract

Development of Point Generation Technique for a Meshless Method

Jae Sang Rhee

School of Mechanical and Aerospace Engineering

The Graduate School

This study aims to develop meshless point generation technique which can be applied to complicated geometry or moving boundary. Unlike the conventional finite volume method, meshless method requires only point system as a computational domain. Therefore Generation of computational domain is relatively easier than conventional FVM.

In this study, meshless point generation technique is developed. For the validation, the results obtained from the meshless method were compared with the results obtained from the conventional FVM. Practical models, such as Space shuttle or Missile, were selected as a validation model.

For the steady calculation, governing equation is Euler equation. And for the unsteady calculation, Euler equation in Arbitrary Lagrangian Eulerian form is selected as governing equation

Meshless method developed by Huh is used for a flow solver. In both meshless method

and FVM, AUSMPW+ was used for numerical flux scheme, minmod limiter was used for limiting process and LU-SGS was used for time integration.

From the results, the robustness and the accuracy of meshless point generation technique are verified.

Chapter 1. Introduction

1.1 Meshless method

A meshless method is a newly suggested computational fluid dynamics (CFD) algorithm in recent year. This method requires only neighboring points of each point which is called local points cloud without using the concept of mesh. Generally, the conventional finite volume method requires a large amount of time for generating mesh for a complex geometry. Therefore it is less restrictive when generating the computational domain for a complicated or moving geometry than mesh based methods.

1.2 Motivation

A meshless method was introduced in 1977 at first. Since then, a variety of Meshless algorithms have been studied by former researchers. Since 2000, meshless algorithms which analyze compressible flow using moving least square method (LSM) have been developed by Katz (2009) [1] respectively and so on.

The ultimate goal of meshless method is to analyze the unsteady compressible flow around multi-bodies which consider 6-DOF (Degree of Freedom) motion. However the previous researchers did not consider all kind of moving such as 6-DOF motion. As part of the development of the ultimate point generation technique, point generation technique for one body which has complicated geometry was developed in this study. Validation models are Space shuttle, NASA X TM2059, moving cylinder and moving sphere. Numerical analysis on the flow around those models are carried out using meshless solver developed by Huh [2], [4]. And those results are compared with the structured finite volume method

for validation. In both methods, AUSMPW+, minmod limiter, and LU-SGS are used

Chapter 2. Point generation technique

2.1 Meshless point system

The meshless point system consists of two point systems. The first is the near surface point system, and the other is the background point system. The near surface point system is used for boundary layer. Therefore, it is generated along the surface, as shown in Figure 4.

Figure 4 the near surface point system

On the other hand, the background point system is generated outside the near surface point system. And it is created from the Cartesian grid point. As shown in Figure 5

Figure 5 the background point system

2.2 Near surface point system

As explained in chapter 2.1, near surface point system is used to enhance the accuracy of calculation in the boundary layer. In this study, the near surface point system is generated along the Electric field line from the surface. The E-field line is easily computed using surface mesh information using Coulomb's law. It is shown in Eq. (1)

$$\begin{aligned} E_{x,i} &= \sum_j \frac{k_j}{d^2} (x_{S,j} - x_i) \\ E_{y,i} &= \sum_j \frac{k_j}{d^2} (y_{S,j} - y_i) \\ E_{z,i} &= \sum_j \frac{k_j}{d^2} (z_{S,j} - z_i) \end{aligned} \quad (1)$$

In Eq. (1), $E_{x,i}$, $E_{y,i}$, $E_{z,i}$ are x, y, z component of the electric field at point i which is located outside the surface, $x_{S,j}$, $y_{S,j}$, $z_{S,j}$ are x, y, z-coordinate of the surface mesh point which has index j . And x_i , y_i , z_i are x, y, z-coordinate of the point i , d is the distance between point i and j , and k_j is the constant which is determined by users. The electric field line can be obtained by Eq. (1). Figure 6 shows the generated three dimensional near surface point system of the concave-shaped object.

2.3 Background point system

The background point system is generated from the Cartesian grid point. In order to generate the background point system, three input values are needed in each x, y, z direction. The first is interval of point, the second is coordinate of initial point, and the last is the number of points. From these input values, the coordinates of the background point can be derived, as shown in Eq. (2).

$$\begin{aligned}
x_{i,j,k} &= x_{ini} + (i - 1)\Delta x, & (1 \leq i \leq N_x) \\
y_{i,j,k} &= y_{ini} + (j - 1)\Delta y, & (1 \leq j \leq N_y) \\
z_{i,j,k} &= z_{ini} + (k - 1)\Delta z, & (1 \leq k \leq N_z)
\end{aligned} \tag{2}$$

In Eq. (2), Δx , Δy , Δz denote the interval of point, N_x , N_y , N_z are the number of points, and x_{ini} , y_{ini} , z_{ini} are the coordinates of the initial point. Among the background points, the points which are located in the near surface point system are excluded from the calculation. The total point system is shown in both Figure 7 and Figure 8.

