ABSTRACT

Nowadays we are more and more exposed to various emotional stimuli used as communication strategies in order to convey different messages. More specifically, in recent years, one kind of emotional advertising has become particularly popular: fear appeals.

Thanks to its wide diffusion, many writers have discussed the topic and several reaction models have been developed. However, despite the numerous studies now available, some contradictions still exist. Therefore, none of these models can be considered as valid for all fear appeal responses.

Starting from the existing literature, the goal of this research is to prove an overall effectiveness of such communication tool on different subjects. In order to do so a video advertisement for road-safety was analyzed.

The results show a general efficiency of fear-based approaches in the reduction of high speed in driving. In addition, the experiment revealed not only the major constraints of the video advertisement considered, but also how health organizations might improve safety campaigns.

Keywords: *Emotional Marketing, fear, positive emotion, consumer behaviour, companies behaviour.*

INTRODUCTION

The interaction of emotion and condition in reacting to advertising messages is a dynamic and intricate phenomenon. Always more, in the communication field, advertisements are created with a specific emotional content that is characterized by the co-presence of different strong emotionally stimuli used with the purpose of motivating individuals to make changes in attitude. Among these stimuli, particular attention has been lately paid on fear communication, extremely common in health campaigns.

Fear appeals are extremely complex messages with multiple emotional characteristics. Their main purpose is to get to the desired cognitive reaction on consumers by appealing to the natural feeling state of fear, an emotional response related to the persons' perception of a possible threat. Thanks to the intensity of the involvement which they create in the audience, fear appeals have been used always more as a communication tactic to convey certain messages to the public, in particular on topics related to public or personal welfare.

With this paper, the purpose of the authors is to analyze the possible effects which may arouse from the audience exposure to these various emotional stimuli, and in particular to understand the rational about cognitive responses to the emotion of fear on social marketing concerns.

The research, supported by a case study, will then try to give a proof of the effectiveness of this emotional communication tool by analyzing the responses of a specific target to fear media campaign.

LITERATURE REVIEW

Fear is a primitive, natural emotional response composed of two dimensions, physiological and psychological, which may arouse when an individual perceives a threat as serious and personally relevant (Witte, 1994). This emotional state, to which no human being is immune, has been described as a maximal state of insecurity and derives from people's uncertainty on what will be the best decision to make and whether they will be able to avoid or escape from the elicited danger (Turner & Ortony, 1990). Since the reaction arising from fear is quite capable of provoking attitudinal and behavioral changes, several advertising campaigns have been using this feeling as leverage in order to move the audience toward desired actions in different contexts. Marketers have been exploited this persuasive form of communication by taking advantage of the relationship between the danger evoked and the personal response produced by its representation.

The Use Of Fear In Marketing: Fear Appeals

Before considering the variety of contexts in which they can be applied, we can firstly define fear appeals by referring to their two main features: a) the content and the structure of their message and b) the audience response they hope for. Regarding the content of the message, many authors referred to a first distinction, elaborated in the previous literature by Schoenbachler and Whittler (1996), which used as determiner the "object" that it would have been affected by the threat represented in the advertisement. Thus, considering this classification, fear appeals can be divided into physical or social, depending on the nature of menace they represent, which might act on the body of the person (as for instance health consequences as cancer or death), or on the individual's social acceptance. This division, which is proven to be useful in determining which variables should be used for different

targets, is however not exhaustive, as some physical negative outcomes can also lead to issues in social acceptance (e.g. mouth cancer, destruction of tissues, etc.).

Consequently, it would be more accurate to refer to the analysis of Jones and Leary (1994), who outlined two other possible categories: appearance-based ads and health-based ads. This classification, which refers to which might be the most important concern for the person, allows to better analyze the effectiveness of a fear advertisement in terms of the content used to convey a message.

In addition to the elements considered above, there is another important element on which it is essential to carefully reflect while creating a message for a specific audience: the level of fear that has to be introduced in the ad. Referring to this subject, many authors in the past decades wrote academic reviews, proposing different models regarding the optimal “amount” of fear in the campaigns.

