Abstract: We address the control synthesis of hybrid systems with discrete inputs, disturbances and outputs. The control objective is to ensure that the events of the closed-loop system belong to the language of the control requirements. The controller is sampling-based and it is representable by a finite-state machine. We formalize the control problem and provide a theoretically sound solution. The solution is based on solving a discrete-event control problem for a finite-state abstraction of the plant. We propose a specific construction for the finite-state abstraction. This construction is not based on discretizing the state-space, but rather on converting the continuous-time hybrid system to a discrete-time one based on sampling. The construction works only for a specific class of hybrid systems. We describe this class of systems and we provide an example of such a system, inspired by an industrial use-case.

Keywords: hybrid systems, discrete-event systems, symbolic control

1. INTRODUCTION

Motivated by applications in the area of high-tech systems, in particular control of printers, Petreczky et al. (2008b), we are interested in the following control problem. The plant is a continuous-time hybrid system which is subject to discrete disturbances and control inputs and which generates discrete outputs and internal events. The disturbances are imposed by the environment and the control inputs can be used to influence the system behavior. The desired *controller* can read the outputs and it generates control inputs. Furthermore, the controller should be realizable by a finite-state machine, and it is activated at equidistant sampling times with sampling rate Δ. The control objective is to ensure that the sequences of internal events generated by the plant satisfy the *control requirements*.

Contribution We present a mathematical formulation of the control problem above. We also propose the following solution.

- **Step 1** Compute an abstraction (over-approximation) of the symbolic (event) behavior of the plant, such that the abstraction has a finite-state representation. This abstraction is based on transforming the original system to a discrete-time one. The states of the abstraction are those states of the hybrid system which can be reached at sampling times. Under suitable assumptions, the thus obtained state-space is finite.
- **Step 2** Solve the related discrete-event control problem for the finite-state abstraction. The solution is a discrete-event controller representable by a Moore-automaton. Interpret the solution as a controller for the original plant.

We prove that the procedure above is theoretically sound. The discrete-event control problem of Step 2 can be solved using game theory, see Grädel et al. (2002) or, under additional assumptions, using classical supervisory control, see Petreczky et al. (2008a). We also present a procedure for constructing a finite-state abstraction. The procedure can be made effective, but it may be computationaly expensive. The finite-state abstraction can be computed only for a specific class of hybrid systems which satisfies the following properties; (**1**) disturbances or internal events do not influence the continuous dynamics, (**2**) output events do not influence the system dynamics, (**3**) only finitely many events are generated on any time interval, (**4**) the set of states reachable at sampling times is finite. For the last property we present sufficient conditions in terms of existence of a Lyapunov-like function. While these assumptions are strong, there are hybrid systems of practical relevance (see Petreczky et al. (2008b) and the example of this paper) for which they hold.

Related work To the best of our knowledge, the contribution of the paper is new. Control of hybrid systems using finite-state approximation is a classical topic, Alur et al. (2000); Gonzalez et al. (2001); Chutinan and Krogh (2003); Förstnera et al. (2002); Moor et al. (2002); Koutsoukos et al. (2000). The main difference with respect to Gonzalez et al. (2001); Chutinan and Krogh (2003); Koutsoukos et al. (2000) is the presence of partial observations, that the generation of events is not synchronous with inputs, and that the hybrid plant contains reset maps. With respect to Förstnera et al. (2002); Moor et al. (2002) the main differences are that we consider hybrid systems as opposed to continuous ones, and we address partial observations. In addition, we do not propose a general purpose finite-state abstraction, rather the proposed abstraction is intended as a vehicle for solving the specific control problem. The results of Raisch and O'Young (1995); Moor and Raisch (1999); Raisch (2000) address a problem which is quite different from the one considered in this paper. The approach of the paper resembles Alur et al. (2000); Tabuada and Pappas (2005); Fainekos et al. (2007); Belta et al. (2005). However, the abstraction notion of this paper and the problem formulation are different. The control problem of this paper is different from Philips et al. (2003). In addition, the computation of the finite-state abstraction proposed in this paper is quite different from that of the papers

cited above. In Chutinan and Krogh (2003); Koutsoukos et al. (2000); Alur et al. (2000); Fainekos et al. (2007); Belta et al. (2005); Philips et al. (2003) the finite-state abstraction is computed by dividing the state-space of the system into regions. In Förstnera et al. (2002); Moor et al. (2002); Raisch and O'Young (1995); Moor et al. (2002); Moor and Raisch (1999); Raisch (2000), the abstraction of the system is constructed by storing the output (or state) response of the system to input sequences of finite length. In contrast, here the abstraction is obtained by sampling the hybrid system in time, not by discretizing it in space. In particular, the abstraction lives on the same state-space as the original system.

Outline of the paper In §3 we state the control problem we want to solve. The reduction of the hybrid problem to a discrete-event one is discussed in §4. In §5 the class of hybrid systems of interest is defined and the computation of a finite-state abstraction of the hybrid plant is discussed. In §6, as an illustration, we present an example.

2. PRELIMINARIES

General notation We use the standard notation and terminology from automata theory Eilenberg (1974). $\mathbb{N}$ is the set of natural numbers including zero. If Σ is a finite *alphabet*, then Σ^* denotes the set of finite *strings (words)* on Σ. The empty word is denoted by ϵ. An *infinite word* over Σ is an infinite sequence $w = a_1 a_2 \cdots a_k \cdots$ with $a_i \in \Sigma$, $i \in \mathbb{N}$. The set of infinite words is denoted by Σ^ω. The length of a (in)finite word is denoted by $|w|$; if w is an infinite word, then $|w| = +\infty$. For any (in)finite word w, and for any $i \in \mathbb{N}$ (in case w is finite word, for any $0 \leq i \leq |w|$), $w_{1:i}$ denotes the finite word formed by the first i letters of w, i.e. $w_{1:i} = a_1 a_2 \cdots a_i$. If $i = 0$, then $w_{1:i}$ is the empty word ϵ. The set of non-negative reals is $\mathbb{R}_+$.

Moore-automata A *Moore-automaton* (Eilenberg (1974)) is a tuple $A = (Q, I, Y, \delta, \lambda, q_0)$ where Q is the finite *state-space*, I is the *input alphabet*, Y is the *output alphabet*, $\delta : Q \times I \to Q$ is the *state-transition map*, $\lambda : Q \to Y$ is the *readout map*, and $q_0 \in Q$ is the *initial state*. The Moore-automaton A is a *realization* of a map $\phi : I^* \to Y$, if for all $w = u_1 u_2 \cdots u_k \in I^*$, $k \geq 0$ and $u_1, u_2, \ldots, u_k \in I$, $\phi(w) = \lambda(q_k)$ where $q_i = \delta(q_{i-1}, u_i)$ for all $i = 1, 2, \ldots, k$.

