29 **ABSTRACT**

30 **Background**

31 The 8th edition of the American Joint Committee on Cancer (AJCC) staging system (2018) for  
32 breast cancer (BC) introduced the prognostic stage. Moreover, multigene assessment has been  
33 indicated to tailor staging in T1/T2/N0, ER-positive/HER2-negative BC. However, many National  
34 Health Systems do not provide reimbursement for routine testing. The aim of this study was to  
35 assess whether Ki67 proliferation index is prognostically relevant for patients candidate for  
36 molecular testing.

37 **Methods**

38 A retrospective series of 686 ER+/HER2- BC were reclassified using AJCC 2018, and in the group  
39 of 521 patients for which AJCC 2018 recommends molecular evaluation, we assessed the  
40 prognostic efficacy of a prognostic stage enriched by Ki67 (Ki67-PS), considering Ki67<20% an  
41 alternative to Recurrence Score<11 provided by Oncotype DX.

42 **Results**

43 We found that a group of BCs (35.6%, 58/163) assigned to IB by prognostic score, were  
44 downstaged to IA with Ki67-PS. The outcome of these 58 cases overlapped with that of lesions  
45 classified as stage IA using prognostic stage, showing a significantly better prognosis compared to  
46 IB tumors (HR = 2.79, p = 0.003).

47 **Conclusions**

48 These data suggest that Ki67 may be a reliable marker to enrich the 2018 AJCC prognostic score in  
49 BC patients candidate for genomic profiling.

50

51 **Background**

52 Breast cancer (BC) is the most common cancer in women. The clinical approach to this  
53 disease varied over the years from radical surgery and aggressive oncological therapy, to the  
54 minimal patient-tailored effective treatment.<sup>1,2</sup>

55 Recently, several studies demonstrated that the biological phenotype of the tumor may be a  
56 superior prognostic variable than lymph node staging.<sup>3</sup> In particular, Mittendorf et al. described that  
57 among T1 BC patients, estrogen receptor (ER) status and histological grade are better predictors of  
58 survival than presence of small-volume nodal metastases.

59 Accordingly, the 8th edition of the American Joint Committee on Cancer (AJCC) staging  
60 system, published in 2018, proposed the use of a dual approach based on the traditional anatomic  
61 stage (AS) (*i.e.* tumor size, lymph node status), which remains unchanged from the 7<sup>th</sup> AJCC  
62 edition and the novel prognostic stage (PS). This latter takes into account biological information,  
63 such as ER, Progesterone Receptor (PR), HER2 status and histological grade and integrates them  
64 with AS.

65 To optimize patient care and in particular to allow appropriate treatment de-escalation,  
66 AJCC 2018 recommends molecular profiling in T1/T2 tumors without lymph nodes metastases and  
67 ER-positive/HER2-negative status. Specifically, four tools have been recommended: Oncotype  
68 DX® (level of evidence, I), MammaPrint®, EndoPredict® and Breast Cancer Index® (level of  
69 evidence, II). In particular, the AJCC suggested that independently from anatomic stage, ER-  
70 positive/HER2-negative tumor should be reclassified as stage IA in case of recurrence score (RS)  
71 <11 by Oncotype DX®.

72 To date, in many European countries, including Italy, none of these molecular tests is  
73 reimbursed by the National Health System hampering the prompt translation of AJCC 2018  
74 recommendations into the routine clinical practice. In addition, even if approved, these tests could  
75 hamper the budget sustainability of pathology laboratories.

76 The proliferation index, assessed using Ki67, is considered an important prognostic  
77 biomarker in BC.<sup>4</sup> Ki67 is typically useful in ER-positive/HER2-negative BC, to discriminate,  
78 together with PR, luminal A from luminal B cases, as recommended by St. Gallen guidelines.<sup>5</sup>  
79 Determination of Ki67 by immunohistochemistry (IHC) is routinely used to integrate the histology  
80 report and to add prognostic information, despite some criticism regarding its reproducibility<sup>6</sup> and  
81 different cut off values proposed in literature.<sup>5,7,8</sup>

82 Since most of the genes assessed by the previously listed molecular assays are related to cell  
83 proliferation, we hypothesized that a proliferative marker like Ki67 could partly substitute  
84 information obtained by genomic profiling.

