#### Abstract

An efficient synthetic approach to the core structure of the manzamine alkaloids is reported, particularly in relation to incorporating a one-carbon unit in ring B from which the aldehyde in ircinal A or the betacarboline unit in manzamine A could potentially be generated. The key steps involve a Johnson-Claisen rearrangement, enolate alkylation, dithiane alkylation and a stereoselective intramolecular dipolar cycloaddition of an azomethine ylide, which provided the desired tricyclic ABC core structure.

## Introduction

The alkaloid manzamine A 1 (Fig. 1) was first reported in 1986 and has a complex pentacyclic ABCDE structure. ${ }^{1}$ This compound, and related alkaloids, ${ }^{2}$ have attracted much attention due to their intricate structures and their reported biological activities. ${ }^{3}$ Several syntheses of manzamine A 1 and ircinal 2 have been published to date. ${ }^{4}$ In addition, several approaches to the synthesis of the core ring system, especially of the ABC ring system, are known. ${ }^{5}$

Our research group has reported the synthesis of the core ring system of manzamine A, ${ }^{6}$ and several simpler analogues. ${ }^{7}$ Our synthetic approach has focused on the formation of rings B and C of manzamine A by using an intramolecular dipolar cycloaddition reaction of an azomethine ylide. ${ }^{8}$ The alcohol $3^{9}$ was converted to the ester 4 by using a Johnson-Claisen rearrangement (Scheme 1). The ester $\mathbf{4}$ was converted in 5 steps to the aldehyde 8. Condensation with $N$-methyl glycine ethyl ester allowed in situ dipolar cycloaddition to give the tricyclic compound 9 as a single stereoisomer (stereochemistry verified by single crystal X-ray analysis). However, the aldehyde $\mathbf{8}$ was
found to be a poor substrate for reaction with other secondary amines. Fortunately, the aldehyde $\mathbf{1 0}$ (Scheme 2) was amenable to reaction with a variety of secondary amines including N -allyl glycine ethyl ester, which gave the desired product $\mathbf{1 1}$ as the major diastereomer. Alternatively, reaction with the primary amine glycine ethyl ester gave the tricyclic product 12, presumably arising from the W -shaped, rather than S -shaped, azomethine ylide.

The examples in Schemes 1 and 2 demonstrate that an intramolecular dipolar cycloaddition approach to the ABC ring system of the manzamine alkaloids is feasible and can provide the desired relative stereochemistry at four of the five stereocentres. One aspect that we were conscious of relates to the need for a strategy that allows the future incorporation of the $\beta$-carboline moiety. Except for the recent approach by Dixon and co-workers, the reported syntheses of manzamine A make use of the alkaloid ircinal A (2). ${ }^{4}$ We were therefore interested in developing chemistry that would allow the incorporation of a one-carbon unit in ring $B$ that could be suitable for conversion to the aldehyde found in ircinal A (and hence to manzamine A itself). This paper describes our efforts in this area.

## Results and discussion

Several approaches for the synthesis of a suitable precursor compound, with an extra carbon atom in ring B were investigated. Ideally this one-carbon unit would be introduced as part of the sequence of steps for the preparation of the aldehyde used in the key intramolecular dipolar cycloaddition step. One approach studied was to alter the Johnson-Claisen rearrangement using the alcohol 3. Based on a literature method, ${ }^{10}$ the alcohol 3 was heated with 3,3-diethoxyacrylic acid ethyl ester in toluene for just 90 min to give an almost quantitative yield of the diester 13 (Scheme 3). Reduction of the diester 13 gave the diol 14 . Treatment of the diol 14 with acetic anhydride gave the monoester $\mathbf{1 5}$ (and $28 \%$ diester) as an inseparable mixture of diastereomers. Reaction of the diol 14 with sodium hydride and TBDPSCl or p-methoxybenzyl chloride gave the alcohols $\mathbf{1 6}$ or $\mathbf{1 7}$ respectively, but these also were a $1: 1$ inseparable mixture of diastereomers.