Monoid automata Recall from Berstel (1979); Eilenberg (1974) that a *monoid* M is a semi-group with a unit element. A *finite-state automaton on a monoid* M, abbreviated as DFA, is a tuple $T = (Q, M, E, F, q_0)$ where Q is a finite set of states, M is the monoid of inputs, $E \subseteq Q \times M \times Q$ is a state-transition relation, where E is a finite set, $F \subseteq Q$ is the set of accepting states, $q_0 \in Q$ is the initial state. An element $m \in M$ is *accepted* by T if there exists $m_i \in M_i$ and $q_i \in Q$, $i = 1, 2, \ldots, k$, $k \geq 0$ such that $(q_i, m_{i+1}, q_{i+1}) \in E$ for $i = 0, 1, \ldots, k-1$, $q_k \in F$ and $m = m_1 m_2 \cdots m_k$. The set $L \subseteq M$ is *recognized by* T, denoted by $L(T)$, if L consists of precisely those elements $m \in M$ which are accepted by T.

Sequential input-output maps will be used to model the discrete-event abstractions of hybrid systems. The concepts below are discussed in more detail in Petreczky et al. (2008a).

Definition 1. A multi-valued map $R : \Sigma^* \to 2^{X^* \times Y^*}$ is called a *sequential input-output map*, if
(1) $R(\epsilon) = (\epsilon, \epsilon)$, and for all $s \in \Sigma^*$, $R(s)$ is a non-empty set. Furthermore, R is *length-preserving* in its X-valued component, i.e. if $(\underline{x}, \underline{y}) \in R(s)$, with $\underline{x} \in X^*$ and $\underline{y} \in Y^*$, then the length of s and $\underline{x}$ are the same, i.e. $|s| = |\underline{x}|$,
(2) R is *prefix preserving*, i.e. for each word $s \in \Sigma^*$ and letter $a \in \Sigma$, if $(\underline{x}, \underline{y}) \in R(sa)$, then there exist $x \in X$ and $y \in Y^*$, $\hat{\underline{x}} \in X^*$, $\hat{\underline{y}} \in Y^*$ such that $\underline{x} = \hat{\underline{x}} x$, $\underline{y} = \hat{\underline{y}} y$ and $(\hat{\underline{x}}, \hat{\underline{y}}) \in R(s)$, **(3)** R is *non-blocking*, i.e. for each $s \in \Sigma^*$, $a \in \Sigma$, $(\underline{x}, \underline{y}) \in R(s)$, $(\underline{x}x, \underline{y}y) \in R(sa)$ for some $x \in X$, $y \in Y^*$.

Definition 2. A DFA $T = (Q, M, E, F, q_0)$ defined over the monoid $M = \Sigma^* \times X^* \times Y^*$ is called a *quasi-sequential transducer*, if **(1)** $F = Q$, i.e. all states are accepting, **(2)** the state-transition relation E is a partial map $E : Q \times \Sigma \times X \times Y^* \to Q$, **(3)** for each state $q \in Q$ and letter $a \in \Sigma$ there exist $x \in X$ and $\underline{y} \in Y^*$ such that $E(q, u, x, \underline{y})$ is defined.

Definition 3. The sequential input-output map $R : \Sigma^* \to 2^{X^* \times Y^*}$ is *quasi-recognizable*, if there exists a quasi-sequential transducer which recognizes the graph of R, i.e. which recognizes the set $\{(\underline{u}, \underline{x}, \underline{y}) \in \Sigma^* \times X^* \times Y^* \mid (\underline{x}, \underline{y}) \in R(\underline{u})\}$.

3. CONTROL PROBLEM

The plant of interest is a hybrid system which reacts to discrete-valued control inputs and disturbances, and generates discrete-valued outputs and internal events. We view the inputs and outputs as discrete events. Thus, the control inputs are events generated by a potential controller, the disturbances are events generated by the environment. The outputs and internal events are events generated by the plant. The only difference between outputs and internal events is that outputs are visible (i.e. detectable by sensors), while internal events are not.

Notation 1. (Plant and events). We denote the plant by H. We denote by E_c the set of *control inputs*, E_d the set of *disturbances*, E_o the set of *outputs*, E_i the set of *internal events*. We assume that E_c, E_d, E_o, E_i are finite sets.

In order to define the input-output behavior of the plant formally, we need the following notion.

Definition 4. Let E be a finite set and let $\perp \notin E$. Consider a (in)finite timed sequence of elements of E.

$$s = (e_1, t_1)(e_2, t_2) \cdots (e_k, t_k) \cdots \tag{1}$$

where $0 \leq t_1 < t_1 < t_2 < \cdots$, $e_{i+1} \in E$, $t_{i+1} \in \mathbb{R}_+$ for $i \in \mathbb{N}$, $i < |s|$. Here $|s|$ is the length of s, and $|s| = +\infty$ if s is an infinite sequence. If $|s| = +\infty$, then we assume that $\sup_{i \in \mathbb{N}} t_{i+1} = +\infty$. We can identify s with a map

$$g : \mathbb{R}_+ \ni t \mapsto \begin{cases} e_{i+1} \in E & \text{if } t = t_{i+1} \text{ for some } i \in \mathbb{N} \\ \perp & \text{otherwise} \end{cases} \tag{2}$$

The map g above, is called a *time-event map*. *The set of all such maps is denoted by* $\mathcal{P}_E$. Denote *the sequence of elements of* E *induced by* g by $\mathbf{UT}(g) = e_1 e_2 \cdots e_k \cdots \in E^* \cup E^\omega$.

I.e., the timed-event function g takes values in the event set E at isolated time instances, and the value $\perp$ encodes the absence of events at a certain time instance. By applying the above definition to $E \in \{E_c, E_d, E_o, E_i\}$, we obtain the sets $\mathcal{P}_{E_c}, \mathcal{P}_{E_d}, \mathcal{P}_{E_o}, \mathcal{P}_{E_i}$ describing the time signals with values in inputs, disturbances, outputs and internal events respectively.

Definition 5. (Input-output map of the plant). The input-output map of H is a *causal* [2] map $\upsilon_H : \mathcal{P}_{E_c} \times \mathcal{P}_{E_d} \to \mathcal{P}_{E_o} \times \mathcal{P}_{E_i}$.

Definition 6. A *hybrid controller* is a map $\mathcal{C} : \mathcal{P}_{E_o} \to \mathcal{P}_{E_c}$.

We study controllers which have a finite-state representation and are activated at fixed sampling rate $\Delta > 0$. The controller can only detect the set of outputs which occurred in a sampling interval. The formal definition is as follows.

[2] By causality of υ_H we mean that the response of υ_H depends only on the past inputs and on the past and present disturbances, i.e. for any $u_i \in \mathcal{P}_{E_c}$ $d_i \in \mathcal{P}_{E_d}$, $(o_i, \hat{o}_i) = \upsilon_H(u_i, d_i)$, $i = 1, 2$, if $d_1|_{[0,t]} = d_2|_{[0,t]}$, $u_1|_{[0,t)} = u_2|_{[0,t)}$ then $o_1(t) = o_2(t)$ and $\hat{o}_1(t) = \hat{o}_2(t)$, for all $t \in \mathbb{R}_+$.