85 The aim of the present study was to evaluate the efficacy of a Ki67-integrated AJCC 2018  
86 prognostic stage (Ki67-PS) for prognostic assessment of patients candidate for molecular assays. In  
87 particular, we firstly reclassified a retrospective series of ER+/HER2- BC using both AJCC  
88 anatomic and prognostic stages. Then, in the subgroup of patients candidate for multigene panel  
89 evaluation according to AJCC, we tested the prognostic efficacy and reliability of a Ki67-integrated  
90 PS (Ki67-PS).

91

## 92 **Methods**

### 93 **Case series**

94 We retrospectively evaluated 686 ER+/HER2- BC patients who underwent conservative surgery at  
95 the Breast Unit of “Città della Salute e della Scienza” University Hospital (Turin, Italy) from April  
96 1998 to December 2012. Data concerning tumor diameter, lymph node involvement, tumor grade,  
97 histological type, ER, PR, HER2, and Ki67 expression levels were obtained from the pathological  
98 reports. In addition, type of therapy and follow up status were collected from clinical reports. All  
99 the cases were anonymously recorded into a dedicated database, and data were accessed  
100 anonymously. The study was conducted in accordance with The Code of Ethics of the World  
101 Medical Association (Declaration of Helsinki) and within the guidelines and regulations defined by

102 the Research Ethics Committee for human Biospecimen Utilization (Department of Medical  
103 Sciences – ChBU) of the University of Turin. Considering the retrospective nature of this research  
104 protocol, which involved only already existing medical data that were previously anonymized with  
105 no impact on patient care, no specific written informed consent was required by the Committee.

106

### 107 **Immunohistochemistry**

108 Tissue sections were routinely immunostained using an automated slide processing platform  
109 (Ventana BenchMark AutoStainer, Ventana Medical Systems, Tucson, AZ, USA) with the  
110 following primary antibodies: prediluted anti-ER rabbit monoclonal antibody (SP1, Ventana  
111 Medical Systems); prediluted anti-PgR rabbit monoclonal antibody (1E2, Ventana Medical  
112 Systems) and anti-Ki67 mouse monoclonal antibody (MIB1, diluted 1:50, Dako). Evaluation of  
113 HER2 expression was performed by an anti-HER2 polyclonal antibody (A0485, diluted 1:800,  
114 Dako). Fluorescence in situ hybridization (FISH) was performed to define HER2 status in IHC  
115 equivocal cases (score 2+).<sup>9</sup> Positive and negative controls were included for each  
116 immunohistochemical run.

117

### 118 **Pathological evaluation**

119 Tumor size was dichotomized at 15 mm, as suggested by previous studies.<sup>10,11</sup>  
120 Cut-off for ER and PR positivity was determined at <1%, according to the Consensus of St. Gallen  
121 2011<sup>12</sup> HER2 was evaluated as recommended by the American Society of Clinical Oncology  
122 (ASCO)/College of American Pathologists (CAP).<sup>13</sup> Ki67 proliferation index was assessed on  
123 surgical specimens and a minimum of 1000 cells were evaluated.<sup>4</sup> The surrogate of molecular  
124 subtypes obtained from ER, PR and HER2 IHC expression is summarized in Supplementary Table  
125 1. Luminal subtypes were defined according to St. Gallen proposal<sup>5</sup> using a Ki67 cut-off value of  
126 20% in line with previously published studies.<sup>7,14</sup>

127

128 **Anatomic and prognostic staging**

129 All cases (n=686) were firstly staged using anatomic and prognostic stages, then BC in which  
130 further molecular testing (T1/T2, N0, M0) would be recommended according to AJCC 2018 were  
131 selected (n=521).<sup>15</sup> We hypothesized that the expression of Ki67 may provide prognostic  
132 information related to those obtained by Oncotype DX. Thus, in analogy to Oncotype DX® RS  
133 <11, we selected a value of Ki67 <20% to identify tumors staged IIA and IB which could be  
134 reclassified as IA. In case of Ki67 values  $\geq 20\%$ , as for RS  $\geq 11$  the PS was not modified.

