Introduction: The mechanism of colorectal cancer (CRC) invasion and metastasis is still unclear. Epithelial-mesenchymal transition (EMT) is one of the key molecular steps in the process of distant metastasis. EMT is referred to conversion of cells with an epithelial phenotype into cells with a mesenchymal phenotype, which lead to loss of cell polarity, with acquisition of migratory and invasive properties of cancer cells.¹ MicroRNAs (miRNAs) are small non-coding RNAs that negatively regulate gene expression at post-transcriptional phase.² MicroRNA-126 (miR-126) originates from a common precursor structure located within the *egf17* gene, which acts as a tumor suppressive miRNA in various carcinomas.³ Our previous studies found that miR-126 was significantly down-regulated in human CRC tissues and negatively related with patient's prognosis.⁴ MiR-126 was also low-expressed in high metastatic cell lines, and inhibited proliferation, invasion and metastasis of CRC in vitro.⁵ However, whether miR-126 can regulate the process of EMT in CRC is still unclear. Ras homologue A (RhoA) is one of most characterized members of Rho GTPases which belong to Ras superfamily. RhoA, as molecular switch, cycles between an active GTP-bound state and inactive GDP-bound state. RhoA and its components of signaling pathway are known to participate in a diverse array of cellular events related to invasion and metastasis of cancer cells.⁶ Our previous study found that miR-126 down-regulated RhoA and ROCK activity in CRC cells.⁵ Whether RhoA activity and RhoA signaling pathway play an important role in miR-126 regulating EMT process, cell proliferation, migration and invasion of CRC remains unclear.

Aims & Methods: To identify RhoA signaling pathway associated with the functions of miR-126 in EMT, proliferation, migration and invasion of CRC cells. Constructed CRC cell lines of miR-126 over-expression or knockdown. Performed MTT, colony formation, wound-healing, migration, invasion assays and RT-PCR, western blot analysis to study the functions of miR-126 in EMT, proliferation, migration, invasion and expression RhoA signaling pathway of CRC cells. Constructed pDsRed2-V14RhoA (constitutively active RhoA, V14RhoA) and pDsRed2-N19RhoA (dominant-negative, N19RhoA) mutants, then transfected them into the CRC cell lines of miR-126 over-expression or knockdown to restore RhoA activity. Pulldown assay detected RhoA activity after transfected. Then repeated the experiments above to investigate the biological behavior changes of CRC cells.

Results: MiR-126 promoted the expression of E-cadherin and suppressed the expression of SLUG, Snail, Vimentin, Fibronectin of CRC cells. MiR-126 also inhibited proliferation, migration and invasion of CRC cells, and negatively regulating RhoA signaling pathway. V14RhoA mutant effectively increased the activity of RhoA and reversed the role of miR-126 by promoting EMT, proliferation, migration and invasion in miR-126 overexpressing HCT116 cells. Conversely, N19RhoA mutant effectively decreased the activity of RhoA and suppressed EMT, proliferation, migration and invasion in miR-126-silenced SW480 cells.

Conclusion: RhoA signaling pathway was the key signaling pathway of miR-126 in suppressing the EMT, proliferation, migration and invasion of CRC cells.

Introduction: Colorectal cancer development is characterised by sporadic mutations and epigenetic alterations. DNA mutations occur randomly and sporadically in growth-related genes, mostly on cytosine nucleotides. Active demethylation of cytosines in relation to RNA expression alterations may lead to genetic instability and DNA mutations. Whole genomic DNA methylation and mutation analysis with RNA expression profiling could demonstrate the primary and secondary order of the epigenetic and genetic changes and their relation to the malignant phenotype development.

Aims & Methods: In this study we aimed the whole genome methylation analysis and targeted mutation analysis of colorectal cancer (CRC)-related genes (12) with upstream whole genomic mRNA expression evaluation. Special focus was set on the p53 pathway and the involved genes. Methyl capture sequencing (Illumina) was performed on normal (N: 6), adenomatous (Ad: 15) and colorectal cancer (CRC: 9) biopsy specimens. Methylation results were confirmed by in silico methylation studies' results (TCGA) and by methylation array-PCR (Qiagen Methylation array). Specimens were further evaluated for 32 mutations of 12 CRC-related genes (APC, BRAF, CTNNB1, EGFR, FBXW7, KRAS, NRAS, MSH6, PIK3CA, SMAD2, SMAD4, TP53) by new generation sequencing (Roche 454 Junior). mRNA expression evaluation was performed by whole genomic expression analysis (HGU 133, Affymetrix). Targeted pathway analysis was performed for the p53 pathway. Bioinformatic analysis included overall quantitative methylation analysis, selection of top hyper/hypomethylated genes, methylation changes on the tumor mutation regions and related pathway gene promoters were evaluated by targeted analysis.

Results: Overall hypomethylation was observed on the N-Ad-CRC sequence in the gene body and non coding genomic regions. In Ad-N comparison e.g. p73, NGFR, PDGFRA genes were hypermethylated for their promoters, FMN1, SLC16A7 genes were hypomethylated, respectively. In CRC-N comparison DKK2, SDC2, SOX1 genes showed hypermethylation, while ERBB4, CREB5, CNTN1 genes were hypomethylated in the promoter regions. In silico analysis on the TCGA database yielded confirmatory results. The common hyper- and hypomethylated genes were also in correlation with methylation array results yielded by methylation specific PCR. A significant negative correlation of the top methylated genes could be demonstrated to the RNA expressions. In the certain mutation hot spot, genebody regions significant DNA methylation alterations (mainly hypomethylation) were detected. APC, P53 and KRAS mutations were found in 30%, 15%, 21% of adenomas, and in 29%, 53%, 29% of CRCs, respectively. RNA expressions profiling could not detect any significant quantitative changes related to these DNA sequence alterations. The p53 gene body was addressed by hypermethylation in adenomas. mRNA expression changes were observed in most of the p53 pathway genes showing promoter methylation alterations.

Conclusion: DNA methylation with consecutive phenotypic effect can be observed in a high number of gene promoters and gene body regions through CRC development. The mutation hot spot areas of the most relevant colorectal cancer mutation genes (APC, p53, KRAS, NRAS) were involved in methylation alterations without detectable quantitative RNA expression changes. p53 cancer-pathway genes are highly methylated in promoters and gene body with corresponding expression changes. The tumor mutation hot spot areas in the p53 gene are hypomethylated and thus genetically unstable and therefore mutated.

Introduction: Colorectal carcinoma is one of the leading causes of cancer-related mortality worldwide. Tumor associated macrophages (TAMs) are critical stromal components intimately involved with the progression, invasion, and metastasis of cancer cells. Recently, increasing studies have demonstrated that microRNA-126 (miR-126) had an important role in colorectal cancer. The expression of miR-126 decreased significantly in colorectal cancer, particularly in highly metastatic cell lines, indicating that miR-126 may inhibit tumor development and metastasis. However, the mechanism underlying miR126 inhibiting cancer is uncertain, and its function in cross-talk between colorectal cancer cells and TAMs are still in its infancy.

Aims & Methods: In this study, we investigate the cross-talk between cancer cells and TAMs in colorectal cancer microenvironment, and find out what role the miR-126-CXCL12-IL6 axis plays in it. Methods: (1)The effect of miR-126 on CXCL12 expression was assessed in the CRC cell line Caco2 transferred with a miR-126 mimic or inhibitor to increase or decrease miR-126 expression; (2) We build a co-culture system of TAMs and transferred cancer cells, and use AMD3100(100 ng/ml) to block CXCL12/CXCR4 axis, then detect the recruitment and inflammation factors secretion of TAMs; (3) Furthermore, the TAMs co-cultured before were taken away from the previous system and put into a new co-culture system with untreated colorectal cancer cells, and IL6 neutralizing antibodies were added in. We detect the expression of EMT associated factors and STAT3 pathway activation by western blot, cell growth by CCK8, metastasis by Transwell. The definition of statistical significance was defined as $P < 0.05$ (two-tailed).

Results: (1)miR-126 negatively regulate CXCL12 expression in post-transcript level; (2)Inhibiting miR-126 of colorectal cancer cells could promote TAMs recruitment and up-regulate inflammation factors IL1 β and IL6 expression. However, blocking CXCL12/CXCR4 axis by AMD3100 could reverse this effect, vice versa;(3) Inhibiting miR-126 of colorectal cancer cells could recruiting TAMs, therefore down-regulate E-cadherin protein, up-regulate slug protein, and activate STAT3 pathway of untreated cancer cells. It could also promote cancer cells growth and metastasis. In addition, IL6 neutralizing antibodies could block this effect, vice versa.

Conclusion: Our results reveal a novel mechanism by that miR-126 repress recruitment and inflammatory factor secretion of TAMs through controlling secretion and paracrine signaling of CXCL12 to inhibit colorectal cancer growth and metastasis.

Introduction: Narrow Band Imaging (NBI) enable detection for vascular-rich small, flat lesion and recognition of mucosal surface compared with normal colonic mucosa and vascular pattern in colonoscopy. However, recent studies reported no significant difference in overall adenoma detection rate with the use of NBI compared with white light imaging (WLI). Blue Laser Imaging (BLI) is next-generation of image enhanced endoscopy technique using LASER light source that were realized with lighting and image processing suitable for visualization of microvessels and structures in the superficial portion of the mucous membrane.

Aims & Methods: Our aim was to determine whether the use of BLI enhances the adenoma detection rate (ADR) and miss rate compared with WLI. A total of 130 patients who underwent screening or surveillance colonoscopy in Saga University Hospital were included. Three patients were excluded because of poor bowel preparation. One hundred and twenty-seven patients were randomized to tandem colonoscopy with BLI followed by WLI (BLI-WLI group) or WLI followed by WLI (WLI-WLI group). Polyp (adenoma) detection rates, miss rates and the number of polyps (adenoma) detected per person (mean adenoma detection rate) were examined between the two groups.

Results: The BLI-WLI group and WL-WL group comprised 64 and 63 patients, respectively. The proportion of patients with polyps (adenoma) was 62.5% in BLI-WL group compared with 63.5% in WL-WL group. There was no significant difference between two groups regarding ADR (.). The number of adenomas detected per person (ADR) of BLI-WL group and WL-WL group were 2.84 and

1.90, respectively. However, the polyp miss rate of BLI-WL group was less than that of WL-WL group (1.6% vs 10.0%: $P = 0.0014$).

Conclusion: There were no significant difference in the overall polyp (adenoma) detection rate with BLI-WLI group or WL-WL group. However, miss rate was higher in WL-WL group compared with BLI-WL group (10.0% vs 1.6%, $P = 0.0014$). Further, BLI detected more polyps per patient compared with WL group (2.84 vs 1.90). BLI may improve polyp miss rate and the number of polyps per subject (mean adenoma detection rate) in the colonoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1103 COLORECTAL CANCER SCREENING COLONOSCOPY - ABSENT DISTAL POLYPS IN ADVANCED PROXIMAL NEOPLASIA

Introduction: The National Health Service Bowel Cancer Screening Programme (NHS BCSP) offers colonoscopy to people testing positive for Faecal Occult Blood Test (FOBT) after the age of 60. In addition, the 'Bowel scope screening' test offers once-only flexible sigmoidoscopy (FS) to people in the UK after the age of 55. The Norwegian (NORCCAP) and Italian (SCORE) trials evaluated the effectiveness of FS screening and reported a non-statistically significant decrease in colorectal cancer (CRC) specific mortality at follow-up. It is unclear if significant proximal neoplasia is being missed in people undergoing flexible sigmoidoscopy alone.

Aims & Methods: We aim to investigate the distributions of pathology within the BCSP at a busy district general hospital in London. In 2015, 22,539 FOBT kits were returned out of the 43,884 (51.4%) sent out in the boroughs of Barking, Havering and Redbridge (BHR). Of those returned, 398 (1.8%) tested positive. We collected data for the 326 patients who attended for colonoscopy at BHR University Hospitals (81.9%). Subgroup analyses included age, sex, histology, location of polyps, number of polyps, polyp size and therapies.

Results: Mean age 67, Male 60.4%. Polyps were found in 199 patients (61%), 488 polyps found in total, mean number of polyps 2.5 (Range 1–14), mean size 7 mm (Range 1 mm–60 mm); 49 (15%) hyperplastic, 156 (47.9%) adenomas and 16 (4.9%) adenocarcinoma. Patients with adenoma/carcinoma were older (67.6 vs. 66.5, $p = 0.02$) but there was no difference in sex (Male 61.4% vs. 59.4%, $p = 0.49$) when compared to those without adenoma/carcinoma. Of 172 patients with adenoma/carcinoma, 111 (64.5%) were proximal to the splenic flexure (SF). 5 out of 16 (31.2%) adenocarcinomas were proximal to SF and 2 (40%) of these patients had no polyps distal to the SF.

Adenoma/Carcinoma according to location in colon

Adenoma/ Carcinoma	SF + Distal (n = 61)	Proximal to SF (n = 111)	*p value
Age	67.4	67.7	0.67
Male	41 (67.2%)	67 (60.4%)	0.32
Number of polyps	1.7	3	<0.01
Size of polyps (mm)	8.6	6.0	<0.01
Carcinoma	11	5	0.71

Conclusion: Patients with adenomas/carcinomas are older and those with proximal adenomas/carcinomas have more polyps but are smaller in size. One in three adenocarcinomas picked up during colonoscopy would be out of reach of a flexible sigmoidoscopy. Furthermore, over one third of the proximal cancers did not have distal polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal cancers have two development theories. One of the development theories is “adenoma-adenocarcinoma sequence” developing from protruded-types “polyps” we know generally. The other is considered to emerge directly from normal epithelium, not through the adenomatous stage. Recently, it is revealed most of this type are depressed-type carcinomas. This theory is called “de novo” pathway. We studied clinicopathological characteristics and long-term prognosis mainly on depressed-type colorectal carcinomas.

Aims & Methods: The aim is to clarify the pathological characteristics of depressed-type colorectal carcinomas compared with flat- and protruded-type. A total of 29030 colorectal neoplasms excluding advanced carcinomas were resected endoscopically or surgically in our Center from April 2001 to December 2016. Of these, 1127 lesions were T1 carcinomas. According to the morphological/development classification, 244 lesions (21.7%) were depressed-type, 385 lesions (34.2%) were flat-type and 498 lesions (44.1%) were protruded-type. We analyzed the pathological features of these lesions.

Results: The rate of distant metastasis or recurrence was 0.9% (10/1127). Among these 10 cases, 5 cases were developed from depressed-type lesions and one showed a para-aortic lymph node metastasis and four showed a lung metastases. The rate of submucosal invasion in all the lesions was 72.4% in depressed-type, 3.2% in flat-type and 2.9% in protruded-type. Within less than 5 mm in diameter, that was 10.6%, 0% and 0% respectively. Among T1 carcinomas, the rate of vessel invasion was 64.3% in depressed-type, 34.3% in flat-type and 38.4% in protruded-type, that of poorly differentiated or mucinous adenocarcinoma was 17.2%, 10.4% and 13.5%, that of massively submucosal invasion was 94.7%, 71.7% and 69.7%, and that of tumor budding was 36.5%, 16.1% and 17.3%, respectively. The rates of these pathological factors were significantly higher in depressed-type lesions. On the other hand, the rate of adenomatous component was 4.9%, 52.2% and 50.8%, respectively. It was significantly lower in depressed-type lesions, suggesting that they emerge directly from normal epithelium without going through the adenoma stage. The rate of lymph node metastasis was 11.6%, 6.8% and 13.0%, respectively. And 2 depressed-type lesions had synchronous liver metastasis.

Conclusion: Depressed-type colorectal carcinomas invade massively even when they are small. They had higher risks of vascular invasion, poorly differentiated or mucinous adenocarcinoma, massive invasion, and tumor budding than flat- or protruded-types. For their rapid growth and malignant potential, whether the lesion is depressed-type or not is very important in the diagnosis of colorectal carcinomas.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1105 ENDOSCOPIC OBSERVATIONS OF MICROSURFACE STRUCTURES MAY REFLECT MOLECULAR SUBCLONES IN COLORECTAL TUMORS

E. Yamamoto¹, H. Aoki², H. Yamano¹, H. Suzuki², H. Nakase¹

Introduction: Recent cancer genome analyses identified extensive genetic intratumoral heterogeneity (ITH), suggesting a Big Bang model in which tumors grow as an expansion producing numerous subclones. As subclone mixing is indicative of an early malignant potential, ITH may be a hallmark to identify precursor lesions at high-risk of developing CRC.

Aims & Methods: We aim to clarify the association between ITH of driver mutations and clinicopathological characteristic in colorectal tumors. A total of 711 specimens from 477 colorectal tumors were analyzed in this study. Subcomponents of the tumors were endoscopically defined using the microsurface structures according to Kudo's pit pattern classification, and biopsy specimens were obtained from respective portions. *BRAF*, *KRAS* and *TP53* mutations were analyzed by pyrosequencing and direct sequencing. Hot spot mutations of 50 cancer related genes were analyzed using the Ion PGM sequencer.

Results: ITH of *KRAS* and *TP53* mutations was frequently observed in colorectal tumors with multiple subcomponents. Heterogeneity of *KRAS* or *TP53* mutations between early and advanced subcomponents (e.g., *KRAS* G12D in early portion and *KRAS* G13D in advanced portion) progressively increased during the steps of carcinogenesis: high grade adenomas (*KRAS*, 8%; *TP53*, 0%), non-invasive cancers (*KRAS*, 14%; *TP53*, 12%) and submucosal cancers (*KRAS*, 25%; *TP53*, 38%). These results suggest that subcomponents defined by microsurface structure may represent genetically distinct subclones. By contrast, only 4 of 41 *BRAF*-mutant lesions exhibited ITH of *BRAF* mutation. Pathological findings of the 4 lesion were low grade adenoma (n=1), non-invasive CRCs with adenoma (n=2) and serrated lesions (n=1), whereas majority of the *BRAF*-mutant lesions without ITH (n=37) were serrated lesions or CRC with serrated lesions. Sequencing of 50 cancer-related genes in 8 tumors with *KRAS*/*TP53* ITH revealed that both subcomponents exhibited identical mutations in genes including *FBXW7*, *HRAS* and *SKT11*, suggesting that these were founder mutations.

Conclusion: Our results demonstrate that degree of ITH of *KRAS*/*TP53* mutations increases during the progression of colorectal tumorigenesis. Intratumoral variations in the microsurface structure may represent molecular subclones in early colorectal lesions and may be predictive of the malignant progression.

Introduction: Hypoxia signalling has been found to enhance cancer cell survival, chemoresistance, motility, tumour angiogenesis as well as self-renewal capacity and proliferation of putative cancer stem cells. One of the key player in hypoxia is carbonic anhydrase IX (CAIX) which is a hypoxia-inducible enzyme. CAIX is overexpressed in a variety of cancers including colon cancer and plays a crucial role in maintaining favourable intracellular pH in hypoxia. There is also evidence that extracellular vesicle (EV) production is increased in response to hypoxia and promotes adaptive response of cancer cells and we have previously demonstrated, that CAIX positive EVs secretion is increased in response to hypoxia in colorectal cancer cell lines SW480 and SW620.

Aims & Methods: Within this study, we explored a possibility to use CAIX for the isolation of hypoxic EVs from colorectal cancer (CRC) patients' plasma. EVs were isolated from plasma samples of 27 CRC patients and 25 healthy donors (HD) by using sequential centrifugation, filtration and size-exclusion chromatography steps. EVs were quantified by Nanoparticle tracking analysis (NTA) and CAIX positive EVs were determined by ApogeeA50.

Results: Statistically significant increase in the amount and size of EVs was observed between CRC and HD cohorts based on NTA data. ApogeeA50 data revealed that there is a tendency for the percentage of CAIX-positive EVs to increase with the stage of CRC and is higher in stage III-IV CRC patients than in HD. In addition, it is higher in patients with metastasis than without distant metastases.

Conclusion: There is an increased total EV number, EV size and CAIX positive EV amount in CRC patient plasma compared to HD plasma, that might have diagnostic and prognostic value. (Financed by Latvian Council of Science Collaboration project No: 625/2014).

Introduction: Colorectal cancer (CRC) is an important contributor to cancer mortality and morbidity worldwide. 80% of CRCs arise via the adenoma-carcinoma sequence, 10–20% CRCs by sessile serrated adenomas (SSA). Hyperplastic polyps are regarded harmless. Current surveillance strategies for CRC following polypectomy are determined by endoscopic and histopathological factors. Such a distinction has also been challenged.

Aims & Methods: The study was aimed for molecular characterization of colonic polyps in patients who underwent screening colonoscopy. Correlation of the genetic analysis with endoscopic, clinical and histopathological data was attempted to potentially better define relevant risk marker or sub-groups at risk for prediction of surveillance intervals. 100 Patients were enrolled in this multicenter study (NCT02595645; Median age: 62.9 y, 50 males, 50 female). Up to 6 representative polyp biopsies were collected and stored in a formalin-free medium and finally embedded in paraffin-blocks, followed by histopathological assessment. Targeted Next Generation Sequencing (tNGS) was performed from identical tissue specimens (38 CRC-related genes; GeneRead DNAseq Targeted Panels V2, Qiagen®) on a MiSeq platform (Illumina®). Genetic and histopathological analysis was done blinded to the endoscopic and clinical data.

Results: In 100 patients, 224 polyps were removed. 121 polyps (54.0%) are sized <10 mm, 71 (31.7%) were ≥10 mm. For 32 polyps (14.3%) no size was available. 90 polyps (40.2%) were located in the left, 126 polyps (56.3%) in the right colon, for 8 polyps (3.6%) no location was noted. 112 polyps (50.0%) were adenomatous and 110 polyps (49.1%) non-adenomatous lesions. No data were available

for 2 polyps (0.9%). Clinical, endoscopic and histopathological data were correlated to molecular characteristics. Significant associations of genetic alterations with endoscopic or histopathological polyp characteristics were observed for BRAF, KRAS, TCF7L2, FBXW7 and CTNNB1 mutations. Multivariate analysis revealed that polyps ≥ 10 mm have a significant higher relative risk (RR) for harboring oncogene mutations (RR 3.467 (1.742–6.933)). Adenomas and right-sided polyps are independent risk factors for CTNNB1 mutations (RR 18.559 (2.371–145.245) and 12.987 (1.637–100.00)).

Conclusion: We were able to show that assessment of the mutational landscape of resected polyps/poly biopsy can easily be integrated in the workflow of current colonoscopy practice. There are distinct genetic patterns related to size and location of polyps and the clinician can appreciate this additional information to better estimate a patient's individual risk.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cell-free DNA (cfDNA) is circulating in human plasma and its amount is different in certain physical conditions. It is well known, that in healthy people the quantity of cfDNA is very low, but it rises in chronic disorders such as cancer. At the same time, very high cfDNA level can be measured in healthy people during physical exercise.

Aims & Methods: We aimed to analyze cfDNA changes (quantity, fragment length, global DNA methylation level) in physiological conditions (during physical exercise) and its alterations in neoplastic and inflammatory colorectal diseases. Plasma was separated from 64 patients (16 colorectal carcinomas (CRC), 13 colonic adenomas (AD), 19 inflammatory bowel disease (IBD), and 16 normal (N) donors without evidence of disease). Plasma samples were also collected from 6 healthy athletes before, during and after physical training. DNA was isolated with High Pure Viral Large Volume NA isolation Kit (Roche). cfDNA was quantified with Qubit fluorometry (Invitrogen). CfDNA fragment length distribution was assessed by Bioanalyzer 2100 using High Sensitivity DNA assay (Agilent). Global DNA methylation was analysed by bisulfite pyrosequencing of long interspersed nuclear element-1 (LINE-1) (Qiagen).

Results: High increase of cfDNA amounts was observed in plasma samples of patients with colonic adenoma (20.61 ± 10.70 ng/ml), colorectal cancer (24.13 ± 20.02 ng/ml) and IBD (22.27 ± 14.60 ng/ml) compared to healthy subjects (10.33 ± 3.22 ng/ml). Highly elevated cfDNA amounts were found in plasma samples of athletes during physical exercise (66.17 ± 29.00 ng/ml), while the cfDNA amount decreased after physical activity (51.87 ± 39.80 ng/ml). Characteristic cfDNA fragment length distribution pattern (with different peak heights at 180 bp, 360 bp, 550 bp) was observed in each patient group. Global DNA hypomethylation was shown in CRC plasma samples with advanced tumor stage (N: $79\% \pm 0.80\%$, AD: $79\% \pm 1.70\%$, advanced CRC: $70\% \pm 0.03\%$).

Conclusion: Remarkable increase was found in plasma samples of colorectal AD, CRC, IBD patients and also in healthy athletes during physical exercise. CfDNA fragment length analysis showed differences between each group. Global DNA hypomethylation could be observed only in CRC patients with advanced tumor stage. Based on our results, the above DNA analysis methods might contribute to non-invasive detection for colorectal diseases.

P1109 ANALYSIS OF SFRP1, SFRP2, SDC2 AND PRIMA1 PROMOTER METHYLATION IN CELL-FREE PLASMA DNA FOR NON-INVASIVE DETECTION OF COLORECTAL ADENOMA AND CANCER

B.K. Bartak¹, A. Kalmár¹, B. Péterfia¹, A.V. Patai¹, O. Galamb², G. Valcz², B. Wichmann², Z.B. Nagy¹, E. Markus¹, K. Szigeti¹, Á. Nagy¹, Z. Tulassay², P. Igaz¹, B. Molnar²

Introduction: Epigenetic instability, primarily aberrant DNA methylation seems to be a common phenomenon in colorectal cancer (CRC) influencing gene expression and contributing to tumor formation. In recent years, blood-based assays came into focus as potential screening tools for colorectal adenoma and cancer cases, as the analysis of the methylation status of circulating cell-free DNA (cfDNA) in plasma samples provides a good opportunity for cancer detection.

Aims & Methods: Our aim was to analyse the methylation pattern of four selected genes in biopsy and plasma samples of healthy, colorectal adenoma and CRC patients. Moreover, we aimed to examine the effect of methylation alterations on protein expression. MethylLight (ML) PCR was used after bisulfite-conversion to study certain DNA sequences of the promoter regions of SFRP1, SFRP2, SDC2

and PRIMA1 in 32 biopsy-plasma pairs and in 121 additional plasma samples. For validation, DNA methylation status (β -values) of the 4 markers was determined using methyl capture sequencing data from our research group. Furthermore, the methylation status of the four candidates' whole promoter regions was examined *in silico* using Illumina Infinium HumanMethylation450 BeadChip methylation array data downloaded from The Cancer Genome Atlas (TCGA) database and from NCBI Gene Expression Omnibus Database (GEO accession number: GSE48684). In order to examine the effect of promoter methylation on the protein expression, immunohistochemistry analysis was performed.

Results: Using ML assays, methylation of SFRP1, SFRP2, SDC2 and PRIMA1 was observed in 85.1%, 72.3%, 89.4% and 80.9% in the plasma fraction of patients with CRC and 89.2%, 83.8%, 81.1% and 70.3% of adenoma patients, respectively. In multiple logistic regression analysis, the four markers together were able to distinguish CRC patients from healthy individuals with 91.5% sensitivity and 97.3% specificity (AUC = 0.978) and could differentiate adenoma samples from healthy controls with 89.2% sensitivity and 86.5% specificity (AUC = 0.937). *In silico* analyses confirmed our results on the altered methylation pattern of the four markers in tissue samples. Immunohistochemistry analysis indicated decreasing protein levels of the four markers along the colorectal adenoma-carcinoma sequence.

Conclusion: Our findings suggest that SFRP1, SFRP2, SDC2 and PRIMA1 can be promising epigenetic biomarker candidates for colorectal adenoma and cancer diagnosis with high sensitivity and specificity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Metabolomics, a dynamic portrait of the metabolic status of living systems, has demonstrated its great potential for use in the diagnosis of various cancers by applying advanced analytic techniques and bioinformatics tools. Recently, very few metabolic markers in CRC have been consistently discovered, but metabolic profiles of patients with CRC including precancerous lesion in colorectum remains poorly understood and warrants investigation due to its non-invasive sampling method. In the last decade, several metabolomic approaches have been applied toward identifying metabolic alterations in CRC using variety of sample types including urine, tissue, serum, and feces. However there are only few urinary metabolomic studies and especially nuclear magnetic resonance (NMR) spectroscopy, which has several advantages including relatively high degree of reproducibility, easy-to-identify metabolites, high throughput, and non-destructive sample treatment, has not been applied to urine samples.

Aims & Methods: In this study, we investigate the differences in urine metabolic profiles of patients with colorectal neoplasia (CRN) including CRC and precancerous lesion, and healthy volunteers using a NMR-based urine metabolomic study. In addition, we evaluate applicability as diagnostic tool of urine metabolomics for early detection of precancerous colorectal lesion with high sensitivity and specificity. Urine metabolomic profiles from patients with colorectal neoplasia (CRN; 36 advanced adenomas and 56 various stages CRC) and healthy controls (n = 156) were analyzed by NMR spectroscopy. Healthy and CRN groups were statistically discriminated using orthogonal projections to latent structure discriminant analysis (OPLS-DA). The class prediction model was validated by three-fold cross-validation. The advanced adenoma and stage 0 CRC were grouped as pre-invasive CRN.

Results: After patients underwent endoscopic resection or surgical resection for CRN, advanced adenoma has been diagnosed in 36 patients, stage 0 CRC in 24 patients, stage I CRC in 8 patients, stage II CRC in 7 patients, stage III CRC in 13 patients and stage IV CRC in 4 patients. CEA and CA 19-9 levels for patient with stage I to IV CRC and healthy control were also assessed. Among patients with stage I to IV CRC, CEA and CA 19-9 were increased only in two patients, respectively. The sensitivity and specificity of CEA and CA 19-9 were 6.2% and 99.3%. The OPLS-DA score plot showed statistically significant discrimination between pre-invasive CRN as well as advanced CRC and normal with a Q2 value of 0.746. In the prediction validation study, the sensitivity and specificity for diagnosing pre-invasive CRN was 96.2% and 95%, respectively. The grades predicted by the PLS-DA model showed that area under the curve was 0.823 for taurine, 0.783 for alanine and 0.842 for 3-aminoisobutyrate. In multiple receiver operating characteristics curve analyses, taurine, alanine, and 3-aminoisobutyrate were good discriminator for CRC patients.

Conclusion: NMR-based urine metabolomic profiles significantly and accurately discriminate between patients with pre-invasive CRN as well as

advanced CRC, and healthy control with high accuracy. It demonstrates an applicability of urine-NMR metabolomics as screening tool for accurate diagnosis of pre-invasive CRN.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1111 VALIDATION OF THE UTILITY OF A FAECAL IMMUNOCHEMICAL TEST FOR HAEMOGLOBIN (FIT) IN PATIENTS PRESENTING TO PRIMARY CARE WITH NEW BOWEL SYMPTOMS

J. Digby¹, J. A. Strachan², C. G. Fraser¹, R. Steele¹, C. Mowat³

¹University of Dundee, Dundee/United Kingdom

²Blood Sciences, Ninewells Hospital & Medical School, Dundee/United Kingdom

³Gastroenterology, Ninewells Hospital & Medical School, Dundee/United Kingdom

Contact E-mail Address: jaynedigby@nhs.net

Introduction: Symptoms alone are poor predictors of underlying colonic pathology.¹ Only 14% of patients referred for colonoscopy from primary care have significant bowel disease (SBD), [colorectal cancer (CRC), high risk adenoma (HRA, defined as ≥ 3 or any ≥ 1 cm) and inflammatory bowel disease (IBD)].² We have reported that undetectable faecal haemoglobin (f-Hb), measured by a faecal immunochemical test (FIT) is a good rule-out test for SBD.^{2,3} Since December 2015, GPs in Tayside have been encouraged to use FIT test as an adjunct to history, examination and mandatory blood tests in patients referred with bowel symptoms. Referrals are vetted by a Consultant and triaged to test or clinic. We have examined the impact of the introduction of the FIT test on referral rates and colonoscopy yield.

Aims & Methods: Patients in primary care with new bowel symptoms were encouraged to complete a FIT in addition to blood count and renal function check. We prospectively recorded FIT tests received, referrals to secondary care and colonoscopy findings over 1 year from December 2015 to December 2016. FIT tests were analysed by HJACKarc (Kyowa Medex Co. Ltd., Japan) with an analytic range of <10 to $>400 \mu\text{g Hb/g faeces}$. Referral rates with FIT were examined along with clinical findings at colonoscopy.

Results: 5,655 FIT tests were received. 76.2% had undetectable fHb, and 152 (2.7%) were untestable. 4,108 patients were referred of whom 2,338 (57%) returned a FIT. In 1,378 patients with a FIT result vetted to colonoscopy, 284 had SBD (20.6%); 86 CRC, 124 HRA and 74 IBD. 44% of patients scoped had undetectable f-Hb in whom prevalence of SBD was 6.6%. Only 13% of SBD was in this cohort; 7/7 CRC patients had co-existing iron deficiency anaemia, 14/25 HRA and 3/6 IBD had anaemia or diarrhoea. 32.2% of those with f-Hb $>10 \mu\text{g Hb/g faeces}$ had SBD rising to 54.9% in those with f-Hb $>400 \mu\text{g Hb/g faeces}$. 2,677 patients completed a FIT but were not referred, in whom 94.1% had undetectable f-Hb. Referrals to secondary care were 14% down on the previous year.

Conclusion: A FIT test is an essential adjunct to the history, examination and blood tests in the assessment of bowel symptoms. Undetectable f-Hb is reassuring Primary Care that SBD is unlikely and referrals to secondary care have reduced. At colonoscopy, yield of SBD has increased and is high in those with detectable f-Hb. Excluding patients with co-existing anaemia or diarrhoea, an undetectable f-Hb is a good rule-out test and will miss only 5% of all SBD. Furthermore, f-Hb concentration could aid triage irrespective of symptoms.

Introduction: The immunological screening test (FIT) for colorectal cancer (CCR) was introduced in January 2015 in Ile de France (15 million habitants) after Hemocult was abandoned due to its low sensitivity. The Hemocult (HC) launched in 2007 had reached less than 30% participation rate.

Aims & Methods: We report one-year on FIT in CRC screening in Ile de France and compare results to those with HC test for speculating on adjustment actions. The raw data were extracted by request from the registry of the screening structure (in various areas 75, 77, 78, 91, 92, 94 and 95) covering a target population of 3026366 habitants. Rates of participation were calculated, and after one-year experience period, profiles of individual with positive tests, rates of those with normal colonoscopy, with polyps (all stages combined) and with cancer + high-grade dysplasia (HGD) were described. Results were compared to those with HC from the launch to the end of the last campaign (Dec 2014) normalized for mean one-year output. The comparisons were made by an X2 test (qualitative variable) or a student t (quantitative variable) and multivariate stepwise analysis was performed for identifying predictive factors for cancer diagnosis.

Results: At the end of the HC-based screening campaigns 2014, 2.5 million individuals were annually invited and the participation rates since 2009, ranged from 28.5% to 24.6%, with females showing higher rates for participation (30.7 to 26.1%) than men (26 to 21.8%, $p < 0.0001$). During the first (2015) year FIT experience, the O Sensor device was used by 450120 (34% estimated participation rate) individuals (versus 294603 participants with HC in 2014 $p < 0.00001$; 24% estimated participation rate), and the rate of positivity was 4.6% (versus 1.9% with HC; $p < 0.00001$). Among all positive FIT individuals, 93% underwent colonoscopies: 35% were normal (vs 41%; $p < 0.01$), 13.2% presenting with cancer or HGD and 52% with polyps (vs. 37.7%; $p = 0.00051$). More women (54.5%) than men (45.5%) responded to invitations while positivity rate in women (3.7%) was lower than in men (5.5%; $p < 0.00001$). More advanced polyps and cancer were found in men (14.5%) than in women (11.3%; $p < 0.00001$) with normal colonoscopy rates lower in men (24.2%) than in women (40.7%; $p < 0.0001$). The levels (mean ng/mL; SD) of FIT were significantly higher ($p < 0.001$) in individuals with cancer +HGD (667; 9) or with polyps (374; 4) than in those with normal colonoscopy (440; 4). In multivariate analysis, risk factors for abnormal colonoscopies with cancer + HGD were male gender, FIT $> 340 \text{ ng/mL}$ and age > 63.5 yrs. More men than women with positive FIT test did not yet undergo colonoscopy.

Conclusion: FIT test has gained a better adhesion in Ile de France probably because to its simplicity and a wider distribution. The lower rate of normal colonoscopies and a higher positive predictive value for cancer leads to more early lesions detected indicating its higher specificity. Men of 63.5 yrs old or more with Hemoglobin levels higher than 340 ng/mL are of very high risk of cancer and should be absolutely conducted to the colonoscopy in case positive FIT test.

Introduction: Most T1 colorectal cancers (CRCs) undergo surgical colectomy in accordance with established clinical guidelines despite the low incidence (approximately 10%) of lymph node metastasis (LNM). Therefore, many patients without LNM undergo unnecessary surgeries.

Aims & Methods: To reduce unnecessary surgeries, we aimed to predict the risk of LNM in T1 CRCs by using artificial intelligence (AI). Data on 690 consecutive patients with T1 CRCs who had undergone colectomy between April 2001 and March 2016 were retrospectively analyzed. Data of a randomly selected 590 patients were used for machine learning for the AI model, which analyzed five clinicopathological factors: tumor location, lymphatic invasion, vascular invasion, tumor budding and histological grade. The remaining 100 patients served as a test set for validating the AI model and output the predicted LNM as positive or negative. To validate the AI model, sensitivity, specificity and

accuracy were calculated and compared with American, European and Japanese guidelines.(1–5)

Results: Sensitivity was 100% (95% CI, 56%–100%) in all models. Specificity and accuracy of the AI model, American, European and Japanese guidelines were 68% (58%–78%) vs. 45% (35%–56%) vs. 12% (6%–21%) vs. 8% (3%–15%), and 71% (61%–80%) vs. 50% (40%–60%) vs. 20% (13%–29%) vs. 16% (9%–25%), respectively. The rate of unnecessary surgeries of the AI model was calculated as 29% in comparison with American 50% ($P=0.004$, odds ratio [OR] 2), European 80% ($P<0.001$, OR 10), and Japanese 84% ($P<0.001$, OR 13).

Conclusion: AI can significantly reduce unnecessary surgeries compared with current guidelines while providing high sensitivity. AI will help in making decisions as to whether additional surgery is indicated after endoscopic resection of T1 CRCs. Grant support: Grants-in-Aid for Scientific Research (Number 17K15972) from the Japan Society for the Promotion of Science.

Introduction: Regular surveillance colonoscopy after colon cancer resection is recommended to detect metachronous adenoma and cancer. However, risk factors of advanced metachronous neoplasm during postoperative surveillance have not been fully evaluated yet.

Aims & Methods: This study aimed to assess the risk of advanced metachronous neoplasm during surveillance colonoscopy in patients who underwent curative colon cancer resection. The patients who underwent curative colonic resection for non-metastatic colon cancer between January 2002 and December 2012 in a single tertiary center were retrospectively reviewed.

Results: A total of 298 patients were enrolled in this study. Surveillance colonoscopy was performed after perioperative clearing colonoscopy. Among the patients, 182 (61.6%) were male, and the median age was 65 years. On perioperative clearing colonoscopy, accompanying high-risk adenomas (≥ 3 , size ≥ 10 mm, with high-grade dysplasia and villous histology) were detected in 95 patients (31.9%) and were significantly associated with old age (≥ 65 years), male sex, alcohol use, smoking, and stage 3 colon cancer ($P<0.05$). During the post-operative follow-up periods (median, 5.35 years), advanced metachronous neoplasm was found in 45 patients (15.1%) during surveillance colonoscopy, including colon cancer in 4 patients (1.3%). In the multivariate analysis, distal colon cancer (distal to splenic flexure; odds ratio [OR]=4.463; $P=0.002$), accompanying high-risk adenomas on perioperative clearing colonoscopy (OR=3.414; $P=0.001$), and hypertension (OR=2.344; $P=0.026$) were significant risk factors of advanced metachronous neoplasm during surveillance colonoscopy.

Conclusion: Patients who had distal colon cancer, accompanying high-risk adenoma on perioperative clearing colonoscopy, and hypertension may need a shorter colonoscopic surveillance interval. A more tailored surveillance strategy is needed to improve overall outcome in patients who undergo curative colon cancer resection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Despite major advances in white light endoscopy detection of colon polyps remains challenging with significant polyp miss rates. The novel second generation full spectrum endoscopy (FUSE) is a new scope with two additional cameras in the sides that provides a panoramic 330° field of view.

Aims & Methods: The aim of this study is to identify the role of the FUSE in improving polyp detection. This was a single-center, prospective, randomized, open label study in patients that presented for routine colonoscopy at an outpatient unit during a six months period. Patients were randomized to either FUSE (FUSE colonoscope CDVL slim c38) or standard frontal view (SFV) colonoscopy (Olympus Evis Exera III 190). The primary outcomes were polyp detection rates (PDR), diverticulum detection rate (DDR) and complete colonoscopy. Secondary outcomes were procedure time, adverse event rates, size and characteristics of the polyps and success of endoscopic treatment (R0 resection). All procedures were performed by experienced endoscopists, who had carried out > 5000 colonoscopies and had cecal intubation rates of > 95%.

Results: A total of 197 patients (49.2% female, 50.8% male, median age 60 years, range ± 16 years) were studied. No significant difference was seen between the 2 groups for the primary endpoints of polyps detection rate (PDR), diverticulum detection rate (DDR) or complete colonoscopy (table 1). About secondary endpoints: R0 endoscopic resection was achieved in 95% in both groups ($p=0.68$). The median procedure time in minutes was higher with SFV (26.1 ± 13 min) than FUSE 21.5 ± 10.7 min (-4.6 , IC95%: -8 a -1.2) ($p=0.008$). There were no significant differences regarding adverse events, determination of colon cleanliness, or others epidemiologic factors. 2 case were excluded of the statistical analysis due to surveillance of polyposis syndrome, to avoid skewing of results.

Conclusion: In expert hands, PDR and DDR exceed 50% with advanced white light and FUSE systems. FUSE was not superior to advanced white light endoscopy for the PDR and DDR. However, with FUSE we can reduce procedure duration without any additional adverse events or increased discomfort. These data further demonstrate the safety and feasibility of the new FUSE system.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Underwater Endoscopic Mucosal Resection (UEMR) has been demonstrated as a safe and effective technique for removal of flat and sessile colorectal lesions. Until now, only UEMR with cap has been described in literature. In addition there is no consensus about the electrosurgical settings.

Aims & Methods: This prospective study was conducted between January and November 2016 in two university tertiary referral centers. UEMR was performed using a standard colonoscope without the distal cap. The lesions were marked with snare tip prior to resection. Insufflation was switched off. Then, the colon lumen was entirely deflated. Water at room temperature was infused using an irrigation pump until complete filling of the lumen was achieved. All gas pockets in the operative field were evacuated. Two sizes of polypectomy snare (13 and 25 mm) were used according to the preference of the endoscopist. No submucosal injection was performed. One of these three different electrosurgical settings (DRY CUT, AUTOCUT and ENDOCUT) was selected. All resection wounds were carefully inspected after UEMR. Endoclips were employed for the management of bleeding and suspected perforation.

Results: Between January and November 2016, 45 patients (27 female, mean age 67 years, range 53–87) with 55 non-pedunculated colorectal lesions (mean size 16 mm, range 10–40 mm) were included. Six lesions were located in cecum, 21 in the ascending colon, nine in transverse, eight in descending colon, five in sigmoid, and six in rectum. In five patients, we selected DRY CUT mode; in fifteen AUTOCUT; and in twenty-five the ENDOCUT mode. All lesions were successfully and completely removed by UEMR. The procedure time was recorded in 24 resections (mean 13 minutes, range 4–40). Thirty-three of them were removed en bloc (60%). Histology revealed the following: 40% tubular adenomas; 20% - tubulovillous adenomas; 25.45% - sessile serrated adenomas; 3.65% - traditional serrated polyps; 7.25% intramucosal adenocarcinomas and

3.65% were superficial submucosal carcinomas (<1000 µm). During UEMR, two cases (both using AUTOCUT mode) of spurting bleeding were observed (4.45%). Hemostasis was easily achieved in both cases by clipping. No patient requires blood transfusion. One patient had abdominal pain on the day after resection without signs of pneumoperitoneum on CT scan. There was no perforation or delayed bleeding.

Conclusion: This study supports the existing data indicating acceptable rates of technical success and low incidence of adverse events with UEMR. The results of this study without cap were similar with the previous ones using cap. Further comparative studies with and without cap, using different settings and especially between UEMR and traditional EMR are needed.

P1117 ADENOMA DETECTION RATE INFLUENCES RISK PREDICTION OF METACHRONOUS ADVANCED COLORECTAL NEOPLASIA IN LOW-RISK PATIENTS

S.H. Kim, S.J. Lee, T.J. Kim, E.R. Kim, S.N. Hong, D.K. Chang, Y. Kim

Introduction: Current guidelines recommend surveillance colonoscopy after 10 years or surveillance in 5–10 years in individuals with no or 1–2 non-advanced adenomas.

Aims & Methods: We hypothesized that risk of metachronous advanced colorectal neoplasia (AN) differs based on clinical characteristics and colonoscopy quality. We identified 7,171 participants with no or non-advanced adenomas at first-time screening colonoscopy. The risk of metachronous AN at surveillance colonoscopy 3–5 years later was investigated according to clinical characteristics and endoscopist adenoma detection rate (ADR).

Results: In multivariate analyses, strong associations between increasing age, male sex, current smoking, family history of colorectal cancer, follow-up interval, increasing number of adenoma, and low ADR and risk of any metachronous colorectal neoplasia were observed. For metachronous AN, increasing age, male sex, increasing number of adenoma, and low ADR were independent risk factors. Among patients with 1–2 small adenomas, women with age ≥60 years or men comprised a hidden-risk group, which had 5.3% risk of metachronous AN at surveillance. Women <60 years old with 1–2 low-risk adenomas had very low risk (1.2%) of metachronous AN as individuals with no adenoma. Furthermore, incidence of metachronous AN was significantly higher in individuals who were colonoscopy screened by endoscopists with a lower ADR (<32%) than in those screened by endoscopists with a higher ADR (≥32%) (3.2% vs. 0.6%, respectively; $P=0.001$).

Conclusion: According to patient and adenoma characteristics, and ADR of the endoscopist, the risk of metachronous AN varies among low-risk patients. In recommending surveillance colonoscopy, these factors should be taken into consideration.

Introduction: The technique of endoscopic submucosal dissection has recently been improved, and large and complexed lesions such as those invading ileocecal valve and appendix orifice can be resected en bloc. However, lesions accompanying severe fibrosis in the submucosal layer and exhibiting the muscle retraction (MR) sign are often difficult to be resected completely¹. We devised a new method called 'Per Anal Endoscopic Myectomy' for rectal lesions involving severe fibrosis, in which dissection is done between the inner circular and outer longitudinal muscles instead of between submucosal layer and muscle layer².

Aims & Methods: The aim of this study is to examine the usefulness and safety of PAEM. The PAEM cases performed in our hospital and an affiliated hospital were retrospectively reviewed. When fibrosis in the submucosal layer was suspected, pocket creation method³ was applied and if severe fibrosis with MR sign was found, PAEM was selected. In PAEM procedure, after dissecting circumferentially around the fibrotic area with a double tunneling method, the inner circular muscle is cut in a circular manner, which makes the outer longitudinal muscle clearly visible. The space between the inner circular and outer longitudinal muscles is sparse and suitable traction with the tunneling method makes it easier to dissect this space. PAEM was performed only for rectal lesions, and no clip closure was carried out after the procedure in most cases.

Results: Ten rectal lesions were treated with PAEM between July 2015 and March 2017. Among them, 7 cases including 2 cases with mucosal cancer, 4 cases with deep submucosal invasion and 1 case with muscle invasion were resected en bloc with negative margin. The other 3 cases showed tumor invasion to the muscle layer and the vertical margin was positive. The clinical course after PAEM was preferable in all cases. Three cases which achieved resection with negative margin but found lymphovascular invasion of the tumor underwent additional surgery or adjuvant chemoradiation. In surgical cases, they could permit anus-preservation.

Conclusion: PAEM for lesions exhibiting MR sign with severe fibrosis will enable complete en bloc resection and lead to accurate pathological diagnosis. No complications were recorded in our experiences. Further investigation into the significance of PAEM would be needed.

P1119 LOCAL RECURRENCE AFTER ENDOSCOPIC MUCOSAL RESECTION FOR HIGH-RISK LESIONS: MAY WE BETTER PLAN THE ENDOSCOPIC FOLLOW-UP ACCORDING TO PROCEDURAL, MORPHOLOGICAL AND HISTOLOGICAL CHARACTERISTICS?

C. Quondamcarlo, C. Lucidi, R. Lapenta

Gastroenterology, Regina Elena Cancer Institute, Rome/Italy

Contact E-mail Address: qcinzia@ymail.com

Introduction: Endoscopic mucosal resection (EMR) is an increasingly used technique for the removal of large sessile and flat-laterally-spreading colorectal lesions. At present, surveillance colonoscopies are ever performed to ensure detection and adequate treatment of residual or recurrent adenoma (RRA), which, occurring in 10–40% of non-pedunculated lesions, currently represents the main limitation of this technique. Fortunately, endoscopic detection of RRA in the post EMR scar is currently highly accurate using HD-WL (high definition-white light) and NBI (narrow band imaging). Anyway, indications for follow-up

colonoscopies and optimal time intervals are currently unclear. An adequate comprehension of the predicting factors of RRA would be very relevant to try to prevent it, better plan surveillance intervals, establish role and timing of surgery and reduce costs.

Aims & Methods: Our aims were to assess the frequency of local recurrence after EMR for high-risk lesions, to identify risk factors for recurrence, and to provide follow-up suggestions. We considered all consecutive patients undergone EMR of flat or sessile adenomas ≥ 10 mm containing high-grade dysplasia or adenocarcinoma until pT1 from May 2015 to April 2016. EMR procedure was performed by 2 endoscopists with extensive EMR "inject and cut" experience and only lesions with a positive lifting sign were endoscopically treated. An endoscopic follow-up was performed at a planned interval of 3, 6 and 12 months by using high-definition instruments white light (HD-WL) and narrow-band imaging (NBI) allowing an appropriate scare assessment with the execution of biopsies when needed. Data collection included: (a) lesion size, morphology, Paris classification, pit pattern (kudo), technique of removal (en bloc vs piecemeal) and histology for all primary lesions and RRA; (b) Information about budding, grading, microinvasion, margins, submucosal extension for all pT1 removed "en bloc".

Results: 50 patients were included (mean age 63 ± 12 years, 54% females). The mean size of lesions was 21 mm (range 10–50 mm), 40% were sessile, 35% granular LST and the reimagining 25% non-granular LST, the most frequent sites of location were sigmoidal colon (40%), ascending colon (25%) and cecum (12%). According to the morphological characteristics, 60% of lesions were removed "en bloc" and 40% "piecemeal". Metallic clips were used as prophylaxis in 35% of patients and only in 1 for intraprocedural bleeding. No post-procedural bleeding or perforation occurred. APC has never been used. During the endoscopic follow-up a suspect early (3-months) RRA was documented and immediately treated in 16% and histologically confirmed only in 8%. At 6-month controls a RRA was again detected only in 2 of these patients. New cases of RRA were not found both at 6 and 12 month controls. Only 1 case of RRA was documented for lesions treated "en bloc" but this was the only one with histological characteristics strongly suggesting high risk of RRA (pT1, > 2 cm, grading G2, free-disease margins < 1 mm). As concerned lesions removed "piecemeal", RRA (70% high grade dysplasia and 30% low grade dysplasia) was higher in pT1, lesions > 2 cm, non-granular LST. No correlation was found with other factors.

Conclusion: EMR results a technique safe and effective particularly for lesions removable "en bloc"; in this cases in fact the rate of RRA seems to be low and easily histologically predictable. Although factors related to RRA in "piecemeal" EMR appear less clear more attention would be applied in relation to determined morphological pattern and presence of in situ carcinoma. Moreover, RRA seems to be ever early suggesting a close follow up only in the first period.

P1120 TREATMENT STRATEGY FOR LOCAL RECURRENCES AFTER ENDOSCOPIC RESECTION OF COLORECTAL NEOPLASMS

S. Ito, K. Hotta, K. Imai, Y. Yamaguchi, Y. Kishida, K. Takizawa, N. Kakushima, M. Tanaka, N. Kawata, M. Yoshida, H. Ishiwatari, H. Matsubayashi, H. Ono

Division Of Endoscopy, Shizuoka Cancer Center, Shizuoka/Japan

Contact E-mail Address: sa.ito@scchr.jp

Introduction: Local recurrences after endoscopic resection (ER) frequently occur, especially after piecemeal resection. Recently, the efficacy of endoscopic submucosal dissection (ESD) for local recurrences has been reported. However, an appropriate treatment strategy for these lesions including ESD remains unclear.

Aims & Methods: This study aimed to clarify the appropriate treatment strategy for local recurrences after ER. A total of 81 patients (81 lesions) who received treatment for local recurrences after ER for colorectal neoplasms between January 2010 and December 2016 were enrolled. Patients with pathological diagnosis of hyperplastic polyp, sessile serrated adenoma/polyp, and submucosal invasive cancer in their first ER were excluded. Seven patients who underwent surgery because of submucosal invasion or technically difficult locations were also excluded. Procedural outcomes, recurrence rate and disease control rate (DCR) were evaluated according to preoperative endoscopic diagnosis of recurrent lesions (adenomatous or cancerous). The DCR was defined as proportion of patients who were diagnosed with curative resection after ER or received additional surgery based on pathological diagnosis after ER.

Results: Seventy-four patients were included in the final analysis. Forty-nine patients diagnosed with adenomatous recurrences were treated by cold polypectomy in 15, by endoscopic mucosal resection (EMR) in 26, and by ESD in 8 patients. Cold polypectomy was applied only to diminutive (< 5 mm) lesions and there was no local recurrence. The en bloc resection rates of EMR and ESD were 53.8% and 100%, respectively ($P = 0.030$). Two cases (7.7%) in the EMR group developed local recurrences, but additional ER achieved curative resection. The DCR of three methods were all 100%. Meanwhile, 25 patients diagnosed with cancerous recurrences were treated by EMR in 7 and by ESD in 18 patients. The en bloc resection rates of EMR and ESD were 28.6% and 83.3%, respectively ($P = 0.017$). Three cases (42.9%) in the EMR group developed local recurrences. One case required surgery because of invasive local

recurrence, the second case required chemotherapy because of distant metastasis, and the third case was followed-up because of severe comorbidities. Therefore, the DCR in the EMR group was significantly lower than that of in the ESD group (28.6% vs. 83.3%, $P = 0.017$).

Conclusion: The selection of ER for local adenomatous recurrences could be based on lesion size. On the other hand, ESD is desirable for local cancerous recurrences to achieve complete disease control.

Introduction: Endoscopic stent placement in acute large-bowel obstruction due to colorectal cancer has been established as a palliative therapy or bridge to surgery with good outcomes in Japan. While, efficacy of chemotherapy after endoscopic colonic stenting has not been evaluated.

Aims & Methods: The aim of this study was to evaluate efficacy of chemotherapy after endoscopic colonic stenting by comparing with that after surgery. Sixty five patients with colorectal cancer of stage IV presenting obstructive symptom visiting Aomori Prefectural Central Hospital from January 2012 to December 2016 were classified into SC group who have underwent chemotherapy after endoscopic colonic stenting (32 patients) and OC group who have underwent chemotherapy after surgery (23 patients). The patient's background, adverse effects and prognosis were compared with two groups.

Results: There have not been any significant differences in patient age (65.5 ± 9.3 in SC vs. 61.5 ± 14.1 in OC, $p = 0.21$), male to female ratio (25:7 in SC vs. 14:9 $p = 0.16$) and performance status (0.6 ± 0.7 in SC vs. 0.7 ± 0.8 in OC, $p = 0.66$). The averaged colorectal obstruction scoring system (0, Requiring continuous decompressive procedure; 1, No oral intake; 2, Liquid or enteral nutrient; 3, Soft solids, low-residue, and full diet with symptoms of stricture; 4, Soft solids, low-residue, and full diet without symptoms of stricture) score was significantly severe in OC (1.7 ± 1.1) than in SC (0.7 ± 0.9 , $p < 0.01$). Adverse effects included perforation (1), stent slippage (6), re-obstruction by tumor progression (3) in SC, and ileus (1), abdominal abscess (1), renal insufficiency (1) in OC. The frequency of combined use of molecular target drugs (Bevacizumab/Panitumumab/Cetuximab) at first chemotherapy has significantly differed ($p < 0.01$) between SC (0/11/9) and OC (12/4/0). The median survival day was not significantly different between SC (595) and OC (459, $p = 0.93$). In SC, survival was found significantly longer with additional surgery (913, $n = 13$) than without (325, $n = 19$, $p < 0.01$). In OC, survival did not significantly differed between with resection of the primary tumor (666, $n = 16$) and without (595, $n = 7$, $p = 0.93$).

Conclusion: This study has demonstrated that the survival of SC was identical to that of OC, and additional surgery was found to significantly improve the prognosis in SC. Chemotherapy after endoscopic colonic stenting has been considered tolerable as a palliative therapy or bridge to surgery for obstructive colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1122 A NEW MANEUVER TO PLACE A THROUGH-THE-SCOPE STENT IN A MALIGNANT COLONIC STRICTURE INACCESSIBLE WITH A STANDARD-CALIBER COLONOSCOPE: "OVER-THE-CATHETER" COLONOSCOPE REPLACEMENT TECHNIQUE

Y. Iboshi¹, Y. Sumida¹, N. Harada¹, H. Tsuru¹, M. Tomonori¹, M. Wada¹, T. Osoegawa¹, M. Nakamuta¹, E. Ihara²

Contact E-mail Address: yoichiroiboshi@gmail.com

Introduction: A self-expandable metallic stent (SEMS) placement is potentially a colostomy-sparing option to manage a malignant colonic obstruction (MCO). However, in patients with coexisting peritoneal dissemination (carcinomatous adhesion), for example, insertion of a standard caliber colonoscope (SCC) is challenging, whereas such an endoscope equipped with a large working channel is suitable for through-the-scope (TTS) SEMS placement. Failure in stenting necessitates continuous tube drainage, stoma formation, or other surgical procedures and decreases quality of life (QOL).

Aims & Methods: We examined feasibility and efficacy of, "Over-the-Catheter" Colonoscope Replacement technique (OTC-CR) detailed below, in palliative (not preoperative) SEMS placement for MCO. From Oct 2012 to Dec 2016, MCO patients were consecutively considered for decompression by SEMS placement unless stoma formation was preferred. When a conventional TTS procedure was unsuccessful, specifically, when the MCO site was inaccessible with an SCC (CF-H260AI, Olympus Medical Systems, Tokyo, Japan) with a 13.2 mm tip diameter and 3.7 mm working channel, needed for a 22 mm (not 18 mm) SEMS

Abstract No: P1122

List of 6 cases with malignant colonic obstruction in whom "Over-the-Catheter" colonoscope replacement technique was tried.

Case No.	Age, Sex	Primary cancer site	Site of stricture	Nature of stricture	Alternative scope	Distance from Reinserted SCC to stricture	Technical/Clinical outcome	CROSS score* change
1	71, F	Peritoneum	Splenic flexure	Extrinsic	PCF-PQ260L	Away (SCJ)	Success/Success	1 → 4
2	66, F	Sigmoid colon	Sigmoid colon	Intrinsic	PCF-PQ260L	Close	Success/Success	2 → 4
3	76, M	Pancreas	Splenic flexure	Extrinsic	PCF-PQ260L	Away (SCJ)	Success/Success	1 → 4
4	41, F	Transverse colon (resected)	Sigmoid colon	Extrinsic	GIF-Q260J	Close	Success/Success	1 → 4
5	55, F	Ovary	Sigmoid colon	Extrinsic	EG-580NW	Away (Sigmoid colon)	Success/Success	0 → 3
6	49, F	Stomach	Transvers colon	Extrinsic	PCF-PQ260L	Close	Success/Success	0 → 3

*CROSS, ColoRectal Obstruction Scoring System (Reference 1)

Among 63 palliative MCO cases, initial attempt to place a 22mm SEMS by TTS procedure was unsuccessful in 6 cases (Table), all of whom had peritoneal dissemination. The reasons for technical failures were; impossible insertion of an SCC to the stricture due to carcinomatous adhesions or narrowing in 5 cases and failure in passing GW through the stenosis due to a limited viewing angle to the stricture in one case. With OTC-CR, approach to the main stenosis with a thinner (alternative) scope, GW traverse, "over-the-catheter" replacement to the SCC, and a 22 mm SEMS placement were successful in all of the 6 cases with adequate clinical improvements (CROSS score change). Notably, ultimate TTS procedures were possible from reinserted SCC distant from the stricture in 3 cases. No adverse events occurred during the procedures.

delivery system passage (e.g. Niti-S Colonic Stent, Taewoong-Medical, Seoul, South Korea) or when a guidewire was unable to be passed through the stricture because of limited maneuverability of the endoscope, procedures below were followed. (1) A thinner scope, PCF-PQ260L/L, with a 9.2 mm tip and a 2.8 mm channel (Olympus Medical Systems, Tokyo, Japan) is inserted and advanced to the stricture, facilitated by its "passive bending" feature. An ultrathin endoscope (for transnasal use) or a gastroscope are alternatives. (2) A guidewire ((GW), 0.035 inch Jagwire) is traversed through the stricture by coordinating manipulation of an ERCP-catheter (Article-No.0130211; MTW Endoskopie, Wesel, Germany). (3) Fluorescent examination through the catheter to delineate the lesion. (4) For colonoscopy replacement, withdraw the scope and the catheter, leaving only GW. (5) Before reinsertion of the SCC, insert the catheter from the channel until it sticks out of the scope tip. (6) Pass GW backward into the catheter tip. Then move the catheter over GW past the anus and further advance it proximally until it reaches the stricture site. (7) Gently move the SCC "over the catheter" into the rectum and advance it in the more straightened (less winding) intestine. (8) After the colonoscopy is advanced only as proximally as possible, shift to a standard TTS maneuver (withdraw only the catheter, leaving GW and insert the SEMS delivery along GW past the stricture where it is deployed).

Results: See table.

Conclusion: "Over-the-Catheter" colonoscope replacement (OTC-CR) technique can be a salvage maneuver which facilitates a successful SEMS placement in MRO cases with peritoneal disseminations that preclude a conventional TTS procedure. Reachability of thin endoscopes and appropriate rigidity and force transmissibility of an ERCP-catheter that enable advancement of an SCC with maximum safety are thought to be linked to reduced chances of technical failures.

Introduction: Colorectal cancer (CRC) is the most common cause of cancer in western countries. In Balearic Islands 700 new cases per year are diagnosed. The cost-effectiveness of CRC screening programmes are clearly demonstrated in the studies and the important public health problem of CRC justifies the development of control strategies. The aim of this study is to present the results and impact during the first round of the program in Balearic Islands.

Aims & Methods: The first round includes the period from January 2015 through December 2016. The program has been developed in the areas of Menorca, Ibiza, Formentera and Tramuntana (Mallorca), including 30% of the Balearic Islands population. The target population (people who reside in these areas aged between 50 and 69 years old) was 75,575 individuals. Exclusion criteria. Colonoscopy performed in the previous 5 years, previous diagnosis of CRC, follow-up

colonoscopies because colon disease and severe illness-contraindication for the participation. People received the invitation by letter. Quantitative immunochemical fecal occult blood testing (i-FOBT/OC-Sensor) was the screening method. The kit was delivered at pharmacies joined the program. The samples were deposited in urns placed in health centres. Participants who tested positive (≥ 100 ng/ml) were referred to pre-endoscopy evaluation and follow-up colonoscopy. The colonoscopies were performed according to the quality criteria of guidelines.

Results: Overall participation rate (number of people who provide their i-FOBT sample) was 36.5% (n=21,555). Positive rate of i-FOBT was 7% (1438) and 94.3% of those positive tests underwent a colonoscopy (5.7% of exclusions in pre-endoscopy evaluation). 996 colonoscopies were performed. 47 adenomas with high grade dysplasia, 24 carcinomas in situ and 60 adenocarcinomas were found. Only 19% of these adenocarcinomas were T3 or T4 lesions while the rest presented earlier stages. 26% of colonoscopies were classified as high risk (≥ 5 adenomas or at least one ≥ 20 mm). They have been reported 2 cases of colon perforations, both resolved by endoscopic treatment.

Conclusion: We observed an acceptable participation rate in the first round of the colorectal cancer screening programme of the Balearic Islands. The index of positivity rate of i-FOBT and the results of the endoscopic explorations are according with the observed in other colorectal cancer screening programmes. We can conclude a successful development of the first round of the programme in our area.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The prevalence, gender distribution, and clinical presentation of irritable bowel syndrome (IBS) differ between Asian and Western countries. The densities of enteroendocrine cells are abnormal in Western IBS patients. This study aimed at studying large-intestine enteroendocrine, Musashi 1 (Msi 1; a marker for both intestinal stem cells and their early progeny), and neurogenin 3 (neurog 3; a marker for early intestinal endocrine cell progenitors) cells in Thai and IBS patients.

Aims & Methods: Thirty Thai IBS patients, and age and sex matched 20 Thai controls were included. Four biopsy samples were taken from each of the sigmoid colon and the rectum during a standard colonoscopy. Sections from these biopsy samples were immunostained for serotonin, peptide YY, oxyntomodulin (enteroglucagon), pancreatic polypeptide, somatostatin, Msi 1, neuro 3. The densities of immunoreactive cells were determined with computerized image analysis (1). **Results:** In both the colon, and rectum the density of serotonin cells was lower in IBS patients than controls. Whereas the density of PYY cells was increased in both the colon and rectum of IBS-D, it was reduced in IBS-M and IBS-C. The density of oxyntomodulin cells was reduced in both the colon and rectum of all IBS subtypes. While the density of PP cells was unaffected in the colon, it was reduced in the rectum. Somatostatin cell density was unaffected in both the colon and rectum. The densities of Msi 1 and neuro 3 were unchanged in both the colon and rectum.

Conclusion: The present findings of abnormal densities of the large-intestine enteroendocrine cells in Thai patients combined with previously reported changes in Western IBS patients (2) support the notion that intestinal enteroendocrine cells are involved in the pathophysiology of IBS. However, the changes in the enteroendocrine cells differed from those in Western patients. The present observations highlight that IBS differs in Asian and Western countries, and show that the changes in large-intestine enteroendocrine cells in Asian and Western IBS patients might be caused by different mechanisms.

Introduction: Opioid-induced constipation (OIC) is a common side effect of opioid therapy that significantly affects multiple aspects of a patient's life. Naldemedine (NAL) is a peripherally-acting mu-opioid receptor antagonist developed for the treatment of OIC. In Phase 3 studies, NAL improved the frequency of spontaneous bowel movements, straining, consistency of stools, and patient assessment of constipation symptoms (PAC-SYM) and quality of life (PAC-QOL), measures of patient's quality of life, compared with placebo (PBO). The aim of this analysis is to assess the impact of NAL on overall satisfaction and to show if a simple score can assess the impact of treatment of OIC with NAL 0.2 mg once daily on patient's satisfaction with constipation and abdominal symptoms in patients with OIC associated with non-cancer pain.

Aims & Methods: In three Phase 3 randomized, double-blind, PBO-controlled trials of NAL (2 of 12-week duration [COMPOSE 1 and COMPOSE 2] and 1 of 52-week duration [COMPOSE 3]), a 7-grade scale (1 = markedly, 2 = moderately, or 3 = slightly worsened; 4 = unchanged; 5 = slightly, 6 = moderately, or 7 = markedly improved) was used to assess overall satisfaction with constipation and abdominal symptoms at the last study visit. The number and proportion of subjects in each grade were calculated and the overall difference between groups was assessed by Wilcoxon rank sum test. The mean subject global satisfaction score (SGSS) was also compared between groups. For SGSS, scores from 1 to 7 were replaced with scores from -3 to +3, with 4 (unchanged) replaced with 0.

This proposed new approach provides a single score that may be easier to interpret than the 7-grade scale.

Results: There were 547 subjects in COMPOSE 1, 550 in COMPOSE 2, and 1246 in COMPOSE 3 (all ≥18 years of age) randomized (1:1) to NAL 0.2 mg once daily or PBO. The baseline characteristics of the study population were consistent between groups in each trial and between trials. Overall satisfaction assessment was completed in 372 subjects in COMPOSE 1, 296 in COMPOSE 2, and 1101 in COMPOSE 3. There were greater improvements in satisfaction with constipation and abdominal symptoms in the NAL group compared with the PBO group in all three studies (all $P \leq 0.0005$; Table). The mean SGSS were 1.5 and 0.9 with NAL and PBO, respectively, in the two 12-week studies pooled, and 1.7 and 1.0, respectively, in the 52-week study.

	COMPOSE 1		COMPOSE 2		COMPOSE 3	
	NAL	PBO	NAL	PBO	NAL	PBO
Total subjects assessed	185	187	204	192	497	504
Global satisfaction category, n (%)						
Markedly worsened (1)	3 (1.6)	7 (3.7)	6 (2.9)	6 (3.1)	12 (2.4)	10 (2.0)
Moderately worsened (2)	11 (5.9)	8 (4.3)	5 (2.5)	10 (5.2)	3 (1.1)	14 (2.8)
Slightly worsened (3)	4 (2.2)	7 (3.7)	3 (1.5)	12 (6.3)	5 (1.4)	11 (2.4)
Unchanged (4)	27 (14.6)	58 (31.0)	28 (13.7)	54 (28.1)	74 (14.9)	169 (33.5)
Slightly improved (5)	49 (26.5)	38 (20.3)	37 (18.1)	39 (20.3)	100 (20.1)	116 (23.0)
Moderately improved (6)	39 (21.1)	41 (21.9)	53 (26.0)	39 (20.3)	129 (26.0)	89 (17.7)
Markedly improved (7)	52 (28.1)	28 (15.0)	72 (35.3)	32 (16.7)	174 (35.0)	95 (18.8)
P-value between groups*	0.0005		<0.0001		<0.0001	

*Wilcoxon rank sum test

Conclusion: Treatment of OIC with NAL 0.2 mg once daily for 12 or 52 weeks led to greater satisfaction with constipation and abdominal symptoms compared with PBO, consistent with previously-reported improvements of PAC-SYM and PAC-QOL with NAL compared with PBO. The proposed SGSS appears to be a simple way to assess the impact on quality of life of OIC treatment.

to study the ability of STW 5 to modulate intestinal permeability under basal and repeated acute stress conditions.

Aims & Methods: C57 bl6 mice were gavaged for 14 days with STW 5 (3 mL/kg). After 10 days of treatment, mice were subjected to water avoidance stress (WAS) during 4 consecutive days. *In vivo* permeability to FITC-Sulfonic Acid (FSA, 400 Da) and Horse Radish Peroxidase (HRP, 44kDa), total transit time and colonic transit (fecal pellet output - FPO) were assessed at Day 0 (D0), D10 and D14 of IB treatment. *Ex vivo* permeability to FSA and HRP was assessed on jejunum, ileum, proximal colon and distal colon at D14 using Ussing chambers. Corticosterone blood level was measured at D11 and D14.

Results: *In vivo* permeability to FSA and HRP as well as total transit time were not modified by STW 5 in basal and WAS conditions. However, STW5 prevented the increase in permeability to FSA induced by WAS in the distal colon *ex vivo*. Conversely, STW 5 prevented the increase in permeability to HRP induced by WAS in the jejunum and proximal colon. Furthermore, while STW 5 tended to increase colonic transit as compared to control in basal conditions, it prevented the increase in colonic transit induced by WAS. Finally, STW 5 did not modify the changes in corticosterone induced by WAS.

Conclusion: Our study suggest that STW 5 can prevent WAS induced changes in paracellular and transcellular permeability in specific regions of the gastrointestinal tract. Such effects could contribute to the therapeutic effects of STW 5 in irritable bowel syndrome and support novel therapeutic indications for pathologies in which barrier functions are altered.

P1129 ALTERING SPHINGOSINE-1-PHOSPHATE WITH AGING INDUCES MOTILITY DYSFUNCTION OF COLON SMOOTH MUSCLE BY BKCA UPREGULATION IN RATS

S. Xiaoxue

The First Affiliated Hospital Of Nanjing Medical University, Nanjing Medical University, Nanjing/China

Contact E-mail Address: shenxiaoxue0066@163.com

Introduction: Large conductance Ca^{2+} -activated K^{+} channel (BKCa channel) was shown to play critical roles in regulating smooth muscle contractility by modulating membrane potential, at the same time, age-associated changes in BKCa expression may contribute to the development of motility disorders of the gastrointestinal tract. Sphingosine-1-Phosphate (S1P), component of Sphingolipids in the cell membranes, may affect BKCa expression. Thus, in this study, we investigated whether altered S1P due to aging may affect the motility of colon smooth muscle (CSM) in rats.

Aims & Methods: Thus, in this study, we investigated whether altered S1P due to aging may affect the motility of colon smooth muscle (CSM) in rats. Forty Sprague-Dawley rats at the same age were randomly divided into five groups. After different times of administration, finally they were divided into different age-group: 10-week group, 20-week group, 40-week group, 60-week group and 80-week group. Colonic motility function and contractility of circular muscle strips were measured. The expression of BKCa and phosphorylated myosin light chain (P-MLC) level were tested in colonic tissues of rats with varying ages by immunohistochemical, RT-PCR and western blot. S1P levels in colonic tissues were tested by LC-MS/MS analysis. Primary cultured colonic smooth muscle cells (SMCs) from normal adult rats were used in complementary *in vitro* studies. In the absence and presence of S1P with different concentrations, the expression of BKCa, P-MLC level, single-channel activity, intracellular Ca^{2+} mobilization were tested. At the same time, in the presence and absence of S1P, SMCs were transfected with anti-S1P antibody. BKCa siRNA transfection was used to investigate whether P-MLC expression and intracellular Ca^{2+} mobilization were affected by BKCa expression in SMCs. The expression and phosphorylation of Akt, JNK, ERK, NF- κ B, and PKC were examined by western blot analysis to investigate the effect between S1P and BKCa.

Results: Aged rats showed prolonged colonic transit time and weakness of circular muscle contraction compared with the young (10 weeks old) SD rats. LC-MS/MS analysis exhibited that the levels of S1P were significantly greater in the CSM from aged rats, demonstrating that S1P varies depending on age. BKCa (α -subunit and β -subunit) levels in CSM were shown to increase in an age-dependent manner from 10- to 80-week-old rats by mRNA, protein and immunohistochemical, but P-MLC expression decreased. In colon SMCs, by BKCa siRNA transfection, we found P-MLC levels increased. Exogenously added S1P upregulated BKCa in colon SMCs in a concentration-dependent manner, impaired intracellular Ca^{2+} mobilization though inhibiting Ca^{2+} influx and induced the decline of P-MLC. Our results also proved that S1P upregulated BKCa through the Akt/ERK/JNK pathways. The expression of BKCa decreased by treatment with inhibitor of Akt/ERK/JNK pathways or siRNA.

Conclusion: The results of our study show that altered S1P due to aging upregulates BKCa via the Akt/ERK/JNK mediated pathway in CSM. BKCa upregulation inhibits Ca^{2+} influx and MLC phosphorylation and thereby reduces the contractility of CSM to evoke contractile dysfunction. These findings represent the first evidence for the mechanism of the contractile dysfunction of CSM observed in older individuals, which may be implicated in age-associated gastrointestinal motility disorders.

P1130 DIABETES-RELATED ALTERATIONS IN THE EXPRESSION OF THE INFLAMMATORY CYTOKINES, TUMOR NECROSIS FACTOR ALPHA AND INTERLEUKIN 6 IN THE MYENTERIC GANGLIA AND ITS MICROENVIRONMENT OF DIFFERENT INTESTINAL SEGMENTS

L. Chandrakumar, D. Mezei, B. P. Barta, Z. Szalai, N. Bódi, M. Bagyánszki
Department Of Physiology, Anatomy And Neuroscience, University of Szeged, Szeged/Hungary

Contact E-mail Address: lalitha.biochem87@gmail.com

Introduction: Growing amount of evidence has indicated that increase of the hyperglycaemia-induced oxidative stress and decreased effectiveness of the endogenous antioxidant protection play the major role in the initiation of diabetes-related neuronal damage^{1,2}. Using a streptozotocin-induced diabetic rat model we recently demonstrated that nitrergic myenteric neurons, which are key regulators of peristalsis, display different susceptibilities to diabetic damage and also to insulin treatment in the different gut segments³. Based on these results we suggested the importance of the molecular differences in the neuronal microenvironment in the pathogenesis of diabetic nitrergic neuropathy.

Aims & Methods: Aim to reveal the quantitative differences in the expression of the pro-inflammatory cytokines like tumor necrosis factor alpha (TNF α) and interleukin 6 (IL6) in the myenteric ganglia and its microenvironment of the different intestinal segments, quantitative immunogold electron microscopy was used. Ten weeks after the onset of diabetes, segments from the duodenum, ileum and colon of streptozotocin-induced diabetic, insulin-treated diabetic, and control rats were processed for post-embedding immunohistochemistry.

Results: The density of TNF α - and IL6-labelling gold particles was strictly region-dependent, with increasing to the distal part of the gastrointestinal tract of controls. In diabetic rats, the number of TNF α gold particles was significantly increased in the duodenal, decreased in the colonic myenteric ganglia, while did not show any significant differences in the ileal ganglia. The number of IL6 gold particles was not affected by diabetes in the myenteric ganglia of different gut regions. The diabetes-related alterations of TNF α - and IL6 expression were not protected by the immediate insulin replacement in any of the investigated intestinal segments. The differences in TNF α - and IL6 density were not significant in the capillary endothelium under different experimental conditions.

Conclusion: Based on these findings we presume that regionally alterations in the TNF α and IL6 expression are correlated with the diabetes-related region-specific nitrergic myenteric neuropathy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1131 ROLE OF SEMAPHORIN 3A IN THE POSTNATAL DEVELOPMENT OF THE ENTERIC NERVOUS SYSTEM

J. Gonzales, C. Le Berre, E. Dikkongue, M. Neunlist, H. Boudin
TENS INSERM U1235, Nantes/France

Contact E-mail Address: jacques.gonzales@univ-nantes.fr

Introduction: Critical developmental stages of the enteric nervous system (ENS) occur during the postnatal period leading to the formation of a mature neuroglial network characterized by the assembly of enteric neurons into ganglia and the formation of a highly organized pattern of neuronal connectivity. However, the mechanisms underlying these maturation processes are poorly understood. Semaphorin 3A (SEMA3A) is a secreted protein playing key roles in the neuronal circuitry formation of the central nervous system. Here, we studied the expression, the cellular distribution and the role of SEMA3A and its receptor neuropilin 1 (NRP1) in the maturation of enteric neurons.

Aims & Methods: Gene and protein expression of SEMA3A and its receptor NRP1 were analyzed in rat distal colon from postnatal day 1 (PN1) to adulthood by qRT-PCR and Western blot respectively. The cellular distribution of SEMA3A and NRP1 was performed at PN7 and PN36 in whole mount distal colon tissue by double immunofluorescence for SEMA3A or NRP1 with specific markers of glia (S100b), neurons (Hu, Tuj-1), and muscle cells (a-SMA). The impact of SEMA3A on neuronal outgrowth was assessed in cultures of enteric neurons cocultured with SEMA3A-transfected COS-7 cells.

Results: A peak of mRNA expression for SEMA3A and NRP1 was observed in distal colon at P7, corresponding to a stage of intense neural circuit remodeling. At the protein level, NRP1 was also found to be predominantly expressed during the early postnatal period. Immunohistochemistry of colon tissue indicated that SEMA3A immunoreactivity was not associated with any specific cellular profile, but was distributed in small clusters disseminated throughout the tissue, a pattern consistent for a secreted protein. NRP1 was found in neurons, mainly associated with axonal processes, and was not detected in glial or muscle cells. Enteric neurons cultured in the presence of SEMA3A-expressing COS cells showed a strong reduction in axon length and complexity, while the ganglion size was unaffected.

Conclusion: This study shows the expression of SEMA3A and its receptor NRP1 in the ENS during early postnatal period. By controlling axonal outgrowth, SEMA3A might be an important factor to restrict the axonal trajectories in the appropriate paths between ganglia.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1132 A POPULATION-BASED STUDY ON BOWEL HABITS IN A PORTUGUESE COMMUNITY: PREVALENCE OF CONSTIPATION

Introduction: Constipation is a chronic disorder with an estimated prevalence of 17% in Europe. Epidemiological studies on bowel habits in the Portuguese general population have not been done previously, as in many other western countries. The aim of this population-based study was to describe bowel habits and the prevalence of self-reported constipation in a Portuguese community.

Aims & Methods: We aimed to describe bowel habits and the prevalence of self-reported constipation in a Portuguese community. Methods: Cross-sectional study with convenience sampling between November 2015 and November 2016. The physician applied a questionnaire, to adult patients at primary health care consultation. The questionnaires were anonymous, and the only personal information the participants were required to give was their age and sex. The questionnaire contained objective questions on possible causes and constipation-associated conditions and medications (according to the criteria defined by the World Gastroenterology Organization), daily water and fiber intake, physical activity, bowel habits and Bristol stool scale (BSS). Descriptive statistics and uni and multivariate analysis were performed using IBM SPSS Statistics 22 with $p < 0.05$ deemed to be statistically significant.

Results: A total of 814 questionnaires were performed to individuals from 35 different municipalities (54% women; mean age 46 ± 18 years). Concerning possible causes of constipation, 43% subjects had a history of constipation-associated condition and 36% were taking constipation-associated drugs. Regarding bowel habits, 35% subjects had <1 bowel movement per day and 2% had <1 bowel movement per week. Using BSS, 66% of the cases reported type III or type IV stool consistency. Among women, 19% reported a change in bowel movements according to the phase of the menstrual cycle. In total, 22% of subjects considered to be constipated, and 78% of these, complied the Roma III criteria for functional constipation. Noteworthy, 6% of subjects with daily bowel movements and 38% of those with <1 weekly bowel movement considered to have constipation. Complaints of excessive straining, tenesmus, feeling of incomplete evacuation and abdominal pain were associated with the presence of constipation (64 vs. 12%, 56 vs. 20%, 54 vs. 19% and 37 vs. 18%, respectively; $p < 0.0001$). No associations were found between constipation and physical activity, daily water or fiber intake.

Conclusion: This study represents the first assessment of bowel habits in the Portuguese population, depicting the high prevalence and related risk factors of a disorder that decreases the health-related quality of life and has major economic consequences. The prevalence of constipation (22%) was higher than that reported in other European countries.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1133 DIAGNOSTIC DISCORDANCE BETWEEN TESTS OF EVACUATION: A PROSPECTIVE STUDY

D. Carter¹, E. Bardan², M. Beer-Gabel²

¹Sackler Faculty Of Medicine, Tel Aviv University, Tel Aviv/Israel

²Gastroenterology, Sheba Medical Center Dept. of Gastroenterology, Ramat Gan/Israel

Contact E-mail Address: dr.dancarter@gmail.com

Introduction: Objective means of evaluation of the defecatory process include high resolution ano-rectal manometry (HRM), balloon expulsion test (BET) and imaging of the defecatory process (X-ray defecography, dynamic trans-pelvic ultrasound (DT-PUS) or MR defecography). These tests have a place in the evaluation of suspected evacuatory dysfunction (ED), fecal incontinence (FI) and chronic pelvic pain (CPP). Test choice may influence subsequent patient management; however, there is only limited information regarding the agreement between HRM, DT-PUS and BET.

Aims & Methods: The aims of this study were to compare the diagnostic yield and agreement between different tests of evacuation and to define the relation between the diagnoses of evacuation dysfunction to objective evacuatory failure. 63 consecutive patients (60 females, mean age 51ys) were prospectively evaluated with HRM, BET and PUS. Inter test agreement for the diagnosis of anismus was assessed using the Kappa statistic. Correlation between anismus to evacuatory failure (assessed by PUS) was also assessed.

Results: 36 patients were assessed for ED, 6 for CPP and 21 for FI. Anismus was diagnosed in 26 patients by HRM and 45 patients by DT-PUS. All cases of anismus diagnosed by HRM or DT-PUS had a positive BET. The Kappa agreement for the diagnosis of anismus between HRM and DT-PUS was poor (0.143 ± 0.01). 9 patients had significant pelvic floor anatomic pathology (4 rectal prolapse, 6 pathological pelvic descent, 4 enterocele and 3 rectocele > 3.5 cm). There was a moderate correlation between diagnosis of anismus on DT-PUS to failure to evacuate the rectum ($r = 0.636$). The correlation between rectal evacuation on DT-PUS to the diagnosis of anismus on manometry was weak ($r = 0.296$).

Conclusion: There is considerable disagreement between the results of various evacuatory tests, and between the diagnoses of evacuatory dysregulation to failure of rectal evacuation. Therefore, more than one test should be applied in order to evaluate the defecatory dysfunction.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1134 DIAGNOSTIC USE OF ENDOSCOPIC FULL-THICKNESS WALL RESECTION (eFTR) IN PATIENTS WITH SYMPTOMS OF CHRONIC INTESTINAL PSEUDO-OBSTRUCTION (CIPO)

P.V. Valli¹, D. Pohl¹, M. Fried¹, R. Caduff², P. Bauerfeind¹

¹University Hospital Zurich, Zürich/Switzerland

²Institute Of Surgical Pathology And Molecular Pathology, University Hospital Zurich, Zürich/Switzerland

Contact E-mail Address: piero.valli@usz.ch

Introduction: Complex gastrointestinal (GI) motility disorders such as chronic intestinal pseudo-obstruction (CIPO) or Hirschsprung's disease (HD) are challenging to diagnose and treat appropriately. Thorough assessment of patient history, radiographic exams, endoscopy and motility measurements aid in diagnostic workup, yet underlying histology is the cornerstone to enable a more distinct diagnosis of neuromuscular GI disorders. Traditionally, surgical procedures have been performed to obtain specimen suitable for accurate histologic analysis.

Aims & Methods: We performed endoscopic full-thickness resection (eFTR) using a full-thickness-resection device (FTRD) under moderate propofol sedation in four patients with suspected severe neuromuscular gut disorders including CIPO.

Results: Patient 1: A 21-year-old male patient with cerebral palsy suffering from acute small bowel ileus with a history of laparotomy, detorquation and appendectomy after cecal volvulus at the age of 15. Histologic analysis revealed irregular configuration of the myenteric plexus, but primary neuro- or myopathic disorder such as HD were ruled out. Thus, GI dysmotility due to cerebral palsy syndrome was suspected. **Patient 2:** After a life-long history of recurrent obstruction, colonic dilatation, ileus symptoms and various colonic segment resections, diagnostic eFTR was performed in a 55-year-old female patient. The diagnosis of hypoganglionosis was established by LDH histochemical and by immunohistochemical reactions with Calretinin and Map2-Kinase. **Patient 3:** A 19-year-old male patient with a history of a sigmoid volvulus and massively dilated large bowel segments. Enzyme histochemistry excluded HD upon histopathological analysis. The inner muscle layer showed fibrosis, eosinophilic leiomyositis and lymphocytic ganglionitis. Congenital CIPO was diagnosed due to degenerative leiomyopathy. **Patient 4:** A 56-year-old male patient with acute ileus and a year-long history of constipation and abdominal pain. Histopathological analysis

revealed hypoganglionosis, severe fibrosis of the inner muscle layer and reduced ICC networks (< 50%). HD was excluded and acquired CIPO was diagnosed due to hypoganglionosis. Technical as well as histological success providing large full-thickness specimen of excellent quality was achieved in all four patients (success rate 100%). The mean procedure time was 12 minutes (range 5–20 min). The mean diameter of the resected specimen was 21 mm (range 20–22 mm). No adverse events connected to the procedure itself occurred during the follow up. **Conclusion:** In conclusion, diagnostic eFTR using the FTRD® as a close-and-resect device is a well feasible and effective technique to provide full-thickness gut specimens of excellent quality and size, allowing detailed routine and sophisticated histologic, histochemical and immunohistochemical analysis for the diagnosis of neuromuscular gut disorders.

P1135 TRANS-ABDOMINAL INTERFERENTIAL ELECTRICAL STIMULATION IS EFFECTIVE IN MANAGING REFRACTORY LOWER GASTROINTESTINAL DYSMOTILITY DISORDERS

J. Moore, P.R. Gibson, R. E. Burgell

Introduction: There is emerging interest in non-pharmacological management of gastrointestinal dysmotility via neuromodulatory techniques. A new method of non-invasive neuromodulation - transabdominal interferential electrical stimulation - has apparent efficacy in a paediatric population with difficult constipation.¹

Aims & Methods: We report our experience of its use in adult patients with functional constipation who are refractory to conventional management.

This is a descriptive case series of consecutive adult patients presenting to a tertiary referral functional gastrointestinal disorders clinic with refractory constipation that were taught and used home-based interferential stimulation for an hour a day over a three-month period by a functional gut nurse-specialist between October 2015 and Feb 2017. The validated PAC-SYM and PAC-QOL questionnaires were given at commencement of stimulation and after three months of use. Overall symptom severity was assessed by 10 cm VAS. An intention to treat analysis was conducted for any patients who commenced stimulation.

Results: Seven patients with refractory constipation (3 with slow-transit and 4 with idiopathic constipation) responding inadequately to pharmacological and non-pharmacological therapies underwent stimulation. Mean (range) age was 47 (26–73) y and 2 were male. All 7 patients completed the stimulation period. There was a reduction in PAC-SYM in all patients (median IQR 24 [18–36] vs 14 [10–21]) and VAS median IQR 8 [7–9] vs 4 [2–5] ($p = 0.004$). PAC-QOL was assessed in 4 patients where this also fell from 75 [69–85] to 38 [19–52]. Four were able to cease previously heavy daily laxative use and 2 were able to halve their use, one currently weaning off prucalopride. One remained on daily laxative use despite soft, formed stool. All reported satisfaction with stool type. Ongoing benefit remains in 2 after 4 and 12 months since ceasing its use, where the rest tend to use the stimulator intermittently.

Conclusion: Interferential electrical stimulation improved symptoms in patients with functional constipation. Randomized placebo controlled trials are justified.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The 5-HT₄ receptor is an attractive drug target that can stimulate gastrointestinal motility. YH12852 is a novel, potent and highly selective 5-HT₄ receptor agonist currently under clinical development for the treatment for gastrointestinal motility disorders (GIMDs).

Aims & Methods: The study aim was to evaluate the safety, tolerability, pharmacokinetic and pharmacodynamic profiles for YH12852 in healthy volunteers with ≤ 3 spontaneous bowel movements per week (SBMs/week) and patients with functional constipation (FC). A randomized, double-blind, placebo- and active-controlled phase 1/2a study was performed in healthy subjects and FC patients, who were administered YH12852 (0.3, 0.5, 1, 2 or 3 mg), prucalopride 2 mg or placebo once daily after breakfast for 2 weeks. Subjects recorded bowel habits throughout the study period. Intensive pharmacokinetic blood samples were also collected (ClinicalTrials.gov identifier NCT02538367).

Results: Twenty-nine healthy subjects and 27 FC patients were enrolled. Treatment-emergent adverse events (TEAEs) were mostly mild and no serious adverse event was reported. The most frequently reported AE in the YH12852

and prucalopride group was headache. TEAEs in the YH12852 groups were similar to those in the prucalopride group. The change from baseline in weekly SBM frequencies averaged over the 2-week treatment period were 3.5, 3.8, 6.3, 4.6 and 3.9 for YH12852 0.3, 0.5, 1, 2 and 3 mg, respectively, 4.0 prucalopride and 2.6 placebo. The proportion of responders (defined as those with a ≥ 1 increase in SBM/week over 2 weeks from baseline) was higher in the YH12852 treatment groups (87.5%, 100.0%, 100.0%, and 100.0% in 0.3, 0.5, 1 and 2 mg, respectively), with the exception of the 3 mg group (80.0%), compared with that in the prucalopride (83.3%) and placebo groups (28.6%). The mean stool consistencies assessed by the Bristol Stool Form Scale were comparable between the YH12852 and prucalopride groups. The time to reach the peak concentration of YH12852 was 4 hours. Steady state was achieved approximately 5 days after the first administration of YH12852 with a half-life of 23–28 hours. YH12852 showed a linear pharmacokinetic profile over 0.3–3 mg.

Conclusion: YH12852 was well tolerated and its safety profile was comparable to that of prucalopride. YH12852 appeared to increase bowel movement greater than prucalopride, particularly at 0.5–2 mg. YH12852 may have a significant potential for the treatment of lower GIMDs.

P1137 HEALTHCARE PROFESSIONALS FAIL TO PROVIDE ADEQUATE COUNSELLING AND SUPPORT ABOUT OPIOID-INDUCED CONSTIPATION TO STRONG-OPIOID USERS

V. Andresen¹, V. Banerji², G. Hall², A. Lass³, A. V. Emmanuel⁴

¹Gastroenterology, Israelitic Hospital, Hamburg/Germany

²InsightDojo, London/United Kingdom

³Medical, Shionogi Limited, London/United Kingdom

⁴Neuro-gastroenterology, National Hospital for Neurology and Neurosurgery, London/United Kingdom

Contact E-mail Address: V.Andresen@ik-h.de

Introduction: Constipation is a common side effect of opioid use. Available laxative therapies for opioid-induced constipation (OIC) leave the patient with significant residual symptoms, which may lead them to adjust or stop their opioid intake in order to have a bowel movement, unless effectively counselled.¹

Aims & Methods: This subgroup analysis of an international survey investigated counselling resources, information-seeking, and sources of support in subjects with constipation caused by the use of strong opioids (e.g. buprenorphine, fentanyl). This was a quantitative, questionnaire-based, online survey conducted in France, Germany, Italy, Spain and the UK among respondents aged ≥ 40 years with largely non-cancer-related chronic pain, treated long-term with strong opioids and having constipation (N=2016). The survey assessed past medical history, opioid use, treatment and treatment-seeking behaviour, symptoms, burden of disease, and effects on quality of life of constipation.

Results: In general, responders find it difficult to combine pain management relief and constipation and dislike having to balance between them (36%). Approximately one-fifth (22%) of respondents were very or somewhat dissatisfied with the effectiveness of their current constipation treatment and only 43% strictly adhered to prescribed treatment regimens, with 32% researching other treatment options. A significant number of responders (44%) admitted that their constipation becomes so bothersome that they have to combine different methods to relieve it, and 40% often cut down their opioid medication or even skip it entirely (9%) to relieve constipation. To manage their constipation, responders regularly used a variety of approaches, including dietary measures (48%), exercise (23%) and single (32%) or multiple (15%) laxative treatments. Only 45% of respondents reported that their healthcare professionals (HCPs) had warned them about constipation as a potential side effect of opioid use. Almost two-thirds of responders (63%) reported that their HCP was the main information source on opioid-induced constipation. Although 58% of responders stated that they would have liked their HCP to provide more information about OIC, 48% preferred to deal with constipation on their own, rather than discuss it with their HCP. Other common sources of information were online search engines (44%) and online health forums (29%). Less than half of responders (43%) strictly adhered to prescribed treatment regimens, with 32% researching other treatments.

Conclusion: A proportion of patients are not satisfied with their current constipation treatment and they sometimes find balancing the need for adequate pain relief with constipation side effects challenging; consequently, many fail to adhere to their prescribed treatment regimens, or resort to using suboptimal strategies, such as reducing their opioid intake, to relieve constipation. Despite this dissatisfaction, many HCPs are not counselling patients adequately about constipation as a common potential side effect of opioid use. While most patients would like to have more support from their HCP, nearly half prefer to deal with constipation on their own, perhaps due to embarrassment or resignation.

P1138 THREE-DIMENSIONAL HIGH-RESOLUTION ANORECTAL MANOMETRY IN CHILDREN AFTER SURGERY FOR ANORECTAL DISORDERS

M. Banasiuk¹, A. Banaszkiwicz¹, M. Dziekiewicz¹, A. Kamiński², P. Albrecht¹
¹Dept. Of Pediatric Gastroenterology, Medical University of Warsaw, Warsaw/Poland

²Dept. Of Pediatric Surgery, Medical University of Warsaw, Warsaw/Poland

Contact E-mail Address: mbanasiu@tlen.pl

Introduction: Three-dimensional high-resolution anorectal manometry (3DHRAM) is the most precise tool to assess function of the anal canal and may be useful in evaluation of children after surgery on lower gastrointestinal tract that may present wide spectrum of symptoms from gastrointestinal tract. Our aim was to evaluate children after surgery for anorectal disorders using 3DHRAM.

Aims & Methods: We performed a prospective study of 43 children (30 male, mean age, 7 years) after surgery for anorectal disorders at the Departments of Pediatric Gastroenterology and Nutrition, Medical University of Warsaw, Poland. The group consisted of 24 children after surgery for Hirschsprung's disease (HD), 12 children after surgery for anal atresia (AA) and 7 children after proctocolectomy for other reasons (PC). In all children conventional manometric parameters were obtained. Pressures of the anal canal was divided into 8 segments and the resting and squeeze pressures of puborectalis muscle (PRM) were recorded in segments covering its anatomical localization. These data were compared to raw data obtained in our laboratory from healthy children published previously (HC group). To assess correlation between manometry and symptoms, all children (after surgery and HC group) were divided into groups with respect to symptoms, as follows: asymptomatic (A), nonretentive fecal incontinent (NRFI), constipated (C) and retentive fecal incontinent (RFI).

Results: The lowest values of resting, squeeze and the pressure of PRM were observed in AA (55.6 mmHg, 121.7 mmHg and 44.17 mmHg, respectively). As compared to asymptomatic children, the lowest mean and maximum resting pressures were observed in NRFI (69.6 mmHg and 61.3 mmHg, respectively; $p < 0.000$). Significantly lower maximum squeeze pressure were recorded in both, NRFI and RFI (168.1 mmHg and 103.8 mmHg, respectively; $p = 0.03$). ROC cut-off value for mean resting pressure between asymptomatic children and patient with fecal incontinence was 68.5 mmHg. Significantly lower PRM resting pressure were observed in NRFI group and lower PRM squeeze pressure in RFI (45.6 mmHg and 63.6 mmHg, respectively). Threshold of urge were significantly higher in group C as compared to A group (87.5 cm³ and 30 cm³, respectively; $p = 0.003$).

Conclusion: Our study demonstrated lower pressure parameters in children after surgery with the lowest values in patients suffering from anal atresia, which was correlated with incontinence. 3DHRAM may be useful tool for assessing the function of the anorectum of children after surgery.

Introduction: Linacotide, a guanylate cyclase C agonist, has been shown in clinical trials to relieve constipation and improve abdominal pain and discomfort in patients with irritable bowel syndrome with constipation (IBS-C), but there are limited UK-specific real-world data to support this.

Aims & Methods: A multi-centre, observational, prospective 52-week study was conducted in eight specialist hospitals in England and Scotland. The primary objective was to describe the change in IBS-Symptom Severity Scale (IBS-SSS) score from baseline at 12 weeks after linacotide initiation. Consenting patients aged ≥ 18 years initiated on linacotide (290 mcg) for IBS-C were recruited. Data on patient demographic and clinical characteristics, concomitant medications, patient-reported outcomes, including IBS-SSS score, and adverse events were collected. Results at 12 weeks (primary endpoint) have been presented previously; here we report analysis of real-world clinical experience 52 weeks post-linacotide initiation.

Results: 202 patients were recruited; 185 (92%) were female. At baseline, median age was 44.9 (range 18–77) years; 84 (42%) reported concomitant laxative use. Mean baseline IBS-SSS score was 339 (standard deviation [SD] ± 92 ; $n = 193$); 129 (67%) patients had IBS-C classified as severe (score ≥ 300), 54 (28%) moderate (175–300), nine (5%) mild (75–175) and one (0.5%) normal (< 75). At 52 weeks, mean IBS-SSS score was 256 (SD ± 116 ; $n = 78$); 31 (40%) patients had severe IBS-C, 27 (35%) moderate, 14 (18%) mild and six (8%) normal. IBS-SSS scores improved significantly between baseline and 52 weeks, with a mean decrease of 71 (SD ± 106) points overall (t-test $p < 0.001$; $n = 76$ with paired data) and 94 (SD ± 102) points in the patients remaining on linacotide ($p < 0.001$; $n = 34$). Of the 76 patients with paired data, 41 (54%) reported responding to treatment (ie reduction in IBS-SSS score of ≥ 50 points, or score fell below 150 [if baseline score ≥ 150]) [Table]. At 52 weeks, 41 (20%; $n = 202$) patients remained on linacotide, 87 (43%) had stopped (< 4 doses in past week),

most commonly due to side effects ($n = 51$) or lack of efficacy ($n = 18$), and 74 (37%) were lost to follow-up/not known. Overall, 174 adverse events possibly related to linacotide were reported in 77 (38%) patients, most commonly diarrhoea (25%; $n = 51$), abdominal pain (9%; $n = 18$) and abdominal distension (6%; $n = 13$).

Table: Change in IBS-SSS score at 52 weeks from start of linacotide

Change in IBS-SSS	Patients, n	Patients, %
–350 < –300	1	1
–300 < –250	5	7
–250 < –200	5	7
–200 < –150	4	5
–150 < –100	11	14
–100 < –50	14	18
–50 < 0	15	20
No change	1	1
> 0 < 50	10	13
50 < 100	7	9
100 < 150	3	4
150 < 200	0	0
200 < 250	0	0
250 < 300	0	0
300 < 350	0	0
Total	76	100

Conclusion: Linacotide was associated with a significant improvement in IBS-SSS score at 52 weeks and was reasonably well tolerated. These results provide valuable insights into the longer-term outcomes of linacotide treatment in patients with IBS-C in real-world clinical practice.

Introduction: Irritable bowel syndrome (IBS) may be associated with disturbances of gut microbiota composition and functions, such as altered bacterial fermentation.

Aims & Methods: The aim was to study the effect of faecal microbiota transplantation (FMT) on gut bacterial fermentation products: short-chain fatty acids (SCFAs). Patients diagnosed with IBS according to Rome III criteria ($n = 13$) were included. They received freshly donated faeces from relatives, instilled into the descending part of the duodenum via gastroscopy. Faecal samples were collected from the donors and the patients before FMT and from the patients after FMT at weeks 1, 3, 12 and 20/28. All the samples were stored at -80°C until analysis. Faecal concentrations of major SCFAs (acetic, propionic and n-butyric acids) and minor SCFAs (iso-butyric, n-valeric, iso-valeric, n-caproic and isocaproic acids) were analysed by vacuum distillation followed by gas chromatography. The patients completed IBS symptom questionnaire (IBS-SQ) before and after FMT at weeks 1, 3, 12, and 20/28, assessing the following domains: nausea, bloating, abdominal pain, diarrhea, constipation and anorexia.

Results: Before FMT, concentrations of several SCFAs were significantly lower in IBS patients compared to donors (Table 1). After FMT, concentrations of SCFAs increased within the first 3 weeks, and the increment lasted up to 28 weeks (Table 1). Symptom scores as assessed by IBS-SQ improved from before FMT until week 20/28 after FMT as follows: nausea ($P = 0.0013$), bloating ($P < 0.0001$), abdominal pain ($P = 0.0005$), diarrhea ($P < 0.0001$), constipation ($P = 0.03$), and anorexia ($P = 0.09$). Correlations were found between abdominal pain and both acetic acid ($r = 0.69$, $P = 0.04$) and total SCFAs ($r = 0.69$, $P = 0.044$) in IBS patients before FMT. Inverse correlations were found 3 weeks after FMT between nausea and iso-valeric acid ($r = -0.65$, $P = 0.014$), and between constipation and propionic ($r = -0.74$, $P < 0.0001$), iso-butyric ($r = -0.79$, $P < 0.0001$), n-valeric acids ($r = -0.79$, $P < 0.0001$) and iso-valeric ($r = -0.72$, $P < 0.0001$).

Abstract No: P1140

Table 1: Concentrations (mmol/kg) of short-chain fatty acids (SCFAs) in faecal samples collected from donors and patients with irritable bowel syndrome (IBS) before and after faecal microbiota transplantation (FMT).

P1141 HEALTHCARE RESOURCE USE IN PATIENTS WITH IRRITABLE BOWEL SYNDROME WITH DIARRHOEA BASED ON A SURVEY OF PHYSICIANS IN THE UNITED KINGDOM

A. Marciniak¹, D. Collomb¹, S. Baker¹, R. Goosey²

¹Allergan plc, Marlow/United Kingdom

²Kantar Health, Epsom/United Kingdom

Contact E-mail Address: Anne.Marciniak@Allergan.com

Introduction: Irritable bowel syndrome with diarrhoea (IBS-D) is a chronic gastrointestinal disorder associated with significantly increased healthcare resource use (HCRU) and a substantial economic burden. In clinical practice, adequate relief (AR) of symptoms is an important measure of treatment effectiveness.^{1,2} However, the difference in HCRU related to IBS-D between patients with AR and those with inadequate relief (IR) has not yet been assessed.

Aims & Methods: This objective of this study was to quantify the HCRU in patients with AR of IBS-D symptoms compared to patients with IR. An online survey assessing HCRU was distributed to general practitioners (GPs) recruited from market research panels in the UK in August 2016. GPs opted-in to complete the survey via an email link and were screened before being invited to complete the main survey. Screening criteria included having seen patients with a chronic gastrointestinal condition in the past three months, having seen patients with IBS-D in the past 3 months and having decided on what treatments were prescribed for patients with IBS. The survey was a 15-minute web-based survey, including 12 questions collecting information on the use of medical services and procedures amongst patients with IBS-D for the first year following diagnosis and for subsequent years. Respondents were required to answer the survey considering patients who had AR of IBS-D symptoms and those who did not (IR), based on the respondents' own assessments. Statistical analyses included t-tests for two independent samples comparing mean scores for those with IR vs those with AR during the first year after diagnosis at a 5% risk level, with p < 0.05 denoting significance.

Results: The online survey was completed by 50 GPs, with responses from 46 GPs included in this analysis (four responses were excluded due to data quality reasons). The reported total number of medical visits was significantly higher for patients with IR vs patients with AR during the first year after diagnosis (mean 10.11 vs 5.20; p < 0.001), with similar results seen for subsequent years (mean 8.20 vs 4.38). Significantly higher numbers of GP office visits, outpatient visits and emergency room visits were reported for patients with IR, with the greatest difference seen for GP office visits (2.37 more visits/year on average; incremental 4-week increase of 0.182; p = 0.003) [Table]. Similarly, the total reported mean number of procedures was significantly higher for patients with IR vs patients with AR (8.11 vs 4.52; p = 0.046), with number of colonoscopies having the greatest difference between the two groups (2.17 vs 0.91; 1.26 more procedures/year on average; incremental 4-week increase of 0.097; p = 0.008). Similar results were seen for the subsequent years after diagnosis, with patients with IR having more medical procedures compared to patients with AR (4.08 vs 2.56).

Table

Mean resource use (standard deviation)	Adequate relief (1 st year after diagnosis)	Inadequate relief (1 st year after diagnosis)	Difference per year	Incremental mean quantity per 4 weeks
Medical visits				
Total	5.20 (4.87)	10.11 (5.30)*	4.91	0.378
GP office	3.33 (2.87)	5.70 (3.12)*	2.37	0.182
Outpatient	0.96 (1.53)	2.30 (1.68)*	1.35	0.104
Emergency room	0.52 (1.24)	1.17 (1.36)*	0.65	0.050
Hospitalisations	0.39 (1.00)	0.93 (1.10)	0.54	0.042
Procedures				
Total	4.52 (6.96)	8.11 (7.58)*	3.59	0.276
Colonoscopy	0.91 (1.47)	2.17 (1.61)*	1.26	0.097

Computerised tomography scan	0.48 (1.01)	0.85 (1.10)	0.37	0.028
X-ray	0.63 (1.53)	0.74 (1.68)	0.11	0.008

* p < 0.05 compared to patients with adequate relief

Conclusion: GPs reported that patients with IBS-D considered as having IR of symptoms had increased HCRU, including more GP office visits and more colonoscopies, compared to patients with AR. These results highlight that IR is potentially an important driver of increased HCRU in patients with IBS-D, emphasising that effective treatments that provide AR may reduce HCRU and the associated economic burden.

P1142 RANDOMISED PLACEBO CONTROLLED ESCITALOPRAM INTERVENTION IN IBS WITH PANIC DISORDER: EVALUATION BY GSRs AND BY EXPERIENCE SAMPLING METHOD

L. Vork¹, M. Drukker², Z. Mujagic¹, D. Keszthelyi¹, J. Van Os², A. A.m. Masclee¹, C. Leue², J. Kruimel¹

Introduction: Selective Serotonin Reuptake Inhibitors (SSRI's) have shown efficacy in reducing symptoms but less so on pain in irritable bowel syndrome (IBS). Comorbid anxiety frequently occurs in IBS. We hypothesized that SSRI's will particularly be effective in reducing abdominal pain in IBS patients with pronounced comorbid anxiety. As methods for symptom evaluation were used 1) gastrointestinal symptom rating scale (GSRs) as primary parameter and 2) a new method called the Experience Sampling Method (ESM). With ESM digital assessments are completed randomly and repeatedly during daily life, therewith capturing fluctuating symptom patterns more accurately than retrospective questionnaire methods.

Aims & Methods: IBS patients with comorbid panic disorder were included in a randomized controlled trial on escitalopram versus placebo. Measurements were completed at baseline (t=0) and after 3 (t=3) and 6 months (t=6). At each time point, the gastrointestinal symptom rating scale (GSRs) and a 7-day ESM period were completed. Subjects completed ESM assessments on a palmtop computer at 10 random moments each day during 7 consecutive days. ESM periods were analysed when at least 1/3 (i.e. 23) of the assessments were completed. Mixed linear modelling was used with the GSRs-abdominal pain domain (GSRs-AP) as the dependent and treatment group as the independent variable, as well as with ESM- abdominal pain scores as the dependent and treatment group and ESM-anxiety scores as the independent variables.

Results: In total, 29 subjects (15 escitalopram and 14 placebo; 21 female; 37±14.8 years; equal abdominal pain and anxiety scores at baseline) were included. Average GSRs-AP scores were not significantly different between escitalopram and placebo at t=3 (B: 0.265, SE: 0.451, p=0.557) or t=6 (B: 0.229, SE: 0.539, p=0.670). For the ESM analyses, at t=6, average abdominal pain scores were significantly lower (B: 1.30, SE: 0.623, p=0.037) (on a 1-7 scale) in the escitalopram group compared to placebo. With increasing anxiety levels (scores 2, 3 and 4) this difference further increased to 1.57, 1.84 and 2.11, respectively. A sensitivity analysis on subjects that completed all 3 valid ESM periods (i.e. at least 1/3 of total number of assessments at t=0, t=3 and t=6) showed similar results.

Conclusion: Using GSRs as primary outcome, no significant effect of escitalopram over placebo on abdominal pain was found over a 6-month period. However, using ESM, a significant improvement in abdominal pain was observed, related to anxiety scores. These data 1) challenge the value of traditional retrospective methods with end-of-period symptom recording and 2) are in favour of novel more accurate momentary symptom registrations such as the Experience Sampling Method.

Introduction: Linacotide, a guanylate cyclase-C agonist, stimulates intestinal fluid secretion and decreases visceral hypersensitivity and is licensed for use in irritable bowel syndrome with constipation (IBS-C). There is a relative paucity of data concerning its effect on gastrointestinal (GI) motility.