A first consideration on this theme can be found in early studies of 1960 in which the experiment outcomes showed that the greater the amount of fear, the lower the effect on behavior, which means that arousing too much tension in the audience would have not been effective (Myers & Reynolds, 1967). This conclusion on the negative relation between fear and effect doesn't find any confirm in latter works which focus on two different alternatives: a positive relation of the two variables; a curvilinear explanation.

In support of the first alternative, i.e. the positive correlation, we can find many relevant works in which various authors stated that the rapport between emotional fear response and persuasion is generally positive and linear. The general finding is that increases in fear can be linked to major change in attitude or behavior in a consistently manner (Sutton, 1992).

On the other side, the curvilinear explanation better helps to explain the possible range of reactions that might be provoked in response to a determined fear representation. This theory, which is mainly based on the work of Ray and Wilkie (1970), states that there is an optimal level of fear which lies in between the two extremes.

Together with the considerations on the right amount of fear, a properly defined message structure is necessary in order to obtain the wished outcome. A first important one is a basis from which each fear ad should start in order to be consistent and effective. This lies on the presence of two essential elements: the representation of a threat, severe and relevant for the audience (e.g. contraction of HIV which can lead to death) so as to arouse fear; and the illustration of a possible safe solution, which can lead to the neutralization of the threat and which can be easily implemented (e.g. use of condoms reduce the risk of contracting HIV).

Both components should be clear enough in order to induce a greater impact on the consumer's mind.

Another essential requisite for the success of the appeal is realism in the representation of the possible damages and threats that can occur in case of compliance with the unsafe behavior. The more realistic this representation, the more the personalization of the audience in the described scene and thus the greater the fear aroused. This factor can be considered together with the credibility of the appeal that lies on the representation of the dangerous situation. It has been proved, in effect, that when the source is specified (e.g. British Heart Foundation, American Association of Cancer Research) the audience is more likely to pay its attention to the message and to get touched by the threat represented.

Perceived threat includes other two components, which are the susceptibility of the menace (i.e. how much the individual believes that the danger refers to him) and also its severity (i.e. how impacting would be on the person) while perceived efficacy refers to the ability of the individual to deal with the aroused problem. Fear appeals results more effective when the message is structured in order to have these two variables perceived as high by the customer (Lennon, Rentfro, & O'Leary, 2010).

Besides being subject to the content and the structure of the message, the effectiveness of a fear appeal can be determined by the target audience to which the advertisement is addressed. Although in this branch of communication individualism is even more accentuated than in other marketing domains, because of the complexity of the psychological response of fear which is influenced by personal beliefs and experiences, an accurate segmentation would allow marketers to reach higher levels of success in the development of the campaign.

The segmenting approach, which takes its basis from the previous assumptions on the message structure, should include four typical and common marketing variables in order to be effective - demography, personality, usage/relevance, socioeconomic factors – and some reactions - guilt, shame, disgust, resistance response, maladaptive coping responses, boomerang effect - (Haefner and Singer 1965; Ray & Wilkie, 1970; Kantrowitz, 1987; Lazarus, 1991; Witte, 1992; Brennan and Binney, 2010; Wu and Fitzsimons 2012).

Several authors have supposed that when people are pushed to change their behavior, they might perceive a constraint to their personal freedom. Feeling this menace to their autonomy, people would be then attracted to the negative attitude even more than before being exposed to the ad. An example can be given by the results of a campaign whose aim was to reduce the tobacco consumption among college students: the researcher not only found that the smokers' response was anger and avoidance, but the study also reported that the appeal increased their desire to smoke a cigarette just after having viewed the ad, while on the other side, the campaign strengthen the non-smokers decision (Wolburg, 2006).

Fear Appeals In Social Marketing

With the term “Social Marketing” economists refer to that branch of marketing which seeks to develop communication concepts with the goal of encouraging behaviors that, since socially relevant, will translate in a greater social good.

Nowadays the trend in the use of social marketing for public associations and governments is continually increasing even if certain worries about its effectiveness still exist (Rothschild, 2005).