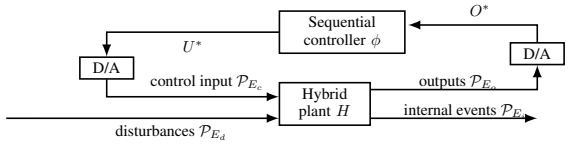

Fig. 1. Control architecture

Definition 7. Let $U = E_c \cup \{\perp\}$ be the *sampled input set*, let $O = 2^{E_o}$ be the *sampled output set*. A *sequential controller* is a map $\phi : O^* \to U$ which has a Moore-automaton realization.

The desired hybrid controller is then a *hybrid controller associated with a sequential controller* and it is defined as follows.

Definition 8. (Sampling-based controller). For a sequential controller ϕ let the *hybrid controller* $\mathcal{C}_\phi : \mathcal{P}_{E_o} \to \mathcal{P}_{E_c}$ *associated with* ϕ be such that for all $o \in \mathcal{P}_{E_o}$, and for all $t \in \mathbb{R}_+$,

$$\mathcal{C}_\phi(o)(t) = \begin{cases} \phi(S_1 S_2 \cdots S_{k+1}) & \text{if } t = (k+1)\Delta \text{ for a } k \in \mathbb{N} \\ \phi(\epsilon) & \text{if } t = 0 \\ \perp & \text{otherwise} \end{cases}$$

where $S_{k+1} = o((k\Delta, (k+1)\Delta]) \cap E_o$ for all $k \in \mathbb{N}$.

Next, we define the relevant aspects of the closed-loop behavior of the system. First, in order to avoid technical difficulties, we restrict attention to disturbances where at most a fixed μ number of disturbance events occurs within a sampling interval.

Definition 9. Let $\mu \in \mathbb{N}$ be the upper bound on the number of disturbances in a sampling interval. Denote by $\mathcal{P}^{\Delta}_{E_d,\mu}$ the set of functions $g \in \mathcal{P}_{E_d}$ such that on any interval $(i\Delta, (i+1)\Delta]$, $i \in \mathbb{N}$ the number of events of g is not greater than μ, i.e. $card\{e = g(s) \in E_d \mid s \in (i\Delta, (i+1)\Delta]\} \leq \mu$.

Definition 10. Let ϕ be a sequential controller and let $\mathcal{C}_\phi$ be the asscociated hybrid controller. *The closed-loop language* $L(H/\mathcal{C}_\phi)$ be the set of (in)finite words of the form $\mathbf{UT}(\hat{o}) \in E_i^* \cup E_i^\omega$, where $\hat{o} \in \mathcal{P}_{E_i}$ and there exist $u \in \mathcal{P}_{E_c}$, $d \in \mathcal{P}^{\Delta}_{E_d,\mu}$, and $o \in \mathcal{P}_{E_o}$ such that $(o, \hat{o}) = \upsilon_H(u, d)$ and $u = \mathcal{C}_\phi(o)$.

That is, $L(H/\mathcal{C}_\phi)$ is the set of sequences of internal events generated by the interconnection of the plant H with the controller $\mathcal{C}_\phi$. The control problem of interest can be stated as follows.

Problem 1. (Sampled-data control). For a specification language $K \subseteq E_i^* \cup E_i^\omega$, find a sequential controller ϕ such that for the closed-loop language satisfies $L(H/\mathcal{C}_\phi) \subseteq K$.

Note that the results of the paper can easily be extended so that the specification language includes events from $E_c \cup E_d \cup E_o$.

4. SOLUTION OF THE HYBRID CONTROL PROBLEM

In this section we present the solution of Problem 1. The main idea is to reduce Problem 1 to a discrete-event control problem. To this end, we model the sampled-data behavior of the plant as a discrete-event system R_H, which reacts to sampled inputs from U and sampled disturbances from D (to be defined below) and generates sampled outputs from O and sequences internal events. In order to define R_H, we need the following.

Definition 11. The set *sampled disturbances of* R_H is defined as $D = \bigcup_{k=0}^{\mu} E_d^k$, where μ is as in Definition 9.

That is, D is the set of all words over E_d of length at most μ.

Notation 2. Let $g \in \mathcal{P}_E$ be a time-event function. For all $t \in \mathbb{R}^+$, let $\mathbf{UT}(g,t) \in E^*$, be the sequence of events of g up to t, i.e. $\mathbf{UT}(g,t) = \mathbf{UT}(g^t)$, where $g^t \in \mathcal{P}_E$ is such that $g^t(s) = g(s)$ if $s \leq t$ and $g^t(s) = \perp$ for all $s > t$

Definition 12. The *sequential input-output map* R_H *of* H is the map $R_H : (U \times D)^* \to 2^{O^* \times E_o^*}$ defined as follows. $R_H(\epsilon) = \{(\epsilon, \epsilon)\}$ and for each sequence of sampled inputs $u_1, u_2, \ldots, u_k \in U$ and disturbances $d_1, d_2, \cdots d_k \in D$, $k \geq 0$,

$$(o_1 o_2 \cdots o_k, \underline{\hat{o}}) \in R_H((u_1, d_1)(u_2, d_2) \cdots (u_k, d_k))$$

for some $o_1, o_2, \ldots, o_k \in O$, and $\underline{\hat{o}} \in E_i^*$, if there exist $g \in \mathcal{P}_{E_d}$, $o \in \mathcal{P}_{E_o}$, $\hat{o} \in \mathcal{P}_{E_i}$ such that $(o, \hat{o}) = \upsilon_H(u, g)$,

$$\forall t \in \mathbb{R}_+ : u(t) = \begin{cases} u_i & \text{if } t = (i-1)\Delta \text{ for } i = 1, 2, \ldots, k \\ \perp & \text{otherwise} \end{cases}$$

$\underline{\hat{o}} = \mathbf{UT}(\hat{o}, k\Delta)$, and $o_i = o(((i-1)\Delta, i\Delta])$, $d_i = \mathbf{UT}(g_i, \Delta)$, where $g_i(t) = g(t + (i-1)\Delta), \forall t \in \mathbb{R}_+$, for all $i = 1, 2, \ldots, k$.

R_H is a sequential input-output map of Definition 13. Intuitively, R_H is the result of composing H with the interfaces converting time-event functions from $\mathcal{P}_{E_o}$, $\mathcal{P}_{E_i}$, $\mathcal{P}^{\Delta}_{E_d,\mu}$, to sequences in O^*, E_i^* and D^*, and with the interface which converts sequences from U^* to maps $\mathcal{P}_{E_c}$.