Aims & Methods: We aimed to compare the effect of linacotide on segmental and pan-enteric motility in IBS-C. 14 patients with Rome III defined IBS-C (3 male, mean age 37 years, range 20-64) underwent a wireless motility capsule (WMC) using a standardized protocol. Segmental transit was derived from measures around known anatomical landmarks as identified by compartmental pH changes. Ileal and colonic motility measures are presented as area under the curve (AUC) derived from contraction amplitude and frequency. Validated questionnaires assessing GI (verbal descriptor anchored visual analog scale (VDVAS)) assessing sensory intensity (VDVAS-I) and unpleasantness (VDVAS-U)) and somatic symptoms (Personal Health Questionnaire (PHQ)) as well as quality of life (EQ-5D) were administered. The WMC and questionnaires were repeated after 28 days of linacotide 290 mcg po od.

Results: Changes in GI motility are shown in Table 1. Linacotide improved VDVAS-I and VDVAS-U (130.7±20.8 vs. 106.5±33, p=0.03 and 113±22 vs. 85.8±33, p=0.01) and quality of life (58.4±21.2 vs. 68±17.6, p=0.02). Linacotide reduced somatic symptoms (8.3±2.2 vs. 5.9±1.4, p=0.007).

Change in pH across the ileocaecal junction correlated with improvement in VDVAS-I and U (r=0.6, p=0.03 and r=0.64, p=0.02).

Table 1: Changes in GI physiology following linacotide.

	Baseline (mean and standard deviation)	Post treatment (mean and standard deviation)	P Value
Gastric emptying time (minutes)	154 ± 64	177 ± 57	0.4
Small bowel transit time (minutes)	353 ± 152	299 ± 139	0.3
Colonic transit time (minutes)	3017 ± 1305	1983 ± 1216	0.04
Whole gut transit time (minutes)	3517 ± 1375	2432 ± 1180	0.04
Ileal contractility (AUC)	262 ± 142.4	221 ± 113.5	0.5
Colonic contractility (AUC)	90.9 ± 78.3	134.6 ± 93	0.006
Change in pH across the ileocaecal junction	-2.4 ± 0.2	-2.1 ± 0.4	0.03

Linacotide improved VDVAS-I and VDVAS-U (130.7±20.8 vs. 106.5±33, p=0.03 and 113±22 vs. 85.8±33, p=0.01) and quality of life (58.4±21.2 vs. 68±17.6, p=0.02). Linacotide reduced somatic symptoms (8.3±2.2 vs. 5.9±1.4, p=0.007). Change in pH across the ileocaecal junction correlated with improvement in VDVAS-I and U (r=0.6, p=0.03 and r=0.64, p=0.02).

Conclusion: Linacotide reduced colonic transit and enhances contractility. These changes in GI motility are accompanied by improvements in symptoms and quality of life and are associated with a reduction in extra-gastrointestinal symptoms. Change in pH across the ileocaecal junction has been proposed as a surrogate marker of caecal fermentation. Thus the beneficial effect of linacotide on symptoms may therefore be related to a reduction in fermentation. This potential biomarker warrants further exploration.

P1144 RELATIONSHIP BETWEEN RIFAXIMIN THERAPY AND SEHCAT TEST IN PATIENTS WITH DIARRHEA-PREDOMINANT IRRITABLE BOWEL SYNDROME OR FUNCTIONAL DIARRHEA

A. Ruiz Cerulla, S. Maisterra, C. Arajol, P. Gilabert, K. Serra, O. Puig, P. Notta, F. Rodriguez-Moranta, L. Rodriguez-Alonso, E. Sanchez-Pastor, J. Guardiola Gastroenterology, Hospital Universitari de Bellvitge, Hospital de Llobregat/Spain

Contact E-mail Address: alexandraruizcerulla@gmail.com

Introduction: Bile acids (BAs) and gut microbiota have been involved in IBS pathophysiology. BA diarrhea (BAD) is often found in patients with irritable bowel syndrome with diarrhea (IBS-D) or functional diarrhea (FD)¹. Colestyramine and rifaximin have both been shown to improve symptoms in these patients^{2,3}. It is unknown whether a SeHCAT test may help to predict response to rifaximin or whether rifaximin treatment affects SeHCAT test result.

Aims & Methods: a) To determine if a SeHCAT test may be used to predict response to rifaximin in patients with IBS-D or FD. b) To assess if rifaximin modifies SeHCAT result.

Consecutive patients diagnosed with IBS-D or FD were prospectively included in the study. All patients received rifaximin (400 mg TID for 2w). A SeHCAT test was performed to evaluate presence of BAD before and 1 month after rifaximin treatment. BAD was defined as SeHCAT retention <10%. Number of daily stools, number of daily watery stools, Bristol stool scale, abdominal pain, distension and presence of urgency were recorded before and after treatment. IBS severity score (IBS-SS) was also calculated.

Results: Forty-one patients were included. BAD was present in 23 patients (56%). No clinical differences were found between BAD or non-BAD patients at study entry. Rifaximin resulted in a significant improvement in the number of daily stools (Δ -1.5; P < 0.01), daily watery stools (Δ -2.1; P < 0.01), Bristol scale (Δ -1.1; P < 0.01), abdominal pain (Δ -0.5; P < 0.01), distension (Δ -0.3; P < 0.01), urgency (Δ -0.7; P < 0.01) and in the IBS-SS (Δ -78; P < 0.01). No differences were found between BAD and non-BAD patients in the improvement of any item. Rifaximin treatment did not modify SeHCAT value (9.5% before treatment and 10.7% after treatment; P=0.4).

Conclusion: Half of the patients diagnosed with IBS-D or FD present BAD according the SeHCAT test. Rifaximin treatment confers significant clinical improvement irrespective of the presence of BAD. Rifaximin treatment does not affect SeHCAT test.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In 10–15% of patients with irritable bowel syndrome (IBS), the onset of symptoms follows an episode of gastrointestinal infection or use of antibiotics. Both antibiotic-induced and post-infectious IBS may be caused by alterations of the gut microbiota, which provides a rationale for treatment with fecal microbiota transplantation (FMT).

Aims & Methods: We performed an open label pilot study in the VU University medical center in Amsterdam from August 2016 through January 2017, to evaluate the effect of FMT in patients with post-infectious IBS (n = 5) and patients with antibiotic-induced IBS (n = 5). Participants with clinical symptoms lasting over six months, an IBS-symptom severity score (IBS-SSS) of at least 175 points, and a negative screening for gastrointestinal pathology were eligible. Donor feces (198 ml) was provided by the Netherlands Donor Feces Bank (NDFB) and administered via a duodenal tube. Participants did not receive pre-treatment or bowel cleansing. Participants were followed for eight weeks via two validated questionnaires: IBS-SSS (range 100–500), and IBS-Quality of Life score (IBS-QOL; range 0–100%). Fecal samples were obtained before and after FMT for microbiota analysis. Following the recommendation of the European Agency Medicines, FMT was considered clinically effective if participants reported an IBS-SSS improvement of at least 30% compared to baseline, eight weeks after FMT.

Results: The mean IBS-SSS of all patients had improved significantly from 328 (±74) points at baseline to 245 (±117) at eight weeks after FMT (p = 0.008); the median IBS-SSS improved with 40% from 340 (range 230–480) to 205 (range 80–470). Also, a significant improvement was seen in abdominal pain (p = 0.039), satisfaction about bowel habit (p = 0.018), and influence of IBS symptoms on daily life (p = 0.011). There was no difference in bloating, or number of days with abdominal pain. The mean IBS-QOL improved from 51% to 66% (p = 0.008). FMT was considered effective in three patients with antibiotic-induced IBS, and one patient with post-infectious IBS (≥30% improvement). In general, fecal microbiota analysis showed that the microbiota composition of responders shifted to that of their corresponding donors. Non-responders initially also did (which was associated with IBS-SSS improvement), however, eight weeks after FMT, the microbiota composition had shifted back towards baseline.

Conclusion: Treatment with FMT appears promising for antibiotic-induced and post-infectious IBS. Based on these results, a randomized placebo controlled trial is warranted.

Introduction: Adequate relief (AR) of irritable bowel syndrome (IBS) symptoms is a commonly used global outcome measure to assess treatment benefit in both clinical trials and real-life clinical practice. Conversely, inadequate relief (IR) is considered an important driver for patients to use healthcare resources such as general practitioner or gastroenterologist consultations. Eluxadoline (ELX) is a mixed μ -opioid receptor (OR) and κ -OR agonist and δ -OR antagonist approved for the treatment of IBS with diarrhoea (IBS-D) in the US and Europe.

Aims & Methods: To evaluate IR in patients treated with ELX in a *post hoc* analysis from two randomised, double-blind, placebo (PBO)-controlled Phase 3 trials (IBS-3001, IBS-3002). Patients meeting Rome III criteria for IBS-D were randomised 1:1:1 to twice-daily (BID) ELX (75 or 100 mg) or PBO. Efficacy was evaluated through Week 26. For evaluation of AR, patients were asked “In the last 7 days, have you had adequate [or satisfactory] relief of your IBS symptoms?” (Yes/No) on a weekly basis, via an electronic diary. As previously described, patients answering “Yes” for $\geq 50\%$ of the total weeks during the target time interval were considered AR responders.^{1,2} Patients answering “No” were considered to have IR. This analysis evaluated the number of consecutive weeks that patients reported IR over Weeks 1–12 and 13–24 of treatment. Patients without AR analysis were ineligible for intention-to-treat (ITT) analysis; missing data were not imputed.

Results: Overall, 2428 patients with IBS-D were enrolled across the two Phase 3 trials and 2423 were included in the ITT analysis. In the pooled dataset, a significantly greater proportion of patients were AR responders² with either ELX 100 or 75 mg BID vs PBO at 12 weeks (56.1% [p < 0.001] and 56.3% [p = 0.001] vs 46.4%, respectively) and at 26 weeks (51.5% [p < 0.001] and 49.0% [p = 0.004] vs 41.8%, respectively).³ Over the first 12 weeks of treatment, a greater proportion of patients reported no IR of IBS-D symptoms with ELX 100 or 75 mg BID vs PBO (Table). Greater proportions of patients reported only 1–<5 consecutive weeks of IR with ELX 100 or 75 mg BID vs PBO. A significantly lower proportion of patients reported IR for >8 consecutive weeks with ELX 100 or 75 mg BID vs PBO (13.2% [p < 0.0001] and 15.6% [p = 0.004] vs 22.6%, respectively). In contrast, a greater proportion of patients reported IR for the full 12 consecutive weeks with PBO vs ELX 100 or 75 mg BID (Table). Similar results were observed in Weeks 13–24 of treatment, with ELX-treated patients generally having fewer consecutive weeks of IR compared to PBO-treated patients (Table).

Table: Consecutive weeks of inadequate relief

	Weeks 1–12			Weeks 13–24		
	PBO (n = 809)	ELX 75 mg BID (n = 808)	ELX 100 mg BID (n = 806)	PBO (n = 809)	ELX 75 mg BID (n = 808)	ELX 100 mg BID (n = 806)
Inadequate relief rate, %						
Number of consecutive weeks with inadequate relief						
0	14.4	23.6	24.8	26.8	39.5	37.1
1–< 5	46.7	50.2	49.2	35.9	33.8	37.6
5–≤ 8	16.3	10.7	12.7	13.1	8.6	8.5
> 8–< 12	5.3	3.8	2.9	4.7	3.9	3.7
≥ 12	17.3	11.8	10.3	19.4	14.1	13.1

Conclusion: In this *post hoc* analysis of the pooled ELX Phase 3 studies, ELX-treated patients experienced fewer consecutive weeks of IR compared to those receiving PBO, within both Weeks 1–12 and 13–24 of treatment. As IR is thought to drive increased healthcare provider visits, these data suggest that ELX could potentially reduce healthcare resource use and subsequent healthcare costs associated with IBS. Further prospective study of the impact of ELX on AR and any subsequent reduction in healthcare costs is required, including the relationship between the number of consecutive weeks of IR and patients’ behaviour towards healthcare resource use.

Introduction: Irritable bowel syndrome with diarrhoea (IBS-D) is a chronic gastrointestinal disorder characterised by recurrent abdominal pain associated with diarrhoea. Eluxadoline, a mixed μ - and κ -opioid receptor agonist and δ -opioid

receptor antagonist, is approved for the treatment of IBS-D in adults, based on two large Phase 3 clinical trials where eluxadoline met the primary composite response endpoint of simultaneous improvement in abdominal pain and stool consistency over 26 weeks.

Aims & Methods: These *post hoc* analyses of two double-blind, placebo-controlled, Phase 3 clinical trials of eluxadoline (IBS-3001 and IBS-3002) aimed to assess responder and non-responder rates over 4-week intervals for eluxadoline vs placebo, and the proportion of responders/non-responders who continued or discontinued treatment. Patients meeting Rome III criteria for IBS-D were randomised to twice-daily treatment with eluxadoline (75 or 100 mg) or placebo. Patients rated IBS symptoms daily, including worst abdominal pain (WAP; 0–10 scale, with 0=no pain and 10=worst imaginable pain), stool consistency (Bristol Stool Form Scale [BSFS]), and Global Symptom Score (GSS; 0–4 scale, where 0=no symptoms and 4=very severe symptoms). A responder for a 4-week interval was defined as a patient with a simultaneous daily improvement of $\geq 30\%$ in WAP score vs baseline and BSFS score < 5 with $\geq 50\%$ of days demonstrating a response and a minimum of 20 days of diary data. The intention-to-treat (ITT) analysis set included all patients randomised to a treatment group. For these analyses, patients with baseline GSS ≥ 3 (severe or very severe symptoms) and self-reported inadequate symptom control with loperamide were classified as having severe IBS-D.

Results: Of the 2423 patients in the pooled Phase 3 ITT population, 249 were classified as having severe IBS-D. Over Weeks 1–4, 26.8% and 30.3% of patients with severe IBS-D were responders with eluxadoline 75 and 100 mg, respectively, vs 8.1% of patients on placebo (Table). Higher proportions of patients were responders with eluxadoline vs placebo over each subsequent 4-week interval, with response rates observed at Weeks 1–4 consistently maintained across all subsequent 4-week time intervals. With both eluxadoline and placebo, proportions of responders discontinuing were $< 2\%$ across each 4-week interval, and discontinuation rates in non-responders were higher than in responders (Table). Similar findings were observed in the ITT analysis set: over Weeks 1–4, 22.7% and 24.6% of patients were responders with eluxadoline 75 and 100 mg, respectively, vs 12.5% of patients on placebo. Over Weeks 21–24, 28.1% and 30.2% of patients were responders with eluxadoline 75 and 100 mg, respectively, vs 20.1% on placebo. Discontinuation rates among responders with both eluxadoline and placebo remained $< 1\%$ across all 4-week time intervals.

Table

Weeks	Placebo (n = 74)				Eluxadoline 75 mg (n = 86)				Eluxadoline 100 mg (n = 89)			
	Responder, %		Non-responder, %		Responder, %		Non-responder, %		Responder, %		Non-responder, %	
	C	DC	C	DC	C	DC	C	DC	C	DC	C	DC
1–4	8.1	0.0	89.2	2.7	25.6	1.2	68.6	4.7	29.2	1.1	58.4	11.2
5–8	18.9	1.4	73.0	6.8	30.2	0.0	55.8	14.0	31.5	1.1	49.4	18.0
9–12	18.9	0.0	63.5	17.6	31.4	0.0	52.3	16.3	30.3	1.1	47.2	21.3
13–16	16.2	1.4	63.5	18.9	30.2	0.0	52.3	17.4	27.0	0.0	48.3	24.7
17–20	24.3	0.0	50.0	25.7	33.7	0.0	40.7	25.6	37.1	0.0	37.1	25.8
21–24	14.9	1.4	54.1	29.7	30.2	1.2	39.5	29.1	29.2	1.1	38.2	31.5

C, patients continuing on treatment; DC, patients discontinuing from treatment

Conclusion: Proportions of responders with eluxadoline 75 and 100 mg were consistently higher vs placebo across all 4-week intervals in the treatment period in patients defined as having severe IBS-D. Furthermore, discontinuation rates among patients showing a treatment response remained consistently low compared to non-responders. However, as these analyses were conducted in a clinical trial setting, the relatively high continuation rates in non-responders may not reflect the real-world situation. These findings suggest that eluxadoline has sustained efficacy in treating the diarrhoea and abdominal pain associated with IBS-D, including in patients with severe and inadequately managed symptoms.

P1148 THE LOW FODMAP DIET REDUCES CAECAL FERMENTATION COMPARED TO TRADITIONAL DIETARY ADVICE: A RANDOMISED CONTROLLED TRIAL

A. D. Farmer¹, N. Saini², A. R. Hobson²

¹Gastroenterology, University Hospitals of North Midlands, Stoke on Trent/United Kingdom

²Functional Gut Clinic, London/United Kingdom

Contact E-mail Address: a.farmer@qmul.ac.uk

Introduction: Diets reducing the content of fermentable short chain carbohydrates (fermentable oligo-, di-, monosaccharides, and polyols (FODMAPs)) as well as the National Institute of Health Care Excellence (NICE) diet have been reported to be effective in the treatment of patients with irritable bowel syndrome (IBS) (1,2). The mechanisms by which this efficacy is achieved are incompletely understood but it has been proposed that such diets reduce fermentation, mediated by changes in the microbiota (3). Change in pH around the ileocaecal junction is considered to be a surrogate biomarker of caecal fermentation (4,5).

Aims & Methods: We aimed to compare the effect of a low FODMAP diet vs. the NICE diet on change in ileocaecal pH. We performed a single centre, randomized controlled trial of adult patients with Rome III defined IBS-mixed bowel habit (IBS-M) comparing the two dietary interventions. At baseline, patients ingested a wireless motility capsule (WMC) using a standardized protocol. Segmental transit times were derived from measures around known anatomical landmarks as identified by compartmental pH changes. Ileal and colonic motility measures are presented as area under the curve (AUC) derived from contraction amplitude and frequency. Validated questionnaires evaluating GI (verbal descriptor anchored visual analog scale (VDVAS) assessing sensory intensity (VDVAS-I) and unpleasantness (VDVAS-U)) and somatic symptoms (Personal Health Questionnaire (PHQ)) as well as quality of life (EQ-5D) were administered. The WMC and questionnaires were repeated after 28 days of dietary interventions. The primary endpoint was change in ileocaecal pH after the intervention. Secondary outcomes included changes in transit times, contractility and symptom scores.

Results: After screening, 32 patients (23 female, median age 37 years, range 18–65) were randomized. Baseline symptom severity and demographics were similar between the two groups. Relative to baseline, there was a reduction in the change in ileocaecal pH with the low FODMAP diet group compared to the m-NICE group (3.37 ± 0.3 vs 0.0003 ± 0.4 , $p = 0.047$) suggesting reduced fermentation. Changes in GI motility are shown in Table 1.

Table 1: Changes in segmental/whole gut transit times and ileal/colonic motility, relative to baseline between the low FODMAP and m-NICE diets. Both the low FODMAP and NICE diets improved VDVAS-I and VDVAS-U (-18 ± 17 vs. -26 ± 27 , $p = 0.4$ and -13.6 ± 26 vs. -29.7 ± 29 , $p = 0.2$, respectively). Similarly, both diets reduced somatic symptoms (-2 ± 1.4 vs. -0.8 ± 1.8 , $p = 0.07$) and improved quality of life (9.5 ± 10.2 vs. 4.4 ± 9.8 , $p = 0.23$).

	Low FODMAP	NICE	P value
Change in Gastric emptying time (minutes)	122 \pm 249	7 \pm 370	0.5
Change in Small bowel transit time (minutes)	63 \pm 43	-33.6 \pm 80	0.07
Change in Colonic transit time (minutes)	512 \pm 1425	53 \pm 1728	0.53
Change in Whole Gut Transit time (minutes)	710 \pm 1486	-35 \pm 1588	0.3
Change in Ileal contractility (AUC)	64 \pm 139	114 \pm 175	0.5
Change in Colonic contractility (AUC)	5 \pm 58	26 \pm 72	0.5

Conclusion: The low FODMAP diet reduces caecal fermentation in comparison to the NICE diet as indexed by a reduction in the change in pH across the ileocaecal junction. Both diets improved GI and extra-GI symptoms as well as quality of life. Neither diet has a demonstrable differential effect on ileal/colonic contractility or segmental/whole gut transit times. It is therefore plausible that the efficacy of the low FODMAP diet in IBS-M is via mediated by alterations in the microbiota.

P1149 ORAL A-GALACTOSIDASE IMPROVES GASTROINTESTINAL TOLERANCE TO A DIET HIGH IN GALACTO-OLIGOSACCHARIDES: ADJUNCT THERAPY TO A LOW FODMAP DIET IN IRRITABLE BOWEL SYNDROME

C. J. Tuck¹, K. M. Taylor², J. S. Barrett¹, P. R. Gibson¹, J. G. Muir¹

Introduction: Galacto-oligosaccharides (GOS) are indigestible short-chain carbohydrates (FODMAPs, fermentable, oligo-, di-, mono-saccharides and polyols)

associated with triggering gastrointestinal symptoms in irritable bowel syndrome (IBS).

Aims & Methods: This study aimed to assess whether oral α -galactosidase ingestion with foods high in GOS and low in other FODMAPs would reduce symptoms and breath hydrogen production in a double-blind, placebo-controlled, cross-over trial approved by Monash University Ethics Committee. Patients meeting the Rome III criteria for IBS who produced >10 ppm hydrogen on two consecutive breath samples following 10 g fructan were recruited. Participants were randomly assigned to full-dose enzyme (300 GALU α -galactosidase), half-dose (150 GALU α -galactosidase) and placebo (glucose). Following a 3-day low FODMAP run-in period, participants consumed provided diets high in GOS for a further 3-days. Gastrointestinal symptoms were measured daily using a 100 mm visual-analogue-scale. Breath samples were taken hourly on the second last day and analysed as area-under-the-curve, faecal samples were taken on the final day.

Results: Thirty-one participants with IBS (20 IBS-D, 4 IBS-C, 7 IBS-M) completed the study. The addition of high GOS foods resulted in a significant increase in overall symptoms (median 13.0 [IQR 1.5–22.0] to 35.5 [12.8–54.0] mm; $p=0.000$, Wilcoxon signed-rank test). No significant increase in overall symptoms was seen with the full-dose enzyme (14.0 [3.5–24.0] vs 14.7 [2.3–32.7] mm; $p=0.422$). Twenty-one participants exhibited GOS-sensitivity (>10 mm increase for overall symptoms). Of those, full-dose enzyme reduced overall symptoms (24.5 [17.5–35.8] mm vs 5.5 [1.5–15.0] mm; $p=0.006$) and bloating (20.5 [9.5–42.0] vs 6.5 [2.0–15.8]; $p=0.017$). Breath hydrogen production was minimal with no differences seen between placebo (mean $5248 \pm SD$ 3339 ppm.12h) and full-dose (5585 ± 3205 ; $p=0.597$, paired samples t-test).

Conclusion: An oral α -galactosidase supplement taken with high GOS foods provides a clinically significant reduction in symptoms in GOS-sensitive individuals with IBS. The lack of change in breath hydrogen suggests the mechanism may not be related to reduced gas and distention, rather suggesting a role of alterations to the microbiota. Future analysis of the faecal microbiota may provide insight for the mechanism of action. This strategy can be easily translated into practice to improve tolerance specifically to high GOS foods for patients with IBS as an adjunct therapy to the low FODMAP diet.

P1150 A SYSTEMATIC REVIEW AND META-ANALYSIS TO DETERMINE WHETHER BALLOON EXPULSION TESTING MIGHT BE AN APPROPRIATE INITIAL OFFICE-BASED TEST FOR DYSSYNERGIC DEFECATION

E. D. Shah¹, J. Farida¹, W.D. Chey²

¹Division Of Gastroenterology, University of Michigan, Ann Arbor/United States of America

²Gastroenterology, Internal Medicine, University of Michigan, Ann Arbor, MI/United States of America

Contact E-mail Address: ershah@med.umich.edu

Introduction: Balloon expulsion testing (BET) is a recommended means of identifying dyssynergic defecation (DD) in patients with chronic constipation (CC) but remains poorly standardized and underutilized outside of specialized centers. We aimed to assess the clinical utility of BET as an initial test for DD and to determine appropriate testing parameters.

Aims & Methods: We performed a literature search (PubMed, EMBASE, conference abstracts from 1950–2016) to identify (1) case-control studies of DD or unselected CC subjects and healthy controls and (2) cohort studies of unselected subjects with CC. Eligible studies reported BET test parameters and results as well as presence of DD defined by constipation symptoms and a positive reference test (anorectal manometry[ARM], defecography, or electromyography[EMG]). Study quality was assessed using QUADAS criteria. We extracted age, sex, enrollment criteria, BET test parameters (subject position, stool surrogate, volume instilled, allowed expulsion time), and DD diagnostic criteria. Data were independently extracted by two authors. Meta-analysis was performed using a bivariate mixed-effects regression model. Meta-regression was performed to evaluate effects of individual test parameters. Between-study heterogeneity of summary results was assessed using an I^2 statistic. Publication bias was assessed using Deeks' funnel plot asymmetry test.

Results: We identified 15 eligible studies comprising 2,090 individual assessments of balloon expulsion, of which 14 studies of 1,760 subjects were eligible for cohort analysis and 15 studies of 1,988 subjects were eligible for case-control analysis. Among cohort studies, the AUC was 0.80 (95% CI 0.61–0.91) with 70% sensitivity (95% CI 52%–83%) and 77% specificity (95% CI 70%–82%). Among pooled cohort and case-control studies, the AUC was 0.84 (95% CI 0.68–0.93) with 70% sensitivity (95% CI 53%–82%) and 81% specificity (95% CI 75%–86%). Further test performance characteristics stratified by subject position are reported in Table 1. Subject positioning (seated vs. left lateral decubitus) did not significantly affect AUC in cohort ($p=0.82$) or case-control ($p=0.43$) analysis. Pooled sensitivity ($p=0.50$) and specificity ($p=0.66$) were similar between seated and left lateral BET in analysis of unselected CC cohort studies, though specificity was higher with left lateral BET in pooled analysis of all studies ($p=0.03$). The allowable time for balloon expulsion did not significantly affect summary

sensitivity ($p=0.92$) or specificity ($p=0.96$) in meta-regression within the evaluated range of 1 and 5 minutes. While there were not enough studies to warrant meta-analysis of balloon distension characteristics, 13 of 17 studies instilled 50–60 mL of water. When pooling cohort and case-control studies, both age ($p<0.01$) and gender ($p<0.01$) appeared to influence test performance. Choice of reference test did not significantly affect test performance (ARM [$p=0.35$], defecography [$p=0.43$], or EMG [$p=0.08$]). Continent of origin ($p=0.34$) and year of study ($p=0.29$) did not appear to significantly influence test performance. There was no evidence of publication bias ($p>0.5$).

Table 1: Sensitivity and specificity of balloon expulsion testing in diagnosing dyssynergic defecation (stratified by subject positioning with 95% confidence intervals)

Summary test characteristic	Seated position	Left lateral position
<i>Case-control and cohort studies (optimal estimates)</i>		
Sensitivity	69% (54% to 85%)	54% (7% to 100%)
Specificity	81% (76% to 86%)	90% (79% to 100%)
<i>Only cohort studies evaluating unselected subjects with constipation (real world estimates)</i>		
Sensitivity	69% (53% to 86%)	76% (70% to 83%)
Specificity	54% (6% to 100%)	76% (51% to 100%)

Conclusion: The performance characteristics of balloon expulsion could support use as an office-based point-of-care test to screen for dyssynergic defecation in chronically constipated subjects.

Introduction: Anal squamous intraepithelial lesions are precancerous lesions of anal squamous cell carcinoma and are largely related to human papillomavirus infection. Immunosuppressed patients have a higher prevalence of these lesions. There are some studies in renal transplant recipients, but no information exists regarding prevalence in liver transplantation.

Aims & Methods: Our aim was to evaluate the prevalence of anal squamous intraepithelial lesions in liver transplant recipients compared with healthy subjects. This was a prospective case-control study involving liver transplant recipients that were compared with a healthy control group. All patients were submitted to anal cytology. Those with abnormal cytological results, namely high-grade squamous intraepithelial lesions (HSIL), atypical squamous cells which cannot exclude high-grade squamous intraepithelial lesions (ASC-H), low-grade squamous intraepithelial lesions (LSIL) and atypical squamous cells of undetermined significance (ASC-US), were submitted to high-resolution anoscopy with biopsies of any suspicious lesion.

Results: A total of 59 liver transplant recipients and 57 controls underwent anal cytology. In the liver transplant group, 37 (63%) were men, with a mean age of 54 ± 10 years. The most common indication for transplantation was alcoholic cirrhosis in 26 patients (44%), the majority of the patients were only on tacrolimus ($n=23$, 39%) and had been transplanted a mean of 8 ± 5 years ago. In the healthy control group, 36 (63%) were men, with a mean age 59 ± 11 years. Regarding anal cytology, 10 (17%) of liver transplant recipients had abnormal results, 7 patients had ASC-US, 1 patient ASC-H and 2 patients HSIL. In the control group only 1 patient (2%) had an ASC-US result ($p=0.005$). Anal squamous intraepithelial lesions were confirmed in 7/10 of liver transplant patients and 0/1 in control group ($p=0.013$) by high-resolution anoscopy with biopsies. Smoking was the only risk factor for abnormal anal cytology (OR = 5.9, 95%CI = 1.224–28.121, $p=0.027$).

Conclusion: Liver transplant patients have a higher risk of anal squamous intraepithelial lesions and screening should be considered especially in smokers.

Disclosure of Interest: All authors have declared no conflicts of interest.

OESOPHAGEAL, GASTRIC AND DUODENAL DISORDERS II - HALL 7_**P1152 IMMUNOHISTOCHEMICAL EXPRESSION OF DIAMINE OXIDASE IN THE UPPER GASTROINTESTINAL TRACT OF PATIENTS WITH GASTROINTESTINALLY MEDIATED FOOD ALLERGY**T. Vasilakis¹, R. J. Rieker², J. Heinrich³, A. Missbichler⁴, A. F. Hagel¹, J. Kressel¹, M. Raithel³¹University Clinical Center Erlangen, Erlangen/Germany²Pathologisches Institut, University Clinical Center Erlangen, Erlangen/Germany³St. Marien Waldkrankenhaus, Erlangen/Germany⁴SCIOTEC Diagnostic Technologies GmbH, Tulln/Austria**Contact E-mail Address:** thomas.vasilakis@gmx.de

Introduction: Gastrointestinally mediated food allergy (GMA) is a common disease, whose prevalence has risen in recent years. The scientific research on this disease has increased, however its diagnosis still remains difficult to date. Diamine oxidase (DAO) is an enzyme that deactivates histamine, the main mediator in allergic reactions, through oxidative deamination. It has been shown that the enzymatic activity of DAO is diminished in the colonic mucosa of patients with GMA. Up to now no studies concerning the expression of DAO in the upper gastrointestinal tract (GIT) of patients with GMA have been published. Therefore, the objective of this study was to analyse the immunohistochemical staining of DAO and its localisation in the upper GIT of patients with or without GMA.

Aims & Methods: The study was retrospective. The GMA group consisted of 21 patients with diagnosed food allergy. The control group (CG) included 17 patients with neither food allergy nor food intolerance. Tissue samples from esophagus, cardia (subdivided in esophageal and gastric region), corpus, antrum and duodenum already obtained during endoscopy were immunohistochemically stained for DAO. The expression of DAO was semi-quantitatively analysed with the following scale based on the staining intensity of DAO (SI-DAO): 0 = none, 1 = low, 2 = medium, 3 = high intensity. The localisation of DAO was also examined vertically from the epithelium to the submucosa in all tissues. The analysis was performed twice by the same examiner in two separate points of time. Furthermore, the tissue samples were immunohistochemically stained for MBP and CD117 in order to count the number of eosinophils and mast cells respectively. Two measurements were performed inside an area of 100µm² in the lamina propria (LP); one in the subepithelial superficial lamina propria (SLP) and one in the deeper lamina propria (DLP). The average of these two measurements constituted the number of these cells for each tissue.

Results: Immunohistochemical analysis found DAO in all segments of the upper GIT, but the SI-DAO was overall low. Across the upper GIT the median SI-DAO in the CG was 1.1 (range 0.9–1.3). The SI-DAO did not differ between the examined tissues. The SI-DAO was also low in the GMA group (median 1.0; range 0.8–1.3) and it was statistically significantly lower compared to the controls (median: 0.8 vs. 1.1; $p=0.04$) only in duodenum. In the GMA group the SI-DAO in the esophageal region of the cardia and in corpus was significantly higher than in duodenum (see Table 1). The strongest DAO-staining was detected in the subepithelial lamina propria (SLP) of all tissues. A strong inverse correlation of SI-DAO with the number of eosinophils across the upper GIT was observed only in the GMA group ($r=-0.89$, $p=0.02$). An inverse correlation of the SI-DAO with the number of mast cells was also observed in both groups, but this result was not statistically significant (GMA: $r=-0.71$, $p=0.11$; CG: $r=-0.6$, $p=0.14$).

Table 1: SI-DAO in the upper GIT. P1-Value: comparison between GMA and control group. **P2-Value:** comparison of the SI-DAO in duodenum with the other segments of the upper GIT in the GMA-group. N = number of tissue samples

Group	Parameter	Esophagus	Cardia	gastric region	Corpus	Antrum	Duodenum
			-esophageal				
GMA	N	9	10	8	18	18	18
	Median	1.3	1.1	1.1	1.2	1.1	0.8
	25th Percentile	0.8	0.8	0.8	0.7	0.7	0.4
	75th Percentile	1.5	1.3	1.1	1.5	1.4	1.3
Control	N	8	9	8	15	14	11
	Median	1.3	1.2	1.3	0.9	0.9	1.1
	25th Percentile	1.1	1.0	0.9	0.8	0.7	1.0
	75th Percentile	1.7	1.4	1.6	1.2	1.1	1.5
	P1 - Value	0.33	0.41	0.46	0.29	0.28	0.04*
	P2 - Value	0.07	0.01*	0.06	0.02*	0.16	x

Conclusion: The above findings indicate that DAO is present in low amounts in all segments of the upper GIT. But only in the duodenum a significant difference was found between GMA and CG, thus indicating that histamine-mediated symptoms most likely arise in duodenum. Therefore, regarding the upper GIT, the immunohistochemical staining for DAO only in duodenum could serve as an additional diagnostic parameter for detecting patients with GMA and possibly other histamine-mediated diseases. The above mentioned distribution pattern of DAO strengthens the theory that DAO acts extracellularly and is responsible for the elimination of the transepithelially absorbed exogenous histamine as well as of the endogenous histamine, as its highest staining intensity is found at the SLP throughout the upper GIT.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Chronic atrophic gastritis (CAG) is claimed to be a pre-cancerous condition for gastric cancer, being serological markers like serum pepsinogens and gastrin-17 (G17) proposed as non-invasive useful tools. OLGA histological classification has been proposed as of prognostic value. Aim of the study was to assess, by using serological markers, the prevalence of CAG in general population and to correlate the results with OLGA classification.

Aims & Methods: One thousand and nine hundred consecutive patients (M = 915; mean age = 53.5, range = 27–82) showing upper-gastrointestinal (GI) troubles entered the study. Exclusion criteria were: previous history of upper-GI neoplasms, previous surgery, concomitant Proton Pumps Inhibitor (PPI) therapy. All patients underwent a blood sample for GASTROPANEL® (BioHit Oyj, Finland) based on: pepsinogen I (PGI), pepsinogen II (PGII), gastrin-17 (G-17) and IgG against *Helicobacter pylori* (Hp-IgG). The normal values are: PGI: 30–120 µg/L, PGII: 2–15 µg/L, G-17: 1–9 pmol/L, Hp-IgG: <30 EIU, respectively. Low levels of PGI (PGI < 30 µg/L) as well as high levels of G-17 (G-17 > 15 pmol/L) were considered diagnostic for CAG. Eighty-three patients with serology suggestive for CAG underwent upper endoscopy and histology according with OLGA staging. The relationship between PGI, G-17 and the different OLGA stages was statistically analyzed.

Results: Eighty-three (M = 44, mean age = 61, range = 49–82) out of 1900 investigated patients showed CAG (4%). Out of the 83 CAG patients, 19.2% was classified as OLGA 2, 56.6% as OLGA 3 and 24.2% as OLGA 4. The relationship between PGI levels and OLGA stage shows a statistically significant difference between the stages OLGA 0, 1, 2 and the stages 3 and 4 (PGI mean values: OLGA 0: 72.45 µg/L, OLGA 1: 85.95 µg/L, OLGA 2: 47.38 µg/L, OLGA 3: 16.00 µg/L, OLGA 4: 10.10 µg/L; $p < 0.001$). The relationship between OLGA stages and G-17 serum levels shows a statistically significant difference (G-17 mean values: OLGA 0: 4.6 pmol/L, OLGA 1: 5.2 pmol/L, OLGA 2: 26.5 pmol/L, OLGA 3: 44.6 pmol/L, OLGA 4: 38.5 pmol/L; $p < 0.01$ by comparing OLGA 0–1 against OLGA 2–4) ($p < 0.02$).

Conclusion: The prevalence of CAG assessed by serological markers is low in the studied population (4%). The majority of patients (56.6%) were classified in the OLGA 2 stage. Both PGI and G-17 showed a statistical significant relationship with the more severe degrees of CAG.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1154 IMPROVEMENT OF SYMPTOMS IN PATIENTS AFFECTED BY CHRONIC ATROPHIC GASTRITIS: A TWO-YEAR PROSPECTIVE STUDY BY USING L-CYSTEINEG. Masciangelo¹, L. Franzoni¹, C. Miraglia¹, P. Crafa¹, S. Scida¹, M. Franceschi², R. Cannizzaro³, N. Dal Bò⁴, C. Scarpignato¹, M. Rugge⁵, F. Di Mario¹¹Department Of Medicine And Surgery, University of Parma, Parma/Italy²Endoscopic Unit, Department Of Surgery, Ulss4, Hospital ULSS4 Alto Vicentino, Santorso/Italy³Oncological Gastroenterology, Centro di Riferimento Oncologico di Aviano S.O.C. di Gastroenterologia, Aviano/Italy⁴Gastroenterological Unit, Treviso Hospita, Treviso/Italy⁵Pathology, Medical School of the Padova University, Padova/Italy**Contact E-mail Address:** francesco.dimario@unipr.it

Introduction: Chronic atrophic gastritis (CAG) is considered to be a precancerous condition of gastric cancer; it is either autoimmune in origin or caused by infection with *Helicobacter pylori*. The majority of CAG patients are asymptomatic or experience aspecific manifestations like epigastric fullness, early satiation, nausea, bloating. The drugs currently used for upper gastrointestinal (GI) diseases, mainly proton pump inhibitors (PPIs), appear inappropriate in such patients, mainly because acid production is virtually lacking. The use of

L-cysteine has been proposed as adjuvant therapy in CAG; the amino acid binds covalently to acetaldehyde (a Group I human carcinogen), removing it from the stomach. The aim of present study was to use L-cysteine to improve the symptoms in patients with diagnosis of CAG.

Aims & Methods: One hundred fourteen consecutive patients (M=43, mean age=52.5 yr, range=31–69 years) (with histological diagnosis of CAG by means of both gastric histology (moderate to severe chronic, atrophic, body gastritis according to the OLGA staging system) and serology (pepsinogen 1 <25 µg/l; gastrin-17 >14 pmol/l - GastroPanel®, Biohit Oyj, Finland) entered the study. Forty-one patients (11 M, mean age 49.4 yr, range 27–71 years) were treated with L-cysteine (100 mg 3 times daily, with meals) for 24 months (Group 1). As a control group we enrolled 73 CAG patients (M=32, mean age=55.3 yr, range=32–77 yrs) followed up for 24 months without any related therapy (Group 2). Symptoms (epigastric fullness, early satiation, nausea, bloating) were recorded at baseline and after 3, 6, 12, 24 months, according to severity score (0–3 for each symptom, min. 0=no symptoms; max. 12=full symptomatic).

Results: The global symptomatic score results as follows, lasting the 24 months follow-up. Group 1: baseline 4.93; 3 months 3.36; 6 months 2.96; 24 months 2.64. Group 2: baseline 5.9, 3 months 6.2, 6 months 5.6, 24 months 5.8 ($p < 0.01$). Subdividing the CAG patients according to the etiology (autoimmune gastritis or previous *Helicobacter pylori* infection) no differences were found in improving symptoms. No relevant side effects were observed during the study.

Conclusion: The administration of L-cysteine to subjects affected by moderate-severe chronic atrophic gastritis seems able to improve the symptoms in a two-year follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

PP155 PROGNOSTIC SIGNIFICANCE OF SERUM INFLAMMATORY MARKERS IN GASTRIC CANCER

A. Powell¹, D. Parkinson², N. Patel³, C. Brown³, W. Lewis³

¹Division Of Cancer And Genetics, Cardiff University, Cardiff/United Kingdom

²Cardiff & Vale University Health Board, Cardiff/United Kingdom

³General Surgery, University Hospital of Wales, Cardiff/United Kingdom

Contact E-mail Address: powella16@cardiff.ac.uk

Introduction: Despite undergoing potentially curative resection a significant proportion of patients develop cancer recurrence. Several cellular and humoral components of systemic inflammatory response have been reported and associated with poor outcome. To date, no study has comprehensively examined the relationship between readily available markers of inflammation and survival in gastric cancer.

Aims & Methods: Patients undergoing surgery for stage I-III gastric cancer between 2004–2016 at a regional unit were identified. Measurements of various systemic inflammation markers were recorded pre-operatively. Pathological factors were recorded from reports issued at the time of resection. The modified Glasgow Prognostic Score (based on CRP and Albumin), Neutrophil-Lymphocyte Ratio, Platelet-Lymphocyte Ratio and Neutrophil-Platelet score were calculated. Pathological variables including TNM stage, differentiation and vascular invasion were also recorded. Survival endpoints of overall survival (OS) and disease-free survival (DFS) were used.

Results: 331 patients were identified and 291 patients underwent potentially curative resection for gastric cancer. On univariable DFS analysis, female gender, proximal location, T-stage, N-stage, TNM, vascular invasion, poor differentiation, lymph node ratio, R1 status, platelet count and mGPS were significantly associated with poor survival. On multivariable DFS analysis, mGPS (Hazard Ratio (HR) 2.51 95% Confidence Interval (CI) (1.35–4.65); $p=0.011$) was the only inflammatory marker to retain independent significance. This was also observed in OS with mGPS (HR 2.75 (95%CI 1.65–4.59); $p < 0.001$). The mGPS was associated with advanced T-stage ($p=0.001$), TNM stage ($p=0.013$) and poor differentiation ($p=0.030$).

Conclusion: The mGPS was the only inflammatory based marker to independently predict poor DFS and OS and may represent the optimum method for systemic inflammatory response quantification.

Disclosure of Interest: All authors have declared no conflicts of interest.

PP156 ANALYSIS OF REBLEEDING PATIENTS IN UPPER GASTROINTESTINAL BLEEDING IN A SINGLE CENTER SERIES

R. Jiménez-Rosales¹, E. Ortega-Suazo¹, P. Abellán-Alfocea¹, F. Valverde López², J.G. Martínez-Cara¹, E. Redondo Cerezo¹

Introduction: Upper gastrointestinal bleeding (UGIB) is one of the main causes of hospital admission and urgent endoscopy in Gastroenterology departments. In-hospital mortality from UGIB has decreased throughout the past 2 decades with a corresponding increase in the performance of endoscopy and endoscopic therapies. This may suggest that improvements in the therapeutic procedures for patients with UGIB could be responsible of the mortality decline. Despite this, UGIB represents a true emergency, associated with significant morbidity, mortality and healthcare costs. Furthermore, rebleeding after initial endoscopic therapy is observed in 10–20%, and it has been associated with a higher mortality rate. Therefore, the definition of predictive factors for rebleeding is of outstanding importance.

Aims & Methods: The aim of our study is to analyze risk factors and outcomes in a population of patients who suffered rebleed. We present a retrospective study on a prospectively built database of patients with GI bleeding admitted to the Emergency Room of "Virgen de las Nieves" University Hospital over 42 months, from January 2013 to July 2016. All patients underwent upper endoscopy, and information regarding patients' demographic data, comorbidities, current medications (including antiplatelet drugs, NSAIDs and oral anticoagulants), clinical presentations, hemodynamics, admission laboratory test results, and endoscopic findings was collected. Interventions were documented, including the need for blood transfusion and the number of packed red cells units per patient, endoscopic therapy, interventional radiology procedures, and surgery. Clinical outcomes documented were in-hospital and delayed 6-months mortality, rebleeding and delayed 6-months bleeding and cardiovascular events.

Results: 507 patients were included (339 males; aged 64.21 ± 16.4). The incidence of rebleeding was 17.3% ($n=88$). In the univariate analysis, factors related with rebleeding were creatinine levels (1.52 vs. 1.15; $p < 0.001$), tachycardia (96.28 vs. 88.24; $p < 0.001$), low levels of albumin (2.80 vs. 3.238; $p < 0.001$) and low systolic blood pressure (103 vs. 113; $p < 0.001$). In a logistic regression analysis tachycardia and high creatinine were independent risk factors for rebleeding, and albumin showed as an independent protective factor (Table 1). Rebleeding was associated with in-hospital mortality ($p < 0.0001$); by contrast, it was not related nor with delayed 6-months mortality, neither with delayed cardiovascular and hemorrhagic events. The UGIB risk scores AIMS 65 and Rockall showed poor predictive ability for acute mortality in the rebleeding patients' group and was similar for Blatchford score (based on AUROC).

	Exp (B)	IC 95%	P
PULSE	1.021	1.007–1.034	0.003
ALBUMIN	0.406	0.267–0.618	0.000
CREATININ	1.403	1.079–1.824	0.012

Conclusion: Rebleeding in UGIB is associated with increased in-hospital mortality; nevertheless, it is not related with delayed 6-months mortality, hemorrhagic and cardiovascular events. High creatinine and low albumin levels were independent risk factors for rebleeding, suggesting a potential predictive role of these parameter. AIMS65, Rockall and Blatchford were predictors for in-hospital mortality but worked poorly in the patients who suffered rebleeding.

PP157 A CASE-CONTROL STUDY ON THE RISK OF UPPER GASTROINTESTINAL MUCOSAL INJURIES IN SUBJECTS PRESCRIBED NSAIDS AND ANTI-THROMBOTIC DRUGS USING THE LARGE ORGANIZED DATABASE OF CLAIMS IN JAPAN (APPROXIMATELY 3.7 MILLION OF POPULATION ON AN ACCUMULATED BASIS)

Introduction: Upper gastrointestinal (GI) adverse effects induced by NSAIDs and anti-thrombotic drugs are increasing along with progressive aging of society. Recently it is essential to perform pharmaco-epidemiological studies to identify adverse effects in the real-world setting using a large-scale medical database. We conducted a case-control study on the risk of upper GI mucosal injuries in subjects prescribed NSAIDs and anti-thrombotic drugs using the large organized database of claims in Japan.

Aims & Methods: The medical claims database developed by Japan Medical Data Center (JMDC) Co., Ltd. was selected as data source in the present retrospective observational study. The JMDC claims database comprised of integrated medical and pharmacy claims, and includes both hospital and outpatient care from over 90 payers (approximately 3.7 million of population on an accumulated basis). Eligible subjects were aged 20 to 74 and registered for at least 3 months in the database from January 2009 to December 2014. The evaluated upper GI mucosal injuries were peptic ulcers (143,271 cases), upper GI bleeding (10,545 cases) and gastroesophageal reflux disease (GERD: 154,755 cases) with diagnosis by ICD-10 codes and implementation of the upper GI endoscopy. For the each test-case, ten controls who matched age, sex and diagnosis month were identified from the database. Multivariate logistic regression analysis was used to calculate odds ratios of occurrence of each upper GI mucosal injuries caused by NSAIDs, COX-2 selective inhibitors, low-dose aspirin, antiplatelet drugs (except low-dose aspirin) and anticoagulants.

Results: The odds ratios of peptic ulcers were 1.45, 1.31, 1.50, 1.53 and 1.62 for NSAIDs, COX-2 selective inhibitors, low-dose aspirin, antiplatelet drugs, and anticoagulants, respectively. All the medicines significantly affected the occurrence of peptic ulcers ($p < 0.0001$ in each). The odds ratios of upper GI bleeding were 1.76, 1.62, 1.96, 1.82 and 2.38, and those of GERD were 1.54, 1.41, 1.89, 1.67 and 1.91, and these odds ratios were statistically significant in each medicine with GI bleeding and GERD ($p < 0.0001$ in each). The odds ratios of all the upper GI mucosal injuries were the highest in the patients with anticoagulants, and the ratios were relatively low in those with NSAIDs and COX-2 selective inhibitors. The odds ratios tended to increase with the number of prescribed

medicines (1 agent <2 agents <3 agents, peptic ulcers: 1.38 < 2.49 < 4.52, upper GI bleeding: 1.74 < 3.95 < 7.77, GERD: 1.61 < 2.96 < 5.88, respectively). The upper GI mucosal injuries were exacerbated in complication of lifestyle-related diseases, including hyperlipemia and diabetes mellitus.

Conclusion: Prescribing NSAIDs and anti-thrombotic medicines was associated with increased risks of developing upper GI injury. The present case-control study utilizing the large organized database of claims in Japan provided precise clinical evidence for safety management of medical drugs in the clinical settings in Japan.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Percutaneous left atrial appendage occlusion (LAAO) is increasingly recognized as valid alternative therapy to reduce thrombo-embolic risk in patients with non valvular atrial fibrillation (AF) and contraindications for long term oral anticoagulation (OAC) therapy^{1,2}. Patients at high thromboembolic risk with previous gastrointestinal bleeding (GIB) might be at risk of bleeding recurrence in case of resuming anticoagulation. They could be selected for alternative therapies like LAAO. Up to now, there is no scientific consensus for patient selection for LAAO based on recurrent GIB risk.

Aims & Methods: We aimed to review the literature on gastrointestinal (GI) bleeding recurrence and proposed to define the reversibility profile of each lesion in an organ by organ and lesion by lesion approach to stratify the risk of bleeding individually. We systematically collected data from both prospective and retrospective studies from pubmed in order to extract rebleeding risk by etiology. The reversibility profile was defined by type of treatment needed to cure the lesion. Low reversibility (LR) profile was defined as a need for heavy treatment (surgery, radiotherapy, embolisation) to cure the lesion or as diffuse lesions.

Results: The most frequent reported causes of bleeding are peptic gastroduodenal ulcer (60%) for upper GI, diverticulosis (40%), colitis (20%) and anorectal diseases (20%) for lower GI and angiodysplasia (23%) for the midgut, these latter being responsible for 5% of all GI bleeding causes. The rate of recurrent GI bleeding under OAC therapy is 5–7% with vitamin K antagonists (VKA), an incidence that might increase with direct OAC. Recurrent bleeding rates for upper GIB, lower GIB and obscure GIB are respectively 5–7%, 16%, and 40.3%.

In the upper GI tract, lesions at high risk of bleeding recurrence are Dieulafoy lesions and angiodysplasia with reported rates up to 40% in some series. In the lower GI tract, lesions at highest risk are diverticular disease, angiodysplasia, colitis and radiation proctitis with bleeding recurrence rates reaching 60%, 20%, 40% and 20% respectively. For the midgut, angiodysplasia (20%) and bleeding of unknown origin (20%) are associated to the highest risk of recurrent bleeding. LR profile lesions with high rebleeding risk are present for diffuse angiodysplasia, colonic diverticulosis and Dieulafoy lesions.

Conclusion: In conclusion, GI lesions at high risk of recurrent bleeding with low reversibility profile are infrequent and include in particular: diffuse angiodysplasia, colonic diverticulosis and Dieulafoy lesions. Patients with AF having those lesions with GIB under anticoagulation might be the best candidates for alternative therapies like LAAO. Larger studies are needed to assess the long term outcome of patients treated by LAAO for GIB under current oral anticoagulant therapies.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1159 AN AUDIT INTO THE MANAGEMENT OF BLEEDING PEPTIC ULCER DISEASE

K. Siau¹, A. Vijayasingam²

¹Royal College Of Physicians, JAG Clinical Fellow, London/United Kingdom

²Postgraduate School of Medicine, Birmingham/United Kingdom

Contact E-mail Address: keith@siau.org

Introduction: Peptic ulcer disease (PUD) accounts for 25–56% of acute upper gastrointestinal bleeding (AUGIB) and is associated with high mortality.

Aims & Methods: In line with international guidelines, we aimed to audit our practice of bleeding PUD at a district general hospital within the West Midlands, UK. We retrospectively identified all patients with AUGIB who had inpatient endoscopic confirmation of PUD between November 2012–2014. We scrutinised all endoscopy and case records to assess management related to PUD, in addition to follow-up records with the general practitioner.

Results: We identified 91 patients (median age 78.4, 65.9% male), of whom 63.7% were admitted with AUGIB, whereas 36.3% developed bleeding during their inpatient stay. The majority were duodenal (74.7%) vs. gastric (25.3%). 31.8% were related to aspirin/non-steroidal anti-inflammatory drug use. 48 (52.7%) had high risk (Forrest 1a-2b) lesions, of whom 38/48 (79.2%) received dual endoscopic therapy and 6/48 (12.5%) received adrenaline monotherapy. 18.8% received the recommended adrenaline volume of 13 ml. Of 90% prescribed intravenous proton pump inhibitor infusion, 85% did not complete the full 72-hour duration. Rebleeding occurred in 12 patients (13.2%) after a median of 3-days post endoscopy. 10 (83.3%) underwent repeat OGD, 2 (16.7%) underwent CT embolisation, whilst 3 (25.0%) underwent surgery. Aspirin resumption was observed in 4/20 (20.0%) after haemostasis for PUD, whilst rebleed planning was documented on the endoscopy report in 33.0%. Regarding *H. pylori*, 51% underwent assessment with serology/biopsy. 10 (36%) had positive results, of whom 7 (70%) received eradication. 12/23 (52.2%) patients underwent follow-up endoscopy following gastric ulcer. The median transfusion requirement per patient was 2 units. Despite this, rates of anaemia at discharge and at 6 months were high at 83.5% and 62.9% respectively, with iron therapy initiated in 12.1%. Overall, our 30-day mortality rate was 12.1%.

Conclusion: In this single-centre study, the management of PUD could be improved in multiple areas in line with international guidelines. Audits in other centres are required to quality assure the management of PUD. Interestingly, rates of anaemia at discharge and on follow-up are high. Such patients may benefit from iron replacement at discharge.

P1160 COMPARISON OF SCORING SYSTEMS FOR NON-VARICEAL UPPER GI BLEEDING; FOCUS ON THE SIMPLE PREDICTION SYSTEM, AIMS65

M.S. Kim¹, J. Choi², W.C. Shin²

¹Internal Medicine, Seoul National University Hospital, Seoul/Korea, Republic of

²Internal Medicine, Sanggye Paik Hospital, Inje University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: kingtta21@naver.com

Introduction: In nonvariceal upper GI bleeding (NVUGIB) patients, it is important to predict the risk early and to take appropriate medical treatment. Recently, the AIMS65 score has been used to make simple predictions.

Aims & Methods: The aim of this study is to compare the risk stratification of each predictor by comparing AIMS65 score with Glasgow-Blatchford score (GBS), full Rockall score and pre-endoscopic Rockall score. We retrospectively studied patients who visited the Sanggye Paik Hospital with NVUGIB between 2013 and 2016. Among these, AIMS65, GBS, and Rockall scores were measured. The primary outcome was inpatient mortality, and secondary outcomes were rebleeding, needs of endoscopic intervention, requirement of transfusion, intensive care unit (ICU) admission. Each scoring system and prognostic factors were compared using the ROC curve.

Results: In this study, 17 of the 512 selected patients died, and re-bleeding was confirmed in 30 patients. AUROC between AIMS 65 and mortality was measured at 0.844 higher than 0.721 and 0.743/0.749 for GBS and pre-endoscopic/full Rockall score. ($p < 0.001$) For AUROC for secondary outcomes, AIMS 65 was superior to other scores in predicting the ICU admission (0.728, $p < 0.001$). There was no significant difference in the superiority of each scoring system by pairwise comparison. GBS was superior to other scores for predicting blood transfusion requirement. ($p < 0.0001$)

Conclusion: The AIMS65 score in NVUGIB patients was not inferior to other scoring systems in predicting the prognosis, such as mortality and ICU admission rate. At the emergent department, we recommend using AIMS65 which is easier to access than other scoring systems.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1161 COMPARISON OF RISK-SCORING SYSTEMS IN PREDICTING NEEDS OF INTERVENTION AND CLINICAL OUTCOMES OF UPPER GASTROINTESTINAL BLEEDING

M. Ooi, W. Low, R. Bryant, N. Q. Nguyen

Department Of Gastroenterology And Hepatology, Royal Adelaide Hospital, Adelaide/Australia/SA

Contact E-mail Address: marieooi_al@yahoo.com

Introduction: There are several risk-scoring systems are available to assist the management of upper gastrointestinal bleeding (UGIB). The aim of this study is to compare the performance of pre-endoscopy (pre-RS), post-endoscopy Rockall score (post-RS), GBS and AIMS65 scores in predicting the need for interventions and outcomes in patients admitted to hospital for UGIB.

Aims & Methods: Data related to the three scoring systems were collected prospectively and scores calculated in consecutive patients who were admitted with acute UGIB to the Royal Adelaide Hospital over 24 months. The performance of these scores, using operating characteristic (ROC) curves, in predicting the following outcomes was assessed: the need for endotherapy, rebleeding risk, transfusion requirement, surgical intervention and death. All patients received high dose acid suppression therapy.

Results: Of the 777 patients (491M; 66.4 ± 0.6yrs) who presented with UGIB, 622 (402M; 65.7 ± 0.6yrs) underwent endoscopy with 123 (38%) required endoscopic therapy, 42 (13%) repeated endo-therapy and 12 (3.7%) surgery for haemostasis. 155 (89M; 68.8 ± 0.6yrs) patients were treated conservatively due to medically unfit (n = 50), low suspicion (n = 25), known diagnosis (n = 17), and suspected MWT (n = 28). Death occurred in 33 (8%) patients, of which 10 (2.4%) were related to bleeding. Patients who required endoscopic or surgical intervention had higher GBS, pre-ERS, post-ERS and AIMS65 scores ($P < 0.001$). On ROC analyses, GBS and post-RS were superior to pre-RS and AIMS65 in predicting the need for (1) endotherapy (AUC: 0.75 and 0.78 vs. 0.65 and 0.59, $P < 0.01$), (2) repeated endoscopy due to re-bleed (AUC: 0.66 and 0.65 vs. 0.56 and 0.60, $P = 0.03$), and (3) blood transfusion (AUC: 0.83 vs. 0.72 and 0.70, $P < 0.01$). The scoring systems performed equally well in predicting the need for surgery (GBS vs. Rockall vs. GBS AUC: 0.72 vs. 0.67 vs. 0.71) and death (AUC: 0.75 and 0.72 vs. 0.69).

Conclusion: Although GBS performs equally well for predicting need of surgery and death, it is superior to both Rockall and AIMS65 scores in predicting the need for endotherapy, repeated endoscopy, and blood transfusion in patients with acute UGIB. These findings suggest that GBS is the best performed risk scoring system in the evaluation of patients with UGIB.

P1162 STEROID ADMINISTRATION IS AN INDEPENDENT RISK FACTOR FOR REBLEEDING IN HEMORRHAGIC DUODENAL ULCER WITH A DOSE-RESPONSE RELATION

W. Hatta, Y. Kondo, T. Koike, T. Kanno, N. Ara, K. Asanuma, N. Asano, A. Imatani, T. Shimosegawa

Division Of Gastroenterology, Tohoku University Graduate School of Medicine, Sendai/Japan

Contact E-mail Address: waku-style@festa.ocn.ne.jp

Introduction: Hemorrhagic gastroduodenal ulcer is commonly seen in routine clinical practice, and there have been many studies investigating risk factors for rebleeding. However, few studies have evaluated hemorrhagic gastric ulcers (HGU) and hemorrhagic duodenal ulcer (HDU) separately. Furthermore, the relation between steroid administration and rebleeding in hemorrhagic gastroduodenal ulcer remains unclear.

Aims & Methods: The aim of this study was to clarify the difference of rebleeding between HGU and HDU, and associated factors for rebleeding of HGU and HDU. Between March 2005 and September 2016, 176 consecutive patients with hemorrhagic gastroduodenal ulcer (106 with HGU and 70 with HDU), who underwent endoscopic hemostasis, were enrolled in this study. Regular dose proton pump inhibitor was administered to all patients after the diagnosis of hemorrhagic gastroduodenal ulcers. Rebleeding was defined as hematemesis or melena with ulcers confirmed by endoscopy or a decrease in the hemoglobin level > 2 g/dl in the presence of endoscopically proven ulcers. First, we compared the rebleeding rate between HGU and HDU. Subsequently, associated factors for rebleeding of HGU and HDU were calculated by logistic regression analysis

individually. The estimated factors were age ($< 65/≥ 65$ years), gender, location of ulcer (upper third/middle or lower third in HGU and 2nd portion/bulbs in HDU), underlying comorbidities (ischemic heart disease, liver cirrhosis, hypertension, diabetes mellitus, and hyperlipidemia), number of ulcers (multiple/single), hemostasis method (pure ethanol injection therapy/other therapies), antiplatelet therapy, anticoagulant therapy, NSAIDs administration, steroid administration, antacid administration in the initial ulcer bleeding, hypoalbuminemia (serum albumin level $≤ 2.5$ g/dl), and hemodialysis. We further investigated the detailed association between steroid administration and rebleeding in HDU, including dose-response relation.

Results: The rebleeding rate of HGU and HDU were 5.7% and 22.9%, respectively, which was statistically significant ($P = 0.001$). There was no missing data in the estimated factors. Although no factor was associated with rebleeding in HGU, multivariate logistic regression analysis revealed that the independent risk factors for rebleeding in HDU were multiple ulcers [odds ratio (95% confidence interval) = 24.2 (2.76–213), $P = 0.004$], steroid administration [14.0 (1.73–113), $P = 0.013$], and hemodialysis [9.53 (1.00–90.7), $P = 0.049$]. Regarding the detail of steroid administration, multivariate analysis showed that middle or high steroid administration ($≥ 20$ mg in prednisolone) (52.7 [3.19–871], $P = 0.006$) was a significant risk factor for rebleeding of HDU, with a dose-response relation (P for trend = 0.015).

Conclusion: HDU developed significantly higher rebleeding after endoscopic hemostasis, compared with HGU. In addition to multiple ulcers and hemodialysis, we firstly demonstrated by multivariate analysis that steroid administration is an independent risk factor for rebleeding of HDU after endoscopic hemostasis, with a dose-response relation.

P1163 EFFICACY AND SAFETY OF BIO-INSERT MINERAL SMECTITE IN CONTROLLING GASTROINTESTINAL HEMORRHAGE: AN ANIMAL PILOT STUDY

J. Wang¹, L. Zhao², M. Wang¹, L. Liu², Z. Fan², X. Wang²

¹The First Affiliated Hospital with Nanjing Medical University, Nanjing/China

²Digestive Endoscopy Center, the First Affiliated Hospital of Nanjing Medical University, Nanjing/China

Contact E-mail Address: kit9178@sina.com

Introduction: Gastrointestinal bleeding is common in clinics, especially after endoscopic operation. Besides from hemoclips, APC or electrocoagulation, more novel hemostasis approaches should be developed to improve endoscopic bleeding management. Granular smectite is bioinert mineral and efficient for curing diarrhea. Inspired by its dehydration and tissue-covering effect, this pilot study was to investigate its efficacy and safety for controlling hemorrhage in rats.

Aims & Methods: 32 rats were divided into four equal groups. For hemorrhage model, a horizontal 10-mm incision was made on the lower part of the left hepatic lobe. Commercial hemostatic powder, smectite, starch and normal saline were respectively applied. Bleeding duration and blood loss were recorded. 1 week later, rats were sacrificed and liver tissue was collected for histopathology.

Results: Smectite demonstrated the best hemostasis effect, and its mean coagulation time was $1.45 ± 0.026$ min. Commercial hemostatic chitosan styptic powder need $2.5 ± 0.04$ min for complete clotting, while Starch group was $4.275 ± 0.056$ min and normal saline group was $4.925 ± 0.108$ min ($p < 0.05$). Similarly, smectite led to less loss of blood ($0.6188 ± 0.034$ g), while rats lost $2.3288 ± 0.123$ g blood ($p < 0.05$) under normal saline treatment. For starch and commercial chitosan, the blood loss was respectively $2.0862 ± 0.061$ g and $1.2325 ± 0.028$ g. Histopathologic results confirmed that smectite was biocompatible to tissue.

Conclusion: The mineral smectite powder was the superior candidate for hemostasis treatment in vivo. Compared with common polysaccharide agents, smectite could induce faster coagulation and reduce blood loss. More importantly, bioinert smectite was biocompatible and even promoted the wound healing. For gastrointestinal application, smectite powder could be delivered through endoscopic spray tube, while its inspiring efficacy required more endoluminal hemostasis tests.

P1164 PREDICTORS OF LIFE THREATENING MUCOSAL ULCERATION AFTER VARICEAL SCLEROTHERAPY

A. S. Hanafy

Internal Medicine, Zagazig University, Zagazig/Egypt

Contact E-mail Address: dr_amr_hanafy@yahoo.com

Introduction: Life-threatening bleeding could occur early after variceal sclerotherapy in cirrhotic patients.

Aims & Methods: We aimed to determine simple predictive factors of this complication in cirrhotic patients. Among 750 patients treated with variceal sclerotherapy (esophageal varices (EV), n = 655, 87.3%) and (gastric varices (GV), n = 95, 12.7%) Zagazig University hospital-endoscopy unit- Internal medicine department, in the period from October 2014 till July 2016. 150 patients (20%, mean age $46.2 ± 9.4$ years) (EV = 129, GV = 21) developed bleeding due to sclerotherapy induced ulcers confirmed by endoscopy $6.4 ± 2.1$ days after the procedure. Cirrhosis was post viral hepatitis C (89%), hepatitis B (10%) and cryptogenic in (1%). A case-control study was performed comparing these

patients with 150 patients who underwent endoscopic variceal sclerotherapy without the development of bleeding due to sclerosant ulceration.

Results: Bleeding occurred 6.4 ± 2.1 days (2–10) following sclerotherapy. Twenty-three patients died following the bleeding (15.3%). Using a multivariate analysis; pre-procedural factors as serum albumin ≤ 2 g/dl [OR 1.3], total bilirubin > 1.6 mg/dl [OR 1.5], high platelet ratio index (APRI) > 1 [OR 1.2], low prothrombin concentration $< 50\%$ [OR 1.5]. Intra-procedural factors as amount of ethanolamine > 15.5 ml [OR 2.6], amacrylate > 3.5 ml [OR 2.9]. Post-procedural factors within 24 hours after endoscopy: leucocytosis $> 12,000$ cell/ul [OR 1.9], drop of hemoglobin $> 10\%$ of the pre-endoscopic value [OR 3.2], prolonged INR > 1.55 [OR 1.2].

Conclusion: Bleeding related to sclerosant ulcers is not uncommon, but may be life threatening. The proposed predictive factors should be watched and minimized before and during variceal sclerotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Few studies were reported on the association between sleep disorders and Rome III-based functional dyspepsia (FD).

Aims & Methods: The aim of this study is to investigate the prevalence of sleep disorders in FD patients and the risk factors associated with sleep disorders. This multicenter, cross-sectional study had been conducted from August 2014 to December 2016 at 6 hospitals in Korea. Inclusion criteria were FD patients (≥ 18 years) met the Rome III criteria among the patients visited the gastroenterology department for dyspepsia. Exclusion criteria were prior surgery to the upper gastrointestinal tract, history of ulcer disease, erosive GERD, history of malignancy, and severe comorbidity. Healthy control group who had no clinical history of gastroduodenal related disorder and no abnormal finding on endoscopy recruited from health examination center for screening. The Pittsburgh Sleep Quality Index was used to assess sleep disturbance. Hospital anxiety and depression scale was used to identify anxiety and depression.

Results: This study included 160 FD patients and 223 healthy control groups. The total Pittsburgh Sleep Quality Index score was higher in FD patients than healthy controls (7.8 ± 4.3 vs 5.6 ± 3.1 , $p = 0.000$). The prevalence of sleep disorder was significantly higher in FD patients than healthy control (41.2% vs 18.4%, $p = 0.000$). In univariate analysis, FD was significant risk factor for sleep disorder (OR 3.12, $p < 0.0001$). The independent risk factors for sleep disorder in multivariate analysis were FD (OR 1.80, $p = 0.026$), female (OR 1.78, $p = 0.028$) and depression (OR 2.91, $p < 0.001$).

Conclusion: FD significantly impacted on sleep disorder. FD was independent risk factor in sleep disorder.

Introduction: Dyspepsia and gastro-oesophageal reflux are highly prevalent in the general population, but the two conditions are felt to be separate entities. However, There are numerous mechanisms implicated in the pathogenesis of functional dyspepsia, some of which are common to gastro-oesophageal reflux symptoms (GORD), including visceral hypersensitivity and delayed gastric emptying. To inform future research on potential shared pathophysiological mechanisms, it is important to estimate the strength of association between the two conditions, and whether this association remains stable depending on the criteria used to define these conditions, as well as geographic location.

Aims & Methods: We conducted a systematic review and meta-analysis to estimate the prevalence of dyspepsia in individuals with gastro-oesophageal reflux symptoms, and to quantify the overlap between the two disorders. MEDLINE, EMBASE, and EMBASE Classic were searched (up until September 2016) to identify population-based studies reporting the prevalence of dyspepsia and GORS in adults (≥ 15 years), defined using specific symptom-based criteria or a questionnaire. The prevalence of dyspepsia and weekly GORS were extracted for all studies. Pooled prevalence, according to study location and criteria used to define weekly GORS or dyspepsia, as well as odds ratios (OR), with 95% confidence intervals (CIs) were calculated. The degree of overlap between the two was examined.

Results: Of 14,132 papers evaluated, 79 reported prevalence of weekly GORS. Nineteen of these study populations, containing 111,459 participants, also reported the proportion of individuals with dyspepsia. The prevalence of dyspepsia in those with weekly GORS was 43.9% (95% CI, 35.1–52.9%). The pooled OR for dyspepsia in individuals with weekly GORS, compared with those without, was 6.94 (95% CI 4.33 to 11.12). The OR for dyspepsia in weekly GORS remained significantly higher in all geographical regions studied, and across all diagnostic criteria used. The pooled degree of overlap between the two conditions was 25.9% (95% CI, 19.9–32.4%), varying from 22% when the Bowel Disease Questionnaire was used to define weekly GORS, to 42.6% with the Mayo Reflux Questionnaire.

Conclusion: The OR of dyspepsia in individuals with weekly GORS was seven-fold that of individuals without GORS, and that there is overlap between the two conditions in up to one-quarter of individuals. Reasons for this remain speculative, but may include shared pathophysiological mechanisms or residual confounding.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Functional gastrointestinal (GI) disorders (FGIDs) have been theorized to be a disorder of the brain-gut axis with both somatic markers (e.g., abdominal pain) and psychological ones. Exactly how abdominal and psychological disorders are related remains poorly understood. While there have been a small number of methodologically rigorous longitudinal studies that examine this question (1,2), even these have typically only studied a small number of psychological traits and only quite general GI symptoms. There remains a need for further longitudinal studies of how psychological traits predict subsequent FGID symptoms.

Aims & Methods: The present study is a longitudinal examination of the influence of a broad range of psychosocial predictors on later bowel-related and epigastric discomfort in a community sample. A sample of 188 individuals randomly sampled from the Australian electoral roll were surveyed, and, of them, 123 met Rome criteria for irritable bowel syndrome (IBS) or functional dyspepsia (FD) while 65 did not meet criteria for FGIDs. Subjects were of mean age 49 (SD = 15, range 20–87) and 73% were female. A broad range of psychological constructs (24 in total) were measured at baseline. Among them were anxiety, depression, somatization, childhood abuse, neuroticism, hypochondriasis, somatic vs psychological symptom attribution, coping, and social support. GI symptoms were measured 18 months later using two Likert-type scales: one concerning epigastric pain and the other concerning bowel symptoms. Exploratory factor analysis (EFA) was used as a data-reduction technique to create a smaller number of composite predictors. Statistical analysis was based on ordinal regression.

Results: Ten composite scores were derived via EFA to be examined as predictors. In the full sample ($N = 188$) a number of psychological traits (including worry, non-sexual childhood abuse, psychological symptom attribution and childhood sexual abuse; see Table 1) were individually related to subsequent bowel symptom severity 18 months later. All four of these were independently associated with epigastric pain severity 18 months later (Table 1). There was evidence of variation in psychological predictors of gastrointestinal symptoms between individuals who met and did not meet criteria for IBS or FD. With respect to bowel symptoms, no psychological trait reached statistical significance.

as a predictor among individuals with FGIDs (Table 1). Epigastric symptom severity was predicted by worry and psychological attribution of symptoms among FGID individuals but no psychological trait predicted symptom severity among non-FGID individuals (Table 1).

Conclusion: A range of psychosocial factors predict later gastrointestinal symptom burden. For bowel symptoms, associations between psychological traits and symptom burden appear to be most clearly driven by the non-FGID subgroup, among whom psychological attributions for symptoms and problem-focused coping are positively related to later symptom burden. For epigastric symptoms, a range of psychological traits were relevant, with the predictive patterns being most clearly driven by individuals who qualified for FGIDs. In light of these results, studies of the brain-gut axis need to consider a greater array of psychological traits, particularly outside of anxiety and depression. Further, the commonly reported associations between psychological traits and gastrointestinal symptoms may be moderated by symptom level but are relatively similar across upper and lower gastrointestinal symptoms.

Introduction: In the recent years, there has been an increasing recognition of the presence of gastrointestinal (GI) dysfunction in patients with neurologic diseases. There are no studies examining a relationship between achalasia and neurodegenerative/demyelinating diseases of central nervous system, although these diseases might have common features. For example, a number of genetic variations have been shown to increase the risk of both conditions (e.g. HLA-DQB1-insertion on chromosome 6 may be strongly associated with both achalasia and multiple sclerosis suggesting that autoimmune processes are involved in their etiopathogenesis). Several other findings (e.g. inflammatory infiltrates, Lewy's bodies, geospatial gradient etc.) are also present in both patients with achalasia and with neurodegenerative/demyelinating diseases.

Aims & Methods: The aim of our prospective study is to examine a prevalence of neurodegenerative/demyelinating diseases in a cohort of consecutive patients with confirmed esophageal achalasia. Achalasia was diagnosed by high-resolution manometry, endoscopy and esophagogram. A total of 140 consecutive patients with esophageal achalasia have been questioned about the occurrence of neurological diseases and symptoms in their personal and family history. Those with a suspicion of a neurological disease were referred for a detailed clinical neurological examination, MR imaging of the brain and electrophysiological study. A total of 106 patients with a neurodegenerative/demyelinating disease have been questioned by using a questionnaire about the occurrence of symptoms typical for achalasia (dysphagia, regurgitation, chest pain).

Results: A total of 51 out of 140 patients (36.4%) exhibited some neurological symptoms—most often visual disturbances in 17 patients (33.3%) and limbs paresthesia in 12 patients (23.5%). Among patients with a presence

of neurological symptoms, 5 patients (3.6%) had definitely been diagnosed with a neurodegeneration/demyelinating disease (multiple sclerosis - 2 patients, Leber's optic neuropathy - 1 patient, Parkinson's disease - 1 patient and Allgrove syndrome - 1 patient). Furthermore, 7 patients with a positive questionnaire had been diagnosed with other neurological diseases (tetany n=2, carpal tunnel syndrome n=3, epilepsy n=2). Fourteen patients (27.4%) among those with neurological symptoms (vs. 0 out of 89 patients without neurological symptoms) had a positive family history of a neurodegenerative or a demyelinating disease. Among 106 patients with a neurodegenerative/demyelinating disease, 30 of them (28%) described dysphagia in their personal history. These patients will be examined by esophageal manometry.

Conclusion: Our results imply an increased prevalence of neurodegenerative/demyelinating diseases in patients with achalasia (3.6% vs. approx. 1.4% in the Czech controls). Also, a high prevalence of dysphagia was found among patients with a neurodegenerative/demyelinating disease. These results warrant further confirmation in a large population-based study.

Introduction: Visceral pain is a complex percept influenced by numerous factors. Of these, differences in the autonomic nervous system (ANS)—in particular, parasympathetic cardiac vagal tone (CVT)—has been suggested to have a physiological role in the regulation and modulation of painful sensory signalling, to the extent of vagal nerve stimulation (to raise subject CVT) being tested as a possible anti-nociceptive.

Aims & Methods: To date, no studies have explored the brain functional connectivity or network properties of CVT in relation to a painful stimulus, and thus this was our aim. In 21 healthy participants (10 male; mean age 30 years (range 21–53 years)), we quantified resting CVT using a Neuroscope. For all subjects, functional MRI data were acquired using a 3T MRI scanner during painful oesophageal balloon distention, as described elsewhere(1). The effect of resting CVT on brain networks during acute oesophageal pain were determined by means of network based statistics(2). Brain nodes were selected *a priori* of previous autonomic/visceral pain literature and included the following: bilateral nucleus accumbens (NAc), amygdala, insula, pallidum, thalamus and single hypothalamus ($\sum \text{Nodes} = 11$) (3). Blood oxygen level dependant (BOLD) signal during oesophageal balloon distention to pain tolerance threshold was extracted from each of these regions and cross-correlated to produce nodal correlation matrices of 55 *r* values. Participants were dichotomised by means of median split based upon resting CVT value, and a two-tailed *t*-test of was undertaken. A primary threshold was applied ($t=1.65$; $p < 0.05$) and permutation tested 50,000 times to ensure statistical stringency applied.

Results: We identified a unique subcortical brain connectivity network in the high resting CVT individuals when exposed to acute oesophageal pain. This complex symmetrical network comprised all 11 nodes with a total of 18 edges (significant

Abstract No: P1167

Table 1: Associations between individual psychological traits and symptom severity. Numeric entries are odds ratios ($SE_{\text{odds ratio}}$), *** indicates $p < .001$, ** indicates $p < 0.01$, * indicates $p < 0.05$, and ^ indicates $0.05 \leq p \leq 0.1$.

Predictor	Bowel Non-FGID	Symptom FGID	Severity Combined	Epigastric Non-FGID	Symptom FGID	Severity Combined
Problem-focused coping	2.92 (1.23)*	0.93 (0.14)	1.16 (0.15)	1.00 (0.44)	1.03 (0.15)	1.12 (0.15)
Worry	1.44 (0.51)	1.35 (0.22)^	1.60 (0.22)***	1.60 (0.65)	1.55 (0.26)**	1.71 (0.24)***
Avoidant coping	0.41 (0.21)^	0.89 (0.14)	0.91 (0.12)	0.97 (0.39)	0.93 (0.15)	0.99 (0.13)
Doctor relationship	2.96 (1.77)^	1.09 (0.16)	1.06 (0.14)	1.00 (0.54)	1.03 (0.16)	0.97 (0.13)
Childhood non-sexual abuse	1.65 (0.68)	1.06 (0.15)	1.33 (0.17)	1.94 (0.88)	1.05 (0.15)	1.32 (0.17)*
Social support	0.53 (0.22)	0.85 (0.12)	0.88 (0.11)	0.68 (0.32)	0.82 (0.12)	0.87 (0.11)
Somatic rather than psychological attribution	0.27 (0.11) ***	0.93 (0.15)	0.72 (0.10)*	0.83 (0.36)	0.64 (0.11)**	0.63 (0.09)***
Doctor reassurance	0.99 (0.31)	1.16 (0.26)	0.94 (0.14)	1.06 (0.34)	1.49 (0.33)^	1.01 (0.16)
Somatisation	2.92 (1.23)*	0.93 (0.14)	1.16 (0.15)	0.30 (0.30)	1.27 (0.18)^	1.54 (0.20)***
Childhood sexual abuse	1.44 (0.51)	1.35 (0.22)^	1.60 (0.22)***	2.16 (0.88)^	1.11 (0.18)	1.16 (0.16)

When considered jointly with other predictors, psychological attribution of symptoms was significantly positively related to both bowel symptom severity (non-FGID: OR = 0.31, SE = 0.13; Full: OR = 0.74, SE = 0.11) and epigastric symptom severity (FGID: OR = 0.63, SE = 0.09; Full: OR = 0.63, SE = 0.11). The same was the case for worry (Bowel: Full: OR = 1.40, SE = 0.21; Epigastric: FGID: OR = 1.58, SE = 0.27; Full: OR = 1.54, SE = 0.23). For bowel symptoms, problem-focused coping (OR = 2.30, SE = 0.98) was an additional independent positive (notably, not negative) predictor among participants without FGIDs.

functional connections). These interconnections included the following: thalamus-amygdala, thalamus-hypothalamus, hypothalamus-NAc, amygdala-putamen, amygdala-NAc and insula-putamen. No significant network was identified for the low CVT group.

Conclusion: During acute oesophageal pain, resting cardiac vagal tone yields a unique functional brain network comprising numerous complex subcortical brain regions, many of which have been previously associated with either visceral pain or modulation of baseline autonomic function either at the physiological or neuroanatomical level (3). Previous research has suggested that a high resting CVT may be protective of nociceptive signalling, and furthermore studies investigating vagal nerve stimulation have included and report that of anti-nociception (4). Given the well-established role of these subcortical regions in pain processing, we suggest that this network identified may be of significance as to the neurophysiological process of parasympathetic modulation of painful sensory signalling. Lastly, to date, no studies have undertaken real-time assessment of the ANS (including CVT) during functional brain imaging and acute visceral pain. Future studies should investigate for this.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1170 RAPID DRINK CHALLENGE (RDC) TEST DURING OESOPHAGEAL HIGH RESOLUTION MANOMETRY (HRM) IN PATIENTS WITH OESOPHAGO-GASTRIC JUNCTION OUTFLOW OBSTRUCTION

D. Biasutto, F. Mion, A. Garros, S. Roman

Digestive Physiology, Lyon I University and Hospices Civils de Lyon, Lyon/France

Contact E-mail Address: d.biasutto@unicampus.it

Introduction: Oesophago-gastric junction outflow obstruction (OGJOO) is of unclear significance. It may be secondary to an incomplete form of achalasia, a mechanical obstruction or be idiopathic. Rapid drink challenge (RDC) test is easy to perform during oesophageal HRM.

Aims & Methods: We aimed to assess the yield of RDC in patients with OGJOO. From a database of 3522 consecutive oesophageal HRM performed from 01/2012 to 03/2017, we extracted patients with OGJOO according to the Chicago Classification v3.0. HRM protocol consisted of 10 5-ml water swallows in supine position and RDC test (200-ml free drinking) in sitting position. Distal contractile integral (DCI) integrated relaxation pressure (IRP), distal and pan-oesophageal pressurization (POP; homogeneous oesophageal pressurization > 30 mmHg) were reported for 5-ml swallows. POP and oesophageal shortening (OS) were analysed during RDC. Symptom severity was assessed with Eckardt score. Causes of OGJOO were determined by reviewing patients' chart for previous history, complementary work up and treatment. Quantitative data were expressed as median (range) and qualitative data as percentage. They were compared using non parametric and Chi square tests.

Results: 75 patients (2%) (29 males, mean age 62 years (25–92)) were included. The dominant symptom was dysphagia (69%), regurgitation (9%), chest pain (5%), other (13%), no symptom (3%). The causes of EGJOO were previous oesophago-gastric surgery (43%), incomplete achalasia (7%), mediastinal neoplasia (7%), miscellaneous (19%) and unknown (25%). RDC test was successfully performed in 70 patients (93%) and associated with POP and OS in 41% and 13% respectively. Dysphagia as dominant symptom was more frequent (79% vs 59%, $p=0.057$) and more severe (Eckardt score 5 (1–11) vs 3 (0–10), $p=0.01$) in patients with POP during RDC compared to those without. The same observation was achieved in patients with OS vs those without (dysphagia 100% vs 62%, $p=0.02$ and Eckardt score 6 (2–10) vs 1 (0–11), $p=0.02$). Manometric parameters are reported in the table. The causes of OGJOO were similar in patients with and without POP during RDC (previous oesophago-gastric surgery 34% and 51% respectively, achalasia 14% and 2%, mediastinal neoplasia 3% and 7%, miscellaneous 10% and 22%, unknown 38% and 17%). OS was not observed in patients with unknown cause of EGJOO vs 20% of patients with an identified cause ($p=0.09$).

Manometry parameters for 5-ml swallows	POP during RDC n=29	No POP during RDC n=41	OS n=9	No OS n=61
Mean IRP (mmHg)	19(15–35)*	18(15–29)	24(16–35)	18(15–29)
Maximal IRP (mmHg)	29(18–57)*	24(16–78)	31(23–78)‡	25(16–57)
Mean DCI (mmHg.s.cm)	2700	1384	1503 (593–4095)	1671 (109–16108)
Mean DCI (mmHg.s.cm)	(496–14492)*	(109–16108)	2264 (1036–10127)	3016 (156–42139)
Maximal DCI	4536	2146	20(0–70) 0(0–40)	0(0–100) 0(0–100)
Maximal DCI	(639–42139)*			

(continued)

: Continued

Manometry parameters for 5-ml swallows	POP during RDC n=29	No POP during RDC n=41	OS n=9	No OS n=61
(mmHg.s.cm)	20(0–100)*	(156–38846)		
%distal pressurization	0(0–100)	0(0–100) 0(0–60)		
%POP				

* $p < 0.05$ vs patients without POP; ‡ $p < 0.05$ vs patients without OS

Conclusion: While RDC test cannot be used to determine EGJOO cause, patients with POP or OS during RDC had more severe dysphagia than those without. In patients with POP, the highest DCI might be secondary to obstruction. Further prospective studies should determine if RDC test could help to select patients who might benefit from treatment.

P1171 THE NORMATIVE VALUES OF A NEW 36 CHANNELS WATER PERFUSION ESOPHAGEAL MOTILITY CATHETER

S. Bor, S. Kipcak

Gastroenterology Sec., Ege Reflux Study Group, Ege University, izmir/Turkey

Contact E-mail Address: kipcaksezgi@gmail.com

Introduction: High resolution manometry (HRM) is performed with solid-state catheters (SS) in many centers. However according to Chicago classification, very limited data from healthy volunteers are available for some catheters and starting from IRP, numerical values are crucial for the diagnosis. Because of the cost of the SS-HRM catheters many centers especially from developing countries use water perfusion HRM (W-HRM) catheters up to 24 channels and normal values are even more limited.

Aims & Methods: We evaluated a prototype 36 channels W-HRM reused catheter allowing to measure 3-D pressure vector volume analysis of lower esophageal sphincter in healthy volunteers and compared to 36 channels SS-HRM catheters (Laborie-MMS Canada). We included 43 healthy volunteers without any upper gastrointestinal complaint. Upper gastrointestinal endoscopy and 24 h impedance-pH monitoring performed in all subjects. Four subjects were excluded because of silent GERD. 39 subjects were analysed (25 males, W-HRM (n=39), SS-HRM (n=33)). Thirty-three patients underwent two esophageal manometry studies within two consecutive days with a random order. Procedures were performed in supine position with receiving ten times 5 ml water, five times solid food and multiple water swallow with 200 ml of water. 36 channel water-perfused 3-D HRM catheter and 36 channel solid state HRM catheter were used (Laborie-MMS Canada).

Results: There was significant differences between two catheters in terms of Integrated Relaxation Pressure (IRP), Distal Contractile Integrale (DCI) and DCI- expanded, LES resting pressure, % of ineffective peristalsis, and esophageal length both with water and solid food swallows (Table). No difference has been shown with distal latency (DL), LES length, breaks size (Table).

		36 ch solid statemean ± SD	36 ch water perfusion (mean ± SD)
5ml	Esophageal length (inspiration) (cm)	23.1 ± 2	22.5 ± 2
	LES resting pressure (mmHg)	34.8 ± 13	17.4 ± 7
	IRP (mmHg)	17.6 ± 5 (7–25)	6.5 ± 4 (0–18)
	DCI (mmHg*s*cm)	1281 ± 759	701 ± 432
solid food	Mean % ineffective peristalsis	15%	28%
	LES resting pressure (mmHg)	33.5 ± 11	17.6 ± 7
	IRP (mmHg)	17.6 ± 5	6.4 ± 4
	DCI (mmHg*s*cm)	1969.1 ± 1051	1159.9 ± 836
	DCI expanded (mmHg*s*cm)	2122.9 ± 1117	1171.1 ± 895
	Mean % ineffective peristalsis	12%	23%

Conclusion: Water perfusion HRM catheter exhibits significantly lower values especially for IRP, DCI, LES resting pressure. Centers which are working with water perfusion catheters should not accept universal normal established with solid state catheters and need to work on their normative values. The ineffective peristalsis pattern is common with water perfusion catheters.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The Chicago Classification V3.0 (CCv3) defined ineffective esophageal motility (IEM) by the presence of 50% or more of weak or failed peristaltic waves during high resolution manometry (HRM). Both low-volume (10 ml) multiple rapid swallow (MRS) and high-volume (200 ml) rapid drinking test (RDT) have been suggested as test to recognize the esophageal peristaltic reserve. Which test might better represent the esophageal peristaltic reserve is still a matter of discussion.

Aims & Methods: The aim of this study was to compare the diagnostic value of MRS and RDT in patients with IEM. From a larger group of patients evaluated for heartburn (twice/week with poor response to standard dose proton pump inhibitors), we enrolled consecutive patients with IEM and with functional heartburn (FH). FH were enrolled as controls. IEM was defined according to the CCv3, and FH were defined according to the Rome IV criteria and with normal peristalsis. HRM was performed according to the Italian Guidelines. All patients underwent 3 MRS (10 ml of water in 5 swallows in less than 10s) and 1 RDT (200 ml of water freely drunk). All patients underwent 24-h impedance and pH recording (MII-pH). Mean DCI of MRS and DCI of RDT were compared with mean DCI of 10 single swallows (SS). The MRS/SS and RDT/SS ratio were calculated.

Results: We evaluated 30 patients with IEM (18 males and 12 females; mean age 45.7 ± 11.4 yrs) and 30 patients with FH (13 males and 17 females; mean age 41.2 ± 13.6). The MII-pH showed higher acid exposure time (AET) and number of reflux events in IEM than in FH ($p < 0.05$). Mean DCI of SS resulted lower in patients with IEM compared to FH ($p < 0.05$). One-hundred and eighty MRS and 60 RDT were evaluated. DCI of MRS was lower than 450 mmHg-s-cm in 39% (35/90) of IEM patients, and in 7% (6/90) of FH ($p < 0.05$). DCI of RDT was lower than 450 mmHg-s-cm in 77% (23/30) of IEM patients, and in 50% (15/30) of FH ($p < 0.05$). The MRS/RDT ratio resulted > 1 in both groups. All results are reported in Table 1.

Table 1: Results of SS, MRS and RDT in patients with IEM and FH

	IEM group	FH group	<i>p</i>
Mean DCI (mmHg-s-cm)	508.7 ± 318.6	1493.7 ± 799.2	0.001
Mean DCI MRS	614.2 ± 437.1	1982.6 ± 974.4	0.001
Mean DCI RDT	506.9 ± 311.5	1269.2 ± 1027.6	0.001
MRS/SS ratio	1.2 ± 0.4	1.6 ± 0.7	0.008
RDT/SS ratio	0.9 ± 0.3	1 ± 0.5	0.351
MRS/RDT	1.3 ± 0.4	1.4 ± 0.7	0.499

Conclusion: MRS is a more reliable test to detect peristaltic esophageal reserve when compared to RDT both in patients with IEM or those with normal esophageal peristalsis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1173 HIGH-VOLUME RAPID DRINKING TEST BETTER DISTINGUISH ESOPHAGEAL BODY INHIBITION COMPARED TO LOW-VOLUME MULTIPLE RAPID SWALLOWS

Introduction: The Chicago Classification (CC V3.0) defined the presence of esophago-gastric outflow obstruction (EGJ-OO) when the value of integrated releasing pressure (IRP) is higher than 15 mmHg during high-resolution manometry (HRM). Both low-volume (10 ml) multiple rapid swallow (MRS) and high-volume (200 ml) rapid drinking test (RDT) were never evaluated to detect the inhibition of esophageal body in patients with EGJ-OO.

Aims & Methods: The aim of this study was to compare the efficacy of MRS and RDT in evaluating the esophageal body inhibition during repetitive swallow in patients with EGJ-OO and in patients with functional heartburn (FH) considered as control group. From a larger group of patients evaluated for dysphagia with negative upper endoscopy, we enrolled consecutive patients with EGJ-OO, and as control group, patients with functional heartburn (FH) defined according to the Rome IV criteria. EGJ-OO was defined according to CC V3.0. HRM performed according to Italian guidelines. All patients underwent 3 MRS (10 ml of water in 5 swallow in less than 10s) and 1 RDT (200 ml of water freely drunk). The mean DCI of MRS and the DCI of RDT were compared with DCI of 10 single swallows (SS) mean value. The MRS/SS and RDT/SS ratio were calculated. The lack of esophageal body inhibition during multiple swallow tests were defined if contraction was identified measuring > 3 cm using the 30 mmHg isobaric contour tool.

Results: We evaluated 30 patients with EGJ-OO (18 females; mean age 49.5 ± 12.4 yrs) and 30 patients with FH (17 females; mean age 41.2 ± 13.6). Impedance and pH 24-h analysis was performed to select patients with FH (normal AET and number of reflux and lack of reflux-symptom correlation). During HRM the mean DCI resulted similar in patients with EGJ-OO compared to FH ($p < 0.839$). One-hundred and eighty MRS and 60 RDT were evaluated. The lack of body inhibition was found in 11% (20/180) during MRS and in 53% (16/30) during RDT in EGJ-OO. No patients in FH showed lack of body inhibition during both MRS and RDT. All results are reported in Table 1.

Table 1: Results of SS, MRS and RDT in patients with EGJ-OO and FH

	EGJ-OO group	FH group	<i>p</i>
Mean DCI MRS	1455 ± 1436.1	1982.6 ± 974.4	0.101
Mean DCI RDT	817.3 ± 665.4	1269.2 ± 1027.6	0.047
MRS weak/failed (90)	24/30	2/4	N/A
RDT weak/failed (30)	6/20	3/12	N/A
MRS/SS ratio	0.9 ± 0.3	1.6 ± 0.7	0.001
RDT/SS ratio	0.5 ± 0.4	1 ± 0.5	0.001
MRS complete body inhibition (%)	89	100	0.001
RDT complete body inhibition (%)	47	100	

Conclusion: Patients with EGJ-OO showed less peristaltic reserve during MRS and RDT. The RDT evidenced more frequently lack of body inhibition in patients with EGJ-OO.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1174 ESOPHAGEAL BOLUS FLOW METRICS ON PRESSURE FLOW ANALYSIS (PFA) OF ESOPHAGEAL HIGH RESOLUTION IMPEDANCE MANOMETRY (HRIM) IN GASTROESOPHAGEAL REFLUX DISEASE (GERD)

Introduction: Esophageal motor dysfunction and abnormal bolus transit are often encountered on high resolution impedance manometry (HRIM) performed prior to anti-reflux surgery (ARS) in gastroesophageal reflux disease (GERD). Esophageal motor dysfunction can be characterized using established software tools embedded in HRIM software, while new paradigms of interrogation of bolus presence and flow have been introduced with automated pressure flow analysis (PFA). The prevalence, and clinical relevance of these motor and bolus flow abnormalities to symptom presentation or symptom outcome from ARS are incompletely understood.

Aims & Methods: Our aim was to evaluate the interrelationships between esophageal motor function and bolus transit using varying bolus consistencies, in health and in the context of symptomatic GERD prior to ARS. HRIM studies (Medtronic, Duluth, GA) from 18 controls (28.4 ± 1 yr, 50% F) and 86 GERD patients (56.2 ± 2 yr, 58% F) were reviewed, all of which were performed using 5 mL water (10 swallows), 5 mL viscous (5 swallows) and 1 cm³ bread boluses (2 swallows). All controls were asymptomatic; all GERD patients completed symptom questionnaires evaluating dominant and secondary symptoms using 5 point Likert scales for symptom frequency and severity (0 = none, 4 = frequent

or severe); the product of frequency and severity constituted the symptom score, assessed at baseline and after ARS. Automated PFA was performed for each test swallow by blinded investigators using purpose built software (Esophageal AIMplot, copyright T Omari) programmed in MatLab (The MathWorks Inc, Natick, MA, USA). The nadir impedance point (NI) indicating peak distension, and the contractile deceleration point (CDP) were determined. Latency was measured from NI to the contraction front at the CDP (distension to contraction latency, DCL). Intrabolar pressures (IBP) were measured during accommodation (IBP-A), compartmentalized transport (IBP-CT) and esophageal emptying (IBP-EE). Bolus clearance in the esophageal body was assessed using the impedance ratio (IR) based on the relationship between NI and impedance at the contractile peak. Bolus flow at the esophagogastric junction (EGJ) was assessed using bolus flow time (BFT) in seconds when both pressure and impedance traces indicated a flow permissive paradigm. Univariate and multivariate analyses were performed to assess the relationships between bolus flow metrics and motor function, taking baseline symptom scores and symptom change following ARS into consideration. **Results:** Of 86 patients, 72.1% had typical symptoms. The mean baseline symptom score was 158.8 ± 15.8 , with a mean decline of 139.9 ± 15.8 following ARS. Peak pressures in the proximal esophagus were lower in GERD patients compared to controls with all bolus consistencies ($p \leq 0.007$). Concurrently, metrics assessing esophageal bolus presence (NI) and clearance (IR) were consistently abnormal in GERD patients (Table, $p = 0.001$ for all bolus consistencies for each comparison to controls). Trans-EGJ bolus flow metrics were similarly abnormal in GERD (BFT, $p \leq 0.001$ for all bolus consistencies compared to controls). IBP metrics were highest with solid swallows, especially in GERD patients compared to controls (Table). Within GERD, a gradient of increasing dysfunction in bolus presence and bolus clearance was noted, with least abnormalities with water swallows and the worst metrics with bread swallows ($p \leq 0.02$ across groups for each comparison). IBP-EE ($p \leq 0.05$) and trans-EGJ BFT ($p \leq 0.004$) were higher during water and viscous swallows with atypical symptoms compared to typical symptoms. NI was consistently lower in patients reporting $\leq 75\%$ symptom improvement following ARS with all bolus consistencies ($p \leq 0.046$).

Pressure Flow Analysis Comparisons Using Water, Viscous and Bread Swallows Between Controls and GERD Patients

	water swallows		viscous swallows		bread swallows	
	controls	GERD	controls	GERD	controls	GERD
Proximal peak pressure (mmHg)	98.5 ± 6	$75.2 \pm 3^*$	105.5 ± 5	$84.7 \pm 2.5^*$	109.1 ± 5	$91.4 \pm 3^*$
Distal peak pressure (mmHg)	72 ± 9	63.9 ± 3	75.0 ± 8	$59.4 \pm 3^*$	68.9 ± 7	60.9 ± 3
Nadir impedance (ohms)	309 ± 27	$882 \pm 59^*$	300 ± 13	$633 \pm 45^*$	302 ± 23	$650 \pm 40^*$
Distension to contraction latency (s)	3.2 ± 0.1	3.4 ± 0.3	1.7 ± 0.3	2.0 ± 1.0	1.5 ± 0.2	1.6 ± 0.2
Impedance ratio	0.3 ± 0	$0.5 \pm 0^*$	0.3 ± 0	$0.4 \pm 0^*$	0.4 ± 0	$0.5 \pm 0^*$
Distal IBP (mmHg)	6.6 ± 1.1	8 ± 0.5	10.5 ± 1.0	$13.4 \pm 0.6^*$	11.4 ± 1.0	$15.3 \pm 0.9^*$
IBP-A (mmHg)	5.2 ± 1.0	5.1 ± 0.5	8.5 ± 0.9	8.6 ± 0.5	8.9 ± 1.1	$12 \pm 1.0^*$
IBP-CT (mmHg)	6.4 ± 1.0	$8.7 \pm 0.5^*$	8.5 ± 0.8	9.5 ± 0.5	9.1 ± 0.9	$11.6 \pm 0.6^*$
IBP-EE (mmHg)	10.3 ± 0.8	11.7 ± 0.5	12.5 ± 0.8	$16.1 \pm 0.6^*$	13.1 ± 0.8	$17.7 \pm 0.7^*$
Bolus flow time (s)	4.1 ± 0.5	$2.0 \pm 0.2^*$	3.8 ± 0.5	$2.1 \pm 0.1^*$	3.3 ± 0.4	$1.8 \pm 0.2^*$

* $p \leq 0.04$ compared to controls. IBP: intrabolar pressure; IBP-A: IPB-accommodation; IBP-CT: IBP-compartmentalized transport; IBP-EE:IBP-esophageal emptying

Conclusion: Automated pressure flow analysis of HRIM studies demonstrates abnormalities of esophageal bolus transit and esophageal emptying in conjunction with lower proximal smooth muscle contractile function with all bolus consistencies in GERD compared to controls. Metrics assessing esophageal bolus presence may have prognostic value in GERD patients undergoing ARS.

Introduction: Oesophageal diverticula are rare diverticula of the gastrointestinal tract known to be associated with oesophageal motor disorders.

Aims & Methods: The aim was to study manometric abnormalities associated with oesophageal diverticula, using both wet and solid swallows. Patients underwent high resolution oesophageal manometry (HRM) in the upright position. 18 patients with oesophageal diverticula were found and were free of previous surgery. Traction diverticulum was excluded in all patients. We also included 10 healthy controls. HRM was performed using wet (5 mL of water) swallows in both groups, followed by solid (meat) swallows in patients. Mean age of the controls was 50 years old while it was 70 years old for patients.

Results: The main reported symptom was dysphagia (76%). HRM found 11 (61%) patients with an oesophageal motor disorder, including 2 oesophagogastric junction outflow obstruction [OGJOO], 4 achalasia (subtype 2: n=2; subtype 3: n=2), 4 distal oesophageal spasms [DES] and 1 jackhammer oesophagus, and was normal in 7 (39%) patients. In those patients with normal findings, solid swallows identified 4 (57%) additional motor disorders, including 2 OGJOO, 1 jackhammer oesophagus and 1 DES. Provocative testing using solid swallows increased the diagnostic yield by 22% in overall patients and by 57% in patients with normal manometry using wet swallows only. Mean pressure slopes at mid-oesophagus and distal oesophagus were greater in patients than healthy controls ($p < 0.05$ for wet swallows), as previously reported¹. Other metrics are summarized in the table.

HRM metrics with comparisons between wet swallows in controls and patients, and between wet and solid swallows among patients. * $p < 0.05$ ** $p < 0.01$ *** $p < 0.001$

	Controls (liquids)	Patients (liquids)	Patients (solids)
Number of swallows	9.30	9.94	9.41
EGJ resting pressure (mmHg)	29.30	28.76	34.66
Mean IRP 4s (mmHg)	11.50	14.32	18.25*
Mean DCI (mmHg.s.cm)	1315.10	2877.99	7343.07***
Distal latency (s)	6.70	6.05	7.11*
Intrabolar pressure (mmHg)	8.10	11.88*	15.19
Mean pressure slope mid-oesophagus (mmHg/s)	-0.65	2.27***	2.59
Mean pressure slope distal oesophagus (mmHg/s)	-0.36	1.41**	0.46

Conclusion: While more than one-third of HRM using wet swallows were normal, provocative testing using solid increased the diagnostic yield of the procedure by more than 50% in these patients. Analysis of pressure slopes confirmed the association of propagating peristalsis with the disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The management of achalasia targets relieving the obstruction at the esophagogastric junction (EGJ) by pneumatic dilation (PD), laparoscopic Heller myotomy (LHM) plus a fundoplication variant (Dor, Toupet and more rarely Nissen/Nissen-Rossetti). However, effective ablation of the LES barrier can induce gastroesophageal reflux disease (GERD). Recently, new metrics to evaluate EGJ function with high resolution manometry (HRM) have been introduced, such as EGJ contractile integral (EGJ-CI). Currently there are few data investigating how achalasia treatments impact EGJ function based on these metrics.

Aims & Methods: We aimed to assess the EGJ-CI metric in achalasia before and after different treatments, to verify if post-operative changes in this metric correlate to symptom relief and iatrogenic GERD following surgical treatments. Methods Between 2014 and 2015, we enrolled consecutive achalasia patients. All patients underwent clinical evaluation with Eckardt and GERDQ score, as

well as upper endoscopy, barium esophagogram and HRM before and 6 months after treatment. Achalasia was classified according to the Chicago Classification V3.0. The EGJ-CI was calculated using the distal contractile integral tool-box during three consecutive respiratory cycles. Patients underwent to pneumatic dilatation (PD), or LHM plus a Dor (LHM-D), Toupet (LHM-T) or a Nissen-Rossetti (LHM-NR) fundoplication. Ethical approval for the study was obtained.

Results: We enrolled 35 achalasia patients (14 Type I, 16 Type II and 5 Type III). Ten patients underwent PD, 11 LHMD, 8 LHM-T and 6 LHM-NR. At baseline, no differences among treatment groups regarding age, sex, pre-operative mean Eckardt score, GERDQ score, integral relaxation pressure (IRP) and EGJ-CI were recorded. All Type III subjects underwent LHM-D (3) and LHM-T (2). After all the procedures, in all the patients there was a significant decrease in Eckardt score, IRP and EGJ-CI ($p < 0.001$, < 0.001 and < 0.05 , respectively). PD and LHM-NR showed higher EGJ-CI (20 ± 9.3 and 25.3 ± 11.1 mmHg*cm, respectively) and IRP (12.2 ± 3.4 and 13 ± 4.5 , respectively) than LHM-D and LHM-T (18.4 ± 5.9 , $p < 0.05$ and 9.3 ± 4.1 $p < 0.05$ mmHg*cm, respectively for EGJ-CI; 5.2 ± 2.5 , $p < 0.05$ and 2.3 ± 3.7 $p < 0.001$ mmHg*cm, respectively for IRP). Post-operative Eckardt score was lower in LHM-D and LHM-T (2.1 ± 0.5 and 2.0 ± 0.6 , respectively) than PD and LHM-NR (4.2 ± 1.0 , $p < 0.01$ and 3.7 ± 1.5 , $p < 0.05$). Post-operative GERDQ score was significant higher in LHM-T (3.0 ± 1.7 vs. 8.2 ± 3.9 , $p < 0.05$). Low post-operative EGJ-CI values correlated with an increased risk of higher post-operative GERDQ score ($p < 0.05$, odds ratio 4.223, 95% CI 0.964–2.123).

Conclusion: All procedures performed to treat achalasia produced an adequate relief of dysphagia. LHM-D and LHMT seem to result in a stronger alteration of the EGJ, with LHM-T resulting in an increased risk of post-operative reflux.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1177 MULTIPLE RAPID SWALLOWING IN JACKHAMMER ESOPHAGUS PATIENTS: EVIDENCE FOR ALTERED NEURAL CONTROL

Introduction: Jackhammer esophagus is a rare esophageal motility disorder. Little is known about its pathophysiology; however, an excess of cholinergic drive has been suggested as an important etiologic factor.¹ Multiple rapid swallowing (MRS) is an adjunctive test in order to evaluate integrity of inhibitory and excitatory neural pathways. In healthy subjects body motor inhibition is observed during MRS and a contraction stronger than single swallows (SS) occurs after MRS, the so-called peristaltic reserve (MRS/SS DCI ratio > 1). In patients with nutcracker esophagus preservation of motor inhibition during MRS has been described with traditional manometry². No study has evaluated peristaltic reserve and motor inhibition with high-resolution manometry (HRM) in patients with jackhammer esophagus.

Aims & Methods: To evaluate MRS in a consecutive multicenter series of 42 Jackhammer esophagus patients (18 Male; 63 years; 55–71) according to Chicago 3 classification. 18 healthy subjects (HS) (seven male; 28 years; 23–33) from a published series were used as a control group.³ All patients underwent solid state HRM with ten 5 ml SS and one to three 10 ml MRS (30 patients performed at least two MRS). Standard HRM parameters during SS were evaluated. During MRS presence/absence of motor inhibition and 4 second integrated relaxation pressure (4sec IRP) were evaluated. After MRS distal contractile integral (DCI) was evaluated and DCI ratio between MRS and SS was measured. Mann Whitney, Wilcoxon and chi-squared tests were used when appropriate; data are shown as median-IQ range.

Results: Descriptive data in jackhammer patients are shown in table 1. Twelve patients did not have motor inhibition during at least one MRS (28% vs 5% in HS, $p < 0.05$). There was a trend toward a lower 4s IRP during MRS compared to SS (see table 1); however, values were higher than those of 4s IRP MRS in HS (5.1 mmHg; 2.2 – 11 vs 1.6 mmHg; 0.3 – 2 , $p < 0.0001$). MRS DCI was significantly lower than SS DCI; interestingly 26 patients had a MRS/SS DCI ratio < 1 (62% vs 22% in HS, $p < 0.005$) and it was lower than the MRS/SS DCI ratio of HS

(0.8 ; 0.4 – 1.1 vs 1.9 ; 1.1 – 2 , $p < 0.0001$) suggesting a reduction of the hypercontractile activity in the esophageal body.

HRM parameters during single and multiple rapid swallows in jackhammer patients. Median; interquartile range.

	SS	MRS	p value
4s IRP, mmHg	7.5; 4.9–13.1	5.1; 2.2–10.1	$p = 0.06$
DCI, mmHg.sec.cm	6506; 5605–8582	5537; 3568–8572	$p < 0.05$
CFV, cm/s	3.9; 2.9–5.5	4.4; 2.9–6.4	$p = 0.10$
DL, sec	6.8; 6.2–7.6	6.8; 5.5–7.4	$p = 0.09$

SS, single swallows; MRS, multiple rapid swallows; 4sec IRP, 4 second integrated relaxation pressure DCI, distal contractile integral; CFV, contractile front velocity; DL, distal latency.

Conclusion: Contrary to what occurs in healthy subjects, MRS reduce DCI value compared to SS in jackhammer esophagus patients, suggesting altered neural control of peristalsis. Differently to what previously observed with traditional manometry, motor inhibition during MRS is altered in a quarter of patients. Studies are needed in order to evaluate if reduction of DCI during MRS can improve dysphagia and chest pain in these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1178 GASTRIC PERORAL ENDOSCOPIC MYOTOMY (G-POEM) AS TREATMENT FOR FUNCTIONAL DELAYED GASTRIC EMPTYING: INITIAL ASIAN EXPERIENCE

M. Cai¹, J. Xu¹, P. Zhou¹

¹Endoscopy Center, Zhongshan Hospital, Fudan University, Shanghai/China

Contact E-mail Address: cai.mingyan@zs-hospital.sh.cn

Introduction: Functional delayed gastric emptying is a difficult-to-treat disorder, which is often expressed clinically as nausea/vomiting, fullness/early satiety, bloating and weight loss. Gastric peroral endoscopic myotomy (G-POEM) has been regarded as a novel and minimally-invasive therapy for functional delayed gastric emptying refractory to medical therapy. We herein report our initial experience of G-POEM in an Asian population with focus on technique in addition to safety and efficacy of this promising endoscopic therapy.

Aims & Methods: The data of consecutive patients who underwent G-POEM by a single expert endoscopist from October 2015 to November 2016 was collected. Procedures were performed, similar to POEM for achalasia, including initial mucosal incision, creating a submucosal tunnel, full-thickness (pyloro)myotomy, and closure of the mucosal entry. Patient demographics, etiology, Gastroparesis Cardinal Symptoms Index (GCSI) and gastric emptying scintigraphy (GES) were recorded before and after the procedure. Treatment outcomes and procedure related adverse events were also evaluated.

