A.J. van Es, R. Helmers<br>Elementary symmetric polynomials of increasing order

The Centre for Mathematics and Computer Science is a research institute of the Stichting Mathematisch Centrum, which was founded on February 11, 1946, as a nonprofit institution aiming at the promotion of mathematics, computer science, and their applications. It is sponsored by the Dutch Government through the Netherlands Organization for the Advancement of Pure Research (Z.W.O.).

# Elementary Symmetric Polynomials of Increasing Order 

A.J. van Es<br>University of Amsterdam<br>R. Helmers<br>Centre for Mathematics and Computer Science<br>P.O. Box 4079, 1009 AB Amsterdam, The Netherlands

The asymptotic behaviour of elementary symmetric polynomials $S_{n}^{(k)}$ of order $k$, based on $n$ independent and identically distributed random variables $X_{1}, \ldots, X_{n}$, is investigated for the case that both $k$ and $n$ get large.

If $k=\alpha\left(n^{1 / 2}\right)$, then the distribution function of a suitably normalised $S_{n}^{(k)}$ is shown to converge to a standard normal limit. The speed of this convergence to normality is of order $\theta\left(\mathrm{kn}^{-1 / 2}\right)$, provided $k=\theta\left(\log ^{-1} n \log _{2}^{-1} n n^{1 / 2}\right)$ and certain natural moment assumptions are imposed. This order bound is sharp, and cannot be inferred from one of the existing Berry-Esseen bounds for $U$-statistics.

If $k \rightarrow \infty$ at the rate $n^{1 / 2}$ then a non-normal weak limit appears, provided the $X_{i}$ 's are positive and $S_{n}^{(k)}$ is standardised appropriately. On the other hand, if $k \rightarrow \infty$ at a rate faster than $n^{1 / 2}$ then it is shown that for positive $X_{j}$ 's there exists no linear norming which causes $S_{n}^{(k)}$ to converge weakly to a non degenerate weak limit.

1980 Mathematics Subject Classification: 60F05.
Key Words \& Phrases: elementary symmetric polynomials of increasing order, normal and non-normal weak limits, Berry-Esseen bound, one-term Edgeworth expansion.

## 1. Introduction and results

Let $X_{1}, X_{2}, \ldots$ be independent and identically distributed random variables with

$$
\begin{equation*}
\mu=E X_{1} \neq 0,0<\sigma^{2}=\sigma^{2}\left(X_{1}\right)<\infty . \tag{1.1}
\end{equation*}
$$

Let for any $1 \leqslant k \leqslant n$,

$$
\begin{equation*}
S_{n}^{(k)}=\binom{n}{k}^{-1} \sum_{1 \leqslant i_{1}<i_{2}<\ldots<i_{k} \leqslant n} \cdots X_{i_{1}} \cdots X_{i_{k}} \tag{1.2}
\end{equation*}
$$

and let

$$
\begin{equation*}
F_{n}^{(k)}(x)=P\left(\left\{\frac{n^{1 / 2}\left(S_{n}^{(k)}-\mu^{k}\right)}{\left(k \mu^{k-1} \sigma\right)} \leqslant x\right\}\right) \tag{1.3}
\end{equation*}
$$

for real x. Let $\Phi$ denote the standard normal distribution function (df).
Clearly $S_{n}^{(k)}$ is a U-statistic of degree k with kernel h given by $h\left(x_{1}, \ldots, x_{k}\right)=x_{1} \ldots x_{k}$. If k is fixed, then Hoeffding's CLT for U-statistics (Hoeffding (1948)) yields that $F_{n}^{(k)}$ converges in distribution to $\Phi$, as $n \rightarrow \infty$, provided assumption (1.1) is satisfied. We shall show that the result remains valid if $k=k(n) \rightarrow \infty$, whenever $k=\alpha\left(n^{1 / 2}\right)$.

THEOREM 1. If $\mu=E X_{1} \neq 0,0<\sigma^{2}=\sigma^{2}\left(X_{1}\right)<\infty$ and $k=o\left(n^{1 / 2}\right)$, then

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \sup _{x}\left|F_{n}^{(k)}(x)-\Phi(x)\right|=0 . \tag{1.4}
\end{equation*}
$$

The speed of convergence to normality in (1.4) is determined in

THEOREM 2. If $\mu=E X_{1} \neq 0,0<\sigma^{2}=\sigma^{2}\left(X_{1}\right), E\left|X_{1}\right|^{3}<\infty$ and $k=\theta\left(\log ^{-1} n \log _{2}^{-1} n n^{1 / 2}\right)$, then, as $n \rightarrow \infty$,

$$
\begin{equation*}
\sup _{x}\left|F_{n}^{(k)}(x)-\Phi(x)\right|=\theta\left(k n^{-1 / 2}\right) \tag{1.5}
\end{equation*}
$$

