Verification of parallel systems via decomposition

CWI is the research institute of the Stichting Mathematisch Centrum, which was founded on February 11, 1946, as a non-profit institution aiming at the promotion of mathematics, computer science, and their applications. It is sponsored by the Dutch Government through the Netherlands organization for scientific research (NWO).

# Verification of Parallel Systems via Decomposition

#### Abstract

Recently, Milner and Moller have presented several decomposition results for processes. Inspired by these, we investigate decomposition techniques for the verification of parallel systems. In particular, we consider those of the form $$
\begin{equation*} \left\|_{i=1}^{n} p_{i}=\right\|_{j=1}^{m} q_{j} \tag{I} \end{equation*}
$$ where $p_{i}$ and $q_{j}$ are (finite) state systems. We provide a decomposition procedure for all $p_{i}$ and $q_{j}$ and give criteria that must be checked on the decomposed processes to see whether (I) does or does not hold. We analyse the complexity of our procedure and show that it is polynomial in $n$, $m$ and the sizes of $p_{i}$ and $q_{j}$ if there is no communication. We also show that with communication the verification of (I) is co-NP hard, which makes it very unlikely that a polynomial complexity bound exists. But by applying our decomposition technique to Milner's cyclic scheduler we show that verification can become polynomial in space and time for practical examples, where standard techniques are exponential.

Key Words \& Phrases: Decomposition, Parallel Processes, Verification, Bisimulation. 1985 Mathematics Subject Classification: 68Q60, 68Q70.

## 1 Introduction

Most common techniques for the automated verification of parallel systems are based on some kind of state-space exploration. Contemporary computer technology limits exploration to state spaces of about $10^{7}$ states. However, state spaces of most parallel systems are substantially larger.

[^0]This problem is identified by many researchers, and various solutions have been proposed. For instance one may apply minimisation techniques when constructing state spaces [2], one may represent the state space using hash techniques [11], or one may restrict the state space using some additional information [7]. A more successful approach seems to be the smart encoding of state spaces, employing the regularity that is often present in the state spaces of parallel systems. In particular, the results based on binary decision diagrams (BDD's) seem more than promising [3]. An argument that one could raise against BDD's is that it is not directly based on notions inherent to processes, such as amount of communication, the structure of processes or the structure of communication, etc. This may obscure the true causes of the success of BDD's, and it may hinder further developments and a proper understanding of applicability.

Recently, some interesting decomposition results have emerged in process theory [16, 17]. Inspired by these results, we study whether decomposition techniques can be applied in order to obtain alternative means for the verification of parallel systems. Basically, the idea is as follows: Consider processes $p=\|_{i=1}^{n} p_{i}$ and $q=\|_{j=1}^{m} q_{j}$. We want to establish whether $p=q$ where ' $=$ ' represents some reasonable process equivalence. In order to do so, we decompose each $p_{i}$ into $p_{i 1} \ldots p_{i m}$ and each $q_{j}$ into $q_{j 1} \ldots q_{j n}$ according to some particular decomposition rules. Then we must verify whether $p_{i j}=q_{j i}$ for all $i$ and $j$. The method is beneficial if the combination of performing the decompositions of the $p_{i}$ 's and $q_{j}$ 's along with checking each $p_{i j}=q_{j i}$ is considerably more efficient than checking $p=q$ directly. We show that this is indeed so in particular cases, but we show also that it is very unlikely to be true in general.

This paper first presents the decomposition scheme (after some preliminaries). Then we analyse what we have actually gained. It turns out that when there is no communication, verification via decomposition has a polynomial time and space complexity in the number and size of the processes $p_{i}$ and $q_{j}$. In the case where communication is allowed, we provide a straightforward proof that verification is co-NP hard even in the case where the $p_{i}$ 's and $q_{j}$ 's are finite and determinate. More results of this kind can be found in [18]. Hence, polynomial verification is rather unlikely in this case.

In order to understand whether this intractability result rules out application of our techniques, we consider an example. This is Milner's scheduler [14], which is generally used as a benchmark for verification tools [ $6,10,12$ ], due to its simple description, and its exponentially growing state spaces that it generates (in the number of 'cyclers' from which the scheduler is constructed). Verification via decomposition uses only polynomial time and linear space. The largest intermediate state space that is used in the verification has size $3 k$ where $k$ is the number of cyclers in the scheduler.

Our conclusions from the complexity analysis is that decomposition can indeed be a good technique for the verification of parallel systems. When there is little communication, i.e. in the case where the system has been adequately structured, the benefits of this technique may be especially high.

## 2 Preliminaries

In this paper we do not employ a particular process language. Rather, it turns out to be handy to work in a setting where processes are viewed as (possibly infinite) transition systems.

Definition 2.1. A transition system $(T S) p=\left(S_{p}, \alpha_{p}, \longrightarrow_{p}, s_{p}\right)$ is a four tuple, where

- $S_{p}$ is a non-empty set of states;
- $\alpha_{p}$ is a set of actions;
- $\longrightarrow_{p} \subseteq S_{p} \times \alpha_{p} \times S_{p}$ is a transition relation; and
- $s_{p} \in S_{p}$ is the initial state of the transition system.

We use $p, q, r$ to range over transition systems, and $\alpha$ to range over sets of actions. Elements $\left(t, a, t^{\prime}\right)$ of a transition relation $\longrightarrow p$ are often written as $t \xrightarrow{a} p t^{\prime}$. We also write $t \xrightarrow{a_{1} \cdots a_{n}}{ }_{p} t^{\prime}$ for $t \xrightarrow{a_{1}} \cdots \xrightarrow{a_{n}} t^{\prime}$. A function $\alpha$ gives the set of actions of a transition system, e.g. $\alpha\left(\left(S_{p}, \alpha_{p}, \longrightarrow_{p}, s_{p}\right)\right)=\alpha_{p}$. The TS $p$ is finite-state if $S_{p}$ is finite, and it is finite if there is no infinite sequence $t_{1} \xrightarrow{a_{1}} t_{2} \xrightarrow{a_{2}} \cdots \xrightarrow{a_{i-1}} p t_{i} \xrightarrow{a_{i}} t_{i+1} \cdots$.

Definition 2.2. A TS $p=(S, \alpha, \rightarrow, s)$ is called determinate with respect to some equivalence relation $\sim$ iff for all $t \in S$ and $a \in \alpha: t \xrightarrow{a} t_{1}$ and $t \xrightarrow{a} t_{2}$ implies $t_{1} \sim t_{2}$. In general it will be clear which equivalence relation is meant, in which case we will simply say that $p$ is determinate.

Definition 2.3. Let $\alpha$ be a set of actions. We have the following 'standard' transition systems.

- The willing process on $\alpha$ is the process that can always do an action from $\alpha$ :

$$
W_{\alpha} \stackrel{\text { def }}{=}(\{s\}, \alpha, \longrightarrow, s) \quad \text { where } \quad \longrightarrow=\{\langle s, a, s\rangle \mid a \in \alpha\}
$$

- The nil process is not willing to do anything: nil $\stackrel{\text { def }}{=} W_{\emptyset}$.

Definition 2.4. Let $p=\left(S_{p}, \alpha_{p}, \longrightarrow_{p}, s_{p}\right)$ and $q=\left(S_{q}, \alpha_{q}, \longrightarrow_{q}, s_{q}\right)$ be TS's. We can define the following useful operations on TS's.

- For an action $a$ the $a$-prefix of $p$ is the TS

$$
a: p \stackrel{\text { def }}{=}\left(S_{p} \cup\{s\}, \alpha_{p} \cup\{a\}, \longrightarrow_{p} \cup\left\{\left\langle s, a, s_{p}\right\rangle\right\}, s\right) \quad \text { for } s \notin S_{p}
$$

- Assuming (without loss of generality) that $S_{p} \cap S_{q}=\emptyset$, the sum or choice of $p$ and $q$ is the TS

$$
p+q \stackrel{\text { def }}{=}\left(S_{p} \cup S_{q} \cup\left\{s_{p+q}\right\}, \alpha_{p} \cup \alpha_{q}, \longrightarrow_{p+q}, s_{p+q}\right) \quad \text { for } s_{p+q} \notin S_{p} \cup S_{q}
$$

where

Figure 1: The process $p=b: a: n i l \| c: a: n i l$

$$
\longrightarrow_{p+q}=\longrightarrow_{p} \cup \longrightarrow_{q} \cup\left\{\left\langle s_{p+q}, a, s^{\prime}\right\rangle \mid s_{p} \xrightarrow{a} s^{\prime} \text { or } s_{q} \xrightarrow{a} s^{\prime}\right\} .
$$

- The parallel composition or synchronisation merge of $p$ and $q$ is the TS

$$
p \| q \stackrel{\text { def }}{=}\left(S_{p} \times S_{q}, \alpha_{p} \cup \alpha_{q}, \longrightarrow_{p \| q},\left\langle s_{p}, s_{q}\right\rangle\right)
$$

where

$$
\left\langle s_{1}, s_{2}\right\rangle \xrightarrow{a}{ }_{p \| q}\left\langle s_{1}^{\prime}, s_{2}^{\prime}\right\rangle \quad \text { iff } \quad\left\{\begin{array}{l}
s_{1} \xrightarrow{a} p s_{1}^{\prime} \text { and } s_{2} \xrightarrow{a} s_{2}^{\prime}, \text { or } \\
s_{1} \xrightarrow[a]{a} s_{1}^{\prime}, s_{2}=s_{2}^{\prime} \text { and } a \notin \alpha_{q}, \\
s_{2} \xrightarrow{a} s_{2}^{\prime}, s_{1}=s_{1}^{\prime} \text { and } a \notin \alpha_{p} .
\end{array}\right.
$$

The synchronisation merge thus forces common actions to synchronise. We write $\|_{i=1}^{n} p_{i}$ for $p_{1}\|\ldots\| p_{n}$ and $\|_{i=1, i \neq k}^{n}$ for $p_{1}\|\ldots\| p_{k-1}\left\|p_{k+1}\right\| \ldots \| p_{n}$. It is clear from the definition that the associativity of the composition operator is immaterial.

