24	Short title: Transseptal or transaortic access for left WPW ablation
25	Key words: Accessory pathway, Wolff-Parkinson-White, transcatheter ablation, transseptal access,
26	transaortic access

28 Abstract

Background. Transcatheter ablation is the most effective treatment for patients with symptomatic or high-risk accessory pathways (AP). At present, no clear recommendations have been issued on the optimal approach for left sided AP ablation. We performed this meta-analysis to compare the safety and efficacy of transaortic retrograde versus transseptal approach for left sided AP ablation.

Methods and Results. MEDLINE/PubMed and Cochrane database were searched for pertinent 33 articles from 1990 until 2016. Following inclusion/exclusion criteria application, 29 studies were 34 selected including 2030 patients (1013 retrograde, 1017 transseptal) from 28 observational single 35 Centre studies and one randomized trial. Patients approached by transseptal puncture presented a 36 significantly higher acute success (98% vs. 94%, p=0.040). The incidence of late recurrences 37 (p=0.381) and complications (p=0.301) did not differ among the two groups, but the pattern of 38 39 complications differed: vascular complications were more frequent with transaortic retrograde approach, while cardiac tamponade was the main transseptal complication. No difference was noted 40 41 in terms of procedural duration and fluoroscopy time (p=0.230 and p=0.980, respectively). Meta-42 regression analysis showed no relation between year of publication and acute success (p=0.325) or incidence of complications (p=0.795); additionally, no direct relation was found between age and 43 acute success (p=0.256) or complications (p=0.863). 44

45 Conclusions. Left sided AP transcatheter ablation is effective in around 95% of the cases, with a
46 very limited incidence of complications. Transseptal access provides higher acute success in
47 achieving AP ablation; late recurrences are rare but observed similarly following both approaches.
48 Retrograde approach is affected by a relatively high incidence of vascular complications.

### 52 Introduction

Wolff-Parkinson-White syndrome is characterized by the concomitant presence of cardiac preexcitation and arrhythmias as atrio-ventricular re-entrant tachycardia or atrial fibrillation (AF). Less than 1% of patients with cardiac pre-excitation may present a significant risk of sudden cardiac death, due to very high conduction properties of the atrioventricular accessory pathway (AP) [1]. Treatment is warranted to prevent this risk of sudden death in high-risk asymptomatic patients, or to prevent re-entrant tachycardias in symptomatic patients [2,3].

The APs can be situated everywhere in the tricuspid or mitral annuli, with the exception of the mitral-aortic continuity. Transcatheter ablation of the AP is the most effective treatment for patients affected by Wolff-Parkinson-White syndrome and for high-risk asymptomatic pre-excitation. The most recent guidelines recommend transcatheter ablation as first-line treatment for these patients [2], due to its high efficacy and safety in experienced Centres.

Bearing in mind the different possible localizations, right APs can be approached for ablation from 64 the femoral or subclavian veins, while left sided APs can be approached by transaortic retrograde 65 pathway or transseptal puncture. These two approaches differ in terms of technique, materials, 66 potential complications and easy access to the AP, and are usually chosen alternatively according to 67 the operators' comfort level and preference. However, no clear recommendation has been proposed 68 on the ideal approach for transcatheter ablation of left sided APs. In particular, common practice is 69 70 mainly based on single-Centre, observational studies, and no large randomized trials or registries 71 have been published.

We therefore performed this systematic review and meta-analysis including randomized and
observational studies comparing the outcome of transaortic retrograde versus transseptal approach,
aiming to assess the optimal approach for left sided AP transcatheter ablation, in terms of both
safety and efficacy.

#### 76 Materials and Methods

#### 77 Search strategy and studies selection

The present study was conducted in accordance with current guidelines, including the recent 78 Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) [4] amendment to 79 the Quality of Reporting of Meta-analyses (QUOROM) statement, as well as recommendations 80 from The Cochrane Collaboration and Meta-analysis Of Observational Studies in Epidemiology 81 (MOOSE) [5]. All subjects included in the studies gave informed consent. 82 MEDLINE/PubMed and Cochrane database were searched for pertinent articles published in 83 English from 1990 until December 2016. The following terms: ("Left accessory pathway" OR "left 84 Wolff Parkinson White") AND "catheter ablation" AND "radiofrequency" were used. Retrieved 85 citations were screened through abstract reading independently by two reviewers (M.M. and A.S.), 86 and divergences resolved after consensus. If the citations were deemed potentially pertinent, they 87 were then appraised as complete full-text reports according to the following explicit selection 88 criteria: (i) human observational or randomized studies, (ii) published in English between 1990 and 89 2016, (iii) investigating patients with left accessory pathways, (iv) including any duration of follow-90 up. Exclusion criteria were (one enough for exclusion): (i) non-human setting, (ii) duplicate 91 reporting (in which case the manuscript reporting the largest sample of patients was selected), (iii) 92 case reports or papers including less than 10 patients; (iv) surgical AP ablation. Data concerning 93 94 study design and year of publication, population characteristics, intervention, complications, acute 95 and mid- or long-term outcome were extracted by two Authors and reviewed independently by a third one (M.A.), being inserted in a single study database. 96