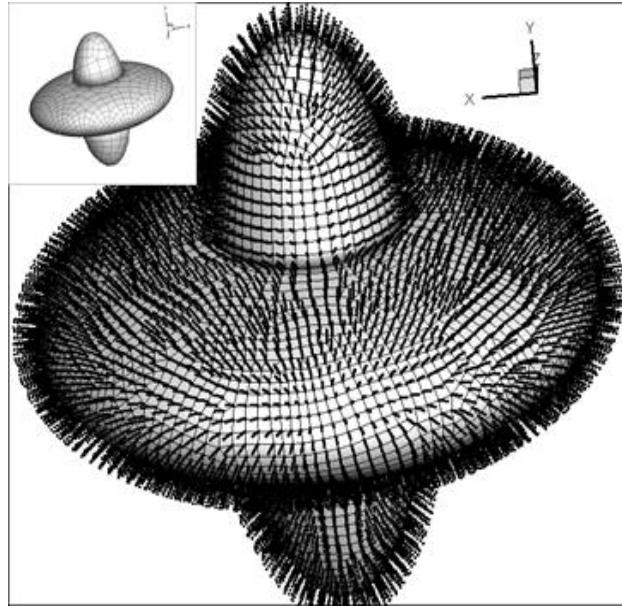

Figure 6 the three dimensional near surface point system

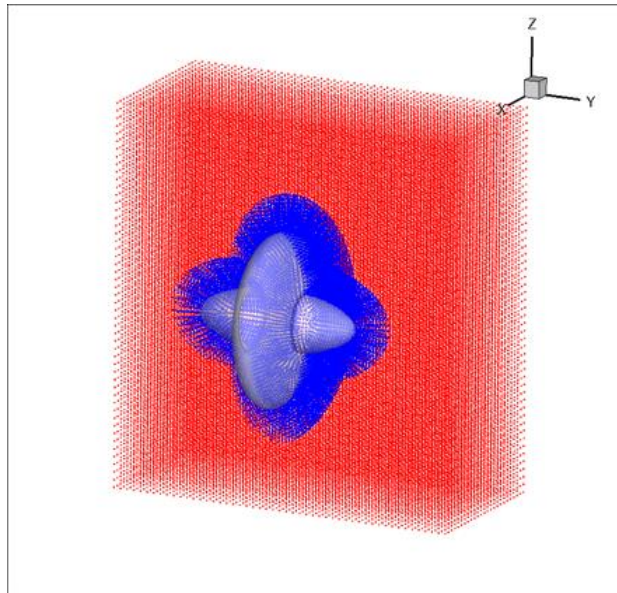

Figure 7 the three dimensional meshless point system

Figure 8 the two dimensional meshless point system

2.4 Local points cloud

Most of computational methods, including finite element method (FEM), finite difference methods (FDM), and finite volume method (FEM), depend on the interlaced grids or finite volumes. In order to discretize PDE, every point require the set of neighboring points not the grid information in meshless scheme. The set of neighboring points is called local points cloud. For the accuracy, the robustness, and the efficiency, appropriate composition of local points cloud is critical. In this paper, the strategy of generation of local points cloud is proposed. The strategy is shown as follows.

2.4.1 Two dimensional local points cloud

In two dimensional space, total 8 points to be chosen for the local points cloud. The criterion for composing the local points cloud is as follows.

- Find the closest point of the central point.
- Divide the region into eight sector equally, which the line between the central point and the closest point is the bisecting line of angle of the sector. As shown in Figure 9.
- Within each sector, the closest point is selected as a point of local cloud.

2.4.2. Three dimensional local points cloud

In three dimensional space, total 18 points constitute the local points cloud. the criterion for composing the local points cloud is as follows.

- Generate virtual cube which has a point as a center.
- Draw square, consist of internal division point between center point and vertex on the face, on each face as show in Figure 10.

- Connect every vertex on the bigger square and the corresponding vertex on the little one
- Then, every face will be split into the five polygon, one square, and four trapezoids.
- If the ratio of internal division is $a: b = (\sqrt{5} + 2)/2$ (golden ratio), 18 zones which have same are generated, as shown in Figure 11. The same zone is denoted as same color.
- Find the closest point in each zone, these points constitute the local points cloud.

Figure 9 two dimensional cloud shape

Figure 10 face splitting on cube

Figure 11 divided region

2.5 Moving principle of points

2.5.1 Moving methodology

When the object moves, the near surface point system moves with same speed of object. On the other hand, the background point system is fixed. Therefore, the near surface point system and the background point system are overlapped, as shown in Figure 13. The overlapped background points must be eliminated for the computation. For the better computational speed, the background point system change their state when the point moves, not being eliminated in this study. For example, when a background point is overlapped, the point is set to 'OFF'. They can be seen as the red points in Figure 12. Then the point become non-overlapped, the point is set to 'ON'. They also can be seen as the green points in Figure 13. Figure 13 Shows the regenerated point system for the next physical time step

Figure 12 initial point system

Figure 13 overlapping and vacancy

Figure 14 regenerated point system

2.5.2 Sorting point for local point cloud

After the regeneration of the point system, points should constitute their own local points cloud again. However, to constitute local points cloud for all points consumes a lot of time. Therefore, points which constitute new local points cloud unconditionally should be sorted. Except those points, they use their old local points cloud. The sorting strategy is as follows.