- Let $\alpha_{1}, \alpha_{2}$ be two sets of actions. The $\left(\alpha_{1}, \alpha_{2}\right)$-projection of $p$ is the TS

$$
\upharpoonright_{\alpha_{2}}^{\alpha_{1}}(p) \stackrel{\text { def }}{=}\left(S_{p}, \alpha_{2} \cap \alpha_{p}, \xrightarrow{a}{ }_{\alpha_{2}}^{\alpha_{1}(p)}, s_{p}\right)
$$

where

$$
s \xrightarrow{a}{ }_{\alpha_{2}(p)}^{\alpha_{1}} s^{\prime} \quad \text { iff }\left\{\begin{array}{l}
s{\stackrel{b_{1} \cdots b_{n} a}{\longrightarrow}}_{p} s^{\prime} \text { with } b_{i} \notin \alpha_{2} \& a \in \alpha_{1} \cap \alpha_{2}, \quad \text { or } \\
s \xrightarrow{a} s^{\prime} \text { for } a \in \alpha_{2} .
\end{array}\right.
$$

The projection operator $\upharpoonright$ is also used for traces: $\left(a_{1} \cdots a_{n}\right) \upharpoonright_{\alpha}$ is the trace $a_{1} \cdots a_{n}$ from which the actions $a_{i} \notin \alpha$ are removed.

Remark 2.5. The projection operator $\vdash_{\alpha_{2}}^{\alpha_{1}}$ has, as far as we know, not appeared in the literature. In this article, it is solely introduced for the purpose of defining the decompositions. For an idea how this operator works, consider the process $p$, given by the diagram in figure 1 . This represents a transition system with actions $a, b$ and $c$, states $s_{1}, s_{2}, s_{3}, s_{4}$ and $s_{5}$, initial state $s_{1}$, and a transition relation as suggested by the arrows. Clearly $p$ is the result of composing $p_{1}=b: a: n i l$ and $p_{2}=c: a: n i l$ in parallel. Using the projection operator $\upharpoonright_{\alpha_{2}}^{\alpha_{1}}$ we can project $p$ onto its parallel components, where $\alpha_{1}$ contains those actions through which the components communicate and $\alpha_{2}$ contains all the actions of that component. That is,

$$
p_{1}=\left.\right|_{\{a, b\}} ^{\{a\}}(p) \quad \text { and } \quad p_{2}=\left.\right|_{\{a, c\}} ^{\{a\}}(p) .
$$

In the composition, the actions $a$ and $b$ appear in $p_{1}, a$ and $c$ appear in $p_{2}$, and $a$ is the action through which $p_{1}$ and $p_{2}$ communicate. Note that when calculating $p_{1}$ and $p_{2}$, the possibility of extending actions backwards is essentially used. Also note that if we take $\alpha_{1}=\emptyset$, then the projection operator $\upharpoonright_{\alpha_{2}}^{\emptyset}(p)$ behaves as the encapsulation operator $\partial_{\alpha(p) \backslash \alpha_{2}}(p)$ from ACP [1] and the restriction operator $p \backslash\left(\alpha(p) \backslash \alpha_{2}\right)$ from CCS [15].

Remark 2.6. We now have three ways of specifying transition systems. We can describe them explicitly, we can write them down algebraically using the operators that have just been introduced, or we can draw a diagram such as in figure 1. In this paper, we also specify transition systems by simple recursive equations containing only choice, action prefix and a single variable. A construction that is sufficient for the exarnples in this paper is the following. Consider an equation

$$
\begin{equation*}
X=e(X) \tag{1}
\end{equation*}
$$

where $e$ consists of action prefixes and choices only. Define the self-loop TS

$$
r=(\{s\},\{\star\},\{(s, \star, s)\}, s)
$$

where $\star \notin \alpha(e(n i l))$. Construct the $\operatorname{TS} e(r)=(S, \alpha, \longrightarrow, t)$. The TS defined by $(1)$ is then the TS $p=(S, \alpha \backslash\{\star\}, \longrightarrow p, t)$ where

$$
\longrightarrow_{p}=(\longrightarrow \cap(S \times \alpha(e(n i l)) \times S)) \cup\left\{\left\langle t_{1}, a, t_{2}\right\rangle \mid t_{1} \xrightarrow{*} t_{1} \text { and } t \xrightarrow{a} t_{2}\right\} .
$$

For the examples in this paper, this definition coincides with the generally accepted interpretation of equations.

Remark 2.7. We can give operational characterisations of the above operators. We do not go into this any further except to list them as follows, and refer the interested yet uninitiated reader to e.g. [9] for understanding in interpreting these.

$$
\begin{array}{ll}
a: p \xrightarrow{a} p & W_{\alpha \cup\{a\}} \xrightarrow{a} W_{\alpha \cup\{a\}} \\
\frac{p \xrightarrow{a} p^{\prime}}{p+q \xrightarrow{a} p^{\prime}} & \frac{q \xrightarrow{a} q^{\prime}}{p+q \xrightarrow{a} q^{\prime}} \\
\frac{p \xrightarrow{a} p^{\prime}}{p\left\|q \xrightarrow{a} p^{\prime}\right\| q}(a \notin \alpha(q)) & \frac{q \xrightarrow{a} q^{\prime}}{p\|q \xrightarrow{a} p\| q^{\prime}}(a \notin \alpha(p)) \quad \underset{p\left\|q \xrightarrow{a} p^{\prime}\right\| q^{\prime}}{p} p^{\prime} \\
\frac{p \xrightarrow{a} p^{\prime}}{\upharpoonright_{\alpha_{2}}^{\alpha_{1}}(p) \xrightarrow{a} \upharpoonright_{\alpha_{2}}^{\alpha_{1}}\left(p^{\prime}\right)}\left(a \in \alpha_{2}\right) & \xrightarrow{p \xrightarrow{b} p^{\prime} \upharpoonright_{\alpha_{2}}^{\alpha_{1}}\left(p^{\prime}\right) \xrightarrow{a} p^{\prime \prime}}\left(a \in \alpha_{1}, b \notin \alpha_{2}\right)
\end{array}
$$

## 3 Basic Axioms

We will prove our results using axioms for $\|, \upharpoonright$ and $W$ only. In this section we introduce these. The axioms hold in strong bisimulation semantics, and therefore in most other reasonable semantics as well.

Definition 3.1. Let $p=\left(S_{p}, \alpha_{p}, \longrightarrow_{p}, s_{p}\right)$ and $q=\left(S_{q}, \alpha_{q}, \longrightarrow_{q}, s_{q}\right)$ be TS's. We call a relation $\mathcal{R} \subseteq S_{p} \times S_{q}$ a $(p, q)$-bisimulation relation iff $t \mathcal{R} u$ implies

1. if $t \xrightarrow{a} p t^{\prime}$ then $u \xrightarrow{a} q u^{\prime}$ for some $u^{\prime} \in S_{q}$ with $t^{\prime} \mathcal{R} u^{\prime} ; \quad$ and
2. if $u \xrightarrow{a} q u^{\prime}$ then $t \xrightarrow{a} p t^{\prime}$ for some $t^{\prime} \in S_{p}$ with $t^{\prime} \mathcal{R} u^{\prime}$.

Two states $t \in S_{p}$ and $u \in S_{q}$ are $(p, q)$-bisimilar, written $t \leftrightarrows_{p, q} u$, iff there is a $(p, q)$ bisimulation relation $\mathcal{R}$ relating $t$ and $u$. We abbreviate $\leftrightarrows_{p, p}$ by $\leftrightarrows_{p}$. The two TS's $p$ and $q$ are bisimilar, written $p \leftrightarrows q$, if $\alpha(p)=\alpha(q)$ and $s_{p \leftrightarrows p, q} s_{q}$.

Lemma 3.2 (Congruence). $\leftrightarrows$ is a congruence with respect to action prefix, choice, parallel composition and ( $\alpha_{1}, \alpha_{2}$ )-projection.

Proof. Standard.

The axioms that we use are presented in table 1. We do not strive for completeness of the axiomatisation. Rather, the axioms need only be sufficiently complete to satisfy our goal.