Scheme 3 Studies using diester 13. i, 3,3-diethoxyacrylic acid ethyl ester, 2,4dinitrophenol, $\mathrm{PhMe}, 110{ }^{\circ} \mathrm{C}, 97 \%$ : ii, $\mathrm{LiAlH}_{4}$, THF, $64 \%$; iii, $\mathrm{Ac}_{2} \mathrm{O}$, pyridine, DMAP, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathbf{1 5 6 8 \%}$, or NaH, THF, TBDPSCl, $1699 \%$, or NaH, THF, PMBCI, $1780 \%$.

As a possible way to distinguish the hydroxymethyl groups, we treated the diol 14 with iodine to give the tetrahydrofuran 18 (Scheme 4). This did result in some preference for cyclization of one of the alcohols, although the selectivity was not high (dr $3: 1$ by ${ }^{1} \mathrm{H}$ NMR spectroscopy) and the diastereomers were inseparable by column chromatography. Protection of the alcohol gave compound 19, but these diastereomers were also inseparable. Despite this result, we treated compound 19 with zinc, which promoted ring opening to give the mixture ( $\mathrm{dr} 3: 1$ ) of diastereomeric alcohols $\mathbf{1 7}$. Therefore this method is able to provide the desired compound 17 with some selectivity (by ${ }^{1} \mathrm{H}$ NMR spectroscopy the major isomer was $\mathbf{1 7 a}$, see below), although this was insufficient for further studies.

Scheme 4 Studies using diol 14. i, iodine, $\mathrm{NaHCO}_{3}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{O}^{\circ} \mathrm{C}, 75 \%$ : ii, NaH , THF, PMBCI, $1760 \%$; iii, Zn dust, $\mathrm{NH}_{4} \mathrm{Cl}, \mathrm{EtOH}, 30^{\circ} \mathrm{C}, 44 \%$.

Two further methods to access a single diastereomer of alcohol 17 were investigated. Following precedent for asymmetric hydroxymethylation of aldehydes, ${ }^{11}$ we treated the aldehyde $\mathbf{2 0}^{6 \mathrm{~b}}$ with proline and aqueous formaldehyde (Scheme 5). However, this gave rise not to the desired $\alpha$-hydroxymethyl aldehyde product but rather the alkene $\mathbf{2 1}$ resulting from elimination. Finally, we performed a simple deprotonation of the ester 4 with LDA followed by addition of formaldehyde (Scheme 5). This gave a mixture of the alcohols 22 and 23 which we were delighted to find were separable by careful column chromatography. Taking a mixture of these isomers through the subsequent chemistry described below gave diastereomeric products that in all cases were inseparable from each other, so it was important to separate alcohols 22 and 23 at this stage.

Scheme 5 Alkylation using 20 or 4. i, $\mathrm{CH}_{2} \mathrm{O}_{(\text {aq })}$, proline, DMF, r.t., 89\%: ii, LDA, THF, $\mathrm{CH}_{2} \mathrm{O}, 63 \%$, 22:23 1:1.

To determine the relative stereochemistry, we took the less polar isomer (which turned out to be compound 23, see below) and treated it with $p$-bromobenzoyl chloride to obtain the ester 24 (Scheme 6). This compound was not crystalline, so the $N$ Boc group was removed with acid and the crude amine product was protected as the sulfonamide $\mathbf{2 5}$. This compound was amenable to single crystal X-ray analysis, which showed the relative stereochemistry as depicted (Fig. 2).