In order to solve Problem 1, we can view R_H as a discrete-event plant, and solve a discrete-event control problem for R_H as a plant and K as a requirement. The discrete-event control problem is as follows.

Definition 13. A *discrete-event plant* is a sequential input-output map $R : (U \times D)^* \to 2^{O^* \times E_i^*}$.

Definition 14. The *closed-loop language* $L(R/\phi) \subseteq E_i^* \cup E_i^\omega$ of the interconnection of R with the sequential controller $\phi : O^* \to U$ is the set of all words $\underline{\hat{o}} \in E_i^* \cup E_i^\omega$ for which there exist $d_i \in D$, $o_i \in O$, $u_i \in U$, $i = 1, 2, \ldots$, and indices $k_1 \leq k_2 \leq \cdots k_i \leq$ such that $\sup_{i \in \mathbb{N}} k_{i+1} = |\underline{\hat{o}}|$, and $\forall i \in \mathbb{N}$,

$$(o_1 o_2 \cdots o_{i+1}, \underline{\hat{o}}_{1:k_{i+1}}) \in R((u_1, d_1)(u_2, d_2) \cdots (u_{i+1}, d_{i+1}))$$

$$u_{i+1} = \phi(o_1 o_2 \cdots o_i) \text{ if } i > 0, \text{ and } u_1 = \phi(\epsilon)$$

Problem 2. (Discrete control problem). For the plant R, and for the *control requirements* $K \subseteq E_i^* \cup E_i^\omega$, find a sequential controller ϕ such that $L(R/\phi) \subseteq K$ holds.

Theorem 1. (Hybrid vs. discrete control). If ϕ is a sequential controller, then $L(H/\mathcal{C}_\phi) \subseteq L(R_H/\phi)$. Hence, if ϕ solves Problem 2 for $R = R_H$, and $K \subseteq E_i^* \cup E_i^\omega$, then the associated hybrid controller $\mathcal{C}_\phi$ solves Problem 1 for H and K.

For more details on the solution of Problem 2, see Petreczky et al. (2008a). A necessary condition for effective solution of Problem 2 is that R is quasi-recognizable, i.e. it is recognized by a quasi-sequential transducer. However, R_H need not be quasi-recognizable. The remedy is to solve Problem 2 not for R_H but for an quasi-recognizable abstraction of R_H. The construction of the latter is discussed in §5.

Definition 15. (Abstraction). The sequential input-output map R is an *abstraction* of the map R_H if for all $s \in (U \times D)^*$, the inclusion $R_H(s) \subseteq R(s)$ holds.

Theorem 2. Assume that R is an abstraction of R_H. Then for any sequential controller ϕ, $L(R_H/\phi) \subseteq L(R/\phi)$. Hence, if ϕ solves Problem 2 for R, then ϕ solves Problem 2 for R_H.

Hence, in order to solve Problem 1, we have to compute a quasi-recognizable abstraction R of R_H as described in §5, and then solve the discrete control problem Problem 2 for R.

5. FINITE-STATE ABSTRACTION OF R_H

First we define the hybrid systems of interest.

Definition 16. (Hybrid systems of interest). A discrete i/o hybrid system H is a tuple

$$(S_H, \delta, \lambda_i, \lambda_o, \{f_q, R_{u,q}, \Phi_{q,e}\}_{q \in Q, u \in E_c, e \in E_i \cup E_o}, h_0) \quad (3)$$

- **Events** E_d is the set of *disturbances*, E_c is the set of *control inputs*, E_o is the set of *outputs*, E_i is the set of *internal events*, and E_c, E_d, E_i, E_o are finite sets.
- **State-space** $S_H = Q \times \mathcal{X}$ is the state-space of H. Here $Q = Q_c \times Q_d$ is the *discrete state-space* of H, Q_c, Q_d are finite sets. The set $\mathcal{X} \subseteq \mathbb{R}^n$ is the *continuous state-space*, $\mathcal{X}$ is a closed set with non-empty interior $\operatorname{int} \mathcal{X} \neq \emptyset$.
- **Discrete-state transition** is determined by the transition functions $\delta_c : Q \times E_c \to Q_c$, $\delta_d : Q \times (E_d \cup E_i) \to Q_d$.
- **Continuous dynamics** is determined by vector fields $f_{q^c} : \mathbb{R}^n \to \mathbb{R}^n$, $q \in Q_c$, and reset maps $R_{u,q} : \mathcal{X} \to \mathcal{X}$, $q \in Q$ and $u \in E_c$. The vector fields f_{q^c}, $q^c \in Q_c$ are continuous and globally Lipschitz.
- **Event generation** is determined by guards $\Phi_{q,e} \subseteq \mathcal{X}$, $q \in Q$, $e \in E_o \cup E_i$, and by discrete partial readout maps $\lambda_o : Q \times E_d \to E_o$, $\lambda_i : Q \times E_d \to E_i$.
- $h_0 = (q_0^c, q_0^d, x_0) \in S_H$ is the initial state of the system. Moreover, $x_0 \in \operatorname{int} \mathcal{X}$, i.e. x_0 is in the interior of $\mathcal{X}$.

The system H is a hybrid system in the sense of van der Schaft and Schumacher (2000), subject to the following restrictions. Consider a discrete state $q = (q^c, q^d) \in Q$ If an event $u \in E_c$ arrives, then the Q_c-valued state component changes to $\delta_c(q, u)$. If $e \in E_d \cup E_i$ occurs, then the Q_d-valued discrete state component changes to $\delta_d(q, e)$. For an event from E_o the discrete state does not change. The continuous dynamics in q is determined by the differential equation $\dot{x} = f_{q^c}(x)$, as long as the continuous state is in the interior of $\mathcal{X}$. As soon as the continuous state reaches the boundary, it will change only if a reset map is applied. The reset maps for an event $u \in E_c$ are specified by $R_{u,q}$. For all the events from $E_d \cup E_o \cup E_i$, the reset maps are the identity. An event $e \in E_o \cup E_i$ is generated either if the continuous state crosses a guard set $\Phi_{q,e}$ or when an event from $d \in E_d$ arrives. In the latter case, $e = \lambda_i(q, d)$ or $e = \lambda_o(q, d)$. Events from $E_c \cup E_d$ are generated by the controller/environment. For the formal definition of the state evolution, we need the following.

Definition 17. (Flow of f_{q^c}). For any time $t \in \mathbb{R}_+$ and for any $q^c \in Q_c$ define the *flow* $f^t_{q^c} : \mathcal{X} \to \mathcal{X}$ of f_{q^c} as follows. Consider the solution of the differential equation $\dot{z} = f_{q^c}(z)$ with the inital state $z(0) = z_0$. Define

$$f^t_{q^c}(z_0) = \begin{cases} z(t) & \text{if } t < \beta(q^c, z_0) \\ z(\beta(q^c, z_0)) & \text{if } \beta(q^c, z_o) \leq t < +\infty \end{cases}$$

where $\beta = \beta(q^c, z_0) \in [0, +\infty]$ is such that for all $t \in [0, \beta)$, $z(t) \in \operatorname{int} \mathcal{X}$ and if $\beta < +\infty$, then $z(\beta) \in \partial X$, i.e. $z(\beta)$ belongs to the boundary of $\mathcal{X}$.