- The outmost points of the near surface point system

The outmost points of the near surface point system move with the object. The neighboring points of these points change when the object moves, because the background points are fixed. It is shown in the Figure 15.

- The newly included points due to the movement of the object

As shown in Figure 14, when the object moves, the background points are generated. These points was 'OFF' in the previous physical time step. They don't have local point cloud. Consequently, these points constitute local point cloud.

- The neighboring points of 'OFF' state points

In Figure 13, the overlapped points are denoted as red color. Because those points are excluded from the computational domain, a point which uses those points as a local point cloud lose their connectivity. Therefore, these points should constitute the local point cloud again.

Figure 15 outmost points of the near surface point system

Figure 16 newly included points (green points)

Figure 17 neighboring point of the overlapped points

2.5.2 Strategy : rapid generation of new local point cloud

When a point searching their new local point cloud, to search point for all domain is not desirable. In order to decrease the time for searching, two strategies are established. The first is for the outmost points of the near surface point system, and the other is for the background point system. Methodology is as follows.

- Outmost points

The outmost points have their own block information. Block information means that Cartesian 'I' and 'J' index of the background point which exists upper-left corner to the outmost point and this point called '*background block point*'. Additionally, the background number of the background block point is required. This number is called 'N'. These are shown in the Figure 18. Using given information, the existing background points which have Cartesian index 'I' or 'I+1' or 'I-1', and index 'J' or 'J+1' or 'J-1' are the candidates of local point cloud. Then, in the old local point cloud, the point which is the near surface point is used again. It is denoted as color dot in Figure 18.

- Background points

Using Cartesian 'I' and 'J' index of the background point, the existing background points which have Cartesian index 'I' or 'I+1' or 'I-1', and index 'J' or 'J+1' or 'J-1' are the candidates of local point cloud. Then the outmost points of the near surface point system are selected for candidate. It is shown in Figure 19

Figure 18 indicating the candidates of local point cloud (near surface point)

Figure 19 indicating the candidates of local point cloud (background point)

Chapter 3. Numerical Method

3.1 Governing Equation

3.1.1 Euler equation

For a non-equilibrium and inviscid gas, the governing equation is a three-dimensional Euler equation which considering species continuity and vibrational energy equation. The equation is as follows.

$$\frac{\partial U}{\partial t} + \frac{\partial F}{\partial x} + \frac{\partial G}{\partial y} + \frac{\partial H}{\partial z} = S \quad (3)$$

Where,

$$U = \begin{bmatrix} \rho \\ \rho u \\ \rho v \\ \rho w \\ E \\ \rho_i \\ \vdots \\ \sum \rho e_{vib,i} \end{bmatrix}, F = \begin{bmatrix} \rho u \\ \rho u^2 + p \\ \rho uv \\ \rho uw \\ (E + p)u \\ \rho_i u \\ \vdots \\ \sum \rho e_{vib,i} u \end{bmatrix}$$

$$G = \begin{bmatrix} \rho v \\ \rho uv \\ \rho v^2 + p \\ \rho vw \\ (E + p)v \\ \rho_i v \\ \vdots \\ \sum \rho e_{vib,i} v \end{bmatrix}, H = \begin{bmatrix} \rho w \\ \rho uw \\ \rho vw \\ \rho w^2 + p \\ (E + p)w \\ \rho_i w \\ \vdots \\ \sum \rho e_{vib,i} w \end{bmatrix}, S = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ W_i \\ \vdots \\ \sum W_{vib,i} \end{bmatrix}, \quad (4)$$

S is source term that includes W_i in the species continuity equations and $W_{vib,i}$ in the vibrational energy equation which are calculates according to Ref. [6] and [7].

3.1.2. Euler equation in Arbitrary Lagrangian Eulerian form

An appropriate choice of *kinematic description* is primarily important consideration when simulating unsteady problems. However, purely Lagrangian and purely Eulerian descriptions have demerits, a technique, combining the best features of both descriptions, has been developed. Such a technique is called Arbitrary Lagrangian Eulerian (ALE) description. In Lagrangian description, the computational nodes are moved with the continuum. Then, in Eulerian description, the computational nodes are held in fixed. On the other hand, in ALE description, the computational nodes are moved with arbitrary speed [8]. And Euler equation in ALE form is shown as follows.

$$\frac{\partial U}{\partial t} + \frac{\partial F}{\partial x} + \frac{\partial G}{\partial y} + \frac{\partial H}{\partial z} = S \quad (5)$$