With both single diastereomers 22 and 23 in hand, we selected one of these for further study. The less polar isomer 23 was protected to give the ether 26 and reduction gave the alcohol 17a (Scheme 7). Conversion of the alcohol to the iodide 27 and displacement with the anion of ethyl 1,3-dithiane-2-carboxylate gave the ester 28. This was converted in three steps (reduction, transacetalisation, and oxidation) to the aldehyde 31.
The key step in our synthetic route to the manzamine alkaloids involves an intramolecular dipolar cycloaddition with an aldehyde tethered to the 4-position of a 3-exomethylenepiperidine. We therefore heated aldehyde 31 with $N$-allyl glycine ethyl ester (Scheme 8). This gave the desired tricyclic product 32 as a single stereoisomer, but only in $20-30 \%$ yield. The yield did improve (to $38 \%$ ) by using the hydrochloride salt of $N$-allyl glycine ethyl ester together with ${ }^{i} \mathrm{Pr}_{2} \mathrm{NEt}$. Other conditions (such as using excess amine or higher temperature) did not improve the yield. In all cases the product isolated was the enol ether 32, in which the cycloadduct had lost methanol. It is not clear why this loses methanol in comparison with the formation of cycloadduct $\mathbf{1 1}$ but sterics may play a part. As an alternative, the aldehyde 31 was heated with glycine ethyl ester to give the tricyclic product $\mathbf{3 3}$. The stereochemistry of these cycloadducts is assumed to be as shown, based on related chemistry (see Scheme 2).

Scheme 8 Key cycloaddition step. i, $N$-allyl glycine ethyl ester• $\mathrm{HCl},{ }^{i} \mathrm{Pr}_{2} \mathrm{NEt}$, $\mathrm{PhMe}, 110^{\circ} \mathrm{C}, 38 \%$; ii, glycine ethyl ester• $\cdot \mathrm{HCl},{ }^{\prime} \mathrm{Pr}_{2} \mathrm{NEt}$, , $\mathrm{PhMe}, 110^{\circ} \mathrm{C}, 60 \%$.

By using the same chemistry as shown in Scheme 7 with a $1: 1$ unseparated mixture of the diastereomers 22 and 23 , resulted in a 1:1 inseparable mixture of the aldehyde $\mathbf{3 1}$ and its diastereomer. Heating this mixture of stereoisomers with $N$ allyl glycine ethyl ester gave the same product $\mathbf{3 2}$ in $18 \%$ yield as the only product that could be isolated. This indicates that the stereoisomer derived from the ester $\mathbf{2 2}$ does not undergo the desired intramolecular dipolar cycloaddition reaction. Analysis of the conformations of the stereoisomers of the azomethine ylides suggests that a favourable conformation exists from the stereoisomer 31 (Fig. 3). The azomethine ylide derived from the other diastereomer of $\mathbf{3 1}$ would suffer from greater steric interactions. This may explain the preference for cycloaddition only from diastereomer 31.

Figure 3 Conformational analysis.

The successful synthesis of the tricyclic product $\mathbf{3 2}$ represents a stereoselective approach to the ABC core ring system of the manzamine alkaloids. One of the drawbacks of the chemistry discussed above is that a 1:1 mixture of the stereoisomers 22 and $\mathbf{2 3}$ is formed and only one of these is suitable for further elaboration. We have found that the undesired stereoisomer 22 can be converted to the desired compound $\mathbf{1 7 a}$ by the sequence of reactions shown in Scheme 9. Protection of the alcohol 22 with methoxymethyl chloride followed by reduction of the ester gave the alcohol 35 (Scheme 9). Protection of this alcohol as its PMB ether and removal of the MOM group selectively with mild acid gave the product $\mathbf{1 7 a}$. Alternatively, it is possibly to simply treat the undesired isomer 22 with sodium ethoxide to
promote epimerization. The resulting $1: 1$ mixture of esters (quantitative yield) can be separated by column chromatography.

## Conclusions

We have described a short and stereoselective route to prepare the ABC tricyclic ring system found in the manzamine alkaloids. This extends our previous work by demonstrating that a one-carbon unit can be located in ring B. This substituent could potentially be used to later generate the aldehyde functional group found in ircinal A and hence the betacarboline unit in manzamine A. Although a mixture of stereoisomers was formed when introducing this one-carbon unit, the undesired isomer can be isomerised. The key steps in the chemistry involve a Johnson-Claisen [3,3]-sigmatropic rearrangement, a dithiane alkylation, and an azomethine ylide dipolar cycloaddition. The dipolar cycloaddition was successful with only one diastereomer of the starting material. The yield in this key step was not particularly high, but the chemistry is significant as it demonstrates the importance of the choice of stereochemistry in such intramolecular cycloadditions when used as part of a synthetic endeavour.