Results: A total of fourteen patients with refractory functional delayed gastric emptying, including eleven post-surgical (78.6%) and three diabetic (21.4%), were enrolled. The median age was 60 (range, 26–82) years. All patients were suffering from nausea, vomiting, bloating and weight loss. They all failed medical therapy including proton pump inhibitor, metoclopramide, mosapride, or domperidone. All fourteen patients underwent G-POEM successfully (100%) with the mean procedure time of 43.71 ± 13.08 mins. Gastric emptying scintigraphy (GES) was performed in five patients with improvement of mean half empty time (191.88 ± 83.19 mins vs. 91.44 ± 32.92 mins), and retention at 2 hours ($70.02 \pm 12.68\%$ vs. $33.48 \pm 20.32\%$). The median hospital stay after procedure was 6 days (range, 4–10). No procedure related adverse event (0%) was observed. During a median follow-up of eight months (range, 3–17.5 months), one patient (post-surgical) had symptom recurrence after 45 days after the procedure because of stenosis related to scan formation. One of the two diabetic patients with severe diabetes and diagnosis as diabetic peripheral neuropathy showed little response to G-POEM, while the GCSI was 34 before and 28 after. The other showed initial improvement with GCSI score 22 before and 10 after during the first follow-up. However, his symptoms reoccurred seven months after G-POEM and the latest GCSI score was 19. Overall GCSI after G-POEM (mean, 5.00 ± 2.57) decreased significantly comparing with the one before (mean, 22.55 ± 3.42).

Conclusion: G-POEM is a promising new endoscopic treatment option for functional delayed gastric emptying. Our initial data suggest it is safe and effective. Large studies are needed to determine safety, efficacy, long-term outcomes and determine which patient population benefits the most from this treatment option.

P1179 EFFECTIVENESS OF CAP-ASSISTED DEVICE IN THE ENDOSCOPIC MANAGEMENT OF FOOD BOLUS OBSTRUCTION IN THE UPPER ESOPHAGUS

M. Ooi, E. J. Young, N. Q. Nguyen

Department Of Gastroenterology And Hepatology, Royal Adelaide Hospital, Adelaide/Australia/SA

Contact E-mail Address: marieooi_al@yahoo.com

Introduction: Although cap-assisted technique has been shown to be effective in retrieving foreign bodies from the upper gastrointestinal tract, there is no data in food bolus obstruction (FBO). This study aimed to assess the performance of cap-assisted technique in the management of esophageal FBO, as compared to conventional endoscopic methods.

Aims & Methods: Outcomes of all patients who presents with FBO requiring emergency endoscopic management between 2011 and 2016 were prospectively collected. The main measured outcomes were procedural success, procedural time, complications and length of hospital stay.

Results: Of the 315 patients (214M:102F; 58.3±18.3 years) with FBO, 267 (84.7%) had evidence of food bolus in the esophagus on endoscopy and 48 (15.2%) patients had spontaneous passage of food bolus. Out of the 199 patients who had impacted FBO, 93 had cap-assisted technique and 106 had conventional approach, with no differences in the type and location of FB. The success rate of cap-assisted technique (100%) was comparable to that of conventional techniques (97.2%, $P=0.10$). Patients who had failed extraction by conventional techniques ($n=3$) were successfully treated when switched to cap-assisted approach. Cap-assisted approach was associated with a shorter total procedural time (34 ± 8 and 43 ± 22 min, $P=0.006$), a shorter length of hospital stay (0.95 ± 0.56 and 1.58 ± 1.36 days, $P=0.0017$) and more en-bloc removal (87.3% vs 22.8% , $P<0.001$). There were more complications in the conventional than the cap-assisted group (7/106 vs. 0/93; $P=0.01$).

Conclusion: Cap-assisted technique is 100% effective in the management of impacted FBO in the esophagus, with a significantly shorter procedural time and no complication. Although the findings suggest that cap-assisted technique should be the first line technique in the management esophageal FBO, further evaluation with a randomized multicenter trial is warranted.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1180 DO THE ENDOSCOPIC FINDINGS OF GASTRITIS BRING THE FD SYMPTOMS?

Introduction: Functional dyspepsia (FD) is defined that there is no evidence of organic disease which is likely to explain the symptoms. However, there was no obvious definition about "organic disease". Therefore, during the endoscopic examination, it happens that we can't judge whether obvious mucosal change like gastric erosion fulfill the exclusion criteria or not. Indeed, this issue was pointed out that there is notable inconsistencies in the exclusion criteria of FD (1). Recently, the Kyoto classification of gastritis has been published and used widely for the management of gastritis in Japan (2). In this classification, endoscopic findings are defined precisely. However, it is not discussed whether we can consider such findings as the "organic disease" or not. If these findings have no relation to FD symptoms, we can diagnose patients group as FD even if they have such endoscopic findings.

Aims & Methods: The aim of this study is to explore which endoscopic findings defined in the Kyoto classification of gastritis bring FD symptoms. To assess the symptoms of patients, we employed the modified-Frequency of Scale for the Symptoms of GERD questionnaire (m-FSSG) (3), which was developed for evaluation of dyspeptic symptoms in patients. It comprised 14 symptoms and was rated on a scale of zero to four in each question. This questionnaire is useful to distinguish between NERD and FD because the m-FSSG contains seven question about reflux symptoms (question 1, 4, 6, 7, 9, 10 and 12) and seven questions about dyspeptic symptoms (question 2, 3, 5, 8, 11, 13 and 14). We investigated 19 endoscopic findings (atrophy, intestinal metaplasia, diffuse redness, spotty redness, mucosal swelling, enlarged fold, nodularity, foveolar-hyperplastic polyp, xanthoma, depressive erosion, regular arrangement of collecting venules: RAC, fundic gland polyp, red streak, raised erosion, hematin, erosion, patchy redness, map-like redness, multiple white and flat elevated lesions) were classified based on the definition in the Kyoto classification of gastritis. Data were extracted from the records of subjects who underwent upper gastrointestinal endoscopy at our department between April 2015 and March 2017. Of the 2,079 subjects analyzed, we focused on 255 subjects who answered m-FSSG at the time of endoscopy after excluding subjects diagnosed with organic disease (GERD, peptic ulcers and cancers) endoscopically. We also excluded subjects who answered had symptoms related acid reflux (score 3 or 4) in m-FSSG. We divided 255 subjects into FD group and Control group. FD group was defined as the subjects who had epigastralgia (score 2, 3 or 4), postprandial fullness (score 3 or 4) or early satiation (score 3 or 4) in m-FSSG. After that, we compared the rate of FD group of patients with or without findings in each 19 finding.

Results: This study included 55 subjects in FD group and 200 subjects in Control group. The ratio was statistically lower in men than women in FD group than in Control group (43.6% vs. 61.0%, $p=0.02$). Atrophy (16.6% vs. 30.4%, $p=0.01$), spotty redness (9.1% vs. 23.0%, $p=0.02$), hyperplastic polyp (9.0% vs. 0%, $p=0.016$), were frequently seen in Control group than in FD group.

RAC (43.0% vs. 67.3%, $p=0.002$) were frequently seen in Control group than in FD group. Multivariate logistic regression (stepwise selection) showed that low age (under 65 years old) (OR 2.427, 95%CI 0.209–0.812, $p=0.01$) and RAC (OR 2.123, 95%CI 0.206–0.821, $p=0.012$) were related to FD. None of the findings of gastritis examined were related to FD.

Conclusion: It is revealed that endoscopic gastritis is NOT related to FD symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There was not available data about the overlap between functional dyspepsia (FD) and pancreatic diseases.

Aims & Methods: We aimed to determine whether epigastric pain syndrome (EPS) accompanying with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by Japan Pancreas Society (JPS) using endosonography. We enrolled 99 consecutive patients presenting with typical symptoms of FD, including patients with postprandial distress syndrome (PDS) ($n=59$), EPS with pancreatic enzyme abnormalities ($n=41$) and EPS without pancreatic enzyme abnormalities ($n=42$) based on Rome III criteria. Gastric motility was evaluated using the ¹³C-acetate breath test. Early chronic pancreatitis was detected by endosonography and graded from 0 to 7.

Results: The ratio of female patients among EPS patients (34/41) with pancreatic enzyme abnormalities was significantly ($p=0.0018$) higher than the ratio of female EPS patients (20/42) without it. Postprandial abdominal distention and physical component summary (PCS) scores in EPS patients with pancreatic enzyme abnormalities were significantly disturbed compared to those in EPS patients without it. Interestingly, AUC₅ and AUC₁₅ values (24.85 ± 1.31 and 56.11 ± 2.51 , respectively) in EPS patients with pancreatic enzyme abnormalities were also significantly ($p=0.002$ and $p=0.001$, respectively) increased compared to those (19.75 ± 1.01 and 47.02 ± 1.99 , respectively) in EPS patients without it. Overall, 64% of EPS patients with pancreatic enzyme abnormalities were diagnosed by endosonography as having concomitant early chronic pancreatitis proposed by JPS.

Conclusion: Further studies are warranted to clarify how EPS patients with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by JPS.

Introduction: Caustic esophageal injury is corrosive burns of esophagus and mostly caused by ingestion of chemical caustic substances such as strong acid or alkali. The caustic esophageal stricture is refractory and patients suffered from multiple dilation. Clinical ESD results revealed that benign stricture would be usually caused by more 75% mucosa loss of circumferential esophagus. Cultured skin tissue was effective for wound healing and preventing undesired fibrosis. We hypothesized that autologous esophageal mucosa transplantation might inhibit refractory fibroplasia and delay the recurrence of esophageal strictures.

Aims & Methods: A man presented with the caustic esophageal stricture (32–40 cm from the incisors), which was caused by accidental exposure of anhydrous acetic acid. Under X-ray, routine endoscopic dilation was firstly applied to a diameter of 1.28 cm. Three days later, with the informed consent, ESD operation was utilized to dissect 5*0.5 cm normal esophageal mucosa at the 18–23 cm location from the incisors. Mucosal defect was cured by fibrin glue after Argon plasma coagulation. Under endoscopic surveillance, the excised mucosa was transplanted to the surface of the narrowed segment and fixed with 3 titanium clips.

Results: The endoscopic follow-up was planned every month. After 1 month, 18–23 cm esophageal region has healed to be normal. Within 6 months, the stricture process was excitingly delayed as expected. The patient stated his symptom was remarkably improved. Gastrosocopy revealed the esophageal implanted lesion was covered with an epithelium and the luminal surface was flat, without ulceration.

Conclusion: Autologous esophageal mucosa transplantation might facilitate tissue re-epithelialization, reduce pathological fibroplasia, and be helpful for managing or preventing esophageal strictures. More clinical controlled trials are required to provide evidenced-based recommendation and promote its clinical application.

Introduction: Functional dyspepsia (FD) is commonly associated with sleep disturbance, which has been attributed to comorbid anxiety, depression and bothersome gastrointestinal symptoms. However, it is unclear whether obstructive sleep apnoea (OSA) is specifically associated with FD.

Aims & Methods: We aimed to compare the prevalence of FD in patients with OSA and healthy volunteers. A total of 60 consecutive OSA patients (defined as Epworth sleepiness scale ≥ 10 , and apnea-hypopnea index ≥ 10 /hour during polysomnography; mean age: 47.6 years, male: 83.3%) and 60 healthy age-and-sex-matched volunteers were recruited in a prospective case-control study. Questionnaires were applied for the diagnosis of functional gastrointestinal disorders (FGIDs) according to Rome III criteria. Anxiety and depression were evaluated using the Hospital Anxiety and Depression Scale (HADS), sleep quality was evaluated by the Pittsburgh Sleep Quality Index, and fatigue was assessed by the Multidimensional Fatigue Inventory (MFI-20) Chinese version.

Results: The prevalence of FD was 28.3% and 8.3% (17 vs 5, $P=0.005$), and the prevalence of symptomatic gastro-oesophageal reflux disease was 18.3% and 5% (11 vs 3, $P=0.023$) in the OSA group and healthy volunteer group, respectively. OSA patients had higher anxiety and depression symptom scores, worse sleep quality, and more fatigue compared with healthy volunteers. In the multivariate logistic regression adjusting for age, sex and body mass index, OSA (odds ratio 4.93, 95% CI 1.01–24.1, $P=0.049$) and depression (odds ratio 4.91, 95% CI 1.44–16.71, $P=0.011$) were independently associated with FD.

Conclusion: To the best of our knowledge, this is the first study showing that OSA is independently associated with functional dyspepsia. Sleep disturbances previously attributed to psychological comorbidities in FGID may in fact arise from undiagnosed OSA. We recommend screening for OSA as part of the management of FD.

Introduction: The assessment of acid secretion is important in order to prescribe PPIs. The gold-standard to measure the maximal acid output (M.A.O.) is the collection of gastric after an i.m. injection of pentagastrin. However, this method is not currently used in clinical practice. Serum pepsinogen I (PGI) has been proposed as a non-invasive surrogate. Aim of this study was to compare in a group of patients with different acid related diseases serum levels of PGI and M.A.O.

Aims & Methods: We enrolled 124 patients ($M=84$, mean age $=45.3 \pm 13.05$ range $=17-80$) affected by chronic atrophic gastritis (28, $M=17$, mean age 51.2 ± 13.7 ys range $20-73$) characterized by achlorhydria or low levels of acid production (Group 1), or by duodenal ulcer (50, $M=42$, mean age $=43.5 \pm 11.5$ range $=17-65$) in which an hypersecretory status is claimed (Group 2). As control group, we studied 46 patients ($M=44$ mean age $=44.0 \pm 13.4$ range $=25-80$) with normal upper GI endoscopy and gastric histology, without previous history of neoplasms or upper gastrointestinal surgery (Group 3). In all patients we measured M.A.O. by means of two hours collection of gastric juice (basal 30', followed by an i.m. injection of pentagastrin at the dosage of $6 \mu\text{g/kg}$) (M.A.O. normal values: $5-25 \text{ mEq/h}$). All patients underwent blood sample for determination of serum PGI (BioHit Ojy, Finland; normal values: $30-120 \mu\text{g/l}$). All determinations, both for M.A.O. and PGI were made off medication.

Results: The mean M.A.O. value in Group 1 was 2.15 mEq/h , in Group 2 52.49 mEq/h , in Group 3 17.48 mEq/h . A statistically significant difference was found between the 3 groups (Group 1 vs. Group 2: $p < 0.000001$; Group 1 vs. Group 2: $p < 0.0001$; Group 2 vs. Group 3: $p < 0.0001$). The PGI mean values in Group 1 was $11.39 \mu\text{g/l}$, in Group 2 $107.72 \mu\text{g/l}$, in Group 3 $84.28 \mu\text{g/l}$ (Group 1 vs Group 2: $p < 0.000001$; Group 1 vs Group 2: $p < 0.00001$; Group 2 vs Group 3: $p < 0.05$). The relationship between M.A.O. and PGI showed a Pearson $R=0.683$ ($p=0.0001$). No statistically significant difference was found comparing M.A.O. and PGI in the single groups ($p=ns$).

Conclusion: Serum PGI levels are fitting with M.A.O. both in hypo- and hyper-acid secretory conditions like chronic atrophic gastritis and duodenal ulcer, as well as in control subjects, suggesting that PGI could be adopted in clinical practice to assess gastric acid production in individual subjects for a proper management of acid related diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1185 THE DISCREPANCY BETWEEN THE ACID REGURGITATION SYMPTOMS AND ENDOSCOPIC GERD GRADE IN DIABETES MELLITUS PATIENTS

K. Sakitani, N. Suzuki

The Institute for Adult Life Diseases, Asahi Life Foundation, Tokyo/Japan

Contact E-mail Address: sakitani-ky@umin.ac.jp

Introduction: Gastroesophageal reflux disease (GERD) is caused by reflux of gastric acid into esophagus. It is reported that chronic inflammation caused by GERD can lead to precancerous changes; Barrett's esophagus. Thus, it could be critical to assess the GERD. Diagnosis of GERD is based on the subjective symptoms such as acid regurgitation. GERD is also diagnosed by endoscopy, and the Los Angeles (LA) classification is commonly used to grade reflux esophagitis endoscopically. It is well known that diabetes mellitus (DM) patients can develop neuropathy and their ability to feel pain can decrease. However, it is not known whether there is a discrepancy between the symptoms and endoscopic GERD grade in DM patients.

Aims & Methods: From May 2015 to September 2016, patients who were taken esophagogastrroduodenoscopy by experienced endoscopists at our institution were consecutively enrolled. All the patients completed the Gastrointestinal Symptom Rating Scale (GSRS); an interview-based rating scale consisting of 15 items including the question on acid regurgitation (*Dig Dis Sci* 1988). The GSRS has a seven-graded Likert type scale (score 1 represents absence of symptom, and score 7 represents very bothersome symptom). Gastric atrophy, reflux esophagitis, and esophageal hiatal hernia were diagnosed endoscopically. The study patients were categorized according to the grade of LA classification of GERD. The prevalence of patients with positive GSRS score (i.e. 2 or more) in the DM group and non-DM group were compared using the Pearson's chi-square test.

Results: A total of 2438 patients (647 females and 1791 males, mean age 62.4 years) were examined. Of these, 1040 patients (42.7%) were DM, and 1398 patients (57.3%) were non-DM patients. The prevalence of gastric atrophy, reflux esophagitis, and esophageal hiatal hernia were not different in DM group and non-DM group. Mild GERD (LA-A) was found in 251 patients (10.6%, 92 DM patients and 159 non-DM patients), and severe GERD (LA-B and more severe) was found in 76 patients (3.12%, 40 DM patients and 36 non-DM patients). Of the 36 non-DM patients with severe endoscopic GERD, 30 patients (83.3%) had positive GSRS score of acid regurgitation; however, of the 40 DM patients with severe endoscopic GERD, 19 patients (47.5%) had positive GSRS score of acid regurgitation. The prevalence ratio of patients with positive GSRS score in severe endoscopic GERD was statistically lower in DM patients than in non-DM patients ($p=0.0016$).

Conclusion: There is a discrepancy between the subjective symptoms and endoscopic GERD grade in DM patients. DM patients' ability to feel acid regurgitation could decrease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1186 SARCOPENIA AS A LEADING RISK FACTOR FOR EROSIVE ESOPHAGITIS: A LARGE-SCALE CROSS-SECTIONAL STUDY

T. Kim, T.J. Kim, H. Lee, J.J. Kim

Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: attack836@naver.com

Introduction: Obesity is an established risk factor for reflux esophagitis. Yet, the association of sarcopenia and obesity status with reflux esophagitis remains unclear. We studied the association between obesity, sarcopenia, and sarcopenic obesity and risk of reflux esophagitis in a large number of asymptomatic men and women.

Aims & Methods: We conducted a cross-sectional study of 32,762 asymptomatic adults who underwent routine health check-ups including screening endoscopy from August 2006 to December 2011. Sarcopenia was defined as appendicular skeletal muscle mass (ASM)/body weight (%) value beyond two standard deviations below the mean for healthy young adults. Participants were categorized into four groups according to obese and sarcopenic status: normal, obese, sarcopenic, and sarcopenic obese.

Results: In a multivariate model adjusted for age, sex, smoking status, alcohol intake, regular exercise, and metabolic variables, risk of reflux esophagitis was higher in obese [adjusted odds ratio (aOR), 1.38; 95% confidence interval (CI), 1.26–1.52], sarcopenic (aOR, 2.20; 95% CI, 1.48–3.29), and sarcopenic obese participants (aOR, 1.68; 95% CI, 1.39–2.03) than in normal participants. The ORs comparing sarcopenic and sarcopenic obese participants to obese participants were 1.59 (95% CI, 1.06–2.38) and 1.22 (95% CI, 1.02–1.47), respectively. In addition, the risk of reflux esophagitis according to sarcopenic and obese status was observed similarly in all subgroups that were evaluated.

Conclusion: Our findings suggest that sarcopenia, regardless of obesity, is more harmful condition for reflux esophagitis than obesity without sarcopenia.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1187 FOOD RATE (FREQUENCY AND TIME SPENT IN EATING) IN PATIENTS WITH MORBID OBESITY. DIFFERENCES AND SIMILARITIES BETWEEN MEN AND WOMEN

J. Perez De La Serna¹, A. Ruiz De León¹, S. Ayllón Cano¹, C. Sevilla Mantilla¹, A. Sánchez Pernaute², E. Rey¹, B. Merchan Gomez¹

Introduction: Obesity is considered one of the 21st century plagues in the Western world. Although its etiology is multifactorial, eating habits represent an important factor in its development. (1). The caloric load, the proportion of its components and its patterns have been the object of multiple studies (1–5). One of the most controversial aspects is the relationship between the frequency of meals and body weight.

Aims & Methods: The aim of the study was to determine the food rhythm (frequency and time spent in eating) in patients with morbid obesity (MO), based on data from the diary of the 24-H esophageal pH-monitoring studies.

This was a retrospective study, including 100 patients (77 women), with MO in whom bariatric surgery was indicated and 118 non-obese subjects from the control group of the Spanish Digestive Motility Group.

All were submitted to esophageal manometry and 24-H esophageal pH-monitoring according to the usual technique. During pHmetry it was recommended that the diet be similar as usual.

The relationship of demographic aspects with the number of meals and the time invested in them, based on data from the pH meter was analyzed.

Statistical analysis was performed with the STATGRAPHICS Centurion program. The limit of statistical significance was set at $p < 0.05$.

The study was approved by the ethics committee of our hospital. The informed consent of the participants was obtained for the performance of the tests.

Results: The mean age of patients with MO was 43.1 years (range 19–68) with no difference between men and women. The mean BMI was 41.55 (M 43.3; F 41, $P < 0.05$).

In the 118 subjects of the control group (63 women), the mean age was 28.3 years (range: 18–72 years), BMI 23.2, (M 24.2; F 22.3, $P < 0.05$). Age and BMI differences between controls and obese were statistically significant.

The number of meals is higher in the obese patients than in the controls. 76.3% of the controls performed ≤ 4 meals. In obese patients this percentage was 56%. The mean time spent at each meal showed statistically significant differences between controls (20.5 ± 7.7 min) and obese (17.7 ± 7.25 min) and between controls and obese women (17.8 ± 7.2 min).

In MO, the relationship between BMI and the number of meals shows a higher BMI in those who do less number of meals, with significant differences between those who perform ≤ 3 meals and those that perform ≥ 4 . This difference is set at the expense of men and not achieved statistical significance in women.

Conclusion: - MO patients eat more times a day than controls, this behavior is more evident in women.

- MO patients eat faster than controls without differences between men and women.

- Our results show an inverse relationship between the number of meals and body mass index. This behavior is more evident in men.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Epidemiologic findings of low-volume alcohol consumption in relation to gastrointestinal cancers including gastric cancer are inconsistent.

Aims & Methods: The association between alcohol intake and esophageal, gastric and colorectal cancer risk was examined in a population-based prospective cohort of 23,323,730 adults in Korea who had undergone a biennial evaluation provided by the National Health Insurance Corporation between the years 2009 and 2012.

Results: After median 5.4 years of follow-up, 9171 esophageal, 135,382 gastric and 154,970 colorectal cancer cases were identified. Cox proportional hazards regression models were used to estimate hazard ratios (HR) and corresponding 95% confidence intervals (95% CI). Light drinking as well as moderate to heavy alcohol consumption significantly increased the risks of the three gastrointestinal cancers (HR 1.51; 95% CI, 1.43–1.60; HR 1.08; 95% CI, 1.06–1.09; HR 1.12; 95% CI, 1.11–1.14) compared with non-drinkers after adjusting for age, sex, smoking, exercise, income, body mass index, and diabetes. For esophageal cancer, there was a dose-dependent linear relationship. However, no association was observed between prediagnostic alcohol consumption and all cause-mortality.

Conclusion: Light drinking including even one alcoholic drink a day is associated with increased risks of esophageal, gastric and colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1189 THE INFLUENCES OF VISCERAL FAT AREA ON THE SITES OF ESOPHAGEAL MUCOSAL BREAKS AND SYMPTOM SEVERITIES IN SUBJECTS WITH GASTROESOPHAGEAL REFLUX DISEASES

Contact E-mail Address: kimjaehak@dumc.or.kr

Introduction: Some studies have suggested the central obesity as a risk factor for gastroesophageal reflux diseases (GERD). However, the associations between visceral adipose tissue (VAT) and the sites of esophageal erosions or the symptom severities of GERD have not been studied yet.

Aims & Methods: The aim of this study was to evaluate the influences of visceral fat area on the locations of erosions and symptoms of GERD. The subjects who underwent abdomen computerized tomography and esophagogastroduodenoscopy for routine checkup at the same day were collected from January 2007 to October 2016. 177 subjects who had erosive esophagitis (LA class A to D) were enrolled. Questionnaires including gastrointestinal symptoms were written before examinations. The abdominal obesity was evaluated by measuring visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), ratio of VAT to SAT, total adipose tissue (TAT), body mass index (BMI) and waist circumference (WC).

Results: Lesser curvature (LC) side of esophagogastric junction (EGJ) was the most frequent site of mucosal breaks (103 cases, 58.2%) followed by posterior wall side (71 cases, 40.1%), anterior wall side (25 cases, 14.1%) and fundus side (16 cases, 9.0%). Mucosal breaks in LC side were frequently observed in male subjects (61.3% vs. 36.4%, $p = 0.04$). BMI (25.6 ± 4.5 vs. 24.2 ± 3.1 , $p = 0.019$) and WC (89.0 ± 11.8 vs. 85.0 ± 9.1 , $p = 0.01$) were significantly higher in LC group. Moreover, VAT, ratio of VAT to SAT, and TAT were significantly higher in LC group. In the multivariate analysis, a higher VAT area (odds ratio (OR) 3.47, 95% confidence interval 1.38 to 8.73, 1st quartile vs. 4th quartile, $p < 0.01$) and ratio of VAT to SAT (OR 2.99, 95% CI 1.15 to 6.70, 1st quartile vs. 4th quartile, $p = 0.02$) were strongly associated with the mucosal breaks in LC

side. However, TAT was not significant in the multivariate analysis. Lower HDL-cholesterol levels (OR 0.28, 95% CI 0.11 to 0.67, $p < 0.01$) and much coffee consumption (OR 2.50, 95% CI 1.06 to 5.86, $p = 0.035$) were associated with the severities of GERD.

Conclusion: Mucosal breaks in LC side of EGJ were associated with visceral obesity measured by VAT, ratio of VAT to SAT, BMI and WC. Life style modification such as in left decubitus sleeping position might be emphasized in the subjects with visceral obesity.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1190 A LESS COMPETENT OESOPHAGO-GASTRIC JUNCTION IS ASSOCIATED WITH OESOPHAGEAL ACID HYPERSENSITIVITY EVEN IN HEALTHY CONTROLS

Introduction: In normal subjects, the oesophago-gastric junction (OGJ) sphincter complex maintains a tight barrier between the oesophagus and stomach acid. However, gastro-oesophageal reflux disease (GORD) caused by acidic reflux has a prevalence of up to 26% [1]. One major factor determining whether gastro-oesophageal reflux occurs and eventually generates symptoms is the competency of the OGJ, which can be studied using distensibility testing. This way, we have previously shown in patients with Barrett's oesophagus and healthy controls that an incompetent sphincter function was associated with more frequent reflux symptoms [2]. In the same patient groups, we also found greater oesophageal acid exposure and lower mucosal baseline impedance to be associated with impaired sphincter function. The latter probably represents a proxy for mucosal damage [3]. Other factors known to increase the perception of gastro-oesophageal reflux episodes are greater acidity, larger volume, and more proximal extent of the reflux content along with impaired mucosal integrity and sensitisation (peripheral and central) [1]. All of this said no studies of our knowledge have specifically addressed the possible association between sphincter function of the OGJ and oesophageal sensitivity.

Aims & Methods: We aimed to characterize oesophageal sensitivity in relation to OGJ competence, hypothesizing that sensitivity increases with impaired sphincter function. Twenty-three patients with Barrett's oesophagus (mean age: 64.2 ± 7.7 years) and 12 healthy controls (mean age: 54.9 ± 10.8 years) were examined. A standard upper endoscopy to locate the OGJ was followed by distensibility testing of the OGJ using the EndoFLIP probe. At a later visit, experimental oesophageal sensitivity was assessed using a multimodal stimulation probe. After placement in the oesophagus just above the OGJ, the probe allows the filling and emptying of an attached polyurethane bag with water, stimulation with electrical current, and infusion of acid. Using this probe, mechanical distension of the bag, thermal stimulation at increasing temperature, electrical stimulation, and acid perfusion with 0.1 M hydrochloric acid (a Bernstein test) were performed. All stimulations were stopped when the subject felt moderate pain, equal to seven on a 0–10 visual analogue scale validated for visceral pain. Data were analysed using multi-level, mixed-effects regression analysis in Stata 12.

Results: Oesophageal acid sensitivity increased with a more incompetent sphincter function: A lower tolerated acid volume was associated with greater distensibility index ($P = 0.03$) and with lower pressure ($P = 0.03$) in the OGJ in all subjects analysed together and separately in healthy controls ($P = 0.006$ and 0.01 respectively). Performing separate analyses in patients with BO, these associations were not present (all $P > 0.7$). Sphincter function was associated with neither oesophageal sensitivity to mechanical, heat, nor electrical stimulation (all $P > 0.13$).

Conclusion: Oesophageal acid sensitivity increased with a more incompetent OGJ. Based on this and previous findings, we suggest that even in some healthy controls, a modest degree of OGJ incompetence allows gastric acid to reflux. This may again lead to low-grade oesophageal inflammation and mucosal damage, thus evoking acid hypersensitivity. The latter mechanism probably constitutes a reflex protective mechanism towards acid reflux.

Disclosure of Interest: B.P. McMahon: Barry P McMahon holds a minor share in Crospon Inc., Galway, Ireland who manufactures the EndoFLIP probe. All other authors have declared no conflicts of interest.

P1191 THE MUCOSAL INTEGRITY IN PHENOTYPES OF GASTROESOPHAGEAL REFLUX DISEASE AND FUNCTIONAL HEARTBURN

P. Ergun, S. Kipcak, S. Bor

Gastroenterology Sec., Ege Reflux Study Group, Ege University, Izmir/Turkey

Contact E-mail Address: pelinergun@yahoo.com

Introduction: Three different phenotypes of gastroesophageal reflux disease (GERD) such as erosive reflux (ERD), nonerosive reflux (NERD), esophageal hypersensitivity (EH) and functional heartburn (FH) might have different pathophysiological changes within the esophageal epithelium and the data is limited.

Aims & Methods: We aim to investigate the electrophysiological differences and diffusion characteristics as a reflection of tissue integrity using Ussing chamber system. Distal esophageal mucosal biopsies from 14 healthy controls (5 men, 40.6 ± 11.2 years) and 62 patients with GERD (40 men, 42.9 ± 12.3 years, $n = 26$ LA grade A/B, $n = 8$ LA grade C/D, $n = 22$ NERD, $n = 6$ EH) and 11 patients with FH were studied from November 2015 until March 2017. GERD and quality of life questionnaires, high-resolution esophageal manometry, 24h impedance-pH monitoring, upper gastrointestinal endoscopy with esophageal biopsies were performed in all patients. Biopsies were put into the chambers to measure the transepithelial resistance (TEER), potential difference (PD) and tissue permeability via fluorescein diffusion within two hours as well as evaluation of dilated intercellular spaces with light microscopy.

Results: Esophageal biopsies of healthy volunteers (163.6 ± 41.1 ohms) had significantly higher TEER when compared to total GERD patients (132.5 ± 38.7 ohms). Although the TEER results of whole GERD subtypes were decreased compared to healthy controls, only ERD groups were significantly lower (123.3 ± 29.8 ohms) (Table 1). There was also no significant difference in any parameters between NERD, FH and EH groups. The mucosal permeability of GERD subtypes was significantly higher than the healthy controls. The PPI-unresponsive subjects ($n = 10$, 94.8 ± 36.5 pmols) were much more permeable to fluorescein compared to PPI-responsive subjects ($n = 52$, 56.0 ± 32.4 pmols) within all GERD patients ($p = 0.009$).

Table 1

GROUPS	TEER (Ohms)	PD (V)	PERMEABILITY (pmols)
Healthy Controls	163.6 ± 41.1	2.2 ± 0.9	43.9 ± 16.6
GERD (total)	$132.5 \pm 38.7^{**}$	2.6 ± 1.5	$62.2 \pm 35.8^{*}$
Esophageal Hypersensitivity	150.6 ± 23.9	2.2 ± 1.0	71.8 ± 34.5
NERD	139.6 ± 50.2	2.2 ± 1.3	$65.6 \pm 39.2^{*}$
ERD (total)	$123.3 \pm 29.8^{*}$	$3.0 \pm 1.6^{**\odot}$	$58.3 \pm 34.7^{**}$
ERD grade A/B	$130.5 \pm 27.8^{*}$	2.9 ± 1.6	54.0 ± 30.5
ERD grade C/D	$105.8 \pm 32.7^{*}$	3.2 ± 1.6	72.6 ± 43.6
Functional Heartburn	145.3 ± 42.7	1.9 ± 0.9	67.0 ± 35.2

Conclusion: The TEER and permeability results imply that ERD and NERD groups showed a barrier disruption. However, epithelial permeability was not different in EH and FH groups. The dilatation of intercellular spaces may contribute to increased mucosal permeability in true-NERD and ERD patients. EH and FH patients might have different pathophysiology than others.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1192 PEPSIN AND PH LEVELS OF HUMAN GASTRIC JUICES IN GASTROESOPHAGEAL REFLUX DISEASE SUBGROUPS AND FUNCTIONAL HEARTBURN

Introduction: The major noxious agents of gastroesophageal reflux disease (GERD) on the esophageal epithelium are gastric acid and pepsin. Nevertheless, there is no precise information about pepsin concentrations in gastric juice.

Aims & Methods: We aim to address the pepsin values and pH results among subtypes of GERD and functional heartburn. 46 patients with GERD (23 erosive reflux disease LA grade A/B (ERD-A/B), 5 ERD-C/D, 14 nonerosive reflux disease-NERD, 4 esophageal hypersensitivity-EH), 8 functional heartburn (FH) and 17 healthy controls (HC) were included into the study. Upper gastrointestinal endoscopies were performed off PPI. Patients were instructed not to aspirate the local anaesthetic solution and biopsy channel of the endoscope was dried before the suction. The gastric juices from the subjects were aspirated during endoscopy into a special beaker and their pH values were measured immediately. The specimens were analysed using the Peptest lateral flow device (RD Biomed Ltd UK), a colorimetric assay containing two unique human monoclonal antibodies that capture and detect pepsin protein.

Results: There were no significance between pepsin levels in any GERD phenotypes, FH and healthy controls (Table 1). The pH results of patients with ERD (1.8 ± 0.6) were significantly lower versus HC (2.6 ± 1.5). The pH levels of the

esophageal hypersensitivity (1.5 ± 0.2) were significantly decreased when compared to HC (2.6 ± 1.6) and also true NERD (4.0 ± 2.0).

Table 1

	Pepsin (ng/ml)	pH
ERD (total)	514.7 \pm 282.1	1.8 \pm 0.6 ^a
ERD-A/B	521.0 \pm 284.9	1.8 \pm 0.6
ERD-C/D	485.5 \pm 299.2	2.1 \pm 1.0
Total NERD	456.9 \pm 322.1	3.5 \pm 2.1
True NERD	428.1 \pm 293.0	4.0 \pm 2.0
EH	536.0 \pm 432.1	1.5 \pm 0.2 ^{a,c}
GERD (total)	494.5 \pm 294.1	2.4 \pm 1.6
FH	654.2 \pm 300.4	2.1 \pm 1.1 ^y
HC	596.2 \pm 302.8	2.6 \pm 1.5

Conclusion: Pepsin may be considered a damaging factor in pathophysiology of GERD, but we could not find any difference between GERD phenotypes and unaffected controls. NERD group had less gastric acid versus other groups but this finding needs more studies to confirm.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1193 NON INVASIVE DIAGNOSIS OF UPPER GI DISEASES IN A PRIMARY CARE SETTING: A STUDY ON 1,900 PATIENTS

Introduction: Gastropanel® is a non invasive test suggested able to perform a kind of "serological biopsy" of gastric mucosa. Aim of the study was to assess a proper diagnosis of different upper gastrointestinal (GI) diseases in a population suffering from upper GI disturbances in a primary care settings by means of serology.

Aims & Methods: We enrolled 1900 consecutive patients (M=769; mean age=56.4 ys, range=29–78 ys) showing upper GI troubles. Exclusion criteria: upper GI surgery, alarm symptoms. All patients underwent a blood sample for Gastropanel® (BioHit Oyj, Finland): pepsinogen I (PGI), pepsinogen II (PGII), gastrin-17 (G-17) and IgG against *Helicobacter Pylori* (Hp-IgG). The normal values: PGI: 30–120 µg/L, PGII: 2–15 µg/L, G-17: 1–9 pmol/L, Hp-IgG: <30 U/L. The diagnosis of Hp-related non-atrophic gastritis was made by means of the levels of PGII >10 µg/L and Hp-IgG >30 U/L; the diagnosis of gastroesophageal reflux disease (GERD) was made when G-17 was low: <2 pmol/L; the diagnosis of chronic atrophic gastritis (CAG) was made when PGI was <30 µg/L and G-17 >14 pmol/L. Finally when all the four parameters were normal, the subjects were classified as normal. All patients underwent upper GI endoscopy to support the serological diagnosis, with appropriate gastric biopsy according with OLGA classification.

Results: Four hundred and eighty eight patients were classified as affected by Hp-related non-atrophic gastritis (26%); 782 patients were classified as GERD patients (41%); 547 patients were classified as normal (29%). 83 patients were classified as CAG (4%). In 96% out of the 488 patients with Hp-related non-atrophic gastritis the features was confirmed by gastric histology (OLGA 0, 1, 2); in 91% out of the 782 patients diagnosed as GERD subjects, the diagnosis was confirmed by oesophagitis at endoscopy in 313 patients, positive Demeester score in 170 out of 221 patients at 24 hours pH-metry or presence of typical symptoms (heartburn and/or regurgitation) in 547 patients. The great majority of 83 patients in which the diagnosis was CAG showed a picture of OLGA 3 (56.6%) or OLGA 4 (24.2%).

Conclusion: Non-invasive diagnosis of upper-GI diseases when alarm symptoms are absent seems to be promising to improve the appropriateness of endoscopy, as well as to address subjects affected by Hp infection to the cure and GERD patients to the therapy for reflux. The diagnosis of a precancerous condition like CAG before performing endoscopy could address to a better biopsic sampling

Disclosure of Interest: All authors have declared no conflicts of interest.

P1194 CHANGES IN ANTHROPOMETRIC AND METABOLIC PARAMETERS RELATED TO GASTROESOPHAGEAL REFLUX DISEASE IN NON-OBESE CASES

Introduction: Prevalence of obesity and the obesity-related diseases have been increasing in recent years(1). In the studies conducted there are views claiming that visceral fat-related central obesity causes digestion system diseases and increase in the number of gastroesophageal reflux symptoms in particular (1–6).

Aims & Methods: In this study, in the cases of non-obese (Body mass index (BMI) <30), it is aimed to assess the effects of insulin resistance and the changes observed in the anthropometric and bioelectrical impedance measurements upon the reflux symptoms. Our study 120 BMI <30 dyspeptic non-obese, gastroesophageal reflux disease (GERD) diagnosed according to FSSG scale (Frequency scale for the symptoms of gastroesophageal reflux disease) and 50 BMI <30 non-dyspeptic, non-obese and not (GERD) diagnosed according to FSSG cases have been included. The cases included in the study concerned have been surveyed by means of the questionnaire including the demographic data and the extra esophageal reflux symptom. Serum biochemistry analyses (fasting glucose, insulin, lipid panel, uric acid, TSH, ALT) have been checked. Waist circumference has been measured. Body compositions and anthropometric measurements have been assessed through the bioelectrical impedance method (TANITA).

Results: In this study a statistically significant difference ($p < 0.05$) has been found when GERH-diagnosed group is compared with the healthy control group in regard to waist circumference, BMI; LDL, Fat, Fat Mass, Total Body Water(TBW), obesity level, reflux score, acid reflux score and total score measurements. Fat free mass (FFM), muscle mass, bone mass, bone mineral density (BMR) measurements in between the both groups have not been found statistically significant difference ($p > 0.05$) (Table 1). Considering the extra esophageal reflux symptoms a significant difference ($p < 0.05$) between the group suffering from sore throat, apnea, teeth grinding and GORH and the healthy control group has been found. Within the patients group a positive correlation between acid reflux score and BMI ($r = 0.298$) ($p < 0.001$), LDL ($r = 0.387$) ($p < 0.001$), visceral fat ($r = 0.180$) ($p < 0.049$) has been determined. A negative correlation between acid reflux score and TBW ($r = -0.273$) ($p < 0.003$) has been determined.

Table 1: Metabolic parameters and bioelectrical impedans findings

	Control Group (n=50) Median (Min.-Max.)	Patient Group (n=120) Median (Min.-Max.)	Total Number (N=170) Median (Min.-Max.)	P Value

Total Score	20.50 (12–30)	33 (17–53)	29 (12–53)	<0.001

Mann Whitney U Test(Monte Carlo) - Min.:Minimum - Max.:Maximum

Conclusion: The frequency and severity of gastroesophageal reflux symptoms in the non-obese is closely related with body fat composition as those in the obese. Increase in abdominal and visceral fat composition may cause high risk of gastroesophageal reflux disease in individuals irrespective of their obesity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Esophageal baseline impedance (BI) levels have been recently proposed as a marker of mucosal integrity. Indeed, patients with non-erosive reflux disease (NERD) showed lower distal esophageal BI levels compared to healthy controls (HCs) due to the presence of abnormal distal esophageal acid exposure time (AET). On the other hand, no differences were found between NERD and HCs at proximal esophagus due to the limited proximal migration of the refluxate. Systemic sclerosis (SSc) is a systemic disease characterized by the deposition of collagen and matrix proteins in the connective tissue of the skin and visceral organs, such as the gastrointestinal tract. This event could potentially affect the conductivity of the esophageal wall and consequently reduce BI levels, also at proximal level, but data in this regard are limited.

Aims & Methods: We aimed to prospectively compare BI levels between a group of NERD patients and two groups of SSc patients, one with a clear manometric picture of scleroderma esophagus (i.e. hypotensive esophago-gastric junction pressure and absent peristalsis) and one without esophageal involvement. Consecutive patients with heartburn and those with a definite diagnosis of SSc underwent upper endoscopy in order to assess the presence of esophageal mucosal lesions. Further, a group of healthy subjects was used as controls (HCs). Thereafter, all endoscopy-negative and SSc patients underwent esophageal high-resolution manometry and impedance-pH testing off-therapy. Impedance-pH tracings were blindly and manually reviewed, and we measured distal AET and BI values at 3, 5, 7, 9, 15 and 17 cm above the lower esophageal sphincter, during the overnight rest, for at least 30 minutes after excluding swallows and reflux induced changes. NERD was diagnosed in case of reflux symptoms and abnormal AET.

Results: Fifty patients [38F; mean age 51yrs] with NERD, 50 SSc patients [44F; mean age 48yrs] with esophageal involvement, 30 SSc patients [28F; mean age 49yrs] without esophageal involvement and 50 HCs [37F; mean age 49yrs] were enrolled. All 50/50 (100%) NERD patients [median 7.2] and 44/50 (88%) SSc patients with esophageal involvement [8.3] showed an abnormal AET compared to 8/30 (26%) SSc patients without esophageal involvement [3.1] and 0/50 (0%) HCs [0.8] ($p < 0.01$). BI details are shown in the Table. Proximal median BI levels (i.e. at 9, 15 and 17) were similar between NERD, SSc patients without esophageal involvement and HCs ($p = ns$), whereas they were much lower in SSc patients with esophageal involvement ($p < 0.05$).

Median BI Values	NERD	SSc patients without esophageal involvement	SSc patients with esophageal involvement	HCs
at 3 cm, Ω	1180	961	1890	2965
at 5 cm, Ω	1250	1114	2310	2688
at 7 cm, Ω	1684	1230	2670	3110
at 9 cm, Ω	2480	1640	2540	2890
at 15 cm, Ω	2770	1520	2960	3320
at 17 cm, Ω	2840	1980	3100	3250

Conclusion: Proximal esophageal BI levels are able to segregate between scleroderma patients with and without esophageal involvement. The advent of novel and poorly invasive methods for the assessment of esophageal mucosal

impedance will allow us to perform this measurement without the need of prolonged probe insertion.

Introduction: Gastroesophageal reflux disease (GERD), is characterized by frequent relapses after withdrawal of therapy and no prognostic markers of relapse are available to predict the outcome of the patients. Gastrin-17 (G-17) has been proposed as a non-invasive marker of reflux disease as well as a good marker of response to the therapy. Pepsinogen I (PG I) and Gastrin-17 (G-17) are claimed to increase in a statistically significant manner after proton pump inhibitors (PPIs) therapy. Aim of the study was to assess the prognostic value of G-17 serum levels in order to single out GERD patients more prone to develop an early reflux relapse in a prospective open study.

Aims & Methods: We prospectively enrolled 221 consecutive GERD patients (F 113, mean age 52.5 years; range 28–74 years) with endoscopically proved diagnosis of esophagitis, according to the L.A. classification, all symptomatic (heartburn and/or regurgitation). All patients were treated with rabeprazole 20 mg once a day for 6–8 weeks, assessing at the end of the therapy the symptoms' modifications by means of a questionnaire. In the group of asymptomatic patients, we performed a one-year follow-up, recording the GERD relapse episodes; only on-demand antacids were permitted. All patients underwent at baseline a blood sample and after the acute course of PPI therapy.

Results: One hundred eighty five patients were asymptomatic after the 6–8 weeks of PPI therapy and entered in the prospective evaluation for 12 months. 19 subjects were lost lasting the follow-up and finally 166 patients were available for the study analysis. 72 patients experienced at least one GERD relapse episode (first group) against 94 ones free of symptoms for one year (second group). The mean values of both PG I and G-17 after the 6–8 weeks of PPI therapy in comparison with the baseline levels, were higher in first group than in the second one (first group: baseline PG I 96 $\mu\text{g/L}$, G-17 2.6 pmol/L; after therapy: PG I 164 $\mu\text{g/L}$, G-17 19 pmol/L; $p < 0.0001$; second group: baseline PG I 98 $\mu\text{g/L}$, G-17 2.9 pmol/L; after therapy: PG I 116 $\mu\text{g/L}$, G-17 6.3 pmol/L; $p = ns$). The good response to full dose of PPI, assessed by an increase of both PG I and G-17, seems to be the pathophysiological background to explain the prognostic value of such markers.

Conclusion: Gastrin-17 and pepsinogen I increase after full-dose of PPI in GERD acute phase seems to be a simple non-invasive marker to predict early GERD relapse in one-year follow-up.

P1197 THE DIAGNOSTIC VALUE OF ESOPHAGEAL MUCOSAL AND BASELINE IMPEDANCE MEASUREMENTS IN PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE

S. Kipcak¹, P. Ergun¹, S. Bor¹

¹Gastroenterology Sec., Ege Reflux Study Group, Ege University, Izmir/Turkey

Contact E-mail Address: kipcaksezi@gmail.com

Introduction: Various biomarkers have been studied to evaluate the integrity of esophageal epithelium in distinguishing phenotypes of gastroesophageal reflux disease (GERD). Baseline impedance (BI) measurement is likely to be one of these and can be measured during the 24-hour ambulatory intra-esophageal impedance-pH study. Mucosal impedance (MI) measurement is a technique introduced in recent years and is a practical method that can be applied during endoscopy, but the validation studies are insufficient. BI & MI measured with the same regular impedance catheter and data from 118 patients with different reflux phenotypes and controls were evaluated.

Aims & Methods: Patients were divided into five groups: mild (ERD A-B, $n = 31$), severe erosive esophagitis (ERD C-D, $n = 11$), non-erosive reflux disease (NERD, $n = 26$), functional heartburn-esophageal hypersensitivity (FH-EH, $n = 17$), healthy controls. High resolution manometry, 24-h MII-pH, upper gastrointestinal endoscopy were performed. BI values were taken at the sleeping period at night where reflux and swallowing did not occur. MI measured during endoscopy, a regular impedance-pH catheter passed through the biopsy

channel of the scope. Distal two rings were contacted to the distal and proximal parts of the esophagus approximately 20–30 seconds. MMS Omega ambulatory recorder and Greenfield (6 imp, 1 pH) impedance catheter were used.

Results: MI can differentiate ERD from non-erosive groups but do not have a diagnostic value to discriminate NERD from FH-EH or controls. However, BI can segregate NERD from ERD addition to controls (Table 1).

Table 1

Groups	Baseline impedance	Distal mucosal impedance	Mucosal impedance (proximal esophagus)
Control (n = 15/n = 18)	2267 ± 393 [#]	2673 ± 547 [#]	3190 ± 515
FH and EH (n = 17)	1906 ± 716 [#]	2654 ± 721 [#]	3350 ± 880
NERD (n = 26)	1305 ± 759 ^{##}	2423 ± 852 [#]	3407 ± 1074
ERD A-B (n = 31)	868 ± 481 [*]	1538 ± 646 [*]	3096 ± 928
ERD C-D (n = 11)	441 ± 301 [*]	1355 ± 672 [*]	3236 ± 1653

Conclusion: As a new diagnostic tool, MI needs validation studies and our results failed to show additional diagnostic value in non-erosive patients compared to healthy controls. Since regular catheters are failed, new balloon-shaped catheters should be validated. BI might be a better tool to discriminate NERD from controls. This implicates that the esophageal epithelial resistance is impaired in this particular group compared to controls.

Introduction: Atrophic body gastritis (ABG) is characterized by loss of oxyntic glands with consequent reduced acid secretion, hypergastrinaemia and, in a later stage, pernicious anemia (PA). Up to 40% of ABG patients complain of dyspepsia. Despite hypochlorhydria, in 21% of autoimmune gastritis (AG) patients gastro-esophageal reflux (GER) symptoms have been reported and in one third of them (mostly non acidic) reflux has been documented at pH-monitoring. At now, data regarding endoscopic and histopathologic GER-related esophageal findings in this setting are lacking.

Aims & Methods: Aim of this study was to assess the occurrence of GER symptoms and endoscopic-histopathologic esophageal findings in ABG patients. During 12-months, 35 consecutive ABG patients [80% female; median age 60 yrs (27–81); BMI 25.7 kg/m² (18.2–32.3); fasting gastrinaemia 329 pg/ml (215–1476); pepsinogen I 10 ng/l (0–44); positive Ab against parietal cells 74.3%], undergoing scheduled gastroscopy for malignancy surveillance irrespective to gastrointestinal (GI) symptoms, were included. The presence of GER typical symptoms (heartburn and regurgitation), atypical (cough, no cardiac chest pain and dysphagia) and dyspepsia [postprandial distress syndrome (PDS) and epigastric pain syndrome (EPS)] was assessed by a standardized questionnaire. Hiatal hernia and erosive esophagitis were evaluated. Biopsies from distal esophageal (at least 2) and gastric mucosa (at least 5) were collected. Histopathological evaluation, performed by experienced pathologist who was unaware of clinical data, assessed: i) dilatation of intercellular spaces (DIS); ii) basal cell layer hyperplasia; iii) intraepithelial eosinophils; iv) neutrophils and iv) mononuclear cells. Gastric biopsies were evaluated according to updated Sydney System. Moderate-severe body gastric atrophy was confirmed in all patients. No patient was in treatment with anti-secretory drugs.

Results: 74.3% (26/35) of ABG patients complained at least one GI symptom: 45.7% (16/35) reported GER symptoms [typical (2/14), atypical (9/14) and both typical and atypical symptoms (5/14)], 48.6% (17/35) PDS and 11.4% (4/35) EPS dyspepsia. One GER patient had erosive esophagitis (LA-C according to Los Angeles classification) with concomitant hiatal hernia and another one presented a short tongue of columnar lined mucosa at distal esophagus with an area of intestinal metaplasia (Barrett's esophagus, C2M2 according to Prague Classification). Among ABG symptomatic patients, 34.6% (9/26) presented GER-related microscopic esophagitis, whereas the remaining symptomatic patients were free of microscopic esophagitis. Esophageal findings, both endoscopic and microscopic esophagitis, were exclusively present in symptomatic ABG patients (Fisher-t: p=0.00027). Evaluating only autoimmune gastritis patients (n=26), the occurrence of esophageal findings was not related to the presence symptoms (Fisher-t: p=0.1915).

Conclusion: A third of ABG symptomatic patients, investigated by specific questionnaire and esophageal biopsies, presented pathological findings of esophageal mucosa ranging from GER-related microscopic esophagitis to Barrett's esophagus. These findings show that, even in hypochlorhydric patients, esophageal

mucosal damage may occur, suggesting the opportunity to accurately investigate GI symptoms, including GER symptoms, in ABG patients.

Introduction: Gastroesophageal reflux disease (GERD) is considered a multifactorial disease characterized by the presence of both typical and extra-esophageal symptoms, as well as related risks factors, such as smoking habits. In primary care setting, dyspeptic symptoms could overlap GERD symptoms, being the differential diagnosis sometimes difficult, almost because when we performed in such patients upper-gastrointestinal (GI) endoscopy, a picture of esophagitis is observed in no more than 30–40% of the subjects. Aim of the study was to search in a primary care settings possible differences in clinical presentations in a group of patients with GERD, in comparison with a group of dyspeptic patients. **Aims & Methods:** One thousand and six hundred consecutive dyspeptic patients (M=766; mean age=51.5 years; range=27–79 yr) were enrolled in the study, according with presence of upper-GI troubles like epigastric pain, fullness, nausea, vomiting but not heartburn or regurgitation. All patients showed a negative upper-GI endoscopy and were *helicobacter Pylori* (H.p.) negative (Urea Breath Test and HpSA). Patients with history of peptic ulcer, neoplasms or upper-GI surgery were excluded. Seven hundred and one patients showing heartburn and/or regurgitation, a picture of esophagitis according with L.A. classification or a positive DeMeester score (>14) at 24 hours pH-metry were enrolled in GERD group. By using a questionnaire, we collected data on both alcohol and smoking habits.

Results: No differences were found for sex and age between the two groups (GERD: M:F=1:1.2, mean age: 56 years; dyspeptics: M:F=0.9, mean age: 53 years; p=ns); heavy smokers was 29% in GERD group, 26% in dyspeptics; p=ns. Heavy drinkers were 23% in GERD group, 22% in dyspeptics; p=ns. In GERD group, typical symptoms were detected in 547 out of 701 patients, being heartburn the prevalent symptom in 479 subjects and regurgitation in 68 ones. Atypical symptoms, mainly chronic cough were present in 303 patients. 313 patients showed grade A esophagitis, 32 grade B, 4 grade C. One hundred and seventy out of 221 patients showed a positive DeMeester score for acid reflux.

Conclusion: Sex, age, smoking habits and alcohol consumption seem no differ in the two studied population. In GERD cohort, the majority of patients experienced Non Erosive reflux Disease (NERD). The majority of GERD patients suffered by typical symptoms; chronic cough represented the most frequent manifestation among the atypical and extra-esophageal ones.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1200 REAL-WORLD RESPONSE OF PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE TO EMPIRICAL TREATMENT WITH PROTON PUMP INHIBITORS: A MULTICENTER, PROSPECTIVE, OBSERVATIONAL STUDY IN CHINA

Introduction: In China, 13.6% of gastrointestinal outpatients suffer from gastro-esophageal reflux disease (GERD), among which only 36.9% undergo endoscopy [1]. For patients with symptoms of GERD, empirical proton pump inhibitor (PPI) treatment is recommended as a diagnostic test of GERD and as a therapeutic trial to control symptoms by Chinese GERD consensus guidelines [2].

Currently, there are no real-world data assessing the efficacy of short-term empirical treatment with PPIs in GERD patients in China.

Aims & Methods: This was a multicenter, prospective, observational study carried out in a real-world setting. The primary objective was to determine the overall responder rate in patients with typical GERD symptoms after 4 weeks of empirical treatment with PPIs. Responders were defined as having heartburn/regurgitation on ≤ 1 day during the prior 7 days, assessed by the Gerd-Q questionnaire. Outpatients aged between 18 and 65 years with a Gerd-Q score ≥ 8 were enrolled if they were prescribed standard-dose PPIs as empirical treatment and were not planned to have an endoscopy within 4 weeks of enrolment. The PPI regimen prescribed was decided completely at the physicians' discretion. Patient demographics, diagnosis, prescribed PPI regimens, Gerd-Q score and symptom frequency were recorded. Data were collected at baseline, 2 weeks and 4 weeks after initiating PPI treatment. Results from the full analysis set (FAS) are presented.

Results: A total of 1,000 patients from 10 centers were screened for this study, of which 987 met the inclusion criteria and were included in the FAS. The mean age was 45.2 ± 11.6 years, the mean body mass index was $23.4 \pm 3.3 \text{ kg/m}^2$, and 50.3% of the patients were male. The mean duration of GERD was 0.8 ± 2.6 years, with a mean baseline Gerd-Q score for the week before screening of 10.5 ± 1.9 . During the 4 weeks' treatment, the proportion of patients receiving at least one dose of PPI was 99.5%. Esomeprazole was the most frequently received PPI (57.1% of patients). Other PPIs (rabeprazole, lansoprazole, pantoprazole and omeprazole) were received by 50.1% of patients and 7.2% of the patients sequentially received ≥ 2 PPIs in the duration of the study. A total of 787 (79.7%) patients either completed the 4-week PPI treatment or withdrew after response, of which the responder rate was 74.0% [95% CI, 70.7%–77.0%] (Table 1). Among the 818 patients who completed 2 weeks' treatment, the responder rate was 57.0% [95% CI, 53.5%–60.4%]. The overall median time to response was 13 days [95% CI, 12–15]. Over the study duration, patients' Gerd-Q score demonstrated a decreasing trend. The proportion of patients with a Gerd-Q score ≥ 8 reduced from 100% at baseline to 29.5% and 17.4% at 2 and 4 weeks, respectively.

Table 1: Responder rate^[1] and median time to response for different PPIs

	Esomeprazole	Other PPIs	Total
4-week responder rate, % [95% CI]	75.2 (342/455) [70.9–79.1]	72.3 (240/332) [67.1–77.0]	74.0 (582/787) [70.7–77.0]
2-week responder rate, % [95% CI]	57.1 (268/469) [52.5–61.7]	56.7 (198/349) [51.4–62.0]	57.0 (466/818) [53.5–60.4]
Median time to response ^[2] , days [95% CI]	12 [11–14]	14 [12–17]	13 [12–15]

^[1] Responder rate = number of responders/number of patients who completed the corresponding treatment or withdrew after response. ^[2] Response was defined as heartburn/regurgitation frequency ≤ 1 days during the prior 7 days.

Conclusion: In Chinese clinical practice, short-term PPI empirical treatment effectively improves symptom control in GERD patients and gains a satisfactory overall responder rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1201 WIRELESS ELECTRICAL STIMULATION FOR MANAGING GASTROESOPHAGEAL REFLUX DISEASE IN THE RABBIT MODEL

M. Wang¹, L. Zhao², L. Liu², X. Wang¹, Z. Fan¹

¹The First Affiliated Hospital with Nanjing Medical University, Nanjing/China

²Digestive Endoscopy Center, the First Affiliated Hospital of Nanjing Medical University, Nanjing/China

Contact E-mail Address: fanzhining@njmu.edu.cn

Introduction: Electrical stimulation of lower esophageal sphincter (LES) has been approved to increase LES pressure (LESP) and commercially treat gastroesophageal reflux disease (GERD). EndostimTM-like active appliance was efficient but need reoperation for replacing the battery part. Therefore, one novel passive LES stimulation system was invented and evaluated here in rabbits.

Aims & Methods: Different from EndostimTM, wireless power technology was firstly applied in the implanted part. The LES stimulation could be easily self-controlled and powered by external system. No reoperation or implantation replacement need. In order to evaluating its efficacy and safety, GERD rabbit model was created by balloon dilation and applied to optimizing stimulating parameters. Body weight, food intake and LESP were recorded in the experimental course.

Results: A total of 12 rabbits (male, 3~4 kg) were successfully applied for equipment implantation. LES stimulation was delivered at 20 Hz, 215 μ s, 3–8 mA in multiple 30-minute sessions. The muscle contraction phenomenon was obviously observed during the surgery in the stimulation group (6 rabbits). The mean LESP was increased significantly in stimulation group than sham group (stimulation group: $9.25 \pm 1.24 \text{ mmHg}$ vs $13.99 \pm 1.28 \text{ mmHg}$, $P < 0.05$; sham control group: $9.00 \pm 1.22 \text{ mmHg}$ vs $9.23 \pm 1.27 \text{ mmHg}$, $P = 0.267$). After operation, the body weight initially decreased but recovered after one week. No serious

implantation or stimulation-related adverse effects were reported in the two-month follow-up.

Conclusion: Electric stimulation represents a prospective approach for treating GERD in clinics. This novel wireless LES stimulation system was also safe and effective for treating GERD rabbits. After implantation, its passive medical strategy will benefit patients and keep the long-term efficacy for clinical GERD management.

P1202 SYSTEMATIC REVIEW AND META-ANALYSIS OF OUTCOMES AFTER LAPAROSCOPIC ANTI-REFLUX SURGERY RELATED TO OBESITY

T. Abdelrahman¹, A. Latif², D. Chan¹, N. Patel¹, C. Brown¹, W. Lewis¹,

T. Havard², X. Escofet²

¹General Surgery, University Hospital of Wales, Cardiff/United Kingdom

²General Surgery, Royal Glamorgan Hospital, Llantrisant/United Kingdom

Contact E-mail Address: tarig007@yahoo.com

Introduction: Laparoscopic Anti-Reflux Surgery (LARS) is an established alternative treatment to pharmacological therapy for patients with Gastroesophageal Reflux Disease (GORD), yet its safety and efficacy in obese patients is controversial. A systematic review and meta-analysis was performed to compare LARS related to obesity.

Aims & Methods: The primary outcome measure was the relative incidence of recurrent reflux related to BMI. Secondary outcome measures were relative incidence of perioperative complications, re-intervention rates in the form of endoscopic dilatation or surgery, conversion to open surgery, and early return to theatre. Embase, MEDLINE and the Cochrane Library (January 1970 to November 2016) were searched for studies reporting clinical outcomes of LARS in patient cohorts stratified by Body Mass Index (BMI). Data was grouped according to BMI, $< 30 \text{ kg/m}^2$ (non-obese) and $\geq 30 \text{ kg/m}^2$ (obese). Results were pooled in meta-analyses as Odds Ratios (OR).

Results: Eleven eligible observational studies comparing LARS in non-obese ($n = 6003$) and obese ($n = 1620$) patients were identified. Recurrence of reflux was significantly lower in the non-obese cohort (OR 0.34, 95% CI 0.19 to 0.60, $p < 0.001$), however no significant differences were observed in rates of operative morbidity (OR 0.87, 0.65 to 1.18, $p = 0.38$), redo surgery (OR 1.08, 0.68 to 1.72, $p = 0.73$), endoscopic dilatation (OR 1.06, 0.49 to 2.33, $p = 0.88$), conversion to open surgery (OR 1.17, 0.55 to 2.48, $p = 0.68$), or early return to theatre (OR 0.77, 0.44 to 1.37, $p = 0.38$).

Conclusion: LARS can be performed safely in obese patients, but risks higher GORD recurrence. Clinicians and patients should be aware that obesity may adversely affect LARS outcome and careful consideration be given in the consent process inherent within the optimal management of GORD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1203 GASTROESOPHAGEAL REFLUX DISEASE REFRACTORY TO PROTON PUMP INHIBITOR THERAPY. INCOMPLETE ACID INHIBITION OR DIAGNOSTIC ERROR?

Contact E-mail Address: jperezsarnab@gmail.com

Introduction: The use of PPIs represents the main treatment in gastroesophageal reflux disease (GERD), having demonstrated its effectiveness both in the control of inflammation and symptomatology. However, between 10–20% of patients present persistent symptoms or lesions despite the treatment.

Aims & Methods: The aim of the study was to assess the presence of acid reflux in patients submitted to our department with the diagnosis of refractory GERD, due to low or no response to PPIs. This was a retrospective study including 190 patients (55 men, 135 women) referred to our service with the diagnosis of GERD from January 2008 to December 2015. Based on the diagnostic criteria, two groups were made. Group 1: included 63 patients (33.2%) diagnosed of GERD due to typical symptomatology and at least one positive complementary test (radiology, pHmetry or endoscopy). All of them underwent a 24-H pHmetry study with a dual channel, esophageal and gastric, on-PPI treatment. In 17 patients the pHmetry was completed with multichannel intraluminal impedance (15 cases) or Bilitac (2 cases). Group 2: included 127 patients (66.8%) who had been diagnosed of GERD only on the basis of typical symptoms; all of them underwent esophageal double channel 24-H pHmetry off-PPI. All of the studies (24-hour pHmonitoring or multichannel intraluminal impedance-pH studies) (MARK III, Delta and Digitrapper pH-Z; Synectics, Gyven, Medtronic) were performed according to standard technique.

Results: Pathological reflux was present in 91 patients (47.9%), 24 from group 1 and 67 from group 2. Pathological acid reflux was therefore ruled out as a cause of symptoms in 52.1% of all cases studied: 60 patients (47.2%) from group 2, and 39 patients (61.9%) from group 1. In addition, out of the 24 patients with pathological reflux in group 1 (true refractory patients), 9 had an incomplete response, with a percentage of time with $\text{pH} < 4$ less than 7.5% (mild reflux), which probably was not the cause of the symptomatology.

Conclusion: Proton pump inhibitors (PPIs) are the drugs of choice in the treatment of GERD. However, its efficacy may be compromised for a variety of reasons including: non-compliance, bioavailability, episodes of nocturnal acid break-through, poor gastric emptying, etc. In most of the patients referred for

studying with the diagnosis of refractory reflux to PPIs, this diagnosis had only been based on GERD-compatible symptoms. When the diagnosis is exclusively clinical, about a half (47.2%) of the patients with persistent symptoms on double doses of PPIs, considered as GERD patients refractory to PPIs, have an incorrect diagnosis (patients do not have pathological reflux). More than half of the patients (61.9%) who have a diagnosis of GERD confirmed by complementary tests that do not respond to treatment with PPIs, acid reflux is not the cause of their symptoms.

Introduction: Recently, low-FODMAP diet has been proposed as potential treatment in patients with irritable bowel syndrome (IBS) given its high efficacy in symptoms relief. Recent data showed that IBS frequently overlap with functional heartburn (FH) and functional dyspepsia.

Aims & Methods: The aim of this study was to evaluate the efficacy of low-FODMAP diet in reducing heartburn in patients with FH and no pathophysiological evidence of gastroesophageal reflux (GERD) compared to patients with non-erosive reflux disease (NERD). As secondary aim we investigated the reduction of lower gastrointestinal symptoms in both groups. We enrolled patients with heartburn and negative upper endoscopy who were scheduled for upper pathophysiological tests (esophageal manometry and impedance and pH monitoring, MII-pH) at Gastroenterology Unit in University of Pisa. We excluded patients older than 75 and younger than 18, those with primary esophageal motor disorders and with previous abdominal surgery. Medical history, volutary habits and response to proton pump inhibitor (PPI) treatment were recorded. By means of MII-pH we splitted patients in two populations: NERD group (abnormal esophageal acid exposure or number of refluxes) and FH group (normal esophageal acid exposure and number of reflux, no symptom-reflux correlation and no heartburn relief during PPI treatment). All enrolled patients were evaluated with validated questionnaires (Likert and VAS) to evaluate heartburn occurrence pre- and post a nutritional approach with low-FODMAP diet for 6 weeks.

Results: We included 31 patients (20 female; mean age 49.1 yrs; mean BMI 24.4) into the study. NERD group was composed of 13 patients (6 female; mean age 48.7 yrs; mean BMI 25.7). FH group was composed by 18 patients (11 female; mean age 50.9 yrs; mean BMI 23.9). All patients showed symptom improvement regarding bloating, abdominal pain and stools composition ($p < 0.001$) after low-FODMAP diet (see Table 1). Moreover, we observed a very important improvement of heartburn in the FH group (from 8.4 ± 2.5 to 2.3 ± 1.1 ; $p < 0.001$ on VAS scale) compared to the NERD group (7.2 ± 2.2 a 6.9 ± 1.9 ; $p = 0.624$ on VAS).

Table 1: abdominal symptoms perception pre- and post- low-FODMAP diet in NERD and FH groups

	NERD group			FH group		
	Pre-diet	Post-diet	P value	Pre-diet	Post-diet	P value
Abdominal pain	3.6 ± 1.8	2.7 ± 0.9	0.041*	5.8 ± 2.1	1.7 ± 1.3	0.0001*
Bloating	4.3 ± 2.6	3.1 ± 1.7	0.187	6.3 ± 1.5	2.1 ± 0.9	0.0001*
Wind	4.9 ± 2.3	3.3 ± 1.7	0.055	6.1 ± 1.9	2.2 ± 1.15	0.0001*
BSC (type 3-5)	3/13	7/13	0.226	2/18	13/18	0.005*

Legend: BSC = Bristol Stool Classification; * = statistically significant ($p < 0.05$)

Conclusion: This pilot study showed that a low-FODMAP diet was able to reduce heartburn perception in patients with FH and who did not obtain any symptom relief after PPI treatment. Larger prospective randomized controlled trial is mandatory to further explore these findings

Introduction: Because of a higher prevalence of BE in males, recommendations in current guidelines are mainly based on male BE patients and make no difference in surveillance according to gender. Nevertheless, it is unknown whether female BE patients have the same neoplastic progression and acceleration rate as male patients.

Aims & Methods: The aims of this study were (1) to evaluate the difference between males and females in probability of and (2) time to neoplastic progression, as well as (3) gender differences in stage distribution of neoplastic progression in surveilled BE patients. In this multicenter prospective cohort study we included 729 patients with BE who met the inclusion criteria of a segment of ≥ 2 cm and confirmed intestinal metaplasia. Endoscopic surveillance was performed according to the American College of Gastroenterology guidelines. Cox regression modelling as well as accelerated failure time modelling were used to estimate differences in probability of and time to neoplastic progression to HGD, EAC and both HGD and EAC between sexes, respectively. All models were adjusted for age, presence of esophagitis and length of BE. In case of a limited number of events, descriptive statistics were used.

Results: 532 males (73%; median age 58 years, IQR 51–67) and 197 females (median age 64 years, IQR 57–70) were included with a median follow-up of 8.2 years (IQR 5.3–10.3). High-grade dysplasia (HGD) was detected in 35 males versus 4 females, EAC in 12 males versus 5 females. The total number of patients with neoplastic progression was 56 (8%), which was twice as high among males compared to females (HR 1.90, 95% CI 0.92–3.92). Especially the risk of HGD was higher in males than in females (HR 3.34, 95% CI 1.17–9.50). The ratio HGD/EAC in males was 2.92, in females 0.80. Apparently in females proportionally more EAC was identified compared to males. Though these data might suggest accelerated neoplastic progression rates in females, time to event was significantly shorter for males in HGD (AR 0.45, 95% CI 0.22–0.94). There was no difference for overall neoplastic progression (AR 0.59, 95% CI 0.32–1.09). Stage distribution is as shown in Table 1, females tend to have a higher stage of neoplastic progression than males.

Conclusion: The risk of HGD and overall neoplastic progression and acceleration rate of HGD development is higher in male BE patients compared to females. On the other hand descriptive statistics show proportionally more EAC in females as well as an advanced stage of EAC at diagnosis. Further research into the differential aspects of neoplastic progression in BE between men and women, may have future consequences for gender specific guideline recommendations, including the timing of follow-up.

Table 1: Stage distribution of neoplastic progression between males and females

	Stage 0		Stage 1		Stage 2		Total
Male	40	85%	4	8.5%	3	6.4%	47
Female	5	56%	3	33%	1	11%	9
Total	45	80%	7	13%	4	7.1%	56

Introduction: Given its proven safety and efficacy, RadioFrequency Ablation (RFA) is the preferred ablation modality for dysplastic Barrett's Esophagus (BE). However, RFA is associated with significant drawbacks, such as the need for large controller units, multiple deployment steps and capital investment. The Focal CryoBalloon Ablation system (FCBA; C2 Therapeutics Inc. Redwood City, CA, USA) is another ablation method -based on the application of extreme cold- that has been recently developed to overcome these RFA drawbacks. Additionally, FCBA might be better tolerated. FCBA comprises a handheld, through-the-scope system with a conformable balloon that is simultaneously inflated and cooled using nitrous oxide, resulting in ice patches of approximately 2cm² on the targeted mucosa. Previous studies applying FCBA to limited areas of BE (1 to 2 small BE islands per patient) have shown promising results. Data on

efficacy and safety of FCBA in the treatment of larger BE segments, however, are lacking. Therefore we aimed to assess the safety and efficacy of a single treatment with FCBA for dysplastic BE.

Aims & Methods: Patients were seen between March and December 2016 at two tertiary referral centers in the Netherlands. Patients with a BE <6 cm in length and with a confirmed diagnosis of low-grade (LGD) or high-grade dysplasia (HGD) or after endoscopic resection for visible lesions, were included. Exclusion criteria included previous focal ablation therapy and strictures. At baseline, all visible BE was treated with side by side ablations of 10 seconds, including circumferential treatment of the gastroesophageal junction (GEJ). Pain scores were assessed directly post-treatment and at days 2 and 7. Follow-up endoscopy with biopsy and photo documentation was scheduled after 3 months. Primary outcomes included dysplasia regression rate and incidence of esophageal stricture or other adverse events.

Results: We enrolled 20 patients with dysplastic BE (85% male, mean age 66 (±8) years), with a median BE length of C0M2 (IQR 0–0; 1–3) and with a baseline diagnosis of LGD (10; 50%), HGD (1; 5%), or mucosal adenocarcinoma (9; 45%). Ten (50%) had undergone endoscopic resection of a visible lesion before cryoablation and 8 (40%) had undergone previous circumferential RFA. During a median ablation time of 16 minutes (IQR 11–19), all BE, including circumferential ablation of GEJ was successfully ablated in all patients. No adverse events occurred, and median pain directly post-treatment was 4 out of 10 (IQR 0–5), whereas this was 1 (IQR 0–2) and 0 (IQR 0–1) at days 2 and 7. At the 3-month follow-up endoscopy, median endoscopic regression of initial BE was found to be 95% (IQR 83–98), this included 3 patients (15%) with a complete 100% regression. All biopsies confirmed squamous regeneration without evidence for subsquamous BE. No significant esophageal strictures or other complications were noted.

Conclusion: Our multicenter, prospective trial shows that a single treatment with Focal CryoBalloon ablation therapy is safe, well-tolerated and effective for eradication of dysplastic BE.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1207 CRYOBALLOON ABLATION OF DYSPLASTIC BARRETT'S ESOPHAGUS CAUSES SHORTER DURATION AND LESS SEVERE POST-PROCEDURAL PAIN AS COMPARED TO RADIOFREQUENCY ABLATION

S. Van Munster¹, A. Overwater², J.J. G.h.m. Bergman¹, B.L.a.m. Weusten²

Introduction: Radiofrequency ablation (RFA) is safe and effective for eradication of dysplastic Barrett's Esophagus (BE), but may be associated with significant post-procedural pain. As an alternative, cryoablation using the Focal CryoBalloon Ablation system (FCBA) has recently been developed, which ablates BE by freezing it using nitrous oxide. Early uncontrolled studies suggest comparable safety and efficacy of FCBA and RFA in eradicating dysplastic BE. Therefore, secondary endpoints like pain might play a determining role in selecting the best treatment modality. In contrast to heat-based ablation, FCBA preserves the extracellular matrix which might be associated with less pain while maintaining sufficient depth of ablation. In this study, we aimed to compare post-procedural pain between focal RFA and FCBA.

Aims & Methods: Between January 2016 and March 2017 all patients undergoing focal ablation therapy of BE, either with RFA or FCBA performed in two tertiary referral centers in the Netherlands, were approached to complete a digital diary. A short questionnaire was daily sent to patients for 14 days post-treatment, to assess (1) odynophagia, (2) chest pain in rest (both were assessed using VAS score ranging from 0 to 10), (3) dysphagia (assessed using a score ranging from 0 to 4) and (4) use of analgesics. Primary outcome included maximum VAS score (maximum score for either item 1 or 2), secondary outcomes included area under the curves (AUCs) for all items assessed, maximum reported VAS score at any time, time to VAS 0 and analgesics use. According to national guidelines, all visible BE was ablated, including circumferential treatment of the gastro-esophageal junction (GEJ). In a standardized way, all patients were advised to use paracetamol (up to 4 times 500 mg daily) as necessary with additional ibuprofen, if needed.

Results: Fifty-five patients were included (35 with focal RFA; 20 with CBA) and median BE length was similar for the two groups (FCBA: C0M2, RFA: C0M1, p=0.72). All other baseline characteristics were similarly comparable for both groups (table 1A). Maximum VAS score was lower after FCBA compared with RFA at all days, reaching statistical significance at 13/14 days (table 1B). All AUC curves were significantly smaller after FCBA compared to RFA: for maximum VAS score (12.3 vs 26.7, $p < 0.01$), for odynophagia (11.6 vs 26.7, $p < 0.01$), for pain in rest (7.8 vs 20.5, $p < 0.01$), for use of analgesics (0.9 vs 3.1, $p < 0.01$) and for dysphagia (2.6 vs 8.2, $p < 0.01$). The maximum median VAS score reported on any of the 14 days was 2 (IQR 0–4) after FCBA and 4 (IQR 3–7) after RFA ($p < 0.01$). After 4 (IQR 1–10) days, half of the FCBA patients reported a pain score of 0, whereas this was 13 (IQR 10–15) days for RFA

($p < 0.01$). FCBA patients used analgesics during median 1 (IQR 1–1) days, compared to 4 (IQR 1–11) days for RFA patients ($p < 0.01$).

Table 1: Baseline characteristics and maximum pain scores

	FCBA (N=20)	RFA (N=35)	P-value
1A. Baseline characteristics			
Male gender, n (%)	17 (85%)	29 (83%)	0.84
Age, mean (SD) years	65 (±8)	66 (±8)	0.66
Worst diagnosis			
prior to FCBA			
LGD, n	10 (50%)	19 (54%)	0.54
HGD, n	1 (5%)	6 (17%)	
EAC, n	9 (45%)	10 (29%)	
Prior treatment			
ER, n	10 (50%)	17 (52%)	0.92
Circumferential RFA, n	10 (50%)	23 (66%)	0.33
BE length			
prior to FCBA			
Circumferential, cm	0 (0–0)	0 (0–0)	0.64
Maximum, cm	2 (1–2)	1 (1–3)	0.72
1B. Maximum pain scores on day 1 to 14 post treatment			
Maximum VAS, median (IQR)			
Day 1	2 (0–4)	3 (1–7)	0.06
Day 2	1 (0–4)	3 (1–6)	0.02
Day 3	1 (0–3)	3 (1–4)	0.03
Day 4	1 (0–2)	2 (1–4)	0.05
Day 5	0 (0–2)	2 (1–5)	0.02
Day 6	0 (0–1)	2 (1–5)	<0.01
Days 7 to 9	0 (0–1)	2 (0–4)	<0.01
Days 10 to 14	0 (0–0)	1 (0–2/3)	<0.01

Conclusion: In this multicenter, non-randomized, open prospective cohort study, patients reported less post-procedural pain and dysphagia after FCBA as compared with RFA and, moreover, FCBA patients used less analgesics. Although a randomized trial should provide definitive evidence for differences in post-procedural tolerability, our results strongly suggest a significantly different post-procedural course, thus favoring FCBA over RFA.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1208 COMPARATIVE OUTCOMES OF RADIOFREQUENCY ABLATION FOR BARRETT'S ESOPHAGUS WITH DIFFERENT BASELINE HISTOLOGY

Introduction: Radiofrequency ablation (RFA) with endoscopic mucosal resection is recommended for Barrett's Esophagus (BO) related neoplasia. In this study, we evaluated RFA treatment outcomes for BO stratified according to baseline histology, i.e. low-grade dysplasia (LGD), high-grade dysplasia (HGD) and intramucosal carcinoma (IMC).

Aims & Methods: The aim of this study was to compare RFA outcomes for BO with low-grade dysplasia (LGD), high-grade dysplasia (HGD) and intramucosal carcinoma (IMC). We retrospectively reviewed the treatment outcomes of patients with dysplastic BO between January 2007–2017. Patients received 3-monthly RFA until endoscopic and histologic remissions were achieved. Outcomes measured were: 1) complete remission of dysplasia (CRD) and intestinal metaplasia (CRIM), 2) stricture rate, and 3) durability of CRD and CRIM. Patients on active treatment protocol were excluded.

Results: We identified 113 patients who completed RFA treatment (21 LGD, 46 HGD and 46 IMC). There were no significant difference between the groups in the age, gender, circumferential and maximum length of BO, and stricture rate. CRD and CRIM were achieved in 94.7% and 78.8% of patients, respectively. When stratified according to baseline histology, there was no significant difference in CRD rate among LGD (95.2%), HGD (95.7%) and IMC (93.5%) ($p = 0.89$). Similarly, there was no significant difference in CRIM rate among LGD (71.4%), HGD (76.1%) and IMC (84.8%) ($p = 0.31$). CRD durability at 12 and 36 months ($n = 107$) were 99.0% and 97.0%, respectively. CRIM durability ($n = 89$) at 12 and 36 months were 98.5% and 92.7%, respectively. When stratified according to baseline histology, CRD durability at 12 and 36 months for LGD and IMC were 100% at both time points, and 97.7% and 93.6% for HGD, respectively (log rank $p = 0.31$). CRIM durability at 12 and 36 months for LGD, HGD and IMC were 100%, 96.4%, 100%, and 100%, 88.5%, 95.5%, respectively (log rank $p = 0.60$).

Conclusion: The treatment outcomes for BO were similar in patients with different baseline histology. Our results showed that once CRD and CRIM were achieved, these were durable over time.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1209 IS IT REASONABLE TO PROPOSE AN ENDOSCOPIC MUCOSAL RESECTION FOR BARRET'S OESOPHAGUS WITH HIGH-GRADE DYSPLASIA ON THE BIOPSIES?

Introduction: Endoscopic mucosal resection (EMR) is currently the first-line treatment for high-grade dysplasia (HGD) in Barrett's esophagus (BE). Despite improvements in the characterization of dysplasia, the management depends on the pathological analysis of biopsies previously performed. However, the level of concordance between cytologists in such situation remains discussed. The aim of this study was to evaluate the discordance between biopsy sample (BS) and EMR specimen in case of HGD, as well as cytologists' inter and intra-observatory variability.

Aims & Methods: This was a retrospective study including a prospective histological relecture (BS and specimen) in two expert centers. The inclusion criteria were: BE with HGD on pre-operative biopsies resected by EMR. The initial biopsies from other centers were collected and re-examined by our cytologists. The BS discordant with EMR specimens were recorded in a numeric file (Teleslide) and a second lecture was carried out by 2 experts and 2 fellows (1 of each per center). Five diagnoses were considered: no metaplasia (no BE), metaplasia without dysplasia, LGD, HGD, Adenocarcinoma. Concordance statistical tests were performed to assess the variability between BS and EMR specimen, and among the cytologists.

Results: Between January 2005 and December 2015, 87 patients have undergone EMR for HGD on biopsies, in both centers. Among them, 41 (47%) had a discordant result between biopsies and resection specimen. The histological diagnosis was LGD in 23 cases (16.4%), metaplasia in 13 cases (14.9%), adenocarcinoma in 4 cases (4.6%) and one patient had no metaplasia. Finally, 33 patients could be analyzed, 29 men and 4 women, with a mean age of 63 years old. The mean length of BE according to Prague classification was C3-M5, with relief abnormalities in 18.2% of the cases. A mean number of 1.4 endoscopic session was performed, with a mean of 2.7 resected pieces per EMR, which was macroscopically complete in 63.6% of the cases. The mean follow-up was 38 months. After histological relecture, the Kappa coefficient for the diagnosis of HGD was low on the initial BS, and ranged between 0 and 0.6 for the EMR specimen. The inter-observatory concordance was 0.2 (for both BS and EMR specimen) for the diagnosis of HGD. For other diagnoses, it was ranged between 0 and 0.5 for biopsies and between 0 and 0.6 for EMR specimen. The kappa coefficient regarding HGD between experts was 0.5 for biopsies and 0 for EMR, whereas it was 0.4 and 0.5 for the fellows, respectively. The intra-observatory (between BS and EMR specimen) after relecture was ranged between 0 and 0.6.

Conclusion: The discordance rate between initial diagnosis of HGD on BS and final results on EMR specimen is high, around 47%. The intra and inter observatory concordance is insufficient, even in expert tertiary centers. Thus, the question about performing EMR based on random biopsies rather than endoscopic assessment has to be asked, and clearly evaluated in further studies. This could have a direct impact on the management of BE.

Introduction: Neoadjuvant chemoradiotherapy (CT-RT) before esophagectomy is standard management for locally advanced squamous cell carcinoma (SCC) of the esophagus and in several cases, it can lead to complete response (CR).

Aims & Methods: The aims of this study were to identify possible immunological predictors of CR after neoadjuvant CT-RT and of cancer persistence/recurrence in patients who had a clinical CR. Eighty-eight consecutive patients with SCC of the thoracic oesophagus who underwent to neoadjuvant CT-RT were included in this retrospective study. Patients were included in the study if they had had neoadjuvant CRT for locally advanced SCC and having had histological samples taken at diagnosis available in our Pathology Unit archive. Immunohistochemistry for PD1, PDL1, CD80, CD4 and CD8 was performed. Outcome details were retrieved and clinical CR and recurrence/relapse rate was compared. Non parametric comparison tests and non parametric combination test were used for small sample size comparison.

Results: After neoadjuvant CT-RT, 23 patients had CR, while 65 had partial response, stable disease or progression. CD8+ and CD4+ lymphocyte rate and

PDL1 leukocyte expression were significantly higher in patients who had CR compared to those who had not ($p < 0.0014$, $p < 0.001$ and $p = 0.004$ respectively). The accuracy of leukocyte expression of PDL1 and CD8+ and CD4+ lymphocyte rate was 0.76 ($p = 0.001$), 0.81 ($p = 0.0001$) and 0.75 ($p = 0.0001$), respectively. Within the CR group, all patients with high infiltration of CD4+ T cell recurred/relapsed while only the 38.9% of those with low CD4+ T cell infiltration did the same ($p = 0.058$).

Conclusion: In our group of patients, CD4+ and CD8+ lymphocyte rate and PDL-1 leukocyte expression were predictive of clinical complete response after neoadjuvant chemoradiotherapy for squamous cell cancer of the thoracic oesophagus with adequate accuracy. Moreover, high infiltration level of CD4+ T cell was associated to recurrence/relapse. These preliminary observations might be used to plan further study aimed to identify reliable predictors of response to chemoradiation in oesophageal SCC.

Contact E-mail Address: s.j.hoefnagel@amc.uva.nl

Introduction: Esophageal adenocarcinoma (EAC) is a highly aggressive malignancy with poor prognosis. Advances in therapy have achieved incremental improvements in overall outcome in EAC, but over- and undertreatment of undefined subgroups of patients might undermine these benefits (Courrech Staal et al. 2010). The biological diversity of EAC complicates patient selection and treatment stratification and impedes the development of new targeted agents. Further insight into the heterogeneous molecular pathology of EAC and a possible relation to outcomes and response to current treatment strategies is urgent.

Aims & Methods: We included ~75 patients with EAC and junctional adenocarcinomas between 2012 and 2017. Most patients received neoadjuvant chemo-radiotherapy (nCRT) with carboplatin and paclitaxel. Pre-treatment tissue samples of the tumor and healthy adjacent mucosa were collected during upper gastrointestinal endoscopy. RNA was extracted from all tumor biopsies and a subset of matched healthy biopsies. Samples were sequenced using Illumina sequencing technology. Count files were obtained, which served as input into the R language and environment for statistical computing for further analyses. We performed unsupervised hierarchical clustering on the tumor RNA profiles to identify distinct clusters associated with clinical outcome.

Results: We could identify three distinct subtypes with a metabolic, immune and cell cycle regulating signature respectively. The subtype with the immune signature was associated with tendency to poorer response to therapy. We will develop a subtype classifier to perform subtype prediction in an independent patient cohort from the TCGA database (The Cancer Genome Atlas Research 2017).

Conclusion: Our studies support the existence of three distinct EAC/junctional subtypes associated with different response to therapy. Based on these subgroups, we will develop an EAC subtype classifier that might improve stratification of patients for (targeted) therapies and subsequently improve outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Esophageal squamous cell cancer (ESCC) is one of the most common carcinomas worldwide. Long noncoding RNAs (lncRNAs) have been reported to play an importance role in the progression of many diseases especially in cancers. Recent studies reveal that lncRNA TRPM2-AS is upregulated in many cancers and may function in tumor development and metastasis. This study aimed to explore the expression of TRPM2-AS and its clinical value in ESCC.

Aims & Methods: To investigate the function of long noncoding RNA TRPM2-AS in ESCC, RT-qPCR was used to monitor the expression level of long noncoding RNA TRPM2-AS in 50 paired ESCC tissues and ESCC cell lines. Moreover, the associations between long non-coding RNA TRPM2-AS expression level and clinical characteristics was analyzed. In addition, over-expression and RNA interference (RNAi) approaches were used to study the biological functions of TRPM2-AS in ESCC cells. Cell growth and proliferation was

analyzed by cell counting kit-8 assay. Cell cycle and apoptosis were evaluated by flow cytometric analysis. Protein levels of p53 were determined by western blot analysis. Differences between groups were tested for significance using Student's *t*-test (two-tailed).

Results: ESCC tissues examined in this study showed an obvious increment in TRPM2-AS expression when compared to normal tissues. Meanwhile, TRPM2-AS expression was positively related to lymph nodes metastasis, TNM stage and clinical stage. And upregulated TRPM2-AS expression was turned to be remarkably correlated with the shorter survival of ESCC patients which could act as an independent prognostic factor for both overall survival time and disease-free survival. In addition, overexpression of TRPM2-AS could promote the proliferation and inhibit the apoptosis of ESCC cells, while knockdown of TRPM2-AS had a reverse function. Furthermore, downregulation of TRPM2-AS enhanced the expression of p53 in ESCC cells.

Conclusion: This study suggested that long non-coding RNA TRPM2-AS could be a potential oncogene of ESCC. TRPM2-AS expression might be served as another potential therapeutic target and prognostic biomarker. In addition, our study presents the first evidences that TRPM2-AS contributes a lot to inhibiting apoptosis of ESCC by regulating the expressions of p53 in vitro, which may be a potential oncogene and therapeutic target for ESCC.

Introduction: Esophageal adenocarcinoma (EAC) is an increasingly common cancer with a poor prognosis. EAC is the final step of a pathway starting with esophageal reflux disease, intestinal metaplasia, and dysplasia. The expression of costimulatory molecules such as CD80 and CD86 in the esophageal cancer tissue is significantly lower than in the normal mucosa of healthy patients. This may be one of the mechanisms of immune escape of cancer cells in the esophageal cancer.

Aims & Methods: The aim of this study was to investigate the role of CD80 in the inflammatory esophageal carcinogenesis and to characterize the immune environment of EAC. Mucosa samples from cancer and from healthy esophagus were obtained during esophagectomy from patients affected by EAC. Fresh biopsies were obtained from patients who underwent endoscopy for screening or follow-up. Immunohistochemistry for CD80 was performed. Fresh biopsies were analyzed by flow cytometry to quantify the expression of CD80, its receptor CD28 and the lymphocytes activation marker CD38 on esophageal epithelial cells and CD8 infiltrating lymphocytes, respectively. A model of reflux induced esophageal carcinogenesis was created with a esophago-gastro-jejunostomy: C57bl/6 mice were randomized to receive or not intraperitoneal injections of anti-CD80 antibody. The esophago-gastric specimens were collected 32 ± 2 weeks after randomization and analyzed in a blinded fashion. Non parametric statistics was used.

Results: Flow cytometric analysis of esophageal biopsies from healthy controls, Barrett esophagus, dysplastic esophagus and esophageal adenocarcinoma reveals that the expression of the costimulatory molecule CD80 by epithelial cells peaks during metaplasia in the inflammatory esophageal carcinogenesis. In the mice that received anti-CD80 antibodies the rate of dysplasia in the fore stomach was significantly higher (5/7) compared to that observed in vehicle treated wild type mice (1/6).

Conclusion: The human and the in vivo data that we obtained suggest that in inflammation-driven esophageal carcinogenesis there is evidence of an active immune surveillance process mediated by the overexpression of CD80 costimulatory molecule on esophageal epithelial cells.

Introduction: Esophageal adenocarcinoma (EAC) microenvironment is characterized by several oncogenes activation and oncosuppressor down regulation within the tumor cells, by lack of cytokines with anti-cancer effect and by high expression of immuno-suppressive factors. The interplay between oncogenes' dysregulation and immune microenvironment and its effect on patients' prognosis is still largely unknown.

Aims & Methods: The aim of this study was to evaluate the effect of the interplay between dysregulation of oncogenes and oncosuppressor genes within the tumor cells and immune microenvironment on EAC prognosis. Mucosa samples from EAC tissue were obtained during esophagectomy from 169 consecutive patient-soperated. Immunohistochemistry for MLH1, MSH2, MSH6, PMN2, cMyc, p16, HER2 and nuclear p53 expression was performed. CD8 infiltration, CD8 and NK cells cytolytic activity (CD107) of tumor infiltrating lymphocytes and antigen presenting cells activity within the tumor (CD80) were analysed with immunohistochemistry. Mutational analysis for BRAF was performed. Cox proportional hazard models were created to investigate the role of each marker adjusted for cancer stage. The association between each marker and the presence of nodal metastasis was assessed with Fisher exact test.

Results: In our EAC patients' series, one patients had BRAF mutation (V600E) and 5 of them had microsatellite instability. CD107 overexpression within the cancer was associated to the presence of nodal metastasis ($p = 0.029$). In patients with EAC, nuclear p53 overexpression revealed to be an independent predictor of early recurrence with [HR = 2.995 (95% CI = 1.1224–7.9896) $p = 0.029$] as well as cancer stage [HR = 2.993 (95% CI = 1.6693 to 5.3666) $p < 0.001$]. On the other hand, nuclear p53 overexpression also tended to be an independent predictor of overall survival [HR = 2.9359 (95% CI = 0.9613 to 8.9663) $p = 0.06$] while cancer stage confirmed to be the main survival predictor [HR = 1.8689 (95% CI = 1.0810 to 3.2314) $p = 0.025$].

Conclusion: In EAC, CD8 and NK cytolytic activity within the tumor was associated to nodal metastasis and CD107 expression might be used as a marker of it. Moreover, nuclear p53 overexpression within the tumor might be used as a marker of early recurrence after esophagectomy and then used to plan follow up strategies. No apparent relation between prognosis and mismatch repair genes expression or BRAF mutation was observed.

Introduction: Altered glucose metabolism has become a recognised feature of tumor cells, which is characterized by an increased glucose uptake and preferential dependence on glycolysis for energy production. As a consequence, cancer cells produce large amounts of lactate, which is pumped out the cytosol by monocarboxylate transporters (MCTs), mainly MCT 1 and 4. MCT inhibition has previously been related to increase apoptosis in cancer cells, but this aspect has not been investigated in esophageal adenocarcinoma (EAC) yet.

Aims & Methods: We aimed to analyze the expression of MCT1 and 4 in human samples of EAC and to evaluate in vitro the effect of extracellular glucose concentration and pharmacological inhibition of MCT1 on lactate concentration, intracellular pH (pHi), and cell apoptosis. MCT1 and MCT4 expression was assessed by immunohistochemistry in 29 human samples of EAC. For the in vitro study, two different EAC cell lines were used: OE33 (ECACC), established from an EAC of the lower esophagus and OACM5.1C (ECACC), obtained from a lymph node metastasis derived from an EAC. MCT1 and MCT4 expression and location were assessed by immunocytochemistry in both cell lines. The MCT1 selective inhibitor AZD3965 (0, 10 and 100 nM) was added to the culture medium under a normoxic and hypoxic atmosphere in standard (11 mM) or high (30 mM) glucose content in the media. Apoptosis was determined by flow cytometry (Annexin V-FITC and propidium iodide). Intracellular lactate concentration was evaluated in a colorimetric assay. pHi was evaluated by flow cytometry with the probe SNARF-1 AM. Experiments were performed at least in triplicate. Statistical analysis was performed by student-t test.

Results: MCT1 and MCT4 expression was found in all the EAC samples evaluated. MCT1 expression was confined to tumor cells, with 62% of the biopsies showing moderate or intense staining, whereas MCT4 was expressed in both tumor and stromal cells, with 40% of moderate/intense stained samples. Both cell lines expressed MCT1 transporter, whereas MCT4 expression was present in OE33 cells and only in a small population of the metastatic cell line. High extracellular glucose concentration increased intracellular lactate levels in OE33 cells but not in the metastatic line, and did not have any effect either in pHi or in apoptosis under any of the conditions evaluated (normoxia and hypoxia) in both cell lines. Treatment with AZD3965 (10 and 100 nM) increased intracellular lactate concentration in OE33 and OACM5.1C cells, but this increase was higher (600–700%) in the metastatic cell line than in OE33 cells (50–70%). Under normoxic conditions AZD3965 significantly increased pHi of both cell lines whereas under hypoxic atmosphere had no effect on metastatic cells. The highest concentration (100 nM) of the MCT1 inhibitor significantly

increased apoptosis of OACM5.1C cells whereas did not affect apoptosis of OE33 cells.

Conclusion: Metastatic and non-metastatic esophageal adenocarcinoma cells exhibit different glycolytic metabolism and response to pharmacological inhibition of MCT1, which increases apoptosis in metastatic cells. Further preclinical studies are necessary in order to define the potential of blocking lactate transporters on the treatment of metastatic EAC.

Introduction: Although endoscopic submucosal dissection (ESD) is accepted as a standard treatment for early stage esophageal neoplasia, esophageal perforation is sometimes experienced as main adverse event. Esophageal perforation causes mediastinal emphysema, mediastinitis, and pneumothorax, those sometimes require emergency surgery.

Aims & Methods: We evaluated the predictive factors for esophageal perforation in patients who received esophageal ESD. This was a retrospective observational study in a single institution. Between May 2004 and March 2016, 549 consecutive patients with 927 esophageal lesions were treated with ESD. Exclusion criteria was cases with lacking data. The primary outcome was determination of the predictive factors for esophageal perforation in patients who received esophageal ESD. The secondary outcome was clinical outcomes. Perforation was defined as a visual hole in the esophageal wall exposing the mediastinal cavity. Logistic regression multivariate regression analysis with generalized estimating equations were used to analyze repeated measures data.

Results: A total of 549 cases with 927 lesions were evaluated. Of those, perforation occurred in 15 cases (2.7%) with 15 lesions (1.6%). A lesion diameter (Odds ratio; OR=1.05, 95% confidence intervals; CI: 1.02–1.07, $p<0.001$) and the proximity of the tumor to a previous ESD scar (OR=6.66, 95% CI: 1.80–24.6, $p=0.004$) were both associated with perforation using crude logistic regression analysis. Multivariate logistic regression analysis also showed that a lesion diameter (OR=1.05, 95% CI: 1.03–1.07, $p<0.001$) and the proximity of the tumor to a previous ESD scar (OR=13.0, 95% CI: 2.48–67.9, $p=0.002$) were independent predictive factors for perforation.

Conclusion: Larger lesion and the proximity of the tumor to a previous ESD scar increased the likelihood of perforation in patients who received esophageal ESD.

Introduction: According to the current Japanese guidelines for the diagnosis and treatment of esophageal cancer, endoscopic resection is indicated for pathological T1a (epithelium/lamina propria mucosae) and relatively indicated for T1a(muscularis mucosae) and T1b(a tumor invading the submucosa to a depth of 200µm or less). In accordance with the guidelines, we have actively performed endoscopic resection for esophageal squamous-cell carcinoma(ESCC). Evidence of submucosal or lymphovascular invasion on histopathological examination of the resected specimens was considered to indicate non-curative resection, chemoradiotherapy (CRT) was additionally administered, taking into account the risk of lymph-node metastasis. In principle, CRT comprised 2 courses of cisplatin plus 5-fluorouracil. Patients who were 76 years or older or who had mild renal dysfunction received 2 courses of nedaplatin plus 5-fluorouracil. The radiation dose was 50.4 Gy in patients who had a tumor-positive vertical margin and 41.4 Gy in those who had a tumor-negative vertical margin. The field of radiation was determined according to the recommendations of the Japan Clinical Oncology Group Study JCOG0508(UMIN-CTR: identification number UMIN00000553).

Aims & Methods: We retrospectively studied patients who underwent endoscopic resection in our hospital to evaluate the clinical utility of additional CRT in patients who had evidence of submucosal or lymphovascular invasion on histopathological examination of the endoscopically resected specimens. Among

364 patients with ESCC (425 lesions) who underwent endoscopic resection from January 2000 through July 2015, a total of 93 patients (93 lesions) had a histopathological diagnosis with submucosal or lymphovascular invasion. Among these 93 patients, 41 received additional CRT (CRT group), and 52 were followed without CRT(follow-up group). CRT comprised cisplatin plus 5-fluorouracil and radiation in 37 patients, nedaplatin plus 5-fluorouracil and radiation in 2, docetaxel plus cisplatin, 5-fluorouracil, and radiation in 1, and radiation alone in 1.

Results: The median age was 68 years (53 to 79) in the CRT group and 72 (59 to 89) in the follow-up group ($p=0.01$). The median tumor diameter was 22 mm (6 to 55) in the CRT group and 25 (3 to 47) in the follow-up group ($p=0.63$). The tumor invades the MM in 9 patients, the SM1 in 3, and the submucosa to a depth more than 200µm (SM2) in 29 in the CRT group and the LPM in 3 patients, the MM in 16, the SM1 in 18, and the SM2 in 15 in the follow-up group ($p=0.91$). Lymphatic invasion was positive in 21 patients in the CRT group and 12 in the follow-up group ($p<0.01$). Vascular invasion was positive in 27 patients in the CRT group and 29 in the follow-up group ($p=0.32$). Involvement of the submucosal vertical margin was found in 7 patients in the CRT group and 9 in the follow-up group ($p=0.97$). CRT-related grade 3 or 4 early adverse events were leukopenia 24.3% (10 patients), neutropenia 29.3% (12), febrile neutropenia 4.9% (2), diarrhea 2.4% (1), anorexia 17.0% (7). In the CRT group, 38 of 40 patients received chemotherapy as scheduled. Treatment was discontinued in the second course in 2 patients, and 7 required dose reduction. Lymph-node metastasis were found in 2 patients in the CRT group and 7 in the follow-up group ($p=0.15$). In 2 patients with recurrence in the CRT group, lymph-node metastases were seen in the irradiated field 46 and 49 months after treatment, respectively. 1 patient in the CRT group and 3 in the follow-up group died of esophageal cancer ($p=0.43$). The overall survival (OS) rate at 2 years was 97.1% in the CRT group and 93.8% in the follow-up group ($p=0.02$). The relapse-free survival (RFS) rate at 2 years was 97.1% in the CRT group and 83.4% in the follow-up group ($p=0.02$).

Conclusion: Additional CRT after endoscopic resection in patients with esophageal squamous-cell carcinoma who have submucosal invasion, lymphovascular involvement, or vertical-margin invasion can become an effective organ-preserving strategy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1218 SAFETY, EFFICACY AND OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR THE TREATMENT OF EARLY BARRETT'S NEOPLASIA

M. Omae, M. Konradsson, P. Elbe, M. Nilsson, M. Lindblad, I. Rouvelas, F. Baldaque-Silva

Gastrocentrum, Karolinska University Hospital, stockholm/Sweden

Contact E-mail Address: masami.nego@jfcir.or.jp

Introduction: Endoscopic submucosal dissection (ESD) was developed in Japan for en bloc resection of large gastrointestinal neoplasias and has progressively been adopted in the West. Currently, early Barrett's neoplasia is mainly treated with endoscopic mucosal resection (EMR) and/or radiofrequency ablation, being the role of ESD in this context not well-established yet. Our aim is to evaluate the safety, efficacy and outcome of ESD for the treatment of early Barrett's neoplasia.

Aims & Methods: Fifty consecutive ESD cases of early Barrett neoplasia were performed in 42 patients in our center between 2011 and 2016. All ESDs were performed under full narcosis after multidisciplinary team conference discussion and patient's consent. The primary endpoint was the rate of en bloc resection. Secondary endpoints included rate of R0 and curative resection, a comparison of pre- and post- ESD histology, procedure time, procedure-related adverse events, and rate of remission at follow-up. This study was approved by the Stockholm Regional Ethical Committee.

Results: Mean age was 67 years-old (range 46–84), being 74% male and 72% long segment BE. The mean specimen size was 52 mm (range 16–150 mm). ESD resections included <25%, 25–50%, 50–75% and 75–100% of the lumen circumference in 4/31/12/3 of cases, respectively. En bloc, R0 and curative resection were obtained in 96% (48/50), 80% (40/50) and 70% (35/50) of cases, respectively. The pre-ESD histology corresponded to low-grade dysplasia (n=5), high-grade dysplasia (n=30) and adenocarcinoma (n=15). One case of LGD was upstaged to intramucosal AC, 10/30 cases of HGD were upstaged to adenocarcinoma. In 8/15 cases of AC, there was submucosal invasion on the ESD specimen. In 14/50 of resected specimens there was multifocal neoplasia. The mean procedure time was 120 minutes. There were 2 perforations (4%) treated endoscopically and 2 (4.0%) postoperative bleedings treated conservatively. Six patients (12%) developed esophageal strictures that were managed endoscopically. The 30 days mortality was 0%. In the 15 non-curative cases, 10 went through esophagectomy, 2 patients to further ESD, 1 received chemoradiotherapy and 2 patients are under surveillance. In the 10 esophagectomy cases, 4 patients had AC in the remnant Barrett's esophagus and 2 patients had lymph node metastasis. Complete remission was

found in 100% (35/35) of patients with curative resection at median follow-up of 21 months (4–60 months).

Conclusion: In the proper setting, ESD is safe and effective for the treatment of early Barrett's neoplasia with high en bloc and complete resection rates and good curative rate. ESD enables full pathological assessment in lesions not suitable for en bloc resection with EMR. There were no recurrences in the curative cases, which increases the role of ESD for the management of early Barrett's neoplasia.

Introduction: Recently, it has been reported that proton beam therapy (PBT) is the effective treatment for patients with esophageal squamous cell carcinoma (ESCC). However, there are few reports regarding the endoscopic evaluation of efficacy after PBT at the primary site.

Aims & Methods: The aim of this study is to clarify the adequate endoscopic evaluation for primary lesion of ESCC after PBT, and the clinical results of salvage endoscopic treatment for local recurrence. Patients with clinical T1 ESCC, and who had been treated with PBT between April 2013 and June 2016 at the National Cancer Center Hospital East were investigated. The total dose of PBT was 60 Gray-Equivalent (GyE). The efficacy of PBT at the primary site was evaluated with endoscopy, and the definition of complete response (CR) was used according to the same criteria as that of conventional chemoradiotherapy (CRT) as follows; disappearance of tumor lesion and ulcer, and absence of cancer cells with biopsy was verified. The endoscopic evaluation was performed within 2 months after the completion of PBT, and we repeatedly evaluated every month if the lesion did not achieve CR. The treatment for local recurrence after PBT was chosen based on the depth of the tumor as follows; endoscopic resection (ER) for cT1a, esophagectomy or photodynamic therapy (PDT) for cT1b or deeper depending on patient's condition.

Results: Among 44 patients who underwent PBT, the median age was 70 years (range, 41–79). The number of patients with clinical stage I was 23 (52%), and those with stage II, III, and IV were 16 (36%), 2 (5%), and 3 (7%), respectively. All patients underwent concurrent systemic chemotherapy. 43 patients (98%) could achieve a CR at the primary site and only one patient (2%) did not show a CR (non-CR) at the primary site. The median time to CR from the start of PBT at the primary site was 85 days (range, 70–554 days) and 6 months or longer period was required to confirm CR due to the remaining PBT induced erosion or ulceration in 7 patients (15%). One patients whose primary site did not reached to CR showed prolonged ulceration for 385 days. Of the 43 patients, 6 patients (14%) developed local recurrence without regional lymph node recurrence or distant metastasis, and the median time to local recurrence from CR was 257 days (range, 111–722 days). The endoscopic finding of local recurrence was resembling submucosal tumors (SMT) in 3 and flat lesion in other 3 tumors. All 6 patients with local recurrence were indicated for endoscopic treatment (ER:4, PDT:2). No complications, such as major bleeding or perforation, were observed. And, 6 patients (100%) were alive without any recurrence at the median follow up period of 11 months (range, 1–32 months).

Conclusion: Longer period was required to confirm CR after PBT with chemotherapy in some cases comparing with the historical reports of that of conventional CRT. Careful closed endoscopic follow-up according to the way of conventional CRT enabled early detection of local recurrence and preferable local control with salvage endoscopic treatment.

P1220 CLINICAL OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL ESOPHAGEAL NEOPLASMS OF PATIENTS WITH HEAD AND NECK CANCER

J. F.D. Oliveira¹, E. Q. Mendonça¹, B. D.C. Martins¹, F. Kawaguti¹, M. S. De Lima¹, S. Geiger¹, C. Pennacchi¹, C. C. Gusmon¹, R. Uemura¹, E. R. Baba¹, A. V. Safatle-Ribeiro¹, L.H. Lenz Tolentino¹, G. De Paulo¹, M. Sorbello¹, M. Minata¹, R. N. Moura¹, U. Ribeiro Jr.¹, F. Maluf-Filho¹

¹Gastrointestinal Endoscopy Unity, Cancer Institute of University of São Paulo, São Paulo/Brazil

Contact E-mail Address: ktpennacchi@yahoo.com.br

Introduction: Surveillance programs of gastrointestinal endoscopy for detection of a second primary cancer in patients with head and neck squamous cell carcinoma (HNSCC) are very important since it can detect synchronous or metachronous esophageal squamous cell carcinoma (ESCC) in up to 15%–25%. The detection of ESCC in an early phase has paramount importance, since superficial lesions are amenable to endoscopic submucosal dissection (ESD) 2.

Aims & Methods: The aim of this study was to investigate the clinical outcomes of ESD in superficial esophageal neoplasm (SEN) of HNSCC patients in an oncology tertiary center. From 2010 to 2016, 3280 endoscopies were performed in patients with HNSCC and in 1887 chromoscopy with Lugol and NBI were performed. A total of 26 SENs, submitted to ESD, in 25 patients were retrospectively analyzed.

Results: The median tumor size was 4,37 cm (± 1.83). The en bloc resection were 100% and free margin (R0) were 92.3%. The two patients with positive margins had a depressed component in endoscopic evaluation. Recurrence occurred in 11,5% (3/26) and one of these patients was successfully treated with mucosectomy. The circumferential extension, number of patients e stenosis rate are show in table 1.

Table 1: The circumferential extension, number of patients and stenosis rate

Circumferential Extension	Number of lesions	Stenosis Rate
25–49%	1 (2.56%)	0 (0%)
50–74%	14 (53.84%)	5 (35.71%)
75–99%	6 (23.07%)	2 (33.33%)
100%	5 (19.23%)	5 (100%)
75–100%	11 (42.30%)	7 (63.63%)

The circumference of the resection $\geq 75\%$ was significantly associated with post-operative stricture (OR = 3.5; P < 0.05). The average number of endoscopic dilations for resolution of stenosis was 9.16 (± 7.62). No procedure-related mortality occurred. Follow-up data median was 11 months.