If $\mathbf{k}$ is fixed, then (1.5) yields the classical rate $n^{-1 / 2}$ for the accuracy of the normal approximation. For this very special case Theorem 2 is a simple consequence of the Berry-Esseen theorem for Ustatistics of degree $k$ given by van Zwet (1984). On the other hand, if $k=k(n) \rightarrow \infty$ but $k=\theta\left(\log ^{-1} n \log _{2}^{-1} n n^{1 / 2}\right)$, then - perhaps somewhat surprisingly - the orderbound (1.5) cannot be inferred from one of the existing Berry-Esseen bounds for U-statistics. Application of Corollary 4.1 of van Zwet (1984) yields the bound $\theta\left(k^{2}\left(1+\frac{\sigma^{2}}{\mu^{2}}\right)^{k} n^{-1 / 2}\right)$, for the 1.h.s. of (1.5), which is of course much worse then the bound given in (1.5). A related Berry-Esseen bound for U-statistics of Friedrich (1985) also does not give us (1.5). It appears that the dependence on k in these bounds is not optimal. In contrast, the bound $O\left(k^{-1 / 2}\right)$ established in Theorem 2 is sharp. To see this we note that, if $k=k(n) \rightarrow \infty$ at a rate slower than $\log ^{-1} n \log _{2}^{-1} n \quad n^{1 / 2}$ and the moment assumptions of Theorem 2 are satisfied, then $F_{n}^{(k)}$ admits an valid one-term Edgeworth expansion $\tilde{F}_{n}^{(k)}(x)=\Phi(x)$ $+\frac{1}{6} n^{-1 / 2} \phi(x)\left(1-x^{2}\right)\left\{\sigma^{-3} E\left(X_{1}-\mu\right)^{3}+3(k-1) \sigma \mu^{-1}\right\}$ with uniform remainder o $\left(k n^{-1 / 2}\right)$. A proof of this assertion may be found in the appendix. There is no need for the usual requirement that $F$ is non-lattice. However, if $k$ is fixed, then we must add the assumption that $F$ is non-lattice, in order to guarantee that our expansion is valid uniformly. This latter statement can be inferred from a recent paper of Maesano(1984), where an Edgeworth expansion for U-statistics of fixed degree $k$ is established. For the case $\mathrm{k}=2$ we also refer to Theorem 1.2 of Bickel, Götze and van Zwet(1986), whereas the classical case $k=1$ is of course well-known and treated, e.g., in Feller(1971).
We do not know whether the assumption $k=\mathcal{O}\left(\log ^{-1} n \log _{2}^{-1} n n^{1 / 2}\right)$ in Theorem 2 can be relaxed. In any case this requirement is only slightly stronger than $k=a\left(k n^{-1 / 2}\right)$, which is already needed to establish asymptotic normality. In section 2.5 we supplement the foregoing discussion, by an example establishing the sharpness of the bound (1.5) for zero-one random variables $X_{1}, X_{2}, \ldots$ in a more direct way.

If $k=k(n) \rightarrow \infty$ at the rate $n^{1 / 2}$ or faster, then the asymptotic behaviour of $S_{n}^{(k)}$ becomes completely different from the one described in the theorems 1 and 2. From a weak limit theorem for the k-th root of $S_{n}^{(k)}$ due to Székely (1982), which considers only strictly positive $X_{j}^{\prime} s$, we derive for positive $X_{j}$ 's the following two results.

THEOREM 3. If $P\left(X_{1}>0\right)=1,0<\sigma^{2}=\sigma^{2}\left(X_{1}\right)<\infty$, and $k \sim c n^{1 / 2}$ for some constant $c>0$ and $n \rightarrow \infty$, then there exists a sequence of positive numbers $\left\{s_{n}\right\}$, such that $s_{n} \rightarrow \mu$ and

$$
\begin{equation*}
s_{n}^{-k} S_{n}^{(k)} \rightarrow \underset{d}{\exp }\left[\frac{c \sigma}{\mu} N\right] \tag{1.6}
\end{equation*}
$$

where $\underset{d}{ }$ denotes convergence in distribution and $N$ stands for a standard normal random variable.
THEOREM 4. If $P\left(X_{1}>0\right)=1,0<\sigma^{2}=\sigma^{2}\left(X_{1}\right)<\infty$, and $\mathrm{kn}^{-1 / 2} \rightarrow \infty$, as $n \rightarrow \infty$, then there exists no linear norming which causes $S_{n}^{(k)}$ to converge in distribution to a nondegenerate limit distribution.

Theorem 4 tells us that for positive $X_{j^{\prime}}$ there exists no linear norming of $S_{n}^{(k)}$ that converges in distribution to a nondegenerate limit if $k n^{-1 / 2} \rightarrow \infty$. In view of Székely's (1982) result (see Lemma 2 in the next section) it turns out that for positive $X_{j}$ if $\mathrm{kn}^{-1 / 2} \rightarrow \infty$ taking the k -th root is essentially required to obtain nondegenerate weak limits, while if $k=o\left(n^{1 / 2}\right)$ there exist linear normings of both $S_{n}^{(k)}$ and its k -th root that converge to a nondegenerate limit. The border case $k \sim c n^{1 / 2}(c>0)$ is
treated in Theorem 3. Again Székely's (1982) result can be used to find that for positive $X_{j}$ the random variable $S_{n}^{(k)}$ can be appropriately scaled to yield a nondegenerate weak limit.

The limit behaviour of $S_{n}^{(k)}$ in the case $k \sim c n(0 \leqslant c \leqslant 1)$ was investigated in detail by van Es (1986), Halász and Székely (1976), Székely (1974,1982) and Móri and Székely (1982). In the latter paper it is shown that in the degenerate case $(\mu=0)$ nondegenerate limit distributions exist of linear normings of $S_{n}^{(k)}$ even if $k \sim c n(0 \leqslant c \leqslant 1)$.