97

98

## 100 Statistical analysis

Since most of the included studies had an observational design, meta-analysis and meta-regressions 101 were performed using random effect models. Primary outcomes of this systematic review were: 102 103 proportions of initial success (calculated as the ratio between successful procedures and number of patients or as the ratio between successfully ablated pathways and the total number of treated 104 pathways), proportion of recurrences after a mid-term follow-up and proportion of complications. 105 106 Secondary outcomes were: total procedural time, fluoroscopy time (excluding those studies characterized by a "zero-fluoroscopy" approach) and number of energy applications per procedure. 107 108 Meta-analysis of proportions was performed using STATA command "metaprop" [6], while meta-109 analysis of continuous variables was performed using STATA command "metan" [7]. Aiming to assess the impact of the type of procedural access (retrograde aortic vs transseptal), subgroup meta-110 analysis was performed for both primary and secondary outcomes and a Q test for heterogeneity 111 between subgroups was computed. In addition, aiming to reduce the impact of potential biases 112 derived from patients' characteristics or year of publication, using the primary outcomes as 113 114 dependent variables, pre-specified meta-regression analysis was performed through STATA command "metareg" [8] to test whether interactions with (i) year when the study was published and 115 (ii) mean age of study participants were present. 116

117 Continuous variables were reported as mean (standard deviation) and categorical variables as counts
118 (percentage). Statistical analysis was performed using STATA version 12.0 (StataCorp, College
119 Station, TX, USA), considering p values < 0.05 statistically significant.</li>

120

121

122

#### 124 **Results**

#### 125 Search Results

The search identified 269 abstracts referring to transcatheter ablation of left sided APs; among this 126 group, 233 were excluded following application of the inclusion and exclusion criteria; 36 of them 127 were selected and full text was read by two Authors; 7 were excluded because reporting repeated 128 data. Twenty-nine studies were finally included meeting all the pre-specified inclusion criteria. All 129 included articles were single-Centre studies; overall 28 observational studies and one randomized 130 trial were included. Complete details of the study flow-chart are described in in the Supplementary 131 Material, Supplementary Figure 1. 132 First Author, study design, publication date and complete main characteristics of each included 133 study are reported in the Supplementary Material, Supplementary Table 1 [9-37]. 134 Overall, 2030 patients have been included in the analysis, 1013 approached by retrograde 135 transaortic access and 1017 by transseptal puncture. Baseline characteristics of the included 136 137 population in both groups are described in Table 1. Briefly, population included mainly young

adults, two thirds of whom were males. The most common location for left sided AP was leftlateral, followed by left posterior.

140

#### 141 Efficacy and safety endpoints

As shown in Figure 1, patients approached by transseptal puncture presented a significantly higher acute success of the ablation (98% vs. 94%, p=0.040) compared to transaortic retrograde approach. Conversely, the incidence of late recurrences of cardiac pre-excitation did not differ significantly among the two groups (3% vs. 2%, p=0.381; Figure 2). Concerning safety, the incidence of overall complications was equally low in both groups (0.4% vs. 1.2%, p=0.301; Figure 2). Of note, complications pattern was different: vascular complications (hematoma, pseudoaneurysm, aortic

148	regurgitation and coronary damage) were more frequent with transaortic retrograde approach, while
149	cardiac tamponade was the main complication of transseptal approach. Detailed complications are
150	reported in the Table 2.

Additionally, procedural duration and fluoroscopy time were investigated, and no difference was
noted between the two groups (p=0.230 and p=0.980, respectively; Figure 2).

153 Aiming to assess the impact of the currently available knowledge and technologies employed for

transcatheter ablation on the outcome and complications of the procedure, a meta-regression

analysis was performed to assess the impact of year of publication, showing no relation between

year of publication and acute success (p=0.325) or incidence of complications (p=0.795).

157 Additionally, due to the wide age range of the included patients, varying from children to middle

age, a meta-regression analysis was performed to assess the impact of age (Supplementary Figure

159 2), showing no direct relation with acute success (p=0.256) or complications (p=0.863).

### 170 Discussion

The present meta-analysis, although mainly based on single high-volume Centres, observational studies, includes the largest series of patients comparing the outcome of left sided AP transcatheter ablation approaching alternatively by transseptal or retrograde transaortic access. This series emerges due to the absence of large randomized trials or prospective registries assessing the comparison between the two approaches for left sided AP ablation, resulting a potentially useful tool to help Electrophysiologists in planning the access for left sided APs catheter ablation procedures.