Where,

$$U = \begin{bmatrix} \rho \\ \rho u \\ \rho v \\ \rho w \\ E \end{bmatrix}, F = \begin{bmatrix} \rho(u - \hat{u}) \\ \rho u(u - \hat{u}) + p \\ \rho v(u - \hat{u}) \\ \rho w(u - \hat{u}) \\ E(u - \hat{u}) + pu \end{bmatrix},$$

$$G = \begin{bmatrix} \rho(v - \hat{v}) \\ \rho u(v - \hat{v}) \\ \rho v(v - \hat{v}) + p \\ \rho w(v - \hat{v}) \\ E(v - \hat{v}) + pv \end{bmatrix}, H = \begin{bmatrix} \rho(w - \hat{w}) \\ \rho u(w - \hat{w}) \\ \rho v(w - \hat{w}) \\ \rho w(w - \hat{w}) + p \\ E(w - \hat{w}) + pw \end{bmatrix} \quad (6)$$

In Eq. (6), \hat{u} , \hat{v} , \hat{w} denote the velocity component of points x , y , z direction respectively.

3.2 Least square method

In the meshless method, least square method based on Taylor series expansion has been used to discretize PDE. Given a function $\phi(\chi)$ with $\chi = (x, y, z)$ in three dimension, the Taylor expansion from the point cloud center (x_0, y_0, z_0) is denoted as

$$\phi(x, y, z) = \Delta x \frac{\partial \phi(x_0)}{\partial x} + \Delta y \frac{\partial \phi(y_0)}{\partial y} + \Delta z \frac{\partial \phi(z_0)}{\partial z} + O(\Delta^2) \quad (7)$$

The least square method with weighted function may be expressed as follows.

$$\min \sum_{j=1}^n \omega_{0j} \left[\Delta \phi_{0j} - \Delta x \frac{\partial \phi(x_0)}{\partial x} - \Delta y \frac{\partial \phi(y_0)}{\partial y} - \Delta z \frac{\partial \phi(z_0)}{\partial z} \right]^2 \quad (8)$$

$$\frac{\partial \phi}{\partial x} \approx \sum_j a_{0j} (\phi_j - \phi_0) \quad (9)$$

$$\frac{\partial \phi}{\partial y} \approx \sum_j b_{0j} (\phi_j - \phi_0) \quad (10)$$

$$\frac{\partial \phi}{\partial z} \approx \sum_j c_{0j} (\phi_j - \phi_0) \quad (11)$$

In Eq. (8), j is an index of point in the local point cloud and n is the number of points in the cloud.

In a three dimensional case, the matrix equation which derives least square coefficient a_{0j} , b_{0j} , c_{0j} is as follows.

$$AX = B \quad (12)$$

Where,

$$X^T = [a_k, b_k, c_k] \quad (13)$$

$$A = \begin{bmatrix} \Sigma \omega \Delta x^2 & \Sigma \omega \Delta x \Delta y & \Sigma \omega \Delta x \Delta z \\ \Sigma \omega \Delta x \Delta y & \Sigma \omega \Delta y^2 & \Sigma \omega \Delta y \Delta z \\ \Sigma \omega \Delta x \Delta z & \Sigma \omega \Delta y \Delta z & \Sigma \omega \Delta z^2 \end{bmatrix} \quad (14)$$

$$B^T = [\Sigma \omega \Delta x \Delta \phi, \Sigma \omega \Delta y \Delta \phi, \Sigma \omega \Delta z \Delta \phi] \quad (15)$$

Solving Eq. (12), the solution is as follows.

$$a_k = \frac{M_{11}}{|A|} \sum \omega \Delta x \Delta \varphi + \frac{M_{12}}{|A|} \sum \omega \Delta y \Delta \varphi + \frac{M_{13}}{|A|} \sum \omega \Delta z \Delta \varphi \quad (16)$$

$$b_k = \frac{M_{21}}{|A|} \sum \omega \Delta x \Delta \varphi + \frac{M_{22}}{|A|} \sum \omega \Delta y \Delta \varphi + \frac{M_{23}}{|A|} \sum \omega \Delta z \Delta \varphi \quad (17)$$

$$c_k = \frac{M_{31}}{|A|} \sum \omega \Delta x \Delta \varphi + \frac{M_{32}}{|A|} \sum \omega \Delta y \Delta \varphi + \frac{M_{33}}{|A|} \sum \omega \Delta z \Delta \varphi \quad (18)$$