## 2. Proofs

### 2.1. Proof of Theorem 1

The Hoeffding decomposition for elementary symmetric polynomials yields

$$
\begin{equation*}
S_{n}^{(k)}-\mu^{k}=\sum_{r=1}^{k} H_{r}\left(X_{1}, \ldots, X_{n}\right) \tag{2.1}
\end{equation*}
$$

where

$$
H_{r}\left(X_{1}, \ldots, X_{n}\right)=\left[\begin{array}{l}
n  \tag{2.2}\\
k
\end{array}\right)^{-1}\left[\begin{array}{l}
n-r \\
k-r
\end{array}\right] \mu^{k-r} \sum_{1 \leqslant j_{1}<\ldots<j, \ldots n} \prod_{i=1}^{r}\left(X_{j_{i}}-\mu\right)
$$

as given by Karlin and Rinnott (1982), page 496. Define

$$
\begin{equation*}
q_{r}=\frac{\sigma^{2}\left(H_{r+1}\right)}{\sigma^{2}\left(H_{r}\right)}, r=1,2, \ldots, k-1 \tag{2.3}
\end{equation*}
$$

A simple computation using (2.2) yields

$$
\begin{equation*}
q_{r}=\frac{\sigma^{2}}{\mu^{2}}(k-r)^{2} /((r+1)(n-r)), r=1,2, \ldots, k-1 . \tag{2.4}
\end{equation*}
$$

Since the summands of the r.h.s. of (2.1) are uncorrelated we find

$$
\begin{align*}
\sigma^{2}\left(S_{n}^{(k)}\right) & =\sum_{r=1}^{k} \sigma^{2}\left(H_{r}\left(X_{1}, \ldots, X_{n}\right)\right)=  \tag{2.5}\\
& =\sigma^{2}\left(H_{1}\left(X_{1}, \ldots, X_{n}\right)\right)\left(1+q_{1}+q_{1} q_{2}+\ldots+q_{1} q_{2} \ldots q_{k-1}\right)
\end{align*}
$$

Because of (2.4) and the assumption $k=\alpha\left(n^{1 / 2}\right)$ we see that for fixed $k$ and $n$, and $n$ sufficiently large,

$$
\begin{equation*}
q_{r}<c \frac{k^{2}}{r n}, r=1,2, \ldots, k-1 \tag{2.6}
\end{equation*}
$$

for some constant $c>0$. This implies

$$
\begin{equation*}
0 \leqslant \sum_{r=2}^{k} q_{1 \ldots q_{r-1}} \leqslant \sum_{r=2}^{\infty} \frac{1}{(r-1)!}\left[\frac{c k^{2}}{n}\right)^{r-1}=e^{c \frac{k^{2}}{n}}-1=o(1) \tag{2.7}
\end{equation*}
$$

as $n \rightarrow \infty$. In view of (2.5) this yields that

$$
\begin{equation*}
\sigma^{2}\left(S_{n}^{(k)}\right) \sim \sigma^{2}\left(H_{1}\left(X_{1}, \ldots, X_{n}\right)\right) \tag{2.8}
\end{equation*}
$$

In other words :

$$
\begin{equation*}
H_{1}\left(X_{1}, \ldots, X_{n}\right)=k n^{-1} \mu^{k-1} \sum_{i=1}^{n}\left(X_{i}-\mu\right) \tag{2.9}
\end{equation*}
$$

is the dominant term in the decomposition (2.1). Application of the CLT of Lindeberg-Levy to
$H_{1}\left(X_{1}, \ldots, X_{n}\right)$ shows that (1.4) is valid if $S_{n}^{(k)}-\mu^{k}$ in (1.3) is replaced by $H_{1}\left(X_{1}, \ldots, X_{n}\right)$. This completes the proof.

### 2.2. Proof of Theorem 2

To establish (1.5) we rewrite (2.1) as

$$
\begin{equation*}
S_{n}^{(k)}-\mu^{k}=U_{n}+R_{n} \tag{2.10}
\end{equation*}
$$

where

$$
\begin{equation*}
U_{n}=H_{1}\left(X_{1}, \ldots, X_{n}\right)+H_{2}\left(X_{1}, \ldots, X_{n}\right) \tag{2.11}
\end{equation*}
$$

with $H_{1}$ as in (2.9),

$$
\begin{equation*}
H_{2}\left(X_{1}, \ldots, X_{n}\right)=\frac{k(k-1)}{n(n-1)} \mu^{k-2} \sum_{1 \leqslant i<j \leqslant n}\left(X_{i}-\mu\right)\left(X_{j}-\mu\right) \tag{2.12}
\end{equation*}
$$

and

$$
\begin{equation*}
R_{n}=\sum_{r=3}^{k} H_{r}\left(X_{1}, \ldots, X_{n}\right) \tag{2.13}
\end{equation*}
$$

is a remainder term of lower order. Clearly $U_{n}$ is a U -statistic of degree 2 with kernel

$$
\begin{equation*}
1 / 2 k \mu^{k-1}(x+y-2 \mu)+1 / 2 k(k-1) \mu^{k-2}(x-\mu)(y-\mu) . \tag{2.14}
\end{equation*}
$$

