Complementary log - log with random effect model using malaysian graduate employability data (Article)

Shahadan, M.A.^a, Khan, R.K.A.W.^b, Ramli, A.M.^c^aFaculty of Human Development, Sultan Idris Education University Malaysia, Malaysia^bFaculty of Human Development, Sultan Idris Education University Malaysia, Malaysia^cKulliyah of Islamic Revealed Knowledge and Human Science, International Islamic University, Malaysia

Abstract

[View references \(20\)](#)

The objective of this research is to investigate the relationship between hazard ratio or survival function of graduate employability and 8 explanatory variables. The 8 explanatory variables are as follows: Gender, CGPA, geographic region, English language proficiency, area of study, curriculum satisfaction, career guidance services satisfaction and monthly family income. In order to study a survival function of graduate employability , we have developed a sequence of binary numbers (employed (1) or unemployed (0)) at a particular time of being employed among first degree graduate students (N=2228). The data is based on a survival study data , which traces the survival function of graduate students within 12 months of window opportunity. We have used the complementary log - log model in various forms. For the simple complementary log - log model , the results showed that the hazard risk with baseline hazard ratio relate to graduates' gender, CGPA, satisfaction with career guidance, the geographic region from which they came from, their English performance, their area of study and their family income. As for subject-specific (random effects), the hazard ratio also relates to the abovementioned variables. © BEIESP.