Conclusion: Endoscopic surveillance of HNSCC is very important for SENs detecting. Esophageal ESD of these lesions are feasible and safe with acceptable complication risks despite the high rates of stenosis in resections >75% of the circumference.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Globally, 80% of all esophageal cancer cases are esophageal squamous cell cancer (ESCC), arising from esophageal squamous cell neoplasia (ESCN). Patients with ESCC have poor prognosis, but when diagnosed at the stage of ESCN, curative endoscopic treatment can be performed. ESCN mainly occurs in developing countries, often with limited endoscopic expertise and resources, like Central and Eastern Asia and Eastern and Southern Africa. Hence, an easy-to-use, low-cost treatment for ESCN would be of great value. Focal Cryoballoon Ablation therapy (FCBA) (C2 Therapeutics Inc. Redwood City, CA, USA) is a new endoscopic ablation therapy that comprises a through-the-scope catheter with a conformable balloon that obviates the need for sizing, a handle, and a small disposable cryogen cartridge. The balloon is simultaneously inflated and cooled with nitrous oxide from the cartridge, resulting in ice patches of approximately 2cm². FCBA is easy to use and requires no capital equipment. Early studies for FCBA of Barrett's esophagus have shown promising results, however, limited data are available for FCBA of ESCN. In this study we aimed to assess the safety, tolerability and efficacy of FCBA in the eradication of ESCN.

Aims & Methods: In this ongoing multi-center prospective trial in China, patients with one flat type (Paris 0-IIb) unstained lesion (USL) on Lugol's chromoscopy, <6cm in length and <50% of circumference, with a confirmed diagnosis of Moderate or High Grade Intraepithelial Neoplasia (MGIN/HGIN) were

enrolled. At baseline, side-by-side ablations of 10 seconds were performed on USLs. Treatment was repeated every 3-months until eradication of ESCN was confirmed. Outcomes: safety and tolerability (11-point visual analog scale (VAS) for pain), complete response (CR) rates (absence of MGIN or worse in biopsies), neoplastic progression and adverse events.

Results: We enrolled 80 patients (63 MGIN, 17 HGIN) with a median lesion of 2 (IQR 2–3) cm in length. Of these, 79 patients (99%) were successfully treated; 3 developed superficial, self-limited mucosal lacerations upon balloon inflation and 2 of them were successfully re-ablated 3 months later. A median of 5 (IQR 4–7) side-by-side ablations were performed per patient, in a median ablation time of 8 (IQR 5–10) minutes. As of April 2017, 77/79 (97%) patients completed a 3-month follow up endoscopy and 69/77 patients (89%) exhibited endoscopic and histologic CR. Eight patients had residual USL and were again treated; 5 had a CR 3 months later and results for other 3 pts are pending. To date, 4 patients have undergone a 12 month endoscopy and all continue to exhibit endoscopic and histologic CR. No significant strictures have been noted on follow-up. Three patients developed fever shortly after treatment which was treated with aspirin. Post-procedure median VAS was 1 (IQR 0–2) at day 2, and 0 (IQR 0–0) at days 7 and 30.

Conclusion: Preliminary results of our multicenter open prospective cohort study suggest that FCBA of ESCN is safe, well-tolerated, and highly effective in inducing endoscopic and histologic remission. Longer term (12 month) follow-up data is pending.

P1222 THE ENDOSCOPIC TREATMENT STRATEGY FOR SUPERFICIAL ESOPHAGEAL CANCER

N. Yamaguchi

Department Of Gastroenterology And Hepatology, Nagasaki University Hospital, Nagasaki/Japan

Contact E-mail Address: naoyuki3435@nagasaki-u.ac.jp

Introduction: Endoscopic submucosal dissection (ESD) allows en bloc removal of superficial esophageal squamous cell carcinoma (SCC). However, esophageal stricture often occurs after ESD when the lesion involves more than three-fourth of the circumference of the lumen. Frequent balloon dilatation via endoscopy is required in such situation, thus causing health economic problem. In this study, we investigated the clinical outcomes, and prevention of post-ESD stenosis.

Aims & Methods: A total of 667 cases in 516 consecutive patients were treated by ESD in our department from April 2006 to December 2016. We investigated the following 2 items. 1. Clinical outcomes and complications. 2. Usefulness of oral steroids administration, the local steroids injection, endoscopic transplantation of tissue-engineered autologous oral mucosal epithelial cell sheets, or steroid oral + local injection combination therapy for the prevention of post-ESD stenosis.

Results: 1. Clinical outcomes: En bloc resection rate was 99.8% and en bloc curative resection rate was 90.0%. The rate of perforation, post-ESD bleeding, and post-ESD stenosis was 0.2%, 0.8% and 6.1%, respectively. 2. Prevention of post-ESD stenosis: (1) Oral steroid vs Steroid injection vs Cell sheet transplantation: In oral steroid group, the stenosis rate was 14.9%, and the ulcer healing period was 59.5 days. In steroid injection group, the stenosis rate was 12.9%, and the ulcer healing period was 66.0 days. In cell sheet transplantation group, the stenosis rate was 40.0% and the ulcer healing period was 36.0 days. There was no significant difference between these 3 therapies, and these therapies prevent post-ESD stenosis to significant extent. However, ulcer healing period of the cell sheet transplantation was significantly shorter compared with the other 2 therapies. (2) The usefulness of SH oral + local injection combination therapy. We investigated limitations of steroid administration, and cell sheet transplantation in order to prevent post-ESD stenosis. The following 4 factors (more than 9/10 of circumferential resection, more than 5 cm of longitudinal resection, cervical esophagus, post history of chemo-radiation therapy or endoscopic resection) were the stenosis prevention treatment-resistance factors. Therefore, we examined the stenosis rate according to the number of these 4 factors. The stenosis rate of the cases which have 0 or 1 factor, the case which has more than 2 factors in semicircular cases, and the complete circular cases is 4.9%, 30.3%, and 44.8%, respectively. The stenosis rate of the cases which have more than 2 factors and complete circular cases are significantly higher, compared to the cases which have 0 or 1 factor. As a result, the cases which have more than 2 factors and complete circular cases were regarded as the stenosis prevention treatment-resistant cases. In contrast, in SH oral + local injection combination therapy, the stenosis rate of the cases which have more than 2 factors and the complete circular cases is 12.5% and 14.3%, respectively. Taken together, the stenosis rate of SH oral + local injection combination therapy is significantly lower, compared to the other 3 therapies.

Conclusion: Esophageal ESD achieved high en bloc resection rate and curability with low rates of complications. Oral steroid, steroid injection therapy and cell sheet transplantation may be effective treatment strategy for reducing post-ESD stenosis. However, the above-mentioned 4 factors are the stenosis prevention treatment-resistant factors in these 3 therapy cases. Furthermore, the cases which have more than 2 factors and complete circular cases were regarded as the stenosis prevention treatment-resistant cases. SH oral + local injection combination therapy is very useful for prevention of post-ESD stenosis and has a potential to overcome treatment-resistant stenosis.

P1223 DIAGNOSIS OF TUMORS IN THE CERVICAL AND UPPER THORACIC ESOPHAGUS: EFFICACY OF ENDOSCOPIC ULTRASONOGRAPHY USING A JELLY-FILLING METHOD WITH WATER-SOLUBLE LUBRICATING JELLY

N. Matsuura¹, N. Hanaoka¹, R. Ishihara¹, S. Yamamoto¹, T. Akasaka¹, Y. Takeuchi¹, K. Higashino¹, N. Uedo¹, H. Ishi¹

Contact E-mail Address: ibura9@yahoo.co.jp

Introduction: Endoscopic ultrasonography (EUS) is the standard modality for qualitative diagnosis of submucosal tumors (SMTs) and determining the depth of invasion of esophageal cancer. Standard EUS, however, comprises a continuous water-filling or water-filled balloon method, which creates some problems (e.g., difficulty filling the water, aspirating water, poor image quality because of balloon compression). Aspiration of water is especially problematic during the diagnosis of lesions in the cervical or upper thoracic esophagus. To resolve such disadvantages, we recently reported a method that includes probe EUS with a jelly-filling technique (EUS-J) for evaluating superficial esophageal squamous cell carcinoma (SCC). The procedure is characterized by filling the esophageal lumen with a water-soluble lubricating jelly (K-Y lubricating jelly; Johnson & Johnson, Tokyo, Japan) that is used for routine endoscopy and is harmless to humans. In the current study, we retrospectively evaluated the usefulness of EUS-J with water-soluble lubricating jelly for lesions located in the cervical and upper thoracic esophagus.

Aims & Methods: Patients with an esophageal SCC or SMT in the cervical or upper thoracic esophagus were included. EUS-J with water-soluble lubricating jelly was performed using a high-resolution probe. Before examination, several 5-mL syringes containing the Water Soluble Lubricating Jelly were prepared. With the patient under conscious sedation with midazolam, an endoscope (GIF-2TQ260M; Olympus, Tokyo, Japan) was inserted into the targeted area in the esophagus. A 30- or 20-MHz miniature probe was then inserted through the left channel of the endoscope, and 40mL of jelly was instilled through the right channel until the esophageal lumen was filled.

Results: From December 2010 to March 2017, we used EUS-J to evaluate 61 patients with esophageal SCCs and 10 with SMTs in the cervical or upper thoracic esophagus. There were 10 lesions in the cervical esophagus and 61 in the upper thoracic esophagus. Among the 61 SCCs, 13 were recurrences following chemoradiotherapy. The other 48 SCCs did not undergo chemoradiotherapy. Of these 61 patients with esophageal SCC, 60 lesions (98.3%) could be detected with EUS-J. 44 lesions treated either by esophagectomy (n=7) or endoscopic resection (n=37). Histologic diagnosis was T1a in 27 lesions, T1b in 17 lesions. The overall accuracy of diagnosing invasion depth was 70.5% (31/44 lesions) by EUS. Among the 10 SMTs, we diagnosed seven leiomyomas derived from muscularis mucosa and one lesion due to vertebral body compression. The remaining two lesions were, respectively, a diminutive SMT (<3 mm) and a small lesion in the cervical esophagus adjacent to the hypopharynx. Neither was detectable using EUS-J because of their small size and difficulty with instrumental maneuvering. There were no adverse events during EUS-J, including aspiration pneumonia.

Conclusion: EUS-J with water-soluble lubricating jelly is useful and safe for diagnosing lesions in the cervical or upper thoracic esophagus. To our knowledge, this is the first report of using EUS with lubricating jelly for lesions located in this anatomic region.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The patients with early gastric cancer (EGC) who have undergone non-curative endoscopic resection (ER) need additional surgery. Our previous study reported short-term data about 29 days were optimal time when considering better surgical outcome. (*Ann Surg Oncol*. 2014 Jan;21(1):232–9.). This study is long-term follow-up study to evaluate the impact of the previously proposed optimal time interval from ER to additive surgery by on the surgical and oncological outcomes.

Aims & Methods: A total of 2850 patients who were diagnosed with EGC under ER at the Severance and Gangnam Severance Hospitals, Seoul, Korea, between January 2007 and December 2014. We analyzed totally 302 (10.6%) patients who underwent additive gastrectomy after non-curative ER. The patients were divided into 2 groups according to the time interval point, as the earlier operation group (group A) and the later operation group (group B). The time interval point, at which operative time and estimated intraoperative blood loss (EBL) of the earlier operation group and the later operation group

showed the greatest disparities, was evaluated. We retrospectively evaluated long-term follow-up study for oncological outcomes about follow-up duration, locoregional recurrence, distant recurrence.

Results: The median follow-up duration is 40.36 ± 20.74 months in all patients. Based on the previous our study, we divided patients into two groups who underwent operation before and after 29 days. Of the 302 patients, 133 were in Group A (≤29days) and 169 in Group B (>29days). There were more differences between two groups about ASA score, ER Specimen size, intra-op. transfusion, POD#1 Hemovac® discharge, Maximal postoperative CRP in the clinicopathological characteristics. Like previous our study the operative time, EBL, tumor size was significantly longer and more in group A compared with group B. There were totally 7 patients locoregional and distant recurrence during follow-up period. There were no differences in oncological outcomes between two groups.

Oncological recurrence for Each Group

Characteristics	Group A (≤29days) n = 133	Group B (>29days) n = 169	p-value
F/u duration (months, mean ± SD)	37.02 ± 20.54	44.18 ± 19.49	0.002
Locoregional recurrence (n, %)	1 (0.8)	1 (0.6)	0.757
Distant recurrence (n, %)	3 (2.3)	2 (1.2)	

Conclusion: Based on long-term follow-up data, surgery time after ER in EGC does not affect oncological outcome. These long-term follow-up results suggest that additive surgery at about 1 month after ER is optimal for better surgical outcomes without affecting the oncological outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1225 THE POINT TO DISTINGUISH EARLY GASTRIC CANCER FROM DEPRESSION TYPE OF GASTRIC INTESTINAL METAPLASIA

T. Wakatsuki, S. Furutachi, H. Yamashita

Department Of Gastroenterology & Hepatology, Okayama Medical Center, Okayama/Japan

Contact E-mail Address: t.wakatsuki0530@yahoo.co.jp

Introduction: This study discusses two endoscopic findings which improve the accuracy of the diagnosis of early gastric cancers (EGC). After successful *Helicobacter pylori* eradication, we often observe multiple reddish depressed lesions called “patchy redness” or “map-like redness” in the gastric mucosa. Even though most are intestinal metaplasia (IM), EGC is found among these lesions. A light blue crest (LBC) has been a highly accurate sign of the IM. There are, now, additional two endoscopic findings that should improve the accuracy of diagnosis of EGC. They are 1) “intraepithelial microinvasion (IEMI)”, and 2) “Over flow”. Over flow is that the endoscopic finding that the structure of the depressed lesion spreads to the outside of the depression.

Aims & Methods: The aim of this study is to clarify the usefulness of two endoscopic findings in order to detect the EGC in the group thought to be an IM. This is a retrospective control study. There were 234 cases of EGC performed endoscopic submucosal dissection (ESD) between November 2011 and August 2016 in Okayama Medical Center. We included 57 cases in this study. As EGC group, we included 45 cases that were 0-IIc, 10 mm or less, pT1a (M), a differentiation type cancer. As IM group, we included 12 cases identified as IM by biopsy in the same period. The EGC group is then divided into 2 groups; 1) eradication group (13 cases) who had a history of eradication and, 2) a small EGC group (32 cases) without a history of eradication. We evaluated 1) the ratio of LBC, 2) the ratio of irregular microsurface pattern 3) the ratio of irregular microvascular pattern, 4) the ratio of IEMI and 5) the ratio of Over flow.

Results: The ratio of LBC was 75% in IM group, which was significantly higher than eradication group (7.7%), and small EGC group (9.4%). The ratio of irregular microsurface pattern was 33% in IM group, which was significantly lower than eradication group (92%), and small EGC groups (84%). The ratio of irregular microvascular pattern was 0% in IM group, which was significantly lower than eradication group (92%), and small EGC group (81%). The ratios of IEMI were 0% in IM group, 39% in eradication group and 41% in small EGC group. The ratios of Over flow were 0% in IM group, 46% in eradication group and 50% in small EGC group. Furthermore, the ratios to have either in two endoscopic findings were 0% in IM, 77% in eradication group and 69% in small EGC group.

Conclusion: IEMI and Over flow leads to the diagnosis of EGC in addition to other endoscopic findings.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1226 IRON DEFICIENCY ANEMIA—ARE THERE ANY PREDICTORS OF GASTROINTESTINAL MALIGNANCY?

S. Xavier¹, J. Magalhães², J. Cotter³

¹Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga/Portugal

²Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães, Guimarães/Portugal

³Pt Government Associate Laboratory, 4 ICVS/3B's, Braga/Guimarães/Portugal

Contact E-mail Address: smaxavier@gmail.com

Introduction: Iron deficiency anemia (IDA) may be the only sign of gastrointestinal (GI) malignancy. The identification of predictive factors of GI malignancy in patients with IDA could help the physician to establish patients' priority to endoscopic assessment, contributing to an earlier diagnosis.

Aims & Methods: Retrospective study of 344 patients submitted to endoscopic assessment for IDA. Included adult patients with IDA and excluded patients with GI or extra-GI bleeding, total gastrectomy, exclusively vegetarian diet or insufficient medical records.

Results: Included 121 patients with mean age of 68.5 ± 17.0 years and 54.5% females. GI malignancy was identified in 14.9% of patients (gastric in 12, colonic in 6 patients). A statistically significant association was found between the presence of GI malignancy and age (75.2 ± 12.9 vs 67.2 ± 17.4, p < 0.05), male gender (72.2% vs 40.8%, p = 0.01), GI symptoms (61.1% vs 11.7%, p < 0.01), weight loss (61.1% vs 5.8%, p < 0.01), need for hospitalization (88.9% vs 49.5%, p < 0.01), iron serum levels and transferrin saturation (19.7 ± 10.1 mg/L vs 30.4 ± 18.9 mg/L, p < 0.01 and 6.1 ± 4.1% vs 9.2 ± 6.3%, p < 0.03, respectively). At logistic regression analysis only weight loss (p < 0.01), GI symptoms (p < 0.01), transferrin saturation (p < 0.01) and need for hospitalization (p = 0.02) showed a significant relation with the diagnosis of GI malignancy. Transferrin saturation showed a weak discriminative capacity (AUC = 0.67, p = 0.01) however, values of transferrin saturation ≤ 11% had a sensibility of 94.4% and a negative predictive value of 97.1% for GI malignancy (CI 95% 85.1–99.9%).

Conclusion: In patients with IDA the diagnosis of GI malignancy is established in a significant percentage of patients and patients with GI symptoms, weight loss or with need for hospitalization should be given priority in the performance of endoscopic examinations. Transferrin saturation may help the physicians in establishing the urgency of endoscopic assessment, since patients with values over 11% have a very low probability to have GI malignancy.

Contact E-mail Address: hu.jianwei@zs-hospital.sh.cn

Introduction: Detection of gastric cancer in its early stage is pertinent in reducing disease-specific mortality. However, this has not been achieved in many countries where the incidence of gastric cancer is high. In order to overcome this problem, we developed an e-learning system for international endoscopists to improve endoscopic diagnosis of early gastric cancer. However, it has not been investigated whether such learning system is useful in clinical practice.

Aims & Methods: The objective of this trial is to investigate whether the intensive on-site TTT course is useful for increasing early detection rate of gastric cancer in Chinese high-volume endoscopy center. Five Chinese doctors (the TTT group) who were invited to the TTT course and the other five age and experience-matched Chinese doctors (the non-TTT group) in the same facility who did not attend the TTT course were included in this trial. Endoscopists of the TTT group attended 2-day learning course 4 times from March 20, 2015 to March 25, 2016. Endoscopists of the non-TTT group did not attend any learning program during the same period. Lectures of the TTT course included the detection of early gastric cancer by screening endoscopy using white-light endoscopy alone and the feature of the detected subtle gastric mucosal lesion using white-light endoscopy or magnifying endoscopy with narrow-band imaging. Contents used in the lecture had been reported to be useful by an e-learning trial [1, 2]. All the instructions were given by an experienced Japanese endoscopist (K. Yao) who constructed the e-learning system [1, 2]. Endoscopists also received on-site hands-on instructions in order to check whether they obtained enough knowledge and technique. Furthermore, we held case conferences in order to share common experiences. During the period, the number of both newly detected early gastric cancers and screening gastroscopy procedures was recorded. The primary endpoint was to compare the early detection rate between the TTT and the non-TTT group. (Early detection rate = the number of newly detected early gastric cancers/ the number of screening endoscopy procedures)

Results: The data obtained from the 275 consecutive cases of screening gastroscopy procedures by the TTT group endoscopists and from the 323 consecutive cases of screening endoscopy procedures by the non-TTT group endoscopists were analyzed. In the TTT group, four cases with early gastric cancers were detected and no early gastric cancer was detected. The early detection rates of

the TTT and the non-TTT group were 1.5% and 0%, respectively. There was a significant difference in early detection rate between the TTT and the non-TTT group (Fisher's exact test, $P=0.046$).

Conclusion: This clinical trial clearly showed that the systematic intensive TTT course is useful for improving early detection rate of gastric cancer in clinical practice at Chinese high-volume endoscopy center. (NCT02385578)

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) is believed to be a possible modality for early gastric cancer. But there is little report about long-term outcomes of the ESD directly compare with the surgery. The purpose of this study is the comparison between the two treatment modalities about the outcomes.

Aims & Methods: We performed a retrospective analysis of 1243 patients with stage I early gastric cancer without lymph node involvement. 551 patients were treated with ESD, and 692 patients were treated with subtotal or total gastrectomy. Long-term overall and disease-specific survival rates, development of new lesions, and complications were analyzed.

Results: The mean age was higher in the ESD group (64.9 ± 9.5 vs. 58.5 ± 11.7 , $P=0.001$) and female distribution was higher in surgery group (30.5% vs. 38.9%, $P=0.001$). In ESD group, diabetes was more frequent (12.9% vs. 7.1%, $P<0.001$). The overall survival rate was similar (96.2% vs. 96.7%, $P=0.136$), but disease-specific survival rate was significantly higher in ESD group (99.8% vs. 98.7%, $P=0.037$, log-rank test). During 10 year follow up period, new lesions were observed in 3.6% of ESD group and in 1.3% of surgery group ($P<0.001$). ESD group showed less complications (4.5% vs. 16.3%, $P<0.001$) and shorter hospital day than surgery group (5.27 days vs. 12.09 days, $P<0.001$).

Conclusion: Although the development of new lesions were more frequent than surgery, ESD has similar overall survival rate and even higher disease-specific survival rate than surgery. Also, ESD has less complications and shorter hospital day than surgery. Therefore, ESD is an effective therapeutic method in early gastric cancer as well as surgery.

P1229 HEMATOLOGISTS SHOULD ORDER ENDOSCOPIC EXAMINATION TO EXPERTS OF ENDOSCOPY IN CASE OF ENDOSCOPIC CHECK-UP OF GASTROINTESTINAL MALIGNANT LYMPHOMA

T. Yamasaki, T. Sakurai, J. Mitobe, M. Mitsunaga, M. Saruta

Department Of Gastroenterology And Hepatology, The Jikei University, Tokyo/Japan

Contact E-mail Address: takusan.yamasan@gmail.com

Introduction: Gastric malignant lymphoma (ML) is most popular lymphoma of the gastrointestinal tract. Especially we often see gastric MALT lymphoma in cases of *H. pylori* (HP) infection positive, and we also sometimes find out HP negative gastric MALT lymphoma. Since gastric carcinoma (GC) is more common rather than gastric MALT lymphoma, typical endoscopic diagnostic characteristics of GC are established on usual endoscopic examination for most of gastroenterologists. On the other hand, endoscopic characteristics of gastric MALT lymphoma on usual endoscopy have not been established for most of gastroenterologists.

Aims & Methods: Our aim of this study is to estimate of the difficulty on endoscopic diagnosis of gastric MALT lymphoma for 24 gastroenterologists (12 experts and 12 trainees of endoscopy) on usual endoscopic examination. We investigated a total of 72 gastric MALT lymphoma cases in our hospital and other 7 hospitals. We estimated total number of endoscopic examinations to achieve diagnosis of gastric MALT lymphoma endoscopically and histologically. In addition, we had analyzed the difference of abilities to diagnose of gastric MALT lymphoma between experts and trainees on endoscopic examinations using past endoscopic profiles (245 profiles).

Results: The average number of endoscopic examinations up-to diagnose gastric MALT lymphoma was 3.4 times (from 1 to 7 times) on whole endoscopies after first appearance of lymphoma. Though average total number of endoscopic

examinations of experts was only 1.2 times, on the other hand average total number of endoscopic examinations of trainees was 5.4 times. There was a significant difference between experts and trainees of endoscopy on average total number of endoscopic examinations ($p=0.022$). Major reason of misdiagnosis was insufficient recognition of endoscopic appearances of ML on endoscopic trainees. Typical representative appearances of gastric MALT lymphoma were erosions, ulcers and surface irregularities. Since these lesions are also appeared as typical appearances of GC and gastritis, most of non-expert of endoscopy cannot distinguish the difference of GC, ML and gastritis due to those similarities. For example, even if typical ML cases, non-expert could not diagnose repeatedly, but expert could diagnose minimal lesions of ML at first endoscopy. Especially HP positive gastric MALT lymphoma was similar to gastritis and GC on endoscopic findings, most of non-expert could not diagnose exactly.

Conclusion: There was significant difference of ability to diagnose gastric MALT lymphoma between specialists and trainees. Therefore, hematologists should order endoscopic examination to experts of endoscopy knowledgeable of ML in case of endoscopic check-up of gastrointestinal malignant lymphoma.

Introduction: Gastric cancer is the fifth most common cancer worldwide and the third leading cause of cancer-related death globally [1]. With the widespread eradication of *H. pylori* and early detection, the incidence and mortality of gastric cancer have been declined rapidly in the past few decades [2–3]. However, the prognosis of patients with metastatic diseases was still dismal and most cases survived less than one year [4]. Current primary and standard therapies for metastatic gastric cancer mainly included chemotherapy, consisting of fluoropyrimidine/cisplatin-based combination regimens[5]. Although radical gastrectomy was the first-line treatment for early gastric cancer[6], the value of gastrectomy in stage IV was still a great controversy.

Aims & Methods: We aimed to investigate the impact of primary tumor resection on survival outcomes among patients with metastatic cancer. We identified an eligible cohort of the population with stage IV gastric cancer from the Surveillance, Epidemiology and End Results (SEER) database between 2004 to 2012. The overall prognosis of advanced patients with or without gastrectomy was assessed by Kaplan–Meier and log-rank analysis. Multivariate Cox proportional hazards regression models was performed to analyze the effect of primary tumor resection on overall and cancer-specific mortality. To further reduce potential baseline bias in patient selection between two groups, we adopted 1:1 propensity score matching to re-examine the effect of resection.

Results: We finally identified 12984 eligible patients with metastatic GC between 2004 and 2012, including 1977 patients with gastrectomy and 11007 without resection. The median survival time for patients with or without surgery were 9.0, 4.0 months respectively. Patients who received surgery had a significantly better survival outcome compared with those without gastrectomy ($P<0.05$). In multivariate Cox analysis, gastrectomy was associated with decreased overall mortality (HR,0.55, 95%CI 0.52–0.58, $P<0.001$) and cancer-specific mortality (HR, 0.55, 95%CI 0.52–0.58, $P<0.001$). In the propensity score matched model analysis, gastrectomy was associated with increased overall (HR,0.54, 95% CI, 0.51–0.58) and cancer-specific survival (HR,0.54, 95% CI, 0.50–0.55).

Conclusion: Based on population-based studies, we demonstrated that there was a survival advantage of gastrectomy in patients with stage IV gastric cancer. Further prospective studies are needed to verify our findings.

P1231 DEVELOPMENT OF AND EXPERIENCE WITH AN INSULATED SCISSORS-TYPE KNIFE (SB KNIFE)

M. Kobayashi

Yokkaichi Municipal Hospital Dept. of Gastroenterology, Yokkaichi/Japan

Contact E-mail Address: makoto-kobayashi@aroma.ocn.ne.jp

Introduction: Endoscopic submucosal dissection (ESD) is technically difficult and is associated with risks of perforation and bleeding. Although knife-type instruments are primarily used to make incisions during ESD, it is necessary to be proficient in endoscopic procedures and be able to perform them simultaneously with electrification and incision. Scissors-type knives are fairly easy to manipulate in colorectal ESD. We have fabricated SB knife Jr type (SB Jr), short scissors-type knife with outer insulated layer, in collaboration with SUMITOMO BAKELITE CO.

Aims & Methods: SB Jr is short length (electrode length: 3.5 mm) to be easy to handle in narrow colorectal lumen. The surface of the rotatable monopolar scissors is coated with insulating material in order to enhance the cutting power and prevent electric effects in the surrounding tissue. The shearing structure make sharp cutting quality and very small round tips prevent to grasp the muscular layer. SB Jr was used in circumference incision, submucosal dissection and hemostasis. After infected hyaluronic acid in submucosal layer, grasped the tissue, confirming safety, make incision. SB Jr was used not only in incision but also in hemostasis. At sites containing blood vessels or bleeding, they were grasped and induced coagulation using SB Jr. It has been used on 180 colorectal lesions from January 2008.

Results: The circumference incision and submucosal dissection were basically performed with High-frequency cutting wave. There were 3 cases of perforation during ESD and 1 case of post-operative bleeding. The procedure itself was fairly easy and was particularly effective at fibrosis sites, sites difficult to stable the endoscope and sites containing blood vessels, where conventional devices would encounter difficulties. Due to the very small round tips of the instrument, detailed operation become simply. For coagulation of blood vessels or bleeding, it is not required to replace SB Jr which is used cutting and coagulation.

Conclusion: This short insulated scissors-type knife (SB Jr) made it easier to perform colorectal ESD, we conclude that it is an effective device and easy for a beginner in colorectal ESD.

Introduction: The gastrointestinal tract (GIT) is the most commonly extranodal site affected in lymphomatous pathology. Infection with *Helicobacter pylori*, human immunodeficiency virus and Epstein Barr and immunosuppression have been studied as possible risk factors. The diagnosis is often late, presenting at an advanced stage, with limited therapeutic options.

Aims & Methods: The objective of this study was to characterize the anatomical distribution, clinical manifestations, risk factors and prognosis of GI lymphomas. Retrospective study of patients diagnosed with GI lymphomas between 1997 and 2016.

Results: During the 20 years, 127 GI lymphomas were identified. The mean age at diagnosis was 58.2 ± 16.5 years, 53% of males. The majority (92.9%) had symptoms at the time of diagnosis, with fatigue (54.3%) being the most common. The most commonly affected organ was the stomach (65.3%) and the most common subtypes were diffuse large B-cell (48.8%) and MALT (27.6%). Most were diagnosed through upper endoscopy (68.5%) and 10.2% after exploratory laparotomy. Sixty-five percent of patients underwent chemotherapy and 26% underwent surgery. In the univariate analysis, lymphomas > 4 cm (p=0.037), anorexia (p=0.006), tobacco use (p=0.038), alcohol consumption (p=0.006), lymphadenopathy (p=0.014), high b2-microglobulin < 0.01, ECOG > 2 (p < 0.001) and IPI index > 2 (p < 0.001) were associated with lower survival.

Conclusion: The stomach is the main organ affected by lymphomatous disease but, unlike the literature in which MALT lymphoma predominates, the most common subtype was diffuse large B-cell lymphoma. Upper endoscopy was the main form of diagnosis. Alcohol and tobacco consumption, lymphadenopathy, lymphoma > 4 cm, b2 high microglobulin, ECOG > 2 and IPI index > 2 are poor prognostic factors.

Introduction: Previous studies have shown that non-cardiac gastric cancer had no associations with the obesity even if cardiac or gastroesophageal junctional

cancer was related with the obesity. These studies have included high portion of advanced gastric cancer. Patients with most advanced cancer already experienced weight loss.

Aims & Methods: We evaluated the effect of body mass index (BMI) on early gastric cancer in patients undergoing endoscopic treatment for early gastric cancer. A total of 748 patients with early gastric cancer undergoing endoscopic treatment (endoscopic submucosal dissection) including age and sex matched healthy controls consist of this case-control study. Body mass index was classified into underweight (BMI < 18.5), normal (BMI 18.5–23), overweight (BMI 23–25), and obese (BMI ≥ 25) by Asian-Pacific guideline. Adjusted analysis using odds ratio (OR) and 95% confidence interval (CI) was performed to evaluate the effect of BMI on early gastric cancer.

Results: The mean age was 57 years and male sex was 60% (n=447). BMI was higher in gastric cancer comparing to healthy control (24 vs 23, P < 0.001). The OR of gastric cancer was increased according to the BMI increase; 1.57 (95% CI, 0.89–2.79, P=0.12) in normal BMI, 1.88 (95% CI, 1.06–3.35, P=0.03) in overweight, and 2.28 (95% CI, 1.29–4.06, P=0.005) in obese persons comparing to underweight (P value for trend < 0.001).

Conclusion: The early gastric cancer was strongly associated with the increased BMI and its effect has dose-dependent pattern.

Introduction: Gastrointestinal subepithelial tumors include potentially malignant tumors. When considering the diagnostic yield for subepithelial tumors, it is important to evaluate whether the samples obtained are adequate for histological analysis, as immunohistological analysis is indispensable for a definitive diagnosis. However, it may be difficult to make a correct histological diagnosis with only by the endoscopic ultrasonography-guided fine-needle aspiration (EUS-FNA). Therefore, there has been an interest in exploring an alternative modality for tissue sampling as mucosal-incision assisted biopsy (MIAB) based on the endoscopic submucosal dissection.

Aims & Methods: The aim of this study was to compare the usefulness of EUS-FNA and MIAB in the histological diagnosis of gastrointestinal subepithelial tumors (SET). We performed the retrospective study comparing 37 patients who underwent either EUS-FNA (n=18) or MIAB (n=19). Diagnostic yield feasibility and safety of those EUS-FNA and MIAB were compared.

Results: The location of the SET was esophagus (n=6), stomach (n=29), and duodenum (n=2). The histological diagnosis were gastrointestinal stromal tumors (n=10), leiomyoma (n=17), aberrant pancreas (n=3), poorly differentiated adenocarcinoma (n=2), metastatic carcinoma (renal cell carcinoma, n=1), and no-diagnosis (n=4). There were no significant differences in the clinical characteristics-including sex and age-of the patients in the EUS-FNA and MIAB. In EUS-FNAs/MIABs, the morphological findings of the SET by EUS were as follows. The mean diameter of tumor was 29.16 ± 15.6/17.77 ± 7.16 mm (p=0.0034). The rate of intraluminal growth was 55.6%/94.7% (p=0.0078). The mean procedure time was 40.89 ± 10.79 min in EUS-FNA and 55.15 ± 27.42 min in MIAB (p=0.0234). Histological diagnosis was made in 72.2% of the EUS-FNAs and 94.7% of the MIABs (p=0.0897). No complications were found in either method.

Conclusion: The mean procedure time was significantly longer in MIAB than in EUS-FNA. However, the mean diameter of the tumor was significantly smaller in MIAB than in EUS-FNA the higher diagnostic yield in MIAB than in EUS-FNA was borderline significant.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In 2012 the reported incidence of gastric cancer in both sexes was 12.3/100,000 but the mortality was still high (8.7/100,000), being early detection strictly related to a better survival. Parma area is considered at medium-low incidence of gastric cancer. For early diagnosis, the detection of a precancerous condition like atrophic gastritis seems crucial, but the majority of such patient is asymptomatic and the use of non invasive diagnosis like serology (Pepsinogens and Gastrin 17) as suggested in the guidelines of Kyoto and Maastricht V is up to now limited in clinical practice. Aim of the study, therefore was to establish the burden of gastric cancer in the diagnosis of the last six years, focusing on the detection of early gastric cancer.

Aims & Methods: Six years (from July 2010 to July 2016) were considered in search for diagnosis of gastric cancer as reported in the archives of the Pathology Department of Parma University. Overall, 816 cases of gastric cancer were found but we decide to consider only the surgically removed cases, therefore the available sample is based on 584 cases. For every cases we classified the cancer in early, following the Kodama classification, and advanced. The presence of atrophic gastritis nearby the neoplasia was assessed according with OLGA classification. In both early and advanced cancer the node status was investigated.

Results: Overall, 584 cases of gastric cancer was detected in the six years considered interval (M = 318, F = 223, mean age 78ys, range 36–105ys) The diagnosis of early gastric cancer was made in 44/584 (7.53%) (M = 24, F = 20 mean age 75.68ys, range 47–92ys). A diagnosis of advanced gastric cancer was established in 540 pts (M = 318, F = 222, mean age 78.20ys, range 36–105ys). The picture of chronic atrophic gastritis was found in more than 95% of the cases, both in early and advanced ones. The node status was also recorded. Early cancers showed a 25% of node metastasis compared with 84.65% in advanced ones. As regards the number of involved nodes, in early presentation of neoplasia we found 98% of pN1 staging whereas in advanced the pN1 cases were only 9.1%.

Conclusion: Early gastric cancer diagnosis is still confirmed as very infrequent and this could account for the high mortality rate for the gastric neoplasia. The search for precancerous condition like chronic atrophic gastritis is therefore mandatory.

Introduction: Gastric adenocarcinoma of fundic gland type (GAFG) is an uncommon variant of gastric adenocarcinoma which has a distinct clinicopathological, immunohistochemical, and endoscopic features 1–3). However, the molecular biological features of GAFG have not been well elucidated.

Aims & Methods: We evaluated clinical and molecular characteristics of GAFG in comparison with conventional gastric adenocarcinoma. Among 831 patients with gastric adenocarcinoma who underwent surgery or endoscopic resection in Juntendo hospital between January 2010 and December 2016, we enrolled 13 cases of GAFG, defined as an extremely well differentiated adenocarcinoma with expression of pepsinogen-I and/or H⁺/K⁺-ATPase 1). To clarify concurrent mutations of GAFG, next generation sequencing (NGS) was performed for all cases of the tumor and normal tissue formalin-fixed paraffin-embedded samples, using Ion PGM™ system with the Hotspot Cancer Panel v2 targeting 50 genes (Thermo Fisher Scientific). We also carried out immunohistochemical staining including MUC2, MUC5AC, MUC6, and CD10, and analyzed association among genetic alterations and mucin phenotype.

Results: Clinicopathologically, all patients [62.9 y (range 43–80), 8 male, 5 female] had submucosal invasive adenocarcinomas with no *H. pylori* infection; the mean depth of the submucosal invasion was 288.4 (50–700) μm. Neither local recurrence nor metastases were detected at a median of 6.7 months (1–47) follow-up after treatment. NGS analysis revealed that nine of 13 patients (69.2%) had oncogenic driver mutations including *GNAS* (5/13, 38.5%), *KRAS* (2/13, 15.4%), *STK11* (1/13, 7.7%), and *TP53* (1/13, 7.7%), and these alterations were mutually exclusive. Mutations of *APC* and *CTNNB1*, members of the Wnt/β-catenin pathway, were absent in all cases examined. Compared with public data sets of conventional gastric adenocarcinoma 4), the frequency of *GNAS* mutation was significantly higher (38.5% vs. 6.2%, *p* < 0.01) in GAFG. Furthermore, the frequency of *TP53* mutation was significantly lower (7.7% vs. 47.8%, *p* < 0.05) in GAFG. However, there were no significant differences in the frequencies of *KRAS* and *STK11* mutations. In addition, all lesions showed gastric phenotype (i.e. immunopositive for MUC5AC and/or MUC6), and there were no significant differences between genetic alterations and mucin phenotype.

Conclusion: The present clinical and comprehensive genetic analysis identified that GAFG is a neoplasm with low-grade malignancy, and the frequent presence of *GNAS* mutation is a characteristic genetic feature of GAFG.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1237 LNCRNA-HOTAIR INDUCES THE UBIQUITINATION OF RUNX3 IN GASTRIC CANCER

S. Chen¹, M. Xue², L. Chen¹, L. Wang²

¹Gastroenterology, Sir Runrun Shaw Hospital, School of Medicine, Zhejiang University, Hangzhou/China

²The second Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou/China

Contact E-mail Address: 4094108@qq.com

Introduction: Runt-related transcription factor 3 (Runx3) is a transcription factor playing an inhibitory role in the malignant behavior of gastric cancer. Long non-coding RNAs (lncRNAs) exert their functions mainly by binding with corresponding proteins, among which, transcription factors are the most common ones. However, the lncRNAs that could bind with and affect the expression or activity of Runx3 are still unclear.

Aims & Methods: Potential Runx3-binding lncRNAs were screened by an online prediction software RPISeq, and then validated by RNA Immunoprecipitation. Specific HOTAIR binding site with Runx3 was confirmed further by RNA Pull down. The E3 ubiquitin ligases being involved in the ubiquitin-proteasome degradation of Runx3 were recognized through co-immunoprecipitation assay. Besides, the expressions of HOTAIR and Runx3 were measured in human gastric cancer tissues and correlated with each other.

Results: A total of 11 lncRNAs that might bind with Runx3 were selected by *in silico* analysis, among which, HOTAIR, MALAT1, PVT1 and LET were significantly amplified in RNAs precipitated by Flag antibody. Ectopic expression of HOTAIR inhibits the protein expression of Runx3, while addition of exogenous MG132 could partially recover this. RNA Pull down assay with a stepwise deletion of Runx3 shows that HOT-D2 (1951–2100) is a major Runx3 binding site along the sequence of HOTAIR. Mex3b was markedly enriched by Runx3 antibody, and siRNAs targeting either HOTAIR or Mex3b could enhance the stability of Runx3 by impairing its ubiquitination. In addition, HOTAIR was negatively associated with the protein level of Runx3 in gastric cancer tissue.

Conclusion: HOTAIR induces the ubiquitin-proteasome degradation of Runx3 by enhancing its interaction with a E3 ubiquitin ligase Mex3b in gastric cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1238 CAB39L FUNCTIONS AS A TUMOUR SUPPRESSOR IN GASTRIC CANCER THROUGH LKB1-MEDIATED AMPK ACTIVATION

Introduction: Promoter hypermethylation plays a vital role in cancer development through transcriptional silencing of tumour suppressive genes. Using Infinium Human Methylation 450 BeadChip (450K) array, we first identified calcium binding protein 39-like (CAB39L) to be preferentially methylated in gastric cancer (GC) and it may function as a potential tumour suppressor gene.

Aims & Methods: In this study, we aim to investigate the biological function, molecular mechanism and clinical implications of CAB39L in GC. Clinical relevance was validated by bisulfite genomic sequencing (BGS), western blot and immunohistochemistry (IHC). In vitro functional assays were carried out by cell viability, colony formation, apoptosis, cell cycle, cell invasion and migration assays in GC cell lines. In vivo tumorigenicity was evaluated in an orthotopic mice model. Pathway analysis was performed using RNAseq and Phosphokinase Antibody Array. The interaction of CAB39L with its protein partners was determined by co-immunoprecipitation.

Results: CAB39L mRNA was down-regulated in 13 out of 14 GC cell lines. Silencing of CAB39L was associated with promoter hypermethylation, and demethylation 5'- treatment using Azadeoxycytidine (5-Aza) restored the expression of CAB39L. In human GC, CAB39L mRNA and protein level (*p* < 0.0001)

were significantly decreased in GC tissues comparing to adjacent normal tissues both in Chinese cohort ($n=48$ pairs) and TCGA cohort ($n=450$). CAB39L hypermethylation was correlated with poor overall survival in Chinese cohort ($n=87$, $p < 0.005$) and validated in TCGA cohort ($n=354$, $p < 0.005$), which suggesting that CAB39L might function as a tumour suppressor. The functional importance of CAB39L in GC was therefore examined. Ectopic expression of CAB39L in three GC cell lines (AGS, BGC823, MKN45) suppressed cell proliferation in MTT ($p < 0.01$) and colony formation assays ($p < 0.0001$). CAB39L induced apoptosis and G1 cell cycle arrest in GC cells, concomitant with the enhanced expression of cleaved caspase-8, caspase-3, p21 and decreased cyclin D3 expression. Cell migration and invasion abilities were inhibited by CAB39L in wound healing and gel invasion assays, respectively. Conversely, CAB39L knockdown in MKN28 demonstrated opposite effects. Orthotopic mice model also showed inhibited tumorigenicity with CAB39L-overexpressing BGC823 cells. Mechanistically, RNAseq and gene set enrichment analysis (GSEA) revealed that AMPK and ERBB2/ERBB4 signaling were involved in the tumour suppressive role of CAB39L in GC. Consistent with our RNAseq data, Phospho-Kinase Antibody Array identified AMPK as the top activated kinase; whilst ERK1/2 was the most strongly down-regulated in CAB39L over-expressing GC cells, suggesting that CAB39L up-regulates AMPK concomitant with down-regulation of ERBB2/4-ERK signalling. Moreover, co-immunoprecipitation identified a direct interaction between CAB39L and LKB1, a *bona-fide* tumour suppressor that functions to activate AMPK to suppress tumorigenesis. Western blot confirmed activation of LKB1-AMPK α/β cascade in GC cells expressing CAB39L, while an opposite effect was observed in CAB39L-silenced MKN28 cells. Administration of an AMPK activator, AICAR, inhibited growth of control cells but not CAB39L-expressing (thus AMPK activated) cells, suggesting that AMPK activation by CAB39L contributes to tumour suppression. **Conclusion:** CAB39L is a novel tumour suppressor silenced by promoter methylation in GC. CAB39L inhibits gastric tumorigenesis via LKB1-mediated activation of AMPK α/β . CAB39L methylation may serve as an independent prognostic biomarker for GC patients.

P1239 FUNCTIONAL CHARACTERIZATION AND CLINICAL SIGNIFICANCE OF PKNOX2, A NOVEL TUMOR SUPPRESSOR IN GASTRIC CANCER

L. Zhang¹, C.C. Wong¹, W. Li¹, J. Xu¹, L. Cao¹, J. Yu²

¹Chinese University of Hong Kong, Hong Kong/Hong Kong PRC

²Institute Of Digestive Disease, Partner State Key Laboratory Of Digestive Disease, Chinese University of Hong Kong, Hong Kong/Hong Kong PRC

Contact E-mail Address: zhangliforever@126.com

Introduction: Using 450 K DNA methylation array, we identified PBX/Knotted 1 Homeobox 2 (PKNOX2) as a novel gene differentially methylated in gastric cancer (GC). PKNOX2 belongs to the TALE (three-amino acid loop extension) family of homeodomain transcription factors, which play fundamental roles in cell proliferation, differentiation and death. However, the role of PKNOX2 in GC remains largely unknown.

Aims & Methods: We aimed to investigate the function, molecular mechanism and clinical implication of PKNOX2 in GC. PKNOX2 promoter methylation was evaluated by bisulfite sequencing. PKNOX2 expression was determined by RT-PCR and qPCR. Biological functions of PKNOX2 were determined in GC cells by MTT, colony formation, apoptosis, cell cycle, cell migration/invasion assays, and *in vivo* using nude mice tumorigenicity assay. Pathways targeted by PKNOX2 were identified by Cancer pathway PCR array and dual luciferase reporter assay.

Results: PKNOX2 was silenced in 15 out of 18 GC cell lines through promoter methylation, and 5'-Azadeoxycytidine treatment restored PKNOX2 expression. PKNOX2 mRNA expression was down-regulated in GC compared to adjacent normal tissues ($P < 0.001$). Moreover, promoter methylation of PKNOX2 was associated with poor survival in GC patients ($P < 0.05$), suggesting that PKNOX2 may function as a tumor suppressor in GC. We therefore examined its functional effect in GC. Ectopic expression of PKNOX2 in GC cell lines suppressed cell proliferation, induced cell apoptosis and cell cycle arrest, concomitant with increased expression of apoptosis markers cleaved caspase-9,-7,-3 and PARP and cell cycle inhibitors p53, p21 and p27. PKNOX2 also attenuated cell migration and invasion by inhibiting epithelial-mesenchymal transition. PKNOX2 knockdown in HGC27 cells resulted in opposite effects. Tumorigenicity assay in nude mice showed that stable PKNOX2 expression significantly suppressed tumor growth *in vivo*. To probe the mechanism of action of PKNOX2 in GC, we performed Cancer pathway PCR array, which unveiled a profound up-regulation (> 6 -fold) of Insulin like Growth Factor Binding Protein 5 (IGFBP5) in PKNOX2-overexpressing GC cells. IGFBP5 knockdown abolished the growth inhibitory effect of PKNOX2 in GC cells, indicating that IGFBP5 mediated the tumor suppressive function of PKNOX2. Chromatin immunoprecipitation (ChIP) assay showed that PKNOX2 bind directly to IGFBP5 promoter to mediate transcription. Consistent with our data, PKNOX2 expression was positively correlated with IGFBP5 expression in the TCGA GC dataset. IGFBP5 mediated the tumor suppressive effect of

PKNOX2 via activating p53 signaling pathway, as determined by western blot and luciferase reporter assays. Consequently, p53 transcription target genes were coordinately up-regulated in PKNOX2 overexpressing cells, leading to tumor suppression.

Conclusion: PKNOX2 functions as a novel tumor suppressor silenced in GC by promoter methylation. Its tumor suppressive effect is mediated via IGFBP5 and the activation of p53 signaling pathway. Promoter methylation of PKNOX2 may be a useful biomarker for predicting patient prognosis.

Introduction: Gastric cancer is one of the most common malignancies worldwide. A multitude of factors contribute to the progression of gastric cancer, including activation of oncogenes and inactivation of tumor suppressors. To find the key molecules and their mutual relations in gastric carcinogenesis is of great significance for the diagnosis and treatment of gastric cancer. The homeobox (Hox) superfamily genes encode transcription factors and usually regulate the expression of target genes at transcription level. Dysregulation of Hox genes will cause the abnormality in individual development and tissue formation, and may also lead to malignant transformation. Our group have previously screened by gastric cancer tissue microarray and found that the expression of HoxC10 was remarkably upregulated in gastric cancer. At the present time, the function and molecular mechanisms of HoxC10 in gastric cancer remains poorly understood.

Aims & Methods: To investigate the expression of HoxC10 in gastric cancer, tissue samples from two clinical cohorts were used. We analyzed HoxC10 expression in gastric cancer tissues and the corresponding adjacent non-tumor tissues, as well as its correlation with clinical pathological parameters. In addition, we also verified the results by utilizing bioinformatics analysis. We studied the effects of HoxC10 on gastric cancer cell cycle control and proliferation through combination of *in vitro* cell function tests and *in vivo* nude mice model. Then, we screened HoxC10 potential downstream targets by using cDNA microarray and verified the results by RT-qPCR. We studied the effects of HoxC10 on p21 expression and its downstream cell cycle-related proteins and validated the correlation of HoxC10 and p21 expression *in vitro* and *in vivo*. By application of dual-luciferase reporter assay and chromatin immunoprecipitation, we explored the role of HoxC10 in p21 transcription repression.

Results: HoxC10 mRNA expression were significantly higher in fresh frozen gastric cancer tissues than in matching adjacent non-tumor tissues (91.43%, 64/70, $P < 0.01$). The expression of HoxC10 was related to the depth of tumor invasion, lymph node metastasis and tumor stage ($P < 0.01$). Using tissue microarray, HoxC10 protein expression was also found widely upregulated in gastric cancer tissues (91.3%, 137/150, $P < 0.01$) and was closely correlated with patient survival (HR = 2.8; 95% CI 2.0–7.2). Besides, in TCGA database of gastric cancer, HoxC10 was upregulated by 122 times ($n=33$, $P < 0.01$), and in Kaplan-Meier Plotter database, high HoxC10 expression was associated with poor prognosis of patients with gastric cancer (HR = 1.8; 95% CI 1.5–2.16). HoxC10-overexpressing gastric cancer cells showed accelerated G1-S phase transformation and proliferation, whereas HoxC10 knocking-down induced cell cycle arrest in G1 phase and repressed cell proliferation. Moreover, over-expression of HoxC10 accelerated gastric tumor growth in a mouse xenograft model, while knocking-down of HoxC10 inhibited gastric tumor growth. cDNA microarray showed that HoxC10 regulates multiple downstream genes including p21, a potent cell cycle regulator. A significantly negative correlation between HoxC10 and p21 were detected in gastric cancer cells and tissues. Knocking-down of HoxC10 also altered the expression of some p21 downstream cell cycle-related proteins, such as CDK2 and CDK4. Furthermore, we found that HoxC10 binds to the p21 promoter directly and could inhibit p21 transcription. **Conclusion:** Taken together, our results suggest that HoxC10 functions as a tumor promoting gene in gastric cancer and may be an important regulator of cell cycle control through p21 transcription regulation.

Introduction: The relationship between *Helicobacter pylori* (H.p.) eradication and atrophic changes is debated. Although some studies report a partial restoration of serum pepsinogen I (PGI) levels after eradication, it is not clear whether this finding reflects gastric mucosal healing. L-cysteine, reducing acetaldehyde production after food intake, has been proposed for prevention of gastric carcinogenesis in patients with chronic atrophic gastritis (CAG). To assess modifications in gastric function after L-cysteine administration in CAG by means of PGI and gastrin 17 (G17) serum levels

Aims & Methods: 62 patients (18 men, mean age 47.2 yrs), with histological diagnosis of moderate to severe chronic, atrophic, body gastritis (according to the O.L.G.A. staging system) and PGI serum levels <25 µg/L, underwent upper gastrointestinal endoscopy with gastric biopsy samplings and PGI and G-17 measurement by means of Gastropanel[®]. 22 out of 62 patients had autoimmune gastritis while 40 of them reported previous H.p. infection. All patients, *Helicobacter pylori* negative at baseline, were treated with L-cysteine (100 mg three times daily), up to now 24 out of 62 reached 36 months-treatment. Serum PGI and G-17 were measured at baseline and after 3, 6, 12, 24, 36 months after starting therapy.

Results: The PGI showed an increased serum level after the starting of L-cysteine administration, as it follows: PGI mean value at baseline was 8.42 µg/l, but after 3 months therapy was 10.58, after 6 months 11.65, after 12 months 12.19, after 24 months 13.88, and after 36 months was 14.21 (p: 0.0001). The G-17 serum level resulted gradually decreased over the 36 months therapy, as it follows: G-17 mean value was 51.33 pmol/l at baseline, 43.13 after 3 months therapy, 38.66 after 6 months, 28, 34 after 24 months and 26.03 after 36 months (p: 0.0041).

Conclusion: After L-cysteine administration, patients with chronic, atrophic, body gastritis showed long-lasting improvements of physiological gastric function, reflected by a significant increase of PGI levels and a parallel decrease of G-17 serum levels over a 36 months follow-up period.

Introduction: Signaling pathway mediated by androgen receptor (AR) plays an important role in the development of gender-related tumors, such as hepatocellular carcinoma, prostate cancer. Gastric cancer (GC) is the third cause of cancer related death all over the world, and its incidence in male is also much higher than female. However, the molecular mechanisms of AR in gastric cancer are still poorly characterized.

Aims & Methods: To investigate the role of AR in gastric cancer, we identify the transcriptional downstream targets of AR by chromatin immunoprecipitation. We detected mRNA and protein expression level of AR and its target in paired GC samples and GC cell lines by RT-PCR and western blot. The biological functions of AR signaling pathway in GC cell lines were determined by colony formation and cell migration/invasion assay.

Results: CCRK was demonstrated as the direct target of AR by chromatin immunoprecipitation assay. AR expression was elevated in most (6/7) GC cell lines compared with the immortalized gastric cell line GES1. CCRK was up-regulated in all (7/7) tested GC cell lines. The correlation of AR and CCRK expression was statistically significant. Higher mRNA level of both AR and CCRK were detected in GC tissues compared with the adjacent normal tissues (P < 0.01). Ectopic re-expression of AR or CCRK by stable transfection promoted colony formation and invasiveness (P < 0.05). Consistently, the numbers

of colony formation, migrated cells and invasive cell were reduced by knockdown of AR or CCRK in GC cell lines (P < 0.01).

Conclusion: Our results demonstrate that AR directly regulates CCRK expression in GC. AR and CCRK gene may act as a potential oncogene in gastroduodenal carcinogenesis by playing an important role in promoting of cell proliferation, migration and invasion, which may partially explain the higher prevalence of gastric cancer among males.

P1243 FLYING OFF COURSE WITH A 2WW DIRECT ACCESS TO TEST PILOT: NOTTINGHAM'S EXPERIENCE OF THE SUSPECTED UPPER GASTRO-INTESTINAL CANCER PATHWAY CHANGE WITH GP VETTING AND OGD BOOKING

N. R. Lewis, J. Catton, E. James

Trent Oesophago-gastric Unit, Nottingham University Hospitals NHS Trust, Nottingham/United Kingdom

Contact E-mail Address: nina.lewis@nuh.nhs.uk

Introduction: Timely progress through diagnostic pathways is a leading quality measure for NHS cancer services. A hypothesis of sooner diagnosis being achievable with direct access to hospital tests from primary care is a core part of CRUK ACE program (1), and in the context of UGI cancer pathway, there is known wide variation of direct access (DA) OGD (2). This pilot evaluates the efficacy and utility of DA OGD or clinic (DA OPD) for GP concerns a patient may have OG cancer. Comparison was made with the standard 2WW pathway, where allocation to OGD v OPD first is performed by OG consultant.

Aims & Methods: Pilot and UGI standard 2WW referrals 01/01/16–01/08/16 were identified from Cancer Centre records.

Results: 192 patients were in the pilot pathway, 430 via the standard 2WW. GPs were more likely to allocate patients to DA OGD (52%) compared to 32% having DTT OGD allocated by the hospital. Despite under-utilisation of protected slots for DA OGD, time to DA OGD compared to DTT did not differ (11.0 days [95%CI 10.5,11.2] versus 12.4 days [95%CI 11.0,13.9]). The same was seen for DA OPD. The total time on pathway was not improved in the pilot group at 16.8 days [95%CI 4.9,28.6] compared to 17.9 days [95%CI 16.9, 18.9]. The subgroup of patients allocated in the pilot to DA OGD did have a quicker exit from the pathway, at 12.4 days [95%CI 6.5,18.3] compared to 14.8 days [95%CI 12.9,16.6] on the DTT OGD group. The pilot overall detected 8 cancers (4.2%); the standard 2WW path detected 55 (12.8%). OG cancers were in 4 of the DA OGD (4%) and 14 of the DTT OGD (10.2%). A further 10 non-OG cancers were detected in the DTT group after clinicians requested further investigations to determine the cause of their symptoms. Those patients allocated to OPD first by either GP or hospital were as likely to have cancer as those having OGD, with 4.3% of those in the pilot having a cancer detected this way, but none OG cancer, and 10.3% found to have cancers in the standard 2WW group following investigation directed after clinic visit. Of these 65% were cancers other than OG cancers and would not be detected on OGD alone.

Conclusion: OGD as a sole investigation for symptoms has its utility in excluding or detecting OG cancer. A high proportion of cancers detected via 2WW criteria on OG pathway are outside of OG tract and require other tests to diagnose them. In this pilot no additional utility of opening direct access OGD for GP concerned a patient may have an OG cancer was not demonstrated unless exclusion of OG cancer is viewed as the major purpose of the pathway. Our data demonstrates that such a view would be detrimental and lead to missed opportunity to detect other cancers that cause symptoms overlapping with those often ascribed to OG tumours.

P1244 WHAT IS THE YIELD OF ROUTINE D2 BIOPSIES IN THOSE PRESENTING WITH WEIGHT LOSS AT GASTROSCOPY?

M. Yalchin, S. Zonoozi, M. Hussein, N. Jayasooriya, K. Besherdas
Gastroenterology, Barnet Hospital, DJ/United Kingdom

Contact E-mail Address: m.yalchin@nhs.net

Introduction: Coeliac disease is a common cause of malabsorption in Western countries. The gold standard method of diagnosing coeliac disease is by way of duodenal biopsy. Weight loss is a symptom of malabsorption. Patients referred for upper gastrointestinal endoscopy with symptoms of a weight loss commonly undergo duodenal biopsy to assess for presence of coeliac disease. We hypothesise that those patients with weight loss and who routinely have duodenal biopsies very rarely have coeliac disease unless there are other pointers towards malabsorption.

Aims & Methods: A single-centre, retrospective analysis of consecutive patients undergoing upper gastrointestinal endoscopy for the sole indication of weight loss was undertaken within a large associate teaching hospital within North London from 2005–2016. Of these patients, we reviewed those that had duodenal (D2) biopsies and the results. If they proved abnormal, we looked back for additional markers of malabsorption, clinically and biochemically.

Results: 142 consecutive patients, 65 were Male, 77 were female, underwent OGD for weight loss. Out of this cohort, 62% (n=88) had a duodenal biopsy. 89% (n=78) of these had a normal biopsy. 11% (n=10) had an abnormal biopsy,

and 6 of these patients had coeliac, whilst 4 had other pathology such as granulomas or duodenitis.

For all the patients who had abnormal D2 biopsies, they had other clinical markers of malabsorption, such as abdominal pain and diarrhoea, or biochemical indices such as anaemia or elevated TTG antibodies.

Conclusion: From this study we conclude that the yield of routine duodenal biopsies in patients endoscoped for the sole indication of weight loss is poor. In patients with weight loss in whom coeliac disease is identified on biopsy is always associated with additional symptoms or abnormalities in blood indices. We conclude that there is no need to take biopsies of the duodenum on a routine basis for weight loss alone unless there are other signs of malabsorption. This will save time (both from taking the biopsy and sampling in the lab), lower the cost (forceps and pot) and improve the safety (potential perforation and bleeding risk) of the procedure.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1245 FUNDING DISPARITIES IN DIGESTIVE CANCER RESEARCH IN THE UNITED STATES

P. S. Liang¹, K. O'Connell², M. Du²

¹Medicine, New York University, New York/United States of America

²Memorial Sloan Kettering Cancer Center, New York/United States of America

Contact E-mail Address: petersliang@gmail.com

Introduction: In 2015, the five most common digestive cancers (colorectal, pancreatic, liver, gastric, and esophageal) accounted for 16% of incident cancer cases and 24% of all cancer deaths. It is unclear whether the amount and recent trends in US federal funding for digestive cancer research corresponds to the burden of disease.

Aims & Methods: We obtained the total annual funding for cancer (including the five most common digestive cancers) from 2008 to 2015 using a public database of research funded by US federal agencies. We calculated funding in 2015 constant USD using the Consumer Price Index. Cases and deaths estimated by the American Cancer Society were used to calculate funding per death or case for each cancer. For comparison, we also extracted data for the three most common cancers (breast, lung, prostate) and all cancers combined. As funding for research in the United States was boosted by the American Recovery & Reinvestment Act in 2009–2010 and declined thereafter, we analyzed trends in funding and disease burden from 2010–2015 using the Spearman correlation.

Results: In 2015, 8 billion USD in federal funding was issued to all cancer research and 658 million USD to the five common digestive cancers. The five digestive cancers accounted for 23–24% of all cancer deaths from 2010–2015, but only received 7% of cancer funding in 2010, and 8% of funding in 2015. The ratio of the proportion of all cancer death to the proportion of all cancer funding, a marker of funding disparity, was 2.9. In comparison, breast cancer accounted for 7% of cancer deaths in all years, 11% of funding in both 2010 and 2015, and had lower proportional death than proportional funding (ratio = 0.6). Prostate cancer likewise had lower proportional death than funding (ratio = 0.8). Funding disparity, measured by proportional death and funding, was highest for esophageal and gastric cancer among digestive cancers and for lung cancer overall. The estimated number of deaths and cases decreased for colorectal cancer but increased for the other digestive cancers during the study period. Funding per death among digestive cancers in 2015 was highest for liver cancer and lowest for esophageal cancer. Funding per death for breast cancer was more than 3-fold that of liver cancer and nearly 7-fold that of esophageal cancer. From 2010–2015, funding per death for digestive cancers decreased by 20% for esophageal cancer, 24% for colorectal and gastric cancer, and 28% for liver cancer; funding per death increased by 10% for pancreatic cancer. Statistically significant trends were observed for colorectal and liver cancer ($p < .05$ for both). Over the same period, funding per incident case decreased by 15% for esophageal cancer, 21% for colorectal cancer, 34% for gastric cancer, and 37% for liver cancer; funding increased for pancreatic cancer by 6%. Statistically significant trends were observed for liver ($p < .01$), colorectal, and gastric ($p < .05$) cancer. Despite the larger relative funding decrease for liver cancer, it remained the best-funded digestive cancer relative to both incident case and death. Liver cancer received more than 2.5-fold funding per incident case than colorectal and gastric cancer in 2015. Gastric cancer was the only digestive cancer to measure in the bottom two for both funding per death and per incident case.

Conclusion: From 2010 to 2015 in the US, federal research funding relative to the burden of disease has decreased for all digestive cancers except pancreatic cancer. Although a similar trend was observed for all cancer research, there appears to be a funding disparity for digestive cancers—especially gastric cancer—compared to breast cancer and all cancers combined. Greater investment and more equitable funding allocation may improve digestive cancer outcomes.

Introduction: *Helicobacter pylori* infection induces aberrant DNA methylation in gastric mucosa. We evaluated the long-term effect of *H. pylori* eradication on promotor CpG island hypermethylation in gastric carcinogenesis.

Aims & Methods: *H. pylori*-positive patients with gastric adenoma or early gastric cancer who underwent endoscopic resection were enrolled. According to *H. pylori* eradication after endoscopic resection, the participants were randomly assigned to *H. Pylori* eradication or non-eradication group. *H. pylori*-negative gastric mucosa from normal participants provided the normal control. CpG island hypermethylation of tumor-related genes (p16, CDH1, and RUNX-3) was evaluated by quantitative MethyLight assay in non-tumorous gastric mucosa. The gene methylation rate and median values of hypermethylation were compared after one year by *H. pylori* status.

Results: In *H. pylori*-positive patients, hypermethylation of p16 was found in 80.6%, of CDH1 in 80.6%, and of RUNX-3 in 48.4%. This is significantly higher than normal control (p16, 10%; CDH1, 44%; RUNX-3, 16%) ($p < 0.05$). In the *H. pylori* eradication group, methylation rates of p16 and CDH1 decreased in 58.1% and 61.3% of the patients, and the median values of hypermethylation were significantly lower at one year compared with the non-eradication group. However, RUNX-3 hypermethylation did not differ significantly at one year after *H. pylori* eradication. The non-eradication group hypermethylation did not change after one year.

Conclusion: *H. pylori* infection was associated with promotor hypermethylation of genes in gastric carcinogenesis, and *H. pylori* eradication might reverse p16 and CDH1 hypermethylation

Disclosure of Interest: All authors have declared no conflicts of interest.

P1247 CURCUMIN DOWNREGULATES INTERLEUKIN (IL)-17 BY INCREASING THE EXPRESSION OF INDOLEAMINE 2,3-DIOXYGENASE (IDO) IN HELICOBACTER PYLORI-INFECTED HUMAN GASTRIC MUCOSA

T. Larussa, R. Liparoti, S. Gervasi, E. Suraci, R. Marasco, M. Imeneo, F. Luzzza
Department Of Health Sciences, University of Catanzaro, Catanzaro/Italy

Contact E-mail Address: tiziana.larussa@gmail.com

Introduction: IDO promotes the effector T-cells apoptosis by catalyzing the rate-limiting first step in tryptophan (Trp) catabolism. We demonstrated that the high expression of IDO in *H. pylori*-infected human gastric mucosa attenuates Th1 and Th17 immune responses. The anti-inflammatory and anti-microbial properties of the nutraceutical compound curcumin suggest its use as an anti-*H. pylori* agent, but mechanisms that underlie its helpful activity are still not clear.

Aims & Methods: Five antral biopsies were taken from 22 patients (10 M, median age 47.5 yrs, range 20–74) who underwent gastroscopy for dyspeptic symptoms: 1 for urease quick test (Eurospital, Trieste, Italy), 2 for histology (Giemsa staining for *H. pylori*), and 2 for organ culture. ¹³C-urea breath test was also performed (at least two tests positive and all the three tests negative to be considered *H. pylori*-infected or uninfected). Biopsy samples were immediately placed in an organ culture chamber, treated with and without curcumin 200 μM (Sigma, St. Louis, MO, USA) for 20 hours and evaluated for the expression of IDO and IL-17 by Western blotting. Levels of IL-17 were also measured in culture supernatant by ELISA. Further antral biopsies from a subgroup of 14 patients were treated with curcumin in addition with the IDO inhibitor 1-methyl-L-Trp (1-MT, Sigma, St. Louis, MO, USA) and the expression of IL-17 was assessed in total protein extracts by Western blotting. The ratio of IDO and IL-17 with β-actin was calculated by densitometry, while results from ELISA were normalized on protein content. Values were given as means ± SD arbitrary units (a.u.) and pg/mL, respectively. Data were analysed using the Mann-Whitney U test.

Results: In gastric biopsies cultures from *H. pylori*-infected patients ($n = 13$), IDO significantly increased in curcumin-treated compared with untreated samples (1.26 ± 0.64 a.u. vs 0.87 ± 0.61 , $p = 0.02$). Levels of IL-17 were significantly lower in curcumin-treated compared with untreated samples, both in gastric biopsies (0.53 ± 0.26 a.u. vs 0.85 ± 0.31 a.u., $p = 0.02$) and culture supernatant (22.91 ± 13.72 pg/mL vs 40.46 ± 21.69 pg/mL, $p = 0.04$). In the subgroup of *H. pylori*-infected patients ($n = 9$), samples treated with curcumin in addition to IDO inhibitor 1-MT, IL-17 expression was significantly higher compared with untreated samples as well as with those treated with curcumin alone (1.44 ± 0.52 a.u. vs 0.91 ± 0.34 a.u. and vs 0.78 ± 0.21 a.u., $p = 0.04$ and $p = 0.01$, respectively). Both IDO and IL-17 expression were very low in untreated *H. pylori*-uninfected samples and did not significantly change when treated with curcumin alone or in addition to IDO inhibitor 1-MT.

Conclusion: Curcumin is capable of down-regulating IL-17 production in *H. pylori*-infected human gastric mucosa. This effect is, at least in part, mediated by increasing IDO expression. This endorses the potential role of curcumin in dampening *H. pylori*-induced immune-mediated inflammatory changes.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Alterations in salivary microbiota have been linked to elevated inflammatory responses and has been reported in patients with inflammatory bowel disease and pancreatic cancer. As yet, the potential association between salivary microbiota and patients with gastric pathology has not been determined.

Aims & Methods: In this study, we characterized the salivary microbiota in patients with *H. pylori* (HP)-associated gastritis and the potential changes of salivary microbiota after receiving HP eradication. We enrolled subjects who were scheduled for diagnostic upper GI endoscopy. We excluded patients with peptic ulcer or cancer found on endoscopy, who have received prior HP eradication therapy, and who have recent exposure to antibiotics or acid suppressive therapies. Unstimulated saliva samples were obtained from subjects during fasting state prior to endoscopy. During endoscopy, gastric biopsies were obtained for determination of HP statuses by rapid urease test and histology. Another gastric biopsy was obtained for characterization of gastric microbiota. Serial salivary samples were obtained from HP-infected subjects 8-week after completing HP eradication therapy. Bacterial DNA was extracted for 16s rRNA sequencing by using the MiSeq Platform (Illumina). OTU clustering was performed and taxonomy assigned to the Greengene and HOMD database. Alpha and beta diversity were determined. Linear Discriminant Analysis Effect Size (LEfSe) was used to identify differentially expressed bacterial DNA in different groups.

Results: We enrolled 16 subjects with confirmed HP-gastritis and 14 HP-negative subjects. Baseline salivary samples of all subjects were found to have significantly higher microbial diversity than corresponding gastric samples. The predominant microbial family identified in the stomach is *Helicobacteraceae* (55.2%) whereas *Helicobacteraceae* constitutes only 0.1% of salivary microbiota. In contrast, the predominant families in saliva microbiota are *Prevotellaceae* (23.9%) and *Neisseriaceae* (20.3%). When compared to HP-negative subjects, salivary microbiota in HP-positive patients showed a significant increase in the *Bacteroidetes* and *Spirochaetaceae*, and a decrease in *Flavobacteriaceae* families. HP eradication therapy resulted in a significant reduction in the relative abundance of families *Bacteroidetes* and *Spirochaetaceae*, and an increase in *Flavobacteriaceae*.

Conclusion: There was a significant difference in the microbial diversity and compositions between gastric and salivary microbiota in HP-infected subjects, with *Helicobacteraceae* dominating the gastric microbiota. HP-infected subjects have distinctive microbiota in the saliva which is reversed by HP eradication therapy. The significance of these microbial alterations in the saliva of HP-infected subjects and its correlation with gastric diseases deserves further investigation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Seroconversion of *Helicobacter pylori* occurs more often in seronegative adults living with a *H. pylori*-infected family member or in those with a history of upper gastrointestinal endoscopy. Nonetheless, there are controversies on alcohol drinking and seroconversion; a positive correlation was found in Korea, but an inverse correlation was found in Japan.

Aims & Methods: In this study, we tried to elucidate the risk factors for seroconversion including alcohol drinking. Korean adults who showed negative finding on the serum anti-*H. pylori* IgG assay were analyzed. Subjects were included if they underwent serum anti-*H. pylori* IgG assay, serum pepsinogen assay, and upper gastrointestinal endoscopy annually at our center. Subjects were excluded if they had a history of *H. pylori* eradication or gastrectomy.

Results: Of the 267 included subjects, 26 (9.7%) showed seropositive findings at the mean follow-up of 39.0 ± 19.1 months. Subjects with seroconversion showed a higher body mass index (p = 0.033), heavier alcohol drinking (p = 0.001), more intake of nonsteroidal anti-inflammatory drug (p = 0.015), and longer follow-up period (p = 0.038). On multivariate analysis, heavy alcohol drinking [odds ratio (OR) = 6.867, 95% confidence interval (CI) = 2.089–22.577, p = 0.002] and social drinking (OR = 5.026, 95% CI = 1.410–17.913, p = 0.013) were independent risk factors for seroconversion.

Conclusion: In Korean adults, the amount of alcohol drinking positively correlates with seroconversion in *H. pylori*-seronegative subjects. Although seroconversion does not indicate an active *H. pylori* infection, our study findings suggests that drinking is a significant risk factor for new *H. pylori* infection in Korean adults.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Autoimmune gastritis (AIG) results in hypo/achlorhydria due to parietal cells destruction¹. It is characterized by lower levels of serum pepsinogen (Pg) I and PgI/PgII ratio and increased levels of gastrin². Some Authors support an association between AIG and *Helicobacter pylori* (HP) infection³.

Aims & Methods: The aim of our study was to assess epidemiologic, serologic and pathologic features of AIG patients with and without previous HP infection. Two hundred and eleven consecutive patients with AIG, undergoing endoscopy were included. Serum gastrin, PgI, PgII and Cromogranin A levels were determined in all patients. Multiple gastric biopsies were obtained for histology, OLGA staging and HP detection. Previous or current HP infection (HP+) was confirmed in patients by anamnestic and/or pathologic and/or serologic data. Statistics was performed using non parametric tests.

Results: Present or previous HP infection was confirmed in 50/211 patients while 161 were negative (HP-). When we compared HP+ vs HP- AIG, no differences were found for age and gender distribution, antral and fundic/body atrophy, OLGA staging, PgI, PgII, PgI/PgII ratio and Cromogranin A levels. Gastrin levels and Gastrin/PgI ratio, a global marker of gastric damage we previously identified, were higher in HP- vs HP+ (p < 0.02). Interestingly, 15% HP- presented antrum atrophy. Severity of ECL hyperplasia was higher in HP- (p = 0.02) with a 3.5 RR of developing nodular or carcinoid lesions when compared with HP+. Serum PgI, PgII PgI/PgII and gastrin levels correlated with disease severity in HP- (p < 0.01) but not in HP+.

Conclusion: HP+ AIG have/have had a mild infection without differences in OLGA staging when compared with HP-. HP+ are characterized by lower gastrin and gastrin/PgI levels that, considered the lack of differences in OLGA staging, seem to suggest an impairment of gastrin release and could have a selective G Cell damage leading to lower levels of gastrin and Gastrin/PgI ratio. Consequently, they have lower degrees of ECL hyperplasia and a lower risk of developing carcinoids when compared with HP-. The presence of antrum atrophy in HP- could be explained with the supposed autoimmune antrum-damage hypothesis in AIG⁴⁻⁵. In conclusion, HP+ and HP- AIG have some differences in serological phenotype and HP infection may correlate in AIG with lower ECL hyperplasia and lower risk of neuroendocrine tumor.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: This study was conducted to determine the differential expression patterns of microRNAs, non-coding RNAs that control gene expression mainly through translational repression, in gastric mucosa of *Helicobacter pylori* (*H.pylori*) positive patients. Several miRNA have been associated with promoting the inflammatory response initiated by the *H. pylori* infection, increasing the malignant progression of the gastric epithelium, and enhancing the invasiveness and migratory capacity of cancer cells. Using serum specimens, expression patterns of hsa-miR-155, hsa-miR-21, hsa-miR-146-a and hsa-miR-223 were determined by Real-Time Polymerase Chain Reaction (Real-Time PCR).

Aims & Methods: Patients who underwent upper gastrointestinal endoscopy, in Mersin University Faculty of Medicine, Department of Gastroenterology and diagnosed *H.pylori* positive and negative were recruited. *H. pylori* status was assessed by the rapid urease test. Serum specimens of patients, were taken for miRNA isolation. hsa-miR-155, hsa-miR-21, hsa-miR-146-a and hsa-miR-223 expression levels were determined using comparative 2^{-ΔΔCT} analysis by using Real-Time PCR Systems, SDS 2.0.3 software programme. Statistical analysis of miRNAs between *H.pylori* positive and negative groups were compared with the Mann-Whitney U test. $p < 0.05$ was considered statistically significant. The relationship between categorical variables were tested using Pearson's chi-square test.

Table 1

	H.pylori positive N = 46		H.pylori negative N = 49		p value
	Average	Median	Average	Median	
hsa_miR_155	0,990199 ± 2,006536	0,393990	0,749915 ± 1,276566	0,295334	0,48
hsa_miR_223	6,929772 ± 19,222485	2,031475	7,064999 ± 18,103347	2,108900	0,97
hsa_miR_146a	4,730933 ± 8,343877	2,138397	9,332742 ± 28,023032	1,447617	0,28
hsa_miR_21	4,412535 ± 5,519648	2,030767	4,669136 ± 8,019229	1,858662	0,85

Results: *H.pylori* positive (n = 46) and negative (n = 49) were included. *H.pylori* was not able to effective the hsa-miR-155, hsa-miR-21, hsa-miR-146-a and hsa-miR-223 expressions in serum specimens and nuclear factor-κB (NF-κB) and Transforming growth factor, beta (TGFB) pathways. There was no statistically difference between *H. pylori* positive and negative individuals in the analysis of hsa-miR-155, hsa-miR-21, hsa-miR-146-a and hsa-miR-223 miRNA expressions levels (Table 1). In surveys, there is no statistically difference between in each groups, the level of education, intake of smoking-alcohol, hypertension, diabetes, cardiovascular disease, family history of gastroduodenal disease, type of gastroduodenal disease.

Conclusion: This study may contribute to the literature in terms of preventing pro-cancerous progression in the cases of cancer resulting from *H. pylori* infection before the onset of the cancer process.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1252 INTERLEUKIN LEVEL IN PATIENTS INFECTED WITH CAGA(+) AND CAGA(–) STRAINS OF *HELICOBACTER PYLORI*

N.V. Baryshnikova¹, Y.P. Uspenskiy², A. Suvorov¹

¹Science Research Institute, St-Petersburg/Russian Federation

²First Pavlov Saint-Petersburg State University, St-Petersburg/Russian Federation

Contact E-mail Address: baryshnikova_nv@mail.ru

Introduction: Change of interleukin level can be in patients with of chronic infections, in particular at *Helicobacter pylori* invasion. Change of interleukin level in *H. pylori*-infected patients is intensively studied. For example, increase in level of interleukin-8 according to a number of works is accompanied by infection with virulent strains of a microorganism. CagA gene coding synthesis of the cytotoxin (CagA) of the same name capable, in addition, to exert impact on development of interleukin, in particular interleukin-8 is considered a marker of presence of pathogenicity island of *H. pylori*.

Aims & Methods: The aim was to define features of change of level of interleukin-1β and interleukin-8 (pro-inflammatory) and interleukin-4 (anti-inflammatory) at patients with the chronic gastritis associated with *H. pylori* infection depending on existence or lack of a gene of cagA in a microorganism genome. 40 patients with the chronic gastritis associated with *H. pylori* have been examined. Endoscopy was made for all patient for specification of a condition of stomach mucosa and taking biopsy from stomach antrum (2 biotates) for the purpose of verification of *H. pylori* infection. Detection of a microorganism was made by rapid urease test, a histologic method and molecular-genetic research—the polymerase chain reaction (PCR) with definition of genes of urease (ureC, ureI). Besides, the PSR method presence of a cagA gene in a genome of *H. pylori* was detected. All patients were divided on two groups: with cagA (+) strains and with cagA (–) strains. Levels of interleukins 1-β, -4, -8 decided by immunofluorescent analysis (the Vektor-Best sets, Russia).

Results: cagA gene was detected in 30 patients (cagA(+) group) and absence in 10 patients (cagA(–) group). In cagA(+) patients mean level of interleukin-1-β was 395.6 pg/ml, but in cagA(–) patients—311.2 pg/ml ($p < 0.05$). Level of interleukin-8 in cagA(+) patients was 2.4 pg/ml but in cagA(–) patients—0.32 pg/ml ($p < 0.05$). Level of interleukin-4 y cagA(+) patients was 21.6 pg/ml, but in cagA(–) patients—83.4 pg/ml ($p < 0.05$).

Conclusion: presence in a genome of *H. pylori* cagA gene is accompanied by reliable increase in level of pro-inflammatory interleukins (1-β, 8) and decrease in level anti-inflammatory interleukin-4 that can be an additional factor of development of an inflammation during *H. pylori* invasion.

Introduction: The incidence and mortality rate of gastric cancer are high in Japan. The International Agency for Research of Cancer (IARC) reported that 80% of gastric cancer is caused by *Helicobacter pylori* (*H. pylori*) infection and that the incidence of gastric cancer can be reduced by 30%–40% through *H. pylori* eradication. *H. pylori* eradication therapy for chronic gastritis was approved for national health insurance in February 2013 in Japan. However, the success rate of *H. pylori* eradication by conventional primary triple therapy has been decreased by resistance to clarithromycin. Vonoprazan, which is a potassium ion-competitive acid blocker (P-CAB), became available in Japan in February 2015, before its release on the world market. There have been some reports on the usefulness of vonoprazan for *H. pylori* eradication.

Aims & Methods: The aim of this study was to investigate the transition of *H. pylori* eradication therapy including therapy with vonoprazan in our institution. This study was a retrospective single center study between January 2010 and December 2016. The subjects were patients who had received *H. pylori* eradication therapy. The subjects were divided into a conventional triple therapy group (PPI: omeprazole lansoprazole, esomeprazole, and rabeprazole) and a group who received triple therapy with vonoprazan instead of a PPI. Regimens with amoxicillin, clarithromycin and a PPI or vonoprazan were regarded as 1st line treatment, and a regimen with metronidazole instead of clarithromycin was regarded as 2nd line treatment. Success rates of 1st line treatment and 2nd line treatment with a PPI or vonoprazan were compared.

Results: There were 1278 patients who underwent *H.pylori* eradication therapy. The mean age of the patients was 61.5 years (13–92), and the patients included 722 males and 556 females. The patients who received *H.pylori* eradication therapy included 857 patients with chronic gastritis, 300 patients with stomach/duodenal ulcers, 82 patients with gastric cancer, 27 patients with polyps, and 12 other patients. The number of patients with chronic gastritis undergoing

eradication therapy of *H. pylori* increased remarkably from 48.4% in 2012 to 73.8% in 2016. The total success rate was 76.5%. The success rate of the conventional PPI regimen was 75.8% (846/1116), and that of the vonoprazan regimen was 85.1% (74/87). The success rate of vonoprazan regimen was significantly higher than that of the PPI regimen (Fisher's exact test: $p < 0.05$). The success rate of *H. pylori* eradication in 2nd line treatment was 84.7% (210/248). The success rate of *H. pylori* eradication in patients who received the conventional PPI regimen was 84.4% (35/224), and that in patients who received the vonoprazan regimen was 87.5% (21/24).

Conclusion: Vonoprazan is considered to be useful for *H. pylori* eradication instead of a PPI in first line treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Clarithromycin (CLA)-containing quadruple therapy, i.e. concomitant therapy (CT), and bismuth-containing quadruple therapy (BQT) have been suggested as first line therapies for eradication of *H. pylori* infection. Both treatments are reported to have an eradication rate higher than 90%. International guidelines recommend that choosing one regimen vs the other should be based on the regional prevalence of antimicrobial resistance, knowledge of patient's previous antimicrobial exposure or allergy to amoxicillin, and patient's wish. However, this therapeutic approach has never been tested systematically.

Aims & Methods: The primary endpoint of this study was to evaluate the eradication rate in *H. pylori*-infected subjects naive to treatment in an area of high (>15%) CLA resistance using CT or BQT, based on knowledge of patient's previous antimicrobial exposure or allergy to amoxicillin, and patient's wish. Secondary endpoint was to assess any difference between CT and BQT in terms of efficacy, safety and compliance. Because in Italy bismuth compounds are not available, BQT was by using the new three-in-one pill (TiOP) (metronidazole 125 mg + tetracycline 125 mg + bismuth 140 mg). **Patients and Methods:** 1) Observational study on 144 consecutive dyspeptic patients (57 M and 87 F, median age 51 yrs); 2) Diagnosis of *H. pylori* infection was through ¹³C Urea Breath Test (UBT), or rapid urease test and histology in patients who performed endoscopy; 3) Groups of treatment: a) 84 CT (36 M and 48 F, median age 52 yrs) and 60 BQT (21 M and 39 F, median age 50 yrs) patients; 4) Regimens: a) CT: esomeprazole 40 mg bid + amoxicillin 1 g bid + clarithromycin 500 mg bid + tinidazole 500 mg bid; b) BQT: esomeprazole 40 mg bid + TiOP 3 tablets qid. Both for 10 days; 5) Evaluation of eradication was performed at least 45 days after the end of therapy by UBT; 6) Compliance to and side effects of both regimens were assessed by a questionnaire at the end of therapy; 6) Statistics: ITT and PP analyses; significance of differences by chi square test ($p < 0.05$).

Results: 1) Eleven/144 patients (7.6%, 95%CI 4.3–13.5) [6/84 (7.1%, 95%CI 3.3–15.4) in the CT group and 5/60 (8.3%, 95%CI 3.6–19.3) in the BQT group] discontinued therapy because of severe side effects (p : ns); 2) Overall eradication rate was 122/133 (91.7%, 95%CI 87.2–96.5) in the PP analysis and 122/144 (84.7%, 95%CI 79–90.1) in the ITT analysis; 3) PP eradication rate was 69/78 (88.5%, 95%CI 81.6–95.8) in the CT group and 53/55 (96.4%, 95%CI 91.6–101.4) in the BQT group (p : ns); 4) ITT eradication rate was 69/84 (82.1%, 95%CI 74.3–90.8) in the CT group and 53/60 (88.3%, 95%CI 80.6–96.8) in the BQT group (p : ns); 4) Among patients who completed therapy, no significant differences between the two groups were found as to the incidence of side effects (29.4% in the CT group and 35.8% in the BQT group) or compliance to treatment.

Conclusion: 1) In an area of high CLA resistance, use of CT or BQT as first-line therapy, based on patient's previous antimicrobial exposure, allergy to amoxicillin and wish, is a highly effective strategy with an eradication rate > 90%; 2) BQT was more effective but with more side effects compared to CT, however differences were not statistically significant.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1255 CYP3A5 GENOTYPE STATUS AFFECTS OUTCOME OF FIRST-LINE VONOPRAZAN-CONTAINED *HELICOBACTER PYLORI* ERADICATION THERAPY

Introduction: Potent acid inhibition with acid inhibitory drugs is crucial to the success of eradication for *Helicobacter pylori* infection. Vonoprazan competitively inhibits the binding of potassium ion to H⁺/K⁺-ATPase in gastric parietal cells and inhibits H⁺/K⁺-ATPase activity at 400-fold more potent than that of lansoprazole, proton pump inhibitor (PPI). Therefore, the eradication regimen contained vonoprazan has advantage for increasing the eradication rate compared with a PPI-based therapy. Although vonoprazan is mainly metabolized by CYP3A4/5, it is unclear whether its acid inhibitory effect and outcome of *H. pylori* eradication differ among CYP3A4/5 genotypes. Our aim was to clarify the influence of CYP3A4/5 genotypes on outcome of *H. pylori* eradication including vonoprazan in Japanese.

Aims & Methods: We investigated the influence of CYP3A4/5 and CYP2C19 genotypes and susceptibility to antimicrobial agents for outcome of vonoprazan-contained eradication regimen for 7 days in 105 Japanese: (1) with amoxicillin 750 mg and clarithromycin 20 mg twice daily (bid) as the first-line treatment ($n = 76$); (2) with amoxicillin 750 mg and metronidazole 250 mg bid as the second-line ($n = 29$). Eradication status was assessed at eight weeks via a ¹³C-urea breath test. CYP3A4*22, CYP3A5*3 and CYP2C19*2/*3 were genotyped for all patients.

Results: Eradication rate on intention-to-treat analysis was 82.9% (95% confidence interval: 72.5%–90.6%, 63/76) in the first-line treatment and 93.1% (77.2%–99.1%, 27/29) in the second-line. None with CYP3A4*22 was observed. 38.3% of patients (46/120) were CYP3A5 *1/*3 type and 55.0% were *3/*3 type. In naive patients, the prevalence of clarithromycin-resistant strain was 42.4% (14/33). Eradication rate in patients with CYP3A5 *1 carrier type (CYP3A5 *1/*1 and *1/*3 types) was 72.7% (54.5%–86.7%, 24/33), which was significantly lower than that in the *3/*3-type (90.7%, 77.9%–97.4%, 39/43, $p = 0.039$) in the first-line treatment. However, no significant differences of clinical outcome in the second-line therapy were seen among CYP3A4/5 genotypes.

Conclusion: Eradication rates of vonoprazan-based eradication therapy can be achieved high compared with PPI-based therapy. However, because CYP3A5*3 genotype may be one of determinate for outcome of eradication regimen including vonoprazan, genotyping of CYP3A5*3 will be required to be paid attention for clinical outcome before treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1256 COMPARISON OF *HELICOBACTER PYLORI* ERADICATION RATES: VONOPRAZAN VS. PROTON PUMP INHIBITOR

N. Kozawa, T. Mochida, A. Igarashi, C. Kamitsuma, J. Tsuchiya, M. Ike, K. Yasuda, M. Kaneshiro, H. Ikemiyagi, Y. Fukami, K. Yoshino, S. Sakita
 Gastroenterology, Yokohama-city Red Cross Hospital, Yokohama/Japan

Introduction: Proton pump inhibitor (PPI) based therapy is one of most popular *H. pylori* eradication in the world. On the other hand, eradication rates have been decreasing because of resistance to the clarithromycin (CAM). It is known that most antibiotics are not effective under strong acid secretion. So in order to improve the eradication rate, gastric acid must be reduced more rapidly and strongly. Vonoprazan (VPZ) is a new potassium competitive acid blocker and the usefulness is expected in Japan.

Aims & Methods: Our aim was to investigate the efficacy of the VPZ-based eradication therapy. The subjects were 999 patients who were diagnosed as *H. pylori* infection in our institution from June 2014 to December 2016. The patients were grouped into three: VPZ group and conventional PPI (Lansoprazole or Rabeprazole) group. We evaluated the first-, the second-line eradication rate and statistical analysis. Each regimen of VPZ group was first-line eradication (VPZ 20 mg bid+ amoxicillin 750 mg bid+ CAM 200 mg bid for 7 days), second-line eradication (VPZ 20 mg bid+ amoxicillin (AMPC) 750 mg bid+ Metronidazole 250 mg bid for 7 days). Each regimen of PPI group was first-line eradication (PPI bid+ AMPC 750 mg bid+ CAM 200 mg bid for 7 days), second-line eradication (PPI bid+ amoxicillin 750 mg bid+ Metronidazole 250 mg bid for 7 days). One of the following PPI was used: Lansoprazole (LPZ) 30 mg, Rabeprazole (RPZ) 20 mg. After several months, eradication status was examined by urea breath test, stool antigen testing and blood antibody test.

Results: The number of first-line regimen of VPZ patients was 109, and the eradication was achieved in 97 patients (87%). RPZ patients were 308, and the eradication was achieved in 228 patients (74%), and LPZ patients were 377, and the eradication was achieved in 300 patients (80%) respectively. The eradication rate of VPZ was statistically higher than RPZ and LPZ ($P = 0.0006$, and $= 0.019$ respectively). The number of second-line regimen of VPZ patients was 24, and the eradication was achieved in 19 patients (79%). RPZ patients were 68, and the eradication was achieved in 60 patients (88.2%), and LPZ patients were 68, and the eradication was achieved in 60 patients (88.2%) respectively. There were statically no significant differences in second-line regimens. Adverse events

such as eruption and diarrhea were reported in 6.6%(9/136) of patients in VPZ, in 15.5%(58/375) in RPZ and in 6.1%(28/456) in LPZ.

Conclusion: The first-line regimen with VPZ was superior to conventional PPI regimen, and was a result not to be inferior in the safety either.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1257 CAN TWO WEEK BISMUTH BASED QUADRUPLE THERAPY FOR RESISTANT *H. PYLORI* INFECTION STILL BE USED IN THE UK?

H. Logan-Ellis, L. Bensaid, R. P.H. Logan

Gastroenterology, King's College Hospital, London/United Kingdom

Contact E-mail Address: hughloganellis@nhs.net

Introduction: Eradication of *H. pylori* infection cures peptic ulcer disease (PUD); however, current treatment strategies are far from ideal and many patients require repeated courses of treatment. We, and others, have recently documented that currently, within the UK, less than 30% of patients with proven PUD, are subsequently documented to have been cured by *H. pylori* eradication⁽¹⁾. Currently there is no consensus regarding 2nd line treatments, but the British National Formulary recommends a two regimen containing bismuth subcitrate, omeprazole, tetracycline and metronidazole. However since 2016, bismuth subcitrate has not been available in the UK, but is thought to be an important in treating persistent *H. pylori* infection⁽²⁾.

Aims & Methods: The aim of this observational cohort study was to evaluate the effectiveness of a 2 week bismuth based quadruple therapy in patients who had persistent infection following previous failed eradication therapy. Patients were identified from electronic hospital records using endoscopy data set, patient administration records, and pathology data sets from Jan 2011 to Dec 2016. Initial failed *H. pylori* eradication was defined by either by a positive ¹³C-Urea Breat Test (¹³C-UBT) or positive HpStool Antigen test (HpSA) following *H. pylori* treatment in either primary or secondary care. All patients were seen, assessed and warned about the importance of compliance with treatment and of possible side effects by the specialist (RL) or the dyspepsia nurse specialist (LB). After treatment with omeprazole 20 mg bd, tetracycline 500 mg qds, metronidazole 400 mg qds and bismuth subcitrate qds for two weeks, eradication was assessed at least 4 weeks after finishing treatment by ¹³C-UBT (or HpSA in those patients unable to attend hospital appointment). Endoscopy was also performed in those patients whom had failed multiple previous treatments to ascertain the clinical need for further treatment by assessing any underlying ulcer diathesis and for *H. pylori* culture and sensitivity testing.

Results: Within the inclusion period, (and from >560 patient records), 41 patients (22 female), mean age 44 yr, (range 17–84 yr) were identified as having persistent *H. pylori* infection by +ve ¹³C-UBT (n=25), HpSA (n=10) or histology/CLOtest (n=6). All had failed at least one treatment, but 14/41 (34%) had failed 2 or more. Most patients were non or light drinkers (90%) and non-smokers (74%). OGD was performed in 19 patients to clarify indication for further attempts at *H. pylori* eradication and showed evidence of ulcer disease (ulcer, scarring or erosions) in 13/19 (68%). Culture and antibiotic sensitivity testing was unsuccessful in 5/5 patients. At least 6 weeks after the end of treatment a repeat ¹³C-UBT or HpSA was negative in 34/36 (94% (95%CI 82–98%). 5 patients failed to attend for assessment of eradication. During the follow up period from 2011 onwards, 11 patients underwent repeat ¹³C-UBT or HpSA testing, and all remained cured of infection.

Conclusion: Two week standard bismuth based quadruple therapy remains a highly effective treatment for persistent *H. pylori* infection in those patients in whom eradication of infection is mandated by the an underlying ulcer diathesis. The high eradication rate is likely due to the use of bismuth/high doses of antibiotics, but also by specialists ensuring patients complied with their medication. These data, together with the poor outcomes of *H. pylori* eradication when undertaken by general physicians, also highlight the need for *H. pylori* eradication to be only undertaken by specialists who have access to alternative sources of colloidal bismuth subcitrate.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1258 MAY PROBIOTICS MONOTHERAPY ERADICATE *HELICOBACTER PYLORI*? A SYSTEMATIC REVIEW WITH POOLED-DATA ANALYSIS

G. Losurdo, R. Cubisino, M. Barone, M. Principi, E. Ierardi, A. Di Leo

Emergency And Organ Transplantation, University of Bari, Bari/Italy

Contact E-mail Address: giuseppelos@alice.it

Introduction: Despite several evidences in literature have demonstrated a role for probiotics as adjunctive treatment for *Helicobacter pylori* (*H. pylori*) eradication, national and international guidelines as well as meta-analyses suggest that only co-administration of probiotics may have a beneficial effect on the prevention of side effects and eradication rates. Herein, we performed a systematic review with pooled-data analysis aimed to clarify whether probiotics alone may eradicate the bacterium.

Aims & Methods: Methods of analysis and inclusion criteria were based on PRISMA recommendations. Relevant publications were identified by a research in PubMed, MEDLINE, Science Direct and EMBASE. The end-point was to estimate the mean eradication rate and variations of delta value at urea breath test across all studies and, overall, with a pooled data analysis. The data have been expressed as proportions/percentages, and 95% confidence intervals (CI) were calculated. For continuous variables, we calculated the weighted mean difference. Odd ratios (OR) were calculated, where available, based on the Mantel-Haenszel method. Data were entered into the RevMan 5.3 software.

Results: Ten studies (both randomized clinical trials and open label pilot studies) were selected. In one study patients with peptic ulcers were selected, while in the remaining 9 only dyspeptic patients were recruited. Probiotics eradicated *H. pylori* in 50 out of 391 cases. The mean weighted eradication rate was 14%, with a 95% CI of 2–25% (p=0.02). Most of studies investigated a probiotic formulation based on a single lactobacilli strain. Lactobacilli eradicated the bacterium in 30 out of 235 patients, with a mean weighted rate of 16% (95% CI 1–31%). Multistrain combinations were effective in 14 out of 105 patients, with a pooled eradication rate of 14% (95% CI –16–43%). In the comparison probiotics versus placebo, we found an OR = 9.65 in favor of probiotics, with a 95% CI of 1.97–47.36 (p=0.005). Finally, probiotics induced a mean reduction in delta values of 8.61‰ (95% 5.88–11.34, p < 0.00001). No study provided data about adverse events.

Conclusion: Probiotics alone show a minimal effect on the eradication of *H. pylori*, thus suggesting a presumable direct effect. However, they cannot be indicated as a therapeutic regimen for the low eradication rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The new bismuth-containing quadruple therapy is currently advised due to emergence of *H. pylori* strains resistant to several antibiotics. Our aims was to assess the real-life effectiveness and safety of this therapeutic regimen in a large population of patients who were infected by *H. pylori*.

Aims & Methods: Consecutive dyspeptic *H. pylori*-positive patients were enrolled, both naïve for treatment and already unsuccessfully treated. Patients were treated with Pylera® (3-in-1 capsules containing bismuth subcitrate potassium 140 mg, metronidazole 125 mg and tetracycline 125 mg) 3 capsules four times a day plus omeprazole 20 mg or esomeprazole 40 mg two times a day for 10 days. Eradication was confirmed using a urea-breath test (at least 30 days after the end of treatment). Efficacy and safety were assessed.

Results: Three hundred and twenty patients were included in the study: 131 (40.9%) patients were naïve, and 189 (59.1%) patients with previous failure treatment. *H. pylori* eradication was achieved in 299 (93.4%, 95% confidence intervals (CIs) 83.1 to 1.0) patients. No difference in eradication rate was found either between naïve and previously treated patients (95.4% vs 92.1%, P = 0.336). Treatment-emergent adverse events occurred in 61 patients (19.1%, 95% CIs 14.6 to 24.549). They were mild in all cases except in ten, who discontinued the study due to diarrhea (four patients) and diffuse urticarial rash (6 patients).

Conclusion: This bismuth-containing quadruple therapy achieved a remarkable eradication rate in real life, irrespective as first treatment or as a salvage therapy, despite the frequent occurrence of mild adverse events.

P1260 COMPARISON OF CLARITHROMYCIN- AND LEVOFLOXACIN-CONTAINING TRIPLE THERAPIES FOR FIRST-LINE *HELICOBACTER PYLORI* ERADICATION IN IRAN

H. Fakheri¹, A. Sadoogh², S. Tirgar Fakheri²

¹Gut And Liver Research Center, Mazandaran University of Medical Sciences, Sari/Iran

²Mazandaran University of Medical Sciences, Sari/Iran

Contact E-mail Address: septirgar74@gmail.com

Introduction: According to the Maastricht IV consensus report, Clarithromycin-containing triple therapy can be considered as a suitable option for first-line *Helicobacter pylori* (*H. pylori*) eradication in areas with less than 20% resistance rates to Clarithromycin. On the other hand, resistance to Clarithromycin is increasing in Iran, influencing the efficacy of standard triple therapy in this country. Therefore, regimens containing other antibiotics have to be considered in Iran.

Aims & Methods: One hundred and forty patients with peptic ulcer disease and naive *H. pylori* infection were randomly divided into two groups to receive either 10-day standard triple therapy (Pantoprazole 40 mg, Amoxicillin 1 gr and Clarithromycin 500 mg, all given twice daily) or 10-day Levofloxacin-containing triple therapy (Pantoprazole 40 mg BD, Amoxicillin 1000 mg BD and Levofloxacin 500 mg/daily). Eight weeks after the treatment, *H. pylori* eradication was assessed by ¹⁴C-urea breath test.

Results: One hundred and thirty three patients completed the study. According to intention to treat analysis, *H. pylori* eradication rates were 75.7% (95% confidence interval (CI): 65.7%–85.7%) and 58.5% (95% CI = 47.1%–70%) in standard and Levofloxacin-containing therapies, respectively. Also, per-protocol eradication rates were 83% (95% CI: 74%–92%) and 61% (95% CI = 49%–73%), respectively. The rates of severe adverse effects of therapy were 7.1% and 2.9% in the mentioned groups, respectively.

Conclusion: Both Clarithromycin-containing triple therapy and Levofloxacin-containing triple regimen do not seem to be suitable options for first-line *H. pylori* eradication in Iran. We suggest using Clarithromycin in quadruple regimens such as hybrid or concomitant therapies and reserve Levofloxacin to be used in second-line eradication regimens, as it is recommended by Maastricht V Consensus Report.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1261 EFFICACY AND TOLERABILITY OF REBAMIPIDE IN TRIPLE THERAPY FOR ERADICATION OF *HELICOBACTER PYLORI*: A RANDOMIZED CLINICAL TRIAL

S. S. Vyalov

Gastroenterology, Peoples Friendship University of Russia, Moscow/Russian Federation

Contact E-mail Address: svialov@mail.ru

Introduction: Rebamipide is an orally prostaglandin E₂ and I₂ synthesis inductor. A latest clinical trial showed that the adhesion of *H. pylori* to stomach wall was reduced by rebamipide. This could improve eradication rates by increasing the availability of *Helicobacter* to antimicrobial.

Aims & Methods: We aimed to determine eradication rate, the effectiveness and advantage of rebamipide in triple eradication therapy of *H. pylori* infection. Subjects comprised patients undergoing eradication therapy for *H. pylori* infection in our clinics. Patients with a history of eradication therapy, gastrectomy, or allergy to medications in triple therapy were excluded. Written informed consent was obtained for each patient. This trial was performed as a randomised open-labelled clinical study with the permission of an institutional review board. All patients was tested on *H. pylori* infection. The number of cases was 160 (80 cases in each group). Each patient was randomly enrolled for rebamipide therapy group (RBD) (esomeprazole 40 mg, amoxicillin 1000 mg, clarithromycin 500 mg, rebamipide 100 mg twice a day for 14 days) or standart triple therapy group (STD) (esomeprazole 40 mg, amoxicillin 1000 mg, clarithromycin 500 mg, twice a day for 14 days). Before starting therapy, we checked the background characteristics of each patient (age; gender; weight; height; drinking habit; smoking habit; use of probiotics, bismuth, PPI; and endoscopic findings). After the therapy, we asked physicians and patients about medication compliance and side effects. The primary endpoint was the eradication rate. The secondary endpoints were the rates of side effects.

Results: For RBD therapy group and STD therapy group, the eradication rates were 94.0% (95% confidence interval, 85%-100%) and 82% (95% confidence interval, 74%-95%) respectively, and the rates of side effects were 8.5% (95% confidence interval, 7.0%-26.5%) and 29% (95% confidence interval, 17.5%-41.0%) respectively. For each group, statistically significant difference in eradication rate was seen. The RBD group revealed trends of high eradication rates and low rates of side effects.

Conclusion: The findings suggest that rebamipide is effective in eradication of *H. pylori* infection, significantly improve eradication rate in triple therapy. The advantage of rebamipide has efficacy and good tolerability.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Intestinal graft-versus-host disease (GVHD) represents one of the most serious complications of allogeneic stem cell transplantation (allo-SCT). Almost 10%-40% of patients who undergo allo-SCT develop significant clinical acute graft-versus-host disease (GVHD) [1]. Endoscopic and histological proofs are required because of the number of differential diagnoses manifesting as diarrhoea. Previous studies reported that endoscopic features, such as atrophied terminal ileum [2,3], are useful in diagnosing acute GVHD. However, these previous studies did not address details of the random sequence, and were performed in a single centre.

Aims & Methods: The present study investigated the incidence of the characteristic finding, particularly microvilli atrophy of the terminal ileum, of colonoscopy, and inter-observer agreement of the finding among experienced endoscopists in multiple centres. Consecutive patients who underwent allo-HSCT were referred to the Okayama University Graduate School of Medicine between May 2008 and September 2015. Fifty-four patients underwent colonoscopy after allo-SCT as intestinal acute GVHD was suspected. We recorded the colonoscopic imaging. Subsequently, they were checked by three observers, from different institutions, to determine whether microvilli atrophy in the terminal ileum is present. Demographic information, disease, symptoms, and histological finding were obtained from the patients' medical records retrospectively. All study participants provided informed consent. The local ethics review committee granted ethical approval (approval 1610-013), and was registered in the University Hospital Medical Network Clinical Trials Registry (UMIN-CTR) as number UMIN 000025390.

Results: Definitive pathological and non-pathological GVHD were found in 22 patients and 32 patients, respectively. In the analysis of all 54 lesions, for three observer (A, B, and C), sensitivity of the microvilli atrophy in the terminal ileum was 86.4%, 77.3%, and 79.2%, whereas specificity of the appearance were 62.5%, 62.5%, and 86.2%. In addition, the positive predictive value of the appearance was 61.3%, 58.6%, and 82.6%, and negative predictive value (NPV) was 87.2%, 87.2%, and 83.9%, respectively. The kappa coefficient of the inter-rater reliability was 0.85, 0.63, and 0.63 in observers AB, AC, and BC.

Conclusion: Conclusions: Microvilli atrophy in the terminal ileum is an effective colonoscopy finding for real-time predictive histological diagnosis of acute intestinal GVHD. We achieved substantial inter-observer agreement for the analysis of microvilli atrophy in the terminal ileum and excellent agreement for predictive histological diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Chemotherapy-induced mucositis is a common complication during anticancer treatment. Epigallocatechin-3-gallate (EGCG), derived from green tea, has been shown to have antioxidant effects and immunomodulatory activities. However, studies on EGCG for chemotherapy-induced mucositis have been scarce.

Aims & Methods: In this study, we aimed to prove the protective effect of EGCG in murine chemotherapy-induced mucositis model. Twenty-four 8-wk-old male C57BL/6 mice were randomized to 4 groups: control, EGCG, 5-Fluorouracil (5-FU), EGCG plus 5-FU. Mucositis was induced by intraperitoneal injection of 5-FU (400 mg/kg). EGCG (50 mg/kg) was administered orally for 5 days from the day before administration of 5-FU. After 6 days of 5-FU injection, the mice were sacrificed and intestinal tissue was obtained. WBC count was performed with whole blood from inferior vena cava of mice. The end points were villus height, villus/crypt ratio, histologic characteristics, and mRNA expression of tumor necrosis factor (*TNF*)- α , and interleukin (*IL*)-6.

Results: In 5-FU group, neutropenia was confirmed by laboratory test (5-FU, 0.650 K/ μ L; Control, 5.317 K/ μ L), indicating sufficient 5-FU effect. Histologic findings showed that crypt dilatation, villus stunting, and villus atrophy were reduced in EGCG plus 5-FU group than in 5-FU group (Figure 1). Quantitatively, mean villus height (EGCG plus 5-FU, 352 μ m; 5-FU, 319 μ m) and villus/crypt ratio (EGCG plus 5-FU, 3.28; 5-FU, 2.31) in EGCG plus 5-FU group, compared with 5-FU treated group, were significantly higher. mRNA expression of *TNF*- α was significantly lower in EGCG plus 5-FU group compared with 5-FU group ($P < 0.05$) (Figure 2). Figure 1. Effects of EGCG administration on chemotherapy-induced mucositis in mice jejunum (A) control (B) 5-Fluorouracil (5-FU) group with significant villus atrophy and crypt dilatation (C) EGCG group (D) EGCG plus 5-FU group with mild villi destruction and less crypt dilatation Figure 2. mRNA expression of *TNF*- α . 5-FU plus EGCG group showed significantly lower 2^{-ddCT} than 5-FU only group. (*, ** $P < 0.05$)

Conclusion: EGCG derived from green tea reduced 5-FU induced intestinal mucositis, suggesting a possibility for novel treatment of chemotherapy-induced mucositis.

Introduction: Proton pump inhibitors (PPIs) have become one of the most commonly prescribed medicine due to their strong effects of suppressing gastric acid and high curative effects for acid related diseases. On the other hand, their side effects have been attracting more attention. One of them is the increased incidence of infectious intestinal diseases. Those are mostly reported by clinical publications, and the exact mechanism has not been clarified. To investigate whether PPIs can increase the susceptibility to peroral enteropathogenic bacterial infection, we used *Citrobacter rodentium* (*C. rodentium*), a well-known attaching/effacing-associated pathogen, which is used for the model of human enterohemorrhagic *Escherichia coli* (EHEC) and enteropathogenic *Escherichia coli* (EPEC) infection: the major causes of food poisoning.

Aims & Methods: To investigate whether LAZ can influence the steady-state intestinal environment, C57BL/6J mice were divided into two groups, and 8 mg/kg/day of lansoprazole (LAZ group) or saline (control group) were administered intraperitoneally for two weeks. The ileal contents and feces were collected before and after LAZ administration. Genomic DNA of the gut microflora was analyzed by 16S ribosomal RNA (16S rRNA) gene sequencing, and the metabolites were analyzed by a CE-TOFMS platform. To examine the changes of immune cell distribution by LAZ, hematopoietic cells in the lamina propria

were analyzed by flow cytometry. The changes of gene expressions of the ileum were comprehensively analyzed by microarray. Finally, mice were orally inoculated with *C. rodentium* after LAZ administration, and the establishment of enteritis was evaluated by body weight loss, histology and inflammatory cytokine expressions examined by real-time PCR.

Results: At steady-state, no prominent change of metabolites and gut microflora were observed in the feces of LAZ group. On the other hand, the concentrations of short chain fatty acids, such as butyrate and propionate, were decreased in the ileum of LAZ group. The result of 16S rRNA analysis also showed that the composition of ileal microflora were different between LAZ and control group. However, it did not show the change of immune cell distribution in the intestine. The gene expression levels in the ileum were not altered either. Interestingly, the ileal microflora of LAZ group became similar to that of the feces. As mice have a habit of coprophagia, it was assumed that perorally invaded bacteria could survive and pass through the stomach due to suppression of gastric acid by LAZ. Accordingly, in the LAZ group, infectious inflammation was established by less numbers of *C. rodentium* inoculation, indicating that PPIs could raise the susceptibility to peroral enteropathogenic bacterial infection.