It follows directly from (2.10) that to prove (1.5) it suffices to show that both

$$
\begin{equation*}
\sup _{x}\left|P\left(\left\{\frac{n^{1 / 2} U_{n}}{\left(k \mu^{k-1} \sigma\right)} \leqslant x\right\}\right)-\Phi(x)\right|=\theta\left(k n^{-1 / 2}\right) \tag{2.15}
\end{equation*}
$$

and

$$
\begin{equation*}
P\left(\left\{\frac{\left|R_{n}\right|}{\left(k \mu^{k-1} \sigma\right)} \geqslant k n^{-1}\right\}\right)=\theta\left(k n^{-1 / 2}\right) \tag{2.16}
\end{equation*}
$$

are satisfied.
To prove (2.15) we shall need characteristic functions (ch.f) arguments. We shall only treat the case that $k \rightarrow \infty$. If k is fixed then Theorem 2 is a simple special case of Corollary 4.1 of van Zwet(1984). Let $\rho_{n}^{(k)}(t)$ denote the ch.f of $n^{1 / 2} U_{n} /\left(k \mu^{k-1} \sigma\right)$, i.e.

$$
\begin{equation*}
\rho_{n}^{(k)}(t)=E \exp \left(i t n^{1 / 2} U_{n} /\left(k \mu^{k-1} \sigma\right)\right) \tag{2.17}
\end{equation*}
$$

The usual argument based on Esseen's smoothing lemma implies that

$$
\begin{equation*}
|t| \leqslant k^{-k} n^{1 / 4}|t|^{-1}\left|\rho_{n}^{(k)}(t)-e^{-1 / 2 t^{2}}\right| d t=\theta\left(k n^{-1 / 2}\right) \tag{2.18}
\end{equation*}
$$

and

$$
\begin{equation*}
k^{-4} n^{1 / 4} \leq|t| \leq k^{-1} n^{k}|t|^{-1}\left|\rho_{n}^{(k)}(t)-e^{-1 / 2 t^{2}}\right| d t=O\left(k n^{-1 / 2}\right) \tag{2.19}
\end{equation*}
$$

together will yield (2.15). The statements (2.18) and (2.19) may be proved by modifying the proof of Theorem 2.1 of Helmers and van Zwet (1982). Our proof of (2.19) will require the assumption $k=O\left(\log ^{-1} n \log _{2}^{-1} n n^{1 / 2}\right)$. For details of the proof the interested reader is referred to the appendix.

It remains to establish (2.16). An application of Chebychev's inequality yields :

$$
\begin{equation*}
P\left(\left\{\frac{\left|R_{n}\right|}{\left(k \mu^{k-1} \sigma\right)} \geqslant k n^{-1}\right\}\right) \leqslant n^{2} k^{-4} \mu^{-2 k+2} \sigma^{-2} \sigma^{2}\left(R_{n}\right) \tag{2.20}
\end{equation*}
$$

Using (2.13) and an argument like (2.5)-(2.7) yields

$$
\begin{align*}
\sigma^{2}\left(R_{n}\right) & =\sum_{r=3}^{k} \sigma^{2}\left(H_{r}\left(X_{1}, \ldots, X_{n}\right)\right)=  \tag{2.21}\\
& =\sigma^{2}\left(H_{1}\left(X_{1}, \ldots, X_{n}\right)\right) \sum_{r=3}^{k} q_{1} \ldots q_{r-1}= \\
& =k^{2} n^{-1} \mu^{2 k-2} \sigma^{2} \sum_{r=3}^{k} q_{1} \ldots q_{r-1} \leqslant \\
& \leqslant k^{2} n^{-1} \mu^{2 k-2} \sigma^{2} \sum_{r=3}^{k} \frac{1}{(r-1)!}\left[\frac{c k^{2}}{n}\right]^{r-1} \leqslant \\
& \leqslant c^{2} k^{6} n^{-3} \mu^{2 k-2} \sigma^{2} \sum_{r=3}^{k} \frac{1}{(r-1)!}\left[\frac{c k^{2}}{n}\right]^{r-3} \leqslant \\
& \leqslant c^{2} k^{6} n^{-3} \mu^{2 k-2} \sigma^{2} 2^{-1} \sum_{r=1}^{\infty} \frac{1}{(r-1)!}\left(\frac{c k^{2}}{n}\right]^{r-1} \leqslant \\
& \leqslant c^{2} k^{6} n^{-3} \mu^{2 k-2} \sigma^{2} 2^{-1} e^{c \frac{k^{2}}{n}}= \\
& =\mathcal{O}\left(k^{6} n^{-3} \mu^{2 k-2}\right)
\end{align*}
$$

Together with (2.20) this gives

$$
\begin{equation*}
P\left(\left\{\frac{\left|R_{n}\right|}{\left(k \mu^{k-1} \sigma\right)} \geqslant k n^{-1}\right\}\right)=\mathscr{O}\left(k^{2} n^{-1}\right) \tag{2.22}
\end{equation*}
$$

which implies (2.16). This completes the proof.

### 2.3. Proof of Theorem 3

The following result of Székely (1982) will be used.
LEMMA 1. If $P\left(X_{1}>0\right)=1,0<\sigma^{2}=\sigma^{2}\left(X_{1}\right)<\infty$ and $k=\alpha(n)$, then, as, $n \rightarrow \infty$

$$
\begin{equation*}
n^{1 / 2}\left(\left(S_{n}^{(k)}\right)^{1 / k}-s_{n}\right) \rightarrow \underset{d}{ } N\left(0, \sigma^{2}\right) \tag{2.23}
\end{equation*}
$$

where $\left\{s_{n}\right\}$ denotes a sequence of positive numbers, such that $s_{n} \rightarrow \mu$, and $N\left(0, \sigma^{2}\right)$ stands for a normal random variable with expectation zero and variance $\sigma^{2}$.