Where,

$$|A| = \sum \omega \Delta x^2 \sum \omega \Delta y^2 \sum \omega \Delta z^2$$

$$\left[1 - \frac{(\sum \omega \Delta x \Delta z)^2}{\sum \omega \Delta x^2 \sum \omega \Delta z^2} - \frac{(\sum \omega \Delta x \Delta y)^2}{\sum \omega \Delta y^2 \sum \omega \Delta x^2} - \frac{(\sum \omega \Delta y \Delta z)^2}{\sum \omega \Delta z^2 \sum \omega \Delta y^2} \right]$$

$$+ 2 \left[\sum \omega \Delta x \Delta y \sum \omega \Delta y \Delta z \sum \omega \Delta x \Delta z \right] \quad (19)$$

$$M_{11} = \sum \omega \Delta y^2 \sum \omega \Delta z^2 - \left(\sum \omega \Delta y \Delta z \right)^2 \quad (20)$$

$$M_{12} = \sum \omega \Delta x \Delta z \sum \omega \Delta y \Delta z - \sum \omega \Delta x \Delta y \sum \omega \Delta z^2 \quad (21)$$

$$M_{13} = \sum \omega \Delta x \Delta y \sum \omega \Delta y \Delta z - \sum \omega \Delta x \Delta z \sum \omega \Delta y^2 \quad (22)$$

$$M_{21} = \sum \omega \Delta y \Delta z \sum \omega \Delta x \Delta z - \sum \omega \Delta x \Delta y \sum \omega \Delta z^2 \quad (23)$$

$$M_{22} = \sum \omega \Delta x^2 \sum \omega \Delta z^2 - \left(\sum \omega \Delta x \Delta z \right)^2 \quad (24)$$

$$M_{23} = \sum \omega \Delta x \Delta z \sum \omega \Delta x \Delta y - \sum \omega \Delta y \Delta z \sum \omega \Delta x^2 \quad (25)$$

$$M_{31} = \sum \omega \Delta x \Delta y \sum \omega \Delta y \Delta z - \sum \omega \Delta x \Delta z \sum \omega \Delta y^2 \quad (26)$$

$$M_{32} = \sum \omega \Delta x \Delta y \sum \omega \Delta x \Delta z - \sum \omega \Delta y \Delta z \sum \omega \Delta x^2 \quad (27)$$

$$M_{33} = \sum \omega \Delta x^2 \sum \omega \Delta y^2 - \left(\sum \omega \Delta x \Delta y \right)^2 \quad (28)$$

3.3 Spatial Discretization

3.3.1 AUSMPW+ for meshless method

The AUSMPW+ scheme [9] is used for chemically reactive flow, i.e. equilibrium and non-equilibrium flow.

The main feature of AUSMPW+ is to remove oscillations of AUSM+ near wall or across a strong while maintain the accuracy of the original scheme. In this study, AUSMPW+ modified for the meshless scheme is used. Ignoring source term and three dimensional term, Eq. (3) can be simply expressed as

$$\frac{\partial U_i}{\partial t} + \sum_{j=1}^n a_{ij} \Delta f_{ij} + \sum_{j=1}^n a_{ij} \Delta f_{ij} + \sum_{j=1}^n b_{ij} \Delta g_{ij} = 0 \quad (29)$$

Then,

$$\frac{\partial U_i}{\partial t} + \sum_{j=1}^n \Delta \mathcal{F}_{ij} = 0 \quad (30)$$

In Eq. (30), $\mathcal{F} = af + bg$ is a directed flux along the metric weight vector (a, b) . Because AUSMPW+ scheme uses mid flux at $j+1/2$ instead of the flux at j , Eq. (30) can be expressed as follows [10].

$$\sum_{j=1}^n \Delta \mathcal{F}_{ij} = 2 \sum_{j=1}^n \Delta \mathcal{F}_{ij+\frac{1}{2}} = 2 \sum_{j=1}^n (\mathcal{F}_{ij+\frac{1}{2}} - \mathcal{F}_{ij}) \quad (31)$$

The numerical flux of AUSMPW+ is given by

$$\mathcal{F}_{\frac{1}{2}} = \bar{M}_L^+ c_1 \Phi_L + \bar{M}_R^- c_1 \Phi_R + (P_L^+ P_L + P_R^- P_R) \quad (32)$$

$\Phi = (\rho, \rho u, \rho H)^T$ and $P = (0, p, 0)^T$. The subscripts $1/2$ and (L,R) stand for a quantity at a midpoint on the edge of Figure 20 and the left and the right states across the edge, respectively. The Mach number at midpoint is defined as

$$m_{\frac{1}{2}} = M_L^+ + M_R^- \quad (33)$$

When \bar{M}_L^+ and \bar{M}_R^- are given as follows.

i) $m_{\frac{1}{2}} = M_L^+ + M_R^0 \geq 0$, then

$$\bar{M}_L^+ = M_L^+ + M_R^- [(1-w)(1+f_R) - f_L] \quad (34)$$

$$\bar{M}_R^- = w(1+f_R) \quad (35)$$

i) $m_{\frac{1}{2}} = M_L^+ + M_R^0 < 0$, then

$$\bar{M}_L^+ = M_L^+ + w(1+f_L) \quad (36)$$

$$\bar{M}_R^- = M_R^- + M_L^+ [(1-w)(1+f_L) - f_R] \quad (37)$$

In Eq. (34)~(37), w does not mean the z-directional velocity. w is given as follows.

$$w(P_L, P_R) = 1 - \min\left(\frac{P_L}{P_R}, \frac{P_R}{P_L}\right)^3 \quad (38)$$