Conclusion: Our data showed that administration of PPIs could alter the intestinal environment such as microflora and luminal metabolites. However, neither the gene expressions nor distribution of immune cells in the intestinal tissue were affected. It was assumed that the increased risk of peroral enteropathogenic bacterial infection was not because of the immunological modification by PPIs, but it was mainly because of the increased number of pathogenic bacteria passing through the stomach.

Introduction: Because recent studies have demonstrated that amino acid transporters, which transport amino acids into cells, are correlated to various cancers and are major transporters that supply essential amino acids to tumor cells, these transporters are considered as novel biological tumor markers. On the other hand, because anticancer agents are frequently used clinically, the number of patients suffering from anticancer agent-induced intestinal mucosal injuries is increasing; hence, it is important to take appropriate measures for reducing these side effects. Because the L-type amino acid transporter (LAT) transports a wide range of nonselective amino acids, including essential amino acids, it is considered to be a gastrointestinal transporter that is important for nutrient absorption. Furthermore, the involvement of other amino acid transporters in inflammation has been reported in several studies.

Aims & Methods: We aimed to clarify the pathophysiological role of an amino acid transporter in gastrointestinal tract inflammation caused by an antitumor agent in this study. The antitumor agent fluorouracil (5-FU) was orally administered to mice. The severity of mucositis was assessed based on the length, villus height, mucus production, cell infiltration, and immune response of the intestinal tract. We measured the mRNA expressions of LATs in the tissues of the small intestines. In addition, we compared the protein expressions among the small intestines using anti-LAT antibodies.

Results: After the administration of 5-FU, the body weight, food intake, water consumption, and fecal volume decreased; thus, a systemic influence was observed. The length and villus height of the intestinal tract decreased because of the administration of 5-FU, and mucosal damage with histological change was observed. The number of PAS-positive cells decreased in the small intestinal mucosa, and it was assumed that the defensive function of the epithelial cells had decreased. In addition, an increase in the mRNA expression of IL-1 β , IL-6, and *TNF*- α in the Peyer's patch along with an increase in the cell infiltration after the administration of 5-FU significantly enhanced the immune response associated with the inflammatory cytokine production. Furthermore, on investigating the mRNA and protein expressions of LAT1 and LAT2 in the tissues of the small intestines, we observed that LAT1 expression significantly increased and LAT2 expression decreased after the administration of 5-FU.

Conclusion: It was considered that the uptake capacity of amino acids, such as Gly, Ala, Ser, Thr, Cys, Asn, and Gln, that transported through LAT may be decreased in case of small intestinal mucosal injuries. On the other hand, LAT1 expression associated with the production of inflammatory cytokines suggested that LAT1 is a gastrointestinal inflammatory marker.

Introduction: Acetyl salicylic acid (ASA) has been used for the secondary prevention of cardiovascular diseases. Especially, the enteric coated ASA is widely used to prevent ASA-induced gastric mucosal injury. Recent technology such as video capsule endoscopy and balloon endoscopy enabled us to look inside the small intestine in more detail. Consequently, not a few cases of ASA-induced small intestinal mucosal injury have been reported. However, the effective prophylaxis and treatment is not clear yet. Previously, we reported direct detrimental effect of ASA on small intestinal epithelial cells using an *in vitro* model [1]. However, there are the thick mucus layer between intestinal lumen and epithelial cells. The mucus has been reported to prevent foreign objects such as bacteria, medicine and food from epithelial cells.

Aims & Methods: This study was conducted to clarify the role of mucus on ASA-induced small intestinal mucosal injury using a rat model. Male Sprague-Dawley rats, 9 weeks old was used. These rats were divided into four groups; group 1: sham (carboxy methyl cellulose: CMC alone), group 2: polysorbate-80 (P80) alone, group 3: ASA alone, and group 4: P80 plus ASA. CMC and/or 50–200 mg/kg ASA was injected into the proximal duodenum of fed rats. P80, an emulsifier, which has been reported to reduce mucous thickness [2], was administered via drinking water for 2 weeks before ASA treatment. Indeed, P80 also reduced the thickness of mucous layer in our analyses. One hour after ASA treatment, 1% Evans blue was injected into a vein of rats to visualize small intestinal lesions. Ninety minutes after ASA treatment, the entire small intestine was removed for histological assessment. To further investigate the importance of mucus, rebamipide (Reb, 300 mg/kg) or saline were orally administered for one week prior to P80 and ASA treatment. Reb is a gastric mucoprotective drug widely used for the treatment of gastric ulcer, and increases mucous secretion by small intestinal goblet cell.

Results: Evans blue method suggested that high-dose ASA (200 mg/kg) induced severe jejunal mucosal lesions, which was further confirmed by the histological examination. Although lower doses of ASA (50 and 100 mg/kg) did not cause mucosal damage, P80 significantly induced Evans blue exudate and severe mucosal lesions in jejunum at these concentrations, suggesting the pivotal role of mucus in these phenomena. Moreover, orally administered Reb significantly suppressed reducing small intestinal mucus and the exacerbation of ASA-induced mucosal lesions by P80, indicating that mucus is inevitable in the protection of ASA-induced small intestinal mucosal injury.

Conclusion: A mucous secretion increasing therapy might be a useful for the prevention of ASA-induced small intestinal mucosal injury.

Introduction: Food allergy is characterised by a T helper type-2 immune response against a food antigen, manifesting as symptoms including nausea, diarrhoea, vomiting or anaphylactic events. It is estimated that 10% of the Australian population have a food allergy, and common allergens include cow's milk, shellfish and peanuts. Epidemiological studies have identified antibiotics as a significant risk factor for food allergy in infants.

Aims & Methods: We examined how the broad spectrum antibiotic amoxicillin influenced mucosal immune responses to peanut proteins and the development of peanut allergy in mice. Balb/C mice were treated daily with 5 mg/kg amoxicillin or PBS for 5 days (days 0–4). On days 5 and 6 animals received 0.2 mg peanut

extract or PBS vehicle by oral gavage. Animals were rechallenged with peanut or vehicle by oral gavage on days 11 and 13 and sacrificed on day 16 and immune responses to peanut challenge in blood and intestinal tissues were assessed by protein, mRNA and histological analysis.

Results: The proportion of circulating eosinophils was increased in the blood of mice treated with both antibiotics and peanut. Histological examination revealed an increase in small intestinal eosinophils, predominantly at the villous tips, indicating recruitment to the mucosa. RNA and protein analysis revealed an increase in IL-5 associated with increased Nod-Like Receptor Protein 3 (NLRP3) inflammasome activation.

Conclusion: These studies demonstrate that antibiotic treatment prior to food antigen challenge can lead to altered mucosal immune homeostasis, facilitating IL-5-mediated eosinophil recruitment, characteristic of allergic responses. Importantly, we have demonstrated an adjuvant-free model of food sensitisation and small intestinal eosinophilia. These findings contribute to a better understanding of how disruption of mucosal homeostasis by antibiotics contributes to the development of allergic sensitisation and reaction.

Introduction: Intestinal mucositis is a severe side-effect of chemotherapy with a current deficiency in effective treatments.

Aims & Methods: This study investigated three prebiotics, galacto-oligosaccharide (GOS), mannan-oligosaccharide (MOS) and fructo-oligosaccharide (FOS) for their potential to reduce the severity of 5-Fluorouracil (5-FU)-induced intestinal mucositis in rats. Female Dark Agouti rats (n=8/group) were orally gavaged with either 5% FOS, GOS, MOS or water (controls) for 16 days, and received an intraperitoneal injection of 5-Fluorouracil (5-FU: 150 mg/kg) or saline (controls), on day 13. Rats were housed in metabolic cages for the duration of the study, and metabolic data was recorded daily. Rats were killed on day 16 and visceral organ weights and lengths were analyzed post mortem. Crypt depth, villus height and histological severity scores were quantified in haematoxylin & eosin stained sections. Sucrase and myeloperoxidase [MPO] activity were quantified by biochemical assay. White and red blood cell types were quantified by whole blood analysis. Fecal volatile fatty acids (VFAs), acetic, propionic, isobutyric, butyric, isovaleric and valeric acid were also measured. Statistical analysis was by one-way ANOVA or Kruskal Wallis and Mann Whitney U test, where p < 0.05 was considered statistically significant. Data are expressed as mean ± standard error of the mean

Results: %Bodyweight loss was significantly decreased in all treatment groups following 5-FU injection. Total fecal output was increased in rats treated with GOS or FOS, pre and post 5-FU compared to saline treated controls (p < 0.05). Ileal villus height was significantly higher in GOS treated rats pre 5-FU (284.16 ± 11.95 µm) compared to respective water controls (240.40 ± 8.83 µm; p < 0.05). Villus height and crypt depth was significantly decreased in all treatment groups after 5-FU injection (p < 0.05) and prebiotic treatment did not significantly modify this parameter. Similarly, jejunal and ileal sucrase activity was decreased in all groups after 5-FU injection (p < 0.05), correlating with histological measurements. Tissue MPO activity was significantly increased post 5-FU injection, reflecting increased neutrophil activation, and was unchanged by prebiotic treatment. Interestingly, MOS and GOS both lowered %circulating neutrophils pre 5-FU compared to water controls (p < 0.05). Pre 5-FU treatment with GOS significantly increased the fecal VFAs acetic acid (16.76 ± 1.22 mM/L) and propionic acid (4.60 ± 0.99 mM/L) compared to saline treated controls (7.73 ± 0.92 mM/L and 3.05 ± 0.28 mM/L respectively; p < 0.05). MOS and GOS treatment also significantly increased fecal acetic and propionic acid post 5-FU compared to water control (p < 0.05).

Conclusion: Our study has found that prebiotics, MOS, GOS and FOS modified some parameters of intestinal health and immune regulation in healthy rats; however, these prebiotics were not protective against 5-FU induced intestinal damage. Furthermore, our findings have demonstrated that prebiotic treatment significantly increases VFA production, suggesting functional changes to the intestinal microbiome. Further studies are indicated to investigate prebiotics, both alone and in combination, during the repair phase of intestinal mucositis, and to determine their effect on gut microbial composition.

Introduction: Crohn's disease has been thought to be caused by abnormal immune responses affecting many parts of digestive tract in which Th1 cells are particularly dominant. The recruitment of Th1 cells is regulated by interaction of their expression of chemokine receptor CXCR3 and its ligands. There have been many IBD murine models showing the increase of CXCR3 expression and its roles on the disease promotion. However, there are limited evidences in the roles of CXCR3 in human IBD. In fact, a small study in large bowel in a cohort of 10 Crohn's disease patients showed lower expression of CXCR3 on T lymphocytes, compared to colon cancer patients. In terms of inhibition of T-lymphocyte migration into intestine in IBD patients, anti a4b7 (Vedolizumab) therapy is currently shown to be effective.

Aims & Methods: Our study aimed to assess expression of CXCR3 by different subsets of small intestinal lamina propria T-cells and its association with a4 and b7 integrin in Crohn's disease (CD) patients. Total of 56 duodenal biopsies were obtained from CD (n=15), functional dyspepsia (FD)/irritable bowel syndrome (IBS) (n=24) or iron deficiency patients (n=17) with ethical approval. Lamina propria (LP) cells were isolated from biopsies using EDTA, collagenase and gradient density centrifugation with Ficoll. Expression of CXCR3, a4, and b7 on isolated T-lymphocytes was examined by flow cytometry. Statistical significance was assessed using T-test or Spearman correlation.

Results: The expression of CXCR3 on CD4 lymphocytes was significantly lower (35.6%) in CD patients, compared to 61.6% in control group (FD/IBS/iron deficiency). Although the expression of CXCR3 on CD8 lymphocytes was higher than CD4 lymphocytes, it was not different between CD and other group (75.8% in CD patients vs 82.2% in controls). Similar observation was obtained on the double positive CD4 and CD8 lymphocytes. Interestingly, only expression of CXCR3 on CD4 lymphocytes positively correlated with expression of the gut-homing integrins, a4 and b7.

Conclusion: These observations showed significant expression of CXCR3 across different patients with GI-related disease, with consistently higher expression seen in CD8⁺ lymphocytes compared to CD4 lymphocytes. An unexpected reduction of CXCR3 expression was seen in small intestinal of CD patients, which associated with gut-homing integrins. This result showed CXCR3 expression may play a role in migration of CD4 lymphocytes but not CD8 lymphocytes into duodenum in relation with integrins, a4 and b7. However, CXCR3 expression on CD4 lymphocytes in CD patients' small intestine may have protective role. This propose further study to clarify.

P1270 METHODOLOGICAL QUALITY OF CLINICAL PRACTICE GUIDELINES ON PROBIOTICS IN ACUTE GASTROENTERITIS IN CHILDREN USING THE APPRAISAL OF GUIDELINES FOR RESEARCH & EVALUATION II INSTRUMENT (AGREEEII)

A. Maruy Saito¹, J.C. Herrera Rodriguez¹, R. Rojas Galarza²

¹Dept. Of Pediatrics, U Peruana Cayetano Heredia, Lima/Peru

Contact E-mail Address: aldo.maruy@gmail.com

Introduction: Acute Gastroenteritis (AGE) is one of the diseases that most frequently affects paediatric population. Successful treatment in AGE has been mainly based on prevention and treatment of its complications; every day, we find more publications on the use of adjuvants to decrease its duration. Probiotics have gained greater importance because some of them report benefits. We look for Clinical Practice Guidelines (CPG) that recommend their use in AGE in children. The AGREE II instrument was developed to address the issue of variability in guideline quality, so it is a tool that assesses the methodological rigour and transparency in which a guideline is developed.

Aims & Methods: To assess the methodological quality of clinical practice guidelines (CPG) on the use of probiotics in infant diarrhoea. The search was conducted in December 2016, of CPG based on the evidence, the last 10 years and unrestricted language, PubMed, ScienceDirect, and Lilacs. In PubMed, the search terms were: probiotics AND infants; limit: 'guideline'. In ScienceDirect: Probiotics AND infants; limit: Medicine and Dentistry and LILACS: 'probiotics' AND 'infants' and 'probiotics' AND 'guia'. The CPG selected were evaluated with the instrument AGREE II by two evaluators who were independent one from the other and by a third evaluator, when there were discrepancies. The concordance of the evaluations was measured with the index of kappa.

Results: Ten documents were recovered only in PubMed, and selected only 03 that fulfilled the criteria about probiotics. The other two were located in a direct way. The 5 CPG were: 1. Diarrhoea and vomiting caused by GE - NICE; 2. CPG on the diagnosis and treatment of the AID in Pediatrics - Peru; 3. ESPGHAN-ESPID evidence-based guidelines for the management of AGE in children in Europe. Update (2014); 4. Clinical practice guideline ILA on the management of GEA in children under 5 years and 5. Use of probiotics for management of

AGE. A position paper by the ESPGHAN Working Group for Probiotics and Prebiotics. All of the CPG consider that the administration of *Lactobacillus rhamnosus* GG and *Saccharomyces boulardii* should be considered in the management of children with AGE as an adjunct to rehydration therapy with different level of evidence. The concordance between evaluators was >0.9 and <1.0 for all guidelines. Four CPG had one rating higher than 60% in 4 or more domains and one in only one domain. Only a CPG was greater than 60% in all domains. Four had an overall score greater than or equal to 5 and were 'recommended', and one with modifications, according to the instrument AGREE II. The CPG 5 is a Position Paper of a Working Group, not a Guideline, and its the reason for the lower rates obtained.

Domain	CPG1 NICE	CPG2 Gonzales et al	CPG3 Guarino et al	CPG4 Polanco et al.	CPG5 Swajeska et al.
1.Scope and purpose	97.22%	100%	83.33%	88.89%	19.44%
2.Stakeholder Involment	88.89%	80.56%	77.78%	69.44%	30.56%
3.Rigour and Development	79.17%	75.00%	73.96%	67.71%	54.16%
4. Clarity of Presentation	97.22%	100%	80.56%	69.44%	61.11%
5.Applicability	68.75%	58.33%	54.17%	41.67%	27.08%
6.Editorial Independence	68.75%	75.00%	62.5%	62.50%	58.33%
Rate Overall	7	6	5	5	3
Recommendation	Yes	Yes	Yes	Yes	Yes with modifications

Conclusion: Conclusions: The selected CPG have good methodological quality, but are not specific to probiotics. Despite, they should be spread for better decision making.

Introduction: The excessive use of pesticides, often found as residues in our diet and as contaminants in drinking water, has become a public health problem. Most of these substances are considered as endocrine disruptors and their daily exposure is likely to have severe and irreversible consequences. Indeed, preliminary studies have shown that chronic exposure to low doses of chlorpyrifos (CPF) causes intestinal imbalance (dysbiosis) in vitro.

Aims & Methods: The objective of this study is to evaluate the preventive potential of a prebiotic (inulin) in co-exposure with the CPF on the intestinal dysbiosis, the bacterial translocation and the integrity of the intestinal mucosa. For this we used an in vitro system: the SHIME® (Simulator of the Human Microbial

Intestinal Ecosystem). The SHIME® consists of series of fermenters, mimicking the human intestinal environment from the stomach to the colon.

The SHIME® was exposed to a daily dose of 3.5 mg of CPF, combined with 10 g of inulin for 30 days. The samples were collected at day 0 (baseline, without CPF or inulin), D15 and D30 to determine the profile and microbial metabolism.

Results: Contrary to the previous results with CPF alone showing dysbiosis, prebiotic supplementation seems to reestablish CPF-induced imbalance, particularly in the potentially pathogenic microflora (*Staphylococcus*), which an increase in short term (D15: $p < 0.001$), and a recovery at D30. (difference vs D0: NS). The same happened for the beneficial flora (*Bifidobacteria*).

Inulin also beneficially influences the fermentation profile, with higher production of volatile fatty acids (VFA), especially propionic acid and butyric acid.

Conclusion: The CPF/inulin co-exposure therefore had a positive impact on bacterial profile and metabolism, suggesting that prebiotic supplementation could reduce some intestinal damages caused by an exposure to CPF.

Perspective: In a second step, the Caco-2/TC7 cell line, which mimics a functional human intestinal epithelium, will be exposed to samples from the colic fermenters of the SHIME® (D0, CPF ± inulin at D15 and D30) in order to measure the impact on the epithelial barrier.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1272 THE DIET FEATURES OF DIARRHEA PREDOMINANT IRRITABLE BOWEL SYNDROME PATIENTS WITH SMALL INTESTINAL BOWEL OVERGROWTH

H. Wei, Z. Liu, K. Wang, W. Zheng, L. Duan

Gastroenterology, Peking University Third Hospital, Beijing/China

Contact E-mail Address: weihui2012@bjmu.edu.cn

Introduction: Lactulose methane and hydrogen breath test (LMHBT) is now widely used in assessing small bowel bacterial overgrowth (SIBO) and irritable bowel syndrome (IBS). SIBO and IBS have similar clinical symptoms such as floating, diarrhea and abdominal pain. Although there is no clear relationship between IBS and SIBO yet, they are both in relationship with dysbiosis. Diet is associated with disease closely, especially for gastrointestinal diseases. Different dietary structures have different effects on the structure, metabolism and function of intestinal microbiota. Reduce fermentable oligosaccharides, disaccharides, monosaccharides and polyols (FODMAPs) diet can release parts of IBS symptoms obviously. There were rare reports for the effects of diet on LMHBT, especially for IBS-D with SIBO patients, nor sufficient researches of the effects of diet on intestinal microbiota profiles in IBS-D or SIBO patients. High fat diet may change the intestinal microbiota profiles and SCFAs was reported in the past researches, most of which were animal experiments, lacking of effects diet on the clinical manifestations and intestinal microbiota profiles in patients with IBS-D, especially for high-fat diet.

Aims & Methods: We aimed to analyze the characteristics of diet and lactulose methane and hydrogen breath test (LMHBT) in patients of diarrhea predominant irritable bowel syndrome (IBS-D) with small intestinal bacterial overgrowth (SIBO), and comparing with health controls. IBS-D patients (18–65 years old), who met Rome III criteria were enrolled in Gastrointestinal outpatient clinic of Peking University Third Hospital from. Health volunteers were enrolled as controls (HC). All subjects underwent colonoscopy to excluded colonic organic disorders. All subjects completed the case report form (CRF), IBS symptom severity scale (IBS-SSS), the MOS item short form health survey (SF-36). The patients were divided into IBS-D with SIBO (IBS-P) group and IBS-D without SIBO (IBS-N) group according to the LMHBT. Diet information was collected by food frequency questionnaire (FFQ) and three days recalls. The high fat diet is defined as the daily total calories supplying from fat is more than 50%. Statistical analysis was performed by SPSS 20.0 software, $P < 0.05$ was considered statistically significant.

Results: Eighty-eight IBS-D patients and 32 HC were enrolled. The positive rate of LMHBT in IBS-D was significantly higher than that of HC [39.8% (35/88) vs. 12.5% (4/28), $P = 0.005$]. The 28 HC with negative LMHBT were enrolled in the follow-up analysis. (1) There were no significant differences in age and gender ratio among IBS-P, IBS-N and HC. The BMI of IBS-P was significantly lower than IBS-N [(21.57 ± 0.54) vs. (23.30 ± 0.53) kg/m², $P = 0.032$]. High fat diet IBS-D patients and along with IBS-P had higher abdominal pain scores. (2) The proportion of dietary protein and carbohydrate in IBS-D was significantly higher than that of HC (14.39% vs. 12.22%, $P = 0.001$; 53.94% vs. 46.25%, $P = 0.003$, respectively), while the intake of fiber was a little lower than HC [(16.85 ± 1.54) vs. (21.29 ± 3.07) g/d, $P = 0.169$]. The proportion of diet fat was

significantly higher in IBS-P than IBS-N [(47.19 ± 2.62)% vs. (40.74 ± 1.66)%, $P = 0.038$]. IBS-P had more high fat diet individuals than IBS-N [37.1% (13/35) vs. 20.8% (11/53), $P = 0.088$]. (3) The positive rate of LMHBT in IBS-D was significantly higher than that of HC [39.8% vs. 12.5%, $P = 0.005$]. IBS-D patients with high fat diet had higher LMHBT positive rate than that of non-high fat diet patients [54.2% (13/24) vs. 17.2% (11/64), $P = 0.001$]. The baseline of breath methane in IBS-P was significantly higher than that of in IBS-N [(8.69 ± 0.39) vs. (6.39 ± 0.47) ppm, $P = 0.002$]. Breath methane peak value was positively related with the fat proportion of diet ($r = 0.413$, $P = 0.022$).

Conclusion: About 39.8% IBS-D patients existed SIBO. IBS-D patients with high fat diet had higher morbidity of SIBO, and the proportion of diet fat was positively correlated with breath methane baseline of LMHBT. SIBO can worsen nutritional status for IBS-D patients. High-fat diet might be one of the risk factors for IBS-D with SIBO.

Introduction: Alterations to the gut microbiota and bacterial translocation have been implicated as relevant factors for the progression of chronic liver disease (CLD). While the sequence of events leading to translocation remains unclear, deficiencies in local host immune defences, increased permeability of the intestinal mucosal barrier and dysbiosis of the gut microbiota are suggested to play a role. Small intestinal bacterial overgrowth (SIBO), in which an excessive and/or abnormal type of bacteria is present in the small bowel has been implicated as a potential factor in translocation. However, systematic assessments of the extent of SIBO in CLD remain limited. We therefore aimed to compare the prevalence of small intestinal bacterial overgrowth (SIBO) in patients with chronic liver disease (CLD) and controls.

Aims & Methods: Using the search terms ‘small intestinal bacterial overgrowth (SIBO)’ and ‘chronic liver disease (CLD)’ or ‘small intestinal bacterial overgrowth (SIBO)’ and ‘cirrhosis’, 19 case-control studies that met inclusion criteria were identified. Data were extracted to calculate prevalence rates and 95% confidence intervals (CI).

Results: The final dataset included 1,000 adult patients with CLD and 488 controls. Nine studies employed glucose breath tests (GBT), four lactulose breath tests (LBT), with one each of glycine-1-¹⁴C-labeled glycocholate and ¹⁴C-D xylose breath test. Five studies utilised culture methods and one quantitative PCR. Across all testing methods, the prevalence of SIBO in patients with CLD was 38.9% (95% CI 36.9–42.0) versus 9.8% (95% CI 7.5–12.8) in controls. Prevalence of SIBO in CLD was increased as compared to controls (RR = 7.15, 95% CI 4.9–10.4). In patients with cirrhosis the prevalence of SIBO was 40.1% (95% CI 36.6–43.8) compared to 7.3% (95% CI 4.9–10.8) in the respective controls. When the method of detection was limited to breath tests, the prevalence of SIBO in CLD was 35.8% (95% CI 32.6–39.1) compared to 8.0% (95% CI 5.7–11.0) in controls. In contrast, based upon culture techniques, the prevalence of SIBO in CLD was 68.3% (95% CI 59.6–76.0) vs 7.94% (95% CI 3.44–12.73) in controls.

Conclusion: Regardless of the diagnostic modality, prevalence of SIBO is significantly increased in patients with CLD when compared to controls. It is notable that culture-based detection leads to a higher prevalence in CLD, suggesting breath tests may underestimate overall prevalence. Given the levels of SIBO detected, further studies need to explore the role of intestinal dysbiosis for the progression of CLD.

Introduction: In humans, enteric methane (CH₄) production is highly variable and related to the gastrointestinal microbiome and diet. Previous work suggests that CH₄ production is more common in patients with 'constipating' conditions such as encopresis and diverticulosis. We aimed to explore the link between gastrointestinal symptoms breath CH₄ exhalation in patients with unexplained GI symptoms.

Aims & Methods: Consecutive patients (n = 100) with unexplained GI symptoms underwent a combined H₂/CH₄ breath test after ingestion of 75 g of glucose. H₂ and CH₄ were measured by Breathtrac microlyser (Quintron, USA). Gastrointestinal symptoms were assessed utilising the (Structured Assessment of Gastrointestinal Symptoms Instrument (SAGIS). The association between methane exhalation and symptoms during the 2 weeks prior the test were evaluated using non parametric test.

Results: 100 consecutive patients (55f), aged 52.2 ± 15.7 yrs (mean ± SD) were included. Of these, 14 with positive GBT and 19 without SAGIS data were excluded, resulting in 67 data-sets available for analysis. Methane peak and methane baseline values were highly correlated (r = 0.96, p < 0.001). Methane peak (and baseline) were inversely correlated with the SAGIS diarrhoea score (-0.35, p < 0.01, Figure 1). Contrary to current opinion, CH₄ exhalation was not associated with constipation (r < 0.1, P > 0.4). In addition, excessive belching and acid eructation were significantly associated with the baseline and peak CH₄ exhalation (r all ≥ 0.3, p all < 0.04).

Conclusion: There is an inverse association between CH₄ exhalation and diarrhoea symptoms. At the same time, CH₄ is associated with bloating and acid eructation. These data suggest that CH₄ or metabolic products from CH₄ producing microbes modulate human gut function.

Introduction: The prevalence of osteoporosis is higher among patients suffering a distal radius fracture than in healthy controls [1]. Celiac disease (CD) is associated with low bone mineral density [2], and overall findings indicate an increased risk of fracture in CD patients [3, 4]. This study is to our knowledge the first case control study investigating whether there is a higher prevalence of CD in adult patients suffering a peripheral fracture (distal radius or ankle) than in healthy age- and sex matched controls.

Aims & Methods: Main objective was to investigate if patients with a recent fracture of the distal radius or ankle have a higher risk of having CD than healthy controls. 400 consecutive patients over the age of 40 with acute distal radius fracture (n = 293) or ankle fracture (n = 107) were included in a case control study by referral from the orthopedic department at Forde General Hospital, Norway. The controls were 197 age- and sex- matched subjects from Sogn and Fjordane County identified from the National Population Registry, with no previous fracture history. BMD of the hips and spine was measured and history of previous fracture, comorbidities, medication, life-style factors, body mass index (BMI) and nutritional factors were registered. Serum analysis to detect secondary osteoporosis including IgA tissue transglutaminase was performed.

Results: See table.

	Ankle fracture	Distal radius fracture	All fractures	Controls
N	107	293	400	197
Fracture cases %	26.8	73.3		
Female gender %	69.1	80.2	77.3	82.7
T-score < -2.5 %	23.4	44.7	39.0	22.3
T-score -1.0--2.5 %	36.4	33.8	34.5	34.0
Mean age	62.9	57.1	61.4	60.3
Mean BMI ¹	26.5	28.6	27.1	27.2
Known CD ² %	0 (n = 0)	1.4 (n = 4)	1.0 (n = 4)	1.5 (n = 3)
Positive TTG ³ %	2.8 (n = 3)	2.4 (n = 7)	2.5 (n = 10)	1.3 (n = 2)
Known CD or positive TTG	2.8 (N = 3)	3.8 (n = 11)	3.5 (n = 14)	2.8 (n = 5)
Vitamin D deficiency ⁴ %	6.6	2.4	3.6	5.6

¹body mass index ²celiac disease ³IgA tissue transglutaminase ⁴Vit D < 37 nmol/l

Conclusion: The prevalence of celiac disease was in preliminary analyses not significantly higher among persons suffering a distal fracture (3.5%) than among healthy age- and sex- matched controls (2.8%). Osteoporosis and low Vitamin D levels are significant risk factors for distal radius fracture, but this is not the case with ankle fractures.

Introduction: Celiac disease (CeD) is an immune disorder, triggered by gluten intolerance in genetically susceptible patients. Clinical outcome includes several extraintestinal manifestations, including neurologic complications in about 10% of patients. Previous studies confirmed the subclinical changes of autonomic nervous system (ANS) activity resulting to impaired gastric myoelectric activity. In CeD disturbances of parasympathetic-sympathetic balance of the ANS activity with sympathetic dominance is observed. Tight junctions impairment is one of postulated pathomechanism in CeD and its complications. Transmembrane proteins of tight junctions include claudin and occludin. There is lack of publications referring to soluble claudin and occludin concentrations in CeD. Interleukin-1 beta (IL-1beta) is an important mediator of the, and there are no data concerning on its influence on gastric myoelectric activity and ANS activity in CeD.

Aims & Methods: The study was aimed to evaluate occludin, claudin and IL-1beta concentrations in serum in neurologically asymptomatic patients with CeD and its correlation with selected parameters of ANS activity markers (heart rate variability, electrogastrography HRV) and gastric myoelectric activity (EGG). Thirty four patients with CeD (70% females, mean age 34 years, 41.2 ± 16.6) without neurological symptoms were tested for occludin, claudin, IL-1beta concentrations in serum using ELISA, and HRV and EGG.

Results: Biochemical parameters. Patients with CeD presented with lower average level of occludin (1.41(0–2.9) ng/mL) than healthy subjects (1.68(0.39–4.8) ng/mL) (*P* = 0.07, the Mann-Whitney test). No significant impact of CeD on the average results of IL-1 beta concentrations was observed (*P* = 0.44, the Mann-Whitney test). **The rest HRV.** In the celiac group the assessment of HRV revealed a negative statistically significant correlation of claudin concentration and very low frequencies (VLF-RRI; Spearman's rank correlation coefficient: *r* = -0.51, *P* = 0.018) as well as positive correlation between IL-1beta and LF/HF was demonstrated (*r* = 0.51, *P* = 0.032). Statistically significant, negative and strong correlation of IL-1 beta concentration and DP (Dominant Power of EGG) (*r* = -0.58, *P* = 0.038) was shown.

Conclusion: ANS activity measured by EGG and HRV seems to be correlated to presence of IL-1beta. In celiac group the serum concentration of claudin and occludin do not correlate to ANS activity. Due to former research on autonomic imbalance in CeD with sympathetic overdrive, the hypothesis of influence of IL-1beta on ANS activity should be considered.

Introduction: Small bowel villous atrophy (VA) is mainly related to coeliac disease (CD) that develops in HLA DQ2/DQ8 positive patients and improves on a gluten-free diet. Other forms of VA unrelated to CD are common variable immune-deficiency, autoimmune enteropathy, small bowel malignancies, medication-related enteropathies, HIV, tropical sprue, and giardiasis [1–3]. However, there are also forms of VA in which CD can be neither confirmed nor excluded and there are forms of VA in which, although CD is excluded, a definitive diagnosis cannot be made. Some years ago, we coined the terms undefined sprue (US) and non-coeliac refractory sprue (NCRS) to define these two

conditions [4]. Although other Authors described similar patients [2,3], it is still unclear whether US and NCRS are two independent conditions or whether they are two faces of the same coin. Alternatively, they could be umbrella terms covering one or more atrophic enteropathies still awaiting to be identified, as was the case of olmesartan-associated enteropathy until a few years ago.

Aims & Methods: Our aim was to clarify the nature of these forms of VA. We retrospectively re-evaluated the clinical notes of patients referred to our Clinic from January 1999 to October 2016 with a previous diagnosis of refractory CD. Patients with VA in whom CD could not be confirmed and in whom other causes of VA were ruled out were selected.

Results: 7 patients (2F, age at diagnosis of VA 46 ± 26 years, all with severe malabsorption) were identified. 3 were DQ2 positive and so were diagnosed as US: case 1 (F, 32 years) died of ulcerative jejunitis 8 years later; case 2 (M, 38) died of pulmonary embolism complicating systemic candidiasis 1 year later and case 3 (M, 71) died of intestinal lymphoma after 4.5 years. The remaining 4 patients were HLA DQ2/DQ8 negative, so a diagnosis of NCRS was made. 3 were DQ7.5 positive: case 4, (F, 61) died of EATL type 2 after 4.5 years; case 5 (M, 25) is still alive 10 years after diagnosis of VA and in good clinical conditions; case 6 (M, 69) is still alive but could be affected by a form of enteropathy due to candesartan. He is in good clinical condition and has been refusing follow-up. The last patient, case 7 (M, 29) is DQ7.3 positive. He is still alive 11 years after the diagnosis of VA, although complains of diarrhoea.

Conclusion: We described 7 patients with VA unrelated to CD or other known enteropathies. Although overall mortality among them is very high (57%) and mainly due to lymphoproliferative disorders, 3 of the 4 DQ2/DQ8 negative patients are alive many years after the diagnosis of VA with no evidence of malignancy. This suggests that these 7 patients are not affected by the same condition. We speculate that DQ2 positive patients who died of lymphoma could be affected by a form of CD who escaped diagnosis and get complicated. However, we feel that the 3 DQ2/8 negative patients with long survival are affected by a still unidentified form of VA.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1278 EVERYDAY LIFE RESTRICTIONS CAUSED BY LONG-TERM TREATED CELIAC DISEASE: PREVALENCE AND ASSOCIATED FACTORS

L. Kivela¹, S. Alin¹, S. Kröger¹, K. Kaukinen², K. Kurppa¹

¹Tampere Center For Child Health Research, University of Tampere, University of Tampere/Finland

²School Of Medicine, University of Tampere, Tampere/Finland

Contact E-mail Address: laura.kivela@fimnet.fi

Introduction: Strict gluten-free diet (GFD) in celiac disease is burdensome and difficult to maintain, which might predispose to poor dietary adherence and impaired quality of life. We aimed to evaluate adult patients' experience of living with celiac disease diagnosed in childhood, and identify factors associated with possible everyday life restrictions caused by the disease.

Aims & Methods: 232 adults (women 69%, median age 27.0 yr) with a childhood diagnosis of celiac disease fulfilled a questionnaire evaluating their experiences about general health and lifestyle, possible co-morbidities, adherence and attitudes towards GFD and long-term follow-up of celiac disease. In addition, they completed validated Gastrointestinal Symptom Rating Scale (GSRS) and Psychological General Well-Being (PGWB) surveys for gastrointestinal symptoms and quality of life. Patient records were used to confirm clinical and histological presentation at diagnosis and other relevant medical data.

Results: Altogether 108 (47%) out of the 232 responders felt that celiac disease restricts their daily life. This was experienced especially when eating in a restaurant (72%), traveling abroad (38%) and visiting a friend (30%). Patients reporting restrictions had more often anemia (38% vs 22%, $p=0.013$) and severe symptoms (16% vs 6%, $p=0.047$) at diagnosis, whereas the groups did not differ in age, gender or other clinical and histological presentation. Current age (median 26.3 vs 27.7 yr, $p=0.315$) and time from the diagnosis (18.6 vs 17.9 yr, $p=0.468$) were also comparable, as well as were self-experienced general health and concern about health, presence of co-morbidities and complications, smoking, physical exercise, socioeconomic status, membership of celiac society and presence of celiac disease in relatives. There was also no difference in specific gastrointestinal symptoms as measured by GSRS scores, but patients considering the disease restrictive reported more overall symptoms possibly related to celiac disease than those without restrictions (32% vs 17%, $p=0.007$). Furthermore, despite similar dietary adherence (strict GFD 78% vs 82%, $p=0.770$) they experienced adhering to the diet more challenging (somewhat difficult 33% vs 7%, $p<0.001$) and had significantly lower PGWB vitality scores (median 17 vs 18, $p=0.023$).

Conclusion: Almost half of the patients diagnosed in childhood experienced celiac disease to cause marked restrictions in adulthood. This was associated with current symptoms, lower vitality scores and difficulties to maintain GFD. Patients with severe symptoms and anemia at diagnosis might require special attention and tailored follow-up in these circumstances.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1279 SYSTEMATIC REVIEW OF THE ECONOMIC BURDEN OF COELIAC DISEASE

T. Boulanger¹, A. J. Taylor², D. A. Leffler³, E. S. Mearns¹, M. Gerber³

¹IBM Watson Health, Boston/United States of America/MA

²Takeda, London/United Kingdom

³Takeda, Cambridge/United States of America/MA

Contact E-mail Address: aliki.taylor@takeda.com

Introduction: The prevalence of diagnosed coeliac disease (CD) has rapidly increased in developed countries over the last 30 years. The economic burden of diagnosing, managing, and monitoring CD can be substantial but is poorly understood. To assess the economic burden of CD, we systematically reviewed current evidence quantifying economic costs and health resource utilization (HRU) for CD in North America and Europe.

Aims & Methods: Searches of Medline, Embase, EconLit, the Cochrane Library, and conference abstracts systematically identified literature published in English during the last 10 years assessing direct and indirect costs, cost-effectiveness analyses, and HRU for CD.

Results: Of 33 studies meeting criteria for inclusion, most (20) were from Europe, and most (18) reported or modeled costs associated with screening and diagnosis. Cost per positive CD diagnosis of screening patients already undergoing upper gastrointestinal biopsy for other indications, such as anaemia or irritable bowel syndrome, ranged from approximately \$1,300 in Canada to more than €44,000 in the Netherlands (costing year not reported). In these populations, screening was judged to be cost-effective with various strategies combining diagnostic modalities, including serology then biopsy, compared to no screening. Strategies using either endoscopy/biopsy or serology alone were not considered cost-effective. Direct annual excess costs to a US payer per diagnosed CD patient totaled \$4,000 (US\$ 2007) to \$6,000 (US\$ 2013) more than for a person without CD, chiefly due to outpatient care, with higher costs among patients with poor disease control. High use of outpatient care is also reflected in studies of HRU, although hospitalization, emergency visits and medication use are also more common in individuals with CD than in controls. After initiation of a gluten-free (GF) diet, patients visit primary care providers less often, but use more medications. Patients often pay out of pocket for gluten-free (GF) foods, which cost 240–518% more than gluten-containing equivalents. Three studies on absenteeism from Scandinavia found fewer days missed from school and work following diagnosis and initiation of a GF diet.

Conclusion: Most economic studies of CD have focused on the cost of screening and diagnosis, especially in Europe. Methods of screening generally are considered cost-effective when they combine diagnostic modalities, such as serology then biopsy, in people being evaluated for symptoms. Much of the cost to a payer of managing CD derives from outpatient care, especially for patients with poorly controlled disease. Patients on a GF diet lose fewer days from work and school but pay high costs for GF foods.

Introduction: Metabolic syndrome (MS) and hepatic steatosis (HS) are frequent in patients with celiac disease (CD) after commencing gluten-free diet (GFD), but data about predictive factors for such a condition are still scarce.

Aims & Methods: We aimed to evaluate the role of PNPLA3 rs738409 in the development of MS and HS in CD patients after starting GFD. From June 2014 to September 2016 we consecutively enrolled all patients referred to academic gastroenterological centre, suffering from CD, with or without HS. All patients underwent anthropometrics and serological investigations, ultrasonography (US) evaluation to assess the degree and severity of HS and genotyping of PNPLA3 rs738409 polymorphism.

Results: Finally, 370 subjects were enrolled (136 with HS and 234 without HS). At genotyping assays, CC genotype was found in 194 subjects (52.4%), CG genotype in 138 subjects (37.3%), while 38 individuals (10.2%) showed the GG genotype. At binary logistic regression, only G and GG alleles were predictive for the development of HS (OR 1.97; $p<0.01$ for G carriers and OR 6.9; $p<0.001$ for GG carriers), while BMI (OR 3.8; $p<0.001$) and waist circumference (OR 2.8; $p=0.03$) at CD diagnosis were the only independent factors for the development of MS. The intergroup comparison among HS patients showed that

the severe grade of HS was more frequently observed in GG than in CC carriers (74% vs 11.3%, $p < 0.001$, OR 21.8).

Conclusion: PNPLA3 G and GG carriers with CD have higher susceptibility to hepatic steatosis, but not to metabolic syndrome. Moreover, patients with GG alleles display a more relevant disease in terms of severity of HS based on US evaluation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1281 PROTON PUMP INHIBITORS AS RISK FACTOR FOR METABOLIC SYNDROME AND HEPATIC STEATOSIS IN PATIENTS WITH CELIAC DISEASE ON GLUTEN-FREE DIET

Contact E-mail Address: nicola.imperatore@alice.it

Introduction: Recent research has shown that patients with celiac disease (CD) are at-risk of developing metabolic syndrome (MS) and hepatic steatosis (HS) after commencing gluten-free diet.

Aims & Methods: We aimed to evaluate the predictive factors for MS and HS in CD after one year of GFD. All consecutive newly diagnosed CD patients were enrolled. We prospectively collected data about: BMI; waist circumference; blood pressure; cholesterol; triglycerides, glucose and insulin blood levels; insulin resistance (through the homeostatic model assessment HOMA-IR); treatment with proton pump inhibitors (PPI). Diagnosis of MS was made in accordance with current guidelines and HS was diagnosed by ultrasonography. The prevalence of MS and HS was re-assessed after 1 year of GFD. A logistic regression analysis was performed to identify risk factors for MS and HS occurrence after 1 year of GFD.

Results: Of 301 patients with newly diagnosed CD, 13 (4.3%) met criteria for diagnosis of MS and 25.9% presented HS at the time of CD diagnosis; 99 subjects (32.8%) had long-term exposure to PPI during the study period. After 1 year, 72 (23.9%) patients had developed MS (4.3% vs 23.9%; $p < 0.001$, OR 6.9) and 112 (37.2%) had developed HS (25.9% vs 37.2%; $p < 0.01$, OR 1.69). At multivariate analysis, high BMI at diagnosis (OR 10.8; $p < 0.001$) and PPI exposure (OR 22.9; $p < 0.001$) were the only factors associated with the occurrence of MS; HOMA-IR (OR 9.7; $p < 0.001$) and PPI exposure (OR 9.2; $p < 0.001$) were the only factors associated with the occurrence of HS.

Conclusion: PPI exposure adds further risk of occurrence of MS and HS for patients with CD on GFD. The use of PPI in patients with CD on GFD should be limited to strict indications.

Introduction: Patients with coeliac disease (CD) are usually stable clinically and biochemically at their annual review. Due to pressures on out-patient services we reviewed data to assess which patients actually require specialist gastrointestinal (GI) input, and raise the question on who ought to see CD patients in clinics.

Aims & Methods: Barnet Hospital is a District Hospital serving a population of 500,000 just outside North West London. This was a single-centre, retrospective study, of confirmed CD patients, under the care of three different gastroenterologists. Data was obtained from each consultant from their database. We reviewed the electronic records relating to each patient's last three clinic appointments, and assessed whether or not they were stable clinically and biochemically. We excluded patients with other significant GI co-morbidities and who were newly diagnosed within the last two years.

Results: There were 192 patients with CD of whom, 160 fulfilled the inclusion criteria. Female=107;67%. In each of the last 3 clinic reviews 83% (n=133) were stable. Only 17% (n=27) required specialist GI input; including 18% (n=7) due to poor adherence to a gluten-free diet, 28% (n=11) due to GI symptoms, 18% (n=7) due to weight loss, 18% (n=7) due to anaemia, 8% (n=3) due to elevated TTG and 10% (n=4) other. Annual reviews by a gastroenterologist occurred in 83% (n=133). Dieticians saw patients less than once per year in 62.5% (n=100) of cases, and 37.5% (n=60) were actually never referred to a dietician.

Conclusion: BSG guidelines recommend that patients with CD are seen annually by a dietician and/or clinician for a clinical review, biochemical checks and for dietary adherence and advice¹. NICE guidelines also state that patients should be seen annually for clinical review, height and weights check, bloods and to assess the need for nutritional advice². We have demonstrated that in a hospital that does not have a dietician-led coeliac service, gastroenterologists typically see straight forward and stable patients annually 83% of the time. Assuming a 10 minute consultation, this equates to 22 hours per annum of specialist time, equivalent to 6.3 clinics a year. Given the need to access our services for urgent referrals or unwell patients with other conditions, this study forms the

basis for a business case to set up a dietician-led coeliac service, with access to gastroenterologists where needed.

P1283 MONITORING PATIENTS WITH COELIAC DISEASE: WHO ACTUALLY NEEDS A DEXA SCAN?

M. Yalchin, R. Eckersley, T. Coysh, S. Mann

Gastroenterology, Barnet Hospital, DJ/United Kingdom

Contact E-mail Address: m.yalchin@nhs.net

Introduction: Patients with coeliac disease (CD) should be seen annually for a clinical review, blood tests and a DEXA scan if needed^{1,2}. The indication for a DEXA scan is unclear due to conflicting recommendations in current guidelines^{2,3}. The aim of our study was to audit our practice, with a focus on requests for DEXA scans.

Aims & Methods: This was a single-centre, retrospective study of CD patients under the care of 3 consultants. We accessed the electronic records to identify if haematological and biochemical profiles were being monitored annually. We also identified when patients had their first DEXA scans and whether or not they were indicated^{2,3}.

Results: Data were collected on 160 patients (Female=107[67%]). Annual checks of FBC occurred in 94% of patients, vitamin B12 in 74%, folate in 77%, ferritin in 88%, calcium in 85% and vitamin D in 69%. DEXA scans occurred in 74% of patients (n=119), including 65% (n=77) who were screened around the time of diagnosis. However, only 24% (n=28) actually warranted the scan according to guidelines^{2,3}, and 68% (n=81) did not fulfil criteria for a DEXA. In 8% of patients (n=10), there was inadequate data. Of the 81 patients who did not warrant a DEXA scan, 77 results were available: normal in 48% (n=37), osteopenia in 43% (n=33) and osteoporosis in 9% (n=7). Of the 7 patients that had osteoporosis, 4 patients were under 50 years old (57%). Of the appropriate DEXA requests, 25% (n=7) were normal, 39% (n=11) had osteopenia and 36% (n=10) had osteoporosis.

Conclusion: Most CD patients require very little clinical input at their routine appointments. Annual blood checks and adherence to a gluten-free diet are standard enquiries. However, there is a cohort of patients who are not getting their regular blood tests: 33% for bone profile and 25% for haematinics. Clinicians tend to order a DEXA in most CD patients because it is easier than attempting to judge an individual's risk in the setting of conflicting guidance^{2,3}. The pick-up rate of osteoporosis in 36% of appropriately screened patients (vs 9% in inappropriate scan requests) suggests that targeted screening allows for a more rational and cost-effective use of a limited resource. We hope that the guidelines can now be updated with more clarity for the practitioners who request DEXA scans in CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A life-long gluten-free diet (GFD) is the only available treatment for patients with celiac disease (CD). Adherence to the GFD is associated with symptoms remission, reversal of mucosal atrophy and, possibly, prevention of CD-related complications. However, data on the long-term effects of a good or poor adherence to the GFD are limited.

Aims & Methods: The aim of this study was to assess the rate and accuracy of compliance to a strict GFD in patients with a CD history of more than 30 years and to compare endpoints such as complications, symptoms and histology between patients following a strict GFD and patients not compliant to the diet. Between 2015 and 2016, data from all patients diagnosed with CD at the Fondazione IRCCS Ca' Granda before 1985 were retrieved. Patients not undergoing regular follow-up at the clinic were contacted in order to collect recent clinical updates as regards symptoms, adherence to the GFD, laboratory data and complications occurrence. All patients were asked to fill in a questionnaire investigating their knowledge on gluten free products and behavioral rules; in case of patients with CD diagnosis in childhood, the same questionnaire was administered to their parents.

Results: Clinical data from 196 patients were collected and analyzed. Patients were divided into 3 groups according to their adherence to GFD: 133 patients reporting a lifelong strict GFD, 29 patients on GFD at the time of follow-up but with a history of at least 5 years of gluten-containing diet (GCD), and 35 patients who reported to be on a GCD. No significant differences were found between groups regarding symptoms and histology at diagnosis, onset of associated autoimmune disorders, family history of CD and compliance to follow up. The onset of complications at follow-up did not significantly differ in the three groups as well. Follow-up histology was available in 63 patients (32.1%). Persistence of villous atrophy was as expected more frequent in patients on GCD as on GFD (41% vs 7%, $p=0.008$); however 20 patients showed normal histology during long-term GCD. The questionnaire was returned by 90 patients and 66 parents: a slightly better knowledge about the GFD and its behavioral rules was found between patients on lifelong GFD and patients with ongoing or past GCD ($p=0.03$).

Conclusion: Poor adherence to the GFD is reported by almost one-third of patients with a long-term history of CD, confirming the high rate of poor compliance to such a strict diet among patients. Poor adherence to the GFD was confirmed as a major predictor of persistence of villous atrophy, but this does not necessarily imply the development of CD complications. Moreover, results from follow up biopsies showed that a GCD does not imply recurrence of villous atrophy in all patients, attesting the possibility that some CD patients may maintain a gluten tolerance over time.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Parenteral support (PS) volume needs vary depending on disease severity in patients with intestinal failure associated with short bowel syndrome (SBS-IF). Patient classification has focused on the diagnosis that led to resection and the remnant bowel anatomy.

Aims & Methods: Recently, the idea that grading severity of SBS-IF is based on magnitude of PS volume needs led to this clinical trial data post hoc analysis of patients with SBS-IF based on their baseline PS volume. STEPS (NCT00798967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of teduglutide (TED) 0.05 mg/kg/day in patients with SBS-IF. Three baseline PS volume groups were evaluated: Group I, ≤ 9 L/week; Group II, > 9 to ≤ 18 L/week; and Group III, > 18 L/week.

Results: The predominant diagnosis leading to SBS-IF in Group I (12/28; 43%) and Group II (15/41; 37%) was vascular gut complications; in Group III (8/16; 50%), Crohn's disease. Baseline PS volume and TED-induced volume reduction (% change) at Week 24 was highest in Group III (Table). Evaluation of individual patient response showed a close, linear, and significant correlation between absolute PS volume reduction at Week 24 in relation to TED treatment and daily volume at baseline ($y = -0.387x + 90.03$, $R^2 = 0.61$; $P < 0.0001$); no significant correlation was observed in the placebo group ($y = -0.06x - 220.15$, $R^2 = 0.02$;

$P = 0.36$). Adverse events were reported by 93% (Group I), 80% (Group II), and 71% (Group III) of TED patients.

Table: Baseline PS Volume and Percent Change at Week 24

	Baseline PS Volume					
	≤ 9 L/week		$> 9 - \leq 18$ L/week		> 18 L/week	
Mean (SD) PS Volume, Actual Based	TED (n = 15)	PBO (n = 13)	TED (n = 20)	PBO (n = 21)	TED (n = 7)	PBO (n = 9)
Baseline, mL/day	806.9 (328.11)	856.1 (310.24)	1791.8 (338.33)	1870.2 (408.27)	3826.1 (715.49)	3527.4 (749.04)
Change at Week 24, %	-28.5 (18.45)*	-29.2 (35.49) [†]	-33.5 (20.97) [‡]	-19.1 (20.40) [§]	-36.7 (13.97)	-14.9 (17.07) [§]

PBO = placebo. *n = 13; [†]n = 12; [‡]n = 19, [§]n = 8.

Conclusion: Higher baseline PS volume in patients with SBS-IF correlates with greater absolute reduction in PS volume with TED treatment. This research was funded by Shire International GmbH, Zug, Switzerland.

Introduction: Plasma citrulline has been proposed as a biomarker for remnant intestinal length, but it is unclear if plasma citrulline levels reflect intestinal absorptive function.

Aims & Methods: This post hoc analysis investigated the relationship between reductions in parenteral support (PS) volume and changes in plasma citrulline levels with teduglutide (TED) in patients with intestinal failure associated with short bowel syndrome (SBS-IF). STEPS (NCT00798967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of TED 0.05 mg/kg/day in patients with SBS-IF. Plasma citrulline levels were assessed at baseline and Week 24 in all patients randomised to TED and in patients stratified by bowel anatomy.

Results: In the TED arm (n = 42), plasma citrulline levels at baseline were significantly correlated with remnant small bowel length ($R^2 = 0.14$; $P = 0.02$; n = 36) but not with baseline PS volume ($R^2 = 0.03$; $P = 0.30$; n = 39). The correlation between baseline plasma citrulline and plasma citrulline change at Week 24 was significant ($R^2 = 0.80$; $P < 0.0001$; n = 39). No correlation was found between change in plasma citrulline levels and change in PS volume at Week 24 with TED ($R^2 = 0.05$; $P = 0.16$; n = 39). When patients were analysed by bowel anatomy subgroups, significant increases in plasma citrulline were seen with TED but not placebo (Table).

Table: Mean (SD) Change From Baseline at Week 24 in PS Volume and Plasma Citrulline Stratified by Bowel Anatomy

	No Colon, Stoma Present, No Colon-in- Continuity		$\geq 50\%$ Colon, No Stoma, Colon-in- Continuity		Other Bowel Anatomies	
Mean (SD) Change at Week 24	TED (n = 17*)	PBO (n = 16 [†])	TED (n = 18)	PBO (n = 20)	TED (n = 7)	PBO (n = 7 [‡])
PS Volume mL/day	-919 (644) [§]	-340 (436)	-355 (306)	-327 (349)	-728 (532)	-297 (498)
%	-40 (18)	-19 (29)	-23 (16)	-24 (22)	-40 (19)	-19 (31)
Citrulline μM	30.1 (18.9) [§]	2.2 (6.9)	11.8 (9.9) [§]	0.8 (5.3)	24.0 (20.9) [§]	-2.7 (7.6)
%	138 (50) [§]	8 (31)	87 (63) [§]	21 (71)	116 (85) [§]	-1 (40)

PBO = placebo.

*n = 14 with data; [†]n = 13 with data; [‡]n = 6 with data; [§] $P \leq 0.01$; ^{||} $P < 0.05$.

Conclusion: Plasma citrulline may serve as a marker of remnant small bowel length in patients with SBS-IF, but plasma citrulline does not predict PS

volume reductions with TED. Plasma citrulline changes with TED may reflect increased enterocyte mass. This research was funded by Shire International GmbH, Zug, Switzerland.

²Dept. Of Gastroenterology, Alfred Hospital Dept. of Gastroenterology, Melbourne/Australia

Contact E-mail Address: vpytan@hku.hk

Introduction: Prevalence rates of Functional Dyspepsia (FD) in East Asia are three times higher than Irritable Bowel Syndrome (IBS) rates. Many researchers have suggested that IBS subjects in the region experience their pain and discomfort in the upper abdomen, leading to misdiagnosis as FD.

Aims & Methods: We aimed to compare patterns of gastrointestinal (GI) symptom genesis in the Chinese population with FD or IBS during provocative hydrogen breath testing (HBT) with lactulose, lactose and fructose. Subjects fulfilling the ROME III classification of FD and IBS, and control subjects with no known GI disorder/symptoms were recruited. All subjects underwent HBT +/- methane assessment with lactulose (10ml), lactose (25g) and fructose (25g). Subsequent breath tests were performed after a washout period of at least one week. Breath tests were performed after an overnight fast, with the patient sedentary. Breath samples taken every 15 minutes for 3 h. GI symptoms were recorded during these 3 h and at a telephone follow-up 24 hours later.

Results: A total of 353 subjects completed at least one breath test examination and 313 subjects completed all three breath tests. 16%, 55% and 29% were control, FD and IBS subjects. All study subjects were ethnic Chinese, the mean age was 53 [Range; 18–76] y and 27% [95% CI; 23–32%] were male. 85% [95% CI; 82–89%] of subjects were hydrogen-producers and 100% methane-producers. Symptoms were induced in a relatively low proportion of healthy controls. Both FD and IBS subjects experienced similar proportions of epigastric pain on consumption of lactulose, lactose and fructose. See Table 1. Subjects with FD experience more belching than subjects with IBS when lactulose [58 vs. 42%, $p=0.011$] and lactose [62 vs. 46%, $p=0.014$] were ingested, respectively. Subjects with IBS experience significantly more “lower GI” symptoms of abdominal pain and development of loose stools when lactulose was ingested when compared with subjects with FD. In general subjects with IBS experienced both epigastric pain and abdominal pain when any of the three carbohydrate solutions were ingested. Healthy controls experienced minimal symptoms.

Conclusion: Chinese subjects commonly co-produced hydrogen and methane. Ingestion of poorly absorbed sugars induces symptom patterns in patients with FD in similar proportions. Chinese IBS subjects commonly experienced epigastric and abdominal pain. Reducing poorly absorbed short-chain carbohydrates (FODMAPs) might be efficacious in FD as it is in IBS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Table 1: Induction of Gastrointestinal Symptoms with Lactulose, Lactose and Fructose Hydrogen Breath Testing in Functional Dyspepsia and Irritable Bowel Syndrome Subjects

	Functional Dyspepsia	Irritable Bowel Syndrome	P-value
Lactulose % [95% Confidence Interval]			
Epigastric Pain	40% [33–47%]	29% [20–38%]	0.056

Introduction: Inflammatory bowel disease (IBD) and mesenteric vascular (Vasc) disease are underlying conditions for intestinal failure associated with short bowel syndrome (SBS-IF). Fluid balance, urine production, and parenteral support (PS) volume are variable among patients with SBS-IF.

Aims & Methods: This is a post hoc analysis of the impact of teduglutide (TED) on fluid composite effect (FCE = sum of urine volume output increase, oral fluid intake reduction, and PS volume reduction) in patients stratified by diagnosis. STEPS (NCT00798967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of TED 0.05 mg/kg/day in patients with SBS-IF. Three groups were evaluated: SBS-IBD, SBS-Vasc, and Other.

Results: The SBS-IBD group included more patients with stoma (95%; SBS-Vasc, 19%; Other, 41%) and fewer with colon-in-continuity (11%; SBS-Vasc, 78%; Other, 62%). At Week 24 (Table), PS volume reductions were significantly higher in SBS-IBD patients treated with TED vs placebo ($P=0.02$) and vs TED patients in the SBS-Vasc ($P=0.04$) and Other ($P=0.02$) groups. Change in FCE was greater in SBS-IBD patients treated with TED vs placebo ($P<0.02$) and vs TED patients in the SBS-Vasc ($P<0.01$) and Other ($P=0.05$) groups.

Table: Components of Fluid Composite Effect at Baseline and Week 24 and Fluid Composite Effect at Week 24 by Diagnosis

	SBS-IBD		SBS-Vasc		Other	
Mean (SD), mL/day	TED (n = 11)	PBO (n = 8)	TED (n = 15)	PBO (n = 17)	TED (n = 16)	PBO (n = 18)
Baseline						
PS volume	2268 (1480)	3088 (1156)	1827 (982)	1338 (731)	1399 (811)	1928 (855)
Oral fluid intake	2456 (1176)	1521 (532)	1780 (761)	1634 (536)	1600 (575)	1692 (708)
Urine output	1160 (160)	1302 (243)	1385 (252)	1389 (327)	1448 (114)	1387 (226)
Change at Week 24						
PS volume	-1102 (654)*	-357 (453) [‡]	-513 (539)	-277 (428) [§]	-450 (280) [#]	-363 (345)
Oral fluid intake	-220 (338) [†]	246 (608) [‡]	-24 (500)	188 (531) [#]	79 (611) [#]	254 (470)
Urine output	191 (180) [†]	-138 (239) [‡]	52 (286)	31 (243) [#]	222 (341) [#]	128 (466)
FCE	-1437 (900) [†]	27 (818) [‡]	-588 (995)	-147 (575) [#]	-593 (444) [#]	-237 (588)

PBO = placebo. * $n=9$; [†] $n=8$; [‡] $n=7$; [§] $n=16$; [#] $n=15$.

Conclusion: TED had the largest absolute effect on FCE in the SBS-IBD group; TED effect on FCE was not as major in SBS-Vasc or Other patients at Week 24. This research was funded by Shire International GmbH, Zug, Switzerland.

Introduction: Intestinal resection resulting in short bowel syndrome (SBS) can lead to intestinal failure (SBS-IF). SBS-IF arises from different aetiologies, including vascular catastrophes and inflammatory bowel disease, resulting in a heterogeneous population.

Aims & Methods: This post hoc analysis reports baseline characteristics and clinical response to teduglutide (TED) in patients based on residual bowel anatomy. STEPS (NCT00798967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of TED 0.05 mg/kg/day in patients with SBS-IF. Three groups

were evaluated: Group 1 (no colon/stoma present/no colon-in-continuity), Group 2 ($\geq 50\%$ colon/no stoma/colon-in-continuity), and Group 3 (other bowel anatomies). Clinical response was defined as $\geq 20\%$ reduction from baseline in weekly parenteral support (PS) volume at Weeks 20–24. Data presented as mean (SD).

Results: The predominant diagnosis in Group 1 was Crohn's disease, whereas the predominant diagnosis in Group 2 was vascular complications (Table). Group 1 patients required the highest baseline PS volumes compared with Group 2 or Group 3. TED-induced PS volume reduction (change in L/week) took longer to be realised in Group 2 (Week 12, -0.9 [1.2]; Week 24, -2.5 [2.1]) compared with Group 1 (Week 12, -5.5 [3.8]; Week 24, -6.4 [4.5]) or Group 3 (Week 12, -2.7 [1.2]; Week 24, -5.1 [3.7]). Response rates were higher with TED versus placebo in all groups, but the difference was significant only in Group 1 (76% vs 19%, $P=0.001$; Group 2, 56% vs 40%, $P=0.36$; Group 3, 57% vs 29%, $P=0.33$). Adverse events were reported by 94%, 72%, and 86% of Group 1, Group 2, and Group 3 patients receiving TED, respectively.

Table: Baseline Patient Characteristics

Parameter	Group 1: No Colon, Stoma Present, No Colon-in-Continuity		Group 2: $\geq 50\%$ Colon, No Stoma, Colon-in-Continuity		Group 3: Other Bowel Anatomies	
	TED (n = 17)	PBO (n = 16)	TED (n = 18)	PBO (n = 20)	TED (n = 7)	PBO (n = 7)
Mean (SD) age, year	52.1 (10.3)	50.7 (12.9)	51.3 (14.9)	50.3 (18.7)	49.6 (11.7)	46.0 (13.2)
Sex, n (%)						
Men	8 (47)	7 (44)	9 (50)	10 (50)	3 (43)	2 (29)
Women	9 (53)	9 (56)	9 (50)	10 (50)	4 (57)	5 (71)
Mean (SD) BMI, kg/m ²	23.6 (3.6)	22.4 (3.2)	22.1 (2.9)	22.3 (3.0)	20.8 (2.1)	22.0 (3.6)
Cause of SBS–IF, n (%)						
Crohn's disease	9 (53)	7 (44)	0	0	1 (14)	1 (14)
Vascular complications	2 (12)	2 (13)	9 (50)	13 (65)	2 (29)	1 (14)
Injury	1 (6)	3 (19)	3 (17)	1 (5)	0	0

P1290 GENE EXPRESSION PROFILING OF SUPERFICIAL SPORADIC NON-AMPULLARY DUODENAL EPITHELIAL TUMORS

Y. Sakaguchi¹, N. Yamamichi¹, S. Tomida², C. Takeuchi¹, Y. Takahashi¹, N. Kageyama-Yahara¹, M. Fujishiro¹, K. Koike¹

¹Dept. Of Gastroenterology, University of Tokyo, Tokyo/Japan

²Graduate School Of Medicine, Dentistry And Pharmaceutical Sciences, Okayama University, Okayamashi/Japan

Contact E-mail Address: sakaguchi-ky@umin.ac.jp

Introduction: Sporadic non-ampullary duodenal epithelial tumors (SNADETs) are rare, accounting for less than 1% of gastrointestinal neoplasms, and thus

the mechanism behind the pathogenesis and carcinogenesis of these neoplasms is still poorly understood. However, with the overall increase of small bowel cancer in recent years, there is an increasing need to clarify the morphology of SNADETs. This study was conducted with the objective of identifying genetic markers and pathways specific to superficial SNADETs through gene-expression analysis.

Aims & Methods: This was a prospective pilot study on patients with a diagnosis of superficial SNADETs who were treated at the Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo Hospital, Tokyo, Japan. Before enrollment, all patients had undergone endoscopic evaluation to preclude ampullary lesions, and had a preoperative histologic diagnosis of either adenoma or adenocarcinoma. Patients with familial polyposis were excluded. Immediately before resection of the target lesions, a single biopsy sample from the duodenal tumor and a paired sample from the surrounding normal duodenal mucosa were endoscopically obtained from each patient, followed by RNA extraction. Gene expression profiling with an oligonucleotide microarray was performed in a training set of 4 matched tumor-normal tissue superficial SNADET pairs. Genes and pathways with consistent differences between pairs were identified, followed by a set-level gene enrichment analysis with a pre-validated curated gene set. Results were confirmed with rt-PCR in all other independent SNADET pairs.

Results: From Nov 2014 to Jan 2016, a total of 12 consecutive patients were enrolled in this study. One patient was excluded due to a post-treatment diagnosis of familial polyposis. In a training set of 4 tumor-mucosa pairs, 626 probes (168 up-regulated, 458 down-regulated) which consistently demonstrated over a 2-fold expression difference between tumor and normal mucosa in all matched pairs were identified. Rt-PCR of genes most highly differentially expressed between the tumors and normal mucosa was performed in the 4 pairs in the training set as well as 7 independent pairs. Consistent gene expression patterns concurrent with microarray results were demonstrated in all pairs, confirming the results of this study. Gene set enrichment analysis of the training set using a curated data set demonstrated a strong association between SNADETs with colorectal adenomas ($p < 0.00001$) and APC down-regulation ($p < 0.00001$). No other significant associations were demonstrated.

Conclusion: Superficial SNADETs demonstrate gene expression characteristics with a strong resemblance to colorectal adenomas. Gene expression characterization of these lesions has also demonstrated the significant role of APC down-regulation in the pathogenesis of SNADETs, suggesting that an adenoma-carcinoma sequence similar to colorectal adenomas may be seen in SNADETs. Further analysis of genes which may play a key role in the carcinogenesis of these neoplasms is required.

P1292 USE OF 3D COMPUTED TOMOGRAPHIC ENTEROCLYSIS TO OBTAIN INFORMATION ON THE LENGTH OF THE SMALL INTESTINE AND ON THE SIZE, SHAPE, LOCATION OF INTESTINAL NEOPLASIAS

T. Yoshikawa, K. Ohno, T. Kurokami

Dept. Of Gastroenterology, Shizuoka General Hospital, Shizuoka/Japan

Contact E-mail Address: t-yoshi@med.nagoya-u.ac.jp

Introduction: We established a new imaging technique, 3D computed tomographic (CT) enteroclysis, to explore the small bowel (1). In our hospital, this examination is performed routinely to detect gross lesions in the small intestine. In our study, we analysed the clinical performance of 3D CT enteroclysis to evaluate its safety, feasibility, and usefulness for small intestinal neoplasias.

Aims & Methods: Data on 3D CT enteroclysis performed in our hospital from January 2010 to March 2017 were reviewed. In 3D CT enteroclysis, the small bowel was inflated with air using a nasoduodenal tube. CT images were taken, and then 3D overviews, virtual endoscopy views, and virtual dissection views were generated using a virtual colonoscopy system. Total volume of injected air, intrainstestinal pressure, and length of the depicted small bowel were recorded. The images of small intestinal neoplasias were collected and compared to intraoperative findings.

Results: One-hundred thirty-nine 3D CT enteroclysis were performed for 93 males and 46 females. The mean age was 49.2 y (17–87). Examinations were performed for definite/suspected Crohn's disease in 55, intestinal obstruction in 54, small intestinal neoplasias in 25, and others in 5 patients. Vomiting/belching and abdominal pain (requiring pain medication) were noted in 10 and 5 patients, respectively, but no additional treatments were necessary. The volume of air and intrainstestinal pressure were recorded in 77 examinations for patients without previous resection of the small bowel. The mean total volume of injected air was 1872 ± 656 ml, the mean maximum intrainstestinal pressure was 2.7 ± 0.8 kPa, the mean length of the depicted small bowel was 517 ± 102 cm, and whole small bowel tracing was achieved in 71.4% of these 77 examinations. Twenty small intestinal neoplasias were depicted in 4 cases of submucosal tumors, 3 cases of gastrointestinal stromal tumors (GISTs), in 3 cases of neuroendocrine tumors, in 2 cases of cancers, in 2 cases of lipomas, 2 cases of malignant lymphomas, 1 case of metastatic cancer, 1 case of Peutz-Jeghers syndrome, 1 case of Peutz-Jeghers type polyp, and 1 case of pyogenic granuloma. Surgery was performed for 12 cases; the total length of the small intestine and estimated location of the lesion by 3D CT enteroclysis were comparable to intraoperative findings in 9 cases (no measurement in 3 cases). In a case of multiple GISTs, some of the lesions of 6–8 mm in size were missed and no lesion smaller than 4 mm was depicted.

Conclusion: 3D CT enteroclysis can be performed safely, and the whole small bowel could be examined in most cases. 3D CT enteroclysis can depict stenosis and lesions bigger than 1 cm, measure the length of the small intestine, measure

the size and locate the position of the lesions, and present objective information for surgery and follow-up of small intestinal neoplasias. Therefore, 3D CT enteroclysis is a powerful new tool for diagnosis, pre-surgical evaluation, and follow-up for small intestinal neoplasias.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1293 INK TATTOOING FOR BALLOON-ASSISTED ENTEROSCOPY—TIME WELL SPENT?

C. Römmele¹, A. Ebigo¹, H. Messmann¹, S. Gölder¹

¹Department Of Internal Medicine Iii, Klinikum Augsburg, Augsburg/Germany

Contact E-mail Address: christoph.roemmele@klinikum-augsburg.de

Introduction: Balloon-assisted enteroscopy is a well-established tool in the diagnosis and therapy of small bowel diseases. Ink tattooing of the small bowel is used in some centers to mark pathologic lesions or the depth of small bowel insertion.

Aims & Methods: The purpose of this study was to determine the safety, the detection rate within a surgical operation or video capsule endoscopy and the clinical relevance of ink tattooing during balloon-assisted enteroscopy (BAE). Between 01.01.2010 to 31.12.2015 229 BAE were performed in 156 patients (pts) at the endoscopy unit of Klinikum Augsburg. We performed a retrospective analysis of all 81 (52%) patients who received an ink tattooing during BAE.

Results: Main indications for BAE were known angiodysplasia (37 pts), suspected bleeding of the small intestine (32 pts) and anemia (19 pts). Other indications were known or suspected tumor of the small intestine (17 pts) and Crohn's disease (3 pts). In 27 patients no pathologic findings were found. In 41 patients an active bleeding, angiodysplasia or hemangioma were found and further therapeutic interventions were performed. Tumor/polyps (11 pts), inflammatory lesions (7 pts) and ulcerative diverticula (1 pts) were other findings. In all 81 patients ink tattooing of the small intestine was performed with no complications. 46 (57%) of 81 patients received a follow-up mainly due to re-bleeding. 5 Patients underwent surgery directly after enteroscopy with ink-tattooing and therefore received no follow-up. In total 26 (32%) patients received a capsule endoscopy after BAE at our hospital. The ink tattooing could be detected via capsule endoscopy in 19 of these 26 patients (73%). The ink tattooing of the previous antegrade BAE could be detected via retrograde BAE only in 2 of 11 (18 %) patients. Nine patients received a second ink-tattooing of the small intestine within these examinations without any complications. Ink tattooing had no clinical relevance or therapeutic consequence in 62 of the 81 (72%) patients within the observation period. 5 of these 62 Patients received no further diagnostic or therapeutic steps due to their clinical situation. In 9 patients ink tattooing influenced the choice of approach (antegrade versus retrograde) for re-enteroscopy after a video capsule endoscopy. In 7 patients the ink tattooing was used for intraoperative localization and in 3 patients for intraoperative localization as well as for enteroscopy. The intraoperative detection rate of the ink tattooing was 100%.

Conclusion: Ink tattooing of the small intestine is a minimally invasive and safe endoscopic procedure to mark the depth of scope insertion or a pathologic lesion during balloon-assisted enteroscopy. It is a useful tool to avoid unnecessary examinations and aids the intraoperative localization of pathologic lesions. A complete enteroscopy of the small intestine via BAE from retrograde and antegrade is achieved rarely in our setting.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1294 THE ROLE OF CAPSULE ENDOSCOPY IN THE DETECTION OF SMALL BOWEL TUMOURS IN A LOW-RISK POPULATION; A SINGLE-CENTRE EXPERIENCE

M. Hussey¹, G. Holleran², T. Nuzum¹, S. Crowther³, D. McNamara¹

Introduction: Small bowel tumours (SBT) are very rare and generally grow insidiously, with alarm symptoms such as obstruction and overt GIB often occurring at a later stage of disease. The introduction of small bowel capsule endoscopy (SBCE) has enabled earlier detection of SBT and has been shown to affect the therapeutic course. However, the reported frequency of small bowel malignancies diagnosed by SBCE is highly variable.

Aims & Methods: We aimed to review the frequency of small bowel tumours diagnosed by SBCE in a high-volume tertiary centre, and to assess the clinical presentation and outcome of patients. A retrospective review of the database in our institution was undertaken. All patients who had undergone SBCE from 2011–2016 were identified. All patients had undergone SBCE using the standard protocol. The Given SB3 Pillcam was used for the majority of procedures from 2014 onwards and the SB2 was used prior to 2014. All videos were analysed by experienced gastroenterologists and reported using the Rapid reader software system (Given Imaging, Covidien, Medtronic, Yocneam, Israel). SBCE reports for all indications were reviewed and all patients with reports suggestive of a small bowel tumour were included initially. A chart review was then performed

and information was obtained on patient demographics, clinical presentation/indication for SBCE, laboratory markers, previous endoscopic or radiological procedures, further endoscopic or surgical interventions carried out, and final histological diagnosis. Only patients who went on to have a histological diagnosis of a small bowel malignancy were included in the final analysis.

Results: A total of 1670 SBCEs were carried out. The overall indications for SBCE were as follows: suspected small bowel Crohn's disease 34% (n=568), iron deficiency anaemia/obscure occult GIB 41% (n=685), obscure overt GI bleeding 16% (n=267), non-specific abdominal pain 6% (n=100), known or suspected polyposis syndrome 2% (n=33) or Coeliac disease 1% (n=17). In total 1% (n=19) of SBCE reports identified a possible small bowel tumour. Of these, a final histological diagnosis of a small bowel malignancy was made in 14 patients. Of the 5 patients with a benign diagnosis, one patient was diagnosed with myoepithelial hamartoma, two patients an adenomatous polyp, one a lymphangioma, and one ganglion cells only. Of the 14 patients diagnosed with a small bowel malignancy, the majority, 71% (n=10) were female and the mean age was 58 years (18–90). The indication for referral in 12 (86%) patients was obscure gastrointestinal bleeding, with occult bleeding in 57% (n=8) and overt bleeding in 29% (n=4). Only one patient was referred for SBCE due to abnormal imaging and the other patient had persistent diarrhoea. The mean length of time from presentation to diagnosis of their small bowel tumour by SBCE was 18.8 months (16–24). Patient's mean Haemoglobin at diagnosis was 10.6 g/dL (7.4–12.4). Only 3 patients had a recognised risk factor, 2 with coeliac disease and 1 patient had previous colorectal cancer. In 79% (n=11) of all patients, SBCE was the first investigation suggestive of a small bowel tumour. In all, 7 (50%) patients underwent cross sectional imaging prior to SBCE, of which 3 (42%) had a reported no small bowel abnormalities. All patients had undergone at least one negative upper and lower endoscopy prior to referral, and SBCE was the third investigation in 50% (n=7) of patients. After SBCE, 60% (n=8) of patients underwent a double balloon enteroscopy (DBE) for further evaluation of findings and to obtain tissue samples. In terms of histological diagnoses, adenocarcinomas were found in 43% (n=6), Neuroendocrine tumours in 29% (n=4), Gastrointestinal stromal tumours (GISTs) in 14% (n=2), and lymphoma in 14% (n=2). All patients eventually underwent surgical resection of their small bowel tumours and 80% (n=11) patients remain well at present, after a mean follow up time of 15.2 months (2–36).

Conclusion: SBT are rare but accounted for 1% of significant SBCE findings in our cohort. The lack of concordance between SBCE and cross sectional imaging suggests this modality should remain an early diagnostic test in OGIB.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The western diet (WD) high in fat and fructose is considered one of the most relevant cause of metabolic disorders and cardiovascular diseases (CVD). The aim of this study was to evaluate whether daily vitamin D₃ supplementation is able to modulate hepatic steatosis, or restore insulin resistance and the metabolic alterations contributing to CVD and heart failure (HF) caused by a westernized diet, in a rat model without specific vitamin D deficiency.

Aims & Methods: Eighteen adult male Wistar rats were divided into 3 groups, each of 6 rats, fed with: Group 1: Standard Diet, 3.3 kcal/g (SD); Group 2: Western Diet, 5.6 kcal/g, (WD) containing 13 IU/day/rat of vitamin D₃; Group 3: Western Diet + Vit D (WD Vit D) containing 23 IU/day/rat of vitamin D₃. The experiment was conducted for 6 months. Standardized tail-cuff blood pressure (BP) measurements of conscious rats and transthoracic echocardiography were performed in basal condition (Time 0), and after 3 and 6 months of diet. Hepatic steatosis and collagen myocardial fibrosis were assessed using standard methods. Serum insulin and 25(OH)D₃ concentrations were determined using rat-specific ELISA kits. Insulin resistance was determined according to the Homeostasis Model of Assessment (HOMA-IR) method.

Results: In WD rats the percentage of hepatocytes with steatotic vacuoles was 61%, while in WDVitD group was only 27%. In WD group HOMA-IR was significantly higher than in SD (41.9 ± 8.9 vs 6.17 ± 1.3, p < 0.01) and it was reduced by vitamin D supplementation in WDVitD group (41.9 ± 8.9 vs 19.4 ± 5.2, p < 0.05). At baseline, no differences in systolic blood pressure (SBP) were detected among the three groups showing normal systolic blood pressure. SD did not increase SBP, significantly, during the study period. On the contrary, WD, enhanced SBP by 27 ± 12% p < 0.001 at 3 months, and by 47 ± 11%, p < 0.001 at 6 months. At the end of the study, SBP resulted to be higher in WD group (117 ± 3 mmHg) compared with both SD (84 ± 3 mmHg, p < 0.001) and with WDVitD (101 ± 4 mmHg, p < 0.01). During the study period, WD group showed a significant increase of left ventricular mass (LVM) (52 ± 25% at 3 months p < 0.05, and 123 ± 43% at 6 months p < 0.001, vs basal conditions). Supplementation of VitD abolished the WD-induced increase of LVM (25 ± 19% at 3 months, and 34 ± 20% at 6 months, p < 0.05 vs baseline respectively). At the end of the study LVM resulted to be higher in the WD group in comparison to both SD and WDVitD groups, while

no difference was detected between SD and WDVit.D. However, some collagen staining resulted still present in WDVit.D rats.

Conclusion: These results suggest that a daily supplementation of vitamin D₃ is able to improve insulin sensitivity, and to prevent diabetes. Vitamin D₃ also reduced hepatic steatosis and prevent cardiac alterations such as the increase of systolic blood pressure and left ventricular hypertrophy in WD rats.

Introduction: Gastric balloons (IGB) are an emerging option for overweight and obese patients with a body mass index (BMI) greater than 31 kg/m² and they provide greater efficacy with lower risks than do conventional surgical procedures. The balloon treatment is based on gastric space-occupying effects that increase the feeling of satiety and may also effect gut neuroendocrine signaling. However, widespread use of current generation IGBs has been limited by several factors: placement and removal endoscopies require sedation, special training and equipment; patients lost to follow-up are susceptible to IGB deflation and unplanned passage into the gastrointestinal tract. The Elipse™ is the world's first procedureless gastric balloon that not require endoscopy or anesthesia.

Aims & Methods: We conducted a study to prospectively analyze the safety and effectiveness of IGB ELIPSE in overweight adults. Six patients, 1 male and 5 female (average age 40, mean BMI = 40 kg/m²), were included in this study. Each patient swallowed Elipse™ balloon intended to remain in the stomach for 16 weeks. Each balloon was filled with 560 mL of filling fluid. Patients returned every 2 weeks for abdominal ultrasound which documented the correct positioning of the device. All patients were followed up by a nutritionist with a specific semiliquid diet.

Results: All 6/6 patients successfully swallowed the device. There were no major adverse effects. All 6 patients had a significant weight loss (about 16 Kg). In all of the patients, the balloon remained full throughout 16 weeks, self-emptied, and were passed spontaneously without needing endoscopic removal.

Conclusion: This study demonstrates the efficiency, security and simplicity of the Elipse™ system. Moreover, we highlighted the non necessity of deep sedation and use of invasive endoscopic examinations for positioning and removal of the IGB.

Disclosure of Interest: All authors have declared no conflicts of interest.

²Department Of Nutrition, Attikon University General Hospital, Athens/Greece

Contact E-mail Address: ktriant@med.uoa.gr

Introduction: There is evidence that the level of nutrition is a major determinant for the outcome of hospitalized patients. The Malnutrition Universal Screening Tool (MUST) is a five-step screening tool using the Body Mass Index (BMI), unintentional weight loss before admission and the effect of acute disease on subject's nutritional status to identify adults who are malnourished, at risk of malnutrition or obese. It also includes management guidelines which can be used to develop a care plan. Although it is simple and quick, its use varies widely among different health care settings.

Aims & Methods: We aimed to evaluate the need of nutritional support consultation, the rate of MUST tool use by the treating physicians and the rate of nutritional support services utilization in a tertiary Greek hospital. This was a prospective, cross-sectional, nutritional service-utilization, chart-review study of hospitalized patients with follow-up until discharge, in a tertiary 500 beds hospital in Athens, Greece. We reviewed data of patients admitted during three consecutive hospital on-call days in March 2017 regarding the number of patients at need for nutritional consultation during hospitalization and at

discharge. Intensive care, psychiatric, pediatric, obstetrics and day clinic admissions were excluded. We used data from patient's MUST tool (in case of absence of these data, we calculated the MUST score using subject's data) to identify patients at high risk of malnutrition and we used BMI to identify overweight and obese subjects. We measured the utilization of the nutrition department services according to the actual consultations.

Results: We included data from 461 patients (50% males, aged 67 ± 19 yrs). MUST evaluation for malnutrition was not available in any of the reviewed charts. We therefore calculated the MUST score using the available data in the charts. There were 73 (15.8%) overweight-obese and 85 (18.4%) at high risk of malnutrition patients admitted at the internal medicine (n = 127) and surgery (n = 31) sections of the hospital. Nutritional consultation was requested in 4 (3.1%) and 1 (3.2%) internal medicine and surgery patients, respectively by the treating physician during hospitalization. Among the 383 patients discharged at the end of our observation, there were 72 (18.8%) overweight-obese and 46 (12%) at high risk of malnutrition patients. Nutritional consultation was recommended in 24 (6 obese, 15 undernourished and 3 patients with low MUST score) of them.

Conclusion: MUST -a simple screening tool for malnutrition- is not used by the medical staff and nutritional support services are significantly underutilized in a tertiary Greek hospital.

²Surgery, Min-Sheng General Hospital, Taoyuan/Taiwan

Contact E-mail Address: minglun@ms18.hinet.net

Introduction: Bariatric surgery is an effective treatment for morbid obesity. In Taiwan, the numbers of patient who received bariatric surgery increased gradually. However, for long-term follow-up, nutritional deficiency may develop in post-bariatric (metabolic) surgery patients, especially in patients who received mal-absorptive or combination procedure. Deficiency of nutrition may cause anemia, peripheral neuropathy, secondary parathyroidism and osteoporosis. Follow-up of the nutritional status for patients after bariatric surgery is an important issue.

Aims & Methods: The aim of our study is to evaluate the change of Vitamin D and bone Mineral Density after bariatric surgery in Chinese population. This prospective cohort study included 50 patients (ranged from 20 to 65 years old) who received bariatric surgery at one teaching hospital in Taoyuan, Taiwan. Patient with osteoporosis before surgery were excluded in this study. Baseline (2012–2014) and one year after bariatric surgery (2013–2015), venous blood was collected from each patients for assessment of the Calcium, Vitamin D and parathyroid hormone (PTH) levels. BMD (g/cm²) was also measured at lumbar spine (L2–L4) by dual energy x-ray absorptiometry (DEXA).

Results: Among 50 patients, 15 patients received laparoscopic sleeve gastrectomy, 24 patients received laparoscopic mini-gastric bypass (MGB), 5 patients received laparoscopic Roux-en-Y gastric bypass (RYGB) and 6 patients received laparoscopic duodeno-jejunal bypass with sleeve gastrectomy (DJB-SG). The characteristic of the study population was shown as table 1. The differences of mean for calcium, vitamin D, PTH and BMD after bariatric surgery were -0.16 mg/dl (P = 0.03), 4.2 ng/ml (P < 0.01), 8.6 pg/ml (P = 0.06) and -0.04 g/cm² (P = 0.14) respectively.

Table 1: Characteristics of study population one year after bariatric surgery

	LSG	MGB	RYGB	DJBSG	OVER ALL
N	15	24	5	6	50
Age, years	34.7 (7.4)	37.4(11.7)	41.4(14.1)	44(10)	37.8(10.5)
Sex(M:F)	7:8	5:19	2:3	3:4	17:33
BMI(kg/m ²)	29.8(4.7)	27.6(4.4)	27.9(2.9)	24(2.4)	
CA(mg/dl)	9.6(0.3)	9.1(0.3)	9.2(0.4)	9.3(0.4)	9.5(0.4)
PTH-I(pg/mL)	63.8(21.3)	70.4(25.9)	73.1(4.2)	50(14)	62(29.4)
VIT.D (ng/ml)	19.4(7.7)	14(6.9)	12.9(8.6)	16.9(5.3)	15.6(7.5)
VIT.D insufficiency (< 10 ng/ml)	1(6.7%)	8(33.3%)	3(60%)	0	12(23.5)
VIT.D deficiency (< 5.3 ng/ml)	0	0	1(20%)	0	1(2%)
BMD(g/cm ²)	1.11(0.25)	1.15(0.23)	1.18(0.26)	1.11(0.19)	1.15(0.17)

Conclusion: One year after bariatric surgery, the prevalence of osteoporosis and osteopenia was low. The serum Vitamin D level increased significantly but no significant change of BMD was noted. Further longitudinal studies are warranted to clarify the long-term effect of bariatric surgery on BMD in Chinese population.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI300 INTRAGASTRIC BALLOON: A LARGE BRAZILIAN MULTICENTRIC STUDY OVER 10,000 CASES AND 20 YEARS OF EXPERIENCE

Introduction: The intragastric balloon has been used for more than 20 years in Brazil as an endoscopic method for assisting weight loss, and some interurrences were observed during more than 10,000 procedures performed. With the assistance of a multidisciplinary team the results have been satisfactory.

Aims & Methods: To assess the efficacy and complications of the weight loss with IGB in patients seen at the 07 private centers. A total of 10,255 patients with IGB implanted from 1997 to 2017 were analyzed from a prospective fed databank. A liquid filled IGB with a volume in-between 620 to 700 ml was used. Initial BMI started at 27 kg/m² (as approved by Brazilian health authorities) and were followed up by a multidisciplinary team during implant. IGB maximum period implant was 09 months. Statistical analysis was performed according to sex and degree of excess weight (overweight and grade I, II and III). Data were analyzed using Student t-test, and Tukey post-test. The level of significance was set at $p < 0.05$.

Results: 492 patients (4.8%) were excluded from the final analysis associated with weight loss: 226 (2.2%) due to early removal—These were analyzed in relation to the previous consultation with psychologist and 94% of them did not make a psychological evaluation before the procedure, 158 (1.54%) due fail on weight loss or weight gain—These were analyzed in relation to follow-up with nutritionist and 88% did not undergo nutritional monitoring during the use of IGB, 108 (1.05%) due to incomplete data. There were also spontaneous hyperinflation on 0.99% (n = 101) and balloon spontaneous deflation or leakage in 0.82% (n = 84). Incidence of complications not leading to removal were 6.65% (n = 682). Complications other happened as fungal contamination in 7.9% (n = 810); Wernick Korsakoff syndrome 0.01% (n = 2), pregnancy during implant period was 1.2% (n = 123) and Dieulafoy lesion 0.009% (n = 1). The incidence of complications with IGB removal was 0.05% (n = 6): gastric perforation. On the 9,763 remaining patients, 7,615 (78%) were women and 2,148 (22%) were men. Mean age was 31.13 years. The patients showed a significant weight loss, with a significantly lower final BMI (27.16 \pm 8.42 kg/m²; range: 15.71–34) than the initial BMI (33.42 \pm 6.62 kg/m²; range: 27–79.35). The mean Weight Loss was -16.98 kg (+/-16.8 kg). Percent EW L was higher in the overweight group (129.92%EWL), followed by obesities grades I (73.64%), II (57.85%) and III (41.33%) sequentially. A total of 5.2% (66/1,268) of the patients followed up for 18 months after withdrawal of the IGB were submitted to bariatric surgery.

Conclusion: The intragastric balloon has been established as an valid endoscopic therapeutic option for weight loss, especially in patients with overweight and obesity grades I and II and multidisciplinary team follow-up is mandatory for successful treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The weight regained has been a described growing problem in patients after bariatric surgery. This weight regained is multifactorial and associated with dilation of Gastrojejunostomy (GJ). For the patients with significant weight regain some revisional procedures had been attempted and more recently endoscopic revisional procedures had been described.

Aims & Methods: To evaluate the safety and effectiveness of argon plasma coagulation (APC) decreasing the diameter of the gastroenteric anastomosis in patients who have undergone RYGB for morbid obesity and regained weight associated to dilation of the GJ. From Jan-2014 to April-2017 554 RYGB subjects with weight regain a dilated anastomosis (>18 mm) and at least 2 years from procedure were submitted APC application. In relation to the anastomotic diameter, the majority of studies use a diameter of more than 20 mm to define anastomosis dilation, although some studies use smaller diameters such as 12 mm, similar to that created manually in the gastrojejunal anastomosis using a 36 Fr Fouchet bougie. In the patients in the present study, the minimum cross-section diameter was 18 mm and the maximum measured in the first session 40 mm. This anastomotic diameter was measured using a 33-mm long Olympus® articulated device. Interval between an APC session was 60 days with a maximum of 03 applications. APC set was at 2–3L/m with 65–85W. GJ diameter target was 8–12 mm estimated with pre-measured grasper. At first APC session, pre-op weight and BMI, post-op weight nadir, actual weight and BMI and estimated diameter of GJ were the variables collected. Complications during treatment were also collected. In the present study, psychological and nutritional evaluations were performed before APC and during treatment and physical activity was strongly recommended. Data were analyzed with descriptive statistics, student's t test and Spearman correlation.

Results: Of the 554 patients, 79.06% were women and 20.94% were men. Average time between bariatric surgery and the first APC was 96.35 months (\pm 42.17) and average weight regained in this interval was 22.08 kg (\pm 11.05). The mean diameter of the anastomosis was 24.78 mm (\pm 6.04) and the average number of APC sessions were 1.78 times (\pm 0.61). The average reduction of anastomotic diameter was 14.86 mm (\pm 7.24) and the final average diameter was 11.79 mm (\pm 3.89). The average weight loss between the first and last APC was 13.37 kg (\pm 7.82) and the average decrease of BMI was 4.59 kg/m² (\pm 2.78). 122 patients (22.02%) did not achieve the target GJ diameter and 05 patient (0.9%) did not lose weight even with the desired GJ diameter. From the 146 subjects (26.36%) followed up to 12 months, the weight regain was less than 20% of the weight loss. Of the 554 patients APC, 51 (9.2%) required dilatation balloon due to symptomatic stenosis at least once. No further complications were reported.

Conclusion: Argon Plasma Coagulation (APC) has been shown to be an effective and safe endoscopic technique for the reduction of gastro enteric anastomosis in patients undergoing bariatric surgery who have regained weight with dilation of the anastomosis. The reintroduction of the patient to the multidisciplinary team is mandatory in cases of weight regain and loss to postoperative follow-up. A psychological and/or psychiatric evaluation is mandatory, as well as nutritional therapy and encouragement of physical activity. The monitoring of food intake and body weight, closer follow-up of the operated patients, appropriate choice of technique according to the patient and the experience of the surgeon, and a good learning curve are all factors that can reduce the failure rate of bariatric surgery. The reintroduction of the patient to the multidisciplinary team is mandatory if better results and sustainable weight loss and comorbidity control are to be obtained.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: With the aging of the population, the incidence of obesity has also increased among the elderly. However, there is a higher incidence of severe comorbidities in this population comparing to adults, which often makes bariatric surgery unfeasible. In this scenario, treatment with the intragastric balloon (IGB) may be an interesting option.

Aims & Methods: We aimed to assess the efficacy and complications of obesity treatment in the elderly using a non adjustable IGB. A total of 77 patients were analyzed. The minimal initial body mass index (BMI) was 28 kg/m². The level of significance was set at $p < 0.05$.

Results: 58 patients were women (75.3%). Mean age was 64.26 (60–80) years. Ten patients had no comorbidities, 52 had hypertension, 45 had dyslipidemia, 32 had insulin resistance, 12 had type II diabetes, and 10 had ischemic heart disease. There was no major complications. Results are shown on table 1. The treatment success rates according to the following criteria: $\geq 10\%$ total body weight loss (TBWL) and $\geq 25\%$ excess weight loss (EWL) were 96.11% (74 patients) and

98.7% (76 patients) respectively. 30 patients reached a normal body mass index (BMI) (23–28 kg/m²) according to the Pan American Health Organization (OPAS). Elderly shows a higher BMI reduction ($p=0.0002$) and %TBWL ($p=0.0003$) than adults.

Table 1

	n = 77
Body weight(kg)	
Baseline	103.37 ± 17.14
Final	81.66 ± 15.71
Reduction	21.71 ± 7.58
%TBWL	21.07 ± 6.07
BMI(kg/m ²)	
Baseline	37.89 ± 5.41
Final	29.86 ± 4.76
Reduction	8.03 ± 2.88
Excess weight(kg)	
Baseline	35.53 ± 16.98
Final	13.82 ± 15.49
%EWL	69.27 ± 30.01

* $p < 0.0001$ for all comparisons between values at baseline and at the end of the study. IGB(intragastric balloon); TBWL(total body weight loss); EWL(excess weight loss)

Conclusion: Endoscopic treatment of obesity with an IGB shows to be an excellent therapeutic option for the elderly.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1303 THE EFFECT OF A CONTROLLED GLUTEN CHALLENGE IN PATIENTS WITH SUSPECTED NON-COELIAC GLUTEN SENSITIVITY: A RANDOMIZED, DOUBLE-BLIND PLACEBO-CONTROLLED CHALLENGE

Introduction: Non-coeliac gluten sensitivity (NCGS) is a new entity with unknown prevalence and mechanisms, and there is a need for a standardized procedure to confirm the diagnosis. The objective of this study was to characterize the response to a gluten challenge, when performed according to the updated Salerno criteria.

Aims & Methods: Twenty patients (14F/6M, age range: 21–62 y) with suspected NCGS, without coeliac disease and wheat allergy, were included while on a gluten-free diet. All patients went through four periods of double-blinded provocation with gluten and placebo containing muffins. They were instructed to eat two muffins a day (11 g gluten) for four days, followed by a three days' wash-out. Gastrointestinal symptoms were recorded with questionnaires at baseline and after each provocation, while fatigue and quality of life were registered at baseline and end of the trial.

Results: Four out of twenty patients (20%) correctly identified the two periods when they received muffins containing gluten, hence were diagnosed with NCGS. The diagnosed group tended to show higher symptom scores than the not-diagnosed group both at baseline, after gluten exposure and after placebo, but no clear difference was seen in symptom change after provocation with gluten and placebo. The not-diagnosed group showed more severe symptoms with placebo than with gluten ($p=0.029$). Symptom severity at baseline was significantly correlated with fatigue ($r=0.63$, $p=0.003$) and reduced quality of life ($r=0.76$, $p=0.0001$).

Conclusion: This randomized, double-blind placebo-controlled challenge with gluten diagnosed four patients with NCGS according to the Salerno criteria. However, according to the symptom registrations there are no clear difference between the diagnosed and the not-diagnosed group, or between symptoms after gluten provocation and placebo, indicating no specific effect of gluten in a group of patients with suspected NCGS.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1304 THE ROLE OF BILE ACIDS AND GUT MICROBIOTA IN CORONARY ARTERY DISEASE: RESULTS OF THE MABAC STUDY IN HUMAN (MICROBIOTA ATHEROMA AND BILE ACID IN CORONARY DISEASE)

Introduction: By targeting specific receptors into the vascular system, bile acids (BA) are cholesterol derivatives that are now considered as hormones. BA regulates the basal energy expenditure and gluco-lipidic metabolism. In animal models of atheroma development (ApoE -/- and Ldl -/- mouse model) a powerful anti-atherosclerotic effect of circulating BA has been evidenced: BA are metabolites of the gut microbiota, suspected to play a role in the development of atherosclerosis. This study examined whether variations in BA or in the gut microbiota composition can describe in the human Coronary Artery Disease pathophysiology.

Aims & Methods: Consecutive patients undergoing coronary angiography between February and May 2015 were enrolled. To avoid physiological or induced variations in circulating BA or in the gut microbiota, highly restrictive exclusion criteria were applied. Circulating and fecal BA were quantified by high pressure liquid chromatography and tandem mass spectrometry. The fecal microbiota composition was assessed by 454 pyrosequencing of the total fecal bacterial DNA.

Results: 80 patients were prospectively included of 406 screened, and divided in two groups: with ($n=45$) and a group without ($n=35$) CAD. The mean serum concentration of total BA was $1.02 \pm 0.16 \mu\text{mol/l}$ in patients with, versus $2.16 \pm 0.38 \mu\text{mol/l}$ in patients without CAD ($P=0.005$). This decrease, (adjusted for gender and age) was an independent predictor of CAD (odds ratio = 0.51; 95% confidence interval 0.31, 0.85; $P=0.01$). The BA concentrations in feces were similar in both groups. There was no group-specific pattern in the fecal microbiota. In a subgroup of 17 patients, one month of statin therapy increased the serum BA concentration from 0.68 ± 0.08 to $1.37 \pm 0.213 \mu\text{mol/l}$; $P=0.01$).

Conclusion: There was no specific microbiota signature associated with CAD. However, the decreased serum BA concentration was a strong predictor of CAD in humans. With respect to the powerful anti-atherosclerotic effect of BA in animal models, and their role in human lipid metabolism and diabetes, this study unraveled the existence of a new metabolic disturbance associated with CAD.

Introduction: The low-FODMAP diet (LFD) is used to treat patients with irritable bowel syndrome (IBS) even if some nutritional concerns have been raised. It starts with an elimination phase and is followed by a reintroduction phase to clearly detect the "symptom trigger" foods in order to suggest a definitive and less restrictive diet tailored to the patient.

Aims & Methods: The aims of this study were to evaluate: 1) the effects of FODMAP reintroduction on a) body composition and nutritional status, using Bioelectrical Impedance Vector Analyses (BIVA), b) abdominal symptoms, c) quality of life, d) anxiety/depression, e) sleep quality. 2) if the patients' perception of the "trigger" foods was accurate.

66 IBS patients (54F, 12 M; 44.8 ± 13.0 yrs.) started (T0) a LFD for 8 weeks (T1) and followed a 9–14 week reintroduction period (T2). They underwent blood tests at T0 and T1. BIVA, anthropometric data, IBS-Symptom Severity Score, Bristol Stool Chart (BSC), SF36, Hospital Anxiety and Depression Scale and Pittsburgh Sleep Quality Index were performed at T0, T1 and T2. The patients were monitored by a nutritionist to verify their compliance.

Results: Neither change of blood tests at T1 nor variations of anthropometric data and BIVA were reported at T1 and T2 in comparison with T0. A significant improvement in abdominal symptoms (IBS-SSS), anxiety and quality of life, was recorded at T1, this remaining unchanged also at T2 ($p < 0.0001$). Depression improved at T2 ($p < 0.01$ vs. T0). Sleep quality improved at T1 ($p < 0.05$ vs. T0) and at T2 ($p < 0.001$ vs. T0). Normal BSC feces were reported by 38 patients at T0 to 60 patients both at T1 and T2. The degree of symptom relief with the diet was 1.5 ± 0.6 at T1 and 1.6 ± 0.7 at T2 and the degree of satisfaction was high

both at T1 (8.4 ± 1.6) and T2 (8.2 ± 1.7). When starting, LFD patients considered as trigger foods lactose (67%), fructans (27%), fructose (17%), galacto-oligosaccharides (GOS) (17%) and polyols (3%); the reintroduction phase (T2) enabled us to detect lactose in 70%, fructans in 30%, fructose in 37%, GOS in 33% and polyols in 27%, as real triggers. The agreement (Cohen's kappa) was moderate for lactose ($k: 0.50$), fair for fructans ($k: 0.39$) and fructose ($k: 0.32$) and poor for polyols ($k: 0.16$) and GOS ($k: 0.01$).

Conclusion: Not only did reintroduction not affect the improvements achieved during the elimination phase, but it also precisely identified the foods responsible for the clinical manifestations. This enabled us to suggest a personalized diet for the patients. The real role played by FODMAPs in generating symptoms was abundantly underestimated and misunderstood by our patients. This underlines the fact that LFD has to be administered and carried out under the guide of an expert nutritionist.

Introduction: Fructose malabsorption (FM) is a frequent finding in patients with abdominal symptoms due to high levels of fructose in Western diets. The role of monosaccharide transporter dysfunction in the small intestine is incompletely understood. The aim of this study was to investigate the histoanatomical distribution of the main fructose transporter GLUT5.

Aims & Methods: The study included 257 patients with FM diagnosed by hydrogen breath test and grouped according to the response to a fructose-free diet. 42 healthy individuals and 31 patients with coeliac disease (CD) served as control. The fructose breath test was done with 50 g fructose. Fructose malabsorption was defined as an increase of 20 ppm of endexpiratory hydrogen. Formalin-fixed and paraffin-embedded duodenal biopsy specimens were obtained in all cases. Histology was assessed using hematoxylin and eosin stained tissue sections. Expression of GLUT5 was studied by immunohistochemistry. Expression patterns of GLUT5 were correlated with clinico-pathological patient characteristics. **Results:** The expression of GLUT5 did not differ significantly between patients with FM complete diet responders ($n=183$) and healthy controls ($n=42$). Also patients with FM responding to a fructose free diet did not differ in GLUT5 expression or in max. H₂ increase and AUC measured in fructose breath testing from patients not responding to the diet ($n=40$). However, in patients with CD ($n=29$) significant differences in GLUT5 expression were found compared to patients with FM and healthy controls ($p=0.009$). The severity of CD assessed by the Marsh score significantly correlated with the GLUT5 expression ($r_s = -0.563$, $p=0.001$).

Conclusion: Changes in GLUT5 expression may not cause symptoms in adult patients with FM. The symptoms induced by FM could be associated with mechanisms known in the pathology of irritable bowel syndrome. However, in secondary malabsorption decreased GLUT5 expression was detected. Further investigation is needed to understand the essential factors in FM and the influence on functional gastrointestinal disorders.

P1307 BETTER RESPONSE TO LOW FODMAP DIET IN JH NEGATIVE PATIENTS WITH DISORDERS OF GUT-BRAIN INTERACTION

V. Schindler¹, A. Zweig¹, A. Becker², J. Zeitz¹, D. Runggaldier¹, M. Fried¹, D. Pohl¹

¹Gastroenterology And Hepatology, University of Zurich, University Hospital Zurich, Zurich/Switzerland

²UniversitätsSpital Zürich, Zürich/Switzerland

Contact E-mail Address: valeria.schindler@usz.ch

Introduction: Previous studies have shown a reduction of gastrointestinal symptoms in patients with disorders of gut-brain interaction (FGID) when following a diet low in FODMAPs. Symptom relief due to a low FODMAP diet has especially been investigated in patients suffering from irritable bowel syndrome (IBS) and has proven to reduce gastrointestinal symptoms in up to 86% of patients with IBS. In addition, there is evidence for an association between gastrointestinal symptoms and joint hypermobility (JH). However, there is no clear data regarding response rates to a diet low in FODMAPs in patients suffering from JH. In this study we aimed to assess and compare the response to a diet low in FODMAPs in JH positive and JH negative patients with FGIDs.

Aims & Methods: Data of patients presenting with FGID at the tertiary ambulatory functional bowel clinic between January 2015 and July 2016 were analyzed. FGIDs were diagnosed according to Rome III criteria. JH was assessed by

physicians using Beighton score and rated positive for scores $\geq 4/9$ points. Patients received professional nutritional counseling on a diet low in FODMAPs. A global symptom response was assessed by a professional nutritionist after 4 to 6 weeks following a low FODMAP diet.

Results: Of all 84 patients screened for JH, 62 (73.8%) were female and 22 (26.2%) were male. Median age was 35 [range 18–79] years. Females were more likely to exhibit JH compared to males (38/62 [61.3%] vs. 6/22 [27.3%]; $p=0.006$). Global symptom response rate to a diet low in FODMAPs was 64/84 (76.2%). Our data showed significantly better response to a low FODMAP diet in JH negative patients than in JH positive patients (36/40 [90.0%] vs. 28/44 [63.6%], $p=0.005$, ITT). Response of 7 patients was unknown because of early therapy discontinuation before nutritional re-counseling. When excluding 7 patients with therapy discontinuation from our calculations, the difference in diet response between JH negative and JH positive patients remained significant (36/39 [92.3%] vs. 28/38 [73.7%]; $p=0.036$).

Conclusion: Our data indicate an association between global symptom response to a diet low in FODMAPs and joint hypermobility status in FGID patients. An underlying structural pathology or different pathophysiological factors (motility, intestinal permeability) causing gastrointestinal symptoms in JH positive patients and limiting response to low FODMAP diet should be considered. Our findings represent a further step towards pathophysiological features in FGIDs and might help to select patients for individually appropriate therapies.

Introduction: Gastrointestinal symptoms are often associated with dietary intolerances and are common in the developed world consuming a western diet low in fiber.

Aims & Methods: To determine the effect of a high-sugar, low-fiber diet on GI symptoms, small intestinal bacteria, and duodenal physiology. This is a prospective single-center study. Healthy adults with baseline fiber intake ≥ 14 g/1000 calories/day; $<10\%$ daily calories from added sugar; ≥ 5 servings of fruits and vegetables/day; and $\leq 13\%$ daily calories from saturated fat were recruited. Exclusion criteria included known GI disease or symptoms, antibiotic/probiotic use within 4 weeks of the study, pregnancy, and vulnerable adults. At baseline visit, participants completed a symptom and demographic questionnaire and underwent esophagogastroduodenoscopy (EGD) with duodenal biopsies and aspirates. Symptoms assessed included: constipation, straining, incomplete evacuation, hard stools, abdominal pain associated with bowel movements, diarrhea, bloating, nausea/vomiting, heartburn, fatigue, and appetite. All participants consumed a 7-day standardized diet with typical United States macronutrient calorie distribution: 50% carbohydrates, 35% fat, 15% protein. The diet was low in fiber (<10 g/1000 calories/day) and high in simple sugar ($\geq 50\%$ daily carbohydrates). After dietary intervention, participants filled out follow up questionnaires and underwent repeat EGD with duodenal biopsies and aspirates. Before and after the diet, quantitative aerobic and anaerobic cultures were performed on duodenal aspirates. Duodenal biopsies were mounted in an Ussing chamber. Intestinal permeability was evaluated using transepithelial electrical resistance (TEER) and FITC flux (4KDa; a measure of paracellular transport). Secretory responses were quantified in voltage clamp mode by measuring baseline short circuit current (Isc) and change in Isc (Δ Isc) in response to increasing concentrations (0.003–300 μ M) of serotonin (5-HT) on the submucosal side. These measurements were repeated after the dietary intervention. Data are presented as mean \pm SEM. Data were analyzed using paired-t test unless specified and $p < 0.05$ was considered significant.

Results: A total of 10 participants (5 female; median age 26; 70% Caucasian) were recruited. Average BMI was 23.1 kg/m². At baseline, all participants were asymptomatic. After dietary intervention, all patients endorsed at least one new symptom and 9/10 participants endorsed multiple (≥ 2) new symptoms. At baseline 4/10 participants had positive duodenal cultures ($> 100,000$ CFU/mL, anaerobic) despite having no symptoms. Of the 6 who had no growth initially, 1 developed bacterial overgrowth following intervention. There was no significant difference in TEER (26.45 ± 1.98 vs 26.18 ± 2.45 Ohms/cm²), FITC flux (217 ± 34.72 vs 217.6 ± 42.57 ng/ml) or baseline Isc (48.27 ± 6.39 vs 51.58 ± 6.83 μ A/cm²) before and after dietary intervention. Interestingly there was a significantly lower Δ Isc response to increasing concentrations of 5-HT after dietary intervention ($P < 0.05$, two-way ANOVA).

Conclusion: A low-fiber, high simple sugar diet led to gastrointestinal symptoms in participants who normally consume a high-fiber diet. This was associated with a significant decrease in 5-HT evoked secretory response in the duodenum, suggesting a potential role for dietary modulation of host serotonergic pathway. There was no correlation with quantitative bacterial cultures and there was no overall significant change in intestinal permeability. Diet may mediate these

effects via a qualitative change in gut bacteria but this still needs to be determined.

Introduction: Recently roles of gut hormones on appetite control have been known. Among them, CCK is well known to suppress appetite and gastric motility. On the other hand, patients of functional dyspepsia (FD) have hyper sensitivity to CCK. And levels of CCK in brain was shown to be high in FD patients. In FD patients, stress have important roles of pathogenesis of the disease.

Aims & Methods: We undertook to clarify whether stress influences the actions of cholecystokinin (CCK) on appetite and gastric emptying. As stress, we gave restraint stress, corticotropin-releasing factor (CRF) or urocortin1 (UCN1) injection intraperitoneally (IP). We also examined the effects of CCK and restraint stress on c-Fos expression in the neurons of appetite center of the brain. In the gastric emptying study, SD rats were fasted overnight. The amounts of the mixture (food and glass beads) left in the stomach were measured at 2 hours after the peroral injection of mixed food, and gastric emptying rate was calculated. In the study on appetite, CCK was IP injected and the amounts of food was measured at 1 and 2 hours after the injection. In some experiments, CRF or UCN1 was IP injected and the interaction with CCK on food intake was examined. In another study, restraint stress was given to rats and the interaction with CCK was evaluated. To study the involvement of brain in the interaction between CCK and stress, c-Fos expression in the neurons was examined and evaluated.