Several studies on compliant attitudes have been recently done and the general findings state that essential requisites to encourage these attitudes were clear regulations, a strong sense of duty and a concern for the social environment (May, 2005). Compliancy refers to a behavior in line with institutional rules, and, since we act in a regulated framework, people are well aware of the legal consequences that may arouse from not complying with these rules (e.g. penalties, fines or legal actions) (Harvey & McCrohan, 1988). Because of this observation it is still unclear if it is right to use the expression “voluntary” when referring to compliant behavior or if the attitude is just the result of a list of specific norms.

In order to solve the above described “voluntary” issue, marketers have developed structured appeals in which the focus is on representing the desired behavior as something which is also individually valuable for the person. Thus, clarity is a major requirement for these advertisements, as individuals should clearly see the possible benefit they might have as a consequence of the aimed behavior. This benefit can be represented by the avoidance of negative situation or the achievement of a personal success, depending on the nature of the message. In facts, as for product purposes, appeals may be positive or negative depending on the feelings they try to provoke in the audience. Even if various authors wrote and debate on the topic of the relationship among emotions and behavior compliance, the link between the intention and the effective change in attitude is still a problematic issue as results have been ambiguous and contradictory (Chandon, 2004). Notwithstanding these complications, emotional appeals achieved resounding success in social marketing, as they have been used always more in the last decade. In particular, many attention has been given to negative appeals, on which social marketing have been focused in order to convey messages for behavior compliance (Brennan & Binney, 2010).

The goal of these appeals is to create a sense of discomfort in the audience which will be therefore more motivated to react, in order to reduce the aroused negative feeling. The possible solution to this threat is then “revealed” by the ad and represents the desired compliant behavior which people should adopt. As already mentioned in the first part of this essay, the most popular negative emotion used in these appeals is fear, on which several campaigns are still based. Anyway, since the audience is getting used to this particular kind of messages, the trend is moving towards more complex ads,

created with the interaction of many negative and positive emotions and which aim to a deeper cognitive response.

The Case Of Anti-Speeding Video Advertisements “Mistakes”

Speeding, which can be defined as exceeding legal limits, driving too fast, or racing, is a dangerous driving behavior which causes an impressive number of vehicles crashes every year (GHSA, 2013). A significant percentage of traffic deaths is, in facts, related to this issue and this is the reason why many road safe associations are focusing always more on this topic, considered of crucial importance.

Even if now many advertisements and campaigns have been developed in order to reduce its impact, not so much attention has been paid on this topic in previous years, as transports safety organizations have been concentrating more on other driving attitudes, such as distracted and drunk driving and seat belt usage. As a result, while several progresses have been reached on these other areas, the impact of speeding continues to increase, becoming the cause of one-third of car fatalities.

Countries are now combating speeding in several ways, implementing many road safety countermeasures. The most common adopted method is a strong communication on the topic, obtained by intensive publicity campaigns, in particular via the television channel and video broadcaster medias (i.e. YouTube). In addition to these structured ads, motor vehicle manufacturers have been encouraged to redesign their messages which should be now focusing on safety rather than on speed. The goal is to increase the awareness of the possible negative consequences of this risky behavior and to persuade people to “slow down”.

Generally, these road safety video ads have mostly relied upon the use of negative emotions and in particular on fear-based approaches (Lewis, Watson, & White, 2009). In order to have an effective negative ad for road safety messages, such ads usually adopt a typical structure, which refers to the representation of a possible bad consequence (e.g. road crash) deriving from the unsafe driving behavior and to the further presentation of the attitude which will permit to avoid the undesired situation (i.e. driving carefully and at a moderate speed). This fear-based approach is still the most used for this topic and many studies have been focused on the possible success of using just fear, without the typical interaction with positive emotions, such as relief. Anyway the trend is to go on the opposite direction and this is the reason why we assist to an increase of complex emotional ads, whose aim is to create a complete cognitive response.

To better understand the effectiveness of these safety campaigns it is essential to consider a single case as a starting point for an analysis. For what it concerns anti speeding commercials, a very good example is the New Zealander ad “Mistakes” which became viral with more than 9 billion views on YouTube. This campaign, launched on January 2014, let drivers think about other road users in order

to make them choose a moderate speed which could avoid the consequences of other drivers' mistakes.