The pressure-based weight function is simplified to

$$f_{L,R} = \left(\frac{P_{L,R}}{P_S} - 1\right), P_S \neq 0 \quad (39)$$

Where

$$P_S = P_L^+ P_L + P_R^- P_R \quad (39)$$

The split Mach number is defined by

$$M^\pm = \begin{cases} \pm \frac{1}{4}(M \pm 1)^2, & |M| \leq 1 \\ \frac{1}{2}(M \pm |M|), & |M| > 1 \end{cases} \quad (40)$$

$$P^\pm = \begin{cases} \pm \frac{1}{4}(M \pm 1)^2(2 \mp M), & |M| \leq 1 \\ \frac{1}{2}(1 \pm \text{sign}(M)), & |M| > 1 \end{cases} \quad (41)$$

The Mach number of each side is

$$M_{L,R} = \frac{U_{L,R}}{C_{1/2}} \quad (42)$$

And the speed of sound $c_{1/2}$ is

$$c_{1/2} = \begin{cases} \min\left(\frac{c^{*2}}{\max(|U_L|, c^*)}\right), & \frac{1}{2}(U_L + U_R) > 0 \\ \min\left(\frac{c^{*2}}{\max(|U_R|, c^*)}\right), & \frac{1}{2}(U_L + U_R) < 0 \end{cases} \quad (43)$$

Where

$$c^* = \sqrt{2(\gamma - 1)/(\gamma + 1)H_{normal}} \quad (44)$$

$$H_{normal} = \frac{1}{2}\left(H_L - \frac{1}{2}V_L^2 + H_R - \frac{1}{2}V_R^2\right) \quad (45)$$

Figure 20 illustration of mid-point value on the edge connecting nodes i and j

3.3.2 Minmod limiter for meshless method

To improve accuracy, TVD scheme is adopted to the meshless scheme. In this study, minmod limiter [11] is used at AUSMPW+. The basic form of spatial interpolation is given by

$$\Phi_L = \Phi_i + 0.5\phi_L(\Phi_j - \Phi_i) \quad (46)$$

$$\Phi_R = \Phi_j + 0.5\phi_R(\Phi_i - \Phi_j) \quad (47)$$

In order to apply to meshless method, it is necessary to modify minmod limiter as follows.

$$\phi = \max(0, \min(1, r_k)) \quad (48)$$

Where $k \in \{\text{local point cloud of node } i \ \& \ \theta_{kij} \text{ is max}\}$

$$r_k = \frac{s_{ik'}}{s_{ji}} = \frac{s_{ki}}{s_{ji}} \cos(\theta_{kij}) \quad (49)$$

$$s_{ki} = \frac{\Phi_k - \Phi_i}{\|\vec{x}_k - \vec{x}_i\|} \quad (50)$$

Since there is no point on the opposite side of point j in the vicinity of point i in general point system, nearest point k to the opposite side is used to calculate r_k shown in Figure 21.

Figure 21 minmod limiter for the meshless method

3.4 Time Integration

Referring to the works of Yoon [12], and Chen [13], LU-SGS is adopted to the meshless method. By applying Eq. (30) and Eq. (31), Euler equation can be rewritten in a semi-discrete form as follows.

$$\frac{\partial U_i^{n+1}}{\partial t} + 2 \sum_{j=1}^n (F_{ij}^{n+1} - F_i^{n+1}) = S_i^n \quad (51)$$

The flux function F_{ij}^{n+1} may be linearized by setting

$$F_{ij}^{n+1}(\omega_i, \omega_j) \approx F_{ij}^n + A_{ij}^+(\omega_i)\delta\omega_i + A_{ij}^-(\omega_j)\delta\omega_j \quad (52)$$

When n is the time level and matrices A_{ij}^\pm are constructed as follows

$$A_{ij}^\pm = \frac{1}{2}(A_{ij} \pm \lambda_{ij}I) \quad (53)$$

Where,

$$\lambda_{ij} \geq \max(|\lambda_A|) \quad (54)$$

Here, λ_A represents eigenvalues of Jacobian matrix.

Using Eq. (52) ~ (54), Eq. (51) can be LU decomposed, the result is as follows.

$$\begin{aligned} & \left(\frac{1}{\Delta t} + \sum_j k|\rho| \right) \Delta U_i + \sum_{j \in LC} 2A^- \Delta U_j + \sum_{j \in UC} 2A^- \Delta U_j - \sum_j A \Delta U_i \\ & = -RES \end{aligned} \quad (55)$$

In Eq. (55), LC denotes lower cloud in the cloud index, and UC denotes upper cloud in the cloud index.