Define

$$
\begin{equation*}
V_{n}=n^{1 / 2}\left(\left(S_{n}^{(k)}\right)^{1 / k}-s_{n}\right) \tag{2.24}
\end{equation*}
$$

and note that because of (2.23) $V_{n}$ is asymptotically $N\left(0, \sigma^{2}\right)$. In addition we have that $s_{n}+n^{-1 / 2} V_{n} \geqslant 0$. A Taylor expansion argument yields

$$
\begin{align*}
S_{n}^{(k)} & =\exp \left[k \log \left(s_{n}+n^{-1 / 2} V_{n}\right)\right]=  \tag{2.25}\\
& =\exp \left[k\left(\log s_{n}+n^{-1 / 2} W_{n}\right)\right]= \\
& =s_{n}^{k} \exp \left(k n^{-1 / 2} W_{n}\right)
\end{align*}
$$

where $W_{n}$ is asymptotically $N\left(0, \sigma^{2} \mu^{-2}\right)$ distributed. This directly yields (1.6) and the proof of the theorem is complete.

### 2.4. Proof of Theorem 4

In view of (2.25) it suffices to prove the statement of the theorem for the random variables

$$
\begin{equation*}
Z_{n}=\exp \left(k n^{-1 / 2} W_{n}\right) \tag{2.26}
\end{equation*}
$$

Let us suppose that there exist sequences $\left\{a_{n}\right\}$ and $\left\{b_{n}\right\}$ with $a_{n}>0$ such that $a_{n}\left(Z_{n}-b_{n}\right)$ converges in distribution to a nondegenerate limit distribution $F$. Then there exist three points $-\infty<u_{1}<u_{2}<u_{3}<\infty$, continuity points of F , with $0 \leqslant F\left(u_{1}\right)<F\left(u_{2}\right)<F\left(u_{3}\right) \leqslant 1$.
It follows from this and (2.26) that

$$
\begin{align*}
& \lim _{n \rightarrow \infty} P\left(\left\{a_{n}\left(Z_{n}-b_{n}\right) \leqslant u_{i}\right\}\right)=  \tag{2.27}\\
& =\lim _{n \rightarrow \infty} P\left(U_{n}^{\prime} \leqslant n^{1 / k} k^{-1} \log \left(\frac{u_{i}+a_{n} b_{n}}{a_{n}}\right)\right)=F\left(u_{i}\right)
\end{align*}
$$

for $i=1,2,3$. This implies

$$
\begin{align*}
& \lim _{n \rightarrow \infty} n^{1 / 2} k^{-1}\left(\log \left(\frac{u_{2}+a_{n} b_{n}}{a_{n}}\right)-\log \left(\frac{u_{1}+a_{n} b_{n}}{a_{n}}\right)\right)=  \tag{2.28}\\
& =\frac{\sigma}{\mu}\left\{\Phi^{-1}\left(F\left(u_{2}\right)\right)-\Phi^{-1}\left(F\left(u_{1}\right)\right)\right\}>0
\end{align*}
$$

and hence

$$
\begin{equation*}
\lim _{n \rightarrow \infty} n^{1 / 2} k^{-1} \log \left(\frac{u_{2}+a_{n} b_{n}}{u_{1}+a_{n} b_{n}}\right)>0 . \tag{2.29}
\end{equation*}
$$

Since $n^{1 / 2} k^{-1} \rightarrow 0$, evidently $a_{n} b_{n} \rightarrow-u_{1}$. But the same argument also holds for $u_{2}$, and $u_{3}$, implying $a_{n} b_{n} \rightarrow-u_{2}$, which is in contradiction with $a_{n} b_{n} \rightarrow-u_{1}$. This completes the proof of the theorem.

### 2.5. An example establishing the sharpness of the bound (1.5)

Consider i.i.d. zero-one random variables $X_{1}, X_{2}, \ldots$ with $P\left(X_{1}=0\right)=P\left(X_{1}=1\right)=1 / 2$. The elementary symmetric polynomial $S_{n}^{(k)}$ then reduces to $S_{n}^{(k)}=0$ if $E_{n}<k, S_{n}^{(k)}=\binom{E_{n}}{k} /\left[\begin{array}{l}n \\ k\end{array}\right]$ if $E_{n} \geqslant k$ where $E_{n}$ denotes the number of ones in $X_{1}, \ldots, X_{n}$. Of course $E_{n}$ is binomially distributed with parameters $\mathbf{n}$ and $1 / 2$. This example is also treated in van $\operatorname{Es}(1986)$ for the case $k \sim c n(0<c<1)$. We prove the following lemma.