Overall, transseptal approach reported a higher acute success compared to transaortic retrograde 178 approach. In fact, in experienced Centres transseptal approach may lead to easier manoeuvrability 179 of the ablation catheters in the left atrium, compared to the more challenging manipulation 180 approaching from the left ventricle across the aortic arch. Additionally, a more direct approach, as 181 conferred by transseptal access through the catheter "entrapment" within the interatrial septum, may 182 183 result in improved catheter stability and optimal contact on the mitral annulus, leading to a more 184 effective radiofrequency delivery towards the left sided AP. Failure of an ablation attempt is in fact usually related to a suboptimal catheter stability and catheter-tissue contact during ablation. Of note, 185 the only randomized trial included in the analysis, limited by the very small case sample (only 22 186 patients), did not find any difference between the two approaches [32]. 187

Concerning recurrence of conduction over the AP, the incidence was limited between both groups, without significant difference. In fact, the mechanism leading to recurrence is related to a transient effect provided by suboptimal site of ablation, along with the oedema generated by the energy delivery [38]. The majority of difficulties for obtaining good stability through the transaortic approach seem therefore to impair acute efficacy, while the incidence of recurrences, although rare, occurs similarly with both approaches.

The overall incidence of complications did not differ between the two groups. It should be noted 194 195 that pattern of complication is different, as transaortic approach was affected by a significantly higher incidence of vascular complications, while pericardial effusion was the most common 196 complication following transseptal approach (although not reaching statistical significance, see 197 Suppl Table 2). However, transseptal puncture needs specific training, and some Electrophysiology 198 labs are not trained for this approach and therefore mandatorily manage left sided AP by transaortic 199 approach. Of note, the number of transseptal access publications increased during recent years: this 200 trend probably relates to the spread of left atrial ablation for atrial fibrillation, which increasingly 201 favours the comfort level for transseptal puncture. However, in the absence of specific training, 202 203 transseptal access may provide additional risk; therefore, the results of this analysis should not be generalized to all Electrophysiology Centres. 204

Of note, the overall incidence of complications did not differ compared to the incidence reported for other left-sided arrhythmias ablation approached by transseptal access [39]. Additionally, also vascular complications were comparable to those reported by other electrophysiological procedures [39], although higher than those reported by coronary artery interventional procedures, probably related to the need of anticoagulation during the procedure. Conversely, thromboembolic events did not differ between the two approaches, highlighting that this is not an access-related complication.

211 The meta-regression analysis, performed to assess the impact of the available knowledge and technologies on the outcome of accessory pathway ablation, showed no significant relation between 212 acute efficacy or complications and year of publication. This finding suggests that left sided AP 213 ablation can be safely and effectively performed even using conventional diagnostic and ablation 214 catheters. In fact, although being related to reduction of radiological exposure for patients and 215 216 physicians (40), the impact on the outcome of AP ablation seems not to be relevant, as previously reported concerning atrial fibrillation ablation. Of note, the overall procedural duration and the 217 fluoroscopy time did not differ between the two approaches. Due to the different tools and 218

technologies, both approaches reported a wide range of both procedural duration and radiological
exposure, which appear shorter in the most recent publications. However, decreasing procedural
and fluoroscopy durations were parallel between the two approaches, demonstrating that both
access types benefit from technological improvements in terms of global simplification and
shortening of the procedure, but not in terms of safety or efficacy.

Finally, age was not related to different outcome, in terms of both safety and efficacy. This finding
emphasizes that left sided AP ablation can be safely performed even in children, in case of clear
indication to perform catheter ablation, such as in case of symptomatic, high anterograde
conduction APs.

228

## 229 Limitations

230 The present analysis includes a large and heterogeneous group of single Centre, observational studies: although heterogeneity was appraised by random effect, the inclusion of non-randomized, 231 retrospective studies may limit the reproducibility of the results. Although excluding case samples 232 and very small series, the experience of each single Centre in performing transcatheter ablation 233 procedures or even left chambers access, including individual operators' comfort level with both the 234 235 approaches, may have affected the access choice and the outcome of each single study results. Additionally, publication bias cannot be excluded, as a more favourable outcome would have driven 236 the potential interest for publication of these series, compared to other single-Centres series that did 237 never reach publication. However, it should be noted that parameters as year of publication, or age 238 of the included patients, did not affect safety or efficacy of the ablation procedure. Finally, meta-239 regression analysis does not allow clinicians to drive causative inferences, but only speculative. 240

241

## 243 Conclusion

244	Left sided AP	transcatheter	ablation is	s effective i	n around	l 95% o	f the	patients i	n trained	operators
-----	---------------	---------------	-------------	---------------	----------	---------	-------	------------	-----------	-----------

hands, and can be performed with a very limited incidence of complications even in younger

246 patients, when indicated. Transseptal access provides a higher acute success in achieving left sided

- 247 AP ablation, while late recurrences are limited, but occur similarly following both approaches.
- 248 While procedural duration and fluoroscopy use are similar, retrograde approach is affected by a
- 249 relatively higher incidence of vascular complications.