Lemma 3.3 (Soundness). The axioms in table 1 are sound with respect to $\leftrightarrows$.
Proof. For each axiom, we must construct an appropriate bisimulation relation. Let $p=$ $\left(S_{p}, \alpha_{p}, \longrightarrow_{p}, s_{p}\right)$ and $q=\left(S_{q}, \alpha_{q}, \longrightarrow_{q}, s_{q}\right)$. We present proofs only for axioms $R_{4}, R_{5}$ and $R_{6}$.
$R_{4}$. We will show that the identity relation on $S_{p}$ is a $\left(\upharpoonright_{\alpha_{2}}^{\alpha_{1}}(p), \upharpoonright_{\alpha_{2}}^{\alpha_{1}}\left(\upharpoonright_{\alpha_{2} \cup \alpha}^{\alpha_{1} \cup \alpha}(p)\right)\right)$-bisimulation.
 $a \in \alpha_{2}$. We distinguish between the following two cases.

(b) $a \in \alpha_{1}$. Then $s \xrightarrow{b_{1} \cdots b_{n} a}{ }_{p} s^{\prime}$ for some $b_{i} \notin \alpha_{2}$. Thus $s \xrightarrow{\left(b_{1} \cdots b_{n}\right) \upharpoonright_{\alpha} a}{ }_{\Gamma_{\alpha_{2} \cup \alpha} \cup(p)}^{\alpha_{1} \alpha_{\alpha}} s^{\prime}$. Therefore we have that $s \xrightarrow{a}{ }_{\mid \alpha_{2}}^{\alpha_{1}}\left(\Gamma_{\alpha_{2} \cup \alpha}^{\alpha_{1} \cup \alpha}(p)\right) s^{\prime}$.
Now suppose that $s \xrightarrow{a}{ }_{\alpha_{2}}^{\alpha_{1}}\left(\left\lceil_{\alpha_{2} \cup \alpha}^{\alpha_{1} \cup \alpha}(p)\right)\right.$ ) We will show that $s \xrightarrow{a} s_{\alpha_{2}}^{\alpha_{1}(p)}$. We know that $a \in \alpha_{2}$. We distinguish between the following two cases.
(a) $a \notin \alpha_{1}$. Then $\left.s \xrightarrow{a}\right|_{\alpha_{2} \cup \alpha} ^{\alpha_{2} \cup \alpha}(p)$. From the side condition that $\alpha_{2} \cap \alpha=\emptyset$ we know that $a \notin \alpha$. Therefore $s \xrightarrow{a} p s^{\prime}$ and hence $s \xrightarrow{a}{ }_{\alpha_{2}}^{\alpha_{1}}(p) s^{\prime}$.
(b) $a \in \alpha_{1}$. Then $s \xrightarrow{b_{1} \cdots b_{n} a}{ }_{\mathrm{L}_{2} \cup \alpha}^{\alpha_{1} \cup \alpha}(p) s^{\prime}$ for some $b_{i} \notin \alpha_{2}$. So $b_{i} \in \alpha$ and therefore $s \xrightarrow{c_{1}^{1} \cdots c_{m_{1}}^{1} b_{1}} p \ldots \xrightarrow{b_{1}^{n} \ldots c_{m_{n}}^{n} b_{n}}{ }_{p}^{c_{1}^{n+1} \ldots c_{m_{n}}^{n+1} a}{ }_{p} s^{\prime}$ with $c_{j}^{i} \notin \alpha_{2} \cup \alpha$. Hence $s \xrightarrow{a}{ }_{\alpha_{2}}^{\alpha_{1}(p)} s^{\prime}$.

```

Table 1: Basic axioms for operators
$R_{5}$. We will show that the identity relation on $S_{p} \times S_{q}$ is a $\left(\upharpoonright_{\alpha_{2}}^{\alpha_{1}}(p \| q),\left.\right|_{\alpha_{2}} ^{\alpha_{1}}(p) \| r_{\alpha_{2}}^{\alpha_{1}}\right.$ $(q))$-bisimulation. Suppose then that $\left(s_{1}, s_{2}\right) \xrightarrow{a}{ }_{\alpha_{2}}^{\alpha_{1}}(p \| q)\left(s_{1}^{\prime}, s_{2}^{\prime}\right)$. We will show that $\left(s_{1}, s_{2}\right) \xrightarrow{a} \underset{\alpha_{2}}{\alpha_{1}}(p) \|_{\alpha_{2}^{2}}^{\alpha_{1}}(q)<\left(s_{1}^{\prime}, s_{2}^{\prime}\right)$. We know that $a \in \alpha_{2}$. We distinguish between the following two cases:
(a) $a \notin \alpha_{1}$. Then $\left(s_{1}, s_{2}\right) \xrightarrow{a} p \| q\left(s_{1}^{\prime}, s_{2}^{\prime}\right)$. We distinguish between the following three subcases:
i. $a \in \alpha_{p} \cap \alpha_{q}$. Then $s_{1} \xrightarrow{a} p s_{1}^{\prime}$ and $s_{2} \xrightarrow{a}{ }_{q} s_{2}^{\prime}$. Therefore $s_{1} \xrightarrow{a}{ }_{\alpha_{2}}^{\alpha_{1}(p)} s_{1}^{\prime}$ and $s_{2} \xrightarrow{a}{ }_{\alpha_{2}}^{\alpha_{1}(q)} s_{2}^{\prime}$. Hence $\left(s_{1}, s_{2}\right) \xrightarrow{a}{ }_{\Gamma_{2}}^{\alpha_{1}}(p)\| \|_{2}^{\alpha_{1}}(q)\left(s_{1}^{\prime}, s_{2}^{\prime}\right)$.
 that $\left(s_{1}, s_{2}\right) \xrightarrow{a} \underset{\alpha_{2}(p) \| \upharpoonright_{\alpha_{2}}^{\alpha_{1}}(q)}{\alpha_{1}}\left(s_{1}^{\prime}, s_{2}^{\prime}\right)$.
iii. $a \notin \alpha_{p}$. This case is symmetric to the case above.
(b) $a \in \alpha_{1}$. Then $\left(s_{1}, s_{2}\right) \xrightarrow{b_{1} \cdots b_{n}} a p\left(s_{1}^{\prime}, s_{2}^{\prime}\right)$ for some $b_{i} \notin \alpha_{2}$. As $a \in \alpha_{1}$, we know from the side condition that $\alpha_{1} \subseteq \alpha_{p} \cap \alpha_{q}$ that $a \in \alpha_{p} \cap \alpha_{q}$. Hence $s_{1} \xrightarrow{\left(b_{1} \cdots b_{n}\right) \upharpoonright \alpha_{p} a}{ }_{p} s_{1}^{\prime}$ and $s_{2} \xrightarrow{\left.\left(b_{1} \cdots b_{n}\right)\right|_{\alpha_{q}} a}{ }_{q} s_{2}^{\prime}$. Thus $\left.s_{1} \xrightarrow{a}\right|_{\alpha_{2}} ^{\alpha_{1}(p)} s_{1}^{\prime}$ and $\left.s_{2} \xrightarrow{a}\right|_{\alpha_{2}(q)} ^{\alpha_{1}} s_{2}^{\prime}$ and we therefore have $\left(s_{1}, s_{2}\right) \xrightarrow{a} \underset{\alpha_{2}}{\alpha_{1}}(p) \| \Gamma_{2}^{\alpha_{2}}(q)\left(s_{1}^{\prime}, s_{2}^{\prime}\right)$.

Now suppose $\left(s_{1}, s_{2}\right) \xrightarrow{a}{ }_{\alpha_{2}}^{\alpha_{1}(p)\| \|_{\alpha_{2}}^{\alpha_{1}}(q)}$ ( $\left.s_{1}^{\prime}, s_{2}^{\prime}\right)$. We will show $\left(s_{1}, s_{2}\right) \xrightarrow{a}{ }_{\alpha_{2}}^{\alpha_{1}}(p \| q)\left(s_{1}^{\prime}, s_{2}^{\prime}\right)$. We know that $a \in \alpha_{2}$. We distinguish between the following three cases.
(a) $a \in \alpha_{p} \cap \alpha_{q}$. Then $a \in \alpha\left(\left.\right|_{\alpha_{2}} ^{\alpha_{1}}(p)\right)$ and $a \in \alpha\left(\left.\right|_{\alpha_{2}} ^{\alpha_{1}}(q)\right)$. Hence $s_{1} \xrightarrow{a}{ }_{\left.\right|_{\alpha_{2}}(p)}^{\alpha_{1}} s_{1}^{\prime}$ and $s_{2} \xrightarrow{a}{ }_{\alpha_{2}}^{\alpha_{1}(q)} s_{2}^{\prime}$. Therefore $s_{1} \xrightarrow{b_{1} \cdots b_{n} a} p s_{1}^{\prime}$ and $s_{2} \xrightarrow{c_{1} \cdots c_{m} a}{ }_{q} s_{2}^{\prime}$ for some $b_{i}, c_{j} \notin \alpha_{2}$. From the side condition that $\alpha_{p} \cap \alpha_{q} \subseteq \alpha_{2}$, we know that $b_{i}, c_{j} \notin \alpha_{p} \cap \alpha_{q}$. Therefore $\left(s_{1}, s_{2}\right)^{b_{1} \cdots b_{n} c_{1} \cdots c_{m} a} \underset{p \| q}{ }\left(s_{1}^{\prime}, s_{2}^{\prime}\right)$. Hence $\left(s_{1}, s_{2}\right) \xrightarrow{a}{ }_{\mid \alpha_{2}}^{\alpha_{1}(p \| q)}\left(s_{1}^{\prime}, s_{2}^{\prime}\right)$.
(b) $a \notin \alpha_{q}$. Then $s_{2} \equiv s_{2}^{\prime}$ and $s_{1} \xrightarrow{a}{ }_{\alpha_{2}}^{\alpha_{1}(p)} s_{1}^{\prime}$. From the side condition that $\alpha_{1} \subseteq \alpha_{q}$, we know that $a \notin \alpha_{1}$. Therefore $s_{1} \xrightarrow{a} p s_{1}^{\prime}$. Thus $\left(s_{1}, s_{2}\right) \xrightarrow{a} p \| q\left(s_{1}^{\prime}, s_{2}^{\prime}\right)$ and so $\operatorname{again}\left(s_{1}, s_{2}\right) \xrightarrow{a} \underset{\alpha_{2}^{\alpha_{2}}(p \| q)}{a}\left(s_{1}^{\prime}, s_{2}^{\prime}\right)$.
(c) $a \notin \alpha_{p}$. This case is symmetric to the previous case.
$R_{6}$. It is sufficient to prove that the relation