LEMMA 2. If $P\left(X_{1}=0\right)=P\left(X_{1}=1\right)=1 / 2$ and $k=o\left(n^{1 / 2}\right)$ then there exists a sequence $x_{n}$, $n$ odd, satisfying

$$
\begin{equation*}
x_{n}=1 / 2(k+1) n^{-1 / 2}(1+o(1)) \tag{2.30}
\end{equation*}
$$

and

$$
\begin{equation*}
F_{n}^{(k)}\left(x_{n}\right)-\Phi\left(x_{n}\right)=(2 \pi)^{-1 / 1 / 1 / 2}(k+1) n^{-1 / 2}(1+o(1)) \tag{2.31}
\end{equation*}
$$

as $n \rightarrow \infty$.
To prove Lemma 2 we first note that (1.3) can be rewritten as

$$
\begin{equation*}
F_{n}^{(k)}(x)=P\left(g_{k, n}\left(E_{n}\right)-n^{1 / 2} k^{-1} \leqslant x\right) \tag{2.32}
\end{equation*}
$$

where the function $g_{k, n}: \mathbb{N} \rightarrow \mathbb{R}$ is defined by

$$
g_{k, n}(m)=0 \quad \text { if } m<k, \quad g_{k, n}(m)=n^{1 / k} k^{-1} 2^{k}\left[\begin{array}{l}
n  \tag{2.33}\\
k
\end{array}\right]^{-1}\left[\begin{array}{l}
m \\
k
\end{array}\right] \quad \text { if } m \geqslant k
$$

Since $g_{k, n}$ is increasing on the set $\{k, k+1, \ldots\}$ it follows that

$$
\begin{equation*}
F_{n}^{(k)}\left(g_{k, n}(m)-n^{1 / 2} k^{-1}\right)=P\left(E_{n} \leqslant m\right), m \geqslant k . \tag{2.34}
\end{equation*}
$$

But this probability is exactly equal to $1 / 2$ if we take $m=1 / 2(n-1)$ (for $n$ odd). Thus defining

$$
\begin{equation*}
x_{n}=g_{k, n}(1 / 2(n-1))-n^{1 / 2} k^{-1} \tag{2.35}
\end{equation*}
$$

we obtain

$$
\begin{equation*}
F_{n}^{(k)}\left(x_{n}\right)-\Phi\left(x_{n}\right)=1 / 2-\Phi\left(x_{n}\right) \tag{2.36}
\end{equation*}
$$

In the appendix it is shown that $\left(x_{n}\right)$ satisfies (2.30). A simple Taylor expansion argument then directly yields, in view of (2.36), relation (2.31). This completes the proof of Lemma 2. Note that (2.31) can also be deduced from the Edgeworth expansion type result, mentioned in section 1, for the case that $k \rightarrow \infty$ but at a rate slower than $n^{1 / 2} \log ^{-1} n \log _{2}^{-1} n$. For $k$ is fixed this is not true, because $F$ is lattice.

## 3. Appendix

### 3.1. Proof of (2.18) and (2.19)

We will indicate how (2.18) and (2.19) can be obtained by modifying the proof of Theorem 2.1 of Helmers and van Zwet (HZ)(1982).

Define functions $g$ and $\psi$ by

$$
\begin{equation*}
g(x)=1 / 2 k \mu^{k-1}(x-\mu) \tag{A.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\psi(x, y)=1 / 2 k(k-1) \mu^{k-2}(x-\mu)(y-\mu) \tag{A.2}
\end{equation*}
$$

and note that the $U$-statistic $U_{n}$ (of (2.11) and (2.14)) can be written as

$$
\begin{equation*}
U_{n}=2 n^{-1} \sum_{i=1}^{n} g\left(X_{i}\right)+2(n(n-1))^{-1} \sum_{1 \leqslant i<j \leqslant n} \psi\left(X_{i}, X_{j}\right) . \tag{A.3}
\end{equation*}
$$

We first prove (2.18).
Let $\chi$ denote the ch.f. of $\sigma^{-1}\left(X_{1}-\mu\right)$, thus

$$
\begin{equation*}
\chi(t)=E \exp \left\{i t \sigma^{-1}\left(X_{1}-\mu\right)\right\} \tag{A.4}
\end{equation*}
$$

and let

$$
\begin{equation*}
a=\frac{E\left|g\left(X_{1}\right)\right|^{3}}{\left(E g^{2}\left(X_{1}\right)\right)^{3 / 2}}=\frac{E\left|X_{1}-\mu\right|^{3}}{\sigma^{3}} \tag{A.5}
\end{equation*}
$$

We now simply follow the proof of relation (3.6) of $\mathrm{HZ}(1982)$ (taking their $p$ equal to 2 ), except that we don't use the second bound given in Lemma 3.1 of $\mathrm{HZ}(1982)$ in the strings of inequalities on page 504 of their paper, to find that ( $\operatorname{cf}(2.17)$ ) uniformly for all $|t| \leqslant a^{-1} n^{1 / 2}$

$$
\begin{align*}
\left|\rho_{n}^{(k)}(t)-\chi^{n}\left(n^{-1 / 2} t\right)\right| & =O\left(\frac{E \psi^{2}\left(X_{1}, X_{2}\right)}{E g^{2}\left(X_{1}\right)} n^{-1} t^{2}\right.  \tag{A.6}\\
& \left.+\frac{E\left|g\left(X_{1}\right) g\left(X_{2}\right) \psi\left(X_{1}, X_{2}\right)\right|}{\left(E g^{2}\left(X_{1}\right)\right)^{3 / 2}} n^{-1 / 2}|t|^{3} \exp \left(-\frac{(n-2)}{3 n} t^{2}\right)\right)
\end{align*}
$$

as $n \rightarrow \infty$. In view of (A.1) and (A.2) it is easily checked that

$$
\begin{equation*}
\frac{E \psi^{2}\left(X_{1}, X_{2}\right)}{E g^{2}\left(X_{1}\right)}=\theta\left(k^{2}\right), \frac{E\left|g\left(X_{1}\right) g\left(X_{2}\right) \psi\left(X_{1}, X_{2}\right)\right|}{\left(E g^{2}\left(X_{1}\right)\right)^{3 / 2}}=\theta(k) \tag{A.7}
\end{equation*}
$$