Results: CCK dose-dependently inhibited gastric emptying. CCK dose-dependently inhibited food intake during 1 hr and 2 hr. CRF (10 µg/kg rat) significantly inhibited food intake. However, there was no interactive action between CCK and CRF on food intake. UCN1 (3 nmol/kg rat) inhibited food intake at 1 and 2 hours. There was a synergistic action between CCK and UCN1 on food intake. Restraint stress amplified suppressive effect of CCK on gastric emptying and food intake. c-Fos expression of the neurons in the nucleus of solitary tract (NTS) and paraventricular nucleus of hypothalamus (PVN) by CCK was amplified by the addition of restraint stress.

Conclusion: The result suggests that stress might amplify anorexic effects of CCK through the activation of satiety center of the brain that might be the possible pathogenesis for postprandial distress syndromes of FD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1310 PEPTIDE TYROSINE-TYROSINE (PYY) ENHANCES EFFECTS OF CHOLECYSTOKININ (CCK) ON GASTRIC MOTILITY AND FOOD INTAKE IN RATS

E. Hosomi¹, N. Yamaguchi¹, K. Maezawa¹, M. Ochiai¹, S. Ro¹, K. Chieko¹, K. Takayama¹, K. Yakabi¹

Contact E-mail Address: hosomi@saitama-med.ac.jp

Introduction: Cholecystokinin (CCK) and peptide tyrosine-tyrosine (PYY) have been known to suppress appetite and gastric emptying. Both peptides raise in blood by feeding, and maintain high levels simultaneously for 1–2 hours. Therefore there might be possible to cause interactive actions between two peptides, inducing satiation to finish food intake.

Aims & Methods: In this study, we undertook to elucidate whether CCK and PYY have the interaction to decrease food intake. Study on gastric emptying. Male SD rats were fasted overnight, and 1 mL of mixture of food and glass beads was given into the stomach and then PYY or CCK or CCK followed by PYY was IP injected. The mixed food left in the stomach 1 hr after the injection was measured and gastric emptying rate was calculated. Study on appetite. PYY or CCK was IP injected to the rats just before setting food to eat. The amounts of food were measured at 1 and 2 hrs after the injection. To clarify the involvement of the brain in the interaction between CCK and PYY, c-Fos expression was examined.

Results: CCK (0.5–10 nmol/kg) dose-dependently inhibited gastric emptying ($p < 0.001$). CCK 10 nmol/kg maximally inhibited food intake ($p < 0.01$). PYY 25–2500 pmol/kg significantly inhibited gastric emptying for 1 or 2 hrs after the injection ($p < 0.01$). PYY 250 pmol/kg significantly inhibited food intake for 1 hr after the injection ($p < 0.01$). The combination of CCK 10 nmol/kg and PYY 250 pmol/kg inhibited gastric emptying more than CCK alone (significant, $p < 0.01$) or PYY alone (not significant). PYY and CCK additively inhibited food intake when PYY was injected 20 minutes later from CCK injection. PYY significantly amplified c-Fos expression induced by CCK in the nucleus of solitary tract (NTS) and paraventricular nucleus of hypothalamus (PVN) in the brain.

Conclusion: The combination of PYY with CCK amplified the suppression of gastric emptying and food intake. The result suggests that the sequencing secretion of CCK and PYY might strengthen the inhibition of food intake through the activation of satiety center in the brain, that is important for terminating food intake and adjusting energy intake.

Introduction: Transcription factors belonging to the p53 family (p53, p63, p73) respond to cellular stress signals by inducing an accurately defined set of genes. In a number of tumors, also in hepatocellular carcinoma (HCC), p53 proteins can exert cancerogenic or tumorsuppressive functions. MicroRNAs are small, non-coding RNA molecules which play an important role in gene regulation. It is known that expression patterns of microRNAs can be controlled by the p53 family. Depending on disease and cellular origin different sets of p53-induced microRNAs have been identified.

Aims & Methods: Little is known about p53-dependent microRNA signatures in HCC. The aim of the study was therefore to identify p53-family-regulated microRNAs in HCC. Hep3B cells were transfected with rAd-p53 and -p73. Microarray analyses were performed to identify p53- and p73-regulated microRNAs. Verification of p53- and p73-dependent microRNA expression was performed by qPCR. To evaluate the effect of HCC-relevant therapeutics on p53-dependent regulation of microRNAs transfected Hep3B cells were incubated with Doxorubicin, Sorafenib, Tivantinib, and Regorafenib *in vitro*.

Results: Overexpression of p53 and p73 induced a rash of microRNAs. p53 induced miR-34a by 2.4-fold, miR-145 by 2.7-fold and led to a slight reduction of miR-149. In the presence of p73 miR-34a was induced by 5.4-fold, miR-145 by 3.2-fold, and miR-149 by 55-fold. p53-dependent expression of miR-34a was further increased in the presence of Doxorubicin (5.7-fold), Regorafenib (2.5-fold) and Tivantinib (1.9-fold) compared to controls. Moreover, incubation with Regorafenib resulted in an up to 5.4-fold increase of p53-dependent expression of miR-149 and miR-192.

Conclusion: p53 proteins affect the microRNA signature in HCC. Beside the already known induction of miR-34a we demonstrate for the first time a regulation of miR-145 and -149 by p53 and p73. We hypothesize that regulation of tumorsuppressive microRNAs represents an effector mechanism by which p53 family members exert their role in tumor development and treatment response. The observed synergistic effect of p53 and HCC-relevant therapeutics on microRNA expression might provide new options for the development of therapeutic and prognostic measures in HCC.

Introduction: p53 transcription factors (p53, p63, p73) respond to cellular stress by transcriptional regulation of specific sets of genes. In hepatocellular carcinoma (HCC) and other tumors p53 family members exert cancerogenic or tumorsuppressive effects. Depending on their splice variants—with transactivation domain (TA)/dominant negative (DN)—and the characteristics of the particular binding site (BS) p53 proteins activate or inhibit specific target genes. We previously identified the IGFBP2 gene (Insulin-Like Growth Factor Binding Protein 2) as one out of 7 putative target genes for p53 proteins with prognostic relevance in HCC.

Aims & Methods: The aim of this study was to characterize the so far unknown regulation of the IGFBP2 gene by p53 family members in HCC. Hep3B cells were transfected with rAd-p53 and -TAp73 and transcriptional regulation of IGFBP2 was determined by qPCR. Intra- and extracellular IGFBP2 protein levels were analyzed by Western Blot and ELISA. Transfection database analyses were performed to identify potential BS for p53 and p73 in the IGFBP2 locus. These sequences were cloned, mutated and analyzed for p53 family binding in luciferase reporter assays. Binding of p53 and p73 to the identified BS was confirmed by CHIP experiments.

Results: TAp73 transfection increased IGFBP2 expression by up to 60-fold and resulted in elevated intra- and extracellular IGFBP2 protein levels, whereas IGFBP2 protein was not detected in controls. p53 transfection induced IGFBP2 expression by up to 7-fold. Two potential p53 and p73 BS are located in the promoter region, another 5 potential p73 and one p53 BS were identified in intron 1 of the IGFBP2 gene. Intron 1-dependent luciferase activity was increased by up to 110-fold after TAp73 transfection and up to 20-fold after p53 transfection. Mutation and deletion of the identified p53 BS in intron 1 resulted in a reduction of luciferase activity by up to 85%. Deletion of one

potential p73 BS reduced luciferase activity by 85%. CHIP analyses verified binding of p53 and Tap73 to the particular BS.

Conclusion: These results clearly identify IGFBP2 as novel target gene for Tap73 and p53 in HCC. We demonstrate for the first time an interaction of Tap73 with IGFBP2 and therefore an important, so far unknown link between the p53 family network and IGF pathways. p53 proteins exert predominantly tumor-inhibiting effects, whereas the IGF axis is of critical importance for proliferative events. The particular ratio of both important signaling seems to be decisive for tumor characteristics and treatment response. Our results therefore not only expand our knowledge of cancerogenic processes, but also indicate that finetuning of these signalling pathways provides new therapeutic options in clinical management of HCC.

P1313 HOW TO IMPROVE THE RELIABILITY OF LIVER FIBROSIS EVALUATION USING 2D-SWE.GE

F. Bende, I. Sporea, R. Sirli, M. Danila, S.A. Popescu

Gastroenterology And Hepatology, University of Medicine and Pharmacy "Victor Babes" Timisoara, Timisoara/Romania

Contact E-mail Address: bendefelix@gmail.com

Introduction: Liver stiffness (LS) evaluation as a marker of fibrosis is usually considered reliable when it fulfills some quality criteria. Classic criteria used for Transient Elastography (TE) are: ≥ 10 valid measurements, $\geq 60\%$ success rate, and interquartile range/median ratio (IQR/M) ≤ 0.30 [1]. However, new quality criteria were proposed using the IQR/M ratio, therefore the LS measurements can be classified into three categories: very reliable (IQR/M < 0.10), reliable ($0.10 < \text{IQR/M} \leq 0.30$), poorly reliable (IQR/M > 0.30) [2].

Aims & Methods: The aim of this study was to assess the impact of using quality criteria for liver stiffness (LS) evaluation by means of 2D Shear Wave Elastography from General Electric (2D-SWE.GE), while using Transient Elastography (TE) as the reference. We included 226 subjects in our study, with or without chronic liver disease, in whom LS was assessed using 2D-SWE.GE (LOGIQ E9, GE Healthcare) and TE (FibroScan, EchoSens). Reliable LS measurements were defined for TE as the median value of 10 measurements with a success rate of $\geq 60\%$ and an interquartile range (IQR) $< 30\%$ of the median LS values. For 2D-SWE.GE 10 LS measurements were acquired in a homogenous area and the IQR and the IQR/M were calculated in each case. We divided our subjects into 3 groups according to the 2D-SWE.GE IQR/M: IQR/M < 0.10 : 41 (18.1%) cases; $0.10 < \text{IQR/M} \leq 0.30$: 155 (68.6%) cases; IQR/M > 0.30 : 30 (13.3%) cases. We calculated the correlation coefficient between TE and 2D-SWE.GE in each group.

Results: All 226 (100%) subjects included had 10 valid measurements by means of 2D-SWE.GE and reliable results by TE. A strong positive correlation was found between LS values obtained by means of 2D-SWE.GE and TE in the IQR/M < 0.10 group ($r = 0.84$, $p < 0.0001$). A strong positive correlation was found between LS values obtained by means of 2D-SWE.GE and TE in the $0.10 < \text{IQR/M} \leq 0.30$ group ($r = 0.80$, $p < 0.0001$). A weak positive correlation was found between LS values obtained by means of 2D-SWE.GE and TE in the IQR/M > 0.30 group ($r = 0.41$, $p = 0.02$). The correlations were significantly stronger in the IQR/M < 0.10 and $0.10 < \text{IQR/M} \leq 0.30$ groups as compared to the IQR/M > 0.30 group (both $p = 0.0013$). No statistical differences were found between the correlations in the IQR/M < 0.10 and $0.10 < \text{IQR/M} \leq 0.30$ groups ($p = 0.43$).

Conclusion: Using the IQR/M < 0.30 as quality criteria significantly increase the reliability of LS measurements by means of 2D-SWE.GE. Using IQR/M < 0.10 criteria does not significantly improve the reliability of 2D-SWE.GE LS measurements as compared to $0.10 < \text{IQR/M} \leq 0.30$ criteria.

P1314 MONITORING OF LIVER FUNCTION IN PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE IN COMBINATION WITH METABOLIC SYNDROME

K. Aksentyichuk, E. Sklyarov, N. Kurlyak, A. Bochar

Therapy #1 And Medical Diagnostics, LNMU by Danylo Galatskyi Dept. of Therapy, Lviv/Ukraine

Contact E-mail Address: akskris@mail.ru

Introduction: 13C-methacetin breath test (13C-MBT) is used to specify the detoxification function of the liver by determination its metabolic capacity and degree of hepatocytes recovery.

Aims & Methods: The study involved 113 patients with MS aged from 37 to 82 years, the average age was 55.8 ± 3.5 . There were 75 men and 88 women. The criteria, which has been examined for the functional state of the liver was 13C-MBT. The control group included 25 patients with a BMI of 25–30 kg/m² without severe concomitant diseases. Indicators of 13C-MBT were metabolic rate, cumulative dose of 13C-methacetin on 40 and 120 minutes. Also evaluation was carried by mathematical deduction which measured the liver dysfunction stage.

Results: The data showed normal detoxication liver function in patients without MS ($20.11\% \pm 0.55$). The results were below normal in patients with BMI higher than 25 kg/m², which indicated that there were initial changes in the functional state of liver. In patients with steatosis - cumulative dose on 120 minute was $15.12\% \pm 0.49$, which corresponded to a moderate reduction of detoxification function with the mass of function hepatocytes 50–100%. The data of 13C-MBT in patients with steatohepatitis showed pronounced changes of the liver detoxification function ($8.88 \pm 0.64\%$). All indicators at steatosis group have indicated the moderate decline detoxification function with the level of function hepatocytes 50–100% ($\text{Mvmax40} = 0.66$, $\text{Cum.Dose 40} = 0.7$, $\text{Cum.Dose 120} = 0.54$). The data of patients with steatohepatitis indicated the detoxification function with declining of the mass of function hepatocytes to 20–50% ($\text{Mvmax40} = 0.46$, $\text{Cum. Dose 40} = 0.5$, $\text{Cum. Dose 120} = 0.32$). The results of the control group showed its compliance with norm, but one of the indicators (Cum. Dose 120) was related to the moderate decline detoxification function. Despite it, most of the criteria have been accorded to the norm. However, the results of data suggest the opportunity of early violation of detoxification liver function in patients with a BMI over 25 kg/m².

Conclusion: In assessing to the data of 13C-MBT, main attention is paid to mathematical calculation of CO₂ labeled methacetin. It allows to identify the early stages of the liver detoxification function violation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1315 IDENTIFICATION OF P73 AS A NOVEL TRANSACTIVATOR OF IGFBP4 GENE EXPRESSION IN HEPATOCELLULAR CARCINOMA

D. Gschwind¹, S. Heckel¹, E. Aschenbrenner¹, K. Pollinger¹, S. Schlosser¹, C. Kunst², M. Müller-Schilling¹

¹Department For Internal Medicine I, University Hospital Regensburg, Regensburg/Germany

Contact E-mail Address: sebastian-heckel@outlook.de

Introduction: Members of the p53-family, including p53, p63 and p73, are known for their involvement in the regulation of cell cycle, cell senescence and apoptosis. In their role as transcription factors and depending on their splice variants—with transactivation domain (TA) or dominant negative (DN) - p53 and its siblings are capable of activating or inhibiting the transcription of specific target genes. We previously identified the gene for Insulin-like Growth Factor Protein 4 (IGFBP4) as potential p53-family target gene with prognostic relevance in hepatocellular carcinoma (HCC). In contrast to p53, the IGF system takes part in tissue growth and cell survival. IGFBP4 acts as inhibitor limiting IGF effects suggesting a possible interaction with p53 affairs.

Aims & Methods: The aim of the study was to characterize the regulatory influence of p53 family members on the IGFBP4 gene. Hep3B cells were transfected with rAd-p53, -TAp63, -TAp73, -DNp63, and -DNp73. Transcriptional regulation of IGFBP4 was determined by real time qPCR. Intra- and extracellular IGFBP4 protein levels were examined by Western Blotting and ELISA. TRANSFAC database analysis was performed to identify potential p53-family binding sites in the IGFBP4 locus. Identified sequences were cloned, deleted and analyzed by luciferase reporter assays to evaluate binding of p53-family members.

Results: IGFBP4 expression was increased by more than 30-fold in Tap73-transfected Hep3B cells, by more than 15-fold in DNp63- and by 3-fold in p53-transfected cells. Induction of intracellular IGFBP4 protein was detected in all transfected Hep3B cells, whereas extracellular IGFBP4 levels were only measurable after Tap73 and DNp63 transfection. Database analysis identified 2 putative p73 binding sites within intron 1 of the IGFBP4 gene. Intron 1-dependent luciferase activity was increased by up to 20-fold in Tap73-transfected cells. This induction was reduced by up to 70% when one of the putative binding sites was deleted.

Conclusion: These results identify the IGF inhibitor IGFBP4 as novel target gene for Tap73 in HCC. By demonstrating for the first time the interaction of Tap73 and IGFBP4 we enhance our knowledge in a so far unknown association of p53-family network and IGF signaling. Since in an independent study we identified IGFBP2 as a novel p53-family target gene, these results highlight the link between p53-family-mediated tumor-inhibiting mechanisms and IGF-dependent cell proliferation. We therefore suppose that the particular balance of these pathways decides on growth, cancerogenesis and treatment response.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1316 NONALCOHOLIC FATTY LIVER DISEASE IN PATIENTS WITH 2 TYPE DIABETES MELLITUS AND CORONARY HEART DISEASE AGAINST THE BACKGROUND OF METABOLIC SYNDROME. HOW TO DIAGNOSE?

K. Aksentiychuk, E. Sklyarov, N. Kurlyak, A. Bochar
Therapy #1 And Medical Diagnostics, LNMU by Danylo Galatskyi Dept. of Therapy, Lviv/Ukraine

Contact E-mail Address: akskris@mail.ru

Introduction: It is known that to determine nonalcoholic fatty liver disease (NAFLD), which develops in progress of body mass index (BMI) from 19% to 35%, using instrumental and laboratory methods, which include an ultrasound, the determination of the transaminase levels, steatostest, ¹³C-methacetin test. However, the above research methods do not allow to clearly differentiate steatosis from the steatohepatitis, that reduces their credibility.

Aims & Methods: 163 patients (75 men, 88 women) with 2 type diabetes mellitus and coronary heart disease with metabolic syndrome, were examined. The average age was 55.82 ± 75. On the above criteria of ultrasound, 72 patients were diagnosed as steatosis group, 66 - steatohepatitis group. In 25 patients liver pathology was not found, which identified as a control group.

For verification of steatosis and steatohepatitis diagnosis the level of ALT, diameter vena portae and data ¹³C-methacetin breath test were evaluated.

Results: The rate of liver metabolism based on ¹³C-methacetin test results in patients without NAFLD was 22.07 ± 0.66%, in patients with steatosis - 17.1 ± 0.84%, steatohepatitis - 14.3 ± 0.62%. Cumulative dose of methacetin on 120 minute was 20.25 ± 0.46% in patients without pathology of liver, 16.1 ± 0.49% in patients with steatosis, 11.4 ± 0.36 in patients with steatohepatitis. ALT level in control group was 0.4 ± 0.05 mmol/l, with steatosis 0.6 ± 0.06 mmol/l, steatohepatitis 0.9 ± 0.1 mmol/l. The diameter of vena portae in control group was 11.2 ± 0.26 mm, in group of steatosis 11.9 ± 0.21 mm, in patients with steatohepatitis 13.7 ± 0.15 mm. There were investigated, that the rate of metabolism and its cumulative dose on 120 minute has decreased in steatosis group in comparison of the control group, with simultaneous significant increasing of ALT level and diameter of the portal vein. However, a significant reduction of the metabolism rate of methacetin and the cumulative dose ¹³CO₂ in the background of the increase of a diameter of vena portae compared with a group of steatosis, were examined in steatohepatitis group. The investigation found that in ALT and the diameter of the portal vein negatively correlated with cumulative dose of ¹³CO₂ on 120 minute in patients with steatohepatitis. Therefore, a decrease in the metabolic capacity from 15 to 10% accompanied by an increase in ALT levels (more 0.68 mmol/l) and diameter of the portal vein (13 mm).

Conclusion: The differentiation between steatosis and steatohepatitis should be moderate with the speed of a metabolism, a cumulative dose of methacetin on 120 minutes via ¹³C-MBT and vena portae diameter measurement. The sensitivity of the method is based on the definition of the three proposed indicators - ALT level, total concentration of ¹³C-methacetin on 120 minute and the portal vein size, which is 75% for steatosis, and 76% for steatohepatitis.

Introduction: Liver fibrosis (LF) is a progressive pathological process resulting in accumulation of excess extracellular matrix proteins. A metalloprotease BMP1 cleaves various matrix proteins and procollagen type I. We have recently discovered that BMP1-3 isoform circulates in the plasma and its neutralization decreases the progression of chronic kidney disease. The role of BMP1 in liver diseases associated with fibrosis has not been investigated. Bone Morphogenetic Protein 1 (BMP1) and mammalian tolloid (mTLD) are alternatively spliced products of the *Bmp1* gene that are essential for tissue patterning and ECM assembly by biosynthetic processing of a wide range of ECM precursors specifically procollagen type I undergoing enzymatic cleavage by BMP1 at the C-terminal end of the procollagen finally leading to liver cirrhosis, portal hypertension and liver failure.

Aims & Methods: We used the model of CCl₄-induced LF in rats. Animals were treated with BMP1-3 antibody at two different concentrations (20 and 50 µg/kg) for 3 and 8 weeks. Extent of LF was assessed by histology, morphometric analyses, shear wave elastography and hydroxyproline (HP) content measurement. Gene expression analyses were performed by qRT-PCR, and protein localization by immunohistochemistry. BMP7 protein (150 µg/kg) was used as a comparative therapy.

Results: In our experiments the presence of BMP1-3 was immunohistochemically demonstrated in both healthy and cirrhotic liver suggesting that at least a part of circulating BMP1-3 is produced in the liver. Administration of BMP1-3 Ab resulted in an effective inhibition of the fibrosis progression. Administration of BMP1-3 Ab at a dose 20 µg/kg and 50 µg/kg exerted antifibrotic activity comparable to that of BMP7. Apart from blocking the BMP1-3 activity, which is important for collagen maturation, administration of BMP1-3Ab was accompanied by the reduced expression of *Tgfb*, *Itgb6* and *α-Sma* gene expression whereas expression of *Decorin* mRNA was enhanced. Decorin has evident anti-fibrotic activity in the liver after injury with CCl₄ and silencing caused an increased activation of HSCs both *in vivo* and *in vitro*. Rats treated with both BMP1-3 antibody concentrations had significantly lower amount of collagen type I when compared to the CCl₄-treated group. Direct proportionality was found between the degree of fibrosis and liver stiffness. We showed for the first time a distinct correlation

between the HP level in liver, morphometric analysis and elastography of the liver.

Conclusion: Our results suggest that neutralization of BMP1-3 is a promising therapeutic approach in preventing the liver fibrosis progression.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1318 LIVER TRANSIENT ELASTOGRAPHY IN NON-ALCOHOLIC FATTY LIVER DISEASE: IS THERE ANY PREDICTIVE ROLE IN THE DEVELOPMENT OF COLORECTAL POLYPS?

Introduction: Recent studies have demonstrated an association between decreased glucose tolerance, dyslipidemia and metabolic syndrome; and increased risk of colorectal polyps. Patients with non-alcoholic fatty liver disease (NAFLD) often have these risk factors. The association between NAFLD and colorectal polyps has been poorly studied.

Aims & Methods: We aimed to evaluate the prevalence and risk factors of colorectal polyps in patients with NAFLD. This was a retrospective observational cohort study of 237 patients with NAFLD submitted to transient elastography by Fibroscan®, between 01/2015-02/2017. Exclusion criteria: age < 18 years, absence of total colonoscopy with good preparation < 3 years, inflammatory bowel disease, hereditary polyposis syndromes and personal/family history of colorectal polyps/neoplasia. Compared patients with colorectal polyps (cases) and without colorectal polyps (controls). Demographic variables, cardiovascular/metabolic risk factors, comorbidities, laboratory parameters and Fibroscan® scores of steatosis (CAP > 300 dB/m) and fibrosis (F4: > 10 KPa) were evaluated.

Results: Of the 237 NAFLD patients who performed Fibroscan®, 103 underwent total colonoscopy. The prevalence of colorectal polyps was 28.2% (n = 29): 19.4% (20/103) hyperplastic, 16.5% (17/103) adenoma and 4.8% (5/103) advanced adenoma/adenocarcinoma. The mean age was 58.32 ± 51 years (vs 57.09 ± 10.53; p = 0.089), with men predominant (51.7% vs 63.5%; p = 0.272), mostly located in the left colon (55.2% vs 44.8%; p = 0.314) and number and mean size of 1.46 ± 0.88 and 6.89 ± 6.56 mm, respectively. After multivariate analysis, colorectal polyps were associated with F4 liver fibrosis (34.5% vs 14.9%; p = 0.026; OR = 3.01) and obesity (BMI > 30 Kg/m²: 55.2% vs 29.7%; p = 0.016; OR = 2.91); hyperplastic polyps were associated with liver fibrosis for a cut-off value of 6.9 Kpa (AUROC: 0.689; p = 0.008; S = 85.7%; Sp = 51.2%), mainly F4 (42.8% vs 14.6%; p = 0.004; OR = 4.38), hyperuricemia/gout (23.8% vs 8.5%; p = 0.042; OR = 3.35) and peptic ulcer disease (9.5% vs 1.2%; p = 0.043; OR = 8.53); adenoma was associated with liver steatosis (88.2% vs 83.7%; p = 0.024; OR = 3.50), F4 liver fibrosis (41.2% vs 16.2%; p = 0.041; OR = 3.24) and obesity (58.8% vs 32.6%; p = 0.040; OR = 2.96); advanced adenoma/adenocarcinoma was associated with F4 fibrosis (20.0% vs 2.1%; p = 0.021; OR = 1.224), hyperuricemia/gout (40.0% vs 10.3%; p = 0.044; OR = 1.50) and dilated cardiomyopathy (20.0% vs 1.0%; p = 0.003; OR = 1.24).

Conclusion: More than 1/4 of the patients with NAFLD have colorectal polyps, being 16.5% adenoma and 4.8% advanced adenoma/adenocarcinoma. Obesity and liver steatosis are independent risk factors for colorectal adenoma. Liver fibrosis, especially F4 is an independent risk factor for all types of colorectal polyps.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a common clinicopathological condition which may progress from simple steatosis to NASH, cirrhosis and hepatocellular carcinoma (HCC). Although obesity is accepted as the main risk factor for NAFLD, non-obese individuals are often diagnosed with NAFLD suggesting that high BMI may not be "a sine qua non" for the presence of NAFLD. Recent studies suggested that there might be a correlation between weight gain and metabolic diseases.

Aims & Methods: In our research; the relationship between NAFLD in non-obese individuals and the amount of weight gain during adulthood was investigated and a new index that is different from BMI was proposed. 362 individuals were included in the survey. The subjects were selected among patients who had abdominal ultrasonography (USG) in our clinic, during the last 6 months. A 5% increase in echogenicity detected in the USG was defined as the diagnostic

limit for hepatosteatosis. The beginning of adulthood was taken as 20 years old. Exclusion criteria were; HBsAg or anti-HCV positivity, alcohol use, liver disease, pregnancy, cancer treatment, renal insufficiency, being younger than 25 years old. Patients were evaluated for the presence of diabetes, hypertension or cardiovascular disease and ALT, AST, fasting plasma glucose and cholesterol values were recorded. Statistical evaluations were done with IBM SPSS.

NAFLD evaluation with SAMI 3 cut-off value

	NAFLD(+)	NAFLD(-)
SAMI > 3	144	38
SAMI < 3	25	77
Sensitivity	85.2%	
Specificity	66.95%	
PPV	79.12%	
NPV	75.49%	

Results: Among 362 participants 169(46.7%) were men with an average age of 44.81 ± 10.73 . 78 (21.6%) participants were obese, the average age of the group being 46.78 ± 9.12 . Out of 78 obese individuals 73 (93.5%) were NAFLD(+). The average age of the 284(78.4%) non-obese subjects was 44 ± 11.05 . Among non-obese people 169(59.5%) were NAFLD(+) and average age was 48.07 ± 10.13 while amongst NAFLD(-) people was 38.74 ± 10.04 . Non-obese NAFLD(+) patients reported they had gained significant amount of weight during their adulthood. This information led us to create, a new index named "Subtracted Adulthood Mass Index" (SAMI) to estimate the risk of NAFLD development in non-obese individuals. SAMI is calculated by dividing the difference between the subject's current weight and his/her weight at the age of 20 years to his/her height squared (kg/m^2). SAMI values for non-obese attendants were calculated. When the cut-off value was set as SAMI $4 \text{ kg}/\text{m}^2$, sensitivity was 76.3%, specificity was 79.1, positive predictive value (PPV) was 84.3% and negative predictive value (NPV) was 69.4%. At a cut-off of SAMI $3 \text{ kg}/\text{m}^2$ sensitivity was 85.2%, specificity was 66.9%, PPV was 79.1%, NPV was 75.4%.

Conclusion: In this pilot study, we found that weight gain in adulthood is an important predictor of NAFLD development in non-obese individuals. The new index named SAMI can correctly identify non-obese people under the risk of developing NAFLD. Cut-off value of SAMI has been set as $3 \text{ kg}/\text{m}^2$. We also observed that NAFLD prevalence increases as SAMI value goes up. We propose that SAMI is appropriate for clinical use to estimate the risk of NAFLD in non-obese individuals.

Introduction: Cisplatin-treated cancer patients often face therapy failure caused by acquired cisplatin (cp) resistance. Development of resistance was previously associated with modulation of transporters mediating cellular copper metabolism. Overexpression of the Wilson disease protein ATP7B, a TGN copper transporter, was proposed to increase cellular cp efflux.

Aims & Methods: The human hepatoma cell line HepG2 was compared with a HepG2-variant lacking functional ATP7B expression (KO) in regard to cp sensitivity. Hepatoma cell lines were generated that displayed cp resistance by stepwise increasing cp concentrations. Cells were examined via growth, cell viability assay (MTT) and analysed for apoptosis (Annexin V staining). Inductively coupled plasma mass spectrometry was used to determine intracellular cp level. Gene expression analysis (RT-qPCR) was carried out to determine the impact of various transporters. Overexpression of individual transporter genes and siRNA treatment were used for confirmation of the data.

Results: Treatment of HepG2 and KO cells with various cp concentrations revealed no significant differences in cell viability and intracellular cp accumulation. To examine how KO cells that lack ATP7B can adapt to high cp levels, a cp

resistant subline (CpR) was generated. Cp resistance was confirmed by viability assays, cell growth, apoptosis and intracellular cp load. Gene expression analysis of more than 16 transporters demonstrated an upregulation of metallothionein 1 (MT1: 8.91 ± 4) and a downregulation of organic cation transporter 3 (OCT3: -5.17 ± 2) compared to control cell lines. Weaning and regrowth of the CpR cell line in the presence of cp revealed a stable phenotype of resistance in the cells. Downregulation of OCT3 was identified to be permanent while MT1 upregulation was transient and rapidly induced by cp. Overexpression of OCT3 in CpR cells resulted in loss of cp resistance to a level of untreated cells indicating that downregulation of OCT3 is responsible for acquired cp resistance.

Conclusion: We suggest that ATP7B does not seem to be involved in cp resistance, at least in hepatic cells. OCT3 represents a novel marker of cp resistance. OCT3 expression could be a valuable tool for improved prognosis of cisplatin therapy.

Introduction: Recent studies have shown that the single nucleotide polymorphism (SNP) rs738409 in the *PNPLA3* gene is strongly associated with severity of nonalcoholic fatty liver disease (NAFLD).^{1,2} However, the traditional direct sequencing (DS) method is time-consuming and labor-intensive. The i-densy™ (ARKRAY, Inc.), which is based on the quenching probe (QP) method, automatically detects target genes in blood samples by fluorescence quenching within 90 min.³

Aims & Methods: The current study compared the QP and DS methods for detecting SNPs in the *PNPLA3* gene, and established the impact of the genotype on prognosis of NAFLD. We enrolled 107 patients with fatty liver irrespective of etiology. We used the i-densy fully automated genotyping system with QP. The requisite number of tips, reaction tubes, reagent packs and blood samples were set in their designated places. The forward and reverse polymerase chain reaction (PCR) primers and guanine QP were 5'-ctctctctctctctctcttcacag-3', 5'-gtgtgagcactcctcagag-3' and 5'-ggcatgaagcaggaacatac-3', respectively. PCR consisted of initial denaturation for 1 min at 95 °C, and 60 cycles of denaturation at 95 °C for 1 s and annealing at 61 °C for 30 s. After completion of the PCR, we analyzed melting temperatures. The SNP genotypes were determined by monitoring the change in fluorescence intensity with increasing temperature. The results obtained with the QP method were compared with those obtained with the conventional DS method. Then, we analyzed 73 patients with NAFLD according to *PNPLA3* genotype in terms of alanine aminotransferase (ALT), aspartate aminotransferase to platelet ratio index (APRI), Fibroscan value, and cumulative hepatocellular carcinoma (HCC) development rate.

Results: The genotypes obtained with the QP method were identical to those obtained with the conventional DS method. In 73 patients with NAFLD, the frequency of the *PNPLA3* genotypes CC, CG and GG was 21 (28.8%), 24 (32.9%) and 28 (38.4%), respectively. Serum ALT, APRI and Fibroscan value according to *PNPLA3* genotypes CC, CG and GG were 26 (14-59), 33 (11-113) and 46 (17-175) U/L, 0.3 (0.1-1.0), 0.5 (0.2-6.8) and 0.7 (0.2-3.1), and 4.4 (2.7-25.1), 5.6 (2.5-26.5) and 6.6 (3.6-38.6) kPa, respectively ($p=0.001$, $p=0.001$ and $p=0.033$ by Jonckheere-Terpstra test). HCC developed in none of the patients with CC genotype, one (4.2%) with CG and four (14.3%) with GG. The cumulative HCC development rate in patients with GG genotype was significantly higher than that in those with CC+CG genotype ($p=0.043$ by log-rank test).

Conclusion: The i-densy using the QP method can automatically, quickly and easily identify *PNPLA3* genotypes in real-world clinical settings. These findings indicate the feasibility of personalized medicine for NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1322 EFFECT OF ORLISTAT ON TOTAL LIVER FAT QUANTIFICATION BY NOVEL MAGNETIC RESONANCE IMAGING IN OBESE PATIENTS WITH NON-ALCOHOLIC STEATOHEPATITIS: INTERIM ANALYSIS OF A PROSPECTIVE, RANDOMIZED, SINGLE-CENTER, OPEN-LABEL TRIAL

J. Ye, W. Yanqin, H. Xuan, Z. Bihui

Gastroenterology, The First Affiliated Hospital Of Sun Yat-Sen University, Guangzhou/China

Contact E-mail Address: sophiazhong@hotmail.com

Introduction: Orlistat is an effective pharmacologic weight loss treatment by inhibiting intestinal lipase to reduce dietary fat absorption. Previous studies have suggested that it lowers liver fat by ultrasound or semi quantitative histological score in nonalcoholic fatty liver diseases (NAFLD).

Aims & Methods: We aimed to examine the efficacy of orlistat versus placebo in reducing liver fat content by the magnetic resonance imaging (MRI) based on chemical shift imaging. A total of 51 NAFLD patients diagnosed by MRI were randomized and to receive twice-daily 120mg oral Orlistat or placebo for 6 months, among them 30 (14 in the Orlistat group and 16 in the placebo group) were included in the interim analysis. Both groups received. Clinical parameters, laboratory tests and liver fat content were measured at baseline and 6 months including body mass index (BMI), waist hip ratio (WHR), liver enzymes, haemoglobin A1c, total cholesterol (CHOL), serum triglycerides (TG), fasting plasma insulin (FPI), homeostasis model assessment IR (HOMA-IR). The primary outcome was a change in liver fat quantified by MRI which is based on Dixon technique with two-point chemical shift-based fat-water separation method^[1]. The chi-squared test and paired t test were used to compare mean differences between fat fractions between two groups.

Results: At baseline, BMI was higher in Orlistat group (31.38 ± 3.19) than that of the placebo group (26.78 ± 3.02 , $p < 0.001$), while the other baseline characteristics including liver fat fraction and the proportion of hypertension, hyperlipidaemia, diabetes mellitus type 2, and hyperlipidemia were similar. Compared to baseline, end-of-treatment liver fat content was significantly lower in the Orlistat arm ($19.38\% \pm 9.52\%$ to $11.56\% \pm 7.49\%$, change was $7.72 \pm 6.39\%$, $P = 0.001$) but not in the placebo ($16.05\% \pm 8.7\%$ to $14.17\% \pm 9.58\%$, change was $1.43 \pm 9.84\%$, $P = 0.640$) arm. Change of BMI was the only independent factors correlated with reduction of liver fat content ($\beta = 0.522$, $p = 0.006$).

Conclusion: Orlistat did significantly decreased liver fat in NAFLD patients via its effect of lowering weight.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1323 LONG-TERM COPPER EXPOSURE OF HEPATIC CELLS LACKING FUNCTIONAL ATP7B

S. Guttman, S. Reinartz Groba, C. Niemietz, P. Ballmaier, R. Muhmann, V. Sauer, A. Zibert, H. Schmidt

Transplantationsklinik, Universitätsklinikum Münster, Münster/Germany

Contact E-mail Address: guttmann.sarah@ukmuenster.de

Introduction: Copper transporter ATP7B is essential for hepatic Cu homeostasis and loss of function results in the inherited autosomal recessive disorder Wilson Disease (WD). Symptoms of WD are i.e. elevated Cu accumulation in liver and brain. Understanding of molecular mechanisms involved in Cu homeostasis is essential to improve therapeutic options. The molecular impact following long-term elevated Cu in hepatic cells lacking functional ATP7B has not been explored.

Aims & Methods: HepG2 cells lacking functional ATP7B (KO) were used for generation of a copper resistant subline (CuR). Cell growth, cell viability (MTT) and intracellular Cu load (atomic absorption spectroscopy) was assessed. RT-qPCR was performed to quantify the expression of genes related to Cu homeostasis genes. Functional analysis of candidate genes was assessed via siRNA transfection. Additional measurements of CTR1 expression was performed by flow cytometry (FACS) and Western Blot.

Results: KO cells can survive for many months in the presence of high Cu and gain resistance (CuR). Characterization of CuR cells revealed increased survival up to 12-fold compared to control, whereas a high intracellular Cu accumulation was noticed. Once Cu resistance was established, the termination of Cu exposure did not result in the loss of resistance indicating a stable modification of the cells. Two genes involved in Cu homeostasis displayed an altered expression pattern (upregulation of MT1 and downregulation of CTR1 by 28.1 ± 2.5 and -3.2 ± 0.4 fold, respectively) which was however transient and dependent on Cu exposure. The role of MDR1 which presented a stable modification was further investigated by siRNA and drug activation (verapamil). Notably, cell viability and intracellular Cu load was significantly affected by siRNA and verapamil indicating that MDR1 is involved in Cu homeostasis. In addition, hepatic cells derived from a WD patient and from the rat animal model confirmed our observations.

Conclusion: Our analysis of long-term Cu exposure presents new insights in copper metabolism and suggests a new role of MDR1 in the pathogenesis of Wilson disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1324 THE NONALCOHOLIC FAT LIVER DISEASE FIBROSIS SCORE IN PREDICTING FIBROSIS IN MORBIDLY OBESE PATIENTS BEFORE BARIATRIC SURGERY THE NONALCOHOLIC FAT LIVER DISEASE FIBROSIS SCORE IN PREDICTING FIBROSIS IN MORBIDLY OBESE PATIENTS BEFORE BARIATRIC SURGERY

Contact E-mail Address: thicianie@hotmail.com

Introduction: Non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) are increasingly common cause of chronic liver disease worldwide. Most patients with severe obesity who undergo bariatric surgery have NAFLD, which is associated insulin resistance, type 2 diabetes mellitus, hypertension, and obesity-related dyslipidemia. Identifying significant fibrosis in patients is crucial to evaluating prognosis and possible therapeutic intervention. Currently, liver biopsy is the gold standard for diagnosis of liver fibrosis.

Aims & Methods: We aimed to evaluate the NAFLD fibrosis score for the assessment of significant fibrosis in patients with morbid obesity before undergoing Roux-en-Y gastric bypass. A total of 69 NAFLD patients (median BMI 47 kg/m²) were prospectively enrolled from June 2015 to November 2016 at one Brazilian university hospital. All patients were evaluated with routine laboratory before bariatric surgery. Age, body mass index, hyperglycemia, platelet count, albumin and AST/ALT ratio were applied to the score formula. Biopsies were interpreted by a single experienced pathologist. NAFLD and fibrosis were classified according to the NASH Clinical Research Network NAFLD activity score. These scores were compared to liver biopsy findings and the area under the receiver operating characteristic curve (AUROC) was calculated for the diagnostic test.

Results: On liver biopsy, 29 patients (42%) had some degree of fibrosis, with 13 patients (18.8%) having significant fibrosis (F2-4). With standard thresholds, the specificity for the NAFLD fibrosis score for identification of significant fibrosis was 58.9%. Using modified thresholds, the specificity could increase. For predicting significant fibrosis, for a cut-off of 1.05, the score had 46.15% sensitivity and 96.43% specificity with AUROC of 0.74.

Conclusion: The nonalcoholic fat liver disease fibrosis score has good accuracy to identify and significant liver fibrosis in morbidly obese patients subjected to bariatric surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1325 COMPARISON OF FIBROSCAN® AND FATTY LIVER INDEX (FLI) TO SCREEN FOR FATTY LIVER DISEASE IN A LARGE COHORT OF EMPLOYEES: WHERE IS THE OPTIMAL CUT OFF?

M. Teufelhart, C. Rabitsch, B. Mehl, R. Winker, B. Meyer, T. Scherzer

Health And Prevention Center, Sanatorium Hera, Vienna/Austria

Contact E-mail Address: manuela.teufelhart@hera.co.at

Introduction: FLI was developed as a simple predictor of steatosis (Bedogni et al., 2006) and a cut-off value ≥ 60 ruled in (positive likelihood ratio [LR+] 4.3) steatosis in Italians diagnosed with ultrasound. Fibroscan®CAP is more sensitive for the diagnosis of steatosis than ultrasound. Aim of this study is to evaluate the use of Fibroscan® in comparison with FLI to screen for fatty liver disease in Austrian bank employees and to recalculate optimal FLI cut-off values. Beside weight reduction and diet EASL guidelines recommend physical activity > 150 min. per week for prevention and treatment of steatosis.

Aims & Methods: More than 1000 Austrian bank employees will be screened for liver diseases with Fibroscan®. A kPa value ≥ 7.9 (M-probe) and ≥ 7.2 (XL-probe) is categorized as fibrosis. Additionally Fibroscan®CAP with a cut-off value ≥ 248 dB/m is defined as steatosis, ≥ 300 dB/m as high-grade steatosis. Heavy drinkers are identified with AUDIT and SIAC questionnaires. Weekly physical activity is classified into "none", " ≤ 150 min" and " > 150 min".

Results: To date 482 employees [age 45.9 ± 8.7 (mean \pm SD); m:207, f:275; BMI 25.4 ± 4.4] have been included in this analysis. 14/482 (2.9%) employees had signs of liver fibrosis and received further investigations. Fibroscan®CAP values ≥ 248 dB/m are shown in 156/482 (32.4%) employees (m:91 [58%], f:65 [42%]), 56/482 (11.6%) had CAP values ≥ 300 dB/m. Furthermore 15/156 (9.6%) patients with steatosis are heavy drinkers. FLI significantly predicts Fibroscan®CAP values (adj.R² = 0.551, t(424) = 22.9, $p < 0.001$), which indicates a large effect size. For this study population, a FLI cut-off value ≥ 40 (CAP ≥ 248 dB/m) and ≥ 50 (CAP ≥ 300 dB/m) rules in fatty liver disease with a LR+ of 4.7 (SN:84%; SP:75%) and 4.8 (SN:83%; SP:83%), respectively. An additional consideration of physical activity level in the current cohort revealed that inactivity increases the LR+ of FLI values to predict NAFLD (trendwise significant, $p = 0.051$), indicating lower cut-off values.

Conclusion: We conclude that Fibroscan® represents an eligible tool to diagnose liver diseases in Austrian bank employees. Compared to the previous work of Bedogni et al FLI predicts fatty liver at a lower cut-off level, at least for the examined population. This difference might be due to the fact that FibroScan®CAP is more sensitive than ultrasound.

Introduction: Nonalcoholic fatty liver disease (NAFLD) is an affection with increasingly prevalence worldwide, having an important impact on morbidity and mortality, especially when it associated severe fibrosis.

Aims & Methods: We aimed to assess the metabolites that are associated with fibrosis stages in NAFLD, using metabolomic method. A total of 40 patients were included in the study, 30 diagnosed with nonalcoholic fatty liver disease (NAFLD) and 10 controls. Steatosis and fibrosis were assessed using Fibromax elaborated by Biopredictive (R) (Paris, France). New metabolomic techniques (high performance liquid chromatography coupled with mass spectrometry (HPLC-MS) and principal component analysis (PCA) were used to identify final products of various metabolic pathways correlated with liver fibrosis.

Results: Of the 30 patients with NAFLD included in the study, 6 patients (20%) had severe fibrosis. The metabolomic profile identified four metabolites that are associated with severe fibrosis: 1,25(OH)vitamin D, ($p=0.03$), lisophosphatidyletanolamine LPE 0:0:22:6 ($p=0.05$), Lysophosphatidylcholine LPC 18:2 ($p=0.003$), and high levels of butenyl carnitine ($p=0.04$). Of these, LPE was the strongest predictor of severe fibrosis (AUROC=0.795, Sensitivity (Se)=88.33%, specificity (Sp)=78.79%), but the others molecules were also significantly associated with severe fibrosis: vitamin D (AUROC=0.776), butenyl carnitine (AUROC=0.737), LPC 18:2 (AUROC=0.768). As the metabolomics permits the evaluation of all these molecules the same time, we can use them combined in order to increase the diagnostic accuracy. In our case, the combined use of the four metabolites determined an AUROC of 0.839, with Se of 100% and Sp of 68.5%.

Conclusion: Using metabolomics, we can identify patients with fatty liver and severe fibrosis who are significantly exposed to a progressive disease and a higher mortality.

Introduction: Chronic renal failure (CRF) is frequently associated bone metabolism and osteoporosis with lowered levels of Vitamine D and/or hyperparathyroidism particular in case of hemodialysis. Younger studies suggest an association of low vitamin D levels with non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH), as well as metabolic syndrome, and diabetes mellitus. Unfortunately, a causality could not yet be proven.

Aims & Methods: Our aim was to identify patients on higher risk to develop NAFLD/NASH in a selected patient cohort being admitted for renal disorders.

176 patients, admitted to the department of nephrology of the University Hospital Marburg for renal disorders whose plasma vitamin D concentration, phosphate and parathormone levels and liver enzyme levels had been quantified beforehand, were enrolled and a retrospective investigation of laboratory parameters (including electrolytes, hormones, and vitamins) and pre-existing medical conditions (including high blood pressure, diabetes, hyperlipoproteinaemia, and more) followed. Appropriate statistical test were used to characterise the cohort (ANOVA; MANN-Whitney-U; FISHER-EXACT) using SPSS™. Other hepatopathies were excluded. Steatosis was assessed by ultrasonography.

Results: Patients were divided into 4 groups according to plasma vitamin D levels (normal >25 ng/ml; low <25 ng/ml) and transaminase levels (AST/ALT/γ-GT >30 U/l; normal: AST/ALT/γ-GT <30 U/l). Low 1,25-hydroxyvitamin D levels correlated significantly with high kreatinine, urea, and LDL levels, while low 25-hydroxyvitamin D levels correlated with high cholesterol and triglyceride levels, suggesting a relationship between low vitamin D levels and fat metabolism disorders. Interestingly end stage renal failure (chronic hemodialysis) was significantly correlated with the development of NAFLD/NASH with significantly higher levels of AST/ALT and γGT, hyperparathyroidism and hyperphosphatemia. Transaminases were significantly lower if Vitamin D was supplemented.

Conclusion: Vitamin D deficiency is often present in patients with kidney diseases such as chronic renal failure. Vitamin D levels are correlated to age and sex of the patient. Patients suffering from renal failure are on high risk developing NAFLD/NASH if diminished vitamin D levels are present. Supplement of Vitamin D saves from NAFLD/NASH. The correlation of hyperparathyroidism and NAFLD/NASH has to be further investigated in larger patient groups.

Introduction: Usually for the determination of nonalcoholic fatty liver disease (NAFLD) there are instrumental and laboratory techniques, including ultrasound diagnosis, determination of aminotransferases, steatostest, 13C-methacetin breath test (13C-MBT). These methods in the diagnosis of NAFLD clinical forms is not specific and do not allow make difference between steatosis and steatohepatitis. The determination of NAFLD clinical forms is a priority in the prediction of further disease and choice of treatment. Steatohepatitis is the active form of NAFLD and progresses to fibrosis often with subsequent liver parenchyma degeneration into cirrhosis. Simultaneously, steatosis could be possibly treated in the early stages of disease.

Aims & Methods: The study involved 65 patients with type 2 diabetes and coronary heart disease with metabolic syndrome, aged 37 to 82 years (mean age 55.82±3.46), 29 men, 36 women. According to the ultrasound, the stage of fatty infiltration were differentiated by such criteria for steatosis as diffuse liver parenchyma echogenicity intensification against the background of a slight increase in its size (liver echogenicity was significantly higher than normal kidney or lumbar muscle echogenicity); for steatohepatitis - hyperechogenicity of liver parenchyma and expansion of portal vein (13 mm or more in diameter).

Results: For steatosis and steatohepatitis determination the ALT monitoring was used, where the level exceeding 0.68 mmol/l signed to steatohepatitis, and below 0.68 mmol/l - to steatosis. Portal vein diameter size above 13 mm subscribed steatohepatitis, and below 13 - steatosis. 13C-MBT data, which assessed the liver antitoxic function was used, where the result 13CO₂ on 120 minute from 10 till 15% was classified as liver detoxification function violation like steatohepatitis, and from 15 till 20 - steatosis. The present study found that indicators of ALT and portal vein diameter negatively correlated with cumulative dose 13CO₂ for 120 minute in case of steatohepatitis. Thus, reduction cumulative dose 13CO₂ on 120 minute from 15% to 10% was accompanied by ALT level increasing (more than 0.68 mmol/l) and portal vein diameter enlargement (over 13 mm).

Conclusion: Differentiation between steatosis and steatohepatitis should be performed by the cumulative dose 13CO₂ on 120 minute evaluation and ALT levels and portal vein diameter assessment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1329 NON-OBESE FATTY LIVER DISEASE IN TYPE 2 DIABETES: NOVEL CONDITION OR SIMILAR TO TYPICAL NAFLD STATE?

Introduction: Non-alcoholic fatty liver disease (NAFLD), the hepatic counterpart of the metabolic syndrome in close relation to obesity and encompasses a disease spectrum spanning simple steatosis through nonalcoholic steatohepatitis (NASH) with/without cirrhosis, and hepatocellular carcinoma [1]. Clearly, not all obese subjects develop NAFLD and NAFLD can also be found in non-obese patients. Globally, the reported prevalence of non-obese NAFLD varies widely, ranging from 3% to 30% [2]. Today remains unclear how patients without obesity develop NAFLD, therefore it is important to understand the clinical and pathological conditions of non-obese NAFLD.

Aims & Methods: In this study, we investigated the liver stiffness and liver fat content in addition to other clinical and metabolic parameters in type 2 diabetes patient with non-obese and obese NAFLD detected on ultrasonography (US). In this cross-sectional study, 245 T2D patients with age of 40–80 years from the Kyiv City Clinical Endocrinology Center were selected. Inclusion criteria were: age over 18 years, presence of T2D in association with fatty liver disease. The diagnosis of fatty liver was based on the results of abdominal ultrasonography, which was done by trained technicians with Ultima PA (Radmir Co., Kharkiv, Ukraine). Of 4 known criteria (hepatorenal echo contrast, liver brightness, deep attenuation, and vascular blurring), the participants were required to have hepatorenal contrast and liver brightness to be given a diagnosis. According to body mass index (BMI) value patients were assigned else to NAFLD group (n = 157, BMI ≥ 30.0 kg/m²) or to non-obese NAFLD (n = 88, BMI < 30.0 kg/m²) group. We performed 10 valid measurements of liver stiffness (LS) measured by Shear Wave Elastography (SWE) in every patient, and a median value was calculated, the result being measured in kPa. Also in all patient we calculated fatty liver index (FLI). FLI a validated prediction score for hepatic steatosis severity designed Bedogni et al [3]. Changes in transaminases activity, serum lipids and cytokines (TNF-α, IL-1β, IL-6, IL-8, INF-γ) levels were evaluated.

Results: Non-obese NAFLD patient had higher LS (7.52 ± 0.2 vs 6.87 ± 0.09, p = 0.001) values measured by SWE, which were accompanied with increased transaminase activity: for ALT 42.1 ± 3.17 vs 35.8 ± 1.28 (p = 0.028) and for AST 40.81 ± 2.68 vs 34.31 ± 1.33 (p = 0.016) respectively. In contrast to non-obese group patient in NAFLD group had significantly higher FLI (86.59 ± 1.09 vs 68.06 ± 1.98, p < 0.001). Markers of chronic systemic inflammatory state were also significantly higher in NAFLD obese as compared to non-obese patient: IL-1β 44.64 ± 2.0 vs 31.02 ± 1.78 (p < 0.001); TNF-α 54.11 ± 2.20 vs 42.28 ± 1.81 (p < 0.001); IL-8 29.18 ± 1.27 vs 22.05 ± 0.99 (p < 0.001) and INF-γ 195.60 ± 9.47 vs 132.47 ± 7.54 (p = 0.016) respectively. Changes of IL-6 between groups were insignificant.

Conclusion: At present, the clinical-laboratory characteristics of non-obese NAFLD are not fully understood. Therefore, we found that non-obese NAFLD associated with higher liver stiffness values and transaminases activities. On the other hand, patient with obese NAFLD are characterized with more pronounced liver fat content and elevation of markers of chronic systemic inflammatory state.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is usually considered as the hepatic manifestation of metabolic syndrome and obesity. However, a subgroup of NAFLD patients are lean. Some studies have reported severe liver fibrosis in lean NAFLD and these patients are still at risk for development of liver cirrhosis.

Aims & Methods: This study aimed to investigate the prevalence and risk factors of lean NAFLD in a cluster of Iranian population. Study population was recruited from Kavar cohort study which has been started from 2006 in Kavar town, a small town near Shiraz. The study sampling was performed between September 2011 and September 2015 among adult subjects (age > 18 years)

who underwent voluntary hepatobiliary ultrasound. NAFLD was diagnosed using ultrasound and absence of chronic liver diseases such as autoimmune hepatitis, hepatitis B or C viruses induced hepatitis, hepato-biliary cancers, Wilson's disease, > 10 g/day alcohol consumption, and receiving some specific medications known to cause hepatic steatosis (like amiodarone, valproic acid, etc). Lean individuals were defined as those with body mass index (BMI) < 25 kg/m². Student's t-test was used for comparisons of continuous variables and Chi-square test was used for comparison of categorical variables. Receiver operating characteristics (ROC) curve analysis using area under curve (AUC) was used for analysis of optimal cutoff values for BMI and waist circumference in association with lean NAFLD.

Results: 1343 individuals were included. 165 individuals (12.3%) was diagnosed to have NAFLD. 129 individuals (9.6%) had mild NAFLD and 36 individuals (2.7%) had moderate NAFLD. None of the participants had severe NAFLD. In univariate analysis, history of diabetes mellitus (DM) (OR = 2.25; 95% CI: 1.15–4.40, P = 0.015) and metabolic syndrome (OR = 2.80; 95% CI: 1.74–4.48, P < 0.001) were associated with NAFLD. Higher BMI and waist circumference, higher systolic and diastolic blood pressure, higher serum triglyceride, total cholesterol, fasting plasma glucose (FPG) and alanine aminotransferase (ALT) were associated with NAFLD (P < 0.05). In multivariate regression analysis, higher BMI and waist circumference, higher serum ALT, FPG and cholesterol were independent predictors of NAFLD in our study population (Table). A cutoff value of 22.3 kg/m² for BMI was predictor of NAFLD (sensitivity = 72%; specificity = 60%; AUC = 0.728, P < 0.001). A cutoff value of 79.5 cm for waist circumference was predictor of NAFLD in our study population (sensitivity = 80%; specificity = 68%; AUC = 0.753, P < 0.001). Table: Multivariate regression analysis showing independent risk factors for lean NAFLD.

	Odds Ratio (OR)	95% Confidence Interval (CI)	P-Value
BMI	1.27	1.106–1.459	0.001
Waist circumference	1.078	1.047–1.112	<0.001
ALT	1.018	1.004–1.033	0.015
Cholesterol	1.008	1.003–1.013	0.003
FPG	1.010	1.003–1.017	0.004

Conclusion: Lean NAFLD was prevalent in our study population and was associated with metabolic risk factors. BMI and waist circumference can be used for prediction of NAFLD in lean individuals.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: While some studies have evaluated the ability of new "real-time" elastography devices such as 2-D Shear Wave Elastography (SWE) and Virtual Touch Quantification (ARFI) in predicting the presence of high-risk gastroesophageal varices, no study has explored the potential role of another point-SWE technique, ElastPQ, in the assessment of clinically significant portal hypertension.

Aims & Methods: The aim of our study was to identify a liver stiffness cut-off value measured by ElastPQ and/or laboratory parameters that could help identify those patients who can safely avoid screening endoscopy, similarly to the recently proposed Baveno VI criteria which recommends a liver stiffness value < 20 kPa measured by transient elastography in combination to a platelet count > 150,000/μl. Data were collected on 1385 patients who underwent ElastPQ measurement from January 2013 to January 2016 in our Department. Inclusion criteria were a liver stiffness value of ≥ 7 kPa and an upper gastrointestinal endoscopy within 12 months, with a diagnosis of compensated chronic liver disease. We choose this specific liver stiffness cut-off value in order to reasonably rule-in all patients with advanced fibrosis and cirrhosis, based on the limited literature available on this specific elastographic technique. Exclusion criteria were history of decompensated liver disease, evidence of porto-spleno-mesenteric vein thrombosis and non-cirrhotic portal hypertension. Varices were graded as low risk (grade < 2) or high risk (grade ≥ 2).

Results: The study included 184 patients (114 [62%] hepatitis C, and 160 [87%] Child-Pugh A). Varices were present in 36% cases, with 10% prevalence of high-risk varices. According to ROC curve analysis liver stiffness measurement and

platelet count were evaluated as predictors of high-risk varices. Overall 74/184 (40%) met the new "BAVElastPQ" criteria (that is, liver stiffness <12 kPa and platelet count >150,000/ μ l). Within this group 11/63 (17%) had any grade of varices and only 1/73 (1%) had high-risk varices. The BAVElastPQ criteria gave sensitivity of 0.95, specificity of 0.44, a positive predictive value of 0.16 and a negative predictive value of 0.98. The AUROC for liver stiffness and platelet count was 0.81 and 0.76, respectively.

Conclusion: The BAVElastPQ criteria correctly identified 99% of patients without high-risk varices. By applying such criteria we could have potentially avoided 40% surveillance endoscopies in our cohort. To our knowledge this is the first study that evaluated the potential role of a new p-SWE technique such as ElastPQ in the non-invasive assessment of clinically significant portal hypertension, similarly to the recently proposed Baveno VI criteria though using ElastPQ as an alternative to transient elastography.

Introduction: Proton pump inhibitors (PPI) are commonly prescribed and predispose to small bowel bacterial overgrowth. Hepatic encephalopathy is a frequent complication of cirrhosis and is associated with intestinal dysbiosis.

Aims & Methods: This study aimed to identify a possible association between PPI intake and hepatic encephalopathy development in cirrhotic patients. Retrospective analysis of consecutive cirrhotic patients hospitalized in two Gastroenterology Departments over 3.5 years. Collection of clinical data, PPI intake, infection and hepatic encephalopathy at hospitalization. Statistical analysis was performed with SPSS 21, considering statistical significance $p < 0.05$.

Results: 386 patients, 321 males (83.2%), mean age 60.3 ± 12.1 years. Main etiologies of cirrhosis were alcohol (67.4%), alcohol plus hepatitis C Virus (16.3%) and hepatitis C virus (5.2%). Hepatic encephalopathy was present in 222 (57.5%) of the patients and 26.9% had PPI intake. In univariate analysis hepatic encephalopathy was associated with infection ($p < 0.001$), gastrointestinal bleeding ($p < 0.001$) and Model for End-Stage Liver Disease (MELD) ($p < 0.001$). There was no association between hepatic encephalopathy and PPI intake ($p = 0.057$), gender ($p = 0.228$) or age ($p = 0.352$). In multivariate analysis, hepatic encephalopathy maintained association with infection ($p < 0.001$), gastrointestinal bleeding ($p < 0.001$) and MELD score ($p = 0.001$).

Conclusion: In our series, PPI intake was not associated with hepatic encephalopathy development in cirrhotic patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The incidence of bacterial infections in cirrhotic patients is significantly higher than that observed in general population, being one of the most important causes of decompensation. In theory, the final result of an infectious disease depends of three major factors: the antibiotic resistance of the bacteria and the prompt administration of treatment; the intrinsic virulence or pathogenicity of the bacteria; and finally the patient status in relation to risk factors such as immune status, age, diet and stress. There are conflicting results regarding the clinical outcome of multidrug-resistant (MDR) bacterial infections in cirrhotic patients.

Aims & Methods: Our aims within this study were to 1) analyze the incidence of MDR bacteria in patients with decompensated cirrhosis at admission (less than 24 hours after hospitalization), 2) to study its impact on 30 and 90-day mortality, and 3) to identify independent risk factors for 30 and 90-day mortality. We conducted a retrospective cohort study which evaluated all admissions due to decompensated cirrhosis in one center between 2010 and 2015. MDR bacterial infections, its acquisition site and the antibiotic resistance patterns were defined according with the European Centre for Disease Prevention and Control (ECDC) criteria.

Results: A total of 681 hospitalizations were evaluated and 41% had a bacterial infection at admission. The 30 and 90-day mortality rate was 14.7% and 38.1%, respectively. The most common infection was spontaneous bacterial peritonitis (SBP; 40.5%), followed by urinary tract infection (UTI; 25%). About 55.6% of the patients had a microbiological documented infection (MDI). MDR bacteria were identified in 18.6% of all bacterial infections, matching 34.5% of the

nosocomial acquired infections and 8.3% of the community-acquired (CA) infections. In 40.6% of the UTI there was a MDI by a MDR bacteria. In patients with documented infections, no difference was noticed between non-MDI, non-MDR bacteria or MDR bacteria regarding the 30 ($p = 0.801$) and the 90-day ($p = 0.525$) mortality rate. In the multivariate analysis, elevated BUN and bilirubin, presence of bacterial infection and lower albumin, sodium and SpO₂ were independently associated with 30 and 90-day mortality. Higher INR and age were independently associated with 90-day mortality.

Conclusion: The presence of bacterial infection, independently of the antibiotic resistance profile, was associated with a worse prognosis in cirrhotic patients. We identified a high incidence of MDR bacteria in patients with UTI. Given the described risk factors for MDR bacteria development, we hypothesize that our results are probably the consequence of a bad antibiotic politics in our district, especially when managing CA UTIs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1334 STATIN THERAPY IN THE REDUCTION OF PORTAL HYPERTENSION IN PATIENTS WITH LIVER CIRRHOSIS: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

J.G. E. Cataluna, J. G. Cervantes

Institute Of Digestive And Liver Diseases, St. Luke's Medical Center - Quezon City, Quezon City/Philippines

Contact E-mail Address: doycataluna@yahoo.com

Introduction: Statins have been shown to decrease intrahepatic vascular resistance and improve vasodilation of the liver vasculature via enhanced nitric oxide production. This meta-analysis of randomized controlled trials (RCTs) was conducted to determine if statin therapy reduces portal hypertension as measured by the hepatic venous pressure gradient (HVPG) among adult patients with liver cirrhosis.

Aims & Methods: The objective of this research was to perform a meta-analysis of randomized control trials (RCTs) and determine if statin therapy reduces portal hypertension as measured by the hepatic venous pressure gradient (HVPG) among adult patients with liver cirrhosis. Specifically, this meta-analysis determined the pooled/standardized mean difference with 95% confidence interval using the random effects models. A comprehensive literature search from the PubMed- Medline, EMBASE, Cochrane Library, and Ovid databases was performed using the following terms: cirrhosis, portal hypertension, HVPG, and statin. Three studies were selected. The quality of the included studies was independently appraised by four authors using the Jadad scale. All disagreements and discrepancies of the reviewers were discussed. Trial results were combined under a random-effects model. Continuous data were analyzed by calculating the standard mean difference with 95% confidence interval (CI) and a significant p value of 0.05. Cochrane Review Manager Software version 5.0 statistical software was used for all analyses.

Results: Three trials comprising of 98 patients met the inclusion criteria. In the random-effect model, the weighted mean difference was 0.76 mmHg, favoring statin therapy over placebo. There was no evidence of significant heterogeneity ($P = 0.51$; $I^2, 0\%$).

Conclusion: Statin therapy reduces portal hypertension as measured by the HVPG among adult patients with liver cirrhosis. The findings of this study reinforce the promising role of statins in decreasing portal hypertension. Further RCTs with larger population and with longer duration of follow-up as well as the use of different statin drugs to explore further on the class effect are recommended.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The place of noninvasive techniques for the prediction of presence of portal hypertension in patients with liver cirrhosis is one of the current research topics.

Aims & Methods: The aim of this study was to evaluate the applicability of the Baveno VI criteria in a cohort of known compensated HCV liver cirrhosis patients, to see how often we misclassify the presence of esophageal varices (EV). Material and method We did a prospective multicentre study, from September 2015 to December 2016, which included all patients with perfectly compensated HCV liver cirrhosis, diagnosed by means of elastography, ultrasound, endoscopic and biological criteria prior to interferon-free treatment. All patients were evaluated by upper gastrointestinal endoscopy, transient elastography (TE) and biological tests. By using Baveno VI criteria we classified the patients in: probably without EV (liver stiffness - LS < 20 kPa and thrombocytes > 150,000/mm³), probably with EV (LS ≥ 25 kPa) and the "gray zone" in between these criteria.

Results: Out of 403 patients, 127 (30.7%) had LS < 20 kPa, 89 (22%) had LS between 20–25 kPa, 190 (47.3%) had LS > 25 kPa, 120 (29.7%) had thrombocytes > 150,000/mm³, while 283 (70.3%) had thrombocytes < 150,000/mm³. For the subgroup probably with EV, the Baveno VI criteria had PPV = 84.6% (Se = 40.7%, Sp = 74.6%, NPV = 26.8%) for predicting the presence of esophageal varices, while for the subgroup probably without EV had NPV = 80.3% (Se = 50.2%, Sp = 58.6%, PPV = 75.6%). The subgroup that had LS < 20 kPa and thrombocytes > 150,000/mm³, was compound of 60 patients. Using these criteria we correctly classified 80% patients, with a Se = 80%, Sp = 28.3%, PPV = 50%, NPV = 61.2%, AUROC = 0.70, CI = (68.2–71.3). The best cut-off value for TE for predicting the presence of EV of any grade in our group was > 23 kPa, AUROC 0.79 (Se = 68.8%, Sp = 56.9%, PPV = 44.7%, NPV = 78.4%).

Conclusion: By using the Baveno VI criteria in patients with liver cirrhosis for the prediction of presence of esophageal varices, we can misclassify only 20% of patients.

Contact E-mail Address: doc.ragesh@gmail.com

Introduction: Non-invasive fibrosis scores (NIFs) are increasingly replacing liver biopsy (LB) for estimation of liver fibrosis. Only limited studies have evaluated the role of NIFs in predicting development of esophageal varices (EV) and decompensation in cirrhotic patients. Similarly there are limited studies evaluating combination of radiologic and blood parameters in predicting fibrosis and outcomes of cirrhosis.

Aims & Methods: We aimed to compare combined radiologic-blood parameters (CRBP) and blood derived non-invasive fibrosis scores (NIF) for predicting pre-treatment cirrhosis, development of esophageal varices (EV) and liver decompensation post antiviral treatment (AVT). 1605 patients (Jan 2002 to June 2015) with CHC underwent liver biopsy (LB) and received AVT with pegylated interferon and ribavirin. Three CRBPs (platelet count-bisplenic diameter index [PSI], platelet count-bisplenic diameter-portal vein index [PSPVI], platelet count-bisplenic diameter-portal vein-caudate lobe length index [PSCLI]) and nineteen blood derived NIFs were calculated from routine blood tests and abdominal ultrasound

done prior to starting AVT. AUROCs were calculated for each of these parameters for predicting cirrhosis on pre-treatment LB and development of EV and decompensation on follow-up after AVT.

Results: Mean age was 41.9 ± 9.7 years (85% males), predominantly genotypes 4 (65%) and 1 (11%). Pretreatment LB (Scheuer criteria) showed stage-0 fibrosis in 1.9%, stage-1 in 32.9%, stage-2 in 39.5%, stage-3 in 19%, and stage-4 (cirrhosis) in 6.6% of the patients. After AVT, there were 1,089 (67.8%) responders, 482 (30%) nonresponders and 34 (2.1%) relapsers. After median follow-up of 6580.5 patient-years post AVT; 39 (2.4%) developed EV (2 patients had both esophageal and gastric varices and one had only gastric varices) and 52 (3.2%) had decompensation (bleed-9, ascites-39, jaundice-22, hepatic encephalopathy-7, hepatorenal syndrome-4). CRBPs had higher accuracy for prediction of cirrhosis and EV, while NIFs had higher accuracy for predicting decompensation (Table 1). The highest AUROCs were seen with PSI for predicting cirrhosis (AUROC = 0.882) and EV (AUROC = 0.885) and with FIB-4 score for decompensation (AUROC = 0.854). At a cut of 1200 PSI had sensitivity of 87.2% and specificity of 75% for predicting cirrhosis and at a cut off of 1100 PSI had sensitivity of 89.4% and specificity of 85.7 for predicting EV. At a cut off of 2.5, FIB-4 score had a sensitivity of 82.5% and specificity of 80.1% in predicting decompensation. **Conclusion:** CRBPs predict cirrhosis and development of esophageal varices with high accuracy. Some of the blood derived NIFs have high accuracy in predicting decompensation post antiviral treatment. Application of these simple scores may help in non-invasive screening of patients at high risk for development of esophageal varices and decompensation after antiviral treatment.

Introduction: Minimal Hepatic Encephalopathy (MHE) is present in more than 30% of patients with chronic liver disease (CLD), and is associated with a poor prognosis including a higher incidence of falls, RTAs and overall mortality. Detection of MHE is often difficult due to time constraints associated with the current gold standard, the psychometric hepatic encephalopathy score (PHES), which includes five paper-based tests. A smartphone application (EncephalApp Stroop Test) has been suggested as a viable alternative.

Aims & Methods: We aimed to validate the use of the EncephalApp Stroop Test as a screening tool for MHE in an Irish population. CLD patients and healthy controls were recruited from outpatients. CLD patients were identified based on clinical and radiological evidence. Written consent was obtained. Exclusion criteria: cognitive impairment from any other cause, colour-blindness or dyslexia. Baseline demographics, level of education and medical history were obtained, and a Child-Pugh score was calculated where relevant. Each patient performed the PHES test and the Stroop test. Outcomes included the time taken to perform each PHES test as well as the total PHES, the Stroop on + off time and time taken to complete 5 correct runs on the Stroop App. Results were analysed using a Stroop cut-off defined by a previous publication: on + off time > 190 seconds. Both tests were compared and correlation coefficients calculated. Results were compared amongst patient groups using a student t-test, where p < 0.05 was considered significant. ROC analysis was used to establish a standard local cut-off for a positive Stroop test.

Results: A total of 96 patients (51 males) were recruited. Overall, the mean age was 51.7 ± 16.6 years; mean years spent in education 13.8 ± 4.2. In all there were 35 CLD and 61 healthy controls. While there was no difference in age or years spent in education, there were more men in the CLD group compared to the controls, 23/35 (66%) vs. 28/61 (46%), p = 0.06. Within the CLD cohort, 30 (86%) patients were Child-Pugh class A, 4 (11%) were class B and 1 (3%) was class C. As expected, more CLD patients had a positive PHES, 4/35 (11%) vs. 3/61 (7%). Overall, correlation between the two tests was poor. 7 (7%) participants had a positive PHES, while 47 (49%) had a positive Stroop test (κ = 0.1516). Among controls, 27 (44%) had a positive Stroop test, while 3 (5%) had a positive PHES (κ = 0.1223). Similarly, 20 (57%) CLD patients had a positive Stroop test and 4 (11%) had a positive PHES (κ = 0.1765). Regarding the Stroop test, the mean time taken to complete 5 correct runs was significantly higher in CLD patients, mean 117.9 s [58.3–217.8 s] vs. 101.2 s [55.3–218.6 s], p = 0.02. However, mean Stroop on + off times were similar, 198.4 s [102.6–307.7 s] in the CLD cohort versus 187.9 s [101.2–420.9 s] in the control group. Of note, CLD patients with a positive PHES had a significantly higher Stroop on + off time compared to those with a negative PHES, mean 260 s vs. 190 s, p = 0.02. ROC analysis gave a Stroop on + off time of > 187 s as a positive cut-off for our cohort, sensitivity = 100%, specificity = 59%. In total, 39 patients had an on + off time > 187 s, 18 (51%), 2 fewer false positives, in the CLD group, and a slightly better correlation (κ = 0.2404). On average, PHES took 20 minutes to complete, and the Stroop test 5 minutes. Older age and limited years of education correlated with a poorer performance on the Stroop test (r = 0.62, p < 0.0001 and r = -0.322, p < 0.0001, respectively). However, neither age nor years of education correlated with performance on the PHES (r = 0.087, r = 0.12, respectively).

Abstract: P1336, Table 1: Predictive Accuracy of Different Combined Radiological and Blood Parameters and Non-invasive Fibrosis Scores for Predicting Cirrhosis, Development of Esophageal Varices and Decompensation

NIFs/CRBPs	Cirrhosis on liver biopsy (pre treatment)*	Esophageal varices (post antiviral treatment)*	Decompensation (post antiviral treatment)*
AST-platelet ratio index (APRI)	0.842 (0.800–0.884), 0.021	0.769 (0.607–0.932), 0.083	0.538 (0.063–0.783), 0.120

PSI*	0.882 (0.700–0.963), 0.042	0.885 (0.794–0.977), 0.047	0.596 (0.319–0.874), 0.142
PSPV	0.872 (0.709–0.936), 0.033	0.845 (0.703–0.983), 0.071	0.551 (0.300–0.803), 0.128
PSPVCLI	0.850 (0.737–0.922), 0.047	0.852 (0.738–0.962), 0.057	0.495 (0.248–0.743), 0.126

*AUROC (95% Confidence interval), standard error

Test	PHES+	PHES -	Stroop+	Stroop -	Kappa
All patients	7	89	39	57	0.107
CLD	4	31	18	17	0.2404

Conclusion: This is the first study investigating the efficacy of the Stroop test in Ireland. It was quicker and easier to perform compared to PHES test. Age and years in education had a greater impact on the Stroop test, which may affect its application and interpretation. While our ROC analysis suggests a similar cut off to previously published values, there is significant variability and local validation is likely to be required. Overall the comparison with the gold standard PHES was poor. However, there were no false negative Stroop tests suggesting it may be a convenient filter test for MHE.

Introduction: Cirrhosis is accompanied by significant changes of the intestinal microbiome including the overgrowth of the intestine with potential pathogens that can translocate through a weakened gut barrier and cause severe infections. We hypothesized that probiotic bacteria repress intestinal pathogen growth and strengthen the gut barrier.

Aims & Methods: Therefore, we conducted a randomized, double-blind, placebo-controlled study to test the effects of the multispecies probiotic Ecologic Barrier (Winlove, Amsterdam, The Netherlands)/Omnibiotic Hetox (Allergosan, Graz, Austria) on microbiome composition, predicted metagenome functions, and tight junction function in cirrhosis patients. A once daily dose of the probiotic mixture (1.5×10^{10} CFU) or placebo was administered to 58 patients with Child's A cirrhosis. We analysed the stool microbiome prior, immediately after the intervention and six months following end of treatment. Hypervariable region 1–2 of the bacterial 16S rDNA was sequenced and predictive communities were identified using Ada Boost Classifier. Functional predictions were analysed by Phylogenetic Investigations of Communities by Reconstruction of unobserved States (PICRUST). Zonulin and calprotectin were assessed in stool as markers for gut permeability and intestinal inflammation, respectively.

Results: A community of 37 operational taxonomic units (OTUs) was sufficient to pinpoint characteristic features of the microbiome before and after the intervention. Within this predictive community, three OTUs were found to be differentially abundant: *Lactobacillus brevis* and *Lactococcus lactis* increased significantly and *Enterococcus durans* decreased significantly in the probiotic group. Zonulin normalized in 20% of patients in the probiotic group. Predicted metagenome functions (assessed by PICRUST) and calprotectin did not show any differences during intervention.

Conclusion: In conclusion, a six months intervention with a multispecies probiotic enriched the microbiome of cirrhotic patients with probiotic bacteria. Additionally, the abundance of *Enterococcus durans* was reduced and the gut barrier was strengthened.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1339 THE IMPACT OF DIABETES MELLITUS ON SHORT-TERM AND LONG-TERM OUTCOMES AFTER LIVER TRANSPLANTATION

Introduction: Diabetes mellitus (DM) is a growing disease worldwide. Some previous studies have reported negative impact of DM in patients with chronic liver disease.

Aims & Methods: This study aimed to investigate the prevalence of DM in patients with liver cirrhosis and its impact on post-liver transplant short-term and long-term outcomes. In a cross-sectional study patients with liver cirrhosis on liver transplant waiting list who had undergone liver transplantation between March 2012 and March 2015 at Shiraz Transplant Center, Shiraz, Iran were included. Clinical and laboratory data of patients were recorded and patients were followed during post-liver transplant period. DM was diagnosed if the patient had fasting plasma glucose (FPG) ≥ 126 mg/dL or random plasma glucose ≥ 200 mg/dL in 2 different checkings or receiving anti-diabetic medications. The impact of DM on post-transplant outcomes was investigated using student t-test and chi-square test. Multivariate logistic regression was used for analysis of independent risk factors of mortality after liver transplantation. Kaplan-Meier method was used for analysis of survival.

Results: 1014 patients were included in the study. 259 patients (25.5%) found to have DM. Prevalence of DM was significantly higher among patients with cirrhosis due to non-alcoholic steatohepatitis (NASH) ($P < 0.001$). Portal vein thrombosis (PVT) was significantly higher among cirrhotic patients with DM (OR = 1.79; 95% CI: 1.18–2.70; $P = 0.005$). Mean model for end stage liver disease (MELD) score, body mass index (BMI) and duration of liver disease were not different in patients with and without DM ($P > 0.05$). Mean blood urea nitrogen (BUN) in 30 days post-transplant period was 16.17 ± 17.4 mg/dL in patients without DM compared to 18.39 ± 11.95 mg/dL in patients with DM ($P < 0.001$). Mean serum creatinine level was 1.46 ± 0.95 mg/dL in patients without DM compared to 1.78 ± 1.92 mg/dL in patients with DM ($P = 0.001$).

Rejection episodes (OR = 1.38; 95% CI: 0.47–1.1, $P=0.129$) and acute kidney injury (OR = 1.33; 95% CI: 0.96–1.84, $P=0.07$) after liver transplantation were not statistically different in patients with and without DM. Using Kaplan-Meier method, mean post-liver transplant survival was 50.94 ± 0.67 months in cirrhotic patients without DM and 45.26 ± 1.46 months in cirrhotic patients with DM ($P < 0.001$). Post-liver transplant survivals at 6 months, 1 year and 4 years were outlined in Table. In patients with DM, presence of hepatocellular carcinoma (HCC) (OR = 4.01; 95% CI: 1.64–9.78, $P=0.002$), acute kidney injury within 30 days after transplant (OR = 2.05; 95% CI: 1.02–4.10, $P=0.042$) and pre-transplant PVT (OR = 2.51; 95% CI: 1.16–5.14, $P=0.019$) were independent predictors of mortality after liver transplantation.

Table: Post-liver transplant survival at 6 months, 1 year and 4 years in patients with and without DM

	6 month survival	1 year survival	4 year survival
With diabetes	$81\% \pm 2.5\%$	$79.1\% \pm 2.6\%$	$75.9\% \pm 2.8\%$
Without diabetes	$90.6\% \pm 1.1\%$	$88.7\% \pm 1.2\%$	$85.4\% \pm 1.3\%$

Conclusion: Diabetes mellitus is prevalent in patients with liver cirrhosis especially among those with NASH. Patients with DM may have lower post-transplant survival and need more intense follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The Baveno VI guidelines propose that cirrhotic patients with a liver stiffness measurement (LS) < 20 kPa and a platelet count $> 150,000/\mu\text{L}$ can avoid screening endoscopy as their combination is highly specific for excluding clinically significant varices.

Aims & Methods: The aim of the study was to validate the Baveno VI criteria. We did a retrospective study, from 2009–2014. We took all the patients with transient elastography data. Inclusion criteria were a LS > 12 kPa and an upper gastrointestinal endoscopy within 12 months, with a diagnosis of chronic liver disease. Varices were graded as low risk (grade < 2) or high risk ($> \text{grade } 2$).

Results: The study included 774 patients (hepatitis C virus 40.5%, hepatitis B virus 16.1%, 31.6% etanolics, 11.8% other etiology, and 47.5% were Child Pugh A). Varices were present in 561/774 (2.4%) cases, with 8% prevalence of high risk varices. 306/774 (39.6%) were at low risk and 468/774 (60.4%) had high risk varices. 59/774 (7.6%) met the Baveno VI criteria. The Baveno VI criteria gave a Se = 62.2%, Sp = 80.6%, NPV = 44.6%, PPV = 89.5%, positive likelihood ratio = 3.4, negative likelihood ratio = 0.47. If we combined the LS < 20 kPa and platelet count $> 150,000$, the AUROC was 0.73, CI (0.68–0.74), $p < 0.0001$.

Conclusion: The Baveno VI criteria has correctly appoint 85.3% of patients who could safely avoid endoscopy.

P1341 MORTALITY PREDICTING MODEL IN LIVER CIRRHOSIS PATIENTS

R. Lupusoru¹, I. Sporea¹, S.A. Popescu¹, A. Stepan¹, A. Pascaru¹, M. Danila¹, A. Barbulescu¹, I.M. Ratiu¹, B. Miutescu¹, R. Sirli¹

¹Department Of Gastroenterology And Hepatology, Victor Babes University of Medicine and Pharmacy Timisoara, Timisoara/Romania

Contact E-mail Address: raluca_lupusoru@yahoo.ro

Introduction: Cirrhotic patients very often need to be hospitalized and it is known that they have a higher mortality rate.

Aims & Methods: The aim of the study was to assess the factors associated with mortality among cirrhotic patients and to create a new score for predicting mortality. The study was retrospective, and we included all hospitalized patients with the final diagnosis of liver cirrhosis on a period of 7 years. We divided them in two cohorts, an initial group, which was analysed; and a control group, in which we validated the score. We performed univariate and multivariate analysis in order to determine a prediction model for mortality.

Results: A total of 1163 cirrhotic patients were included. In-hospital mortality rate was 10%. The initial cohort included 899 patients. Regarding cirrhosis etiology: 384/899 (42%) had hepatitis C, 158/899 (17.5%) had hepatitis B, 293/899 (32.5%) were alcoholic, 6/899 (0.6%) were autoimmune, 7/899 (0.7%) were cardiac, 13/899 (1.4%) were primary biliary cirrhosis and in 5% of cases the etiology was unknown. In univariate analysis, hyponatremia ($p < 0.0001$), hyperpotasemia ($p < 0.0001$), hypoalbuminemia ($p < 0.0001$), high values of bilirubin ($p < 0.0001$), high values of creatinine ($p < 0.0001$) were strongly associate with in hospital mortality. In multivariate analysis, the model including albumin, sodium, potassium, creatinine and bilirubin (all p -values < 0.05) had an AUROC = 0.78, CI (0.75–0.81), $p < 0.0001$. Using this factors as predictors, by multiple regression analysis we obtained in the initial group the following score: ABCPS score = $0.04 + 0.03 \cdot \text{Albumin} + 0.05 + 0.02 \cdot \text{Creatinine} + 0.04 + 0.04 \cdot \text{Bilirubin} + 0.05 + 0.28 \cdot \text{Potassium} + 0.04 \cdot 0.07 \cdot \text{Sodium}$.

Conclusion: Prevention and prompt treatment of kidney injury, hyponatremia, hyperpotasemia, can improve survival. ABCPS score can be an usefull score to rule out patients with high mortality rate.

P1342 BARIATRIC SURGERY IS ASSOCIATED WITH INCREASED RISK OF DEVELOPING ACUTE LIVER INJURY: A NATIONWIDE ANALYSIS

P.T. Kroener¹, P. K. Wander¹, V. Popov², C. C. Thompson³

¹Mt. Sinai St. Luke's/West, New York/United States of America

³Division Of Gastroenterology, Hepatology, And Endoscopy, Brigham and Women's Hospital, Boston/United States of America

Contact E-mail Address: thomaskroener@gmail.com

Introduction: Bariatric surgery provides a durable method of weight loss but is associated with serious adverse events. Some studies report an increase in drug-induced acute liver injury following bariatric surgery.

Aims & Methods: We aimed to assess if bariatric procedures increase the risk of acute liver failure in a large inpatient cohort. We retrospectively analyzed discharge data on patients who developed acute liver injury (ALI) using the Nationwide Inpatient Sample (NIS) database from 2010–2013. Discharges with an ICD-9 code indicating ALI were included. The primary outcome was ALI in patients with a history of bariatric surgery compared to all other patients with an inpatient diagnosis of ALI. Secondary outcomes were mortality in the two cohorts and independent socio-demographic and medical risk factors for mortality in each cohort. Variables tested include age, gender, race, income, Charlson criteria, hospital factors and medical comorbidities including Malnutrition, HTN, Anemia, CKD, Diabetes, CHF, Coagulopathy, Alcoholism, HBV and HCV. Univariate and multivariate logistic regression analyses were performed to identify independent predictors.

Results: During the study period, a total of 437,390 patients were diagnosed with acute liver injury and were included in the study, of which 3,799 had previously undergone bariatric surgery. In the post-bariatric cohort, mean age was 58.7 years and 77% were women. The prevalence of acute liver injury in all inpatient admissions for that time period was higher in patients with history of bariatric surgery (0.85%) than in non-bariatric patients (0.75%), $p < 0.01$. Patients with history of bariatric surgery displayed odds ratio of 1.52 of developing ALI when compared to patients with no history of bariatric surgery (95%CI: 1.43–1.61, $p < 0.01$). The rate of overall inpatient mortality was higher in non-bariatric cohort (15.9% versus 9.3%). Post-bariatric patients admitted for ALI were more likely to be younger, female, Caucasian and residing in more affluent areas. Post-bariatric patients were also more likely to have higher rates of malnutrition, anemia, alcoholism, and significantly lower prevalence of hepatitis B and C, CHF, diabetes and kidney disease. In a multivariate regression model, the presence of CHF and coagulopathy increased mortality risk, and diagnosis of alcoholism was associated with lower mortality risk from ALI in patients with prior history of bariatric surgery (Table).

Comorbidity	Adjusted Odds Ratio	95% CI	p-value
Malnutrition	1.86	0.89–3.88	0.10
HTN	0.64	0.34–1.18	0.16
Anemia	0.63	0.36–1.11	0.12
CKD	1.66	0.79–3.54	0.18
Diabetes	1.04	0.55–1.94	0.91
CHF	3.92	1.77–8.71	<0.01
Coagulopathy	1.75	1.03–2.96	0.04
Alcoholism	0.48	0.25–0.95	0.04
HCV	0.86	0.27–2.72	0.80

Conclusion: Bariatric surgery increases the risk of subsequent acute liver injury. Post-bariatric surgery patients admitted for ALI are more likely to have anemia, malnutrition, and alcoholism, supporting the hypothesis that baseline nutritional status may predispose to drug-induced ALI. Addressing these potentially modifiable risk factors may decrease the significant morbidity and mortality of ALI.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1344 LONGITUDINAL MONITORING OF LIVER STIFFNESS BY ACOUSTIC RADIATION FORCE IMPULSE IMAGING IN PATIENTS WITH CHRONIC HEPATITIS B RECEIVING ENTECAVIR

S. Wu¹, H. Ding², L. Liu¹, N. Xu³, W. Jiang¹

³Zhongshan Hospital, Fudan University, Shanghai/China

Contact E-mail Address: wu.shengdi@zs-hospital.sh.cn

Introduction: Acoustic radiation force impulse (ARFI) imaging measures liver stiffness (LS), which significantly correlates with the stage of liver fibrosis in treatment-naïve patients with chronic hepatitis B (CHB). So far, the use of ARFI elastography to monitor change in liver fibrosis has not been properly evaluated during antiviral therapy in CHB patients.

Aims & Methods: We aimed to prospectively assess the clinical usefulness of ARFI during long-term antiviral therapy in CHB patients. Seventy-one CHB patients were consecutively recruited and received antiviral therapy with entecavir. Paired liver biopsies were performed in 27 patients at baseline and week 78 of entecavir therapy. LS was assessed by ARFI at multiple follow-up sessions.

Results: LS significantly decreased with treatment and continued to decrease after normalization of alanine aminotransferase. Overall, 97.2% patients achieved improvement of LS, whereas 19.7% patients had more than 30% reduction in LS values between baseline and week 104. Multivariate linear regression analysis showed that the degree of LS reduction significantly correlated with the baseline levels of LS value, platelet and cholinesterase. In the 27 patients who received paired liver biopsies, LS significantly correlated with stage of fibrosis and inflammatory grade at baseline. LS values decreased more significantly in patients with fibrosis regression than those with static histological fibrosis. Changes in LS value (change threshold=15%) was significantly correlated with the changes in histological fibrosis staging ($r=0.63$, $P<0.001$).

Conclusion: In CHB patients, LS assessed by ARFI was significantly reduced during antiviral therapy. Longitudinal monitoring of LS might be a promising noninvasive assessment of fibrosis regression during long-term antiviral therapy in CHB. Further studies on large populations are warranted.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In chronic infection with Hepatitis B virus (HBV) hepatic steatosis is mainly attributable to metabolic risk factors, rather than virologic factors. We aimed to assess the presence of hepatic steatosis in chronic HBV inactive carriers using non-invasive methods, namely controlled attenuation parameter (CAP) determined with fibroscan. We also aimed to identify risk factors associated to hepatic steatosis and their impact in the values of fibrosis determined with fibroscan.

Aims & Methods: Fibroscan was performed in chronic HBV inactive carriers, with assessment of hepatic transient elastography and CAP, with simultaneous assessment of anthropometric, clinical and analytical parameters. CAP values of 248,268 and 280 dB/m defined cut-offs of steatosis grade I, II and III, respectively.

Results: Included 49 patients with a mean transient elastography of 5.1 ± 1.5 Kpa and a mean CAP of 248.9 ± 49.3 dB/m. A significant association was found between the value of CAP and the presence of steatosis in the last ultrasound (234.4 ± 46.0 dB/m vs 289.4 ± 34.0 dB/m, $p < 0.01$), the presence of elevated triglycerides (239.9 ± 49.8 dB/m vs 284.1 ± 28.1 dB/m, $p = 0.01$) and obesity (244.0 ± 46.7 dB/m vs 290.7 ± 46.6 dB/m, $p = 0.01$). When comparing patients with CAP > and ≤ 268 dB/m, patients with higher CAP values more frequently were overweight (BMI ≥ 25 kg/m²) (45.8% vs 84.0%, $p < 0.01$) and had metabolic syndrome (MS) (12.5% vs 40%, $p < 0.03$), and also presented with higher values of BMI (24.6 ± 2.6 kg/m² vs 29.2 ± 6.4 kg/m², $p < 0.02$), waist circumference (85.0 ± 9.0 cm vs 97.9 ± 11.3 cm, $p < 0.01$) and triglycerides (95.6 ± 31.4 mg/dL vs 136.1 ± 62.9 mg/dL, $p = 0.01$) and lower values of HDL cholesterol (58.9 ± 14.3 mg/dL vs 50.4 ± 14.4 mg/dL, $p < 0.01$). A significant association was also found between the value of elastography and female gender (females 4.6 ± 1.3 KPa vs males 5.8 ± 1.5 KPa, $p < 0.01$), elevated triglycerides (4.9 ± 1.5 KPa vs 6.0 ± 1.1 KPa, $p = 0.03$) and obesity (4.9 ± 1.4 KPa vs 6.5 ± 1.1 KPa, $p < 0.01$).

Conclusion: Different components of MS seem to contribute both to fibrosis and steatosis in chronic HBV inactive carriers. In this subset of patients, the interpretation of fibrosis values assessed by fibroscan should be made with caution since it may be influenced by metabolic parameters.

P1346 ANTIVIRAL EFFICACY OF UNANI HERBS (SAUSSUREA LAPPA AND ARTEMISIA ABSINTHIUM) IN CHRONIC HEPATITIS B

S. Ansari¹, M. A. Siddiqui¹, S. Malhotra², M. Maaz¹

¹Department Of Moalajat (medicine), School of Unani Medicine, Jamia Hamdard, New Delhi, India, New Delhi/India

²Department Of Gastroenterology, Batra Hospital and Research Centre, New Delhi/India

Contact E-mail Address: drshabnamansari.md@gmail.com

Introduction: Chronic hepatitis B (CHB) is a serious health concern in terms of its high prevalence, as well as restricted and costly health care resources in India.¹ Unani herbal drugs such as root of *Saussurea lappa* and whole plant of *Artemisia absinthium* have been used successfully in the treatment of hepatitis in Unani Medicine for centuries. These drugs have exhibited potential anti-hepatitis B, hepatoprotective, immuno-modulatory, anti-inflammatory and anti-oxidant activities in various animal models.² With this background, present prospective clinical trial was tried to be designed according to the guidelines of American association for the study of liver diseases (AASLD) and implemented after Institutional ethical clearance.

Aims & Methods: Objective was to evaluate the antiviral effect of herbal drugs, *Saussurea lappa* and *Artemisia absinthium* against hepatitis B virus (HBV) in the management of CHB and to collect data to warrant further clinical trials. In an open prospective single-arm study, we assigned 30 patients with HBeAg-negative or HBeAg-positive CHB to receive decoction of root of *Saussurea lappa*, 15 mL (containing approx. 1 g of dried aqueous extract) in the morning and decoction of *Artemisia absinthium*, 15 mL (containing approx. 1 g of dried aqueous extract) in the evening once daily empty stomach for 12 weeks. Physicochemical standardization and TLC and HPTLC fingerprinting of decoctions were also done. Test drug was evaluated for its efficacy in loss of HBsAg (miniVIDAS®) and HBeAg (CLIA tech.), a plasma HBV DNA level (RT PCR) of less than 200 IU/mL at week 12 (after treatment). Normalization of alanine aminotransferase levels [ALT (enzymatic assay)] without any significant adverse effects (clinical parameters, haemogram, kidney function test, and blood sugar fasting and post prandial) at week 6 (mid-treatment) and 12 (after treatment) would be suggestive of resolution of inflammation of liver.

Results: 1. HBsAg loss was observed in 5 (35.71%) patients in HBeAg-positive group (n = 14) ($p < 0.05$) and 4 (25%) patients in HBeAg-negative group (n = 16) at week 12 (after treatment) ($p = 0.10$). These 9 HBsAg negative patients were further assessed on 26th week of treatment, all 9 maintained their negative HBsAg status. 2. HBeAg loss was observed in 71.42% patients at week 12

($p < 0.001$). cVR was achieved in 57.14% patients in HBeAg-positive group ($p < 0.01$) and 37.5% of patients in HBeAg-negative group at week 12 ($p < 0.05$). 3. Normalization of ALT was observed in 85.71% and 81.25% patients in HBeAg-positive and HBeAg-negative group respectively at week 12 ($p < 0.001$) without any significant adverse effects in clinical and laboratory parameters ($p > 0.05$) at mid and after treatment.

Conclusion: 1. Our study has substantiated that *Saussurea lappa* and *Artemisia absinthium* have antiviral effect against HBV in chronic hepatitis B. 2. Test drug effectively suppressed HBV DNA, HBeAg and HBsAg in study patients. 3. Normalization of liver function test showed that the test drug can improve functions of liver without any significant adverse effects for a treatment duration of 12 weeks. 4. Limitation include small sample size, small duration and without control. Unlike other studies on CHB evaluating effect of conventional antivirals, we have enrolled only selected clinically stable CHB patients who were not diabetic and hypertensive, without liver fibrosis, and not have other neurological, kidney and heart disease, being a pilot study. 4. Future recommendation of double blind randomized clinical trial with standard control with large sample size, longer duration and including cirrhotic patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

³Department of Translational Medical Science, University of Naples "Federico II", Napoli/Italy

Contact E-mail Address: assessa1990@gmail.com

Introduction: Serum HBsAg loss is the recommended stopping rule in nucleoside-analogues (NUC) responders, even if this event occurs rarely.

Aims & Methods: We aimed to investigate in patients with chronic HBeAb+ hepatitis the kinetics of HBsAg levels during the NUC therapy to evaluate the predictive parameters of HBsAg seroclearance. Patients with CHB, receiving NUC antiviral therapy with stable viral suppression (HBV-DNA < 20 IU/ml), were recruited at the Gastroenterology Unit of the University of Naples "Federico II". Sequential serum samples from these patients were tested for HBsAg quantification with the ElecsysHBsAg II Quant immunoassay (Roche Diagnostics, Indianapolis, USA). HBsAg levels were determined before starting NUC treatment and on-treatment every 12 months.

Results: A total of 95 HBeAg-positive, HBeAg-negative patients (M/F: 73/22, median age 50 yrs, 34% cirrhotic) with stable viral suppression by NUCs, were enrolled. Precisely 56 patients underwent to Tenofovir, 22 Entecavir and 17 Lamivudine. The median treatment duration was 111 months, range 25-183 months. There was a significant decrease of the HBsAg levels during NUC therapy from 3471 IU/ml at the baseline to 1758 IU/ml at the last determination ($p < 0.001$). The statistically significant HBsAg decrease was also maintained when the patients were clustered according to antiviral therapy, severity of liver disease and previous interferon treatment. HBsAg seroclearance occurred in 18/95 patients (19%). The multivariate analysis showed that the only predictive parameter statistically significant of HBsAg seroclearance is the HBsAg level at baseline. Moreover, HBsAg seroconversion to HBeAb occurred in 4/18 patients, in which undetectable HBsAg value was evidenced at least two years before the seroconversion, and NUC therapy was successfully stopped, without relapse after a mean follow-up period of 24 months.

Conclusion: The results of this study suggest a role of on-treatment HBsAg quantification in the management of NUC-treated patients. HBsAg measurement would be a useful parameter to optimize antiviral treatment schedule.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1348 IMPROVEMENTS IN CHRONIC HEPATITIS B PATIENTS AND THE ALTERATION IN GUT MICROBIOTA AFTER FECAL MICROBIOTA TRANSPLANTATION

C. Xiao, B. Zhang, J. Ren

Zhongshan Hospital Affiliated To Xiamen University, Department of Gastroenterology, Xiamen/China

Contact E-mail Address: xiaooxx@xmu.edu.cn

Introduction: Chronic hepatitis B (CHB) is a common liver disease worldwide, and can be progressed to liver cirrhosis and hepatocellular carcinoma. Unfortunately, only a minority of CHB patients could achieve the clearance or seroconversion of hepatitis B virus e-antigen (HBeAg), the end point of

treatment, even after multiple years of antiviral therapy. Therefore, it is urgent to develop new and effective strategy for treatment of CHB and examine the mechanisms.

Aims & Methods: In this study, we performed 60 times of fecal microbiota transplantation (FMT) by nasointestinal tube for 20 CHB patients who continued with their previous antiviral treatment, and accordingly measured the HBeAg level four weeks after each FMT. Fecal samples of CHB patients before (Baseline) and after FMT as well as donors were collected for analyses of gut microbiota by sequencing 16S V3-V4 regions on Illumina MiSeq using PE 250 reagents.

Results: Results showed that HBeAg of 13 patients (65%) was cleared or reduced after one to seven times of FMT. Based on OTUs at cutoff of 3% dissimilarity, there were significant (PERMANOVA, $P = 0.001$) differences in overall gut bacterial communities among CHB-Baseline, CHB-FMT, and donors, forming three major clusters in PCA ordination. Whereas, no significant differences (ANOVA, $P > 0.05$) were detected in α -diversity indexes among the three groups, including observed OTU numbers, Shannon index, Simpson index, and Pielou evenness. This implies that it is the taxonomic relative abundance, not taxon number, that contributed to the bacterial community differences. Overall, gut bacteria were mainly composed of Firmicutes (Lachnospiraceae, Ruminococcaceae, Veillonellaceae), Bacteroidetes (S24-7, bacteroidaceae, Prevotellaceae), and Proteobacteria (Alcaligenaceae, Enterobacteriaceae). More specifically, Actinomyces was significantly higher in CHB patients (CHB-Baseline) than FMT-treated patients (CHB-FMT) and donors, and was identified as the biomarker of CHB using LEfSe analysis. Conversely, Prevotella and Eubacterium were significantly decreased in CHB-Baseline after FMT to almost equal to the abundances in donors, and were also identified as biomarkers.

Conclusion: In summary, along with the clearance or remission of HBeAg, the gut bacterial communities of chronic hepatitis B patients were remarkably altered after fecal microbiota transplantation, with some taxa abundances changed accordingly, which suggested their potential application as targets for clinical diagnosis and treatments in future.

P1349 EFFICACY OF PEGYLATED INTERFERON ALFA-2A ADD-ON THERAPY VERSUS NUCLEOSIDE ANALOGUE MONOTHERAPY IN TREATMENT-EXPERIENCED CHRONIC HEPATITIS B PATIENTS: A RANDOMISED, CONTROLLED, OPEN-LABEL TRIAL

X. Hu¹, J. Ye¹, W. Yanqin¹, R. Li¹, C. Shao¹, Z. Bihui¹

¹Gastroenterology, the First Affiliated Hospital of Sun Yat-sen University, Guangzhou/China

Contact E-mail Address: 1446989090@qq.com

Introduction: Hepatitis B surface antigen (HBsAg) seroconversion is rarely achieved in chronic hepatitis B (CHB) patients during nucleoside analogue (NA) monotherapy. The efficacy of pegylated interferon alfa-2a (peg-IFN α -2a) add-on therapy in those CHB patients remains unclear.

Aims & Methods: We aimed to compare the efficacy of peg-IFN α -2a add-on therapy with NA monotherapy in treatment-experienced CHB patients. We enrolled hepatitis B e antigen (HBeAg)-negative CHB patients aged older than 16 from the First Affiliated Hospital of Sun Yat-sen University in China. All had received NA monotherapy for 3 years with sustained undetectable plasma HBV DNA. The exclusion criteria included: cirrhosis or other chronic liver diseases, previous immunological therapy, pregnancy and breastfeeding, contraindications for peg-IFN α -2a, or other serious diseases. The eligible patients were assigned to receive peg-IFN α -2a add-on therapy for 48/72 weeks or to continue to receive NA monotherapy for 96 weeks. HBV DNA levels, HBV serologic indicators, liver function, renal function, thyroid function, blood cells count and imaging examination were assessed. The primary end point was HBsAg loss from baseline to week 96.

Results: 71 patients were enrolled (22 to peg-IFN α -2a add-on therapy group and 49 to NA monotherapy group), of whom 9 in peg-IFN α -2a add-on therapy group and 25 in NA monotherapy group completed more than 24 weeks of follow-up, the remaining patients have not yet reached 24 weeks of follow-up. There was no significant difference in age, gender, body mass index (BMI), HBeAg levels, alanine aminotransferase (ALT), or aspartate aminotransferase (AST) between the two groups at baseline. At week 24, HBsAg levels in peg-IFN α -2a add-on therapy group were significantly lower than the baseline (2.96 ± 0.14 vs 2.09 ± 0.82 Log₁₀ IU/ml, $p = 0.009$), but there was no obvious change in NA monotherapy group (3.43 ± 0.46 vs 3.44 ± 0.44 Log₁₀ IU/ml, $p = 0.843$). The HBsAg loss in peg-IFN α -2a add-on therapy group was significantly higher than in NA monotherapy group at week 24 (0.87 ± 0.76 vs -0.01 ± 0.10 Log₁₀ IU/ml, $p = 0.008$). Among those patients who completed 96 weeks of follow-up, two patients in peg-IFN α -2a add-on therapy group (22.22%) achieved HBsAg seroconversion, but none in NA monotherapy group (0%).

Conclusion: The peg-IFN α -2a add-on therapy increased loss of HBsAg in HBeAg negative treatment-experienced CHB patients as compared to NA monotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1350 HEPATITIS C IN LEBANON: BURDEN OF THE DISEASE AND VALUE OF COMPREHENSIVE SCREENING AND TREATMENT

Introduction: As few reliable data on the burden of hepatitis C virus (HCV) are available from the Middle East, we analyzed HCV burden in the Lebanese population and the value of comprehensive screening and treatment at different age groups and fibrosis stages.

Aims & Methods: A multi-cohort, health-state-transition model was developed to project the number of HCV patients achieving a sustained virologic response 12 weeks after treatment (SVR₁₂) or progressing to compensated cirrhosis (CC), decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC), and liver-related death (LrD) from 2016 to 2036. Epidemiology and mortality data were extracted from the Ministry of Health bulletin while costs were collected from insurance claims. The proportion of patients screened for HCV was projected to increase to 60%/85%/99% (low/medium/high screening scenarios) in 2036, with a new cohort of patients being diagnosed each year. SVR₁₂ rates were extracted from clinical trials. Separate models were used for 18–39 and 40–80 age groups to account for difference prevalence and screening rates.

Results: Low, medium and high HCV screening scenarios showed that 3838, 5665 and 7669 individuals would be diagnosed with HCV infection from 2016 to 2036, 40% aged 18–39 and 60% aged 40–80. In the absence of treatment, the projected number of patients reaching CC, DCC, HCC and LrD in 2036 was 899, 147, 131 and 147 respectively for the 18–39 age groups. In the 40–80 age groups, these projections were substantially greater: 2828 CC, 736 DCC, 668 HCC and 958 LrD. The overall economic burden of these liver complications would reach 150 million €. However, introducing direct-acting antivirals (DAAs) for F0–F4 patients would increase by 43% and 62% the proportion of remaining life-years (LYs) spent in SVR₁₂ compared to DAAs given to F2–F4 or to F3–F4 only, respectively. Although DAAs for F0–F4 increase the cost of HCV treatment, they also provide the greatest population health benefit and lowest cost per LY gained in SVR₁₂. Compared to no treatment and screening, adopting the high screening variant and DAAs access to F0–F4 would cost an additional 1,957 € for every LY gained in SVR₁₂ for patients aged 18–39 and 168 € for the 40–80 age group.

Conclusion: An enhanced screening policy coupled with broader access to DAAs will diminish the future clinical and economic burden of HCV in the Lebanese population and provide the greatest health benefits per amount invested, among middle-aged and elder adults with a big difference in additional costs between the 2 groups.

P1351 HEPATITIS C TREATMENT IN HEMODIALYSIS PATIENTS: THE EFFICACY AND SAFETY OF DIRECT-ACTING ANTIVIRALS IN THE REAL LIFE

L. Carvalho, J. Rodrigues, M.A. Túlio, T. Bana, E Costa, L. Lebre, C. Chagas
Gastroenterology, Centro Hospitalar de Lisboa Ocidental, Lisboa/Portugal

Contact E-mail Address: lilipcarvalho@gmail.com

Introduction: Hepatitis C virus (HCV) infection is a prevalent condition in patients with end-stage renal disease (ESRD) and increases the risk of death. Treatment of HCV in these patients reduces both morbidity and mortality rates and improves the outcomes of one future kidney transplantation. Yet patients with hepatitis C and chronic kidney disease have few treatment options. Direct-acting antivirals (DAA) are a well-established, effective and safe treatment regimen of the HCV infection, but proofs on ESRD patients requiring hemodialysis (HD) are scarce. Additional studies are still necessary in order to evaluate the real impact of these agents in the daily clinical practice.

Aims & Methods: Our objective was to assess the efficacy and safety of DAA treatment for HCV-infected patients with ESRD under HD, in the daily practice of a tertiary care centre, describing the HCV infection, treatment type, the evolution of virological response and clinical outcomes (anemia and other adverse effects). The HD and HCV-infected patients treated with DAA between April 2015 and February 2017 were analyzed.

Results: Our sample included 16 patients, 13 males (81%) and 3 females (19%), with a mean age of 59 years (45–72 years). Fourteen Caucasians and 2 diabetics patients. Four patients were treatment-experienced (25%). The mean viral load was 5.5 Log₁₀ (3.9–7.07 Log₁₀). Genotype distribution was the following: genotype 1–81% (13/16) and genotype 4–19% (3/16). Distribution according to fibrosis stages was as follows: F ≤ 2–62% (10/16), F3–19% (3/16) and F4–19% (3/16). All these patients underwent a treatment regimen with ombitasvir/paritaprevir/ritonavir and dasabuvir (3D). Seven of these patients (44%) received concomitant ribavirin at an average dose of 400 mg per week (200–600 mg per week). The treatment duration was 12 weeks for 13 patients (81%) and 24 weeks for others 3 patients (19%). Regarding treatment response rates, 81% (13/16) of patients had Rapid Virological Response (RVR) and 100% (16/16) of patients had End of Treatment Response (ETR). The global sustained virologic response (SVR) rate was 100%. Hemoglobin was monitored throughout the treatment, with 2 cases of severe anemia, one led to a 3D suspension at week 21 and the other one to a

ribavirin suspension at week 4 of treatment. There were no other serious adverse effects.

Conclusion: In our sample of ESRD under HD patients, 3D therapy allowed the eradication of HCV with high efficacy, even in patients who did not meet the expected duration of treatment or dose of ribavirin. The safety of DAA in this group is demonstrated by the non-occurrence of severe adverse effects.

P1352 HEPATITIS C TREATMENT IN RENAL TRANSPLANTATION: THE EFFICACY AND SAFETY OF DIRECT-ACTING ANTIVIRALS IN THE REAL LIFE

L. Carvalho, J. Rodrigues, M.A. Túlio, T. Bana, E Costa, L. Lebre, C. Chagas
Gastroenterology, Centro Hospitalar de Lisboa Ocidental, Lisboa/Portugal

Contact E-mail Address: lilipcarvalho@gmail.com

Introduction: Hepatitis C virus (HCV) infection in renal transplant patients predisposes to graft failure and progression of renal disease, increasing mortality. Due to immunosuppression and oscillating glomerular filtration rate (eGFR) in these patients, the treatment of HCV infection confers a greater challenge. Direct-acting antivirals (DAA) are a well-established, effective and safe treatment regimen of the HCV infection, however evidences on renal transplantation are scarce. Additional studies are still necessary in order to evaluate the real impact of these agents in the daily clinical practice.

Aims & Methods: Our objective was to assess the efficacy and safety of DAA treatment for HCV-infected patients with renal transplantation, in the daily practice of a tertiary care centre, describing the HCV infection, treatment type, the evolution of virological response and clinical outcomes (kidney function, anemia and other adverse effects). HCV-infected and renal transplanted patients treated with DAA between April 2015 and February 2017 were analyzed.