135

136 **Statistical analysis**

137 Categorical data were described as counts and percentages. Disease Free Interval (DFI) was  
138 determined from the date of diagnosis to the date of first recurrence (either locoregional recurrence  
139 or distant metastasis) or, if no recurrence occurred, analysis was censored at time of last follow up.  
140 DFI was estimated with the Kaplan–Meier analysis. The Cox model was used to assess the  
141 prognostic value of a series of patient and tumor characteristics. Hazard ratios (HRs) and 95%  
142 confidence intervals (CIs) were also calculated. The proportional hazard assumption (Schoenfeld  
143 residuals) was always satisfied. The performance of the AJCC 2018 was informally compared  
144 through the Harrell C or the Somer D discrimination statistics in which the higher value was  
145 representative of better system performance. The Akaike information criterion was also computed, a  
146 lower value indicating the better performance of the model. Data were analyzed with Stata (version  
147 15; Stata Corporation, College Station, TX, US). Concordance among different classification  
148 systems were performed using K Cohen. A two-sided *P* value of less than .05 was considered  
149 statistically significant. All statistical tests were two-sided.

150

151 **Results**

152 **Clinico-pathological characteristics**

153 Clinical and pathological information of 686 patients are reported in Supplementary Table 2.  
154 Briefly, 59.5% of the tumors had a diameter <15 mm and 85% were classified as pT1; of these  
155 42.1% were well differentiated (G1) and 11.4% were poorly differentiated (G3). Lymph nodes  
156 resulted free of metastases in 76.1% of cases. The proliferation rate was low (Ki67 <20%) in 74.1%  
157 of cases. Most of tumors expressed PR and 59.3% were classified as Luminal A. All patients were  
158 treated by conservative surgery followed by radiotherapy. Hormonal therapy was administrated to  
159 95.2% of patients, while 23% received chemotherapy. Distant or local relapse was observed in 58  
160 patients (8.4%) and 21 died of BC (3.1%).

161

#### 162 **Classification using AJCC 2018**

163 Patients were staged according to the AJCC 2018 anatomic staging (Fig. 1 - AS). According to this  
164 system, 468 (68.2%), 28 (4.1%), 132 (19.2%) and 39 (5.7%) of tumors were staged as IA, IB, IIA  
165 and IIB respectively, whereas 19 (2.7%) were in stage III (Supplementary Table 3).

166 Then, we re-staged the tumors using AJCC 2018 prognostic stage (Fig. 1 - PS). Applying this  
167 staging system, the majority of tumors were still classified as IA (63.7%); however, the prognostic  
168 stage reassigned to IA and IB stage the majority of patients previously classified as IB or IIA by  
169 anatomic stage (Supplementary Table 3).

170 Conversely, 57 cases changed from IA by anatomic stage to IB (51) and IIA (6) according to  
171 prognostic stage. Only 15 out of 39 cases staged as IIB by anatomic stage were confirmed by  
172 prognostic stage, while 14 cases were upstaged into IIIA, 2 were assigned to IIIB and 8 were down  
173 staged to IB (Supplementary Table 3).

174 Supplementary Table 4 summarized the results obtained by anatomic and prognostic stages,  
175 grouping stage I-II-III patients. Using the new prognostic classification proposed by AJCC the  
176 majority of patients of our series were shifted in stage I [K=0.38, IC95% (0.33-0.41)]. In particular,  
177 using the anatomic stage 5.6% of cases were stage IB, the rate increased to 27.2% using the  
178 prognostic stage.

179

### 180 **Ki67-integrated Prognostic Stage (Ki67-PS)**

181 We selected 521 patients with BC staged as T1/T2N0M0 that were potential candidates for  
182 molecular assessment following AJCC 2018. Differences between AJCC 2018 anatomic and  
183 prognostic staging are summarized in Supplementary Table 5. In this subgroup, Ki67 proliferation  
184 index was used to integrate the prognostic stage with additional information regarding biological  
185 aggressiveness (Ki67-PS) (Fig. 1 - Ki67-PS).