as $k \rightarrow \infty$.
The proof of the classical Berry-Esseen theorem for sums of i.i.d. random variables ensures that

$$
\begin{equation*}
\int_{|t| \leqslant a^{-1} n^{k}}|t|^{-1}\left|\chi^{n}\left(n^{-1 / 2} t\right)-e^{-1 / t t^{2}}\right| d t=\theta\left(n^{-1 / 2}\right) \tag{A.8}
\end{equation*}
$$

as $n \rightarrow \infty$.
Together the relations (A.6)-(A.8) directly imply (2.18). It remains to prove (2.19). In stead of (A.6) we now employ the following bound: Uniformly for any integer $m=1, \ldots, n-2$ and for all $|t| \leqslant a^{-1} n^{1 / 2}$

$$
\begin{align*}
\left|\rho_{n}^{(k)}(t)\right| & =\hat{O}\left\{\frac{E \psi^{2}\left(X_{1}, X_{2}\right)}{E g^{2}\left(X_{1}\right)} m n^{-2} t^{2}\right.  \tag{A.9}\\
& \left.+\exp \left(-\frac{m t^{2}}{3 n}\right)+\frac{E\left|\psi\left(X_{1}, X_{2}\right)\right|}{\left(E g^{2}\left(X_{1}\right)\right)^{1 / 2}} m n^{-1 / 2}|t| \exp \left(-\frac{(m-2) t^{2}}{3 n}\right)\right\}
\end{align*}
$$

as $n \rightarrow \infty$.
The bound (A.9) follows directly from the proof of formula (3.7) of $\mathrm{HZ}(1982)$ similarly as (A.6) was inferred from their relation (3.6). Using (A.1) and (A.2) once more we also have that

$$
\begin{equation*}
\frac{E\left|\psi\left(X_{1}, X_{2}\right)\right|}{\left(E g^{2}\left(X_{1}\right)\right)^{1 / 2}}=\mathcal{O}(k) \tag{A.10}
\end{equation*}
$$

as $k \rightarrow \infty$.
It follows now directly from (A.7), (A.9) and (A.10) that

$$
\begin{aligned}
& k^{-k / n^{1 / 4} \leqslant|t| \leqslant k^{-1} n^{1 /}}|t|^{-1}\left|\rho_{n}^{(k)}(t)-e^{-1 / 2 t^{2}}\right| d t \\
& \quad=O\left\{\frac{k^{2}}{n} \log n \log \left(\frac{\sqrt{n}}{k}\right)+n^{-c / 3} \log \left(\frac{\sqrt{n}}{k}\right)+k^{3 / 2} n^{1 / 4-c / 3} \log n\right\} \\
& \quad=O\left(\frac{k}{\sqrt{n}}\right)
\end{aligned}
$$

provided we take $m=\left[\frac{c n \log n}{t^{2}}\right]$ in (A.9) with $c$ sufficiently large and by requiring $k=O\left(\log ^{-1} n \log _{2}^{-1} n n^{1 / 2}\right)$. This completes the proof of relation (2.19).

### 3.2. Proof of the validity of the Edgeworth expansion $\tilde{F}_{n}^{(k)}$

We derive the one-term Edgeworth expansion for $F_{n}^{(k)}$, referred to in the discussion after Theorem 2 , for the case $k \rightarrow \infty$. Suppose that the moment assumptions of Theorem 2 are satisfied and, in addition that $k=o\left(\log ^{-1} n \log _{2}^{-1} n n^{1 / 2}\right)$.

To begin with we note that the argument leading to (2.22) can easily be modified to find that

$$
\begin{equation*}
P\left(\frac{\left|R_{n}\right|}{\left(k \mu^{k-1} \sigma\right)} \geqslant(\log n)^{-1 / 2} k n^{-1}\right)=o\left(k n^{-1 / 2}\right) \tag{A.13}
\end{equation*}
$$

Thus, $R_{n}$ is of negligible order of magnitude for our present purposes as well. It remains to show that $\tilde{F}_{n}^{(k)}$ is an Edgeworth expansion for $n^{1 / /} U_{n} /\left(k \mu^{k-1} \sigma\right)$, where $U_{n}$ is as in (2.11), with uniform remainder $o\left(k n^{-1 / 2}\right)$. To prove this we again employ Esseen's smoothing lemma and find that it suffices to show that (2.18) and (2.19) remain true, if we replace the region of integration $|t| \leqslant k^{-1 / 2} n^{1 / 4}$ in (2.18) by $|t| \leqslant(\log n)^{-1 / 2} k^{-1 / 2} n^{1 / 4}$, and, similarly in (2.19) the interval $k^{-1 / 2} n^{1 / 4} \leqslant|t| \leqslant k^{-1} n^{1 / 2}$ by $(\log n)^{-1 / 2} k^{-1 / 2} n^{1 / 4} \leqslant|t| \leqslant M k^{-1} n^{1 / 2}$, for any fixed constant $M>0$,
and the two big $\mathcal{O}$ 's on the r.h.s. of (2.18) and (2.19) by little o's. Finally we replace the term $e^{-1 / t^{2}}$ appearing in the common integrand of (2.18) and (2.19) by

$$
\begin{equation*}
\tilde{\rho}_{n}^{(k)}(t)=\dot{e}^{-1 / t t^{2}}\left\{1+\frac{(i t)^{3}}{6 n^{1 / 2}}\left(\sigma^{-3} E\left(X_{1}-\mu\right)^{3}+3(k-1) \sigma \mu^{-1}\right)\right\} . \tag{A.14}
\end{equation*}
$$