3.5 Dual-time stepping for meshless method

For time-accurate unsteady analysis, pseudo-time sub iteration strategy is adopted to solve the unsteady problems.

$$\frac{\partial Q}{\partial t} = -\hat{R} \quad (56)$$

The time derivative term is differenced using a backward second-order three point implicit formula and moved to the right-hand side of the equation:

$$0 = -\frac{1.5Q^{n+1} - 2Q^n + 0.5Q^{n-1}}{\Delta t} - \hat{R}^{n+1} \quad (57)$$

A pseudo-time derivative of Q is added on the left-hand side of Eq. (37)

$$\begin{aligned} \frac{\partial Q^{n+1}}{\partial \tau} &= -\frac{1.5Q^{n+1} - 2Q^n + 0.5Q^{n-1}}{\Delta t} - \hat{R}^{n+1} \\ &= -\hat{R}^{n+1} - \hat{S}^{n+1} \end{aligned} \quad (58)$$

The pseudo-time derivative term is discretized using the first-order Euler implicit formula.

$$\frac{Q^{n+1,m+1} - Q^{n+1,m}}{\Delta \tau} = -\hat{R}^{n+1,m+1} - \hat{S}^{n+1,m+1} \quad (59)$$

Where, a superscript m denotes the pseudo-time iteration level.

The dual-time stepping method adopted here has a second order time accuracy. Then, Eq. (59) can be written as

$$\left[\frac{1}{\Delta \tau} I + \left\{ \frac{\partial \hat{R}}{\partial Q} + \frac{\partial \hat{S}}{\partial Q} \right\}^{n+1,m} \right] \Delta Q^{n+1,m} = -\hat{R}^{n+1,m} - \hat{S}^{n+1,m} \quad (60)$$

Chapter 4. Numerical Analysis

4.1 Steady problems

4.1.1 Space shuttle reentry simulation

The first validation case is Space shuttle reentry simulation. Space shuttle has a highly complex geometry. And the flow condition is also highly extreme. The angle of attack is 40 Degree, and the Mach number is 20. The three cases had been conducted for the validation. The first case is the result from the meshless solver based on the meshless point system (MPS) generated from the meshless point generation technique. And the second is the result obtained from the finite volume method, using the structured grid (SG). Lastly, the third case is the result obtained from the meshless solver, using the structured grid point (SGP). The flow condition is shown in the table 1. And the Figure 22 and the Figure 23 show the meshless point system and the structured grid for Space shuttle respectively. Both methods use AUSMPW+ as spatial discretization, and minmod limiter is chosen as a limiting process. For a time integration, LU-SGS is used.

Altitude (Km)	60
Pressure (Pa)	22.461
Temperature (K)	255.77
Ma	20
Angle of attack (Degree)	40
Species (non-equilibrium)	5 (N, O, NO, N2, O2)

Figure 23 structured grid (space shuttle)

Figure 24, 25, 26 denote results which show the pressure contour. Figure 24 shows the result obtained from the meshless analysis carried on the MPS. Then Figure 25 shows that of FVM. Lastly Figure 26 is the result obtained from the meshless solver based on the SGP.