$\mathcal{R} \stackrel{\text { def }}{=}\left\{\langle s,(t, u)\rangle \mid s \leftrightarrows_{p} t \& \exists v \leftrightarrows_{\left.\right|_{\alpha} ^{\alpha}(p)} u\right.$ such that $v \xrightarrow{b_{1} \cdots b_{n}} p s$ for some $\left.b_{i} \notin \alpha\right\}$ is a $\left(p, p \|_{\alpha}^{\alpha}(p)\right)$-bisimulation relation. Suppose then that $s \mathcal{R}(t, u)$ and $s \xrightarrow{a} p s^{\prime}$. We must show that $(t, u) \xrightarrow{a}{ }_{p\| \|_{\alpha}^{\alpha}(p)}\left(t^{\prime}, u^{\prime}\right)$ where $s^{\prime} \mathcal{R}\left(t^{\prime}, u^{\prime}\right)$. We know that $t \xrightarrow{a} p t^{\prime}$ where $s^{\prime} \leftrightarrows_{p} t^{\prime}$ and that there is some $v \leftrightarrows_{\Gamma \alpha}^{\alpha}(p) u$ such that $v \xrightarrow{b_{1} \cdots b_{n} a}{ }_{p} s^{\prime}$ for some $b_{i} \notin \alpha$. We distinguish between the following two cases.
(a) $a \in \underset{a}{\alpha}$. Then $v \xrightarrow{a}{ }_{1_{\alpha}^{\alpha}(p)} s^{\prime}$ and thus $u \xrightarrow{a}{ }_{\left.\right|_{\alpha} ^{\alpha}(p)} u^{\prime}$ where $s^{\prime} \leftrightarrows_{\Gamma_{\alpha}^{\alpha}(p)} u^{\prime}$. Hence $(t, u) \xrightarrow{a} p \| \upharpoonright_{\alpha}^{\alpha}(p)\left(t^{\prime}, u^{\prime}\right)$ and $s^{\prime} \mathcal{R}\left(t^{\prime}, u^{\prime}\right)$.

Now suppose that $s \mathcal{R}(t, u)$ and $(t, u) \xrightarrow{a} p\left\|\|_{\alpha}^{\alpha}(p)\left(t^{\prime}, u^{\prime}\right)\right.$. We must show that $s \xrightarrow{a} p s^{\prime}$ where $s^{\prime} \mathcal{R}\left(t^{\prime}, u^{\prime}\right)$. We know that there is some $v \leftrightarrows_{\Gamma_{\alpha}^{\alpha}(p)} u$ such that $v \xrightarrow{b_{1} \cdots b_{n}} p$ for some $b_{i} \notin \alpha$. Furthermore, $t \xrightarrow{a} p t^{\prime}$ so $s \xrightarrow{a} p s^{\prime}$ where $s^{\prime} \leftrightarrows_{p} t^{\prime}$. It remains to show that $s^{\prime} \mathcal{R}\left(t^{\prime}, u^{\prime}\right)$. We distinguish between the following two cases.
 From the side condition that $\upharpoonright_{\alpha}^{\alpha}(p)$ is determinate (with respect to $\leftrightarrows_{\Gamma_{\alpha}^{\alpha}(p)}$ ), we have that $s^{\prime} \leftrightarrows_{\Gamma_{\alpha}^{\alpha}(p)} v^{\prime}$. Hence $s^{\prime} \leftrightarrows_{\Gamma_{\alpha}^{\alpha}(p)} u^{\prime}$ and thus $s^{\prime} \mathcal{R}\left(t^{\prime}, u^{\prime}\right)$.
(b) $a \notin \alpha$. Then $u \equiv u^{\prime}$, so again we have that $s^{\prime} \mathcal{R}\left(t^{\prime}, u\right)$.

Example 3.4. The following examples show why the conditions in $R_{4}, R_{5}$ and $R_{6}$ of the last theorem are necessary. For the condition in $R_{4}$, observe that

$$
\upharpoonright_{\{b\}}^{\emptyset}(a: b: n i l) \leftrightarrows \text { nil } \quad \text { whereas } \quad\left\lceil_{\{b\}}^{\emptyset}\left(\upharpoonright_{\{b\}}^{\{b\}}(a: b: n i l)\right) \leftrightarrows b: n i l .\right.
$$

By $n i l_{b}$, we mean the TS nil with alphabet $\{b\}$, which can be defined by $\upharpoonright_{\{b\}}^{\oplus}(a: b: n i l)$. For the first condition in $R_{5}$, observe that

$$
\begin{aligned}
& \stackrel{\mid}{\{b, c\}}\{(a: n i l+b: n i l) \| c: n i l) \leftrightarrows b: n i l \| c: n i l+c: n i l \quad \text { whereas }_{\{c\}}\left(\left(\underset{\{b, c\}}{\{c\}}(a: n i l+b: n i l)\left\|\upharpoonright_{\{b, c\}}^{\{c\}}(c: n i l) \leftrightarrows b: n i l\right\| c: n i l .\right.\right.
\end{aligned}
$$

For the second condition in $R_{5}$, observe that

$$
\begin{aligned}
& \upharpoonright_{\{a\}}^{\{a\}}(b: a: n i l \|(a: n i l+b: n i l)) \leftrightarrows a: n i l+a: a: n i l \quad \text { whereas } \\
& r_{\{a\}}^{\{a\}}(b: a: n i l) \| r_{\{a\}}^{\{a\}}(a: n i l+b: n i l) \leftrightarrows a: a: n i l .
\end{aligned}
$$

Finally, for the condition in $R_{6}$, observe that for $p=a: b: a: n i l+a: b: b: n i l$,

$$
p \| \upharpoonright_{\{a\}}^{\{a\}}(p) \leftrightarrows p+a: b: n i l .
$$

## 4 Verification via decomposition

In this section we formulate our main result which explains how the verification of an equation $p=q$ with $p=\|_{i=1}^{n} p_{i}$ and $q=\|_{j=1}^{m} q_{j}$ can be performed via decomposition. In theorem 4.4 we describe the decomposition and we give some conditions that must be checked in order for the method to be applicable. In the theorem, we use $p$ and $q$ on both the left and right hand sides, so that nothing is apparently gained by applying the theorem. However in remark 4.6 we show how $p$ and $q$ can be eliminated from the right hand side.

We begin with some straightforward lemmata that are used in the proofs to follow.
Lemma 4.1. $p=p \| W_{\alpha}$ whenever $\alpha \subseteq \alpha(p)$. In particular, $p=p \|$ nil.
Proof. $p \stackrel{W_{1}}{=} p\left\|W_{\alpha(p)} \stackrel{W_{2}}{=} p\right\| W_{\alpha(p)}\left\|W_{\alpha} \stackrel{W_{1}}{=} p\right\| W_{\alpha}$.

Lemma 4.2. Let $p=p_{1}\left\|p_{2} . p=p\right\| r_{\alpha}^{\alpha}\left(p_{2} \| W_{\alpha}\right)$ whenever $\alpha \subseteq \alpha(p)$ and $\upharpoonright_{\alpha}^{\alpha}\left(p_{2} \| W_{\alpha}\right)$ is determinate.

## Proof.

$$
\begin{array}{cll}
p & \stackrel{\text { lemma }}{=} \text { 4.1 } & p_{1}\left\|p_{2}\right\| W_{\alpha} \\
\stackrel{R_{6}}{=} & p_{1}\left\|p_{2}\right\| W_{\alpha} \| r_{\alpha}^{\alpha}\left(p_{2} \| W_{\alpha}\right) \\
& \text { lemma 4.1 } & p \| r_{\alpha}^{\alpha}\left(p_{2} \| W_{\alpha}\right)
\end{array}
$$

Lemma 4.3. $\upharpoonright_{\alpha \cup \beta}^{\alpha}(p) \| \upharpoonright_{\alpha}^{\alpha}(p)=\upharpoonright_{\alpha \cup \beta}^{\alpha}(p)$ whenever $\alpha \cap \beta=\emptyset$ and $\upharpoonright_{\alpha}^{\alpha}(p)$ is determinate.

## Proof.

Theorem 4.4 (Verification via decomposition). Let $p=\|_{i=1}^{n} p_{i}$ and $q=\|_{j=1}^{m} q_{j}$. Let $\alpha$ consist of the synchronous (communicating) actions of $p$ and $q$. That is,

$$
\alpha \stackrel{\text { def }}{=} \bigcup_{1 \leq i<j \leq n}\left(\alpha\left(p_{i}\right) \cap \alpha\left(p_{j}\right)\right) \cup \bigcup_{1 \leq i<j \leq m}\left(\alpha\left(q_{i}\right) \cap \alpha\left(q_{j}\right)\right) .
$$

Assume that $\upharpoonright_{\alpha}^{\alpha}\left(p_{i} \| W_{\alpha}\right)$ and $\upharpoonright_{\alpha}^{\alpha}\left(q_{j} \| W_{\alpha}\right)$ are determinate for all $1 \leq i \leq n$ and $1 \leq j \leq m$. Then

$$
p=q \quad \text { iff } \quad \begin{cases}p_{i j}=q_{j i} & \text { for } 1 \leq i \leq n, 1 \leq j \leq m, \\ \Gamma_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}(p)=\prod_{j=1}^{m} p_{i j} & \text { for } 1 \leq i \leq n, \text { and } \\ \upharpoonright_{\alpha \cup \alpha\left(q_{j}\right)}^{\alpha}(q)=\prod_{i=1}^{n} q_{j i} & \text { for } 1 \leq j \leq m,\end{cases}