Notice that for any $z_0 \in \partial X$, $f^t_{q^c}(z_0) = z_0$, i.e. the continuous state evolution stops on the boundary of $\mathcal{X}$. The following assumptions will be used in the rest of the paper.

Assumption 1. A.1. For any $\Sigma \in \{E_o, E_i\}$ and $q \in Q$, $\forall e_1 \neq e_2 \in \Sigma : \Phi_{q,e_1} \cap \Phi_{q,e_2} = \emptyset$.

A.2. For each $q = (q^c, q^d) \in Q = Q_c \times Q_d$, $e \in E_o \cup E_i$ there exist smooth maps $h_{q,e} : \mathbb{R}^n \to \mathbb{R}$, such that
$\Phi_{q,e} \subseteq \{x \in \operatorname{int} \mathcal{X} \mid h_{q,e}(x) = 0\}$, and
if $\Phi_{q,e} \neq \emptyset$, then $\forall x \in \mathbb{R}^n : \operatorname{grad}(h_{q,e})(x) f_{q^c}(x) > 0$.

A.3. For any $q \in Q$, $d \in E_d$, $\lambda_i(q, d)$ is defined. Moreover, if $e = \lambda_i(q, d)$, then for any $\hat{q} \in Q$, $\Phi_{\hat{q},e} = \emptyset$.

Assumption A.1 ensures that at most one output and at most one internal event is generated at any time instance. Assumption A.2 requires each guard set to be a subset of a hyper-surface. In addition, the vector field associated with the discrete state has to be transversal with respect to the hyper-surface. This is a strong condition, but we believe it will be satisfied for a fairly large class of systems, for instance models of production systems and paper processing machines such as printers. Assumption A.2 ensures that only a finite number of outputs or internal events are generated on any finite time interval. Assumption A.3 allows to recognize whether an internal event is generated by a discrete readout map or by crossing a guard. Next, we define the state and output evolution of H.

Definition 18. For any state $h = (q_h, x_h)$, $q_h = (q^c_h, q^d_h)$, input $u \in \mathcal{P}_{E_c}$ and disturbance $d \in \mathcal{P}_{E_d}$, the state-trajectory is a map

$$\xi_H(h, u, d) : \mathbb{R}_+ \ni t \mapsto (q(t), x(t)) \in S_H$$

where $q(t) = (q^c(t), q^d(t)) \in Q$, $q^d(0) = q^d_h$, $q^c(0) = q^c_h$ and $x(0) = x_h$ if $u(0) = \perp$, $q^c(0) = \delta_c(q_h, u(0))$ and $x(0) = R_{u(0),q_h}(x_h)$ if $u(0) \in E_c$, and $\forall t \in \mathbb{R}_+$, $t > 0$

$$q^c(t) = \begin{cases} \delta_c(q(t^-), u) & \text{if } u = u(t) \in E_c \\ q^c(t - r) & \text{if } \exists r > 0 : u((t - r, t]) = \{\perp\} \end{cases}$$

$$q^d(t) = \begin{cases} q^d(t) = \delta_d(q(t^-), e) & \text{if } d(t) = e \in E_d, \text{ or } d(t) = \perp \\ & \text{and } x(t^-) \in \Phi_{q(t^-),e}, e \in E_i \\ q^d(t) = q^d(t - r) & \text{if } \exists r > 0 : \forall s \in (t - r, t] : \\ & d(s) = \perp, u(s) = \perp \text{ and} \\ & x(s) \notin \bigcup_{e \in E_i} \Phi_{q(t-r),e} \end{cases}$$

$$x(t) = \begin{cases} R_{u,q(t^-)}(x(t^-)) & \text{if } u(t) = u \in E_c \\ f^r_{q^c(t)}(x(t - r)) & \text{if } \exists r > 0 : u((t - r, t]) = \{\perp\} \end{cases}$$

Here $q(t^-), x(t^-)$ are the left-hand side limits at t of $q(t)$, $x(t)$.

Definition 19. The *input-output map* of H induced by state $h \in S_H$ is defined as

$$\upsilon_{H,h} : \mathcal{P}_{E_c} \times \mathcal{P}_{E_e} \ni (u, d) \mapsto (o, \hat{o}) \in \mathcal{P}_{E_o} \times \mathcal{P}_{E_i}$$

where $o(0) = \perp$, $\hat{o}(0) = \perp$ and for $t > 0$,

$$o(t) = \begin{cases} e \in E_o \text{ if } x(t^-) \in \Phi_{q(t^-),e} \text{ and } d(t) = \perp, \\ \lambda_o(q(t^-), d(t)) \text{ if } d(t) \in E_d, \\ \quad \text{and } \lambda_o(q(t^-), d(t)) \text{ is defined} \\ \perp \text{ otherwise} \end{cases}$$

$$\hat{o}(t) = \begin{cases} e \in E_i \text{ if } x(t^-) \in \Phi_{q(t^-),e} \text{ and } d(t) = \perp, \\ \lambda_i(q(t^-), d(t)) \text{ if } d(t) \in E_d \\ \perp \text{ otherwise} \end{cases}$$

where $\xi_H(h, u, d)(t) = (q(t), x(t))$. We denote by υ_H the input-output map υ_{H,h_0} induced by the initial state h_0 of H.

Informally, if there are no disturbances, then an output or internal event is generated if the continuous state crosses a guard. If a disturbance arrives, then an output (resp. internal event) is generated according to the readout map λ_o (resp. λ_i).

Construction of a finite-state abstraction of R_H Next, we present the definition of the quasi-sequential transducer, which recognizes an abstraction of R_H. In the sequel H is a hybrid system from Definition 16 satisfying Assumption A.1– A.3.

Definition 20. Let $\mathcal{R}(H) = \bigcup_{i=0}^{\infty} Q \times H_i$ be such that

$H_0 = \{x_0\}$ and $H_{i+1} = H_i \cup \{f^{\Delta}_{q^c}(x), f^{\Delta}_{q^c}(R_{u,s}(x)) \mid x \in H_i, q^c \in Q_c, s \in Q, u \in E_c\}, \forall i \in \mathbb{N}$

where x_0 is the continuous component of the initial state of H.

Assumption 2. In the sequel we assume that $\mathcal{R}(H)$ is finite.

$\mathcal{R}(H)$ will be the state-space of the to be constructed abstraction. Later on we formulate conditions for finiteness of $\mathcal{R}(H)$. The main idea behind the construction of the sampled-time abstraction is that it is enough to look at states which are

reached at sampling times, i.e. at a subset of elements of $\mathcal{R}(H)$. Moreover, the events generated in a sampling interval can be estimated by using the sampled state.