The 60 seconds impressive video shows a conversation of two drivers which are about to crash because of a mistake. The video starts with one man seeing another vehicle coming from the right. Believing to have enough time to move, he decides not to respect the stop signal and proceeds. The other driver, aware of his speed, gets scared and tries to slow down. In this moment time stops and the two men exit their cars and start talking. The one who didn't respect the signal apologizes but the other driver is already excusing himself because unable to stop. The first man is confused and pleads for the safety of his son in the backseat but it's too late: the second one just says he's sorry and that he is going too fast to stop in time. Unable to alter the outcome, both drivers return to their cars and a shot is taken on the speedometer which reads more than 100/km per hour. Real-time suddenly returns and as the father looks worried at his son in the backseat the two cars crash impacting him directly.

Despite the majority of safe driving advertisements that just focuses on the shock of the unexpected car crash, "Mistakes" has a totally different approach. In facts here the accident is anticipated as the audience already knows that there is going to be a collision. Anyway, as time stops and the drivers start talking, people feel that there might be an option and that the result can be changed. This arouses a sense of tension, as everyone knows which is the solution to the feared consequence and aims for it. And it's in this moment that people get involved, as they struggle to get to the safety option.

It's because of this peculiarity that this video reached such a visual impact, passing every other type of speeding ad broadcasted and becoming one of the most viewed videos of 2014. Starting from this impacting video, the following analysis focuses on its immediate effects in changing speeding attitude of a selected group of Italian students.

So as to prove the efficacy of fear appeal ads on unsafe driving authors have developed a small research on a sample of 20 Italian students (10 males and 10 females) of an age comprised between 20 and 30 years old. This experiment has been done in a two months period time with the use of a mobile application, "Road Rider", in order to calculate the maximal speed of the students in driving. All students are frequent drivers and used their vehicles in the city of Turin (highest speed limit: 70Km/h) each day from Monday to Friday.

METHODOLOGY AND HYPOTHESES

The analysis can be divided in two parts, referring to each month. In month 1, all 10 students have been asked to download the app on their smartphone and to report the maximal speed reached each day on a shared excel file on Dropbox. In writing these values they were also asked to state if they

used the car outside the town, so as to evaluate these numbers with the right speed limits. An average of the maximal weekly speed was then calculated for each person. This first part of the process was essential in order to have a range of non-influenced values as benchmark.

Then, on the last week of month 1 and during all month 2, the participants have been exposed to the anti-speeding commercial. The video has been showed to them three times during the first week, and then two times the following weeks, approximately at dinner time. At the first exposure, students were asked to watch it at home on their computer on YouTube and then to answer to three questions related to the emotions that aroused after watching it. Then, as for the previous month, participants were asked to keep recording their speeding values for the following days. Referring to the previous discussed literature on fear appeals and on similar case studies, there were few expectations on the results of this analysis.

A first one is related to the general efficiency of the ad. Considering previous assumptions on levels of emotion and usage I assume that the 20 students will react to the videos but slightly, since they are frequent drivers. This reaction would be seen especially after the first exposure to video, thanks to its novelty, and will decrease during the weeks. This supposition is consistent with precedent experiments since, as already proven in many studies, the more the exposure the less impacting the effect.

The second hypothesis refers to the differences between the two reactions of males and females. In facts, as already outlined in the first part of this essay, one of the variables which might influence the efficiency of an appeal is represented by the audience and, in this particular case, by demographic circumstances. Starting from the driving attitudes of young drivers, I expect females' reaction to be greater than males' one, and therefore that the commercial would be more effective for girls rather than for men. This assumption finds its roots in the riskier male driving behavior, which is proven also by insurance data, as young males are classified as the riskiest category.

RESULTS AND FINDINGS

The results of the analysis are reported in the two tables below (all data are in Km/h).

MONTH 1	Week1	Week 2	Week 3	Week 4	Month Average
FEMALES

Table 1: Records of Month 1 – “Mistakes”

This table reports the results of the first month of the analysis during which the participants have not been exposed to the advertisement. All the numbers in the columns represent the average maximum speed of each week and at the end of the month an average is calculated for all four weeks. These values can be considered as the starting point of the evaluation, as they represent data without the ads influence.