186 Clinical and pathological information of this patient group are reported in Table 1. As shown in  
187 Table 2, 411 patients remained assigned to IA stage using both prognostic stage and Ki67-PS, while  
188 58 out of 89 (65,2%) and 3 out of 19 (15,8%) BCs previously classified as IB and IIA respectively  
189 were downstaged to IA, using Ki67-PS. In terms of absolute differences 61/521 (approximately  
190 12%) patients were differently classified.

191 Table 3 summarizes the results obtained by the three different staging systems, grouping stage I-II-  
192 III patients. Prognostic staging (95.9%) and Ki67-PS (96.5%) moved to stage I the majority of BCs.  
193 In general, we observed an overlap between prognostic stage and Ki67-PS, although stage IA  
194 counted more cases (411 vs 472) according to Ki67-PS.

195

### 196 **Outcome analysis according to different staging systems**

197 To understand which staging system could be more accurate to predict the prognosis in ER+ BC  
198 patients, we used Kaplan Meier analysis (Fig. 2 A-C). Only prognostic stage and Ki67-PS clearly  
199 distinguished stage I from stage II and III (Log-rank test  $p < 0.001$ ) (Fig. 2B and 2C, respectively). In  
200 addition, a significant difference of DFI among stages (I-II-III) was observed at univariate analyses  
201 regardless of the staging system used (Table 4).

202 Based on prognostic stage, DFI was significantly different in stage IA and IB (Log-rank test  
203  $p < 0.001$ ) (Fig. 2D). In particular, the 58 cases that were downstaged from IB to IA using Ki67-PS

204 showed a favorable outcome, similar to those classified as stage IA ( $p=0.307$ ). (Fig. 2D, Table 4)  
205 and a better prognosis compared to IB lesions (HR=2.79,  $p=0.003$ ).

206

207

208

209

## 210 **Discussion**

211 In the present study a retrospective series of ER+/HER2- BC with long follow up was  
212 reclassified using both 8<sup>th</sup> edition AJCC anatomical and prognostic stages. The results obtained  
213 confirm that integration of tumor load (size and presence of node involvement) with tumor type  
214 (grade and prognostic factors) leads to an increased number of patients classified as Stage I, as  
215 previously reported.<sup>16,17</sup> Furthermore, in line with other studies,<sup>18,19</sup> we found that stage I according  
216 to prognostic stage clearly identifies a group of patients with a more favorable outcome,  
217 distinguishing them from other patients with lesions classified as stage II or III and providing more  
218 accurate prognostic information compared with anatomic stage.

219 To furtherly improve patient care and avoid unnecessary treatments, AJCC 2018  
220 recommends the use of multigene profiling in the subset of T1/T2-N0, HER2-negative luminal BCs.

221 However, in many countries, including Italy, the National Health System does not reimburse  
222 these tests, hampering the prompt translation of AJCC 2018 recommendations into the routine  
223 clinical practice.

224 In absence of molecular assays, Ki67 is to date the only recommended marker, together with  
225 PR, that can help oncologists to differentiate luminal A from luminal B surrogate categories.<sup>8</sup>

226 In the present study, we created a prognostic stage integrated with Ki67 (Ki67-PS),  
227 hypothesizing that expression of Ki67 may stratify patients similarly to Oncotype DX<sup>®</sup>. Actually,  
228 Oncotype DX<sup>®</sup> is based, among others, on the expression of 5 genes related to proliferation

229 (namely MKI67, STK15, Survivin, CCNB1, and MYBL2), and the association between both, RS  
230 and single gene expression, with the Ki67 IHC levels has previously been addressed.<sup>20-23</sup>

231 Since use of Oncotype DX® in routine practice requires important financial resources and  
232 its cost-effectiveness has been questioned in the literature,<sup>24,25</sup> especially for low risk BC patients,  
233 Ki67-PS can possibly provide additional information with an inferior burden on National Health  
234 System budget.