Definition 21. For any $q = (q^c, q^d) \in Q$ and $e \in E_i \cup E_o$, the *guard abstraction predicate* $P_{q,e} \subseteq \mathcal{X}$ is either $P_{q,e} = \emptyset$, if $e = \lambda(q, d)$ for some $d \in E_d$, or

$$P_{q,e} = \{x \in \mathcal{X} \mid h_{q,e}(x) \leq 0 \text{ and } h_{q,e}(f^{\Delta}_{q^c}(x)) \geq 0\} \quad (4)$$

Informally, $P_{q,e}$ contains those continuous states, started from which the guard corresponding to e is crossed within Δ time.

Definition 22. Let $\mathcal{P} = \{P_{q,e}\}_{q \in Q, e \in E_i \cup E_o}$ the collection of sets from Definition 21. Define the *finite-state abstraction* H_Δ as a quasi-sequential transducer

$H_\Delta = (\mathcal{R}(H), (U \times D)^* \times O^* \times E_i^*, E, \mathcal{R}(H), h_0)$ where

Initial state $h_0 = (q_0^c, q_0^d, x_0)$ of H_Δ coincides with that of H.
State transition map $E : \mathcal{R}(H) \times (U \times D) \times O \times E_i^* \to \mathcal{R}(H)$ is defined as follows. For each $u \in U$, $d \in D$, $o \in O$ and $\hat{o} \in E_i^*$, $E(h_1, u, d, o, \hat{o})$ is defined and $E(h_1, u, d, o, \hat{o}) = h_2$ if and only if $h_i = (q_i, x_i) \in \mathcal{R}(H)$ where $q_i = (q_i^c, q_i^d) \in Q_c \times Q_d$ and $x_i \in \mathcal{X}$, $i = 1, 2$, and the following holds.
(1) The state components q_2^c and x_2 are defined as follows.

$$q_2^c = \delta_c(q_1, u) \text{ and } x_2 = f^{\Delta}_{q_2^c}(R_{u,q_1}(x_1)) \quad (5)$$

Here, for $u = \perp$, $\delta_c(q_1, \perp) = q_1^c$ and $R_{\perp,q_1}(x_1) = x_1$
(2) Assume that $d = e_1 e_2 \cdots e_k$, $0 \leq k \leq \mu$, $e_1, e_2, \ldots, e_k \in E_d$. Then the sequence $\hat{o}$ is of the form $\hat{o} = z_1 z_2 \cdots z_l$, where $k \leq l \leq |Q_d||E_i| + k$ and $z_1, z_2, \ldots, z_l \in E_i$ and the following holds. There exists a set of indices $I = \{i_1, i_2, \ldots, i_k\} \subseteq \{1, 2, \ldots, l\}$, $i_1 < i_2 < \cdots < i_k$ and discrete states $s_i \in Q$, $i = 0, 1, \ldots, l$ such that $s_0 = (q_2^c, q_1^d)$, $s_l = q_2$ and for all $i = 1, 2, \ldots, l$

$$s_i = \begin{cases} (q_2^c, \delta_d(s_{i-1}, z_i)) & \text{if } R_{u,q_1}(x_1) \in P_{s_{i-1},z_i} \text{and } i \notin I \\ (q_2^c, \delta_d(s_{i-1}, e_r)) & \text{if } i = i_r \text{ and } z_i = \lambda_i(s_{i-1}, e_r) \\ & \text{for some } r = 1, 2, \ldots, k, \end{cases} \quad (6)$$

(3) The output $o \subseteq E_o$ is a subset of E_o such that for any $e \in o$,

$$\begin{array}{l} R_{u,q_1}(x_1) \in P_{s_i,e} \text{ for some } i \in \{1, 2, \ldots, l\} \setminus I, \text{ or} \\ \lambda_o(s_{i_r-1}, e_r) = e \text{ for some } r = 1, 2, \ldots, k \end{array} \quad (7)$$

Intuition The states of H_Δ are those states of H which can be reached from h_0 at sampling times. By assumption, this set is finite. A state transition of H_Δ associated with a discrete input u, disturbance $d \in D$, output $o \in O$ and sequence of internal events $\hat{o} \in E_i^*$ is obtained as follows. If the current state of H_Δ is h_1 then the new state h_2,is the state of H reachable from h_1 in time Δ, under the following conditions; **(1)** H receives input event u at time 0, and no input after that, **(2)** H receives a disturbance g, such that the sequence of events of g on $(0, \Delta]$ is d, **(3)** $\hat{o}$ is the sequence of internal events generated by H while moving from h_1 to h_2, **(4)** o is the set of outputs generated by H while moving from state h_1 to h_2. Condition **(1)** and the fact that the Q_c- and $\mathbb{R}^n$-valued state components depend only on the time and input events yield (5). The computation of the Q_d-valued states along with checking Condition **(2)** – **(3)** is formalized in (6). Finally, Condition **(4)** is formalized in (7).

Theorem 3. The tuple H_Δ is a quasi-sequential transducer, and the sequential input-output map $R(H_\Delta)$ recognized by H_Δ is an abstraction of R_H.

Finiteness of $\mathcal{R}(H)$ based on Lyapunov-like functions
Theorem 4. Consider a finite set $\mathcal{X}_0 \subseteq \mathcal{X}$ and a smooth map $V : \mathcal{X} \to \mathbb{R}$ such that for all $x \in \mathcal{X}$, $q = (q^c, q^d) \in Q$,
(1) $V(x) \geq 0$ and $V^{-1}(0) \subseteq \partial\mathcal{X}$.
(2) There exists $c > 0$ such that $\text{grad}(V)(x) f_{q^c}(x) < -c$,
(3) For all $u \in E_c$, if $x \in \text{int } \mathcal{X}$, then $V(R_{u,q}(x)) \leq V(x)$, and if $x \in \partial\mathcal{X}$, then $R_{u,q}(x) \in \mathcal{X}_0$.
It then follows that $\mathcal{R}(H)$ is finite.