Table 2: Records of Months 2 – “Mistakes”

This table represents the results of Month 2 for the advertisement. A line has been added after each participant and shows the change in percentage of the maximal average speed with the previous week. The percentage in the last column refers to the change between the average of Month 2 compared to Month 1.

As it can be clearly seen in the lines, the exposure to the ad resulted in an overall positive effect, with the reduction of the monthly maximal speed average. In fact, considering the 20 participants, 18 of them reacted in the aimed way and reduced their speed as expected (percentages highlighted in green). Starting from this positive finding, which validates the effects of the videos, it is possible to analyze the other hypothesis assumed before.

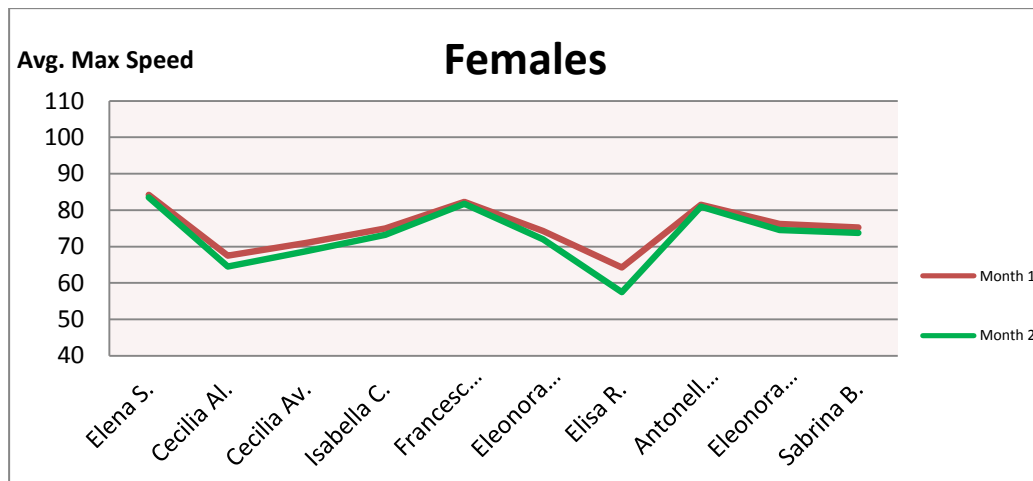

Table 3: Records Females Months 1 vs 2

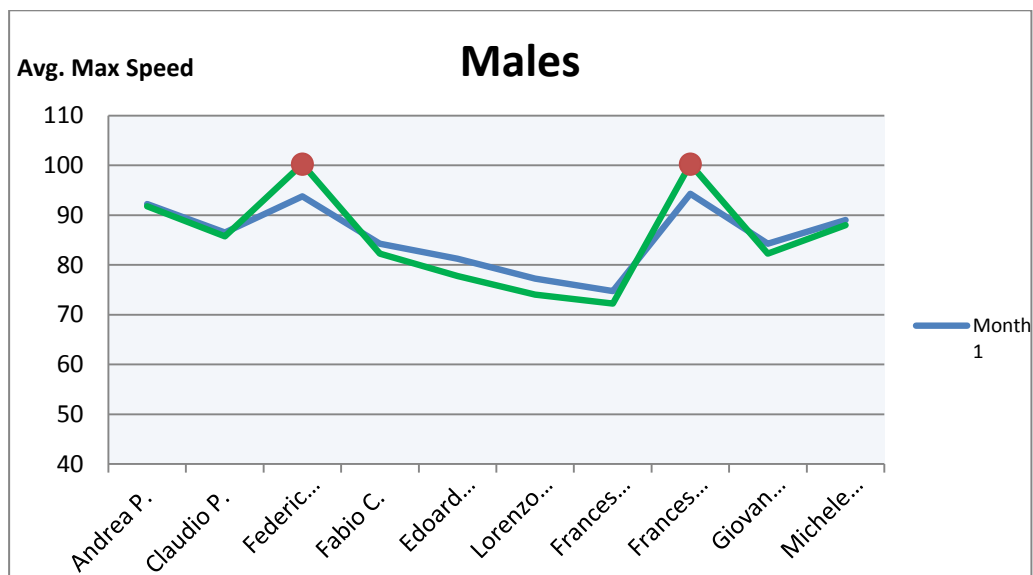

Table 4: Records Males Months 1 vs 2

For what it concerns the differences among male and women, the prediction was a diverse reaction to the advertisement and this is confirmed by this little case study. The values of the percentage reduction for women are significantly higher than the ones of men and this depends on their diverse attitude to fast driving. This finding is also consistent with the study of Lewis, Watson and Tay (2006) that focused their research on the different impact of gender to a reaction to road safety advertisements. The results, in facts, suggested that female were more influenced than men by threats on possible physical harms and therefore that these kinds of ads would have had a greater impact on them.

Taking a step further into the analysis, there are two interesting results that should be considered: the two positive changes in percentage among man (highlighted in red on the table). In facts, two male participants had an opposite response to the ad and increased their speed after the exposure to the

video. This is the so-called “boomerang effect” and it occurs when people deny the represented menace and act in the opposite direction of the desired one showed in the message.

As already mentioned above, many authors discussed on this topic and different theories have been applied in order to explain it. A famous example is represented by the work of Miller and Rollnick (1991), which assumed that this reaction could have been a response to a perceived menace on individual freedom: feeling to be “compelled” to act in a certain way the person perceives the negative response to the ad as a mean to defend his freedom and therefore considers the bad behavior as even more attracting than before.

Another possible option for this result can be assumed by referring to the previous assumptions on usage and relevance for the audience. As already explained and demonstrated (even in the case of visual warning), in facts, the higher the relevance the lower the effect, as this case proves. Taking a look at the monthly averages it can be noticed, in effect, that the two students who had this boomerang effects were the ones with the highest recorded values. This consideration, together with the relation of threat and freedom, fully explains these opposite reactions.