$$

where

$$
p_{i j} \stackrel{\text { def }}{=} \upharpoonright_{\alpha \cup\left(\alpha\left(p_{i}\right) \cap \alpha\left(q_{j}\right)\right)}^{\alpha}(p) \quad \text { and } \quad q_{j i} \stackrel{\text { def }}{=} \upharpoonright_{\alpha \cup\left(\alpha\left(p_{i}\right) \cap \alpha\left(q_{j}\right)\right)}^{\alpha}(q)
$$

## Proof.

$(\Leftrightarrow)$ For each $1 \leq i \leq n$ we can prove that:

$$
\left.p^{\text {lemmaa }} \stackrel{4.2}{=} p\| \|_{j=1, j \neq i}^{n}\right|_{\alpha} ^{\alpha}\left(p_{j} \| W_{\alpha}\right) .
$$

By repeating this process for all $i$ we get

$$
\begin{aligned}
& p \quad \stackrel{\text { lemmas }}{=} 4.2,4.1 \quad\left(p \| W_{\alpha}\right) \|\left(\left\|_{i=1}^{n}\right\|_{j=1, j \neq i}^{n}\left(\Gamma_{\alpha}^{\alpha}\left(p_{j} \| W_{\alpha}\right)\right)\right) \\
& \left\|_{1},\right\|_{2}, W_{2} \quad\left\|_{i=1}^{n}\left(p_{i} \| W_{\alpha}\right)\right\|\left(\left\|_{i=1}^{n}\right\|_{j=1, j \neq i}^{n}\left(\upharpoonright_{\alpha}^{\alpha}\left(p_{j} \| W_{\alpha}\right)\right)\right) \\
& \stackrel{\|_{1, \|_{2}}^{=}}{\|_{i=1}^{n}}\left(\left(p_{i} \| W_{\alpha}\right) \|\left(\prod_{j=1, j \neq i} \Gamma_{\alpha}^{\alpha}\left(p_{j} \| W_{\alpha}\right)\right)\right) \\
& \stackrel{R_{1}, R_{2}}{=} \quad \prod_{i=1}^{n}\left(\Gamma_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}\left(p_{i} \| W_{\alpha}\right) \|\left(\|_{j=1, j \neq i}^{n} \Gamma_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}\left(p_{j} \| W_{\alpha}\right)\right)\right) \\
& \stackrel{\left\|_{1},\right\|_{2}}{=} \quad\left\|_{i=1}^{n}\right\|_{j=1}^{n}\left(r_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}\left(p_{j} \| W_{\alpha}\right)\right) \\
& \stackrel{R_{5}}{=} \quad \|_{i=1}^{n}\left(\Gamma_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}\left(\prod_{j=1}^{n}\left(p_{j} \| W_{\alpha}\right)\right)\right) \\
& \begin{array}{c}
\text { lemma } 4.1 \\
\text { assumption }
\end{array} \\
& \begin{array}{l}
\prod_{i=1}^{n}\left(l_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}(p)\right) \\
\prod_{i=1}^{n} \|_{j=1}^{m} p_{i j}
\end{array}
\end{aligned}
$$

In the same way, we can deduce that $q=\left\|_{j=1}^{m}\right\|_{i=1}^{n} q_{i j}$. Hence from the assumption that $p_{i j}=q_{j i}$ for each $1 \leq i \leq n$ and $1 \leq j \leq m$, we can deduce that $p=q$.
$(\Rightarrow)$ First it is clear that $p=q$ immediately implies that $p_{i j}=q_{j i}$. So we now prove that $p=q$ implies the second condition of the theorem. For each $1 \leq i \leq n$ we can compute the following.

$$
\begin{aligned}
& \prod_{j=1}^{m} p_{i j}=\|_{j=1}^{m}\left(\vdash_{\alpha \cup\left(\alpha\left(p_{i}\right) \cap \alpha\left(q_{j}\right)\right)}^{\alpha}(p)\right) \\
& \text { lemma } 4.1 \quad \|_{j=1}^{m}\left(\upharpoonright_{\alpha \cup\left(\alpha\left(p_{i}\right) \cap \alpha\left(q_{j}\right)\right)}^{\alpha}\left(q \| W_{\alpha}\right)\right) \\
& =\quad \prod_{j=1}^{m}\left(\upharpoonright_{\alpha \cup\left(\alpha\left(p_{i}\right) \cap \alpha\left(q_{j}\right)\right)}^{\alpha}\left(\prod_{k=1}^{m}\left(q_{k} \| W_{\alpha}\right)\right)\right) \\
& \stackrel{R_{5}}{=} \quad \prod_{j=1}^{m} \|_{k=1}^{m}\left(\vdash_{\alpha \cup\left(\alpha\left(p_{i}\right) \cap \alpha\left(q_{j}\right)\right)}^{\alpha}\left(q_{k} \| W_{\alpha}\right)\right) \\
& \stackrel{R_{2}}{=} \quad \prod_{j=1}^{m} \prod_{k=1}^{m} \underset{m}{\left(r_{\alpha \cup\left(\alpha\left(p_{i}\right) \cap \alpha\left(q_{j}\right) \cap \alpha\left(q_{k}\right)\right)}^{\alpha}\left(q_{k} \| W_{\alpha}\right)\right)} \\
& \left.\stackrel{R_{2}}{=} \prod_{\substack{m=1 \\
=}} \|_{k=1, k \neq j}^{m} \upharpoonright_{\alpha}^{\alpha}\left(q_{k} \| W_{\alpha}\right)\right) \| \upharpoonright_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}\left(q_{j} \| W_{\alpha}\right) \\
& \stackrel{R_{5}}{=} \quad \upharpoonright_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}\left(\prod_{j=1}^{m}\left(q_{j} \| W_{\alpha}\right)\right) \\
& \text { lemma } 4.1 \quad \upharpoonright_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}(q) \\
& =\quad \upharpoonright_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}(p)
\end{aligned}
$$

Finally, the third condition can be deduced in the same way.

Remark 4.5. One may wonder whether it is enough to only check $p_{i j}=q_{j i}$ in theorem 4.4. This would be a substantial optimisation. Unfortunately, this is not possible, as shown by the following example. Consider $p=(a: n i l+b: n i l) \| c: n i l$ and $q=a: n i l \|(b: n i l+c: n i l)$. One may try to verify that $p=q$ by applying theorem 4.4. In this case $\alpha=\emptyset$, so the determinacy constraints are easily satisfied. Calculating each $p_{i j}$ and $q_{j i}$ yields the following.

$$
\begin{array}{ll}
p_{11}=q_{11}=\text { a:nil } & p_{21}=q_{12}=\text { b:nil } \\
p_{12}=q_{21}=\text { nil } & p_{22}=q_{22}=\text { c:nil }
\end{array}
$$

So clearly $p_{i j}=q_{j i}$ for all $i$ and $j$, but $p \neq q$.
Remark 4.6. The right hand side of theorem 4.4 can be calculated using the following observations.

$$
\begin{array}{cc}
p_{i j} \quad=, & \upharpoonright_{\alpha \cup\left(\alpha\left(p_{i}\right) \cap \alpha\left(q_{j}\right)\right)}^{\alpha}\left(\prod_{k=1}^{n} p_{k}\right) \\
& \stackrel{\text { lemma 4.1, } R_{5}}{=} \\
\prod_{k=1}^{n}\left(\upharpoonright_{\alpha \cup\left(\alpha\left(p_{i}\right) \cap \alpha\left(q_{j}\right)\right)}^{\alpha}\left(p_{k} \| W_{\alpha}\right)\right) .
\end{array}
$$

We can calculate $\upharpoonright_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}(p)$ using the following:

$$
\begin{aligned}
\upharpoonright_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}(p) & =\upharpoonright_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}\left(\prod_{j=1}^{n}\left(p_{j} \| W_{\alpha}\right)\right) \\
& =\prod_{j=1}^{n}\left(\upharpoonright_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}\left(p_{j} \| W_{\alpha}\right)\right) .
\end{aligned}
$$

Of course this also applies to $q_{j i}$ and $\upharpoonright_{\alpha \cup \alpha\left(q_{j}\right)}^{\alpha}(q)$.
In section 6 we give an application of the above technique which takes advantage of the preceding remark. However we first analyse the verification problem to demonstrate the benefit of the technique.