235 Several works reported a poor reproducibility of Ki67 assessment due to the use of different  
236 clones (e.g. MIB-1, MM1, NCL-Ki-67p)<sup>26</sup> and different pre-analytic procedures, as well as  
237 discordant diagnostic evaluation even in case of dedicated breast pathologists.<sup>27</sup> To overcome this  
238 problem, in Italy, breast pathologists and breast pathological labs perform routinely local, regional  
239 and national quality controls, to standardize pre-analytical and analytical assessment of this marker,  
240 according to recommendation by the St Gallen consensus conference.<sup>5</sup> In addition, our and other  
241 groups demonstrated that 20% is an optimal cut off of Ki67 to stratify patients with luminal  
242 BCs.<sup>14,28,29</sup> Thus, we hypothesized that tumors showing Ki67 <20% may be classified as stage IA,  
243 similarly to those with RS <11.

244 In the present study, we showed that prognostic score clearly separates stage I tumors from  
245 the others. However, using the integrated Ki67-PS, 61/521 (12%) patients were downstaged from  
246 IB (58 patients) and from IIA (3 patients) to IA with an outcome comparable to those classified as  
247 stage IA defined by prognostic stage in terms of DFI. These data support Ki67 as a possible marker  
248 to identify the subgroup of patients with luminal BC with good prognosis in which treatment de-  
249 escalation could be considered.

250 The present study has some limitations that warrant consideration. Its retrospective nature  
251 limits the collection of follow up data. Due to the small number of patients that died of disease, we  
252 could not perform survival analyses. However, to the best of our knowledge, this is the first study  
253 that reports effective integration of the newly introduced AJCC 2018 prognostic staging system  
254 with Ki67 IHC evaluation.

255 In conclusion, our results confirmed that prognostic stage provides better prognostic  
256 information compared to anatomic stage in luminal BC patients. Moreover, the use of Ki67-  
257 integrated prognostic stage may be a reliable method to obtain additional prognostic data, enriching  
258 the 2018 AJCC system in BC patients candidate for genomic profiling.

259 **Additional Information**

260 **Ethics approval and consent to participate:** Ethical approval for this study was obtained from the  
261 Committee for human Biospecimen Utilization (Department of Medical Sciences – ChBU).  
262 Considering the retrospective nature of this research protocol, which involved only already existing  
263 medical data that were previously anonymized with no impact on patient care, no specific written  
264 informed consent was required by the Committee. The study was performed in accordance with the  
265 Declaration of Helsinki.

266 **Consent for publication:** Not applicable.

267 **Data availability:** The dataset analyzed during the current study is available from the  
268 corresponding author on reasonable request. Data generated during this study are included in this  
269 published article [and its supplementary information files].

270 **Conflict of interest:** The authors have declared no conflicts of interest.

271 **Funding:** The author(s) received no financial support for the research, authorship, and/or  
272 publication of this article.

273 **Authors' contributions:** I.C. conceived and designed the study. S.O.A. and G.M. performed  
274 statistical analyses. I.C., E.V., L.B., J.M., and P.C. evaluated and interpreted obtained data. I.C.,  
275 E.V., J.M., L.B., P.C. and A.S. wrote the original draft. All authors contributed to reviewing the  
276 manuscript, its organization and approved the submitted and final version.

374 **Fig. 1:** Study flowchart.

375

376 **Fig. 2:** Disease Free Interval (DFI) of stage I-II-III assessed using AJCC 2018 anatomical stage  
377 (log-rank test  $p < 0.001$ ) (**A**), prognostic stage (log-rank test  $p < 0.001$ ) (**B**) and Ki67-PS (log-rank test  
378  $p < 0.001$ ) (**C**) (Kaplan Meier analysis). DFI of stage IA and IB assessed using prognostic stage and  
379 of stage IA obtained from downstaging of IB using Ki67-integrated prognostic score (Ki67-PS)  
380 (log-rank test  $p < 0.001$ ) (Kaplan Meier analysis) (**D**).