Results: Including 19 patients, 10 males (53%) and 9 females (47%) with a mean age of 57 years (40–70 years). The majority of these patients (89%) were treatment-naïve. Genotype distribution was the following: genotype 1–74% (14/19), genotype 3–16% (3/19) and genotype 4–10% (2/19). Distribution according to fibrosis stages was as follows: F ≤ 2–63% (12/19), F3–21% (4/19) and F4–16% (3/19). Sixteen patients (85%) were treated with sofosbuvir/ledipasvir, 2 (10%) with sofosbuvir/daclatasvir and 1 (5%) with sofosbuvir. Concomitant ribavirin was given in 4 patients. The treatment duration was 12 weeks for 16 patients (84%) and 24 weeks for others 2 (10%). One patient realized only 21 weeks of treatment, needing to suspend it due to severe anemia. Regarding treatment response rates, 74% (14/19) of patients had Rapid Virological Response (RVR) and 100% (19/19) of patients had End of Treatment Response (ETR). The global sustained virologic response (SVR) rate was 100%. Hemoglobin, eGFR and immunosuppression levels were monitored during this period. The eGFR (CKD EPI) did not change significantly, with pre and posttreatment mean values of 66.4 and 65.4 ml/min/1.73m², respectively. There were 2 cases of severe anemia, one that resulted in ADA suspension at week 21 and the other one ribavirin suspension at week 7 of treatment. Immunosuppressive levels remained stable. There were no other serious adverse reactions.

Conclusion: In our sample of HCV-infected with kidney transplant, DAA are effective and well tolerated, even in the more advanced stages of fibrosis, maintaining the integrity and viability of the graft, without interfering with the efficacy of immunosuppressant.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1353 WHAT HAPPENED WITH LIVER STIFFNESS VALUES ASSESSED BY MEANS OF TRANSIENT ELASTOGRAPHY IN PATIENTS WITH HCV LIVER CIRRHOSIS AFTER DAA TREATMENT

I. Sporea¹, R. Lupusoru¹, S.A. Popescu¹, A. Lazar¹, R. Mare¹, L. Gheorghe², S. Iacob², R. Sirli¹

Introduction: Liver stiffness (LS) measurements by Transient Elastography (TE) has been widely accepted as a tool for fibrosis assessment.

Aims & Methods: The aim of this study was to assess LS dynamics in a group of patients with HCV liver cirrhosis after DAA treatment. This bicentric clinical

trial included 276 patients with compensated HCV cirrhosis (all genotype 1b), who received DAA for 12 weeks. All patients were evaluated by means of TE at the beginning and at the end of treatment (EOT), and one subgroup (180 patients) also 12 weeks after EOT, all of them with sustained viral response (SVR 12), and another subgroup (55 patients) also at 24 weeks after EOT (SVR 24). Reliable LS measurements (LSM) were defined as median value of 10 valid LSM, with IQR < 30% and SR ≥ 60%. Both M and XL probes were used. For diagnosing cirrhosis we used a cut-off value of 12 kPa as proposed by the Tsochatzis meta-analysis. We considered a decrease or increase of more than 10% in LSM as being significant.

Results: Out of 276 subjects, reliable measurements were obtained in 92.7%, so that the final analysis included 256 patients. The mean LS values decreased significantly after DAA: 25 ± 11.7 kPa vs. 22.5 ± 12 kPa ($p = 0.009$). Most patients, (59.7%–152/256) presented more than 10% decrease in LS values, 23% (59/256) had stable LS values, while in 17.3% (45/256) cases, the LS values increased. In the subgroup of 180 patients where LSM were also performed 12 weeks after EOT (SVR 12), the mean LS values were significantly lower 12 weeks after EOT as compared to baseline: 20.3 ± 10.8 kPa vs. 25.5 ± 11.4 kPa ($p < 0.0001$) and also as compared to EOT: 20.3 ± 10.8 kPa vs. 22.8 ± 12.2 kPa, ($p = 0.04$). In the subgroup of 55 patients where LSM were also performed 24 weeks after EOT (SVR 24), the mean LS values were significantly lower at SVR 12 and SVR 24 as compared to EOT (18.7 ± 8.2 kPa vs. 21.6 ± 7.7 kPa, $p = 0.05$ and 18.3 ± 6.6 kPa vs. 21.6 ± 7.7 kPa, $p = 0.01$).

Conclusion: In our group mean liver stiffness values evaluated by TE significantly decreased after antiviral treatment at SVR 12 and SVR 24, as compared to EOT. Overall, in our study almost 60% of patients had EOT liver stiffness values lower than at baseline, at SVR 12 almost 75% of patients had liver stiffness values lower than at baseline and at SVR 24 almost 77% of patients had liver stiffness values lower than at baseline.

Introduction: Baveno VI criteria suggest that cirrhotic patients with platelet count (PLT) > 150,000/μl and liver stiffness measure values (LSM) < 20 kPa bare a low risk of having high-risk esophageal varices (EV) and do not require endoscopic screening. The direct-acting antiviral agents (DAA) determine a very high rate of sustained virologic response (SVR) among patients with HCV induced chronic hepatitis and cirrhosis, and therefore, might decrease the risk of decompensation, including variceal bleeding.

Aims & Methods: Therefore, the aim of the study was to assess the influence of DAA therapy on the accuracy of the Baveno VI criteria for in cirrhotic HCV patients. All consecutive patients with compensated HCV liver cirrhosis approved for DAA treatment in our center who gave their informed consent were included. All patients were screened for EV before starting the therapy by esogastroduodenoscopy. LSM (FibroScan®) and usual biological parameters were evaluated at baseline and when assessing SVR 12.

Results: 50 patients were included (59.5 (45–84) years, 54% women) between December 2015 and July 2016. All patients achieved SVR (100%). At baseline, 17/50 patients had EV. After completing DAA therapy, liver enzymes [GOT ($p < 0.0001$), GPT ($p < 0.0001$)], GGT ($p < 0.003$) and LSM ($p < 0.0001$) significantly decreased, while albumin ($p = 0.014$) and PLT ($p = 0.39$) increased. We found a moderate correlation between GOT and LSM both at baseline ($r = 0.31$; $p = 0.001$) and at RVS12 ($r = 0.45$; $p = 0.004$), but the amplitude of the decrease appears not to be correlated [Δ GOT vs.

Δ LSM) = 0.149; $p = 0.3$]. At baseline, according to Baveno VI criteria, 29 patients were classified at low risk of having EV (accuracy 68%, Se 69.7%, Sp 64.7%, PPV 79.31%, NPV 52.38%). At SVR12, 10 additional patients entered this class, but the accuracy (60%) decreased.

Conclusion: DAA therapy induces a significant decrease in liver inflammation and liver stiffness and also a non-significant increase of platelets count. These changes induce a decrease of the accuracy of classification of patients with low risk of having EV (according to Baveno VI criteria), therefore is not advisable to use Baveno VI criteria as surrogate for endoscopy screening for esophageal varices in patients compensated HCV liver cirrhosis who obtained SVR.

P1355 MONOCYTE CHEMOATTRACTANT PROTEIN-1 CONCENTRATIONS IN SERUM DEPEND ON OVERWEIGHT IN CHRONIC HEPATITIS C PATIENTS AND INCREASE AFTER SUSTAINED VIROLOGIC RESPONSE

I. Valkov¹, T. Velikova², K. Tumangelova-Yuzeir², D. Kyurkchiev², K. Antonov¹

Introduction: Monocyte chemoattractant protein-1 (MCP-1) is a chemokine mediator in liver inflammation and fibrogenesis. It contributes to the severity of nonalcoholic fatty liver disease and chronic hepatitis C (CHC) by recruiting proinflammatory activated monocytes and macrophages. Signaling between the mononuclear phagocyte system (MPS) and hepatic stellate cells is key for active fibrogenesis. The extent to which metabolic and immune factors are implicated in fatty liver of patients with CHC is still not clear.

Aims & Methods: The aim of the study was to explore the associations between serum MCP-1, liver fibrosis, fatty liver and metabolic factors in CHC patients before, and after antiviral treatment. We included 21 patients in the study (11 men, 10 women, age 42 ± 9.7) with chronic hepatitis C virus (HCV) infection–17 with genotype 1 and 4 with genotype 3. Liver biopsy was done in 19 and histology showed fatty liver in 8 patients. Fatty liver was present in 17 of all patients on ultrasound. Liver fibrosis was scored mild (F1) in 9, significant (F2) in 7 and advanced bridging fibrosis (F3) in 2 cases (METAVIR). Compensated liver cirrhosis (F4) was diagnosed in 3 cases by liver biopsy or endoscopic screening for varices. Weight was normal in 10, overweight in 5 and obese in 6 patients. MCP-1 was quantified by ELISA in serum. Laboratory panel included complete blood count, liver tests, HOMA-IR and serum lipid levels. Seventeen patients received treatment (standard of care peg-interferon alpha, ribavirin and/or direct-acting antivirals). Sustained virologic response (SVR) was attained by 12 and non-response/relapse (NVR) by 5 patients. Serum probes were obtained before treatment and after response evaluation. Statistical analysis included Spearman's rho, Mann-Whitney U test, Wilcoxon's test and Student's paired t-test.

Results: MCP-1 in serum correlated with BMI ($r = 0.522$, $p = 0.015$). MCP-1 concentrations in overweight and obese patients were higher than in those with normal weight ($p = 0.020$). Patients with F3-F4 had higher BMI ($p = 0.010$) and HOMA-IR ($p = 0.042$). An increase in serum MCP-1 was found in patients after SVR ($p = 0.018$), while no significant variation from baseline values was found in NVR patients. The result remained significant in subgroup analysis of SVR patients with F1-F2 ($p = 0.028$) and in those with fatty liver ($p = 0.017$). MCP-1 in serum did not show any association with assessment of liver fibrosis, fatty liver, insulin resistance and serum lipid levels.

Conclusion: MCP-1 concentrations in serum depend on overweight in patients with CHC. Overweight and insulin resistance are associated with progression of CHC. Serum levels of MCP-1 increase after HCV clearance. Fluctuation of the MCP-1 concentration in serum could reflect an antiinflammatory activation of MPS and a gradient dependent dynamic replacement of the profibrotic cell subsets in the liver with proresolution ones after SVR. Fatty liver plays a role for inflammatory responses in CHC patients after SVR.

Disclosure of Interest: All authors have declared no conflicts of interest.

²Endemic Medicine And Hepatology, Mansoura University, Mansoura/Egypt

³Mansoura Faculty of Medicine, Mansoura/Egypt

Contact E-mail Address: raghda.farag@yahoo.com

Introduction: HCV interferes with the host lipid metabolism leads to insulin resistance and hepatic steatosis. Although it is usually mild in genotype 4, many data suggests that simple steatosis may have the potential to progress to fibrosis, cirrhosis and subsequent hepatocellular carcinoma. Many heritable host factors with observed inter-ethnic variation in the prevalence of steatosis are documented, and in many cases hepatic steatosis may be detected in absence of all these risk factors; so a role for host genetic factors in development of hepatic steatosis in chronic HCV patients may be suggested.

Aims & Methods: In this study, we aim to evaluate the association of HLA class A-B alleles and presence of steatosis in chronic HCV genotype 4 infected patients. This study included two hundred unrelated non diabetic non obese chronic HCV patients with normal lipid profile, 98 of them had biopsy proven steatosis. Serological testing of HLA class I antigens (HLA-A, and HLA-B alleles) were performed with a standard complement-dependent micro-lymphocytotoxicity assay.

Results: The frequency of A02, A03, B15 and B17 alleles were significantly higher in chronic HCV patients with steatosis (OR=1.77, 2.64, 4.44, 5.68) and 95% CI=0.96–3.27; 1.02–7.04; 0.84–31.17; 1.12–38.65 with P=0.034, 0.022, 0.044, 0.015 respectively. On the other hand, the frequency of A01 and B12 alleles were significantly higher in patients without steatosis (OR=0.56, 0.41) and 95% CI were 0.30–1.05; 0.20–0.83 and P=0.015 and 0.005. On logistic regression analysis, patients who carry HLA-A02, A03 and HLA-B15 alleles may have 2.2, 3.9 and 11.18 fold risk to have hepatic steatosis (B coefficient: 0.79; 1.37; 2.41) 95% CI=1.09–4.42, 1.04–11.05, 2.15–58.13; P=0.027, 0.009, 0.004) while carrying HLA-A01 alleles may be protected from having HCV associated hepatic steatosis; (OR=0.34, 95% CI=0.16–0.72; P=0.005) with constant -9.47 and overall accuracy of 69%. In addition, patients who have moderate activity index in liver histopathology have 5.9 risk to have hepatic steatosis (OR=5.92, 95% CI=2.92–11.99, P<0.001).

Conclusion: In chronic HCV genotype 4 patients, carrying HLA-A02, HLA-A03 and HLA-B15 alleles may have a risk for presence of hepatic steatosis while presence of HLA-A01 alleles may have a protective role.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1357 THE VALUE OF 2D-SWEGE FOR THE EVALUATION OF LIVER FIBROSIS IN PATIENTS WITH HCV COMPENSATED CHRONIC HEPATOPATHIES

F. Bende, I. Sporea, S.A. Popescu, R. Sirli, M. Danila, R. Mare, A. Stepan *Gastroenterology And Hepatology, University of Medicine and Pharmacy "Victor Babes" Timisoara, Timisoara/Romania*

Contact E-mail Address: bendefelix@gmail.com

Introduction: Chronic liver diseases are quite frequently encountered in daily practice and are due mainly to chronic viral infections (B or C viruses) and to other conditions such as alcoholic steatohepatitis - (ASH) and to non-alcoholic fatty liver disease (NAFLD). While liver biopsy remains the gold standard method for fibrosis assessment, stage classification and also for necro-inflammatory activity grading, in the last years, non-invasive assessment methods (biological tests and elastographic methods) were developed and they are being used more and more, to the detriment of liver biopsy.

Aims & Methods: The aim of this study was to evaluate the performance of the 2D-shear wave elastography technique from General Electrics (2D-SWE.GE), for the evaluation of liver fibrosis in patients with HCV chronic hepatopathies, using Transient Elastography (TE) as the reference method. The study included 145 consecutive subjects with HCV compensated chronic hepatopathies, in whom

liver stiffness was evaluated in the same session by means of 2 elastographic measurements: TE (FibroScan, EchoSens) and 2D-SWE.GE (LOGIQ E9, GE Healthcare). Reliable LS measurements were defined as follows: for TE—the median value of 10 measurements with a success rate of $\geq 60\%$ and an interquartile range $< 30\%$ and for 2D-SWE.GE - the median value of 10 measurements acquired in a homogenous area and an interquartile range (IQR) $< 30\%$. To discriminate between various stages of fibrosis by TE we used the following cut-offs: $F \geq 2$: 7.1 kPa, $F \geq 3$: 9.5 kPa, $F = 4$: 12.5 kPa [1].

Results: Reliable LS measurements were obtained in 138/145 (95.1%) subjects by 2D-SWE.GE and in 139/145 (95.8%) by TE ($p=0.9$). The final analysis was performed on 134 subjects with valid measurements by both methods. We found a good positive correlation between the LS values obtained by the 2 methods: $r=0.79$, $p < 0.0001$. Based on TE cut-off values [1] we divided our cohort into 4 groups: F0-F1: 36/134 (26.8%), F2: 23/134 (17.2%), F3: 23/134 (17.2%) and F4: 52/134 (38.8%). The areas under the receiver operating characteristic curve (AUROC) were 0.909 for significant fibrosis ($F \geq 2$), 0.954 for severe fibrosis ($F \geq 3$) and 0.942 for cirrhosis ($F = 4$). The best cut-off values for $F \geq 2$ was 7 kPa (Sensitivity 85.7, Specificity 80.5), for $F \geq 3$ it was 9.2 kPa (Sensitivity 85.3, Specificity 91.5) and $F = 4$ it was 10.7 kPa (Sensitivity 84.6, Specificity 91.4).

Conclusion: 2D-SWE.GE seems a reliable method for liver fibrosis staging in patients with HCV compensated chronic hepatopathies. The best 2D-SWE.GE cut-off values for $F \geq 2$, $F \geq 3$ and $F = 4$ in HCV chronic hepatopathies were 7, 9.2 and 10.7 kPa.

Introduction: The risk of developing novo hepatocellular carcinoma (HCC) persists after reaching sustained virological response (SVR) in patients infected with hepatitis virus C. It has been suggested that risk is increased in patients treated with the new direct antiviral agents (DAA). In this prospective study we present our results of incidence and prevalence of novo HCC in cirrhotic patients treated with DAA and SVR, and also, the risk factors involved in its development.

Aims & Methods: We included all cirrhotic patients due to HVC infection without previous HCC who reached SVR after DAA treatment in our hospital from February 2014 until December 2016 (n=197, median of follow-up of 17 months). We evaluated with chi square test the following qualitative variables: age, Child-Pugh stage, alcohol consumption pre-treatment, tobacco consumption pre-treatment, diabetes mellitus (DM) pre-treatment, genotype, radiological and endoscopic portal hypertension features pre-treatment. The quantitative variables were evaluated with student t test: age, no. of platelets pre-treatment, fibroscan value pre-treatment.

Results: During follow-up 11 patients were diagnosed of HCC (5.6% prevalence, 3.9% annual incidence). Among all variables evaluated being in a Child-Pugh B stage vs. an A stage ($p=0.007$), pre-treatment DM ($p=0.002$) and presence of radiological portal hypertension ($p=0.001$) were associated with developing novo HCC. Among the quantitative variables, we evidenced statistically significant differences in the mean value of platelets ($p=0.015$).

Conclusion: In our group of patients, a worse hepatic function evaluated with the Child-Pugh classification and indirect markers of portal hypertension (platelets and radiological features) and also DM are associated statistically significant with the development of novo HCC. The incidence ($> 1.5\%$) of novo HCC justifies the screening of HCC.

P1359 IS AN ACUTE LIVER FAILURE REALLY ALWAYS AN ACUTE LIVER FAILURE? PRE-EXISTING LIVER DISEASE IS COMMON IN PATIENTS WITH ALF DIAGNOSIS

A. Gottlieb¹, J. P. Sowa², M. Kottmann², P. Manka², L. Bechmann¹, A. Canbay¹

Introduction: An acute insult to the liver in patients without pre-existing chronic liver injury can cause acute liver failure (ALF). ALF is a life-threatening condition and requires specialized intensive care. Acute on chronic liver failure (AOCLF) is a not yet clearly characterized situation, where the acute insult occurs in addition to present chronic liver disease without cirrhosis. Though, various definitions of AOCLF are found in the literature. Discrimination of AOCLF from ALF might be trivial for pre-existing alcoholic or viral hepatitis. However, non-alcoholic steatohepatitis (NASH) in obese or diabetic patients might go unnoticed in the critical situation of an ALF/AOCLF. Thus, patients admitted to liver transplantation centers with the diagnosis of ALF might be suffering from AOCLF instead. It is also unclear if the ALF and AOCLF have different impact on disease course, clinical management and transplant organ allocation.

Aims & Methods: Aim of this study was to identify possible differences between patients with ALF and AOCLF regarding routine parameters and clinical course. In this retrospective single-center study all patients were recruited, who were admitted to the University Hospital of Essen with the initial diagnosis of ALF between 2008 and 2015. Patients included in this study were fulfilling the criteria of the acute liver failure study group Germany. The diagnosis of AOCLF was established upon retrospective examination of patient records. In total 163 patients were recruited (ALF: 131; AoCLF: 32). Clinical records, in particular demographic data, serum parameters and outcome were analyzed for differences between ALF and AOCLF.

Results: Patients with AOCLF were significantly older (50.3 ± 15.1 vs. 39.8 ± 16.2 , $p=0.0008$), had a higher BMI (27.5 ± 5.1 vs. 24.5 ± 6.2 , $p=0.0014$) and were more often male (65% in AOCLF vs. 34% in ALF $p=0.0008$). In addition, the insults that caused the liver failure in AOCLF were significantly different from those patients with ALF. Significant differences were also found for liver enzymes, which were significantly lower in AOCLF patients (AST $p=0.01$; ALT $p=0.001$). Cell death markers and the MELD did not differ between ALF and AOCLF. Moreover, the outcome was not different between the two groups neither separated as survived or deceased nor as spontaneous remission or non-spontaneous remission (combined transplantation and deceased). Importantly, MELD and the modified MELD including the cell death marker M65 were similarly effective in predicting outcome for both ALF and AOCLF.

Conclusion: In the present study patients with ALF and AOCLF differed in age and BMI, but did not exhibit differences regarding disease severity (according to MELD) or clinical outcome. While the causes for an acute insult differed between ALF and AOCLF, which might imply a different clinical management, clinical outcome was predictable by common factors for ALF.

P1360 EFFECTS OF PREOPERATIVE TRANSARTERIAL CHEMOEMBOLIZATION ON PATIENTS' SHORT TERM PROGNOSIS AFTER LIVER TRANSPLANTATION

D. Ma

Department Of Hepatobiliary Surgery, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai/China

Contact E-mail Address: madi_1978@163.com

Introduction: To explore the influence of preoperative transarterial chemoembolization on short-term prognosis in patients with hepatocellular carcinoma after liver transplantation.

Aims & Methods: A retrospective study was conducted among patients with hepatocellular carcinoma who received liver transplantation from January 2009 to September 2015 in Ruijin Hospital. A total of 31 patients (Male: 29/Female: 2) were included. Among them, 14 patients received preoperative hepatic arterial chemoembolization was incorporated into observation group ($n=14$), and the other 17 patients were included in the control group ($n=17$). The data including TBL/ALT/AST levels in preoperative and 1, 3, 5, 7 postoperative days, operation time, blood loss, postoperative complications happening (incision infection, vascular complications, biliary complications, complications classification), perioperative mortality and hospitalized time was analyzed to compare the differences between the two groups of patients.

Results: No statistical difference was found in the total operation time, blood loss and length of hospital stay between two groups, and the occurrence rate of vascular complications, biliary complications and postoperative infection also showed no difference. Although more patients above Clavien IIIa were in the observation group, there was no statistically significant difference in the perioperative mortality between two groups. Besides, preoperative TACE could effectively reduce complications caused by immune reaction ($P=0.048$). In terms of postoperative indexes of liver function, TBIL, ALT, AST all had a transient rise during the first 3 days after liver transplantation, but recovered gradually over time. There's no remarkable difference in the liver function recovery level between two groups ($P=0.495$; $P=0.141$; $P=0.101$). No statistical difference was found in the total operation time, blood loss and length of hospital stay between two groups, and the occurrence rate of vascular complications, biliary complications and postoperative infection also showed no difference. Although

more patients above Clavien IIIa were in the observation group, there was no statistically significant difference in the perioperative mortality between two groups. Besides, preoperative TACE could effectively reduce complications caused by immune reaction ($P=0.048$). In terms of postoperative indexes of liver function, TBIL, ALT, AST all had a transient rise during the first 3 days after liver transplantation, but recovered gradually over time. There's no remarkable difference in the liver function recovery level between two groups ($P=0.495$; $P=0.141$; $P=0.101$).

Conclusion: Preoperative TACE won't affect liver function recovery and perioperative safety after liver transplantation. For some patients, it could also reduce complications caused by immune reaction.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Romania has the highest incidence of tuberculosis (TB) in the European Union, representing one quarter of the European TB burden. According to clinical practice guidelines for liver transplantation (LT), the second level of screening for infections consists of screening for *Mycobacterium tuberculosis*, including history of TB, PPD, Interferon-gamma release assays.

Aims & Methods: The aim was to assess the importance of Quantiferon TB Gold test for evaluating patients included on the wait list for LT in Romanian setting. The study was a single-center retrospective cohort study (the single center for LT) that included 264 patients admitted on the wait list for LT from January 1, 2014 to November 18, 2016. All patients underwent mandatory screening for *Mycobacterium tuberculosis*, either using Quantiferon TB Gold test or skin testing using purified protein derivative (PPD). The variables analyzed using Minitab 17 were: age, gender, etiology of liver disease, biochemical test, MELD score.

Results: From a total of 264 patients with liver diseases included on the wait list, 60.6% were males, the average age at diagnosis was 47.78 ± 9.92 years. The etiology of liver cirrhosis was HCV infection in 31.43%, HBV and HBV-HDV coinfection in 45.06%, and alcoholic liver cirrhosis in 18.93%; 24.62% of patients have been diagnosed with superimposed hepatocellular carcinoma. Eighty three patients (31.43%) had positive results for Quantiferon test, 150 patients (56.81%) were negative and 17 patients (6.43%) had indeterminate results. Only 14 patients (5.3%) were skin tested using PPD, 2 (0.75%) of them with positive results. Comparing the subgroups, positive Quantiferon test was associated with HCV etiology (p value = 0.049) and lower lymphocyte counts, but did not achieve statistical significance ($p=0.187$). Patients with indeterminate Quantiferon associated hyperbilirubinemia ($p=0.044$), hypoalbuminemia ($p=0.032$) and had a higher MELD score ($p=0.019$). After assessment by a multidisciplinary team that included a pneumologist, 38.63% of patients were diagnosed with latent TB. Isoniazid chemoprophylaxis along with pyridoxine was postponed after LT, in order to prevent further hepatic dysfunction. 48.5% of patients underwent LT, followed by TB prophylaxis and no cases of TB reactivation have been reported during a follow-up period of 14 months.

Conclusion: Patients transplanted for HCV-related liver cirrhosis should benefit from a careful follow-up on the WL and prompt TB prophylaxis after LT in order to prevent TB reactivation during early immunosuppression. Delaying TB prophylaxis after LT in order to avoid liver toxicity of anti-bacillary drugs was not associated with TB reactivation.

P1362 A NATIONAL STUDY OF CANCER DIAGNOSES IN IRISH LIVER TRANSPLANT RECIPIENTS WITH PRIMARY SCLEROSING CHOLANGITIS

S. M. O'Reilly¹, K. Harterly¹, M. Walshe¹, S. Deady², E. O'Leary², G. A. Doherty¹, D. Houlihan³, G. Cullen¹, H. Mulcahy¹, J. Sheridan¹

¹Centre For Colorectal Disease, St Vincent's University Hospital, Dublin/Ireland

²National Cancer Registry Ireland, Cork/Ireland

³National Liver Unit, St Vincent's University Hospital, Dublin/Ireland

Contact E-mail Address: susannemoreilly@gmail.com

Introduction: Primary sclerosing cholangitis (PSC) is associated with an increased risk of cholangiocarcinoma, colorectal cancer (CRC) and gallbladder cancer. Orthotopic liver transplantation (OLT) patients are at increased risk of developing de novo malignancies, however limited and conflicting data exists regarding cancer risk post OLT for PSC.

Aims & Methods: To examine all recorded malignancies over 2 decades in OLT PSC pts and compare to our non-transplanted PSC cohort. To analyse factors associated with the development of malignancies post OLT. We retrospectively studied PSC patients attending the Irish National Liver Unit (INLU) and the Centre for Colorectal Disease (CCD) at St. Vincent's University Hospital from 1/1/94–30/9/16. We integrated this database with the National Cancer Registry in Ireland. This enabled accurate determination of the no. of malignancies recorded in the PSC cohort. Analyzed data included age of recipient at OLT, gender, primary OLT indication, immunosuppressive regime, de novo malignancy post OLT, time from OLT to diagnosis of malignancy or death. Statistical analysis was primarily descriptive. Cox Proportional Hazard Model was used to analyse factors associated with mortality in the PSC OLT cohort.

Results: 107 of 173 patients had undergone transplant for PSC. 27/107 pts were transplanted for cholangiocarcinoma. 12 post-transplant de novo cancers and 12 BCC/SCC carcinomas were found in 107 patients during 737.8 person years of follow-up. Median time to cancer diagnosis post OLT was 5 years (IQR 2.8–5.9). Recurrence of PSC was observed in 21 patients (19.6%). Post-transplant lymphoproliferative disease (PTLD) remains a major complication after OLT. Prior studies have reported rates of 1–3% in adult OLT pts. 5 pts were diagnosed with lymphoma post OLT representing 4.7% of cohort. Median time to diagnosis was 5.3 yrs [IQR 2.8–10.2]. Regarding CRC, 2 patients developed CRC post OLT. 4 patients developed colonic dysplasia; 3/4 underwent colectomy. All those who developed colonic dysplasia/CRC post OLT had co-existing IBD. All 5 colectomy specimens for dysplasia/CRC showed significant co-existing inflammation. One patient post OLT underwent a completion colectomy for rectal cancer. As expected, cholangiocarcinoma as indication for OLT ($p=0.005$, RR 2.573, 95%CI 1.3–4.95) and an older age at transplant ($p=0.05$, RR 1.027, 95% CI 1–1.054) were associated with higher mortality.

Table 1

Cancer	SIR	95% CI
Any cancer	3.239	1.885–5.186
Excluding skin cancer	1.97	0.848–3.882
Lymphoma	36.574	14.65–75.36
Colorectal cancer	1.779	0.023–9.898

Conclusion: These findings represent national cancer figures in our PSC OLT cohort. The rate of cancer is more than three times higher in this population than the general population. The rates of PTLD are >30 times higher than those in the normal population, and slightly higher than previously reported in unselected liver transplant groups. We could not find any association between the development of PTLD and aggressive immunosuppressive regimes for co-existing IBD post OLT. The study highlights that IBD/PSC patients remain at significant risk of colonic neoplasia after OLT and require intensive surveillance.

²Department Of Immunogenetics, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

³Transplantcentre, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: drastich@hotmail.com

Introduction: Primary sclerosing cholangitis (PSC) is a chronic liver disorder of unknown etiology, characterized by inflammation, fibrosis and stenoses of both extra- and intrahepatic bile ducts. For those who develop end-stage liver disease, orthotopic liver transplantation (OLT) remains the only effective treatment currently available. PSC is accompanied with concomitant ulcerative colitis (UC) in a significant proportion of patients. Benefits of routine HLA typing in donor and recipient prior to OLT were proved in the past.

Aims & Methods: The aim of this study was to assess the impact of HLA-DR mismatch on acute cellular rejection (ACR), PSC recurrence (rPSC) and course

of UC after OLT. After applying inclusion/exclusion criteria we retrospectively evaluated records of 57 patients transplanted at Institute for Clinical and Experimental Medicine (Prague, Czech Republic) between July 1994 and November 2011. Only patients with proper records ± 5 years from OLT were included. We evaluated likelihood for each variable (ACR, rPSC, course of UC) in patients with either single, or double mismatch in HLA-DR. Input data were analysed with χ^2 and Fisher's exact test using MedCalc statistical software. A p -value <0.05 was considered as statistically significant.

Results: Out of 57 patients, 27 (47.4%) had single mismatch ("M1" group) and 30 (52.6%) had double mismatch ("M2" group) in HLA-DR. No patient had full match. 33/57 (57.9%) patients had ACR: 15/27 (55.6%) of M1 and 18/30 (60%) of M2 ($p=0.94$). 4/27 (14.8%) of M1 and 2/30 (6.3%) of M2 had corticosteroid resistant ACR ($p=0.57$). Multiple-episodes of ACR occurred in 11/57 (19.3%) patients: 6/27 (22.2%) of M1 and 5/25 (20%) of M2 ($p=0.74$). 12/57 (21.1%) had de-novo UC after OLT: 7/27 (25.9%) of M1 and 5/30 (16.7%) of M2 ($p=0.60$). In 37 (68.5%) patients, UC was diagnosed prior to OLT. 9/16 (56.3%) patients with M1 and 6/21 (28.6%) patients with M2 had more severe course of UC as compared to course prior to OLT ($p=0.17$). 38 patients were evaluated for rPSC, which was diagnosed in 17 (44.7%) individuals. 6/19 patients with M1 and 11/19 with M2 had rPSC ($p=0.19$).

Conclusion: Patients with single mismatch in HLA-DR have slight tendency towards development of rPSC and worsening of UC after OLT as compared to patients with double mismatch. Analysis of combined mismatch in HLA-DR and HLA-DQ could demonstrate more substantial linkages in respective clinical variables. Therefore, these data have to be considered as preliminary as typing for HLA-DQ from frozen blood samples is currently underway. Contact E-mail Address: es18497@gmail.com

Introduction: Liver biopsy remains the gold standard in the diagnosis of graft dysfunction in post-liver transplantation (GDPLT). Liver transient elastography is a valid non-invasive method for liver fibrosis evaluation, with a good correlation in chronic liver diseases. The progression of fibrosis represents a major problem in the post-liver transplantation.

Aims & Methods: We aimed to evaluate the predictive role of liver transient elastography in the evaluation of GDPLT and to determine the predictive factors of liver transplantation fibrosis. This was a retrospective observational cohort study of total of 49 patients with post-liver transplantation status who underwent liver transient elastography by Fibroscan®. Selected patients who underwent percutaneous/transjugular liver biopsy. In case of more than one liver biopsy, it was selected the biopsy closer to Fibroscan®. The fibrosis and steatosis evaluated by Fibroscan® were compared with those obtained by liver biopsy. Significant fibrosis was considered if $\geq F2$. Demographic, analytical and associated liver transplantation variables were evaluated.

Results: A total of 32 patients underwent Fibroscan® and liver biopsy. Mean age of 48.53 ± 11.20 years and male gender in 68.8% ($n=22$). The mean time between Fibroscan® and liver biopsy was 29.77 ± 36.90 months. The mean elastography score was 13.45 ± 8.31 KPa with IQR/med of 17.11 ± 8.66 %. Mean CAP score was 207.12 ± 57.35 dB/m. Regarding liver biopsy, 34.4% ($n=11$) had significant fibrosis and 25.0% ($n=8$) presented steatosis. Comparing two methods, there was no concordance for steatosis ($\kappa=0.273$; $p=0.117$) or inflammation ($\kappa=0.063$; $p=0.710$). On the contrary, a moderate agreement for significant fibrosis ($\kappa=0.431$; $p=0.003$) was verified. The mean elastography score showed an accuracy of 79.7% in predicting histological fibrosis (AUROC=0.797; $p=0.007$) to a cut-off value of 11.6 KPa ($S=81.8\%$; $Sp=76.2\%$). In relation to analytical parameters, only serum albumin was predictive of histological fibrosis (OR=2.79; $p=0.043$).

Conclusion: Liver transient elastography represents a non-invasive and valid alternative procedure to liver biopsy in the evaluation of post-liver transplantation fibrosis but not steatosis or inflammation. Liver transient elastography scoring ≥ 11.6 KPa and low values of serum albumin are predictors of post-liver transplantation fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1365 NEW-ONSET DIABETES AFTER TRANSPLANT (NODAT): INCIDENCE, RISK ANALYSIS AND IMPACT ON SURVIVAL. NEW-ONSET DIABETES AFTER TRANSPLANT (NODAT): INCIDENCE, RISK ANALYSIS AND IMPACT ON SURVIVAL

Y. Abbas¹, K. Nawaz¹, M. Salih², N. Ullah², S. Saadat³

³Nephrology, Shifa International Hospital, Islamabad/Pakistan

Contact E-mail Address: dryasirab@gmail.com

Introduction: Orthotopic liver transplant has become the standard of care for end-stage liver disease and hepatocellular cancer. Better immunosuppressant paved way for improved survival rates post-transplant. But with this longevity comes a higher prevalence of chronic diseases such as New Onset Diabetes After Transplant (NODAT). Hypertension, metabolic syndrome etc. which have a negative impact on graft function and patient survival.

Aims & Methods: Primary: To determine the incidence of New Onset Diabetes After Transplant (NODAT). Impaired Fasting Glycaemia (IFG) and post-transplant hyperglycemia in living-donor liver transplant recipients. Secondary: To determine the risk factors associated with NODAT and IFG. To determine impact of NODAT on survival and mortality. It was a retrospective cohort study of 283 living donor liver transplant recipients from 29/4/2011 till 26/4/2016. Data was collected from records. Simple means and standard deviation was calculated for continuous variables while frequency statistics were calculated for categorical ones. Risk factors were assessed using binary logistic regression analysis.

Results: A total of 130 post liver transplant patients were analyzed after exclusion. NODAT was present in 41/130 (31.5%) patients, while 19/130 (14.6%) patients had impaired fasting glycaemia. Acute cellular rejection, Post-transplant Hyperglycemia and Pre-transplant prediabetes showed increased odds of acquiring NODAT post-transplant. NODAT had significant association with mortality and decreased survival ($p=0.05$).

Conclusion: This cohort showed that NODAT is an important post-transplant entity with significant impact on mortality and survival. Early identification of at-risk patients is suggested.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: vera_anapaz@hotmail.com

Introduction: Serum vitamin B12 (vB12) levels are increased in myeloproliferative diseases by increased production of the haptocorrin transporter and in liver diseases by release of vB12 from hepatocytes death.

Aims & Methods: The aim of this study was to evaluate vB12 as a prognostic marker in patients with cirrhosis and acute on chronic liver failure (ACLF) induced by infection. Retrospective assessment of 58 patients admitted to an intensive care unit with ACLF in the context of infection (group 1) and 53 patients with compensated hepatic cirrhosis followed as Hepatology outpatients (group 2). Evaluation of vB12 as a predictor of 30 days' mortality.

Results: 111 patients, 68% male, age 58 ± 18 years. Group 1 had more advanced liver disease (CPT 11.9 ± 0.3 vs. 6.5 ± 0.2 and MELD 27.0 ± 1.0 vs. 10 ± 0.5), higher vB12 (1413 ± 149 vs. 735 ± 56 pg/mL) and lower survival (1.6 ± 0.4 vs. 6.4 ± 2.7 years). vB12 positively correlated with hepatic function scores (CPT: $R=0.524$; MELD: $R=0.566$). MELD and vB12 were independent factors of mortality at first month (OR 1.205 and 1.002 for increase of one unit of MELD or vB12). In patients with ACLF, vB12 correlated with liver disease severity (CPT: $R=0.411$; MELD: $R=0.534$) and multiorgan failure (number of organ failures: $R=0.536$, SOFA: $R=0.553$). In group 1, survival was lower in patients with high vB12 (8 ± 3 vs. 37 ± 11 months), and 1 month' mortality was associated with vB12, CPT, MELD, number of organ failure, urea, lactates and fibrinogen, in univariate analysis ($p < 0.001$). In multivariate analysis only fibrinogen maintained statistical significance ($p < 0.001$).

Conclusion: There was a strong association between high levels of vB12 and clinical decompensation of liver cirrhosis. vB12 correlated with scores of liver function and multiorgan failure, as well as early mortality in patients with ACLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1367 OUTCOMES OF LIVER TRANSPLANTATION IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

A. Eshraghian¹, S. Nikeghbalian², S. Ali Malek-Hosseini², B. Geramizadeh²

¹Gastroenterology And Hepatology, Shiraz University of Medical Sciences, Shiraz/ Iran

²Transplant Research Center, Shiraz/Iran

Contact E-mail Address: eshraghiana@yahoo.com

Introduction: Hepatocellular carcinoma (HCC) is the second leading cause of cancer-related mortality worldwide. Patients with viral hepatitis and those with non-alcoholic fatty liver disease (NAFLD) are especially susceptible to HCC. Parallel to an increase in prevalence of NAFLD, the prevalence of HCC is estimated to be increased in next years. Liver transplantation is now considered as a modality of treatment for patients with HCC.

Aims & Methods: This study aimed to investigate outcomes of liver transplantation in patients with HCC compared to other causes of liver transplantation. In a cross-sectional study patients who had undergone liver transplantation between March 2012 and March 2015 at Shiraz Transplant Center, Shiraz, Iran were included. Patients' characteristics including age, gender, model for end stage liver disease (MELD) score, rejection episodes, laboratory data and information about mortality of patients were recorded. Characteristics of tumor including size, number and vascular invasion were recorded. Based on these findings HCC patients were divided to those within Milan criteria and those beyond Milan criteria. The impact of HCC on post-transplant outcomes was investigated using student t-test and chi-square tests. Multivariate logistic regression was used for analysis of independent risk factors of mortality after liver transplantation. Kaplan-Meier method was used for analysis of survival.

Results: Totally 1014 liver transplant patients were included. 94 patients with HCC underwent liver transplantation. There was no statistically significant difference between those with and without HCC in terms of gender, portal vein thrombosis (PVT), diabetes mellitus (DM), hepatic encephalopathy and hospitalization before liver transplantation ($P > 0.05$). HCC was significantly more prevalent in cirrhosis due to viral hepatitis ($P < 0.001$). Acute rejection episodes was not different in patients with and without HCC in early post-transplant period (OR = 0.563; 95% CI: 0.27–1.14, $P=0.108$). In regression analysis, presence of pre-transplant DM (OR = 3.89; 95% CI: 1.36–11.11, $P=0.011$) and acute kidney injury within 30 days after liver transplant (OR = 4.38; 95% CI: 1.44–1327, $P=0.009$) were independent predictors of post-transplant mortality. Mean post-liver transplant survival in HCC patients within Milan criteria was 40.48 ± 3.69 months compared to 36.80 ± 6.28 months in those beyond Milan criteria ($P=0.82$). Mean post-transplant survival in patients with HCC + DM was 32.75 ± 4.7 months compared to 48.51 ± 2.60 months in HCC patients without DM ($P=0.009$).

Conclusion: Liver transplantation can be used for patients with HCC, however, post-transplant survival seems to be lower. Diabetes mellitus and acute kidney injury were predictors of mortality among our patients with HCC after liver transplantation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Liver is one of the most common metastatic sites of colorectal cancer, nearly 50% patients develop hepatic metastases during the course of their disease. Metastatic spread influences survival rate of those patients. The diffusion weighted imaging (DWI) is MRI sequence designed to detect random movement of water protons in extracellular compartment. Biophysical parameter expressing the flexibility of Brownian motion is the diffusion coefficient (ADC). ADC values for b parameter lower than 300 s/mm² are influenced by perfusion whereas ADC values for b greater than 300 s/mm² depend mainly on diffusion. Aggressive malignant process often develops necrotic areas within neoplastic lesion. Necrotic changes are characterized by high ADC values. We suppose that low ADC values correlate with presence of necrosis in highly malignant lesions effecting in lower survival rate.

Aims & Methods: This is a post hoc analysis of prospective study to assess the predictive value of the ADC in survival outcomes of patients undergoing radiofrequency ablation due to metastatic colorectal cancer lesions in the liver. We analyzed the MRI studies of 52 patients (18 F, 34 M, aged 4383) performed on 1.5 T scanner one day before the percutaneous RFA treatment. The total number of analyzed lesions was 110 (15 per patient), 83 of them were completely ablated, 27 incompletely, what was assessed in follow-up CT studies. The standard protocol of the liver MRI was applied including DWI sequence in b values of 0, 15 and 500 s/mm². ADC maps were calculated for b values of 015 and 0500 s/mm². The mean ADC value was obtained by threefold marking ROI covering the whole metastatic lesion. In cases of multiple foci only the lesion with the highest ADC value was included into analysis. On basis of ROC analysis the cut-off values of ADC were established: 2.49 mm²/s for b value of 015 s/mm² and 1.43 mm²/s for b value of 0500 s/mm². The survival outcomes were assessed by mean of Kaplan-Meier estimator. The p value lower than 0.05 was considered significant.

Results: The statistical analysis included KaplanMeier estimator for 52 patients with 9 censored cases (17.3%). In ADC maps for b value of 0500 s/mm², the ADC value ≥ 1.43 mm²/s correlated with longer survival time, whereas ADC value < 1.43 mm²/s correlated with shorter survival time. Statistically significant differences were identified by log rank test = 2.6998, p = 0.007. Such a correlation was not observed for ADC values in ADC maps for b value of 015 s/mm² (p = 0.058).

Conclusion: The study showed significant differences in survival rate depending on diffusion influenced ADC values of metastatic lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Type II diabetes and nonalcoholic fatty liver disease (NAFLD) are frequently associated, NAFLD being considered the hepatic expression of the metabolic syndrome.

Aims & Methods: The aim of the present study was to assess the severity of liver fibrosis and steatosis in a cohort of type 2 diabetic patients, using non-invasive methods: Transient Elastography (TE) and Controlled Attenuation Parameter (CAP). The study included 354 type 2 diabetic patients, who were prospectively randomized (every first 6 patients who were referred to the Metabolic Disease Outpatient Clinic on a consultation day), evaluated in the same session by means of TE and CAP (FibroScan EchoSens) to assess both liver fibrosis and steatosis. Each patient was evaluated for the presence of viral hepatitis (B, C) and an AUDIT-C score was performed to exclude alcohol abuse. Reliable liver stiffness measurements (LSM) were defined as the median value of 10 LSM with an IQR/median $< 30\%$. For TE and CAP, M and XL probes were used. A cut-off value of 8.2 kPa [1] was used to define severe fibrosis ($F \geq 3$). For differentiation between stages of steatosis we used the following cut-off values [2]: S2(moderate) - 255 db/m, S3(severe) - 290 db/m.

Results: Out of 354 diabetic screened we excluded those with associated viral hepatitis, those with an AUDIT-C score ≥ 8 and those with unreliable LSM. The final analysis included 239 subjects (59.4% women, 40.6% men, mean age 60.4 ± 9.3 ; BMI = 31.8 ± 6.1 kg/m²) with reliable LSM. Accordingly to BMI, 10.8% had normal weight, 26.4% were overweight and 62.8% were obese (35.6% obesity grade I, 17.2% obesity grade II and 10% obesity grade III). Moderate and severe steatosis by means of CAP was found in 18.4% and 69.5% cases respectively. Severe fibrosis was detected by means of TE (LSM ≥ 8.2 kPa) in 29.3% (70/239) of subjects.

Conclusion: In our group, 87.9% of diabetic patients had moderate and severe steatosis by CAP and 29.3% of them had severe fibrosis (TE ≥ 8.2 kPa), suggesting the need for their systematical assessment.

Introduction: Nowadays liver fibrosis can be assessed using non-invasive elastographic techniques. ElastPQ is a quite novel point share wave elastography integrated into an ultrasound system.

Aims & Methods: The aim of our study was to evaluate the learning curve of obtaining reliable liver stiffness measurements (LSM), using ElastPQ. LSM of a trainee were compared to LSM of an elastography expert (with an experience of more than 500 examinations). Our study group included 50 subjects (mean age- 52.7 years, 66.6% men, mean BMI = 25.6 kg/m²). Both the trainee and the expert obtained LSM for each subject, using ElastPQ (EPIQ 7, Philips Healthcare, Bothell, WA, USA). Reliable LSM were defined as the median value of ten measurements acquired in a homogenous area avoiding large vessels and with an IQR/median $< 30\%$. The learning curve was evaluated using the Receiver Operating Curve analysis using the expert's results as reference.

Results: The trainee's performance in obtaining reliable LSM was good (AUC: 0.735, 95% CI (0.557–0.913), p = 0.01). The trainee started to have similar results with the elastography expert after the 30th subject. When looking at the IQRs, they became significantly lower after the 30th subject (2.6 ± 2.1 kPa vs 6.5 ± 9.2 kPa, p = 0.03).

Conclusion: Obtaining reliable LSM using ElastPQ can be easily achieved after 30 LS examinations.

Introduction: In patients with liver cirrhosis, hepatocellular carcinoma (HCC) can be diagnosed by noninvasive imaging methods (contrast-enhanced ultrasound CEUS, contrast CT/MRI).

Aims & Methods: The aim of this study was to evaluate which is the most common enhancement pattern of HCC on CEUS in all three phases (arterial, portal and late phase). We performed a retrospective study that included patients with a final diagnosis of HCC established by an imaging method (contrast enhanced CT or MRI) or biopsy. A total of 249 patients with HCC were examined (180 men, 69 women, mean age 64 ± 10 years); 181 patients had liver cirrhosis and 68 patients chronic hepatopathy with severe fibrosis. All 249 HCCs were evaluated by CEUS using low mechanical index ultrasound, following an intravenous bolus of 2.4 ml SonoVue. CEUS was considered conclusive for HCC if a typical pattern was present following contrast examination (hyperenhancement in the arterial phase accompanied by portal and/or late phases washout). The nodules were classified according to their size in ≤ 3 cm and > 3 cm. We re-evaluated all 249 HCCs CEUS studies using the ACR CEUS LI-RADSv 2016 algorithm.

Results: After CEUS examination a conclusive diagnosis of HCC was obtained in 190/249 cases (76.3%). Arterial phase hyperenhancement pattern was present in 227/249 cases (91.2%), isoenhancement in the arterial phase was observed in 17/249 cases (6.8%) and hypoenhancement in 5/249 cases (2%). In the portal phase washout was observed in 111/249 cases (44.6%); in 121/249 (48.6%) patients the nodules were iso-enhancing and in 17/249 (6.8%) the arterial hyperenhancing pattern was maintained. In the late phase washout was observed in 197/249 (79.1%) cases. The nodules ≤ 3 cm were diagnostic conclusive on CEUS in 63.7% (72/113), while nodules > 3 cm had a conclusive result in 86% of cases (117/136), $p < .0001$. CEUS examination was conclusive for HCC in 76.3% of the cases (190/249), while using the ACR CEUS LI-RADSv 2016 algorithm in 72.2% of all HCCs (180/249), $p = 0.35$.

Conclusion: In our study, CEUS arterial hyperenhancement is the most common pattern observed in HCC (91.2% of cases), followed by washout in the late phase (79.1% of cases). The size of the nodule modifies CEUS sensitivity for the diagnosis of HCC $p < .0001$.

Introduction: Contrast-Enhanced Ultrasound (CEUS) is an imaging method that can be used to discriminate between hepatocellular carcinoma (HCC) and other focal liver lesions.

Aims & Methods: This study aimed to test the latest approved version of a contrast-enhanced ultrasound algorithm (ACR CEUS LI-RADSv 2016) for detecting hepatocellular carcinoma (HCC), in a real-life cohort of high-risk patients. We re-evaluated the CEUS studies of 298 focal liver lesions in patients at high-risk for HCC (liver cirrhosis of any etiology, chronic hepatitis B or C, with severe fibrosis, current or prior HCC) using the ACR CEUS LI-RADSv 2016 algorithm. CEUS LI-RADS categories used for the diagnosis of HCC were: CEUS LR-5 (definitely HCC), CEUS LR-5V (HCC with macrovascular invasion), CEUS LR-Tr (treated HCC). Contrast-enhanced CT, contrast-enhanced MRI or histology were used as reference methods to evaluate the CEUS LI-RADS classification of the 298 lesions.

Results: According to reference method, the 298 lesions were classified as follows: 211 HCCs, 60 non-HCC-non-malignant lesions (fatty infiltration, hemangiomas, simple cysts, regenerative nodules) and 27 non-HCC malignant lesions (liver metastases, cholangiocarcinoma, indeterminate). The diagnostic accuracy of ACR CEUS LI-RADSv 2016 for the diagnosis of hepatocellular carcinoma was 74.4%. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were 65.4%, 96.5%, 97.8% and 53.5%, respectively. When we used CEUS alone, a conclusive diagnosis of HCC was obtained in 69.6% of the cases (147/211), while using the algorithm in 65.4% of all HCCs (138/211), $p = 0.35$.

Conclusion: In our study 65.4% of all HCCs (138/211) were correctly diagnosed using ACR CEUS LI-RADSv 2016 algorithm, showing good sensitivity, excellent specificity and PPV for the diagnosis of HCC.

PI373 DICKKOPF-1: AS A SERUM BIOMARKER FOR PREDICTION OF HEPATOCELLULAR CARCINOMA TREATMENT RESPONSE

A. L. Sharaf¹, E. G. El-Badrawy¹, N. A. Khalifa²

¹Tropical Medicine Department, Zagazig University, Zagazig/Egypt

²Clinical Pathology Department, Zagazig University, Zagazig/Egypt

Contact E-mail Address: drahmed_lotfy@hotmail.com

Introduction: Hepatocellular carcinoma (HCC) is the 5th most common cancer worldwide and the 3rd leading cause of cancer-related mortality. In Egypt, HCC is the 2nd most common cancer in men and the 6th most common cancer in women. Egypt has the highest prevalence of HCV worldwide and has rising rates of HCC. HCC is a disease with fast infiltrating growth and poor prognosis. This bad prognosis is due to the lack of an effective method for early diagnosis. So, it is necessary to find a specific & sensitive marker for early diagnosis of HCC and for monitoring of treatment response.

Aims & Methods: The aim of this work is to assess prognostic value of serum DKK1 in predicting treatment response, complication and survival in HCC patients. This study included 60 Patients divided into two groups. Group A: consisted of 30 patients with liver cirrhosis. Group B: consisted of 30 patients with HCC. Group B patients underwent either radiofrequency ablation or ethanol injection. Clinical assessment, routine laboratory evaluation, CT studies and measurement of serum alpha-fetoprotein (AFP) and DKK1 were performed to all patients and repeated to group B patients 1 and 3 months after treatment.

Results: DKK1 significantly can be used for HCC diagnosis even in HCC with inconclusive AFP. The optimum cut off value of DKK1 for diagnosis of HCC was 4.3 ng/mL (AUC 0.89, sensitivity 66.7% and specificity 96.6%) ($P < 0.001$). Serum DKK1 level significantly decreases after HCC treatment with either radiofrequency ablation or ethanol injection ($P < 0.001$).

Conclusion: DKK1 has a promising prognostic value and can be used for follow-up of HCC patients before and after treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI374 EFFECT OF FIBROBLAST GROWTH FACTOR-2 AND ITS RECEPTOR GENE POLYMORPHISMS ON SURVIVAL IN PATIENTS WITH HEPATITIS B VIRUS-ASSOCIATED HEPATOCELLULAR CARCINOMA

J. Cheong

Gastroenterology, Ajou University Hospital, Suwon/Korea, Republic of

Contact E-mail Address: jaeyoun620@gmail.com

Introduction: Fibroblast growth factor (FGF), vascular endothelial growth factor, and hepatocyte growth factor play a critical role in the pathogenesis of hepatocellular carcinoma (HCC).

Aims & Methods: We determined the association of single nucleotide polymorphisms (SNPs) in growth factor signaling-related genes with the development and progression of tumors and overall survival in patients with hepatitis B virus (HBV)-associated HCC. We assessed nine SNPs in the *FGF1*, *FGF2*, FGF receptor (*FGFR*)-2, *Flt-1*, and *c-MET* genes in 245 HCC patients and 483 chronic HBV carriers without HCC.

Results: None of the SNPs was associated with the risk of HCC development in chronic HBV carriers. The FGF2 rs308379 A allele was significantly associated with small tumor size, early tumor stage, and less vascular invasion. The Flt-1 rs4771249 C allele was associated with low alpha-fetoprotein levels. Kaplan-Meier analysis showed that the patients with the FGF2 rs308447 TT genotype had lower survival rates than the patients with the CC or CT genotype ($P = 0.016$) and that the FGF2 rs308379 A allele carriers had shorter survival rates than those of patients with the TT genotype ($P = 0.020$). The FGFR2 rs1219648 CC genotype was significantly associated with increased survival rates ($P = 0.047$). Multivariate Cox proportional analysis revealed that the FGF2 rs308379 A allele (hazard ratio = 1.663, $P = 0.004$) and advanced tumor stage (hazard ratio = 3.430, $P < 0.001$) were independent prognostic factors for overall survival rates in patients with HCC.

Conclusion: These observations suggest that the SNPs of the *FGF2* and *FGFR2* genes can be potential prognostic indicators in patients with HBV-associated HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Extrahepatic HCC metastasis are associated with a poor prognosis. Nevertheless there are some effective therapies available.

Aims & Methods: The aim of this study was to assess the main sites of extrahepatic metastasis in hepatocellular carcinoma (HCC) patients and to evaluate the clinical evolution and treatment. This was a retrospective single-center study in which patients with HCC confirmed extrahepatic metastasis between January 2010 and December 2016 were evaluated.

Results: We evaluated 51 consecutive patients, 80% male, with a mean age of 64 ± 11 years at the time of metastasis. In 41% of the patients the metastasis were present at the time of HCC diagnosis. In patients with subsequent metastasis, the median time until its development was 9 months (IQR 5–16). The diagnosis of metastasis was incidental in 51% of the patients. Computed tomography (CT) was the main diagnostic method (86%) and in 18% of the cases histological confirmation was obtained. Nineteen patients underwent thoracic CT and five performed bone scintigraphy prior to metastasis. A total of 70 metastatic sites were identified, the more frequent were lung (33%) and bone (14%). The MELD score at the time of metastasis was higher than the MELD score at the HCC diagnosis ($p = 0.009$). Metastasis detection implied changes in HCC therapy in all patients, 41% started sorafenib and 55% were referred for supportive therapy. Seven patients performed metastasis targeted treatment, namely 3 patients underwent radiotherapy. The median overall survival (OS) after metastasis was 4.0 months (95%CI 2.1–5.8 months) and the mortality rate was 81% at 12 months. Patients who underwent metastasis targeted treatment presented a longer OS than those who did not (median 18.5 vs 3.1 months; $p = 0.002$). In multivariate analysis, MELD score at the time of metastasis ($p = 0.004$) and metastasis treatment ($p = 0.005$) were independently associated with OS estimation.

Conclusion: A systematic HCC staging, with thoracic CT and bone scintigraphy, may provide an earlier metastasis detection and enable a targeted treatment with a consequent improvement in survival in this difficult-to-treat population.

P1376 MANAGEMENT OF INTERMEDIATE STAGE HEPATOCELLULAR CARCINOMA

A. Deguchi

Division Of Gastroenterology, Kagawa Rosai Hospital, Marugame-shi, Kagawa/Japan

Contact E-mail Address: akihiro41@me.com

Introduction: According to the Barcelona Clinic Liver Cancer (BCLC) staging system, intermediate stage contains very heterogeneous hepatocellular carcinoma (HCC) patients. Recently, subclassification of intermediate stage on the basis of Milano criteria and up to 7 criteria is proposed. In this study, the effectiveness of drug-eluting bead-transarterial chemo-embolization (DEB-TACE) in intermediate stage was investigated.

Aims & Methods: 120 patients (M: F=90:30; median age=76; Child A: B: C=72:44:4; BCLC stage A: B: C: D=6:85:23:6) with unresectable HCC who received DEB TACE in our hospital were studied. The objective radiological response was classified according to the modified Response Evaluation Criteria in Solid Tumors (mRECIST) v.1.1 by using dynamic CT at one or two months after therapy. Adverse events were evaluated using NCI CTCAE v. 4.03.

According to Bolondi's subclassification, the patients of BCLC B stage were divided into four groups (B1: 24, B2: 31, B3: 19, B4: 10). The response rate and tumor factor associated response in these patients group were examined.

Results: The overall response rate and disease control rate in intermediate stage were 36% and 89%, respectively. Considering the subclassification, the response rate in B1 group (61%) was significantly higher than that of B2+B3 group (29%). Although B2+B3 group was constituted by the patients who did not satisfy the up to 7 criteria, only in the patients with less than 7 tumors, the response rate (60%) was similar to that of B1 group. Tumor factors associated response and found to be significant on univariate analysis were simple gross classification (simple nodular type) and number of tumor. Tumor diameter was not associated with the response.

Conclusion: For the treatment of intermediate stage of HCC, although DEB-TACE is considered to be most effective in B1 group, it is suggested that DEB-TACE is also effective in the patients with less than 7 tumors in B2+B3 group. In cases with more than 7 tumors, as the response rate is considered to be extremely low, sorafenib and arterial infusion therapy are recommended in B2+B3 group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1377 HEPATOCELLULAR CARCINOMA RECURRENCE RATE IN HCV INFECTED PATIENTS TREATED WITH DIRECT ANTIVIRAL AGENTS. A SINGLE-CENTER EXPERIENCE

G.G. Di Costanzo, R. Granata, M. Guarracino, M. Sanduzzi Zamparelli, M. Guarino, G. Cordone, G. D'Adamo, R. Tortora
 Hepatology Unit, Cardarelli Hospital, Naples/Italy

Contact E-mail Address: raffaellatortora@live.com

Introduction: In the last few years many HCV patients with previous diagnosis of hepatocellular carcinoma (HCC) have been treated with direct antiviral agents (DAAs) for HCV infection. However there are conflicting data on HCC recurrence rate after DAAs therapy.

Aims & Methods: Aim of this study was to prospectively evaluate the rate of HCC recurrence following sustained virological response (SVR) by DAAs. From April 2015 to September 2016 we consecutively enrolled HCV infected patients previously treated for HCC at Liver Unit of Cardarelli Hospital. All patients had a free-disease survival from HCC of at least 6 months before starting antiviral therapy. The efficacy of HCC therapy was evaluated according to mRecist criteria at CT or MRI. Radiological evaluation was carried out within 30 days from the start of therapy. All patients underwent DAAs therapy, selected on an individual basis according to the recommendation issued by the Italian association of the study of the liver.

Results: A total of 71 patients were enrolled. Among them, 42 patients had available data on SVR status and were considered for the analysis. There were 21 males (58.3%) and 15 females. The median age of the patients was 73 years (range:52–85). The median follow-up was 12 months after the beginning of treatment (range: 6–18 months). Genotype distribution was as follows: 36 patients infected with genotype 1 (85.7%), 5 with genotype 2 and 1 patients with genotype 3. SVR was achieved in 38/42 patients (90.5%). HCC recurrence was observed in 11/38 patients with SVR (28.9%). The median time for recurrence was 9 months from the start of therapy with a range of 1–13 months; with 2 patients who showed recurrence during therapy. Among the patients who did not achieve SVR, 1/4 showed HCC recurrence after 10 months from end of treatment.

Conclusion: Treatment with DAAs are highly effective with a SVR of about 90% even in patients with advanced liver disease. Nonetheless, in patients with previous history of HCC, the eradication of HCV did not reduce the risk of short and medium-term recurrence.

P1378 PATTERN OF DISTANT EXTRAHEPATIC METASTASES IN PRIMARY LIVER CANCER: A SEER-BASED STUDY

W. Wu¹, X. He², L. Li¹, D. Fang¹, D. Shi¹, Y. Li¹, J. Ye¹, F. Guo¹

¹State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China, Hangzhou/China

²Department of Gastroenterology, Sir Run Run Shaw Hospital, Zhejiang University Medical School, Hangzhou, China, Hangzhou/China

Contact E-mail Address: wwr725@zju.edu.cn

Introduction: Primary liver cancer is the sixth most common cancer in the world, after cancers of the lung, breast, colorectal, prostate and gastric[1]. However, the extremely poor prognosis for primary liver cancer makes it the second leading cause of cancer-related death globally (745,000 deaths, 9.1% of the total death)[2]. Histologically, the majority of primary liver cancer is either

hepatocellular carcinoma (HCC) or intrahepatic cholangiocarcinoma (ICC), while combined hepatocellular carcinoma and cholangiocarcinoma is less common[3]. Though these treatments have shown modest improvement in overall survival in early stage disease, the 5-year relative survival for distant metastasis patients is still low (3.1%). As we all know, primary liver cancer preferentially metastasize to the portal vein and extrahepatic metastasis include lungs, bones, brain, lymph nodes, and adrenal glands[4–6]. To date, few detailed studies explored extrahepatic metastasis profiles due to rare data of liver cancer metastasis. Patterns of extrahepatic metastasis still need further clarification. Besides, it is unclear whether different metastatic sites would be translated into distinct clinical outcomes.

Aims & Methods: The objective of this study was to further evaluate extrahepatic metastatic patterns of different histological subtypes and assessed effects of extrahepatic metastasis on survival of advanced disease. **Methods:** Based on the Surveillance, Epidemiology and End Results (SEER) database, we identified eligible population diagnosed with primary liver cancer. We adopted Chi-squared test to compared metastasis distribution among different histological types. Overall survival (OS) and cancer-specific survival (CSS) were compared between subgroups with different extrahepatic metastases.

Results: We finally identified 8677 patients who were diagnosed with primary liver cancer from 2010 to 2012 and 1836 patients were in distant metastasis stages. Intrahepatic cholangiocarcinoma was more invasive and had a higher percentage of metastasis compared with hepatocellular carcinoma. Lung was the most common metastatic site and brain was least common site for both hepatocellular carcinoma and intrahepatic cholangiocarcinoma. Extrahepatic metastasis was an independent prognostic factor for liver cancer patients. Patients with brain metastasis had the worst prognosis, compared with other metastasis in OS and CSS analysis.

Conclusion: Different histological subtypes of liver cancer had different metastasis patterns. There were profound differences in risk of mortality among distant extrahepatic metastatic sites. Results from our studies would provide some information for follow-up strategies and future studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: BCLC-C stage hepatocellular carcinoma (HCC) includes a wide spectrum of tumor and patients' characteristics. Refining prognosis according to prognostic factors may allow the selection of those subjects who could benefit of curative treatments.

Aims & Methods: The aim of this study was to investigate the prognostic factors for survival of BCLC-C stage HCC patients in a real-life setting. Consecutive caucasian cirrhotic patients with BCLC-C stage HCC were included in the analysis. Pre-treatment (Child-Pugh score, performance status (PS), number and maximum size of lesions, vascular invasion, metastases, the combination of vascular invasion and extrahepatic spread, alfa-fetoprotein (AFP) levels, NIACE score) and post-treatment (the number of treatments after the progression to BCLC-C stage and disease control (DC) considering stable+partial+complete response as the best treatment

outcome) variables were considered as prognostic factors. The analysis was adjusted for sex and age.

Results: 116 patients were included in the analysis. After a median follow-up of 22.9 mo (95%CI 17.3–38.1), the cumulative median survival of the overall population was 13.4 mo (95%CI 10.6–17). At the univariate analysis, tumor size, vascular invasion with or without extrahepatic spread, and AFP > 200 as pre-treatment factors and DC as post-treatment variable were associated with survival. Multivariable cox regression revealed that the only independent predictors of mortality were AFP > 200 (HR 2.2, 95%CI 1.27–3.8, p=0.004) and DC (HR 0.222, 95%CI 0.12–0.4, p=<0.0001). However, the influence of these factors was not homogeneous during time. Indeed, in the early and intermediate period AFP > 200 was an independent predictor of worse outcome (at 6 mo: HR 16.602, 95%CI 1.97–139.5, p=0.009; at 1 yr HR 3.069, 95%CI 1.07–8.76, p=0.036). As expected, in the multivariable post-treatment prognostic model DC was associated with a better mid- and long-term survival (at 1 yr: HR 0.245, 95%CI 0.06–0.87, p=0.030; at 2 yrs: HR 0.356, 95%CI 0.12–1.03; p=0.05; at 3 yrs: HR 0.094, 95%CI 0.02–0.29, p=<0.0001).

Conclusion: In patients with BCLC C HCC, AFP > 200 ng/mL is a strong prognostic factor in the early and intermediate period, while DC is associated with long-term patients' survival.

P1381 INTRAHEPATIC PORTAL HYPERTENSION WITHOUT CIRRHOSIS: EXPERIENCE OF A MORROCCAN UNIVERSITY CENTER (33 CASES)

I. Nakhcha, I. Benelbarhdadi, F.Z. Ajana

Service Medecine C Rabat Maroc, Hopital Ibn Sina Rabat, Rabat/Morocco

Contact E-mail Address: Ibtissamnakhcha2@gmail.com

Introduction: Non-cirrhotic intrahepatic portal hypertension is defined as a portal hypertension (PH) without cirrhosis in liver biopsy and without an obstruction of the portal and the hepatic veins.

Aims & Methods: This is a retrospective study conducted on the last 19 years in "Medecine C" department at Ibn Sina hospital in Rabat. 33 non-cirrhotic patients with intrahepatic portal hypertension were considered. We analyzed medical data of all patients with hypertension portal without cirrhosis in liver biopsy and without an obstruction of the portal and the hepatic veins.

Results: 33 patients were included in this study, 22 were women. Mean age was 34 years old (18–70). The PH has been revealed by a digestive bleeding in 10 cases (30%) and ascitis in 7 cases (21.2%). Clinical examination found a splenomegaly in (75.7%). Abdominal ultrasonography combined with Doppler showed signs of PH in all patients and confirmed the absence of obstacle on or above the liver. Upper gastrointestinal endoscopy found esophageal varices in 26 cases (78.7%). Transparietal liver biopsy was performed in 29 cases (87.9%). Various etiologies were identified; in 21.2% (7 cases), intrahepatic PH was due to liver tumors and in 11.7% (n=4), the etiology was hepatic tuberculosis. Etiological investigations retained: 3 cases (9%) of primary biliary cirrhosis in pre cirrhotic stage, 6 cases (18.18) of hepatic portal sclerosis, 4 cases (12.12%) of hepatic sarcoidosis, 2 cases (6%) with hematological malignancies, 2 cases (6%) of polycystic liver, one case (2.9%) hepatic angiomatosis liver, a case chronic hepatitis B, a case of Gaucher disease and one case secondary to hamartoma of the liver. Treatment was indicated according the etiology of PH and its severity (beta blockers, ligation).

Conclusion: Non-cirrhotic intrahepatic portal hypertension is mostly asymptomatic, related to a heterogeneous group of diseases with a good prognosis excepted solid and hematological malignancies.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1382 CONSERVATIVE MANAGEMENT OF EXTERNAL BILIARY FISTULAS COMPLICATING SURGERY OF HYDATID CYST OF THE LIVER

O. Baraket, K. Ayed, W. Triki, M. A. Lahmidi, A. Itami, I. Abbassi, S. Bouchoucha

General Surgery. Hopital Habibi Bouguetfa Bizert, Faculty of Medicine of Tunis. University Tunis ElMANAR, Bizerte/Tunisia

Contact E-mail Address: oubaraket@gmail.com

Introduction: Surgical treatment is nowadays the only curative treatment of hydatid cyst of the liver. Surgical approach exposes to many complications especially biliary fistulas. Many modalities are described for the treatment of these complications.

Aims & Methods: A retrospective study including 250 patients who underwent a surgical treatment for a hydatid cyst of the liver between 2007 and 2015. The aim of this study is to evaluate the place of conservative management and his benefits in biliary fistulas.

Results: Conservative surgical treatment of hydatid cyst was done in 180 cases and radical surgery in 70 cases. A complication occurs in 66 cases. An external biliary fistula occurs in 45 cases (18%). Management of all this biliary fistulas was conservative and prolonged drainage of the residual cavity and elevation of the drainage. No major ionic and electrolytic troubles were observed. The fistula healed in 44 of patients with a median time of 4 weeks [range, 1–7]. In one case endoscopic treatment was necessary to heal fistulas. The median hospital stay was 15 days [range 12–60] when biliary fistulas occurred compared to 8 days [6–15] when there is no biliary complications.

Conclusion: External biliary fistulas are a common complication after surgical treatment of hydatid cyst of the liver. Conservative management of this complication is safe and very useful when we respect the indications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1383 THE EVOLUTION OF ESOPHAGEAL VARICES IN NON CIRRHOTIC PORTAL HYPERTENSION CAUSED BY PORTAL VEIN THROMBOSIS

Introduction: Portal vein thrombosis (PVT) is defined as a partial or complete occlusion of portal vein and/or its tributaries by a thrombus. It exposes to portal hypertension (PHT) by infrahepatic occlusion and consequently to upper digestive hemorrhage, usually due to rupture of gastro esophageal varices.

Aims & Methods: The aim of this study is to specify the evolution of esophageal varices and thus risk of rebleeding in patients with PHT by PVT unrelated to cirrhosis. It is a retrospective study from January 2010 to February 2017, including 101 patients followed for PHT by PVT without liver disease in the department of hepatogastroenterology (medicine C) at Ibn Sina University hospital of Morocco. PVT was diagnosed by abdominal doppler ultrasonography in all patients.

Results: The mean age of patients was 36 ± 15 years with extremes ranging from 11 years to 70 years. The sex ratio M/F was 0.42. Five percent of patients had a splenectomy for undocumented reasons before the diagnosis of PHT. Concerning the reasons of hospitalization, 10.9% (n=11) were hospitalized for melena, 60.4% (n=61) for hematemesis and melena and 28.7% (n=29) for non-specific abdominal pain. Clinical examination was normal in 10.9% (n=11), showed an ascites in 11.9% (n=12), and signs of PHT such as splenomegaly and collateral abdominal venous circulation in 95.1% (n=96). Complete blood count showed that 16.8% (n=17) had thrombocytopenia, 12.9% (n=13) had bicytopenia, and 42.6% (n=43) had pancytopenia. In all patients, upper GI endoscopy was performed. Hypertensive gastropathy was found in 30.7% (n=31), grade I esophageal varices (OV) in 5.9% (n=6), grade II in 30.7% (n=31), grade III in 48.5% (n=49) and gastric varices were noted in 13.9% (n=14). These varices were with red spots in 18.8% (n=19). All patients had abdominal doppler ultrasonography showing a PVT in 60.3% (n=61), this was partial in 33.6% (n=34), complete in 11.9% (n=12) and extended to the splenic vein in 14.9% (n=15). Portal cavernoma was found in 39.6% (n=40). All patients performed an etiologic assessment of thrombosis, myeloproliferative syndrome was found in 8.9% (n=9), deficiency in inhibitors of coagulation in 31.7% (n=32), celiac disease in 4.9% (n=5), neoplastic lesions in 2.9% (n=3), no etiology was found in 51.4% (n=52). Endoscopic variceal Ligation (EVL) was performed in 70.3% (n=71), the mean number of ligation sessions was 3 and eradication of esophageal varices was noted in 69.3% (n=70). All patients received anticoagulant therapy except those having portal cavernoma with no obvious cause and 42.6% of patients (n=43) received beta-blockers for secondary prophylaxis. During follow up, 5.9% (n=6) of patients have not been seen at consultation and no rebleeding was noted in 89.1% (n=90). Concerning portal thrombosis, it dissolved in 49.5% (n=50) and stabilized in 10.8% (n=11).

Conclusion: The evolution of esophageal varices in non-cirrhotic portal hypertension due to PVT seems to be better than in cirrhotic portal hypertension. Indeed 89.1% of patients in this study didn't rebleed after eradication of esophageal varices.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1384 EVALUATION OF COMMON BILE DUCT CLEARANCE AFTER ENDOSCOPIC MANAGEMENT OF DIFFICULT BILIARY STONES BY DIRECT PERORAL CHOLANGIOSCOPY: PRELIMINARY RESULTS OF A PILOT STUDY

A. Anderloni, A. Fugazza, F. Auriemma, R. Maselli, S. Carrara, M. Di Leo, E. Ferrara, P.A. Galtieri, R. Seneraro, G. Lollo, G. Amvrosiadis, A. Repici
Digestive Endoscopy Unit, Division Of Gastroenterology, Humanitas Research Hospital, Rozzano, Milan, Italy, Rozzano/Italy

Contact E-mail Address: andrea.anderloni@humanitas.it

Introduction: Incomplete stones clearance after endoscopic management of difficult biliary stones poses the risk of complications such as cholangitis. Confirmation of complete stones clearance is normally confirmed fluoroscopically with obvious risk of false negative/false positive results, leading to possible under/over-treatment. Direct peroral cholangioscopy (POC) refers to the use of nonspecific endoscopes for the direct visualization of the common bile duct (CBD).

Aims & Methods: We aimed to evaluate the feasibility and safety of POC to confirm CBD complete clearance after endoscopic treatment of difficult biliary stones. From 1st June 2016 to 30 March 2017 all consecutive patients treated with Dilated assisted stone extraction (DASE) for difficult biliary stones at our institution, underwent POC to verify CBD stones complete clearance. Ultraslim (5.9 mm diameter) or Slim (8.5 mm diameter) endoscopes (FujiFilm EG 530NW or EG 530FP) or standard gastroscope (9.9 mm diameter) (Olympus GIF-HQ190), under CO₂ insufflation, were used by the peroral route for intubating

all accessible bile ducts. Technical success rate, procedural time, outcome and safety of POC were assessed. All adverse events were recorded.

Results: POC was performed in 26 patients (17F/9M mean age 74.6 ± 11.9) under propofol sedation (23 patients) or deep sedation (3 patients). Mean CBD size was $15 \text{ mm} \pm 3.65$; mean stone diameter ($13.5 \text{ mm} \pm 1.70$); mean balloon dilation ($13.5 \text{ mm} \pm 2.12$). Intubation of the papilla and distal biliary duct was successful in 26 (100%) cases (guide-wire assistance in 17 cases, 65.4%). Hepatic hilum was reached in 13/26 (50%) patients with a complete CBD evaluation. Mean investigation time was 6.3 ± 1.5 min (range of 5–9 minutes). POC showed persistent large amount of sludge in 2(7.7%) cases, completely suctioned through the endoscope, and stones in 4 (15.4%) cases with subsequent endoscopic stones removal. In the remaining patients, POC confirmed complete duct clearance. No adverse events occurred.

Conclusion: CBD complete clearance confirmation using POC is a feasible, quick and safe procedure that can help on clinical decision making (for example obviating the need for possible plastic stent or naso-biliary drainage placement) without substantial increase of time or costs. Our experience, however, is preliminary and was specifically aimed to assess the feasibility of the procedure, which could represent the first step for the development of a possible new indication in the setting of difficult biliary stone management.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1385 LONG-TERM OUTCOMES OF PATIENTS WITH ACUTE CALCULOUS CHOLECYSTITIS AFTER SUCCESSFUL REMOVAL OF GALLBLADDER STONES WITH PERCUTANEOUS TRANSHEPATIC CHOLANGIOSCOPY: A DECADE EXPERIENCE AT A SINGLE TERTIARY CENTER

S. Dong, C.H. Oh, J.R. Moon

Department of Internal Medicine, Kyung Hee University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: gidrdong@hanmail.net

Introduction: Percutaneous cholecystostomy (PCT) has been an alternative treatment of acute calculous cholecystitis (ACC) for the patients unsuitable for early cholecystectomy. Lithotomy with percutaneous transhepatic cholangioscopy (PTCS) after PCT track maturation is particularly considered for those patients with gallbladder (GB) stones who are poor surgical candidate. We examined the long-term outcomes of 171 patients with ACC treated by PTCS.

Aims & Methods: This study was a retrospective observational study of 171 consecutive patients who treated with PTCS for ACC in the period from 1 Jan 2005 to 31 Dec 2015. Outcome measures included the success rates, adverse events, recurrence rate and mortality. All data were collected from patients' medical records.

Results: PTCS achieved complete clearance of GB stones in 157 patients (91.8%). The complication rate of PTCS was 3.5% (6/171). The adverse events included GB perforation (n=3, 1.8%), hemorrhage (n=2, 1.2%), disruption of the percutaneous transhepatic biliary drainage fistula (n=1, 0.6%), and all of which resolved with conservative treatment. The overall recurrence rate of gallstone diseases was 11.5% during the follow up period. The incidence of recurrent gallstone diseases was significantly higher in those with completely removed GB stones than in those without complete clearance (10.2%, 16/157 vs 21.4%, 3/14; $p < 0.05$). The frequency of recurrence of gallstone disease in patients with contrast passage to the duodenum on cholangiography after PTCS was lower than that in patients without contrast passage.

Conclusion: Gallbladder stone removal with PTCS would be recommended as an effective and safe treatment modality for the patients with acute cholecystitis who are unsuitable for surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1386 SINGLE DEVICE TECHNIQUE FOR ENDOSCOPIC TREATMENT OF BILE DUCT STONES

M. Sen-Yo, S. Kaino, S. Amano, S. Shinoda, I. Sakaida

Gastroenterology And Hepatology, Yamaguchi University Graduate School of Medicine, Ube/Japan

Contact E-mail Address: mnbs730@gmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) with sphincterotomy is a well-established standard method for treating bile duct stones (BDS). After cannulation of the common bile duct (CBD), a guidewire is placed into the CBD and a sphincterotomy is performed. Subsequently, stone extraction using a balloon or basket catheter is performed. Because of this multi-step process, endoscopic treatment for BDS always comes with a risk of losing CBD cannulation. A combination catheter that combines a sphincterotome and a retrieval balloon in a single instrument can eliminate one step in the process of bile duct (BD) clearance and may be able to accomplish BD clearance by using only single device. Additionally, a newly developed 0.025 inch guidewire that is, at once, rigid and flexible enables us to inject contrast agent through the Y-connector smoother. Therefore, the combination catheter with a Y-connector and a 0.025 inch guidewire may become a single device that can facilitate complete BDS clearance. Despite its utility, the success rate of bile duct cannulation and cost benefit requires further analysis.

Aims & Methods: We aimed to evaluate the therapeutic efficacy of a combined catheter as a single device required for BDS clearance. From January 2016 to July 2016, 11 consecutive patients with BDSs ≤ 10 mm in size were enrolled in this study (Stonetome group). In all cases, the combined catheter (Stonetome) was

used for initial bile duct cannulation. Subsequently, sphincterotomy and stone extraction were performed using the combined catheter. The success rate of performing the combined procedure, procedure-related time, adverse events, and the cost of devices were compared with those in 10 patients with BDSs ≤ 10 mm in size who had undergone endoscopic stone clearance from April 2015 to December 2015 as historical control.

Results: The success rate of selective cannulation and stone clearance did not differ significantly (Stonetome group: 90.9% and 100% vs control group: 100% and 100%, respectively). The median time after bile duct cannulation to complete stone clearance and total procedure time in the Stonetome group were significantly shorter than those in the control group (401.5 s versus 982.5 s, 645.5 s versus 1380 s, respectively). In the Stonetome group, delayed bleeding occurred in 1 patient. In the control group, bile duct injury caused by the guidewire occurred in 1 patient. The costs of the used devices did not differ significantly (Stonetome group: \$678 versus control group: \$669).

Conclusion: The combined catheter has the same selective cannulation ability as a conventional catheter and a similar capacity to remove BDSs as common retrieval balloon. Therefore, the combined catheter can reduce the procedure time to remove BDSs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1387 ACCURACY OF ASGE CRITERIA IN THE IDENTIFICATION OF PATIENTS WITH SUSPECTED CHOLEDOCHOLITHIASIS

C. Macedo, N. Almeida, D. Gomes, E. Camacho, S. Mendes, L. Tomé, A. M. Ferreira

Gastroenterologia, Centro hospitalar e Universitário de Coimbra, Coimbra/Portugal

Contact E-mail Address: claudia.macedo.07@hotmail.com

Introduction: The American Society for Gastrointestinal Endoscopy (ASGE) emitted, in 2010, guidelines for the clinical orientation of patients with suspected choledocholithiasis (CL), suggesting the direct referral to endoscopic retrograde cholangiography (ERC) in certain groups. However, the ERC is an invasive exam and some studies demonstrated that a significant amount of patients classified with very strong risk of CL did not have alterations in ERC.

Aims & Methods: The aim of this work was to assess the accuracy of the ASGE guidelines in portuguese population. This is a retrospective study that included 212 patients (52.8% female sex; 47.2% male sex; mean age 73.9 (± 14.6) years) admitted to the hospital from 2014 to 2016.

Results: Of the 212 patients, 28 (13.2%) had intermediate risk of CL and 184 (86.8%) had high risk, according to the ASGE criteria. These patients were submitted to the following exams/interventions: ERC (154 patients); magnetic resonance cholangiography (50 patients) and endoscopic ultrasound (8 patients). In patients initially classified with high risk of CL, this was confirmed in 119 (64.7%). The same was seen in 10 (35.7%) of the patients with intermediate risk. The ASGE criteria, when applied to this population, demonstrated an accuracy of 64.3% (21.7% sensitivity; 92.3% specificity) in the high-risk group, and an accuracy of 35.5% (78.3% sensitivity; 7.8% specificity) in the intermediate-risk group. Of the patients with intermediate probability, 12 (42.8%) underwent ERC, and CL was found only in 4 of these patients. The presence of cholangitis, a common bile duct > 6 mm, a common bile duct stone visualized on transabdominal US and a total bilirubin > 4 mg/dL were strong predictors of CL. The overall ERC complication rate was 13% (20 patients), of whom 8 had no CL.

Conclusion: The ASGE guidelines showed a limited diagnostic accuracy in the identification of patients who actually require ERC, conditioning a significant number of unnecessary procedures with subsequent complications associated with it. It is urgent to rethink the orientation of these patients, with greater use of less invasive diagnostic techniques such as magnetic resonance cholangiography and endoscopic ultrasound.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1388 DOES FIBRIN GLUE APPLIED ON THE CHOLANGIOTOMY IN LAPAROSCOPIC COMMON BILE DUCT EXPLORATION REDUCE THE RISK OF BILE LEAKAGE? A RANDOMIZED STUDY

B. Darkahi¹, G. Sandblom², T. Nordén¹

¹Surgery Department, Enköping/Sweden

²Surgery Department, Uppsala/Sweden

Contact E-mail Address: bahman.darkahi@gmail.com

Introduction: Laparoscopic choledochotomy as a method of extracting common bile duct stones is a technique with many advantages. One problem, however, is bile leakage along the T-tube. To some extent the leakage may be reduced if the incision is sutured around the T-tube, but this technique has some disadvantages. The aim of this study was to investigate whether application of fibrin glue around the tube results in less leakage than suturing.

Aims & Methods: Between 2012 and 2016 a total of 1347 cholecystomies were performed in Enköping Hospital. From this group, 42 patients were included in the study and randomized to suturing or fibrin glue for closing the cholangiotomy around the T tube. Postoperative cholangiography was performed after 7–

10 days after surgery. The amount of flow in the abdominal drain and the level of in the fluid bilirubin was measured daily. In case the flow ceased, the abdominal drain was extracted three days after surgery.

Results: No significant difference between the groups was seen regarding the flow of the abdominal drain or the T-drain for the first three days or operation time

Conclusion: Discussion Fibrin glue may be an option to seal cholangiotomy around the T-tube, but studies with greater statistical power are needed to confirm this.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1389 THE IMPACT OF BARIATRIC SURGERY ON ACUTE CHOLANGITIS MORTALITY AND OTHER OUTCOMES: A NATIONWIDE ANALYSIS

Introduction: Rapid weight loss after bariatric surgery (BS) has been associated with the formation of gallstones, and subsequent acute cholecystitis and cholangitis (AC). However, the complex post-surgical anatomy limits the possibility of performing an ERCP as part of AC treatment. Therefore, the aim of this study was to assess the impact of bariatric surgery on mortality and resource utilization among patients with AC using a national database.

Aims & Methods: This was a case-control study using the National Inpatient Sample 2013, the largest publicly available inpatient database in the United States. All patients with an ICD-9 CM code for a principal diagnosis of AC were included. There were no exclusion criteria. Patients with a past history of BS were identified using the appropriate ICD-9CM codes. The primary outcome was all cause mortality. The secondary outcome was resource utilization: use of ERCP, cholecystectomy, length of hospital stay (LOS), total hospitalization charges and costs. Multivariate regression analyses were used to adjust for the following confounders: Age, sex, race, income in patients' zip code, Charlson Comorbidity Index, hospital region, location, size and teaching status.

Results: A total of 274,775 patients with AC were included in the study, of which 4,240 (1.7%) had undergone BS. The mean patient age was 51 years and 48% were female. After adjusting for confounders, patients with and without history of bariatric surgery had similar adjusted odds of mortality (adjusted Odds Ratio (aOR): 1.37, 95% CI: 0.51–3.65, $p=0.52$). As far as resource utilization, patients with bariatric surgery had lower adjusted odds of ERCP (aOR: 0.28, 95% CI: 0.09–0.83, $p=0.02$), but higher odds of cholecystectomy (aOR: 3.18, 95% CI: 1.00–10.05, $p=0.04$). Both patient groups had similar adjusted length of stay (adjusted mean difference: 1.19 days, 95% CI: 0.09–0.83, $p=0.16$) total hospitalization costs (adjusted mean difference: \$2237, 95% CI: -\$2308 - \$6782, $p=0.49$), and total hospitalization charges (adjusted mean difference: \$7477, 95% CI: -\$9595–\$24549, $p=0.39$).

Conclusion: Bariatric surgery has no impact on inpatient all-cause mortality among patients who develop acute cholangitis, despite its association gallstone acute pancreatitis and limited ERCP performance. In addition, bariatric surgery does not affect resource utilization in this patient population as measured by length of stay and total hospitalization costs and charges.

Introduction: Prevalence of gallbladder polyps in the Netherlands is 943 per 100,000 cholecystectomies. Histopathologically these gallbladder polyps can be divided in neoplastic polyps (with malignant potential) and nonneoplastic polyps (without malignant potential). Although cholecystectomy is only indicated for neoplastic polyps, 47% of polyps after cholecystectomy are nonneoplastic. Further information on the pathological characteristics and subsequent clinical and radiological features could be useful to predict neoplastic or nonneoplastic nature of the gallbladder polyp before surgery.

Aims & Methods: To assess pathological characteristics of neoplastic and nonneoplastic gallbladder polyps and identify preoperative clinical and radiological predictors for neoplastic and nonneoplastic polyps. Data of the Dutch Pathology Registry was used. In this search 2081 histopathologically proven gallbladder polyps (or (focal) wall thickening > 5 mm) were identified in patients of ≥ 18 years undergoing primary cholecystectomy between 2003 and 2013. Of these

polyps 56.3% was neoplastic (adenoma, dysplasia, carcinoma or other malignancies) and 43.7% nonneoplastic (all other types of polyp). Age and sex of the patient, number of polyps, size of the polyp, coincidence with gallstones and presentation as protruding polyp or wall thickening were extracted from the excerpts. Additional clinical and radiological information was collected from patients' medical records at three hospital in the Netherlands (n=178). The following clinical and radiological predictors were considered: age, gender, ethnicity, BMI, medical history (PSC, Hepatitis, metabolic syndrome, gallbladder disease, *Salmonella typhi* or *Helicobacter pylori* infection), family history of gallbladder diseases, presence of abdominal symptoms and radiological features (size, number, shape, surface and echogenicity of the polyp). Associations between possible predictors and gallbladder polyps were assessed using univariate and multivariate logistic regression analysis.

Results: Patients with neoplastic polyps were found to be significantly older than patients with nonneoplastic polyps (mean age 65.0 vs 54.2 years, $p < 0.001$). Neoplastic polyps were significantly larger (mean size 18.1 mm (SD 17.9) vs 7.5 mm (SD 5.9), $p < 0.001$), more frequently presented as wall thickening (29.2% vs 15.6%, $p < 0.001$) or as a single polyp (88.3% vs 68.0%, $p < 0.001$). Gallstones were more frequently found in gallbladders with neoplastic polyps (50.1% vs 40.4%, $p = 0.001$). No preoperative clinical features were predictive for neoplastic or nonneoplastic polyps. Presence of a single polyp on ultrasound was a predictor for neoplastic polyps (OR 6.00 (95%CI 1.32–27.31)). Size and type of polyp were often not mentioned in ultrasound report, or different from histopathological confirmation.

Conclusion: Except for age, no clinical characteristics for neoplastic polyps were identified in this cohort. Although pathological characteristics of neoplastic and nonneoplastic polyps are confirmed, identification of these characteristics on preoperative radiological investigations is poor.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1392 METFORMIN INDUCES APOPTOSIS AND MODULATES PROLIFERATION IN THE BILE DUCT CANCER CELLS

Introduction: Metformin has evidence of antineoplastic activity in some cancer cells.

Aims & Methods: This study was performed to demonstrate in the bile duct cancer cells whether metformin inhibits the proliferation of cancer cells by inducing apoptosis and affects the expression of gene-related proteins involved in cancer growth, and to identify how metformin affect molecular mechanisms involved in the inhibition of cancer cell growth. Human extrahepatic bile duct cancer cells were cultured. 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assays were performed to determine the effect of metformin on cell proliferation. Apoptosis was measured by a cell death detection enzyme-linked immunosorbent assay and caspase-3 activity assay. Various protein expressions with or without specific siRNA transfection were measured by Western blot analysis. The migratory activity of the cancer cells was evaluated by wound healing assay.

Results: 1) Metformin suppressed cell proliferation in bile duct cancer cells by inducing apoptosis. 2) Metformin inhibited mammalian target of rapamycin (mTOR) by activation of pAMPKThr172 - tuberosus sclerosis complex 2 (TSC2) pathway, and hyperglycemia impaired metformin-induced AMPKThr172 activation and enhanced phosphorylation of AMPKser485. 3) Metformin blocked inhibitory effect of insulin-like growth factor 1 receptor (IGF-1R), insulin receptor substrate 1 (IRS-1) and Akt pathway on TSC2, and hyperglycemia impaired metformin-induced inhibition of IGF-1R-IRS-1-Akt pathway. 4) Metformin modulated invasiveness of bile duct cancer cells, and the effect was impaired by hyperglycemia.

Conclusion: This study shows that metformin has antineoplastic effect in bile duct cancer, and the effect of metformin is attenuated in the hyperglycemic environment. In addition, AMPK and IGF-1R play a key role in the proliferation of bile duct cancer cells, thus they are expected to be important targets for future development of chemotherapy agents.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Molecular pathology of gall bladder anomalies and progression to carcinoma is still obscure and understudied; but is critically relevant to India which harbors the highest number of cases globally, and to ethnically distinct northeast India (NEI) where the cases have been increasing alarmingly.

Aims & Methods: Evaluate the associative role of genetic alteration(s) and promoter hypermethylation of key BER pathway genes in the predisposition to gall bladder diseases and progression to gall bladder carcinomas (GBC) in the ethnically distinct NEI population. Whole blood and surgically resected tissue samples were collected from clinically and histopathologically confirmed cases of GBC (adenocarcinomas, N=49) along with non-neoplastic control sections, cholelithiasis (CL, N=78) and cholecystitis (CS, N=56); along with blood from voluntary controls (N=122) with informed consent. The BER pathway genes polymorphisms were screened by PCR-RFLP using DNA samples of the enrolled cases and controls. Differential mRNA expression profile of BER short and long patch pathway genes was studied by RT-PCR. Difference in protein expression was studied by immunofluorescence microscopy. Estimation of oxidative stress in DNA was done using 8-OH-dG EIA kit. The difference in percentage promoter methylation of BER pathway genes was analyzed using RT-PCR based HRM method.

Results: The genetic alterations in hOGG1 and XRCC1 gene were highly prevalent in both controls and gall bladder disease cases in NEI population, and was associated with susceptibility and severity of gall bladder anomalies compared to controls; most significantly for XRCC1codon280 polymorphism in GBC cases compared to controls [OR=1.986, $p=0.047$]. Differential mRNA expression profile clearly showed a sharp down-regulation in hOGG1, APE1, polβ and PARP1 expression in GBC, CL and CS cases compared to controls; and in GBC compared to CL and CS cases. The mRNA expression XRCC1, a component of both short and long patch pathway, was down-regulated in majority of the GBC, CS and CL cases compared to controls; and in GBC cases compared to CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in GBC cases compared to controls. The oxidative stress marker 8-oxo-dG estimation showed significantly increased levels in CL, CS and GBC cases DNA compared to controls, the highest being in GBC cases. The higher 8-OH-dG levels in GBC correlated significantly with the variant hOGG1 genotype ($p < 0.001$). The percent methylation of both XRCC1 and hOGG1 in cases and controls was between 0–30%. Hyper-methylation of XRCC1 and hOGG1 promoter was noticeable in GBC cases compared to controls.

Conclusion: The data indicates an important role of oxidative stress in the pathogenesis of gall bladder diseases and progression to GBC in NEI population; which inturn is due to genetic, expression and epigenetic deregulations in the key genes of the BER short and long patch pathway. The data also suggests the prognostic significance of BER pathway parameters, as well as potential therapeutic targets for the disease, and hence holds clinical relevance.

Contact E-mail Address: gyacy14@yahoo.co.jp

Introduction: Gallbladder cancer (GBCa) is often diagnosed at advanced stage resulting poor prognosis, because the patients with early GBCa has not showed any symptoms and the tissue cannot be obtained easily with anatomical reason. To overcome the weakness of the current methods for the diagnosis of GBCa, we focus on the possibility of "liquid biopsy" with bile juice on the concept of non-invasive diagnostic method as circulating tumor DNA in blood. To achieve good treatment effect in future, so called "precision medicine" approach based on the character of the each tumor is mandatory.

Aims & Methods: Thirty patients with GBCa were enrolled in this study. Bile juice obtained from 24 of 30 patients was analyzed for mutations of 50 oncogenes (Cancer panel; Haloplex, Agilent Technology) by next generation sequencing (NGS; Illumina, San Diego, CA, USA). Tumor tissues from 20 of 30 patients were analyzed as well as bile juice. Each sample was obtained prior to the

treatment. As negative controls, 19 non-GBCa bile juice and 33 non-GBCa tissue samples were analyzed for mutations of 50 oncogenes in the same way.

Results: The median (range) age was 77 (44-90) years and the male/female ratio was 0.43 (9/21). Six, six, and twelve patients were diagnosed as stage I, II, III, and stage IV, respectively. We set cut-off value at 5% for rare mutation rate based on the results of healthy samples to avoid false positive. Eleven of 20 (55%) tumor tissue samples were positive for mutation. TP53, MET, SMAD4, CTNNB1 and AR were detected in 7/20 (35.0%), 1/20 (5.0%), 1/20 (5.0%), 1/20 (5.0%) and 1/20 (5.0%) respectively. In this study, 14 of 30 (46.7%) patients had both tumor tissue samples and bile juice samples. Eight of 14 (57.1%) tumor tissue samples were positive for mutation. In these eight patients, 7 (87.5%) bile juice samples had the same mutation (TP53, ERBB2/3 were detected in 6/8 (75%), 1/8 (12.5%), respectively). On the other hand, bile juice samples of other 6 patients without tumor tissue mutation had no mutation. With regard to only bile juice, 14 of 24 (58.3%) bile juice samples with GBCa were positive for mutations. TP53 mutation, ERBB2/3, KRAS were detected in 11/24 (45.8%), 2/24 (8.3%), 1/24 (4.2%), respectively. Bile juice analysis for mutations indicated that sensitivity, specificity, positive predictive value (PPV) and negative predict value (NPV) were 58.3%, 100%, 100% and 65.5%, respectively. None of negative control samples had any mutations.

Conclusion: Mutations in tumor could be detected in bile juice using NGS. Liquid biopsy with bile juice may help us to diagnose GBCa because of high PPV (100%). It may allow us to make new genetic diagnosis of GBCa.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1395 EFFICACY OF INTRADUCTAL RADIOFREQUENCY ABLATION USING A NOVEL ENDOLUMINAL RADIOFREQUENCY ABLATION CATHETER IN A SWINE MODEL

H. Kim¹, O. Shin², B. Jeon¹, H. Choi¹, S. Kim¹, S. Kim¹, H. Chae¹

Contact E-mail Address: hykkim@catholic.ac.kr

Introduction: Intraductal radiofrequency ablation (RFA) is a new endoscopic ablative technique with direct effect to local tumor have been developed to improve the duration of self-expandable metal stents (SEMS) in the unresectable malignant biliary obstruction. However, there is the concern for the complication such as bile duct perforation or bleeding because the ideal power setting of intraductal RFA has not been clearly revealed still.

Aims & Methods: Therefore, we aimed to investigate the effects of ablative injury after in vivo intraductal RFA according to the time variation using a novel RFA catheter (ELRA®, STARmed, Goyang, Korea). This novel catheter is a bipolar device and has a temperature sensor within the distal tip, therefore it has a characteristic of target temperature controlled mode. Nine female pigs were divided into three groups according to RFA time variation (60, 90 and 120 seconds) with the same power setting (10 watts) and RFA target temperature (80°C). All pigs underwent endoscopic retrograde cholangiography (ERC) and intraductal RFA. Additional cholangiogram was taken immediately after RFA and then a plastic stent was inserted. All the pigs were humanely sacrificed 24 hours after the intraductal RFA. Necropsy was performed and the common bile duct was excised for histologic analysis.

Results: The ERC and application of the intraductal RFA was successful in 100%, and post-RFA cholangiogram did not show the contrast leakage. Median depth of microscopic ablation was significantly different between three groups according to the ablation time (60 vs 90 vs 120 seconds = 1.90 (1.17-2.23) vs. 2.44 (2.31-2.60) vs. 2.52 (2.47-2.64) mm, $p=0.018$). There was also a linear relationship between ablation time and microscopic ablation depth ($r^2=0.552$, $p=0.002$). However, there were no statistical differences in macroscopic ablation length and microscopic ablation length. In addition, focal ablation injuries of adjacent liver were found in five out of nine pigs (2 of 3 pigs in 60 seconds, 1 of 3 in 90 seconds, 2 of 3 in 120 seconds).

Conclusion: Intraductal RFA using a novel RFA catheter successfully ablated the normal bile duct wall without serious complications in vivo swine model. The optimal time of intraductal RFA was presumed between 90 and 120 seconds at the power setting 10 watts and target temperature of 80°C. However, focal ablation injury was found in even short ablation time in which microscopic ablation depth was superficial. Further studies are needed to validate the optimal power setting of RFA in a swine model and then human clinical studies are also warranted.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1396 PREDICTIVE MODEL FOR THE NEOPLASTIC POTENTIAL OF GALLBLADDER POLYPS

J.K. Lee

Gastroenterology, Samsung Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: jongk.lee@samsung.com

Introduction: While many studies have attempted to define the risk factors for neoplastic potential of gallbladder polyp, precise adaption of the risk factors individually in an real treatment strategy of gallbladder polyp remains elusive. Estimating the probability for neoplastic potential of gallbladder polyp using a combination of several risk factors before surgical resection would be useful in patient consultation.

Aims & Methods: This study was designed to provide the statistical predictive model for neoplastic potential of gallbladder polyps. We collected data of patients confirmed as GBP through cholecystectomy at Samsung Medical Center between January 1997 and March 2015. Those with a definite evidence for malignancy, such as adjacent organ invasion, metastasis on preoperative imaging studies, polyp larger than 15mm, and absence of proper preoperative ultrasonography imaging, were excluded. A total of 1976 patients were enrolled. To make and validate the predictive model, we divided the cohort into the modeling group ($n=979$) and validation group ($n=997$). Clinical information, ultrasonographic findings, and blood tests were retrospectively analyzed. A prediction model for the probability of neoplasia was fitted from the training set using the logistic regression method equipped with backward elimination with significance level for removal of $P < .05$ for variable selection. The performance of a fitted prediction model was evaluated by the area under the curve (AUC) of a receiver operating characteristic (ROC) curve. A cutoff value of the fitted risk score was chosen by the Youden Index.

Results: Clinical factors of older age, single lesion, sessile shape, and polyp size showed statistical significance of neoplastic potential of GBP in the modeling group. A predictive model* for neoplastic potential of GBP was constructed utilizing the statistical outcome of the modeling group. Statistical validation was performed with the validation group to determine the optimal clinical sensitivity and specificity of the predictive model. Optimal cut-off value for neoplastic probability was 7.4%. *Probability of Neoplastic GB polyp = $e^{(ps)}/1 + e^{(ps)}$ where $e=2.7182$ is the base of the natural logarithm and PS (predictive score) = $-7.3633 + 0.0374 \times [\text{Age}] + 0.6667 \times [\text{Number}] + 1.5784 \times [\text{Sessile}] + 0.2189 \times [\text{Size}]$.

Conclusion: The predictive model for neoplastic potential of GBP may support clinical decision before cholecystectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1397 COMPARISONS OUTCOMES FOR CONTROLLED PHOTODYNAMIC THERAPY IN HIGH GRADE UNRESECTABLE HILAR CHOLANGIOCARCINOMA

E.T. Park, B.C. Yun, S.U. Lee, B.H. Han

Internal Medicine, Kosin University, Gospel Hospital, Busan/Korea, Republic of

Contact E-mail Address: euntpark@hanmail.net

Introduction: Photodynamic therapy (PDT) provide clinical benefit for patients with unresectable biliary malignancy. In this study, we evaluate the efficacies of controlled PDT for unresectable primary and secondary high-grade hilar cholangiocarcinoma (CC).

Aims & Methods: In cases of high-grade unresectable hilar CC (Bismuth type III or IV) and gallbladder (GB) cancer invasion to hilar portion (Group A), we performed controlled PDT. Controlled PDT means malignant stricture dilatation by using balloon catheter up to 10 mm through percutaneous transhepatic cholangioscopy (PTCS) before PDT. And then applied appropriate laser light source by using straight angled cylindrical diffuser. Finally, gemcitabine-based chemotherapy was done for 6 cycles. We compared to transpapillary approach with non-straight cylindrical diffuser using PDT with gemcitabine-based chemotherapy in similar patients (Group B) in terms of clinical parameters and developing complications.

Results: Between July 2010 and June 2015, 26 cases(31) of high grade unresectable hilar CC (Bismuth type III or IV), 5 cases of GB cancer with hilar invasion were enrolled for Group A, 23 cases(26) of high-grade unresectable hilar CC (Bismuth type III or IV), 3 cases of GB cancer with hilar invasion were enrolled for Group B. On three months later, serum bilirubin levels decreased from 7.3 ± 5.2 to 2.4 ± 1.8 mg/dL in group A, 6.9 ± 5.5 to 5.2 ± 3.7 mg/dL in group B ($p < 0.05$). PDT-induced cholangitis is developed in Group A (3/31, 9.6%) and B (7/26, 26.9%) within seven days ($p < 0.001$). Progression free survival is superior Group A to Group B that of 14.8 months vs. 8.9 months ($P < 0.05$).

Conclusion: Controlled PDT with straight applying cylindrical diffuser promise efficacy for clinical parameters and progression free survival compared with transpapillary PDT in unresectable high-grade hilar CC and GB cancer. Additionally, diminished post-PDT cholangitis within 7 days affect improving long term progression free survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: IAC is a major manifestation of IgG4-related disease (IgG4-RD), a multi-organ inflammatory disorder of unknown cause. IAC may present with jaundice, abdominal pain and weight loss; immunosuppression is the preferred treatment. Since the disease presentation may closely mimic that of malignancies of the pancreatobiliary tract and accurate diagnostic tests have only recently been developed, misdiagnosis and unnecessary surgery are common as has been consistently reported in literature.

Aims & Methods: Our aim is to assess the incidence of Immunoglobulin G4-associated cholangitis (IAC) in patients resected for presumed perihilar cholangiocarcinoma (PHC). All patients that underwent resection for presumed PHC at our institution between 1984 and 2015 were included. Benign histological specimens were re-evaluated by a pathologist and scored according to the international pathological consensus criteria for IgG4-RD. Patients with benign disease who were still alive were re-evaluated to assess IgG4 serum levels and IgG4/IgG RNA ratio to detect activity of IAC.

Results: Between 1984 and 2015, 321 patients underwent liver and bile duct resection for presumed PHC. Of all patients 15% (47/321) were found to have benign disease on histological examination. 45% (21/47) of patients with benign disease had evidence of IAC after surgery based on histological criteria (n=17) or laboratory parameters (n=4). The remaining specimens showed unclassified sclerosing inflammation. Out of 12 patients with benign disease that were re-evaluated, 9 had ongoing active IgG4-RD requiring immunosuppressive treatment.

Conclusion: Benign biliary disorders mimicking PHC have led to a considerable number of liver and bile duct resections during the last three decades. There was evidence of IAC in 45% of these patients. When left untreated, IgG4-RD can remain active years after surgery. Novel accurate diagnostic tests for IAC might reduce misdiagnosis and unnecessary surgery.

Introduction: Digital cholangioscopy provides higher-resolution imaging of the pancreatobiliary tract compared to the 1st fiberoptic generation. The impact of a new single-operator digital cholangioscope (d-SOC) in diagnosis and treatment of pancreatobiliary diseases has not been intensely assessed.

Aims & Methods: The aim of this retrospective analysis of prospective case series from 8 centers from the Czech (n = 7) and Slovak (n = 1) Republics was to assess (1) diagnostic yield of d-SOC visual diagnosis and biopsies in patients with undetermined biliary strictures; (2) the efficacy of d-SOC directed treatment of difficult lithiasis and (3) to analyze procedure related adverse events (AEs). The main outcomes were (1) sensitivity and specificity for visual diagnosis with/without biopsies (2) achievement of a complete duct clearance in patients with difficult lithiasis (3) procedure-related AEs.

Results: A total of 150 patients underwent 166 d-SOC procedures (165 cholangioscopies and 1 pancreatoscopy); 81 (48.8%) for diagnostic intents (with biopsy in 66/81 patients (81.5%), and 85 (51.2%) for therapeutic intents (1 patient had pancreaticolithiasis). The most frequent indication for diagnostic d-SOC was undetermined stenosis (n = 59). Reliable views of a target lesion were obtained in all patients. The sensitivity, specificity and diagnostic accuracy of d-SOC for visual diagnosis of malignant lesion was 88.9% (95%CI, 70.8–97.7), 81.2% (65.6–92.3) and 84.6% (73.5–92.4). The mean number of biopsies obtained per patient was 4 (range 1–13) and the specimen was adequate for histopathological analysis in 95.5% of patients (63/66). The sensitivity, specificity and diagnostic accuracy of d-SOC guided biopsies for malignancy were 78.3% (95%CI, 56.3–92.5), 96.4% (81.6–99.9) and 83.3% (70.7–92.1). The diagnostic accuracy of visual inspection was not statistically influenced by the presence of biliary stent (Yates' p=0.9). Of 63 patients attended for d-SOC-guided stone therapy, a complete intraductal clearance was achieved in one session in 37 and in two sessions in further 10 patients, respectively and the overall success rate was 77%. A total of 11 patients (11/166; 6.6%) experienced an adverse event (cholangitis n=6, pancreatitis n=3, perforation n=2), one patient with severe cholangitis died. The incidence of cholangitis was higher among patients who had received prophylactic antibiotics (n=5) compared to those who had not received it (n=1).

Conclusion: Our, so far the largest case series analyzing outcomes and safety of a new generation of d-SOC shows that (1) It provides high diagnostic yield in patients with undetermined biliary stenosis; (2) The SOC directed biopsies have a high diagnostic accuracy; (3) d-SOC guided stone lithotripsy is effective in three quarters of patients and (4) Severe adverse events may occur and prophylactic antibiotics may not be effective in preventing post-d-SOC cholangitis.

Introduction: Intrahepatic cholangiocarcinoma (ICC) is famous for its poor prognosis. Deepen the knowledge of the mechanism of ICC contributes to improving the treatment. Osteopontin (OPN) is believed to promote tumorigenesis and metastasis in many kinds of cancers, while its role in ICC is controversial.

Aims & Methods: This study aims to investigate the prognostic value and biological function of OPN in ICC. Human Transcriptome Array 2.0 (HTA 2.0) were used to find out ICC-specific genes. Quantitative PCR was used to investigate the relationship between SPP1 and overall survival (OS) in 85 patients. Immunohistochemistry was used for detecting the prognostic value of OPN, as well as the correlation between OPN and clinicopathological characteristics. Stably transfected ICC cell lines which express either higher or lower level of OPN were conducted by lentivirus. Cell-IQ, the live cell imaging and analysis system, was used for proliferation assay. Wound healing assay and Transwell assay was taken to investigate the ability of migration and invasion among transfected cell lines. PCR array was taken to screen the potential oncogenes regulated by OPN.

Results: SPP1 is the most highly expressed genes in ICC with fold change of 43.35 according to HTA 2.0. ICC cell lines express higher level of SPP1 and OPN than normal live cell line (P < 0.01). SPP1 is higher in tumor than adjacent tissues. Patients with higher expression of SPP1/OPN in ICC has better OS than those with low expression (P < 0.01). Both SPP1 and OPN are independent prognostic factor. Higher expression of OPN correlates with better differentiation of ICC and less lymph node metastasis. Compared with negative controlled (NC) cells, ICC cell lines expressing more OPN showed accelerated proliferation rate, stronger ability of migration and invasion. Likewise, ICC cells lines expressing less OPN than NC cells proliferated slower, their capability of migration and invasion was inhibited as well. MMP1, MMP10 and CXCR4 were down regulated in OPN high expression cells and up regulated in OPN low expression cells.

Conclusion: High expression of OPN in ICC tumor tissues indicates less aggressive behavior of ICC and better overall survival for patients after resection. OPN is an advantage prognostic factor in ICC. OPN might function as an inhibitory factor of MMP1, MMP10 and CXCR4 to weaken the capability of migration and invasion in ICC cell lines.

Introduction: Adenoma of the major duodenal papilla is clinically important because this lesion is premalignant and should be resected completely. Endoscopic papillectomy of ampullary adenomas is a promising alternative to surgical resection, however acute and delayed pancreatitis represent a major complication of this procedure.

Aims & Methods: We evaluated the clinical importance of pancreatic duct drainage after endoscopic papillectomy in order to prevent early (acute pancreatitis) and late (pancreatic duct orifice stenosis) complications of this procedure. Our single-centre, retrospective study with a minimal follow-up of 1 year, includes 19 patients who underwent endoscopic ampullectomy between 2012 and 2016. Careful preoperative evaluation was performed by EUS (100% of patients) and CT/MRI (94%). After a collective evaluation between the surgeon and the endoscopist, patients were candidate for endoscopic ampullectomy. Outcome parameters included ampulloma characteristics, biopsial accuracy as well as safety, efficacy, recurrence rate, and survival.