## 5 On the complexity of verification by decomposition

In this section we consider the complexity of verification through decomposition. We do this in the setting of bisimulation equivalence, as the verification of trace based equivalences is generally intractable on finite state systems [13]. We show that in the case where there is no communication between the components, the verification is polynomial. In the case where there is communication between the components, we show that the verification is co-NP hard, and hence inherently intractable. The proof that we give is a simplified variant of those given in [18]. From these observations we draw the conclusion that verification via decomposition is especially worthwhile when there are relatively many asynchronous or non-communicating actions, and that its use is rather limited if almost every action is used for communication. But it is exactly the former case that leads to enormous state graphs, while in the latter case state graphs remain relatively small, and therefore, they can be more readily handled by existing means.

We start out by reformulating theorem 4.4, but now with the restriction that there are no communication actions among the component processes, which means that $\alpha=\emptyset$. For convenience, we write $\upharpoonright_{\beta}$ for $\upharpoonright_{\beta}^{\emptyset}$.

Corollary 5.1. Let $p=\|_{i=1}^{n} p_{i}$ and $q=\|_{j=1}^{m} q_{j}$ with $\alpha\left(p_{i}\right) \cap \alpha\left(p_{j}\right)=\emptyset$ for all $1 \leq i<j \leq n$ and $\alpha\left(q_{i}\right) \cap \alpha\left(q_{j}\right)=\emptyset$ for all $1 \leq i<j \leq m$. Then

$$
p=q \quad \text { iff } \quad \begin{cases}p_{i j}=q_{j i} & \text { for } 1 \leq i \leq n, 1 \leq j \leq m \\ p_{i}=\prod_{j=1}^{m} p_{i j} & \text { for } 1 \leq i \leq n, \text { and } \\ q_{j}=\prod_{i=1}^{n} q_{j i} & \text { for } 1 \leq j \leq m\end{cases}
$$

where

$$
p_{i j} \stackrel{\text { def }}{=} \mathrm{P}_{\alpha\left(q_{j}\right)}\left(p_{i}\right) \quad \text { and } \quad q_{j i} \stackrel{\text { def }}{=} \mathrm{P}_{\alpha\left(p_{i}\right)}\left(q_{j}\right)
$$

Proof. From $R_{1}, R_{2}, R_{7}$, lemma 4.1 and remark 4.6, we can show that $p_{i}=\Gamma_{\alpha\left(p_{i}\right)}(p)$ and $q_{j}=\Gamma_{\alpha\left(q_{j}\right)}(q)$, and from $R_{2}, R_{7}$, lemma 4.1 and remark 4.6, we can show that $\upharpoonright_{\alpha\left(p_{i}\right) \cap \alpha\left(q_{j}\right)}$ $(p)=\Gamma_{\alpha\left(q_{j}\right)}\left(p_{i}\right)$ and $\Gamma_{\alpha\left(p_{i}\right) \cap \alpha\left(q_{j}\right)}(q)=\Gamma_{\alpha\left(p_{i}\right)}\left(q_{j}\right)$. The result then follows directly from theorem 4.4.

In order to verify that $p=q$, we must check the three identities at the right hand side of the curly bracket in corollary 5.1. In table 2 we have put the complexities for each step and the complexity for the total calculation. Here, $S_{r}$ and $\longrightarrow_{r}$ represent the sets of states and transitions, respectively, of TS $r$. We assume that the number of states of our TS's is smaller than the number of transitions, as it is reasonable to assume that all states are reachable. The complexities in table 2 are motivated as follows.

1. In order to calculate $p_{i j}$, we take $p_{i}$ and remove all transitions labelled with actions not in $\alpha\left(q_{j}\right)$. Then we remove all unreachable states, along with their outgoing transitions. This takes $O\left(\left|\longrightarrow p_{i}\right|\right)$ time and space. In the same way we construct $q_{j i}$. In order to calculate $p_{i j}=q_{j i}$, we apply a standard bisimulation algorithm [13], which takes $O\left(\left(\left|\longrightarrow p_{i}\right|+\left|\longrightarrow q_{j}\right|\right) \log \left(\left|S_{p_{i}}\right|+\left|S_{q_{j}}\right|\right)\right)$ time and $O\left(\left|\longrightarrow p_{i}\right|+\left|\longrightarrow q_{j}\right|\right)$ space. As this must be repeated for each $1 \leq i \leq n$ and $1 \leq j \leq m$, we obtain the complexities as given in table 2.1.
2. We obtain the second complexity measures via the following observation:

Lemma 5.2. Let $r_{0}=\left(S_{r_{0}}, \alpha_{r_{0}}, \longrightarrow_{r_{0}}, s_{r_{0}}\right)$ and $r_{1}=\left(S_{r_{1}}, \alpha_{r_{1}}, \longrightarrow_{r_{1}}, s_{r_{1}}\right)$ with $\alpha_{r_{0}} \cap$ $\alpha_{r_{1}}=\emptyset$. For all $u, u^{\prime} \in S_{r_{0}}$ and $v, v^{\prime} \in S_{r_{1}}$ :

$$
u \leftrightarrows_{r_{0}} u^{\prime} \text { and } v \bigoplus_{r_{1}} v^{\prime} \quad \text { iff } \quad\langle u, v\rangle \leftrightarrows_{r_{0} \| r_{1}}\left\langle u^{\prime}, v^{\prime}\right\rangle .
$$

Proof. Straightforward.

| Equality | Time complexity Space complexity |
| :---: | :---: |
| $\begin{array}{ll} p_{i j}=q_{j i} & (1 \leq i \leq n \\ & 1 \leq j \leq m) \\ & \\ p_{i}=\prod_{j=1}^{m} p_{i j} & (1 \leq i \leq n) \\ \\ q_{i}=\prod_{i=1}^{n} q_{j i} & (1 \leq j \leq m) \end{array}$ | $\begin{aligned} & O\left(\operatorname{mn}\left(\max _{i, j}\left(\left\|\longrightarrow p_{i}\right\|+\left\|\longrightarrow q_{j}\right\|\right)\right) \log \left(\max _{i, j}\left(\left\|S_{p_{i}}\right\|+\left\|S_{q_{j}}\right\|\right)\right)\right) \\ & O\left(\max _{i, j}\left(\left\|\longrightarrow p_{i}\right\|+\left\|\longrightarrow q_{j}\right\|\right)\right) \\ & O\left(\operatorname{mn} \max _{i}\left\|\longrightarrow p_{i}\right\| \log \left(\max _{i}\left\|S_{p_{i}}\right\|\right)\right) \\ & O\left(\max _{i}\left\|\longrightarrow p_{i}\right\|\right) \\ & O\left(\operatorname{mn} \max _{j}\left\|\longrightarrow q_{j}\right\| \log \left(\max _{j}\left\|S_{q_{j}}\right\|\right)\right) \\ & O\left(\max _{j}\left\|\longrightarrow q_{j}\right\|\right) \end{aligned}$ |
| $p=q$ | $\begin{aligned} & O\left(\operatorname{mn}\left(\max _{i, j}\left(\left\|\longrightarrow p_{i}\right\|+\left\|\longrightarrow q_{j}\right\|\right)\right) \log \left(\max _{i, j}\left(\left\|S_{p_{i}}\right\|+\left\|S_{q_{j}}\right\|\right)\right)\right) \\ & O\left(\max _{i, j}\left(\left\|\longrightarrow p_{i}\right\|+\left\|\longrightarrow q_{j}\right\|\right)\right) \end{aligned}$ |

Table 2: Complexities of deciding bisimulation in non-communicating processes

Reading this lemma from right to left, it says that if $r_{0} \| r_{1}$ is not minimised with respect to bisimulation, i.e. it contains different states that are bisimilar, then this is due to the fact that either $r_{0}$ or $r_{1}$ was not minimal with respect to bisimulation. Reversing this reasoning says that if we ensure that $r_{0}$ and $r_{1}$ are minimal, then $r_{0} \| r_{1}$ will also be minimal.