Computation Notice that if the reset maps, flows of the vector fields (as in Definition 17), and the functions $h_{q,e}$ defining guards are (numerically) computable then so is H_Δ. However, the computational complexity can get large as Δ decreases.
Assumption 3. The reset maps of H are affine in $\text{int } \mathcal{X}$, the vector fields are of L'ure-type, the state-space is a polyhedron, and the maps defining the guards are affine, i.e.

$$\begin{array}{l} \mathcal{X} = \{x \in \mathbb{R}^n \mid n_i^T x - b_i \leq 0, i = 1, 2, \ldots, K\} \\ R_{u,q}(x) = M_{u,q} x + b_{u,q}, \quad \forall x \in \text{int } \mathcal{X} \\ h_{q,e}(x) = g_{q,e}^T x + d_{q,e}, \quad \forall x \in \mathbb{R}^n \\ f_{q^c}(x) = A_{q^c} x + \sum_{j=1}^{m} B_{q^c,j} \phi_{q^c,j}(r_{q^c,j}^T x), \quad \forall x \in \mathbb{R}^n \\ \mu_1 \sigma + \gamma_1 \leq \phi_{q^c,j}(\sigma) \leq \mu_2 \sigma + \gamma_2, \quad \forall \sigma \in \mathbb{R} \end{array}$$

for matrices $M_{u,q}, A_{q^c} \in \mathbb{R}^{n \times n}$, vectors $b_{u,q}, r_{q^c,j}, B_{q^c,j}, g_{q,e}$, $n_i \in \mathbb{R}^n$, and scalars $d_{q,e}, b_i, \mu_1, \mu_2, \gamma_1, \gamma_2 \in \mathbb{R}$, $q = (q^c, q^d) \in Q$, $e \in E_i \cup E_o$, $u \in E_c$, $i = 1, 2, \ldots, K$, $j = 1, 2, \ldots, m$. The maps $\phi_{q^c,j} : \mathbb{R} \to \mathbb{R}$, $j = 1, 2, \ldots, m$ are piecewise-affine, continuous, globally Lipschitz.

If H satisfies Assumption 3, then the reset maps and the maps $h_{q,e}$ are computable. The solution of $\dot{z} = f_{q^c}(z)$ can be computed using numerical integration. Hence, if we can detect reaching the boundary of $\mathcal{X}$, then the flow $f^t_{q^c}$ is computable. In fact, the definition of H_Δ can be modified so that it is enough to detect if the solution of $\dot{z} = f_{q^c}(z)$ has crossed the boundary, the precise point where the boundary was crossed is not needed. The latter is easy if the sign of each $n_i^T f_{q^c}(x)$, $i = 1, 2, \ldots, K$ is independent of x. Finiteness of $\mathcal{R}(H)$ can be checked effectively using Theorem 4 and the following.

Proposition 1. Assume that H satisfies Assumption 3. If for some $j \in \{1, \ldots, K\}$, $c > 0$, it holds that for all $x \in \mathcal{X}$,
(1) $n_j^T(A_{q^c} x + \sum_{l=1}^{m} \mu_{i_l}(B_{q^c,l} r_{q^c,l}^T x + \gamma_{i_l} B_{q^c,l})) > c$, for any sequence $i_1, i_2, \ldots, i_m \in \{1, 2\}$, and for any $q^c \in Q$,
(2) If $x \in \text{int } \mathcal{X}$, then $n_j^T(M_{u,q} x - x + b_{u,q}) \geq 0$, for all $u \in E_c$, $q \in Q$
then $V(x) = (b_j - n_j^T x)$ satisfies Theorem 4.

6. ILLUSTRATING EXAMPLE

Below we illustrate the theory by an example related to a control problem for printers from Petreczky et al. (2008b).

Formal model of the plant We will use the following parameters, meaning of which is described in Petreczky et al. (2008b): $\mathbf{Fp}, \mathbf{Cp}, \mathbf{V}_{max}, \mathbf{V}_{min}, \mathbf{T}_{fo}, \mathbf{T}_{pl,max}, \mathbf{T}_{pl,min}, \mathbf{A}, \mathbf{D}$. Formally, the plant model H is of the form (3). The components of H are explained below. The event sets are $E_c = \{\mathbf{c}_{FU}, \mathbf{c}_{FD}, \mathbf{c}_A, \mathbf{c}_D\}$, $E_o = \{\mathbf{e}_{o,PL}\}$, $E_d = \{\mathbf{e}_{d,PL}\}$, $E_i = \{\mathbf{e}_{NPIF}, \mathbf{e}_{i,PL}, \mathbf{e}_{min,PL}, \mathbf{e}_{max,PL}, \mathbf{e}_{FUc}\}$. The discrete state-space $Q = Q_c \times Q_d$ is defined as follows. Q_d is the set of maps $\phi : \mathbf{Var}_d \to \{True, False\}$, where $\mathbf{Var}_d = \{\mathbf{S}_{PL}, \mathbf{S}_r, \mathbf{S}_{FUc}\}$. Q_c is the set of all maps $\phi : \mathbf{Var} \to \{True, False\}$ where $\mathbf{Var} = \{\mathbf{S}_{FU}, \mathbf{S}_{FD}, \mathbf{S}_A, \mathbf{S}_D\}$. I.e. the elements of Q_d and Q_c are valuations of predicates from $\mathbf{Var}_d$ and $\mathbf{Var}_c$ respectively. In the sequel, we will write $\phi(X)$ instead of $\phi(X) = True$, and $\neg\phi(X)$, instead of $\phi(X) = False$ for all $\phi \in Q_d$, $X \in \mathbf{Var}_d$, or $\phi \in Q_c$ and $X \in \mathbf{Var}_c$. The continuous state-space is $\mathcal{X} = \{x = (\mathbf{P}, \mathbf{V}, \mathbf{C}_{fu}, \mathbf{T}) \in \mathbb{R}^4 \mid \mathbf{P} \leq \mathbf{Cp}\}$ where $\mathbf{P}, \mathbf{V}, \mathbf{C}_{fu}, \mathbf{T} \in \mathbb{R}$ are state variables. The

vector fields f_{q^c}, $q^c \in Q_c$ and the reset maps $R_{u,q}$, $q \in Q$, $u \in E_c$ are as follows. For any $x = (\mathbf{P}, \mathbf{V}, \mathbf{C}_{fu}, \mathbf{T}) \in \mathcal{X}$,

$$f_{q^c}(x) = \begin{bmatrix} \max\{\mathbf{V}_{min}, \mathbf{V}\} & f_{2,q^c}(x) & 1 & 1 \end{bmatrix}^T$$

$$f_{2,q^c}(x) = \begin{cases} \mathbf{A}\phi_{min}(x)\phi_{max}(x) & \text{if } q^c(\mathbf{S}_A) \\ -\mathbf{D}\phi_{min}(x)\phi_{max}(x) & \text{if } q^c(\mathbf{S}_D) \text{ and } q^c(\mathbf{S}_{FD}) \end{cases}$$

$$\phi_{min}(x) = \begin{cases} 1 & \text{if } \mathbf{V} \in (\mathbf{V}_{min} + \epsilon, +\infty) \\ \dfrac{(\mathbf{V} - \mathbf{V}_{min})}{\epsilon} & \text{if } \mathbf{V} \in (\mathbf{V}_{min}, \mathbf{V}_{min} + \epsilon] \\ 0 & \text{if } \mathbf{V} \in (-\infty, \mathbf{V}_{min}] \end{cases}$$

$$\phi_{max}(x) = \begin{cases} 1 & \text{if } \mathbf{V} \in (-\infty, \mathbf{V}_{max} - \epsilon) \\ \dfrac{(\mathbf{V}_{max} - \mathbf{V})}{\epsilon} & \text{if } \mathbf{V} \in [\mathbf{V}_{max} - \epsilon, \mathbf{V}_{max}) \\ 0 & \text{if } \mathbf{V} \in [\mathbf{V}_{max}, +\infty) \end{cases}$$

$$R_{u,q}(x) = \begin{cases} (\mathbf{P}, \mathbf{V}, 0, \mathbf{T}) & \text{if } u = \mathbf{c}_{FD} \text{ and } \mathbf{P} < \mathbf{Cp} \\ (\mathbf{P}, \mathbf{V}, \mathbf{C}_{fu}, \mathbf{T}) & \text{if } u \neq \mathbf{c}_{FD} \text{ and } \mathbf{P} < \mathbf{Cp} \\ (\mathbf{Cp}, \mathbf{V}_{max}, \mathbf{T}_{fo}, \mathbf{T}_{pl,max}) & \text{if } \mathbf{P} = \mathbf{Cp} \end{cases}$$