CONCLUSIONS AND LIMITATIONS

Given the weight of this topic and the rate of speeding on car accidents, it is easy to understand why creating an optimal road-safety campaign has become an important public health concern.

As demonstrated by previous studies and in this tiny experiment, video fear advertisements can be considered successful communication tools as they increases the awareness of an issue which has been underestimated during the years. Anyway, even on this topic, many other researches must be done so as to understand the real impact in continuous behavior and not only on immediate one. School programs and other educational tactics should be then used as well, in order to create a 360° campaign. Furthermore, as in many cases there are proofs of boomerang effect, additional analysis should be conducted on how avoiding these opposite reactions and how to better reach the young male segment. Just with the interactions of all these potential instruments it can be possible to effectively act on speeding. The purpose of this paper was to measure the potential effectiveness of fear appeals, with a particular focus on social marketing topics. Considering two different aimed outcomes such as the cessation of an unsafe behavior and the adoption of a coping one (i.e. drive at a moderate speed), the attempt was to prove how different fear-based tools could have acted on consumers’ cognitive reactions. As a result, it has been showed how diverse variables may have an impact in the success of these campaigns and how each no-profit organization can manipulate them in order to better reach its goals. These outcomes could then help these associations to implement more efficient campaigns aimed at solving various public health issues which undermine social welfare.

Furthermore, additional efficiency considerations have been highlighted by the two practical cases, which underlined which factors should be considered referring to a particular topic. Finally, thanks to the case study, an overall proof of effectiveness has been made on fear-based approaches, which have had positive consequences on the desired purposes.

Before validating the results of the study it is essential to first consider its major limitations. This little experiment, in fact, represents just an attempt to test the response of a very viral fear appeal on a restricted target of twenty young students. Therefore, in order to collect relevant results, a similar test might be proposed but the number of participants should be largely increased. People should then belong to different social classes and the test should be applied at least at a national level. The students here selected, in effect, were representing a very small range of young adults and no real conclusions can be assumed by such a reduced sample. In addition, all of them knew the purpose of the study, and thus the results might be biased.

Another important constraint has been represented by the duration of the test. Much more emphasis should be made on the period of time, as two months cannot be considered enough to state an actual change in behavior.