We use this observation as follows in constructing $\|_{j=1}^{m} p_{i j}$. First construct $p_{i 1}$ as indicated above. This takes $O\left(\left|\longrightarrow p_{i}\right|\right)$ time and space. Minimise $p_{i 1}$ with respect to bisimulation, obtaining $\hat{p}_{i 1}$. Using the ordinary bisimulation algorithms, this takes $O\left(\left|\longrightarrow p_{i}\right| \log \left(\left|S_{p_{i}}\right|\right)\right)$ time and $O\left(\left|\longrightarrow p_{i}\right|\right)$ space. Now construct $p_{i 2}$ and its minimised variant $\hat{p}_{i 2}$ likewise. Then calculate $\hat{p}_{i 1} \| \hat{p}_{i 2}$, but stop if the number of states of the result exceed those of $p_{i}$. As $\hat{p}_{i 1}$ and $\hat{p}_{i 2}$ are minimal w.r.t. bisimulation, $\hat{p}_{i 1} \| \hat{p}_{i 2}$ is minimal. Hence if the number of states of $\hat{p}_{i 1} \| \hat{p}_{i 2}$ exceed the number of states of $p_{i}$, then $p_{i}$ cannot be bisimilar to $\|_{j=1}^{m} p_{i j}$. The complexity of calculating $\hat{p}_{i 1} \| \hat{p}_{i 2}$ is therefore $O\left(\left|\longrightarrow p_{i}\right|\right)$. We thus calculate $\|_{j=1}^{m} p_{i j}$ by stepwise adding $p_{i 3}, p_{i 4}, \ldots, p_{i m}$ in the same way. This takes $O\left(m\left|\longrightarrow p_{i}\right| \log \left(\left|S_{p_{i}}\right|\right)\right)$ time and $O\left(\left|\longrightarrow p_{i}\right|\right)$ space. The verification of $p_{i}=\|_{j=1}^{m} p_{i j}$ can then be done without increasing the time and space complexities. The steps above must be repeated for each $1 \leq i \leq n$. So we obtain the figures in table 2.
3. The analysis in this case is the same as in case 2 , using $q$ instead of $p$.
4. Combining the above gives these complexities for calculating $p \leftrightarrows q$.

The procedure sketched above is rather wasteful, e.g. $p_{i j}$ and $q_{j i}$ are calculated rather often. We have not investigated optimisations, as we expect that they will not improve the time and space complexities. However, the example in section 6 gives the impression that by using the regularity of processes $p_{i}$ and $q_{j}$, substantial improvements can be expected.

In the case where there is communication between the processes, then the verification of $\left\|_{i=1}^{n} p_{i}=\right\|_{j=1}^{m} q_{j}$ becomes co-NP hard for each process equivalence between trace and bisimulation equivalence. We give a straightforward proof of this fact, actually showing that in the case that $p_{i}$ and $q_{j}$ are all finite and determinate, this verification is co-NP complete. In [18] it is shown that this verification becomes P -space hard if $p_{i}$ and $q_{j}$ are finite state. It also gives an EXPSPACE completeness result in case abstraction of actions is allowed.

The proof technique in this section is a straightforward reduction from 3SAT [4]: Let $x_{1}, \ldots, x_{k}$ be variables and $l_{i j} \in\left\{x_{1}, \ldots, x_{k}, \neg x_{1}, \ldots, \neg x_{k}\right\}$. The question whether

$$
\bigwedge_{i=1}^{n}\left(l_{i 1} \vee l_{i 2} \vee l_{i 3}\right)
$$

is satisfiable is well-known to be NP-complete. There is a straightforward polynomial way of reducing an instance of 3SAT to an instance of 3SAT such that $k_{i 1}<k_{i 2}<k_{i 3}$ where $l_{i j}$ refers to a variable $x_{k_{i j}}{ }^{1}$. So 3SAT with this restriction is still NP-complete.

Lemma 5.3. Determining whether $\left\|_{i=1}^{n} p_{i}=\right\|_{j=1}^{m} q_{j}$ holds is co-NP complete for finite determinate $p_{i}$ and $q_{j}$.

Proof. First we show co-NP hardness by reducing from 3SAT with the ordering restriction to the question whether $\left(\|_{i=1}^{n} p_{i}\right) \| p=p^{\prime}$, for finite determinate $p_{i}, p$ and $p^{\prime}$, does not hold. Consider the following instance of 3SAT with restriction over variables $x_{1}, \ldots, x_{k}$ :

$$
\begin{equation*}
\bigwedge_{i=1}^{n}\left(l_{i 1} \vee l_{i 2} \vee l_{i 3}\right) . \tag{2}
\end{equation*}
$$

The processes $p_{i}, p$ and $p^{\prime}$ are constructed as in figure 2. Process $p_{i}$ has actions $l_{i 1}, l_{i 2}, l_{i 3}$, $\neg l_{i 1}, \neg l_{i 2}, \neg l_{i 3}$ and $\sqrt{ }$. Here $\neg l_{i j}$ stands for $\neg x$ if $l_{i j} \equiv x$ and for $x$ if $l_{i j} \equiv \neg x$. A step $l_{i j}$ corresponds to considering a valuation $\sigma$ that assigns true to $l_{i j}$, and a step $\neg l_{i j}$ corresponds to considering a valuation $\sigma$ that assigns false to $l_{i j}$. Clearly, $p_{i}$ can perform a $\sqrt{ }$ step iff $\sigma\left(l_{i 1} \vee l_{i 2} \vee l_{i 3}\right)$ is true.

The process $p$ is used to guarantee that in $\left(\|_{i=1}^{n} p_{i}\right) \| p$, first a step corresponding to $x_{1}$ must be performed, then one corresponding to $x_{2}$ etc. It has actions $x_{1}, \ldots, x_{k}, \neg x_{1}, \ldots, \neg x_{k}$

[^1]

Figure 2: The processes $p_{i}, p$ and $p^{\prime}$
and $\sqrt{ }$. The process $p^{\prime}$ is equal to $p$ with the only difference being that it has no $\sqrt{ }$ step at the end.

We have the following fact, from which our co-NP hardness result follows immediately.

$$
\bigwedge_{i=1}^{n}\left(l_{i 1} \vee l_{i 2} \vee l_{i 3}\right) \text { is satisfiable } \quad \text { iff } \quad\left(\prod_{i=1}^{n} p_{i}\right) \| p=p^{\prime} \text { does not hold. }
$$

Here ' $=$ ' represents any equivalence between trace and bisimulation equivalence [8]. We now prove this fact:
$(\Rightarrow)$ Let $\sigma$ be a valuation satisfying (2). Then $\left(\|_{i=1}^{n} p_{i}\right) \| p$ can perform the trace $a_{1} \cdots a_{k} \sqrt{ }$ where

$$
a_{i}= \begin{cases}x_{i} & \text { if } \sigma\left(x_{i}\right)=\text { true } \\ \neg x_{i} & \text { if } \sigma\left(x_{i}\right)=\text { false } .\end{cases}
$$

Clearly, such a trace cannot be performed by $p^{\prime}$. So, $\left(\|_{i=1}^{n} p_{i}\right) \| p$ and $p^{\prime}$ are not trace equivalent.
$(\Leftarrow)$ If $\left(\|_{i=1}^{n} p_{i}\right) \| p$ can perform a trace $a_{1} \cdots a_{k} \sqrt{ }$, then the assignment $\sigma$ defined as:

$$
\sigma\left(x_{i}\right)= \begin{cases}\text { true } & \text { if } a_{i}=x_{i}, \\ \text { false } & \text { if } a_{i}=\neg x_{i} .\end{cases}
$$

is clearly a satisfying truth assignment for (2). Thus if (2) is not satisfiable, then $\left(\|_{i=1}^{n} p_{i}\right) \| p$ cannot perform traces ending in $\sqrt{ }$. So exactly the traces $a_{1} \cdots a_{k}$ with $a_{i} \equiv x_{i}$ or $a_{i} \equiv \neg x_{i}$ can be performed by both $\left(\|_{i=1}^{n} p_{i}\right) \| p$ and $p^{\prime}$, and hence they are trace equivalent. As all processes are determinate, $\left(\|_{i=1}^{n} p_{i}\right) \| p$ and $p^{\prime}$ are also bisimulation equivalent [5].

Figure 3: A cycler and a scheduler
For completeness it is sufficient to guess a trace $a_{1} \cdots a_{k} \sqrt{ }$ and to check whether for each $1 \leq i \leq n, a_{k_{i 1}} a_{k_{i} 2} a_{k_{i 3}} \sqrt{ }$ is a trace of $p_{i}$, where $l_{i j}$ refers to a variable $x_{k_{i j}}$. This can clearly be done in polynomial time. As $a_{1} \cdots a_{k} \sqrt{ }$ is always a trace of $p$, it must also be a trace of $\left(\|_{i=1}^{n} p_{i}\right) \| p$, while it cannot be a trace of $p^{\prime}$.

It is not difficult to extend the proof above to include only two-way communication (see [18]) or to use only two actions. However this is outside the setting of this paper, and it complicates matters slightly.