The state-transition maps δ_c and δ_d are such that for each $q_1 = (q_1^c, q_1^d) \in Q$, $u \in E_c$, $e \in E_i \cup E_d$, $\delta_c(q_1, u) = q_2^c$ and $\delta_d(q_1, e) = q_2^d$ if and only if the following holds.

$$(q_2^c(\mathbf{S}_{FD}), q_2^c(\mathbf{S}_{FU})) = \begin{cases} (True, False) & \text{if } u = \mathbf{c}_{FD} \\ (False, True) & \text{if } u = \mathbf{c}_{FU} \\ (q_1^c(\mathbf{S}_{FD}), q_1^c(\mathbf{S}_{FU})) & \text{otherwise} \end{cases}$$

$$(q_2^c(\mathbf{S}_A), q_2^c(\mathbf{S}_D) = \begin{cases} (False, True) & \text{if } u = \mathbf{c}_D \\ (True, False) & \text{if } u = \mathbf{c}_A \\ (q_1^c(\mathbf{S}_A), q_1^c(\mathbf{S}_D)) & \text{otherwise} \end{cases}$$

$$q_2^d(\mathbf{S}_{PL}) = \begin{cases} True & \text{if } e = \mathbf{e}_{d,PL} \text{ and } q_1^d(\mathbf{S}_r) \\ q_1^d(\mathbf{S}_{PL}) & \text{otherwise} \end{cases}$$

$$q_2^d(\mathbf{S}_r) = \begin{cases} True & \text{if } e = \mathbf{e}_{min,PL} \text{ and } \neg q_1^d(\mathbf{S}_r) \\ False & \text{if } e = \mathbf{e}_{max,PL} \text{ and } q_1^d(\mathbf{S}_r) \\ q_1^d(\mathbf{S}_r) & \text{otherwise} \end{cases}$$

$$q_2^d(\mathbf{S}_{FUc}) = \begin{cases} True & \text{if } e = \mathbf{e}_{FUc} \\ q_1^d(\mathbf{S}_{FUc}) & \text{otherwise} \end{cases}$$

The readout maps λ_o and λ_i are defined as follows; $\lambda_i(q, e_d) = \mathbf{e}_{i,PL}$ and $\lambda_o(q, e_d) = \mathbf{e}_{o,PL}$. The guard are defined as follows.

$\Phi_{q,e} \subseteq \{x \in \text{int } \mathcal{X} \mid h_{q,e}(x) = 0\}, \forall e \in (E_i \cup E_o) \setminus \{\mathbf{e}_{o,PL}, \mathbf{e}_{i,PL}\}$,
$\Phi_{q,\mathbf{e}_{o,PL}} = \Phi_{q,\mathbf{e}_{i,PL}} = \emptyset$ and $\Phi_{q,e_1} \cap \Phi_{q,e_2} = \emptyset, \forall e_1 \neq e_2 \in E_i$

$$h_{q,\mathbf{e}_{FUc}}(x) = \begin{cases} (x_3 - \mathbf{T}_{fo}\} & \text{if } q^c(\mathbf{c}_{FU}) \\ 1 & \text{otherwise} \end{cases}$$

$$h_{q,\mathbf{e}_{min,PL}}(x) = \begin{cases} (x_4 - \mathbf{T}_{pl,min}) & \text{if } \neg q^d(\mathbf{S}_r) \text{ and } \neg q^d(\mathbf{S}_{PL}) \\ 1 & \text{otherwise} \end{cases}$$

$$h_{q,\mathbf{e}_{max,PL}}(x) = \begin{cases} (x_4 - \mathbf{T}_{pl,max}) & \text{if } \neg q^d(\mathbf{S}_{PL}) \text{ and } q^d(\mathbf{S}_r) \\ 1 & \text{otherwise} \end{cases}$$

$$h_{q,\mathbf{e}_{NPIF}}(x) = \begin{cases} x_1 - \mathbf{Fp} & \text{if } q^d(\mathbf{S}_{PL}) \text{ and} \\ & (q^c(\mathbf{S}_{FD}) \text{ or } (q^c(\mathbf{S}_{FU}) \text{ and } \neg q^d(\mathbf{S}_{FUc}))) \\ 1 & \text{otherwise} \end{cases}$$

The initial state $h_0 = (q_0^c, q_0^d, x_0)$ is of the following form.

$q_0^c(X) = False, X \in \mathbf{Var}_c \setminus \{\mathbf{S}_{FD}) \text{ and } q_0^c(\mathbf{S}_{FD}) = True$
$q^d(Y) = False, \forall Y \in \mathbf{Var}_d \text{ and } x_0 = (0, \mathbf{V}_{max}, 0, 0)$

Control requirements $K = (E_i \setminus \mathbf{e}_{NPIF})^* \cup (E_i \setminus \mathbf{e}_{NPIF})^\omega$. **Solution** It is easy to see that Assumption A.1– A.3 and Assumption 3 are satisfied for H. We can solve Problem 1 for H and K above using the procedure outlined in §4. Notice that H_Δ is computable, and $\mathcal{R}(H)$ is finite. For the latter, define $\mathcal{X}_0 = \{(\mathbf{Cp}, \mathbf{V}_{max}, \mathbf{T}_{fo}, \mathbf{T}_{pl,max})\}$, and define the map $V : \mathcal{X} \to \mathbb{R}$ as $V(x_1, x_2, x_3, x_4) = (\mathbf{Cp} - x_1)$. It follows from Proposition 1 that V and $\mathcal{X}_0$ satisfy Theorem 4. In Petreczky et al. (2008b) controllers were synthesized based on an algorithm and a model related to the one presented above.

7. DISCUSSION AND CONCLUSIONS

We have presented a control problem for a class of hybrid systems and we have proposed a solution based on computing finite-state discrete-event abstraction of hybrid systems. We believe that the results are relevant for practice. Future research includes extension of the results to other classes of systems and the study of robustness and computational issues.