Figure 24 meshless result with MPS

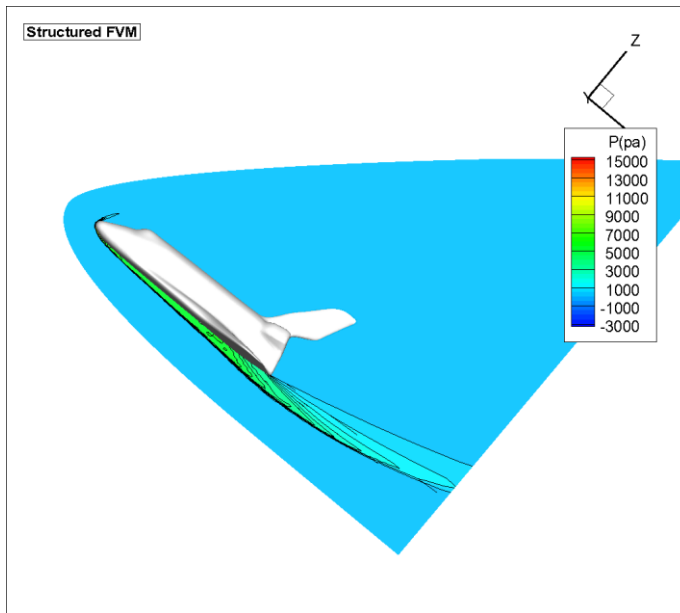

Figure 25 FVM result with SG

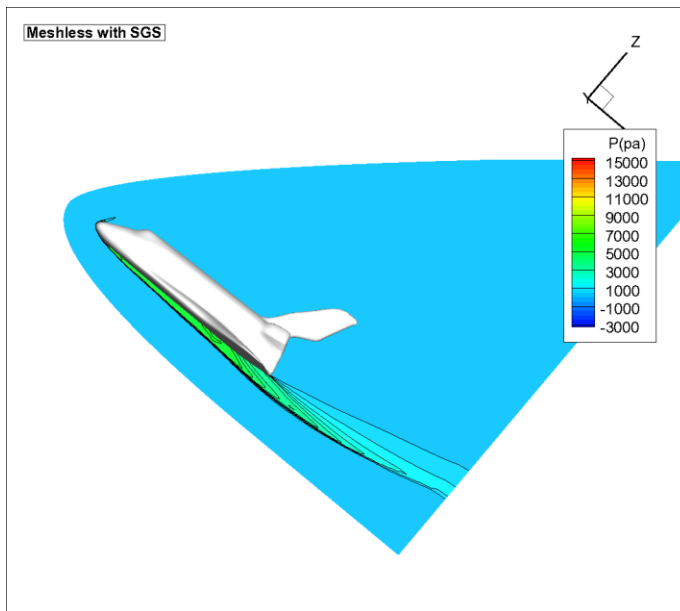

Figure 26 FVM result with SGP

Figure 27 and 28 show the pressure contour at $x=300$. Figure 27 is the comparison of two solvers on the same computational domain. The left is the result obtained from the meshless method calculated on the SGP. And the right is that of the structured finite volume method. And Figure 28 shows the meshless results which are calculated on the different point systems, SGP and MPS. The left figure is same as the left contour in Figure 27. And the right contour denotes the meshless result using MPS. and the Figure 29 shows the comparison of the pressure coefficient along the surface. The, Table 2 denotes the comparison of the aerodynamic coefficients.

From those results, though the meshless method requires the short time for pre-process, the meshless method has almost same level of accuracy, compared with FVM.

4.1.2 NASA TM X 2059

An analysis on the flow around a highly complicated geometry is the one of the main goals. In order to generate such a model, the modified NASA TM X 2059 model [14] is selected as a next validation model. Four tail fins, the twenty-degree conical nozzle [15] and four vanes are added to the model. Consequently, this model integrates the internal flow and the external flow. In Figure 32, the generated model is shown.

Figure 30 the configuration of NASA TM X 2059

Figure 31 the twenty-degree conical nozzle

Figure 32 the modified NASA TM X 2059

For a validation, 2 splices flow is analyzed. The freestream flow is air and the nozzle flow is plume. Its freestream conditions are at altitude 10 km and the Mach number is 5. The flow conditions are shown in Table 3. And the meshless point system for the model is shown in Figure 33. For a spatial discretization, AUSMPW+ was used, and as a limiting process, minmod limiter was selected. LU-SGS was selected as a time integration method.

Altitude (km)	10
Pressure (Pa)	26,500
Temperature (K)	223.25210
Mach number	5
Angle of attack (Degree)	0
Spices	Air

Table 3 flow conditions (the modified NACA TM X 2059)

Figure 33 the computational domain for the second validation

Figure 34 ~ 35 show the results and Figure 36 shows the convergence history.

Figure 35 shows that 2 spices flows are successfully analyzed.

From the figure 34 ~ 36, no matter how geometry is complicated, the generation technique is available. Consequently, the robustness of the meshless point generation technique and the meshless method was verified.

4.2 Unsteady problems

4.2.1 moving sphere

in order to verify the meshless point generation technique for moving system, an analysis on the flow around moving sphere was carried out. For verification, the steady state result which has freestream Mach number 2 is selected as the reference. Then, three unsteady cases are carried out. They have three different Mach number of the sphere and three different freestream Mach number respectively. In all the unsteady case, freestream Mach number observed from the sphere is 2. The unsteady results are compared with the reference. It indicates that all cases have same result, because the relative velocity of the four cases is same. The information of the case is shown in the Table 4

	Freestream Mach number	Mach number of the sphere
Case 1	0.0	2.0
Case 2	1.0	1.0
Case 3	1.5	0.5
Case 4(reference)	2.0	0.0

Table 4 the outline of the unsteady problem (moving sphere)

The results are shown in Figure 37 and Figure 38. Figure 37 denotes the comparison of the pressure coefficient along $z=0$. It indicates that all cases have almost same pressure coefficient. Additionally, Figure 38 shows the comparison of the density contour. The shock of the two cases are almost same. These results verify that the point generation technique is available for the unsteady problem including moving boundary.

(upper : unsteady, nether : steady)

Chapter 5. Conclusions

In this study, the point generation technique was developed. Using hybrid of the near surface point system and the background point system, both the effectiveness and the accuracy were considered. Additionally, hybrid point system is useful for the moving point system. Through the developed technique, no matter how the geometry is complex, it is possible to generate the computational domain is easily using the developed method.

The three cases are carried out for validation. the first case is the space shuttle reentry simulation. This case verified the robustness of the point generation technique for the complex object which has both concave and convex geometry. Additionally, it is verified that the method is available to hypersonic region including highly strong shock. The second case is flow around the missile body. Because this model integrates the internal flow and the external flow, it can be considered as highly complicated geometry than Space shuttle. With successful analysis of the second case, the tremendous robustness of the point generation technique and the meshless method was verified. The last case is the flow around the moving sphere. This validation showed a success of expansion to unsteady region of the meshless point generation technique. Consequently, a result which has similar levels of accuracy can be obtained within a short time using the developed method.