## 6 An application

In this section, we apply the decomposition theorem to Milner's scheduler [14], which is constructed out of simple components, called cyclers. The scheduler is often used as a benchmark for programmes which calculate process equivalences [6,10,12], because its state space grows exponentially with the number of cyclers. Using our decomposition technique, we can avoid this exponential blowup.

The scheduler schedules $k$ processes in cyclic succession, so that the first process is reactivated after the $k$ th process has been activated. However, a process must never be reactivated before it has terminated. It is constructed of $k$ cyclers $C_{0}, \ldots, C_{k-1}$, as depicted in figure 3 , where cycler $C_{i}$ is dedicated to process $i$. The left part of the figure shows the transition system for cycler $C_{i}$, while the right part depicts the architecture of the scheduler. The dotted lines indicate where the cyclers synchronise. Cycler $C_{i}$ first synchronises on a signal $g_{i}$ which indicates that it may start. It then activates process $i$ via an action $a_{i}$. Next, it waits for termination of process $i$, indicated by $b_{i}$, and in parallel, using $g_{i+1}$, activates the next cycler. Here, the indices are taken $\bmod k$, so that $g_{k}=g_{0}$. It then returns to its initial state. The cycler $C_{i}$ is described by:

$$
\begin{aligned}
& C_{0}=a_{0}:\left(b_{0}: g_{1}: C_{0}+g_{1}: b_{0}: C_{0}\right), \\
& C_{i}=g_{i}: a_{i}:\left(b_{i}: g_{i+1}: C_{i}+g_{i+1}: b_{i}: C_{i}\right) \quad \text { for } \quad 1 \leq i<k .
\end{aligned}
$$

The first cycler is assumed to have been initiated. The complete scheduler for $k$ processes is thus described by:

$$
\text { Sched }_{k}=C_{0}\left\|C_{1}\right\| \cdots \| C_{k-1} .
$$

A correctness criterion for the scheduler has been formulated in [14]. The $a_{i}$ and $b_{i}$ actions must happen alternately, and the $a_{i}$ actions must happen cyclically. For the purposes of this example, we are also interested in the precise relationship between the synchronisation actions $g_{i}$ and the actions $b_{j}$. Therefore we prove the scheduler $S c h e d_{k}$ equal to the specification Correct $_{k}$ from which the behaviour of the scheduler can easily be understood. The process Correct $_{k}$ is defined by

$$
\text { Correct }_{k}=D_{0}\left\|D_{1}\right\| \cdots\left\|D_{k-1}\right\| B B_{k}
$$

where

$$
\begin{aligned}
& B B_{k}=a_{0}: g_{1}: a_{1}: \cdots: g_{k-1}: a_{k-1}: g_{0}: B B_{k}, \\
& D_{0}=a_{0}: b_{0}: g_{0}: D_{0}, \\
& D_{i}=g_{i}: a_{i}: b_{i}: D_{i} \quad \text { for } \quad 1 \leq i<k .
\end{aligned}
$$

The letters $B B$ in $B B_{k}$ stand for 'backbone'. It is easy to see that $C o r r e c t_{k}$ satisfies the correctness criteria as given by Milner. This can be shown formally by applying hiding, but as this is rather standard, we do not prove that here. For an idea of the proof, see the verification of the scheduler in [14].

We wish to apply theorem 4.4 to verify that Sched $_{k}=$ Correct $_{k}$. We thus let $p_{0}=C_{0}^{\prime}$ and $p_{i}=C_{i}$ for $1 \leq i<k$, and define $q_{j}=D_{j}$ for $0 \leq j<k$ and $q_{k}=B B_{k}$.

First note that $\alpha=\left\{a_{i}, g_{i} \mid 0 \leq i<k\right\}$. A small calculation tells us that $\upharpoonright_{\alpha}^{\alpha}\left(p_{i} \| W_{\alpha}\right)$ is bisimilar to $E_{i} \| W_{\alpha}$, where $E_{i}$ is defined by

$$
\begin{aligned}
& E_{0}=a_{0}: g_{1}: g_{0}: E_{0}, \\
& E_{i}=g_{i}: a_{i}: g_{i+1}: E_{i} \quad \text { for } \quad 1 \leq i<k,
\end{aligned}
$$

and that $\upharpoonright_{\alpha}^{\alpha}\left(q_{j} \| W_{\alpha}\right)$ is bisimilar to $F_{j} \| W_{\alpha}$, where $F_{j}$ is defined by

$$
\begin{aligned}
& F_{0}=a_{0}: g_{0}: F_{0}, \\
& F_{j}=g_{j}: a_{j}: F_{j} \quad \text { for } \quad 1 \leq i<k \\
& F_{k}=B B_{k} .
\end{aligned}
$$

Obviously these are all determinate, so theorem 4.4 is applicable. We use remark 4.6 to calculate $p_{i j}, q_{j i}, \upharpoonright_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}(p)$ and $\upharpoonright_{\alpha \cup \alpha\left(q_{j}\right)}^{\alpha}(q)$. For $i \neq j$, we find that

$$
\begin{aligned}
p_{i j} & =\prod_{l=0}^{k-1} \Gamma_{\alpha \cup\left(\alpha\left(p_{i}\right) \cap \alpha\left(q_{j}\right)\right)}^{\alpha}\left(p_{l} \| W_{\alpha}\right) \\
& =\prod_{l=0}^{k-1} \Gamma_{\alpha}^{\alpha}\left(p_{l} \| W_{\alpha}\right) \\
& =\prod_{l=0}^{k-1} E_{l} \| W_{\alpha} \\
& =B B_{k},
\end{aligned}
$$

and

$$
\begin{aligned}
q_{j i} & =\prod_{l=0}^{k} \upharpoonright_{\alpha \cup\left(\alpha\left(p_{i}\right) \cap \alpha\left(q_{j}\right)\right)}^{\alpha}\left(q_{l} \| W_{\alpha}\right) \\
& =\prod_{l=0}^{k} \upharpoonright_{\alpha}^{\alpha}\left(q_{l} \| W_{\alpha}\right) \\
& =\prod_{l=0}^{k} F_{l} \| W_{\alpha} \\
& =B B_{k} .
\end{aligned}
$$

For $i=j$, we find that

$$
\begin{aligned}
& p_{i i}=\|_{l=0}^{k-1} \gamma_{\alpha y\left(\alpha\left(p_{i}\right) \cap \alpha\left(q_{i}\right)\right)}^{\alpha}\left(p_{l} \| W_{\alpha}\right) \\
& =\prod_{l=0}^{k-1} \upharpoonright_{\alpha \cup\left\{b_{i}\right\}}^{\alpha}\left(p_{l} \| W_{\alpha}\right) \\
& =\prod_{l=0, l \neq i}^{k-1} E_{l}\left\|C_{i}\right\| W_{\alpha}
\end{aligned}
$$

and

$$
\begin{aligned}
& q_{i i}=\prod_{l=0}^{k-1} \Gamma_{\alpha \cup\left(\alpha\left(p_{i}\right) \cap \alpha\left(q_{i}\right)\right)}^{\alpha}\left(q_{l} \| W_{\alpha}\right) \\
& =\cdot \|_{l=0}^{k-1} \upharpoonright_{\alpha \cup\left\{b_{i}\right\}}^{\alpha}\left(q_{l} \| W_{\alpha}\right) \\
& =\left\|_{l=0}^{k} F_{l}\right\| D_{i} \| W_{\alpha}
\end{aligned}
$$

$$
\begin{aligned}
& g_{i}
\end{aligned}
$$

The initial sequences of actions $a_{0} g_{1} \cdots g_{i}$ in the two diagrams above are only present if $i \neq 0$. Obviously, $p_{i j}$ and $q_{j i}$ are thus equivalent. Note that the number of states of each intermediate term is always smaller than $3 k$, i.e. linear in $k$.

Now note that $p_{i i} \| B B_{k}=p_{i i}$ and hence $\|_{j=0}^{k} p_{i j}=p_{i i}$. Similarly, $\|_{i=0}^{k-1} q_{j i}=q_{j j}$. Hence

$$
\begin{aligned}
\upharpoonright_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}(p) \stackrel{r e m a r k}{=} 4.6 & \prod_{j=0}^{k-1}\left(l_{\alpha \cup \alpha\left(p_{i}\right)}^{\alpha}\left(p_{j} \| W_{\alpha}\right)\right) \\
& =\prod_{j=0}^{k-1}\left(l_{\alpha \cup\left\{b_{i}\right\}}\left(p_{j} \| W_{\alpha}\right)\right) \\
& \stackrel{(3)}{=} \\
& \prod_{j=0}^{k} p_{i j} .
\end{aligned}
$$

Equally, from remark 4.6 and (4) we have that $\upharpoonright_{\alpha \cup \alpha\left(q_{j}\right)}^{\alpha}(q)=\|_{i=0}^{k-1} q_{j i}$ So according to theorem 4.4, it follows that $p=q$.