Note that $\tilde{\rho}_{n}^{(k)}$ is the Fourier-Stieltjes transform of $\tilde{F}_{n}^{(k)}$.
Let (2.18) ${ }^{*}$ and (2.19) ${ }^{*}$ denote the above mentioned modifications of (2.18) and (2.19). We first prove (2.18)*. Taylor expanding $\rho_{n}^{(k)}(t)$ we find that uniformly for all $|t| \leqslant(\log n)^{-1 / 2} k^{-1 / 2} n^{1 / 4}$

$$
\begin{align*}
& \left|\rho_{n}^{(k)}(t)-\tilde{\rho}_{n}^{(k)}(t)\right|=  \tag{A.15}\\
& \quad=0\left(\frac{E \psi^{2}\left(X_{1}, X_{2}\right)}{E g^{2}\left(X_{1}\right)} n^{-1} t^{2}\right)+o\left(k n^{-1 / 2}|t| P(|t|) \exp \left(-\frac{1}{4} t^{2}\right)\right)
\end{align*}
$$

as $n \rightarrow \infty$, where $P$ is a fixed polynomial.
To check this we follow the pattern of the proof of Theorem 1.2 of Bickel, Götze and van Zwet(1986) (see also Callaert, Janssen and Veraverbeke(1980)) with some slight modifications. Combining (A.15) with the first part of (A.7) directly yields (2.18)*. To prove (2.19)* we simply follow the calculations leading to (A.11) and the argument following it, to find that with minor changes the same proof also yields (2.19)*, provided we require $k=\rho\left(\log ^{-1} n \log _{2}^{-1} n n^{1 / 2}\right)$ instead of $k=O\left(\log ^{-1} n \log _{2}^{-1} n n^{1 / 2}\right)$. Since $M k^{-1} n^{1 / 2}=o\left(n^{1 / 2}\right)$, as $k \rightarrow \infty$, we do not need a non-lattice condition here. This completes the proof of (2.19) ${ }^{*}$ and the validity of the expansion $\tilde{F}_{n}^{k}$ is established.

### 3.3. Proof of (2.30)

We first treat the case $k \rightarrow \infty$. Using the refinement of Stirling's formula given on page 54 of Feller(1968), we find, for odd $n$,

$$
\begin{align*}
& g_{k, n}(1 / 2(n-1))=n^{1 / k} k^{-1} 2^{k}\left[\begin{array}{l}
n \\
k
\end{array}\right)^{-1}\left[\begin{array}{c}
1 / 2(n-1) \\
k
\end{array}\right]  \tag{A.16}\\
& =n^{1 / 2} k^{-1} 2^{k} n^{-n-1 / 2}(n-k)^{n-k+1 / 2}(1 / 2(n-1))^{1 / 2(n-1)+1 / 2}(1 / 2(n-1)-k)^{-1 / 2(n-1)+k-1 / 2}\left(1+O\left(\frac{1}{n}\right)\right) \\
& =n^{1 / k} k^{-1} \exp \left\{(n-k+1 / 2) \log \left(1-\frac{k}{n}\right)+1 / 2 n \log \left(1-\frac{1}{n}\right)-(1 / 2 n-k) \log \left(1-\frac{2 k+1}{n}\right)\right\}\left(1+O\left(\frac{1}{n}\right)\right) \\
& =n^{1 / 2} k^{-1} \exp \left\{-1 / 2 \frac{k^{2}}{n}(1+o(1))\right\}\left(1+O\left(\frac{1}{n}\right)\right) \\
& =n^{1 / k} k^{-1}\left(1-1 / 2 \frac{k^{2}}{n}(1+o(1))\right)\left(1+O\left(\frac{1}{n}\right)\right) \\
& =n^{1 / 2} k^{-1}-1 / 2 k n^{-1 / 2}(1+o(1))+O\left(n^{-1 / 2} k^{-1}\right)
\end{align*}
$$

and therefore

$$
\begin{equation*}
x_{n}=g_{k, n}(1 / 2(n-1))-n^{1 / 2} k^{-1}=-1 / 2(k+1) n^{-1 / 2}(1+o(1)) \tag{A.17}
\end{equation*}
$$

and (2.30) is proved. If k is fixed the calculation simplifies to

$$
\begin{align*}
g_{k, n}(1 / 2(n-1)) & =\frac{n^{1 / k} k^{-1} 2^{k}(1 / 2(n-1))(1 / 2(n-1)-1) \ldots .(1 / 2(n-1)-k+1)}{n(n-1) \ldots(n-k+1)}  \tag{A.18}\\
& =n^{1 / k} k^{-1}\left(1-1 / 2 \frac{k(k+1)}{n}+\theta\left(\frac{1}{n^{2}}\right)\right)
\end{align*}
$$

$$
=n^{1 / 2} k^{-1}-1 / 2(k+1) n^{-1 / 2}+\theta\left(n^{-3 / 2}\right)
$$

which also yields (2.30) in this case.