Results: Endoscopic resection was successful in 15 patients (79%). Histological review of the resected specimens revealed non specific changes (10.5%), low or medium-grade dysplasia (52.6%), high-grade dysplasia (15.8%) and carcinoma (21%). Biopsial accuracy was 68.4%. In 4 cases histologic specimen revealed an invasive carcinoma: 2 patients underwent pancreaticoduodenectomy and two were treated conservatively with placement of biliary and pancreatic stents, due to the high preoperative risk. After complete endoscopic resection (15 patients), pancreatic stents were placed in 10 cases (66%). In five cases the positioning of pancreatic stents was not possible due to anatomical difficulties: 2 developed mild pancreatitis after papillectomy; 1 patient developed, as late complication, a stenosis of the pancreatic orifice: the patient died of severe necrotic pancreatitis two years later. Hemorrhage was observed in 2 patients, all with pancreatic stents. Recurrence occurred in 2 patients (10.5%), both were retreated by snare papillectomy and diathermal ablation (APC).

Conclusion: Pancreatic stent placement after endoscopic ampullectomy is mandatory to prevent acute and delayed pancreatic complications. Preoperative strategy should be accurate by MRI, EUS and ERCP, in order to define the anatomy of the pancreatic duct aiming to improve the success rate of pancreatic stent placement after papillectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cholangiocarcinoma is a neoplasm arising from the intra- or extra-hepatic bile duct lining epithelium. Cholangiocarcinoma presents less than 2% of human malignancies, however, it is the second common primary hepatic malignancy. Till date, many carcinogens have already been identified and the relevant information with regard to these agents is available. One example is the potentially harmful presence of heavy metals that can cause serious health problems. People may be exposed to heavy metals over the course of their lifetime. The heavy metals in drinking-water pose the greatest threat to public health in this regard. Nile River water is seriously contaminated with heavy metals, pesticides, and hydrocarbons as a result of increasing discharge of untreated industrial wastes and agricultural irrigation wastewater. Several reports on Dakahlia Province show high levels of heavy metal and organochlorine pesticides in the soil and water in this region. High concentrations of heavy metals, including cadmium, are among the pollutants in the water. Plants and fish grown in this

water are also contaminated with heavy metals, which can in turn accumulate in humans and animals that feed on these contaminated foods. The serum cadmium levels of residents of Dakahlia Province are almost 10-fold higher than those of residents from cadmium-polluted areas in Cairo and 32 times higher than reference levels for healthy populations in the United States.

Aims & Methods: We aimed to assess serum levels of Heavy metals namely Zinc (Zn), lead (Pb), Cobalt (Co), Cadmium (Cd), Chromium (Cr) and Iron (Fe) as a markers of exposure in cholangiocarcinoma patients and healthy control subjects from the same region in Egypt and its correlation with differentiation of cholangiocarcinoma and tumour marker CA 19-9. This study included 45 patients with cholangiocarcinoma (diagnosed after radiological & histopathological examination) and 20 healthy control subject attending Mansoura Surgical Gastroenterology centre. All patients and control were permanent residents of North Delta region and the patients were recruited before receiving chemotherapy or radiotherapy. There were no restrictions based on age, sex, or tumor stage. The serum samples were analyzed for concentrations of zinc, lead, cobalt, cadmium, iron and chromium by the acid digestion method followed by using atomic absorption spectrometry. "Buck Scientific Accusys 214 atomic absorption spectrophotometer". The results are reported in mg/L. In addition to CA 19-9 was assayed by IMMULITE® 2000 XPI immunoassay system supplied by Siemens Healthcare (GmbH Henkestr. Erlangen Germany) using its commercial kits.

Results: The serum levels of Zn, Pb, Co, Cd and Fe were significantly higher in patients having cholangiocarcinoma more than control subjects ($P < 0.001$). Progressive increase in the median values of serum levels of lead (Pb) was found in well differentiated to moderately differentiated to undifferentiated tumours. ($P < 0.05$). When correlation was made between the heavy metals and CA-19-9 and the survival of the patients, it was found that Cd only has a positive correlation with CA19-9 and negative correlation with the survival of the patients ($P < 0.5$, ($P < 0.01$) respectively.

	Cholangiocarcinoma	control	Significance test
Sex (N&%):	22 (48.9%) 23 (51.1%)	22 (48.9%) 23 (51.1%)	$\chi^2 = 0.44$, $P = 0.5$
Male Female			
Age (mean \pm SD)	54.2 \pm 7.9	52.5 \pm 8.99	$t = 0.8$, $P = 0.4$
	Median (Min-Max)	Median (Min-Max)	
Zn	0.341(0.02–0.92)	0.106(0.002–0.55)	$Z = 3.05$, $P = 0.002$
Pb	1.16(0.067–2.98)	0.353(0.019–0.932)	$Z = 4.79$, $P < 0.001$
Co	4.304(0.224–14.1)	0.3255(0.03–2.834)	$Z = 5.88$, $P < 0.001$
Cd	0.211(0.0–0.951)	0.0091(0.002–0.11)	$Z = 5.53$, $P < 0.001$
Fe	1.991(0.662–5.774)	0.9565(0.0231–2.652)	$Z = 3.89$, $P < 0.001$
Cr	0.7063(0.0–2.03)	0.452(0.0663–1.0619)	$Z = 1.91$, $P = 0.057$

Conclusion: The results from this study suggest that cholangiocarcinoma in the Nile Delta region is significantly associated with high serum levels of heavy metals especially Cadmium and lead.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1403 SELF-EXPANDABLE METAL STENT ARE SUPERIOR TO PLASTIC STENT FOR PREOPERATIVE BILIARY DRAINAGE IN RESECTABLE MALIGNANT DISTAL BILIARY STRICTURE: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Tringali¹, M. Cintolo¹, L. Cristofori¹, E. Forti¹, F. Pugliese¹, L. Dioscoridi¹, R. Manta², M. Mignani¹

Introduction: Early surgery is the standard treatment in patients with resectable perihilar or pancreatic head cancer with jaundice. However, early surgery is not always feasible and PBD could be a necessary for patient with jaundice at diagnosis or for those undergoing neoadjuvant treatment. Most studies considered plastic stents for PBD, although SEMS are currently considered superior. A recent RCTS showed that fully covered SEMS are associated with better outcomes compared to plastic stent.

Aims & Methods: Aim compare the rate of endoscopic reintervention (Stent failure of PBD) before surgery and post operative outcome of metal vs plastic. We conducted a bibliographic search using PUBMED, EMBASE including randomized and non randomized trials. OR using the Mantel-Haenszel method was used for dichotomous variables. Weighted mean differences (WMD) were used as the summary statistic for quantitative analysis of continuous variables. Quantitative synthesis was performed using Review Manager version 5.0.

Primary outcome was the rate of endoscopic reintervention before surgery. Secondary outcomes were rate of overall complications, 30 days surgical post-operative complications, hospital readmission, overall pancreatic fistula, overall biliary anastomotic leak, overall postoperative mortality. Clinical heterogeneity was assessed by I^2 value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity.

Results: Three RCTs and five non RCTs were selected including 909 patients. Of these, 300 patients (33%) were treated with SEMS and 609 (67%) with plastic stents. The rate of endoscopic reinterventions after PBD was significantly lower in the metal stent (3.4%) than in the plastic (14.8%) group ($p > 0.0001$). The rate of post operative pancreatic fistula was significantly lower in the metal stent group as well (5.1% vs 11.8%, $p < 0.04$) (OR 0.23 95%CI 0.06–0.96). The overall pancreatic anastomotic leak was significantly lower in the metal stent group (OR 0.44 95%CI 0.20–0.96) ($p = 0.04$). The rate of postoperative surgical complications, hospital readmission, overall biliary anastomotic fistula and postoperative mortality did not differ between the two groups.

Conclusion: Metal stents are more effective than plastic and should be preferred for PBD in patients with resectable periampullary or pancreatic head tumor when early surgery without PBD is not feasible. However, more RCTs are needed before a firm conclusion could be made.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1404 THE EFFICACY AND SAFETY OF PREOPERATIVE BILIARY DRAINAGE IN PATIENTS WITH OBSTRUCTIVE JAUNDICE: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Tringali¹, M. Cintoletti¹, L. Cristofori¹, E. Forti², F. Pugliese¹, L. Dioscoridi¹, M. Mutigiani¹

¹Endoscopy Unit, Niguarda Hospital, Milano/Italy

Contact E-mail Address: albttri10@gmail.com

Introduction: There is considerable controversy as to whether temporary relief of biliary obstruction prior to major definitive surgery (pre-operative biliary drainage) is of any benefit to the patient. A Cochrane meta-analysis revealed a major morbidity with no difference in mortality in the group subjected to PBD. However, the clinical status of patients was heterogeneous between studies.

Aims & Methods: We aimed to investigate the benefits and harms of pre-operative biliary drainage versus no pre-operative biliary drainage (direct surgery) in patients with obstructive jaundice. A computerized medical literature search was performed by using MEDLINE, EMBASE, Cochrane Library, from 1980 to June 2016 aimed at identifying RCTs comparing PBD versus direct surgery. Data from RCTs related to safety and effectiveness of PBD versus no PBD were extracted by two independent reviewers. Risk ratio or mean differences were calculated with 95 per cent confidence intervals. Clinical heterogeneity was assessed by I^2 value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity. Outcomes were mortality and morbidity.

Results: Nine trials including 734 patients with malignant or benign obstructive jaundice comparing PBD (375 patients) with no PBD (359) were included in this review. There was no significant difference in mortality (risk ratio 0.89, 95%CI 0.67 to 1.18; $P = 0.42$) between the two groups. Complications were higher in the PBD group (RR 1.41; 95%CI 1.09–1.81 $p = 0.008$). Overall serious morbidity was higher in the PBD group than in the direct surgery group (RR 1.66 95%CI 1.28–2.16 $p = 0.0002$). There was no significant difference in length of hospital stay between the two groups: mean difference 4.55 (95% CI –1.51 to 10.61) days ($P = 0.14$).

Conclusion: There is currently not sufficient evidence to support or refute the routine pre-operative biliary drainage for patients with obstructive jaundice. PBD in patients undergoing surgery for obstructive jaundice is associated with similar mortality but increased serious morbidity compared with no PBD. Therefore, PBD should not be used routinely. Further RCTs are needed.

Introduction: Dietary fat consumption affects the human body fat composition. It has been described that unsaturated fatty acids, enriched in human pancreatic necrosis collections, worsen acute pancreatitis (AP) [1]. Preliminary reports analyzing indirect data have also suggested that patients with AP from world regions with a high unsaturated fat intake have a worse outcomes at lower body mass index [2]. We have also described that oleic acid (an unsaturated fat acid) chlorohydrins are associated to worse outcomes [3]. The Mediterranean regions have a higher unsaturated fatty acid intake.

Aims & Methods: We aimed to compare the incidence of necrotizing AP, persistent organ failure (POF) and mortality among patients with AP from centers located in the Mediterranean region (group M) and patients from centers in other regions (group C). This was a retrospective analysis of a prospective multicenter (23), nation-wide cohort of patients with AP: the ATLANTIS database. Group M included patients from Spanish autonomous regions in contact with the Mediterranean Sea. Group C included all other autonomous regions. Necrotizing AP and POF were defined according to the revised Atlanta classification. Chi² was used for univariate analysis. Multivariate analysis was performed by means of binary logistic regression, including in the model: sex, body mass index > 30, alcoholic etiology and Charlson score (it includes age and comorbidity) ≥ 3 .

Results: We analyzed 1655 patients, 854 (52%) from group M (12 centers) and 801 (48%) from group C (11 centers), 984 (60%) with biliary etiology, 891 (54%) males. The incidence of necrotizing AP was 281 (17%) patients, persistent organ failure: 113 (7%), mortality 70 (4%). The proportion of patients with necrotizing AP was higher in group M: 178 (21%) vs 103 (13%), $p < 0.001$. POF was also more frequent in group M: 74 (9%) vs 39 (5%), $p = 0.002$. Finally, mortality was higher in group M: 49 (6%) vs 21 (3%), $p = 0.002$. In multivariate analysis, group M was independently associated to necrotizing AP [adjusted OR (aOR) 1.7 (1.3–2.3), $p < 0.001$], to POF [aOR 2 (1.3–3.1), $p = 0.001$] and mortality [aOR 2.6 (1.5–4.5), $p = 0.001$].

Conclusion: Patients from the Mediterranean regions of Spain have a higher incidence of necrotizing AP, POF and mortality. We hypothesize that this disbalance is associated to a higher diet unsaturated fat intake.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Exocrine pancreatic insufficiency and exocrine function alterations are characteristics of pancreatitis. They are frequent in diabetes mellitus (DM) patients with a prevalence up to 50%. Although reduced levels of insulin may explain many of the proposed mechanisms of pancreatic dysfunction following DM, the same phenotype is also detected in insulin-independent DM. This highlights the concept that additional factors are likely to contribute to the pathophysiology of acinar cells. We recently discovered that 1-deoxy-sphingolipids (1-deoxySLs), the levels of which increase in DM and metabolic syndrome are cytotoxic for beta cells¹. Our preliminary results showed that 1-deoxySLs are also cytotoxic for acinar cells *in vitro*. Furthermore, the high level of 1-deoxySLs in diabetic animal model aggravated acinar cell damage whereas lowering levels of 1-deoxySLs improved cell deterioration.

Aims & Methods: In this research, we investigate molecular and cellular factors that contribute to compromise acinar cell functionality in the context of DM. Based on the endocrine and exocrine pancreas crosstalk, we hypothesize that elevated 1-deoxySLs levels affect directly the pancreatic exocrine compartment by compromising pancreatic acinar cells in DM, thus increasing its predisposition to develop exocrine pancreatic diseases. *in vivo* mouse models with STZ-induced diabetes and cerulein-induced pancreatitis were used in this study. Reduction of 1-deoxySLs synthesis was achieved by oral L-serine supplementation. Disease severity was assessed with biochemical and immunohistochemical methods. Molecular mechanisms of 1-deoxySL-dependent toxicity were evaluated *in vitro* on AR42J pancreatic acinar cells and primary acinar cells.

Results: DM induction resulted in increased 1-deoxySL levels but also atrophy and fibrosis of pancreatic parenchyma. Reduction of 1-deoxySL synthesis by oral L-serine supplementation ameliorated the damage of the exocrine pancreatic tissue, without restoring insulin production in beta cells. This suggests that elevated 1-deoxySLs rather than insulin deficiency contribute to the exocrine damage in DM. *In vitro* studies showed that treatment with 1-deoxysphinganine, one of the early products of 1-deoxySLs synthesis at low concentration reduced replication and promoted cytotoxicity in pancreatic acinar cells. In addition, this 1-deoxySL-mediated cytotoxicity was associated with mitochondrial dysfunction and endoplasmic reticulum stress.

Conclusion: Our work revealed that 1-deoxySLs are cytotoxic for exocrine pancreatic cells, suggesting a role for these lipids in the exocrine dysfunctions following DM. Oral L-serine supplementation could be a therapeutic treatment for ameliorating exocrine pancreatic diseases in diabetic patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Splanchnic venous thrombosis (SVT) is a common vascular complication of acute pancreatitis (AP). There is paucity of data on its frequency, risk factors, outcome and natural history. Coagulation abnormality has been implicated but not proven as a cause of SVT in AP.

Aims & Methods: We aimed to prospectively study the frequency, risk factors and extent of SVT in patients with AP as well as role of thrombophilia in causation of SVT. Patients with AP presenting to our centre between January 2015 and June 2016 were prospectively evaluated with contrast enhanced computerized tomography (CECT) abdomen for presence of SVT. These patients were subjected to detail analysis of coagulation parameters. Outcome was assessed in terms of presence or absence of necrosis, severity, organ failure, need for intervention and mortality. None of the patients with SVT were given anticoagulation. Follow-up ultrasound Doppler was performed to look for the status of SVT.

Results: Ninety-six patients with AP (73 males, mean age 31.85 ± 13.34 years) were evaluated of which 26 (27.1%) had SVT. Single vessel, two vessels and three vessels were involved in 19 (73.1%), 3(11.5%) and 4(15.4%) patients respectively. Splenic vein, portal vein and superior mesenteric vein involvement were seen in 22(84.6%), 11(42.3%) and 4(15.3%) patients respectively. Necrotizing pancreatitis, CTSI > 6 and Modified CTSI > 6 were found in significantly higher number of patients with SVT than those without SVT (96.2% vs 78.6%, 76.9% vs 47.1%, and 92.3% vs 67.1%, respectively). Coagulation analysis was performed in 42 patients (18 with and 24 without SVT). Protein C, protein S and AT III deficiency were found in 10(23.8%), 14(33.3%) and 13(31.0%) patients respectively. β_2 GPI and lupus anticoagulant were positive in 2 (4.8%) and 5(11.9%) patients respectively. Anticardiolipin antibody was negative in all the patients. Factor V Leiden mutation analysis was done in 33 patients (14 with SVT and 19 without SVT) of which 2 (6.1%) were positive. There was no correlation between abnormal coagulation results and outcome of AP. Coagulation abnormality did not differ significantly between the patients with and without SVT. On follow-up, Doppler study done in 7 patients with SVT, spontaneous resolution of SVT occurred in 5 (71.4%) within 1 year. None of the patients had varices on follow-up.

Conclusion: SVT in AP is more common in patient with necrotizing pancreatitis and higher CTSI and MCTSI indices suggesting that local inflammation plays a major role in its causation. Thrombophilia in some form is seen in one third of the patients with AP but does not increase the risk of AP.

P1408 EVALUATION OF A PROTOCOL OF AN ENDOSCOPIC ULTRASOUND TRANSMURAL DRAINAGE OF INFECTED PANCREATIC NECROSIS (IPN) WITH LOCAL ANTIBIOTHERAPY THROUGH NASOCYSTIC CATHETER

J. Lariño Noia¹, J. López-Díaz², D. De La Iglesia-García², J. Iglesias-García², R. Mejuto-Fernández², F. Macías-García¹, A. Álvarez-Castro², A. McKenzie-Ballesteros², S. García-Rodríguez², J. Díaz-Gutiérrez², J.E. Domínguez-Muñoz²

Introduction: Infected pancreatic necrosis (IPN) is associated to significant morbidity and mortality. Current management of IPN is based on a step-up approach, based on minimally invasive procedures. Our group has recently

published a protocol of local infusion of antibiotics for the treatment of IPN (*Pancreatology* 2016;16:719–25).

Aims & Methods: We aim at analysing the efficacy of this step-up approach for the treatment of IPN in clinical practice. This was a retrospective single-centre study of patients admitted with acute pancreatitis (AP) between January 2015 and December 2016. The cases with the diagnosis of pancreatic necrosis (NP) and IPN (defined by positive culture of necrosis and clinical, analytical, and/or radiological data of infection) were identified and evaluated. IPN was treated following a step-up approach defined by 1. intravenous antibiotherapy, 2. Endoscopic ultrasound (EUS) guided transgastric drainage plus local antibiotherapy, 3. endoscopic necrosectomy. Number of patients responding to each therapeutic step was assessed.

Results: 694 cases of AP were included (mean age 79.5 ± 18.3 , 355 male). CT scan was performed only if clinically indicated. 67 patients (9.6%) had acute necrotizing pancreatitis (ANP), and 21 of them IPN (31% of ANP). IPN patients were treated with intravenous antibiotics (imipenem [n = 15] and meropenem [n = 6]), with good response in 8 (38% of IPN). The remaining 13 cases underwent a EUS guided transmural drainage plus local infusion of antibiotics. Only 3 patients needed endoscopic necrosectomy (14% of all IPN). Overall mortality was 1.5% (11 cases), 6 with edematous pancreatitis (0.96%) and 5 with ANP (7.4% of ANP). Only one patient with IPN died (4.8% of IPN).

Conclusion: By using a step-up approach, nearly two out of three patients with IPN require transgastric drainage. By associating local antibiotherapy through nasocystic catheter to the drainage, only 14% cases with IPN require endoscopic necrosectomy. With this background, comparative studies are needed to evaluate the impact of local antibiotherapy for IPN.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1409 EUS-GUIDED PANCREATIC FLUID COLLECTION DRAINAGE WITH LUMEN-APPPOSING METAL STENTS OR PLASTIC DOUBLE PIGTAIL STENTS: A MULTI-FACTORIAL ANALYSIS

N. Ge, S. Sun

Dept. Of Endoscopy, Shengjing Hospital, Shenyang/China

Contact E-mail Address: ge_nan2013@163.com

Introduction: We aimed to compare the efficiency of plastic and metal stents for symptomatic pancreatic fluid collection drainage and analyze other main associated factors that affect the outcome of drainage therapy.

Aims & Methods: Rates of technical and clinical success, procedure-related side effects (hemorrhage, stent migration, and cyst rupture), re-interventions, and duration of hospital stay.

Results: There were 52 patients, 40 who underwent plastic stent placement and 12 who underwent lumen-apposing metal stent placement. The total rate of technical success was 100%. The total rate of clinical success was 100%. The total rate of adverse events was 7.7% (4/52). On multiple logistic regression analysis, the use of plastic stents ($P < 0.05$, Exp B = 12.168) and presence of a large cyst ($P < 0.05$, Exp B = 1.036) were shown to significantly increase the risk of re-intervention. On multivariate linear regression analysis, etiology of pseudocyst ($P < 0.05$, B = -8.427; -9.785; -5.514) was associated with prolonged hospital stay, while stent type was not shown to be a factor ($P > 0.05$).

Conclusion: Both plastic and lumen-apposing metal stents are proven to be highly efficient in pancreatic fluid collection drainage. The lumen-apposing metal stent is superior in preventing complications such as migration and cyst leakage and reducing the rate of re-intervention. Large cyst size is associated with an increased risk of re-intervention and prolonged hospital stay.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute pancreatitis (AP) is one of the most common diseases of the gastrointestinal tract associated with significant morbidity and mortality. The assessment of severity is crucial in the management of the disease. The pathomechanism of AP is not well understood, it has no specific therapy. Current methods of risk stratification in AP have a limited value, as they provide little additional information thus may delay appropriate management. Early recognition of severe disease may prevent serious adverse events and improve patient management as well as overall clinical outcome. The EASY trial is an observational, multicenter, prospective cohort study for establishing a simple, easy and accurate clinical scoring system for early prognostication of acute pancreatitis.

Aims & Methods: We aimed to create a new scoring system, which can predict the severity of AP in early phase of disease. Evaluation of simple attainable potential prognostic parameters obtained at admission (or not later than 6–12 hours afterwards) from patients diagnosed with AP will be performed to assess their potential correlation with the disease severity. Approximately 1200 (900 + 300) patients from multiple centers will be enrolled into this trial using the Registry. This is an observational prospective cohort study (in which the care or services that patients receive will not be altered); therefore it has a relatively low-risk. The study has an ethical approval by the National Hungarian Ethical Authority (ETT TUKEB). Study management will strictly follow the Ethical Guidelines for Observational Studies.

Results: 600 patients were enrolled in the EASY study from different international centers so far. In early phase of AP vomiting, loss of weight, fever, abdominal tenderness, elevated serum creatinine and lactate dehydrogenase level were more common findings in severe AP, as opposed to the mild and moderate groups.

Conclusion: EASY score may be an easy and accurate system to evaluate the early severity of AP. Although some parameters have shown correlation with the severity of AP in early phase of the disease, we have to include more patients to have reliable results.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1411 EVALUATION OF LOCAL INSTILLATION OF ANTIBIOTICS IN WALLED-OFF PANCREATIC NECROSIS

M. Werge¹, S. Roug², E. Feldager¹, J. D. Knudsen³, L.L. Gluud¹, S. Novovic¹, P. N. Schmidt¹

Introduction: Infected walled-off pancreatic necrosis (WON) is treated with antibiotics. In order to exert its antibacterial effects in WON, systemically administered antibiotics need to overcome a number of limiting steps. First, antibiotics need to cross the capillary endothelium. Thereafter, antibiotics must diffuse across the interstitial space and finally, the capsule surrounding the WON must be crossed. Therefore, the penetration of the intravenously administered antibiotics into WON can be questioned. Using local antibiotics should theoretically increase the antibiotic concentrations in the necrotic tissue and the efficacy.

Aims & Methods: The aim was to evaluate the efficacy of local instillation of antibiotics into walled-off pancreatic necrosis. Between 2012 and 2016 we evaluated all patients treated with endoscopic transmural drainage and necrosectomy (EDTN) and concomitant local instillation of antibiotics. We added antibiotics (either gentamicin, vancomycin, or amphotericin B) to the irrigation fluid according to the microbiological findings. The antimicrobial efficacies of local and systemic antibiotics were evaluated using uni- and multivariate logistic regression analyses and Kruskal-Wallis test by stratification of the isolates in sensitive versus not sensitive/antibiotics not given.

Results: Ninety-one patients were included. At the first drainage 81 (86%) patients had infected and 10 sterile WON. A total of 139 isolates were found at the first drainage. Most patients were infected with enterococci (44%) or other gram-positive cocci. More than a quarter of the infected patients had fungal species cultured. The infected patients often had polymicrobial infections (56%). At the second culture 152 isolates were found. Neither local nor systemic antibiotics were associated with the eradication of microbes between first and second culture. Between second and third culture, the use of local antibiotics was associated with the eradication of microbes (OR = 2.54, P = 0.01), but not systemic antibiotics (P = 0.33) (Table). Between first and second culture 12 patients with fungal infections were treated with local amphotericin B. In all 12 patients the fungus was eradicated. After second culture 20 patients were treated local amphotericin B and in 17 (85%) patients the fungus was eliminated at the third culture.

	Univariate		Multivariate		Kruskal-Wallis Test	
	OR (95% CI)	P-value	OR (95% CI)	P-value	Chi ²	P-value
Culture 1 -> 2						
Local Antibiotics	1.52 (0.73–3.17)	0.261	1.54 (0.74–3.21)	0.249	1.26	0.261
Systemic Antibiotics	1.28 (0.64–2.59)	0.487	1.31 (0.64–2.65)	0.458	0.48	0.488
Culture 2 -> 3						
Local Antibiotics	2.54 (1.25–5.18)	0.010	2.71 (1.31–5.59)	0.007	6.76	0.009
Systemic Antibiotics	0.72 (0.38–1.38)	0.327	0.64 (0.33–1.25)	0.195	0.96	0.328

Conclusion: Our data suggest a better efficacy of local antibiotics in the treatment of infected WON compared to systemic antibiotics. The local instillation of antibiotics may be a promising alternative or supplement to systemic administration. Particularly the use of local instillation of amphotericin B appears to be effective in the treatment fungal infections.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1412 CORONARY DISEASE AND CHRONIC OBSTRUCTIVE PULMONARY DISEASE ARE NOT ASSOCIATED WITH WORSE OUTCOME IN ACUTE PANCREATITIS

J.R. Carvalho, P. Santos, S. Fernandes, M. Moura, T. Antunes, J. Velosa
Department Of Gastroenterology And Hepatology, North Lisbon Hospital Center, University of Lisbon, Portugal, Lisbon/Portugal

Contact E-mail Address: joana.rita.carvalho@gmail.com

Introduction: Pancreatitis is a disease of protean manifestations. In its more severe form, involvement of any organ is possible. Cardiovascular and respiratory failure are possible and feared complications.

Aims & Methods: The aim of this study was to evaluate the effect of chronic ischemic heart disease and chronic obstructive pulmonary disease (COPD) in the outcome of acute pancreatitis (AP), in our population. Retrospective cohort study that included all patients admitted with AP from January 2003 to December 2016, in a tertiary referral centre. Demographic and clinical variables were analyzed by logistic regression (SPSS v23). Clinical outcomes included organ failure (OF), persistent OF (>48 h), intensive care unit (ICU) admission and mortality.

Results: A total of 553 patients with AP were included, 58.4% male, median age 80 (18–98) years. Most common etiologies included gallstones (38.9%) and alcohol (27.3%). Twenty-three percent (n = 129) developed OF (in 43% persistent) and 26.8% (n = 148) were admitted in UCI. Mortality rate was 5.6% (n = 31). Fifty-six patients (10.1%) had previous history of coronary disease and 5.1% (n = 28) had been diagnosed with COPD. The presence of coronary disease and COPD were not associated with higher Ranson's score (≥ 3), $p = 0.076$ and $p = 0.959$, respectively. No association was found between previous history of coronary disease and the development of OF ($p = 0.525$), persistent OF ($p = 0.287$), need for ICU admission ($p = 0.115$) and mortality ($p = 0.262$). There was also no association found between previous history of COPD and the development of OF ($p = 0.803$), persistent OF ($p = 0.588$), need for ICU admission ($p = 0.514$) and mortality ($p = 0.720$). At multivariate analysis (correcting for age and gender) coronary disease and COPD were not independent predictors of worse outcome in AP.

Conclusion: In our population, previous history of coronary disease and COPD were not predictors of worse outcome in AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1413 WORSE OUTCOMES IN ACUTE PANCREATITIS IN PATIENTS WITH TYPE-2 DIABETES MELLITUS

P. Santos, J.R. Carvalho, S. Fernandes, M. Moura, T. Antunes, J. Velosa
Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, Lisbon/Portugal

Contact E-mail Address: patricia.sants@hotmail.com

Introduction: Predicting severe pancreatitis is important for early aggressive management of patients with acute pancreatitis (AP). Despite the established role of type-2 diabetes mellitus (DM) in the risk of AP, the impact of DM on the clinical outcome in AP has not been fully elucidated.

Aims & Methods: Retrospective study including hospital admissions between January 2003 and December 2016 in a single tertiary referral center. Clinical outcomes included organ failure (OF), persistent OF (>48 h) admission to intensive care unit (ICU) and mortality. Variables were analysed by logistic regression (SPSS v23.0). The objective of this study was to assess the risk of mortality and severity in AP among patients with type-2 DM.

Results: A total of 553 patients (58.4% male) with AP were included, median age 80 (18–98) years. Most common etiologies included gallstones (38.9%) and alcohol (27.3%). Twenty three percent developed OF (in 43% persistent) and 5.6% (n=31) were deceased. There were 127 AP patients (23.0%) with type-2 DM. Type-2 DM were not associated with higher Ranson's score. There was an association between DM and development of OF (OR 31.7, CI95% 18.8–53.7, p < 0.001), persistent OF (OR 45.1, CI95% 18.7–108.9, p < 0.001), ICU admission (OR 12.3, CI95% 7.8–19.4, p < 0.001) and mortality (OR 17.1, CI95% 6.8–42.8, p < 0.001). At multivariate analysis DM was an independent predictor of OF development and ICU admission.

Conclusion: In our population, Type-2 DM was associated with severity and increased mortality in patients with AP. Our findings provide evidence of the potential role of DM in the management of severe AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1414 ACUTE PANCREATITIS IN LIVER TRANSPLANT RECIPIENTS: INCIDENCE AND OUTCOME

P. Macinga¹, K. Poc², P. Trunecka³, J. Spicak¹, T. Hucl¹

¹Department Of Gastroenterology And Hepatology, Institute For Clinical And Experimental Medicine, Prague/Czech Republic

²First Faculty Of Medicine, Charles University, Prague/Czech Republic

³Transplantcentre, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: peter.macinga@ikem.cz

Introduction: Acute pancreatitis (AP) is an uncommon but potentially devastating condition that may occur in patients with organ transplantation. Reported incidence ranges from 1.5 to 8% in patients undergoing liver transplantation with significant mortality.

Aims & Methods: The aim of our study was to assess the incidence, potential risk factors and outcome of AP following liver transplantation in our center. We performed a retrospective analysis of medical records of all adult patients who underwent liver transplantation in our center between September 1996 and November 2014. The diagnosis of AP was defined by combination of clinical manifestation, finding on imaging methods (CT, USG) and elevation of serum amylase and lipase.

Results: Nine hundred and sixty-seven orthotopic liver transplantations were performed in 578 males and 389 females (mean age 51 years, range 18–74). AP occurred in 18 patients (1.9%, 16 males, 2 females) and resulted in death in 5 patients (28%). According to timing of AP we recognized two clinical presentation—early AP (<1 month after liver transplantation) and late (>1 month). Four patients (22%) developed early AP, which was severe necrotizing with MODS in all cases and resulted in death in 3 of them (75%). Two of them

were transplanted for fulminant hepatic failure, one for end-stage liver disease due to chronic hepatitis B infection and one for polycystic liver disease. Two patients were treated by surgical necrectomy and died, the third deceased patient was treated conservatively. In the only surviving patient, a successful EUS-guided drainage of walled of pancreatic necrosis and repeated endoscopic necrectomy were performed. We were unable to identify surgical or other factors responsible for development of AP. Late AP occurred in 14 patients (78%) with a median delay of 31 months after liver transplant (range 2–176). In 12 patients AP was mild with no mortality and the following etiologies were represented: 4 post-ERCP, 2 alcoholic, 1 biliary (CBD stones), 1 drug-induced (azathioprine), 1 obstructive (pancreatic cancer); in 3 patients the etiology was unknown. One patient developed a pseudocyst. Two patients with late acute pancreatitis had a severe necrotizing form and both died. One patient with cirrhosis of the liver graft due to chronic rejection had post-ERCP pancreatitis which was complicated by retroperitoneal hemorrhage and graft failure. The other patient with necrotizing pancreatitis of unknown etiology developed MODS and eventually died. Male patients (p=0.01) and patients transplanted for liver cirrhosis resulting from chronic hepatitis B were at a significantly higher risk of AP development (p=0.03).

Conclusion: The incidence of AP after liver transplant in our center is low. In it necrotizing form which is more frequent early after liver transplant, it carries a significant risk of mortality exceeding 80%. Male patients and those transplanted for end stage liver disease resulting from chronic hepatitis B are more likely to develop post-liver transplantation pancreatitis.

Introduction: Biliary sludge (BS) may be one of the factors, related to development of chronic pancreatitis (CP) via sphincter of Oddi dysfunction. As it was demonstrated by Okazaki K et al. in 1988, patients with biliary sludge have higher sphincter of Oddi (SO) pressure and contraction frequency vs. controls.

Aims & Methods: To assess the frequency of CP signs in patients with BS and to investigate the state of major duodenal papilla (MDP) in patients with idiopathic CP with BS by endoscopic ultrasound (EUS); to evaluate whether antispasmodics can be effective in pain relief at CP, that developed on the background of gallbladder sludge. Protocols of computer tomography, endoscopic and transabdominal ultrasound studies of over 6000 patients of gastroenterological tertiary clinic were examined. Those who had signs of BS were selected to evaluate the presence of at least “mild CP” according to the modified Cambridge classification. Exclusion criteria were: established etiology of CP and signs of pancreatic neoplasm. Patients, who received ursodeoxycholic acid and drugs that affect smooth muscle contractility for less than 3 month prior to the study were excluded. Thirty consecutive patients (15 m, 15 f, mean age ± SD: 52.8 ± 15.3), who had both BS and CP were summoned for physical examination, quality of life assessment, US-cholecystography and endoscopic pancreatobiliary ultrasound with elastography, calculation of MPD surface area $S_{MDP} = (h_{MDP} \times w_{MDP}) / (2 \times 1.27)$ and state of MDP before and after 3 weeks of hycromone monotherapy 400 mg tid.

Results: Signs of CP were revealed in 6.3% of BS cases. CP was most common in those who had ointment-like bile (33.3%) vs. patients with heterogeneous bile with clots –7.7% and hypochoic particles –1.7% (chi-square 38.21, p < 0.00001). Mean S_{MDP} was $14.9 \pm 5.2 \text{ mm}^2$ (95%CI 10.9–18.9). S_{MDP} was below the normal range (20–25 mm²) in 78% of patents. S_{MDP} had positive correlation to the volume of evacuated bile according to US-cholecystography ($r_s = 0.683$, p=0.042) and gallbladder contractility coefficient ($r_s = 0.817$, p=0.007). All patients with higher density of MDP at US-elastography had S_{MDP} lower than the normal range and were attributed to “fibrosis” group. Only 38% of patients with CP and BS had normal MDP at EUS. Periapillary diverticula were found in 13% of the cases, papillary edema — in 38%, fibrosis — in 13%. MDP changes were associated with higher AP level and larger MPD diameter. Hymecromone monotherapy resulted in significant improvement in abdominal pain score (t=7.92, p=0.000) and “bodily pain” score of SF-36 questionnaire (t=–3.709 p=0.001). Dynamics of “bodily pain” score by SF-36 demonstrated significant negative correlation to the post-treatment level of abdominal pain ($r_s = -0.395$, p=0.037) Post-treatment pain level had significant negative correlation to the MDP size ($r_s = -0.867$, p=0.002), though no correlation of pre-treatment pain level to MDP features was found, i.e. patients with less MDP size (most of them had decreased elasticity of papilla of Vater, that was considered as indirect marker of fibrosis) had lower hycromone efficacy.

Conclusion: BS may cause MDP changes, resulting in development of obstructive CP. Intensity of pain in biliary CP may be related to sphincter of Oddi dysfunction. Efficacy of antispasmodic therapy in these patents could be predicted by the features of MDP at pancreatobiliary EUS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic exocrine insufficiency is a late complication of chronic pancreatitis; its clinical onset is characterized by steatorrhea and weight loss, borborygmi, flatulence, abdominal pain and malnutrition. Exocrine and endocrine pancreatic function decreases differently in various diseases (autoimmune, paraduodenal, genetic, idiopathic). It has been observed that there has been a recovery of exocrine pancreatic function in autoimmune pancreatitis. In the literature there are no studies analysing the exocrine pancreatic function over time. The fecal elastase test is a good test procedure to evaluate the exocrine pancreatic function

Aims & Methods: The objective of the retrospective study was to re-evaluate a series of patients with chronic pancreatitis with the aim to evaluate the pancreatic exocrine function over time, in particular, by comparing the exocrine pancreatic function in subgroups of patients with different types chronic pancreatitis. Pancreatic exocrine function was estimated through fecal elastase in 143 patients with at least 2 values each (classified into normal, mild and severe exocrine pancreatic insufficiency), the first one taken at the diagnosis of chronic pancreatitis. Patients undergoing surgical pancreatic resection before the second value of fecal elastase were excluded. Etiology was classified in: biliary pancreatitis/sequelae of necrotizing pancreatitis (15), autoimmune (69), paraduodenal (15), genetic (17) and idiopathic (27).

Results: The results show a high frequency of severe exocrine pancreatic insufficiency in the moment of diagnosis of chronic pancreatitis (38%) and it appears stable over the following 5 years. Autoimmune and paraduodenal pancreatitis are correlated with severe exocrine pancreatic insufficiency at diagnosis in a high percentage of cases (51% and 40%), biliary/outcomes of necrotizing pancreatitis and idiopathic pancreatitis in an intermediate (33% and 26%), while genetic in a low percentage (12%).

Conclusion: The exocrine pancreatic function in patients with autoimmune pancreatitis improved in the first five years of the disease, probably due to the efficacy of steroid/immunosuppressive therapy. Pancreatic endocrine function was less compromised at diagnosis, but showed a progressive deterioration in the first five years. Endocrine and exocrine insufficiency were strictly correlated.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1417 "PAINLESS" CHRONIC PANCREATITIS: EPIDEMIOLOGICAL, CLINICAL AND RADIOLOGICAL CHARACTERIZATION

Introduction: The "painless" chronic pancreatitis (CP) represents a specific subset of CP characterized by the lack of pancreatic pain. So far, scarcity of data has been reported in the literature about this matter and what differentiates this group of patients from those with chronic pancreatitis associated with pancreatic pain.

Aims & Methods: The aim of the present study is to characterize "painless" CP from the epidemiologic, clinical, radiological, functional, and follow-up standpoint, through a comparison with other forms of chronic pancreatitis presenting with pancreatic pain. The Institutional Database of the Gastroenterology Unit of the Verona University was queried, and all chronic pancreatitis cases were retrieved. Patients were clustered based on the presence of "pancreatic-specific pain" into "painless" and "pain-associated" CP. A retrospective case-control analysis was carried out.

Results: Of 678 patients included from March 2006 to March 2016, 436 were considered eligible for the present study. Of these, 368 (84%) were affected by pain-associated CP, while 68 (16%) had "painless" CP. "Painless" patients were older (median age of 58.5 ± 10.8 y/o vs. 42.5 ± 15.3 y/o; $p < 0.001$), less frequently presenting with a history of alcohol consumption (35% vs. 55%; $p < 0.001$), more frequently diabetics (18% vs. 1%; $p < 0.001$), presenting with steatorrhea (16% vs. 2%; $p < 0.001$), and asymptomatic (63% vs. 2%;

$p < 0.001$) compared to pain-associated controls. From the radiological standpoint, painless cases were more likely presenting with calcifications at imaging than controls (90% vs. 68%; $p < 0.001$). Moreover, in most of painless cases, the CP cause remained unknown (56%). After a median follow-up of 2.6 ± 2.3 years, the incidence of diabetes was higher in the painless cases than in controls (48% vs. 30%; $p < 0.006$).

Conclusion: The present study represents the first definition of "painless" CP so far reported in the literature. The "painless" CP is a distinct entity from the epidemiologic, clinical, and radiological standpoint when compared to other forms of CP characterized by the presence of pancreas-specific pain.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Recently, EUS-guided pancreatic duct drainage with transmural stenting (EUS-PD) has been used for patients with painful obstructive pancreatitis in whom endoscopic retrograde pancreatography (ERP) has failed. Although the feasibility and safety of EUS-PD with a fully covered self-expandable metal stent (FCSEMS) has been assessed, little is known about the long-term outcomes of EUS-PD with a fully covered self-expandable metal stent (FCSEMS). Removability of an FCSEMS in long-term use and higher cost are the main concerns of EUS-PD with an FCSEMS compared with EUS-PD with a plastic stent.

Aims & Methods: The aim of this study is to evaluate the procedural and long-term outcomes of EUS-PD with an FCSEMS for patients with painful obstructive pancreatitis who failed ERP. Forty-one consecutive patients with painful obstructive pancreatitis underwent EUS-PD with an FCSEMS after failed ERP. Permanent FCSEMS placement without scheduled stent exchange was considered in malignant MPD strictures or complete MPD obstruction in benign pancreatic stricture. Technical and clinical success, adverse events, and stent patency were assessed. An endoscopic examination and CT scan was performed every 6 months to assess stent patency in benign stricture.

Results: 15 patients had malignant MPD obstruction and 26 patients had benign stricture. EUS-PD was successful in all 41 patients (technical success rate, 100%), and symptoms improved in all patients (clinical success rate, 100%). EUS-guided pancreaticogastrostomy (n = 39) and pancreaticojejunostomy (n = 2) were performed. Pain scores improved significantly after FCSEMS placement ($P = .01$). Early mild-grade adverse events occurred in 5 patients (12.2%) with self-limited abdominal pain, which resolved with conservative treatment. Late adverse events developed in eight patients (22.2%), including distal stent fracture (n = 6), stent occlusion (n = 2). These patients were successfully treated endoscopically. No other adverse events related to FCSEMS, including stent migration, pancreatic sepsis, and stent-induced ductal stricture were observed during follow-up periods.

Overall mean stent patency duration was 412 days (range 14–1081) during mean follow-up periods (427 days). Median stent patency in malignant stricture was 95 days (range 14–297). Mean stent patency in benign stricture was 525 days (range 121–1081). No patients with malignant strictures required FCSEMS revision or exchange during follow-up periods. FCSEMS removal and exchange was successful in all benign strictures with stent dysfunction. At the end of the follow-up, two patients (5.6%) showed resolution of stricture after definite stent removal.

Conclusion: EUS-PD with an FCSEMS showed excellent long-term outcomes for patients who failed conventional ERP in both malignant and benign painful obstructive pancreatitis. Endoscopic FCSEMS removal and exchange could be successful in patients with benign strictures until 3-year placement of an FCSEMS. Prospective randomized trial comparing EUS-PD with FCSEMSs and plastic stents may be warranted for painful obstructive pancreatitis after failed ERP.

Introduction: Fundamental aspects in the treatment of pancreatic exocrine insufficiency (PEI) include pancreatic enzyme replacement therapy (PERT). Monitoring the symptoms of maldigestion as well as the nutritional markers is essential.

Aims & Methods: To follow-up patients with PEI receiving PERT and to provide normal nutritional status by optimizing the suboptimal PERT if necessary. Study enrolled 142 patients (88 males, mean age 52 years): 82 patients had chronic pancreatitis (CP), 30- acute pancreatitis (AP), 30- pancreatic cancer/pancreatic resection. 58 patients were re-monitored 6 months after adjusting suboptimal therapy. Alcohol abuse was most common aetiology. Nutritional status was evaluated by prealbumin and retinol binding protein (RBP) via immunonephelometry, fat-soluble vitamins A, D, E via HPLC and LC-MS/MS; magnesium (Mg) and hemoglobin (Hb). We evaluated in addition albumin; cRP; BMI. Imaging morphological data were assessed by Cambridge classification for CT/MRCP (grade I-IV) and cardiovascular risk (CVR)- by apolipoproteins (apo) A-I, B and lipid profile. Statistical analysis was performed via SPSS v22.

Results: Protein malnutrition with prealbumin (mean: 0.208 ± 0.105 g/L) and RBP (mean: 0.0389 ± 0.0258 g/L) below reference limits was observed in 67 and 47 of all patients, respectively. We found correlation between prealbumin and RBP with other nutritional parameters (Hb, Mg, albumin, $p < 0.01$), lipid profile and apolipoproteins in patients with CP ($p < 0.05$) and negative relationship to CRP ($p < 0.001$) in AP. Preadalbumin and RBP related to age, morphological changes and BMI in CP, $p < 0.05$. Mean values of vitamin A, D, E were 527.68 ± 321.12 µg/L, 39.74 ± 24.36 nmol/L, 8.07 ± 6.01 µg/L. Vitamin A, D, E insufficiencies were present in 21.95; 94.49 and 40.96% of all evaluated patients, respectively. Moreover 33.86% had vitamin D deficiency (< 25 nmol/L). We found lowest vitamin levels in patients with pancreatic cancer/pancreatic resection and correlation with structural changes worsening, $p < 0.05$. Within all patients we observed suboptimal PERT with nutritional deficiencies despite an adequate clinical response (prealbumin, RBP, vitamin A, vitamin D and vitamin E deficiencies in 44.82, 36.73, 11.43, 92.86 and 48.57% of all asymptomatic patients, respectively). During second follow-up (6 months after PERT optimization), we demonstrated clinical improvement with a significant increase in BMI ($p < 0.0001$) and nutritional markers, $p < 0.01$. CVR was increased in 62% of patients. Dyslipidemia was more severe in men and in CP, $p < 0.05$. Optimal non-HDL levels were present in 33.59% (mean non-HDL levels: 5.23 ± 2.25 mmol/L). Moderate and high heart attack risk according Apo B/Apo A-I ratio was observed in 34.35% and 45.04% of all patients. In addition, 33 patients suffered from diabetes mellitus.

Conclusion: Proper follow-up and correction of suboptimal PERT as well as CVR screening could reduce the risk of severe malnutrition complications and associated morbidity and mortality by ensuring optimal therapeutic results and better quality of life.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1420 HUR MEDIATED POST-TRANSCRIPTIONAL REGULATION OF HO-1 AND INHIBITORS OF APOPTOSIS PROTEINS IS ASSOCIATED WITH THE POOR CLINICAL OUTCOMES AMONG PATIENTS WITH PANCREATIC CANCER

Z. Dambrauskas, A. Gulbinas, A. Jakštaite, A. Urboniė
 Institute For Digestive Research, Lithuanian University of Health Sciences, Kaunas/Lithuania

Contact E-mail Address: zilvinas.dambrauskas@gmail.com

Introduction: The mRNA binding protein HuR is involved in the post-transcriptional regulation of cytoprotective molecules, such as COX-2, HO-1 and inhibitors of apoptosis proteins (IAP1, IAP2, XIAP, SURVIVIN), and might be related to poor prognosis in numerous cancer types. However, the association of HuR, COX-2, HO-1 and IAPs family, and their impact on chemoresistance and carcinogenesis in PDAC still remain unclear.

Aims & Methods: The aim of our study is to assess the relevance and correlation of the IAP regulation by mRNA stabilizing protein HuR and HO-1 and/or COX-2 signaling pathway, and to determine the association with clinicopathological parameters and prognosis of PDAC. Data of 32 patients after pancreatoduodenectomy for PDAC between 2011–2016 were analyzed. Patient's mRNA expression levels of HuR, COX-2, HO-1, IAP1, IAP2, Survivin and XIAP in PDAC were compared with normal pancreatic tissue obtained from organ donors. Additionally, the correlations among HuR, COX-2, HO-1, IAP1, IAP2, Survivin and XIAP, as well as their respective correlations with clinicopathological parameters were analyzed. The Kaplan-Meier method and log-rank tests were used for univariate analysis. Cox proportional hazard model was applied to identify prognostic factors that were independently associated with survival.

Results: HO-1, COX-2, HuR, IAP1, IAP2 mRNA expression were accordingly 3-fold, 8.8-fold, 1.5-fold, 4.8-fold and 5-fold higher, while XIAP and Survivin mRNA expression were 3.8-fold and 3.4-fold lower when compared to normal pancreatic tissue. Expression of HuR was positively associated with COX-2, HO-1, IAP1, IAP2, XIAP. High expression levels of HuR were significantly correlated with higher G stage and microvascular invasion, while high levels of XIAP were negatively associated with microvascular and perineural invasion. Univariate analysis revealed that high expression of HuR, lymph-node metastases, tumor differentiation and perineural invasion were significantly associated with overall survival (OS) of PDAC patients. In multivariate analysis, high levels of HuR, lymph-node metastases, tumor differentiation and perineural invasion were independently correlated with lower OS in patients with PDAC.

Conclusion: Our results suggested that upregulation of HuR in PDAC patients were significantly related with poor outcome. Even though, significant correlation with IAP proteins in PDAC was noticed, more data is needed to analyze the mechanism underlying HuR and IAPs interaction.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Hypoxia-induced reprogramming of cell energy metabolism and changes in glycosylation are hallmarks of cancer promoting the induction of an invasive and treatment-resistant phenotype, triggering metastases at an early stage of tumor development.¹ We examined the impact of hypoxia on O-GalNAc glycosylation in human HEK293, PDAC cell lines and clinical specimens and its link to cancer cell signalling.

Aims & Methods: We profiled the expression of 88 glycosylation related genes by qPCR in HEK293 cells subjected to hypoxia either induced by 1% O₂ or 200 mM COCl₂ identifying key O-GalNAc glycosyltransferases downregulated. Functional assays and glycoprotein analysis displayed a pronounced rate of O-GalNAc modified cytosolic proteins derived from hypoxia-treated cells and PDAC specimens. Glycosidase assays could validate specificity of detection method used. Aberrant glycotype could be induced by HIF pathway activator

ML 228 and inhibited using Echinomycin. PTK and STK analysis of cell lysates displayed correlation between phosphorylation and O-glycosylation in hypoxic samples.

Results: Mechanistically we could show, that hypoxia-induced decreased levels of CIGALT1C1 results in reduced T-Synthase activity with subsequent expression of truncated O-glycans (Tn antigen). Differential O-GalNAc glycosylation is inducible using HIF pathway activator ML228 under normoxia and the effect is reversed using 5 μ M Echinomycin under hypoxia underscoring the role of HIF1 α regulated transcription. Interestingly, the pattern of Tn antigen modified proteins derived from hypoxic samples differs significantly from engineered COSMC-deficient cells, displaying O-GalNAc moieties in addition to O-GlcNAc in cytosolic protein fractions. Further, we could show PI3K/AKT/MAPK signalling is depending on the state of cellular O-glycosylation providing a new rationale for the correlation of PDAC Tn antigen glycotype and cancer cell properties.²

Conclusion: Our findings point to a novel crosstalk of O-GalNAc and O-GlcNAcylation under hypoxia extending the knowledge base of differential O-GalNAc glycosylation in pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1422 THE EXPRESSION AND FUNCTION OF MIR-195 IN PANCREATIC CANCER THE EXPRESSION AND FUNCTION OF MIR-195 IN PANCREATIC CANCER

Y. Zhang, Q. Zhan

Digestive Department, Wuxi People's Hospital, Wuxi/China

Contact E-mail Address: zhangq33@163.com

Introduction: Pancreatic cancer is one of the more common malignant tumors in digestive system. The 5-year survival rate is less than about 6% of pancreatic cancer. Pancreatic cancer with poor prognosis and survival rate is low, due to the early clinical symptom is not easy to find, have a high transfer possible, and the operation difficulty, radiotherapy and chemotherapy is not sensitive. Radical surgical resection is the only opportunity to pancreatic cancer patients get longer survival. Therefore, a deeper understanding of the molecular mechanism of pancreatic cancer occurs, explore new effective treatment is imminent.

Aims & Methods: Pancreatic cancer is a highly malignant tumor and fourth leading cause of cancer-related death in the world. The median survival after diagnosis is 2–8 months, and approximately 3–6% of all patients with pancreatic cancer survive 5 years after diagnosis. This is mostly due to the fact that it is diagnosed at a stage when it is either locally advanced or has already metastasized to the distant organs. Hence, there is a paramount need to understand the molecular mechanisms underlying its initiation, progression and therapy. The recent discovery of microRNAs (miRNAs) has revealed a novel mechanism of gene regulation and provided new ways for cancer research. MicroRNAs are small, non-coding RNA molecules, which regulate the gene expression at post-transcription level. It is widely reported that miRNAs can act as oncogene or tumor suppressor gene. MiR-195 has been recognized as a tumor suppressor gene that is down-regulated in several types of cancer such as HCC, breast cancer, bladder cancer and gastric cancer. In PC, the role of miR-195 remains unclear. The purpose of this experiment was to explore the regulation role of miR-195 in PC development process. We measured miR-195 expression in three pancreatic cancer cells (PANC-1, SW-1990, PANC 03.27) by qRT-PCR, and HPDE cells were used as a control. We performed study of miR-195 by transfecting Panc-1 cells with miR-195 mimic. We used miRNA qRT-PCR to study the transfection efficiency of miR-195 mimic. The biology behaviors of Panc-1 cells transfected with miR-195 and negative control were analysed by CCK-8 proliferation assay, cell cycle, cell migration and invasion assay. We performed Real-Time PCR and western blot to detect the expression of CDK4, Cyclin E1 in Panc-1 cells which were transfected with miR-195 mimic and negative control.

Results: We found that miR-195 was decreased in three pancreatic cancer cells (PANC-1, SW-1990, PANC-03.27). We also found that over-expression of miR-195 could suppress the proliferation, migration, invasion and cell cycle of Panc-1 cells. That means the malignancy potential of Panc-1 cells is inhibited by miR-195. Over-expression of miR-195 could down regulate the expression of CDK4, Cyclin E1 in Panc-1 cells.

Conclusion: The expression of miR-195 was down regulated in pancreatic cancer cells. Over expression of miR-195 suppressed cell proliferation, cell cycle, migration and invasion of Panc-1 cells by down regulated the expression of CDK4 and CyclinE1. Moreover, this finding suggests a potential novel strategy for therapeutic interventions of this disease.

Introduction: Pancreatic cancer (PDAC) is one of the most lethal diseases worldwide, still exhibiting almost equal mortality as incidence rates. In spite of strong efforts in clinical and basic research, the molecular mechanisms responsible for this unusual aggressive phenotype still remain not completely understood and insufficient diagnostic and therapeutic tools still substantiate its ranking as the 4th-leading cause of cancer-associated deaths in western countries. This devastating prognosis is partially due to frequent occurrence of intrinsic or acquired chemoresistance in PDAC specimens against the nucleoside analogue gemcitabine which is still the standard for chemotherapeutic treatment of locally advanced and metastatic PDAC. In principle, cancer cells are well known for their ability to divide uncontrollably and it was initially thought that high glucose consumption is the main energy-source for proliferating tumor cells, but a large body of evidence suggest that most of the cell mass that makes up new cells resulted from amino-acid metabolism.

Aims & Methods: The aim of this study was the identification of new biomarkers for chemoresistant pancreatic cancer. A secretome survey of chemoresistant PDAC cells was performed using SILAC-based mass-spectrometric analyses. Relative differences in protein-concentrations among samples were investigated and led to the identification of previously unknown proteins. The impact of RNAi-mediated knockdown of selected genes in proliferating PDAC cells were analyzed using MTT-viability assays. Gene- and protein-expression analyses were performed using Real-Time-PCR and immunohistochemistry using patient-derived PDAC samples.

Results: SILAC-based identification of the Tryptophan degrading enzyme Kynureninase (KYNU) in chemoresistant PDAC cells revealed an overexpressed and secreted form of the KYNU protein, compared to the chemosensitive counterpart. We further identified various stress-related external stimuli (Gemcitabine, IFN γ , Hypoxia) as main inducers of KYNU expression/secretion. A RNAi-mediated KYNU knockdown approach was linked to substantially lower proliferation of chemoresistant and aggressive PDAC cells. Global expression analyses using a tissue-microarray of PDAC patient samples (n = 368) revealed that high KYNU expression is significantly correlated with a worse outcome in PDAC patients.

Conclusion: The tryptophan degradation pathway member KYNU is overexpressed in a subset of PDAC patients and is linked to substantially increased cancer cell proliferation. Abundant KYNU expression in PDAC patients is linked with a worse clinical outcome. We found that KYNU is a new secreted biomarker of chemoresistant PDAC cells.

Introduction: The progression of pancreatic ductal adenocarcinoma (PDAC) is promoted by its highly abundant tumor stroma. As one of the main components of the tumor stroma human pancreatic stellate cells (hPSCs), precursor cells of pancreatic tumor stromal myofibroblasts (CAFs), support PDAC progression by enhancing tumor cell growth, invasion and metastasis [1]. The collagen binding transmembrane receptor integrin α 11 (ITGA11) is known to be overexpressed by myofibroblasts [2].

Aims & Methods: The aim of the presented study was to investigate the expression of ITGA11 in human PDAC and to study the role of ITGA11 in CAF regulation. ITGA11 expression was evaluated using immunostaining on human PDAC sections and various other organs. The relation between ITGA11 levels, CAF activation markers and tumor growth was studied in a stroma rich co-injection model in mice. The biological role of ITGA11 in CAF differentiation was studied in hPSCs and hPSCs activated with TGF- β or conditioned medium from Panc-1 endothelial tumor cells using qPCR, immunostaining, western blot, wound healing, collagen contraction and cell growth assays.

Results: In this study we have for the first time stained ITGA11 in human PDAC specimens. We found that ITGA11 was highly expressed in stromal myofibroblasts of PDAC patients, as shown by co-localization with the myofibroblasts marker alpha smooth muscle actin (α -SMA). Interestingly, there was no expression in healthy human pancreas and various other tissues from human organs. Furthermore, we induced subcutaneous tumors in mice by injecting Panc-1 or Panc-1 + hPSCs and found that ITGA11 was significantly overexpressed in stroma-rich Panc-1 + hPSC tumors. The quantitative gene and protein expression of ITGA11 in subcutaneous tumors, positively correlated with the expression of the CAF markers α -SMA, Colla1 and PDGF β R. Activation of hPSCs with TGF- β or conditioned medium from Panc-1 resulted in the significant upregulation of ITGA11 and α -SMA. Stable ITGA11 knockdown, mediated by shRNA, significantly inhibited hPSC differentiation, migration potential, contractility and cell growth.

Conclusion: In conclusion, this study introduces ITGA11 to be highly and specifically expressed in the tumor stroma of human PDAC and explores its role in the regulation of the phenotype of pancreatic tumor stromal myofibroblasts.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The dismal prognosis of pancreatic ductal adenocarcinoma (PDAC) is mainly due to chemoresistance linked to the tumor microenvironment. Recent developments in therapeutic ultrasound (US), particularly US-induced cavitation, could help overcome chemoresistance by breaking microenvironmental barriers and increase cytotoxic drug availability. Three-dimensional (3D) culture in the form of spheroids is a useful model for reproducing multicellular resistance and analyzing the effects of cavitation.

Aims & Methods: The objective of this work was to study the effects of acoustic cavitation on a model of PDAC spheroids and to investigate possible potentiation of chemotherapy by US. CAPAN-2 PDAC cell line-derived spheroids were cultured as previously described by Ivascu et al. Four conditions, i.e. control, 400 nM-gemcitabine-based chemotherapy (CT) alone, US alone, CT-US combination (n = 12 spheroids per condition), were studied. Experiments were carried out to optimize US settings, in order to observe the occurrence of controlled acoustic cavitation. Comparisons between groups were based on proliferation and growth. Proliferation was evaluated 24 hours after treatment(s) by Uptiblu. Growth was assessed by diameter measurement on light microscopy at day 7 and day 10.

Results: Compared to the control group, cell proliferation was decreased in spheroids treated with CT (p < 0.0001), but not with US alone. Proliferation was also further impaired in spheroids treated with CT-US combination compared to those treated with CT alone (p < 0.0001), but this synergistic effect of US and CT did not impact growth of spheroid, meaning that spheroid diameter did not decrease after US-CT compared to CT alone.

Conclusion: This study shows the feasibility of applying an ultrasonic treatment (acoustic cavitation) in a three-dimensional culture model of PDAC. The combination of CT and ultrasonic cavitation synergistically reduced cell proliferation. Further analysis of the cytotoxic effects of acoustic cavitation on PDAC spheroids is in progress.

Introduction: Intraductal papillary-mucinous neoplasm (IPMN) are a heterogeneous group of pancreatic tumors mucin-producing with uncertain biologic behavior. We know, nowadays, that they can be also considered as a precursor of pancreatic carcinoma (PAC), one out of these lesions will develop into a malignancy of different types. There are no established guidelines for pathologic diagnosis/reporting of IPMN.

Aims & Methods: The aim of this study was to analyze the IPMN subtypes distribution related with clinicopathological, histologic and immunohistochemical and identify which one is more related to development of malignancy. This prospective study reports a 3-year-follow up, with consecutive patients, where we analyzed the clinical findings, radiological aspects, and morphologic features in patient's suspects of IPMN or PAC undergoing to pancreatic surgery. The lesions were classified based on morphological and immunohistochemically defined by the current WHO criteria.

Results: We analyzed 28 patients (16 women), mean age 66 y-old (range 50–83). 15 (53%) patients were asymptomatic, and 13 (47%) showed abdominal pain (8), chest pain (4), and recurrent acute pancreatitis (1). 10 patients were submitted to

subtotal pancreatectomy, 9 to duodenopancreatectomy, 7 to gastroduodenopancreatectomy, 2 subtotal pancreatectomy and splenectomy. The neoplasm was located in head, body and tail, and entire pancreas in 18, 9, and 1, respectively. 14 patients (50%) had involvement of the main pancreatic + branch ducts (mixed type), 7 (25%) had only the main pancreatic duct involved, 6 (21.5%) had only the branch-duct involved, and 1 (3.5%) had not informed. The mean size of the lesion was 3.3 cm \pm 6.1 (1–11 cm). Morphologic features showed multi-loculated (23) solid-cystic (4) and solid (1). The immunohistochemically expressed MUC1, MUC5AC, and MUC2 in 18 (64%), 17 (61%), and 11 (39%), respectively. The histopathologic patterns founded was gastric-type (9), Intestinal-type (3), pancreatobiliary-type (9), mixed-type [6 (Pb-t + I-t (4), and Pb-t + G-t (2)), and onco-cytic-type (1) (table 1). The IPMN with a low-grade, and high-grade dysplasia and invasive carcinoma was found in 18 (64.2%), 6 (21.5%) and 4 (14.2%), respectively. We observed that the all pancreatic intraepithelial neoplasia (PanIN) founded was related to Pb-t 13 (46%). The invasive PAC was presented in 4 patients (14.2%) with the follow subtypes (Pb-t (2), and Pb-t + I (1)), and colloid PAC [I-t (1)] (table 2). Was found a synchronic neoplasia in 2 patients (colon adenocarcinoma, and NET).

Conclusion: IPMN of the pancreas is a common cystic lesion located more frequent on both duct (mixed-type), showing more aggressive behavior than others pattern. Pb-t was the most common lesion and were more connecting to invasive PAC and HGD, as well as connected with PanIN. MUC stains are helpful for the diagnosis and papillary histological subtyping. Prospective studies are needed to confirm these findings.

Introduction: Because of the progression of systemic chemotherapies (CT) for locally-advanced pancreas cancer (LA-PC), chemoradiotherapy (CRT) was selected for limited case. However, very long survival cases were reported in CRT and detection of prognostic factors were warranted. In this analysis, we analyzed the LA-PC cases received CRT compared with CT.

Aims & Methods: Gemcitabine (GEM) and S-1 combination chemoradiotherapy (GS-CRT) was performed according to our previous Phase 1 trial (*Journal of Japan Pancreas Society* 2010). Till March 2016, 30 LA-PC cases received GS-CRT, and the selection criteria were LA-PC with 1) pathological diagnosis, 2) large vessels (CA, SMA, CHA, PV, SMV) invasion, 3) allochronic and concurrency without multiple primary cancer, 4) unexecuted antitumor therapy. The chemotherapy in CRT administration of GEM (200 mg/m²) once a week for 6 weeks, administration of S-1 (80 mg/m²) for 2 weeks a week withdrawal was done twice. Radiation was performed 1.8 Gy in power of 10 MeV in a week 5-day period for 5.5 weeks, and total dose was 50.4 Gy (Total 28 times). As after treatment, GEM 1000 mg/m² was continued until PD. The patients of CT group were also recruited by the same criteria. One of the regimens among GEM alone, S-1 alone and GEM + S-1 was selected for the primary treatment, and total 26 cases were implemented in more than 2 courses.

Results: Baseline characteristics in CRT and CT group were median age (62, 72.5; p = 0.004), male (20, 12; ns) and tumor location Ph/Pb (17/13, 16/10; ns), respectively. Efficacy were disease control rate (DCR) in 3 months after treatment (90%, 57.7%; p = 0.01), response rate (RR) (26.7%, 0%; p = 0.005) and conversion surgery (10%, 0%; ns). There were significant differences in progression free survival (PFS) (8 months, 5 months; p = 0.002) and overall survival (OS) (13M, 9M; p = 0.0165), respectively. The cases who survived for 18 months and longer were significantly (p = 0.0495) more in CRT (43.3%) than CT group (19.2%). Grade 3/4 adverse events in CRT group were 13 cases of neutropenia (G4:3 cases) and one case of gastrointestinal symptom, and those in CT group, neutropenia was 11 cases (G4:4 case), interstitial pneumonia (IP) aggravation was one case.

Conclusion: For LA-PC, GS-CRT showed better local tumor control and longer survival, and was considered as good candidate of neo-adjuvant therapy. More long survival cases in CRT than CT was other benefit for LA-PC. We should think about good selection criteria of CRT and improve the survival of LA-PC.

P1428 HIGH-INTENSITY FOCUSED ULTRASOUND (HIFU) THERAPY FOR UNRESECTABLE PANCREATIC CANCER

A. Sofuni, Y. Asai, M. Fujita, T. Tsuchiya, S. Tsuji, R. Tanaka, R. Tonozuka, M. Honjo, S. Mukai, K. Yamamoto, Y. Matsunami, K. Kamada, T. Itoi
Gastroenterology & Hepatology, Tokyo Medical University, Tokyo/Japan

Contact E-mail Address: a-sofuni@amy.hi-ho.ne.jp

Introduction: High-intensity focused ultrasound (HIFU) is expected as new advanced therapy for unresectable pancreatic cancer (PC). HIFU therapy with chemotherapy is being promoted as new method to control local advance by ablation tumor, and mainly achieve relief of pain caused by PC.

Aims & Methods: We have evaluated the therapeutic effect of HIFU therapy in locally advanced and metastatic PC. We treated PC patients by HIFU as optional local therapy as well as systemic chemo/chemo-radiotherapy, with whom an agreement was obtained in adequate IC, from the end of 2008 in our hospital. This study took approval of member of ethic society of our hospital. HIFU device used is FEP-BY02 (Yuande Bio-Medical Engineering Co.LTD., China). The subjects were 140 PC patients, i.e. 69 cases in stage III, 71 cases in stage IV. Performance status (PS) was PS:0; 79, PS:1; 58, and PS:2; 3 cases. Mean age was 62.3±10.6 years. The details of therapy before HIFU treatment (overlap) was chemo-radiotherapy in 34, chemotherapy in 92, arterial infusion chemotherapy in 5, immunotherapy in 8, operation in 17, and BSC in 7 cases.

Results: All tumors were visualized by HIFU monitor system. Tumor location was head in 38, uncus in 19, body in 59, body~tail in 6, tail in 2, and others (recurrence) in 16 cases. Treatment data was followed; mean tumor size before and after therapy was 33.5±10.7 and 33.7±11.5 mm, mean treatment sessions: 2.3±0.7 times, mean total treatment time: 105±65.6 min, mean total number of irradiation: 1967.8±1106 shots. The effects of HIFU therapy were the following; the rate of complete tumor ablation was 87.9%, the rate of symptom relief effect was 69.4%, the effectiveness of primary lesion was CR:0, PR:21, SD:85, PD:34 cases, primary disease control rate (DCR) more than SD was 75.7%. The therapy after HIFU treatment was operation in 8, chemotherapy in 116, immunotherapies in 4, and best supportive care (BSC) in 14 cases. MST after diagnosis in HIFU with chemotherapy and chemotherapy alone (38 patients in our hospital) was 1028.3 vs 366.6 days, respectively ($p < 0.001$). MST after HIFU therapy was 606.1 days. Combination therapy of HIFU with chemotherapy was better result than common chemotherapy alone.

Conclusion: This study suggested that HIFU therapy has the potential of new method of combination therapy for PC.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) has a dismal prognosis with an overall 5-year survival rate <6%. Surgically resected patients, although undergoing a possibly curative treatment, have nevertheless a 5-year survival <25%. In fact, it has been recently suggested that patients with a tumor of more than 2 cm might harbor micrometastases at diagnosis. In this view, given the availability of new highly effective chemotherapy regimens that might be employed in the neoadjuvant setting, the correct evaluation of the T stage of pancreatic cancer plays a key role. The new proposed AJCC Staging System for Pancreatic Adenocarcinoma TNM (8th edition), in fact, differs from the 7th edition mostly for the evaluation of the T, giving high importance to the diameter of the lesion. This reclassification has already been shown to predict survival differences more efficiently compared to previous editions. In this context, an efficient preoperative evaluation of the T is of high importance as it might shift the therapeutic decision from upfront surgery to neoadjuvant chemotherapy, that could be preferred in tumors being >2 cm (T2). Few studies compared the accuracy of CT scan and EUS in evaluating the dimension of the tumor with heterogeneous results and often dated machines, and no study adopted the new TNM system to evaluate the preoperative staging defined by CT and EUS.

Aims & Methods: The aim was to evaluate the accuracy of CT scan and EUS, alone and in combination, in establishing the T stage of surgically resected PDAC as defined by the new upcoming TNM 8th edition and to establish the sensitivity and specificity of the two imaging modalities in discriminating T1

stage from more advanced T stages. We conducted a retrospective study on a cohort of surgically resected histologically-confirmed PDAC patients at a pancreatic cancer referral center between 2015–2017, who were prospectively included in a dedicated database. Inclusion criteria: a) having both preoperative EUS and CT scan with pancreatic phase evaluation at the centre; b) CT and EUS were performed, at the latest, 30 days apart from each other and from surgical resection; c) no neoadjuvant chemo or radiotherapy was performed. The evaluation of the T by both imaging modalities was compared to the final pathology T re-established based on the new TNM 8th edition, in order to calculate specificity and sensitivity. T-test was used for comparison of continuous variables, Fisher's test was used for comparison of categorical variables.

Results: Among the 184 PDAC patients surgically resected between 2015 and 2017 at our center, 30 met inclusion criteria. Of these, 19 (63.3%) were males, with mean age at resection being 67.8±9.5 years. The tumor was located in the head in 23/30 (76.7%) patients. Mean diameter of the tumor at pathology was 24.9±10.8 mm, mean diameter at EUS was 24.0±8.6 mm ($p = 0.74$), and mean diameter at CT was 25.9±10.9 mm ($p = 0.73$). In 4/30 (13.3%) cases CT scan was not able to detect the lesion; mean diameter of undetected lesions was 21.2±2.9 mm. Accuracy in T assessment was 60% (18/30) for both EUS and CT scan; when considering detection of ≥T2 lesion in any of the two imaging modalities the accuracy increased to 80% (24/30). The sensitivity and specificity in discriminating T1 lesions from ≥T2 lesions was respectively 64.7% and 76.9% for EUS and 76.5% and 72.7% for CT.

Conclusion: This is the first study evaluating the accuracy of CT and EUS imaging modalities in establishing the T in the setting of the new TNM 8th edition. In our study, CT scan and EUS have both a relatively low accuracy in determining the correct T stage for pancreatic cancer when used alone, while the accuracy raises significantly when used in combination. CT scan was not able to detect up to 13.3% of lesions. EUS resulted having a lower sensitivity but higher specificity in discriminating T1 lesions from ≥T2 lesions compared to CT scan. These preliminary results suggest how EUS, often adopted only as a means to obtain a cytological specimen, has a key role in determining the T stage, and that the two imaging modalities should be used in combination to better assess the proper therapeutic management as neoadjuvant chemotherapy or upfront surgical resection.

Introduction: Pancreatic adenocarcinoma is associated with a 5–6% survival at 5 years and a poor quality of life. In Romania there are few information about the prognostic influence of known risk factors for pancreatic cancer.

Aims & Methods: The aim of this study is to evaluate the association between risk factors and the occurrence of pancreatic adenocarcinoma and patients' survival, which may constitute a theoretical basis for screening. We performed a prospective, multicentric study of patients with suspected pancreatic tumors detected in abdominal ultrasound or CT examination, during January 2015–December 2016, in which were analyzed risk factors and possible association with survival adjusted statistically according to tumor stage (Chi square test, ANOVA, log-rank test).

Results: There were 279 patients with pancreatic adenocarcinoma included in the study. Male patients were 58% from all patients, and the mean age was 63.5 years. Smoking, new-onset diabetes and history of chronic pancreatitis are risk factors for pancreatic adenocarcinoma ($p < 0.05$). At 12 months of follow-up, almost one-third of patients with pancreatic adenocarcinoma died (median survival = 5 months). It was demonstrated a statistically significant association adjusted for tumor stage between the presence of new-onset diabetes and survival: 5 months vs 3 months with a HR = 3. Other risk factors (alcohol, obesity, sex, genetics, coffee intake, some infections and abdominal surgery, history of chronic pancreatitis) had no prognostic role.

Conclusion: In our study, the risk factors for pancreatic cancer were smoking, history of chronic pancreatitis and new-onset diabetes, but the only prognostic factor was diabetes.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: According to the 2012 International guidelines on the management of intraductal papillary mucinous neoplasms (IPMN), main-duct IPMN patients with main pancreatic duct (MPD) diameter of ≥ 10 mm should have surgical resection, whereas surgery is not always mandatory in those with MPD diameter between 5 and 9 mm.

Aims & Methods: The aim of the study was to analyze the prevalence of malignancy (high grade dysplasia or invasive carcinoma) in resected IPMN with MPD diameter between 5 and 9 mm and to identify predictive factors of malignancy. Retrospective analysis of patients with surgically resected IPMN between 2001 and 2016. Demographics, clinical presentation, imaging and histological features were compared between patients with preoperative evidence of MPD diameter between 5–9 mm (Group A) and ≥ 10 mm (Group B). Malignancy was defined as high-grade dysplasia or invasive carcinoma.

Results: From 122 patients with IPMN submitted to surgery, 66 with MD- or mixed-IPMN entered the final analysis. Mean age was 66 ± 12 years and 48 (72.7%) patients were men. Group A comprised 47 patients and Group B 19. Abdominal pain was present in 23 (34.8%) patients, jaundice in 19 (28.8%), diabetes in 18 (27.3%), pancreatitis in 15 (22.7%) and weight loss in 12 (18.2%), with no statistical differences between study groups. The most common location of the MD-IPMN was the head of pancreas (60.6%), and it was multifocal in 34.8% of the patients. The prevalence of no dysplasia, low-grade dysplasia, high-grade dysplasia and invasive carcinoma was 10.6%, 42.6%, 8.5% and 38.3% in group A and 10.5%, 10.5%, 21.1% and 57.9% in Group B patients. The overall malignancy rate was 46.8% in group A and 79% in group B. Jaundice ($p=0.017$), weight loss ($p=0.035$), and complete involvement of MPD at pathological analysis ($p=0.018$) were significantly more common in patients with malignancy.

Conclusion: Almost half of resected IPMN with MPD diameter between 5–9 mm harbor histologically proven malignancy. In these patients, particularly in those with jaundice and weight loss, surgery rather than follow-up should be recommended.

P1432 CLINICAL SIGNIFICANCE OF CHEMOTHERAPY FOR ELDERLY UNRESECTABLE PANCREATIC CANCER PATIENTS

S. Kaino, M. Sen-Yo, S. Shinoda, S. Amano, I. Sakaida

Department Of Gastroenterology & Hepatology, Yamaguchi University Gastroenterology & Hepatology, Ube/Japan

Contact E-mail Address: kaino@yamaguchi-u.ac.jp

Introduction: Pancreatic cancer has poor prognosis despite of improvements in multimodal treatments. As aging of the population advances, it is expected that elderly pancreatic cancer patients increase.

Aims & Methods: The aim of this study was to investigate the clinical significance of chemotherapy for patients with unresectable pancreatic cancer. At our hospital, 96 patients were diagnosed as having unresectable pancreatic cancer between January 2010 and December 2016. In this study, we defined elderly patients as those older than 75 years. We retrospectively examined the safety and efficacy of

chemotherapy in patients with unresectable pancreatic cancer. We analyzed and compared survival periods and adverse events between young and aged patients.

Results: Twenty-seven patients were older than 75 years (group A), and 59 were younger than 74 years (group B). We treated 6/10/0/2/5/4 patients in group A with GEM/S-1/modified FOLFIRINOX (mFOLFIRINOX)/GEM + nabPTX/best supportive care (BSC)/others, respectively. On the other hand, we treated 12/14/4/11/5/13 patients in group B with GEM/S-1/mFOLFIRINOX/GEM + nabPTX/BSC/others, respectively. Severe adverse events (more severe than grade 3 according to CTCAE v4.0) occurred in 18.2% of the patients in group A and in 33.3% of the patients in group B. No significant difference was found between the two groups. The median survival time of the patients who were receiving chemotherapies was 197.0 days in group A and 291.0 days in group B. No significant differences were also found between the two groups. The median survival time of the patients who underwent chemotherapy in group A (332.0 days) was significantly longer than that of patients who underwent BSC (71.0 days).

Conclusion: Conclusions: Chemotherapy could be safe and effective for patients older than 75 years who have unresectable pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1433 THE USE OF A NEW CORE NEEDLE IN THE ENDOSCOPIC ULTRASOUND ASSISTED TISSUE SAMPLING FOR PANCREATIC SOLID MASSES: A MULTICENTRE PROSPECTIVE STUDY

Introduction: Endoscopic ultrasound-guided biopsy (EUS-biopsy) is considered a reliable, safe, and effective technique for obtaining samples from pancreatic masses with a very high sensitivity and specificity (ranged to 85%-92% and 96%-98%, respectively)[1–3]. A new EUS needle (SharkCore FNB needle, Medtronic, Dublin, Ireland) was introduced in order to improve the tissue acquisition.

Aims & Methods: The aim of the present study was to evaluate the presence of a histological sample using Shark Core Needles. This study was an observational multicenter prospective non-randomized clinical trial (NCT02946840). All consecutive patients referred for EUS examination and sampling of solid pancreatic masses underwent EUS-guided biopsy with 25 G Shark Core needles. This needle has an innovative tip geometry with a cutting surface designed to acquire cohesive units of tissue and to minimize tissue fracturing. Three passes were performed in every mass. At every pass, a macroscopic on-site quality evaluation (MOSE) was done by endoscopist. If a “worm-like” material was observed at gross visual assessment, it was placed into formalin. If only liquid material was obtained, it was smeared between 2 glass slides, fixed with ethanol, and stained with a Papanicolaou-stain for cytological analysis. Endoscopists recorded macroscopic features of the specimens. Pathologists described macroscopic, microscopic features, immunohistochemical studies. The primary outcome was the procurement rates of histologic core. Pathologists defined core all histological samples with architecturally intact histology, measuring at least 5 mm in greatest axis. All the other specimens (< 5 mm) were defined as micro-fragments. The final diagnosis was based on surgical resection, and clinical/radiological follow up. The secondary outcomes were diagnostic accuracy and procedure-related adverse events.

Results: Study population included 82 patients, enrolled in three centres, between August 2016 and April 2017, with a mean age of 64.0 (SD 13.7, range 21–84) and 57.3% female gender. The mean size of the lesions was 27.6 mm (SD 12.2) and the location was the body and tail in 27 patients (32.9%), neck in 11 (13.4%), head and uncinate process in 44 (53.7%). Three needle passages were performed in all but 3 patients who experienced mild bleeding precluding more than one needle passage. At MOSE, endoscopists described presence of “worm-like” material in 192 biopsy samples over 242 (79.3%). In 8 patients only cytological specimens were obtained after 3 needle passes (9.8%). Six cases of mild self-limited bleeding were observed (7.3%). The pathologists described the presence of a core in 80 samples (41.7%), in the other cases, after the specimen preparation, a micro-fragmentation was observed, that didn't affect the histological evaluation. A final histological diagnosis was reached in 73 patients (90%): 50 pancreatic adenocarcinoma, 16 NET, 5 chronic pancreatitis, 2 pancreatic metastasis from other organs.

Conclusion: The new biopsy needle showed a good overall adequacy and a good rate of histological specimens (both core and micro-fragments) during EUS-guided tissue acquisition of pancreatic masses, with a minimum number of passes and no major complications. This ability could allow to avoid the use of rapid on-site evaluation and to perform immunohistochemical, molecular and genetic studies on histological samples.

Introduction: EUS FNA is accepted as the primary modality for tissue diagnosis of solid pancreatic lesions. The presence of on-site cytopathology for immediate evaluation during endoscopic ultrasound-guided fine needle aspiration (EUS FNA) has previously been shown to improve performance characteristics. Due to service pressures EUS FNA is also undertaken in the absence of in-room cytopathology assistance. This is a review of current practice.

Aims & Methods: We retrospectively assessed 700 consecutive EUS-FNA procedures from January 2011 to January 2016. 459 (65.5%) solid pancreatic lesions were included in the final analysis after excluding 230 for biliary strictures, hepatic lesions, lymph nodes, gastric, oesophageal lesions, pancreatic cysts and 11 for insufficient information.

Results: In 399 (86.9%) cases on-site cytopathology support was available, while the remaining was unsupported. There were 228 males (57.1%) in the supported and 29 (48.3%) in the unsupported group. Mean age was 64.6 (SD: 11.4) and 67.4 (SD: 11.9) respectively. The mean number of passes in the two groups were 2.8 (SD: 1.12) and 1.9 (SD: 1.0) ($P < 0.0001$). A conclusive diagnosis (malignant, benign, NET, GIST) was made in 84% (67%, 12%, 5%, 0%) of the supported group and in 38% (23%, 10%, 3%, 2%) of the unsupported ($P < 0.0001$). The mean follow up for the entire cohort was 14.2 months (SD:14.1) and mean survival of in patients diagnosed with malignancy was 10.9 months (SD: 8.7). Overall performance characteristics of EUS FNA were Sensitivity: 90.8% Specificity: 86.9% PPV: 91.8% NPV: 85.4%

Conclusion: This review confirms high performance characteristics of EUS FNA. The presence of on-site cytopathologist significantly increases the diagnostic yield.

Introduction: Pancreatic cystic lesions are a common finding in clinical practice. Classification of cysts as mucinous or non-mucinous cysts, using EUS-FNA with cystic fluid analysis for cytology and CEA became widely used in clinical workup of patients with suspicious pancreatic cysts. Molecular analysis (KRAS and GNAS mutation) is not yet recommended in clinical practice.

Aims & Methods: We aimed to determine if mutation in GNAS and KRAS in addition to CEA level and cytology of cystic fluid obtained by EUS-FNA can help in pancreatic cyst classification and decision making. Evaluation of methylation of the GNAS complex locus was performed for cyst classification.

Between 2008-14, 266 EUS were performed for pancreatic cyst evaluation in a single center. We determined the mutational status of GNAS (exons 8 and 9) and KRAS (exons 2 and 3) genes by Sanger sequencing in 52 patients, in cystic fluid obtained by EUS-FNA after cytology and CEA analysis. In operated patients, cysts were also analyzed for methylation of the GNAS complex locus.

Results: Mainly female (67%), mean age of 59±15 years (29-91). Cysts located in head (42%), body (39%), tail (17%) and multiple (2%), with a mean size of 3.9±2.3 cm (.8-10), and 60% >3 cm. Cyst types (as after EUS-FNA+CEA/cytology): 15 serous cystadenomas (SCAs), 9 pseudocysts, 8 intraductal papillary mucinous neoplasms (IPMNs), 2 mucinous cystic neoplasms (MCNs), 4 adenocarcinomas (ADC), 1 solid pseudopapillary neoplasm (SPN), 1 lymphangioma, 12 non-defined. CEA >192 ng/ml in 33% of patients and cytology with benign cells in 12 (23%), suspicious/malignant in 8 (15%), 1 NET (2%) and 31(60%) acellular samples. Surgery in 11 (21%) patients (surgical specimens: 2SCA, 3MCN, 4IPMN, 1 retention cyst and 1 ADC), chemotherapy/palliation in 6

(12%), endoscopic drainage in 1 (2%) and 34 (64%) on f-up. KRAS Mutation in 19% (9) and in GNAS in 4%(2) of cyst aspirates. By cyst type, GNAS was mutated in 1 IPMN and 1 ADC. KRAS was mutated in 6 patients on fup (2 IPMNs, 3 ADC, 1 pseudocyst- a unilocular 2cm cyst with CEA=125) and in 3 who had surgery (2 IPMNs and 1 MCN). Sensitivity and specificity of CEA >192+cytology and KRAS/GNAS mutations for the classification of mucinous and non-mucinous (table 1-1st part) and malignant and non-malignant (table 1-2nd part) are presented in operated cysts.

Diagnosis of neoplastic mucinous cysts	Sensitivity	Specificity
CEA > 192 + cytology	100%	67%
KRAS/GNAS mutation	42%	100%
Diagnosis of malignant cysts		
CEA > 192 + cytology	100%	33%
KRAS/GNAS mutation	50%	75%

In the surgery group, methylation of the GNAS complex locus was found in 1/2 ADC, 1/3 IPMNs (the malignant IPMN has GNAs mutation and no methylation of the GNAS complex), 1/3 MCNs, 0/2 SCA and 0/1 retention cyst.

Conclusion: Sanger sequencing of KRAS and GNAS genes is highly specific for the diagnosis of mucinous neoplastic cysts of the pancreas and may be useful in selected patients. The specificity of Sanger sequencing of KRAS and GNAS genes for the diagnosis of malignant cystic lesions decreases but is higher than CEA/cytology analysis. Methylation in GNAS complex locus was found in malignant cysts but data are preliminary and need further evaluation. More fluid markers are needed to improve pancreatic cyst classification.

Introduction: Promising method, which helps to distinguish between chronic pancreatitis and cancer, is point mutations of the proto-oncogene KRAS test. This method is not established in routine clinical practice yet.

Aims & Methods: Determination of the sensitivity of the KRAS assay using various kinds of samples of patients with pancreatic mass and testing the effect of the presence of KRAS mutations on the prognosis of survival. 147 patients underwent EUS-FNA examination of pancreatic mass, accompanied by blood sampling with subsequent separation of plasma for the detection of circulating tumor DNA. Part of biopsy sample was left native in a stabilizing solution and part as cytological smear. Samples (native aspirates, cytological smears, plasma) were examined for the presence of KRAS mutation by heteroduplex analysis, denaturing capillary electrophoresis.

Results: Among 147 patients with pancreatic masses, 118x were diagnosed as cancer, 26x chronic pancreatitis, 3x neuroendocrine tumor. In total 147 native aspirates, 118 cytological smears and 94 plasma samples were examined. The highest sensitivity of KRAS mutation was reached in the group of pancreatic cancer patients using cytology, in which 90% of KRAS mutation was detected (106/118 of the samples). When using the native cellular aspirates, mutation was detected in 78% (92/118 samples), and examination of plasma was positive in 27% (24/90 samples). In four patients with chronic pancreatitis KRAS mutations was detected, although none has been cytologically confirmed as a cancer. Two of these four patients were confirmed in the course of the disease as a cancer, one patient died because of alcoholic delirium and the last one was indicated for surgery recently.

Conclusion: Examination of KRAS mutations can be performed in all patients undergoing EUS-FNA, with the cytology being the most reliable type of sample for genetic tests. KRAS examination would be reasonable to introduce into routine clinical practice in a group of patients with unclear differential diagnosis of chronic pancreatitis, especially in those with suspicion of cancer in inflammatory terrain. Financial support by The Ministry of Defence and Armed Forces of the Czech Republic MO 1012.

Introduction: Self-expanding metal stents (SEMS) are increasingly preferred to plastic stents (PS) for pre-operative drainage and palliation of biliary obstruction secondary to a stricture in the head of pancreas (HOP). Their use has increased over the last 5–6 years. Endoscopic ultrasound (EUS) with fine needle aspiration or biopsy (FNA or FNB) is commonly utilised to make a tissue diagnosis and to aid in staging in those with borderline resectable tumours. Stents may reduce diagnostic performance of FNA/FNB by reducing the visible mass to puncture. There have been 2 studies that assessed the impact of stenting on EUS-FNA performance, one¹ found no difference in yield and sensitivity among patients with or without stents and between SEMS and plastic. Whilst a more recent study² found accuracy was significantly reduced by the presence of a stent.

Aims & Methods: The aim was to assess whether stents (SEMS or PS) impair diagnostic performance of EUS tissue acquisition, in a retrospective study of all patients with HOP mass undergoing EUS biopsy between January 2010 and June 2016. Stenting information was obtained from the EUS report and images. Biopsies reported as malignant were considered as such, all other reports were considered benign. A definitive diagnosis of cancer was based on positive pathology or follow up with signs of progression. A benign diagnosis required negative pathology, stable imaging and symptoms for a year or more. Patients with cystic lesions were excluded.

Results: A total of 1861 patients had EUS FNA/FNB of which 731 were for HOP lesions, mean age 65 yrs (410 F), with tissue sensitivity of 72% for all types of needles used. Tissue accuracy was significantly different between the 3 groups ($p=0.0001$); SEMS 67%, PS 71% and 83% in the unstented group. The difference in accuracy was significant between the unstented group versus SEMS ($p=0.0002$) and PS ($p=0.003$) and not significant between PS and SEMS. Stepwise multi-variable analysis revealed significant difference for accurate tissue diagnosis favouring size needle 25G (OR 1.7 [95%CI 1.1–2.7] and tumour size (OR 1.04 [1.02–1.07]) and negative affected by presence of stent SEMS (OR 0.3 [0.2–0.6]) or PS (OR 0.5 [0.3–0.9]). Other needle sizes (19G or 22G), number of passes or types of needle did not significantly affect tissue accuracy.

Conclusion: Our results show a significant adverse impact of both SEMS and PS on tissue accuracy via EUS FNA/FNB. The effect is greatest with SEMS. These results suggest that where possible EUS biopsy if required should be performed before stent placement.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Solid-pseudopapillary neoplasm (SPN) is a rare condition, first described by Frantz in 1959. It occurs mostly in young women, and surgical resection is recommended. Its local recurrence rate is less than 10% and usually occurs within 4 years after surgery. Before such a surgery, especially in young people, EUS-FNA (Endoscopic ultrasonography with fine needle aspiration) is discussed to confirm diagnosis but rarely performed due to suspected needle tract inoculation by neoplastic cells. The aim of our large multicenter study was to assess the short- and long-term safety of preoperative EUS-FNA in SPN.

Aims & Methods: This study is a multicenter retrospective register of all SPN diagnosed in the last decade in 14 European expert centers (GRAPHE task force). Inclusion criterion was realization of preoperative EUS-FNA followed by surgical resection. Patient and tumor characteristics were collected, as the EUS-FNA technique (number of passes, needle size, trans-gastric or trans-duodenal access). Immediate or late complications of EUS-FNA and recurrence of SPN were then recorded.

Results: During the period study, 49 patients (41 women/8 men) with preoperative EUS-FNA for SPN were recorded. Mean age of patients was 37 ± 15 yo. Tumor location was mostly cephalic (21/36, 59%), but also corporeal in 25% (9/36), caudal in 25% (9/36), isthmus in 11% (4/36) and in uncus in 5% (2/36). Mean tumor size measured on EUS was 40 ± 22 mm. Needle used was a 25G in 3% (1/37), 22G in 76% (28/37), 20G in 8% (3/37) and 19G in 13.5% (5/37). Trans-duodenal EUS-FNA was performed in 56% (24/43) and trans-gastric in 44% (19/43). Mean number of needle passes was 2.2 ± 0.7 . EUS-FNA allowed certain preoperative diagnosis of SPN in 74% of cases (35/47), probable diagnosis in 6% (3/47), negative in 4% (2/47) and wrong in 6% (3/47). No acute complication of EUS-FNA was reported. With a mean follow-up of 36 ± 36 months, only one local recurrence was noted. In this 74 years old man case, a 19G needle was used (2 trans-gastric passes), and recurrence occurred after 84 months.

Conclusion: In this large multicenter retrospective series, a systematic preoperative EUS-FNA did not seem to modify the SPN recurrence rate. Therefore this study allows to validate this attitude as a possible alternative. *The data for the series are incomplete at the date of submission of the abstract. The final data will be completed on the day of presentation.*

Introduction: Pancreatic neuroendocrine tumours (PNETs) are relatively rare, i.e., ≤ 1 per 100,000 individuals per annum, and account for only 1–2 percent of all pancreatic tumours. They are separated into 2 major categories: 1) well-differentiated (WD-NETs) which have round to oval nuclei, coarsely stippled chromatin and finely granular cytoplasm and 2) poorly-differentiated (PD-NETs) which have a diffuse architecture with an irregular nucleus and less cytoplasmic granularity. WD-NETs tend to have an indolent course (survival ~67% at 5 years) but ~50% have metastasised at the time of diagnosis. PD-NETs are high-grade cancers with an aggressive course resembling NETs arising in lung. WD-NETs contain neurosecretory granules which stain for synaptophysin and/or chromogranin. Endoscopic ultrasonography guided fine-needle aspiration biopsy (EUS-FNA) can provide a non-operative cytological diagnosis of PNETs when the pathologist is provided with a good specimen such as the pellet of cells obtained through SurePath (SP).

Aims & Methods: EUS-FNA samples of pancreatic tumours were collected into a SurePath vial and slides prepared from the cellular pellet. The slides were stained for synaptophysin and Ki67 by immunohistochemistry (IHC) and examined by 2 independent senior cytopathologists.

Results: Sixteen (16) patients with a mean age 65 (8 male) were identified by EUS with a suspected PNET. The mean tumour size was $16.2 \text{ mm} \pm 4.2 \text{ mm}$. All had the morphology of a PNET and stained positive for synaptophysin.

Conclusion: SP prepared cytology slides from solid pancreatic tumours provides enough diagnostic material for IHC staining for synaptophysin and Ki67 without the need for a formal excision biopsy. Morphology of SP slides is often diagnostic but a positive stain for synaptophysin makes the diagnosis irrefutable. The

mitotic index derived from Ki67 staining helps identify WD-NETs which can be monitored and PD-NETs which need aggressive treatment.

P1440 EFFECTS OF IGF2BPS ON GROWTH AND PROLIFERATION IN NEUROENDOCRINE PANCREATIC TUMOR CELL LINES

L. Niefeld¹, F. Sperling¹, K. Theuerkorn¹, H. Griesmann¹, S. Krug¹, S. Hüttelmaier², P. Michl¹

Introduction: Pancreatic neuroendocrine neoplasms (PNET) are highly angiogenic tumors which—despite of various targeted options including mTOR and VEGF inhibition—frequently develop secondary drug resistance. IGF2BPs (IGF2 mRNA-binding proteins) represent a family of canonical RNA-binding proteins (RBP) comprised of three members (IGF2BP1–3) which have been described to promote stem and/or progenitor cell maintenance with reported expression and oncogenic roles in aggressive cancers. IGF2BPs show a differential expression pattern in various solid tumors including pancreatic neuroendocrine tumors.

Aims & Methods: We aimed to characterize the role of IGF2BPs in progression and resistance of pancreatic neuroendocrine neoplasms. We used three different siRNA-pools (IGF2BP1/2/3) to inhibit the different IGF2BP's in pancreatic neuroendocrine BON1 tumor cells. Cellular effects were investigated by Western blot analyses, flow cytometry, clonogenic survival, cell viability and migration assays.

Results: In the pancreatic neuroendocrine tumor cell line BON1, knock-down of IGF2BP1 resulted in a significant reduction of cell viability. Cell cycle analysis by FACS showed a decreased S phase progression paralleled by a reduction in the proliferation marker PCNA and a markedly reduced MEK/ERK activation. In contrast, Akt signaling was unaffected. Moreover, knock-down of IGF2BP1 significantly reduced clonogenic growth as assessed by colony formation assays and led to decreased cell migration as determined by scratch assays. Interestingly, knock-down of IGF2BP1 was insufficient to induce apoptosis, as assessed by PARP and caspase-3 cleavage as well as annexin-V FACS. Rather, si-IGF2BP1 increased the expression of both the anti-apoptotic and pro-survival factor BCL-2 and the cell cycle inhibitor CDKN1B. In contrast to IGF2BP1, knock-down of IGF2BP3 rather induced cell viability, whereas IGF2BP2 modulation had no impact on cell viability and cell cycle progression indicating opposing effects of the three IGF2BPs on PNET progression. These in vitro findings were paralleled by distinct expression patterns of IGF2BPs in human and murine PNET tissues. Elucidation of IGF2BP-modulated RNAs in PNET cells is ongoing.

Conclusion: In summary, our data suggest that IGF2BP1 promotes tumor progression by enhancing cell cycle progression and clonogenic growth, whereas IGF2BP2 and -3 exert no tumor-promoting role in PNET.

Introduction: Intraductal papillary mucinous neoplasms (IPMNs) and neuroendocrine tumors (NETs) of the pancreas are rare tumors. Up to now 15 patients with association of endocrine and exocrine neoplasms of the pancreas have been reported in the literature, but this association is not expected to be frequent. The aim of this study is to describe a series of nine patients with IPMN and concomitant NET of the pancreas followed in our center and to look for any common findings between them that could help early recognition and further comprehension of this association.

Aims & Methods: Among all the patients who were followed in our clinic for IPMN or NET, we identified 9 with both diseases, diagnosed on imaging or after biopsies requested for uncertain results of previous investigations. We collected data about the patients (age, sex, symptoms, past and current medical history, blood chemistry, type of imaging) and about the lesions (classification, dimension, localization, imaging features, fine-needle aspiration (FNA) biopsies results and histology).

Results: All patients (4 men and 5 women), except one were asymptomatic. Average age at diagnosis was 61 years. All IPMN were branch duct, localized in the head (n=4) and in body-tail (n=5), with a medium diameter of the cysts of 12mm (range 8mm-16mm). All NETs underwent endoscopic ultrasound examination with FNA; 8 were non functional G1 with a Ki67 of 1%, positive for Chromogranin A and Neuronospecific Enolase staining. One NET was a symptomatic insulinoma located at the tail (Ki67 of 2%, 20 mm diameter) and underwent distal spleno-pancreatectomy. Among NETs, 6 were in the head and 3

at body-tail, with a medium diameter of 11 mm (range 6 mm–15 mm). In 4 patients, the first diagnosis was IPMN, followed by identification of NET with second level imaging. In 5 patients, who underwent magnetic resonance imaging for NET, a concomitant IPMN was found.

Conclusion: Our study describes 9 cases of endocrine-exocrine pancreatic neoplasms association. In the 15 cases reported by literature one out of the two lesions, had a malignant behavior. In our records, except in one patient, both IPMN and NET in all patients behave in an indolent fashion. All the IPMN were branch type and all the NET, except one, were G1; mainly patients are asymptomatic and a hormone production symptom was observed in only one case. We found neither sex or age predisposition, nor predominant localization or common pathologic background in the patients. No other concomitant neoplastic diseases were found. Although the frequency of association between NET and IPMN is not too large and no diagnostic hallmark were found, it is still to be proven that this association is fortuitous. Further studies in the future are required.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The chemopreventive effect of aspirin (ASA) and other NSAIDs have been observed in the setting of colorectal cancer, showing a reduction in the incidence and mortality. However, the impact of aspirin use on clinical outcome of patients with gastro-entero- pancreatic neoplasms (GEP NEN) has not yet been evaluated.

Aims & Methods: Aim of the study was to retrospectively evaluate the clinical outcome of GEP NEN patients treated with ASA at three different European referral Centres for NENs. All the GEP NENs patients followed up in three European Centres (Fondazione IRCCS Ca' Granda Ospedale Policlinico Milano, Italy; Fondazione IRCCS Istituto Tumori Milano, Italy; Mater Misericordiae University Hospital, Dublin, Ireland), from January 2005 and September 2016, were retrospectively enrolled. The possible association between ASA and disease grading, staging, primary site, overall OS and PFS were evaluated. At the time of enrolment, clinical data and biochemical parameters were collected for every patient. Chromogranin A (CgA) and specific circulating peptides were evaluated. Morphological and functional imaging (computed tomography, magnetic resonance and Gallium 68PET) were performed to follow up the patients at each Centre.

Results: In the 253 patients included (121 M, median age 64 yrs), the primary neuroendocrine tumor was located at the stomach (#35), pancreas (#82), small bowel (#80), appendix (27), colon (#19) or unknown (#7). Grading was G1 in 154 patients, G2 in 64, G3 in 5 and not available in 28. TNM staging was I in 99 patients, II in 16, III in 32 and IV in 86. No clear impact on OS or PFS was observed in patients taking ASA compared to those not taking it. Interestingly, in pNEN an inverse relation was observed between Ki67 and ASA assumption ($r = -0.35$, $p = 0.008$). In small bowel NEN an inverse relation was observed between positive lymphnodes at surgery and ASA assumptions ($r = -0.3$, $p = 0.02$). As expected, the intake of ASA was related with the older age of the patients.

Conclusion: According to present data, ASA therapy seems not to have a direct clinical impact on disease progression or survival of NENs, even if it is associated with lower Ki-67 values and less node involvement. Further studies are needed to confirm this observation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Von Hippel-Lindau disease (VHL) is a rare heritable genetic syndrome that may affect different systems and organs: pancreatic manifestations of the disease are frequent during lifetime of the patients. The key feature is the presence of simple cysts, but serous cystadenomas (SCAs) or neuroendocrine tumors (NETs) can be frequently found as well. The aim of this study is to describe pancreatic manifestations in patients with VHL, considering the peculiarity and rarity of this disease.

Aims & Methods: All patients who referred to the established multi-disciplinary team in our center (Molinette Hospital - Turin) for management and follow-up of VHL disease were included in the study: we then considered the ones with pancreatic involvement (simple cysts, SCAs or pNETs). We collected data about the patients (demographics and medical history), about the lesions (imaging features, histological and cytological analysis) and about the management.

Results: We enrolled a total of 24 patients, 18 of which (75%) had a pancreatic involvement. Multiple simple pancreatic cysts were found in 13 patients, SCAs were found in 2 patients and NETs in 7 patients. The mean age of the patients with pancreatic lesions was 42 (min 25 - max 75), 11 were males and 7 females (1.6:1 M:F). Simple cysts affected 13 patients, are always multiple (ranging from 12 to 80 mm) mostly in the head, 3 patients underwent surgery for symptomatic disease. All pNETs were well differentiated (G1, Ki67 <2%); 7 were located in the head and 2 in the tail (2 patients had multiple tumors), 5 out of the 7 pNET patients underwent surgery. The two SCAs were multiple (max 65 mm), mostly affecting the head in 1 case and the tail in the other. No surgery was performed.

Conclusion: 75% of our VHL patients showed pancreatic involvement, mostly in males compared to females. 72% of patients with pancreatic lesions suffered from simple cysts, 39% from NETs and 11% from SCAs. To note that all NETs were G1 and behaved in a benign fashion. Surgery was performed only in patients with NETs in the pancreatic head and in patients with symptomatic cystic disease. The mean age of incidence of VHL-related pancreatic lesions was lower than in sporadic cases, thus confirming literature data. Although all lesions in our patients were benign or stable, constant monitoring is needed.

Introduction: Neuroendocrine tumours (NET) consist of a diverse group of neoplasms that derive from diffuse neuroendocrine cells throughout the body. Commonly found in gastrointestinal (GI) duct and lung, they also arise in the pancreas. The relationship between tumour size and metastasis rate is poorly recognized in patients with pancreatic neuroendocrine tumours (PNETs). The impact of tumour size on prognosis was controversial in previous investigations.

Aims & Methods: The aim of this study is to evaluate the prognostic impact of tumour size on survival outcomes and its correlation with risk of metastasis in a large PNETs cohort, including all stages. Methods: PNETs cases diagnosed from 1988 to 2013 were retrieved from the Surveillance, Epidemiology, and End

Results (SEER) database. Clinicopathologic features were retrospectively analyzed. Survival was calculated by the Kaplan-Meier method. Multivariable Cox regression models with hazard ratios (HRs) were constructed to analyze survival outcomes and risk factors. Cubic spline analysis was used to assess relationship between tumour size and probability of metastasis.

Results: A total of 5424 patients were identified. There were 1226 patients (22.6%) with tumour size of 2 cm or less. The probability of metastasis increased in a non-linear fashion with increasing tumours size. Univariate analysis showed that tumour size was significantly correlated with survival ($P < 0.001$), no matter surgery was performed or not. However, subgroup analysis suggested this association to be linear for patients with localized and regional tumours ($P < 0.001$), but stochastic in patients with distant stages ($P = 0.703$). On multivariate analysis, tumour size was an indicator for metastasis (HR = 1.010, 95% CI: 1.008–1.013, $P < 0.001$) and size ≤ 20 mm was an independent prognostic factor for good survival (HR = 1.211, 95% CI: 1.048–1.399, $P = 0.009$ for size of 21–40 mm; HR = 1.282, 95% CI: 1.116–1.474, $P < 0.001$ for size > 40 mm). For tumours ≤ 20 mm, surgical treatment was associated with significantly improved survival compared with those patients who did not undergo operation ($P < 0.001$).

Conclusion: Tumour size affects the probability of metastasis. Its prognostic impact on survival is restricted to patients with localized and regional disease. For patients with tumour size ≤ 20 mm, surgical treatment should be considered preferably.

PI445 THE LARGEST FAMILY IN TURKEY WITH MULTIPLE ENDOCRINE NEOPLASIA-TYPE 1 AND A NOVEL MUTATION

A. Çetin¹, D. G. Duman²

¹Internal Medicine, Marmara University School of Medicine, Istanbul/Turkey

²Gastroenterology, Marmara University Hospital, Istanbul/Turkey

Contact E-mail Address: alicetindir@gmail.com

Introduction: Multiple Endocrine Neoplasia type-1 (MEN-1) occurs usually sporadically but because it is an autosomal dominant disorder it may affect other family members too. The combination of parathyroid tumors, pancreatic islet cell tumors, and anterior pituitary tumors is characteristic of MEN-1 although it may be accompanied by a substantial number of non-endocrine tumors. The mutations of the MEN-1 result in the alteration of MENIN production which is a protein encoded by this gene and is responsible for tumor-suppression under normal circumstances. Herein we present the largest MEN-1 family in Turkey to the best of our knowledge and a newly discovered mutation in MEN-1 that effects this family.

Aims & Methods: The family inherited the specific MEN-1 mutation is originally Ş ebinkarahisar, Giresun and most of the members have moved to Istanbul and Yalova. Consanguineous marriages have been practiced within the family. Family mapping was structured and contained fifty-five members. Among them, eleven patients underwent biochemical, radiologic and if necessary endosonographic evaluation along with the genetic testing. Additionally, we learnt that 2 members of the family had died of pancreatic malignancy. Diagnostic criteria for familial MEN-1 syndrome include; 1- the presence of at least one MEN-1 associated tumor that are from parathyroid, pituitary, or GEP tract origins, 2- at least one first-degree relative with one or more of these endocrine tumors and/or 3-positive genetic testing for abnormal MEN-1 mutation. For our index case, DNA sequencing of the MEN-1 gene performed using Sanger sequencing technique at ABI 3500 system. For the other family members only the targeted mutation analysis is performed.

Results: Among the family members we had peripheral blood DNA from 9 and we used the tumour tissue DNA from 1 patient. MENIN gene is analyzed with Sanger sequencing. Our index case was ZK who had hypophysis adenoma, parathyroidectomy and pancreatic neuroendocrine tumour and had whipple operation. A three nucleotide deletion p.ser560argfs*3(c.1680_1683 del TGAG) mutation causing a frameshift was detected. Seven out of ten who were analysed tested positive for the mutation. Genetic counseling and information about pre-implantation genetic diagnosis (PGD) was given to all patients who are tested positive for the mutation. All 7 patients had p.ser560argfs*3(c.1680_1683 del TGAG) three nucleotide deletion same with that of index case. Out of 15 patients, MEN-1 diagnosis was confirmed in 11. Tumours detected at patients with MEN-1 diagnosis were; nonfunctional pancreatic neuroendocrine tumour at three, parathyroid adenoma/hyperplasia at 6 patients and hypophysis adenoma

at 4 patients. The mean age of our MEN-1 patients were 51 and the age at diagnosis was 41.8. The mean plasma calcium level was 11.46 mg/dl and there was no history of renal calculus at any of them.

Conclusion: The family presented here is the one which had the largest number of affected individuals with genetic and clinical properties of MEN-1 at Turkey. Besides the mutation detected here is the novel pathogenic mutation causing loss of function that is described for the first time. Also at MEN-1 families, counseling to prevent the neoplasia development and to prevent the new family member to be effected with PGD has a pivotal importance. We could point out that awareness is the most important caution for prevention.

Introduction: Several inflammatory response materials could be used for prediction of prognosis in cancer patients. The neutrophil lymphocyte ratio (NLR), platelet lymphocyte ratio (PLR), thrombocytosis (the platelets number $>400 \times 10^3/\text{mm}^3$) have been introduced for prognostic scoring system in various cancers.

Aims & Methods: The objective of this study was to determine whether the NLR, the PLR or thrombocytosis could predict the clinical outcomes in G1-G2 neuroendocrine tumors. We performed a retrospective review of 31 patients with neuroendocrine tumors with ki 67 below 20% diagnosed in Fundeni Clinical Institute between 2011–2017. Data about site of the primary tumor, presence of metastasis, NLR, PLR, thrombocytosis (platelet count >400) and survival were collected and analysed.

Results: The patients characteristics were: primary tumor location was: 61.29% pancreas, 22.58% gastrointestinal tract, 16.13% unknown, 61.29% had hepatic metastasis, 6.45% had locally advanced tumor. The primary tumor was resected in 35.48% patients. The overall 2-year survival rate was 77.42%. The Ki 67 index ($p < 0.04$), PLR (cut off >300) $p < 0.01$ have statistical significant impact on survival in univariate analysis and on multivariate analysis ($P < 0.05$). Other factors like ki 67 index, metastatic disease, thrombocytosis and NLR have an impact on survival statistical significant on multivariate analysis.

Conclusion: This study demonstrates the prognostic role of different variables like Ki 67 index, PLR and PLT value, thrombocytosis and metastasis. This factors may be integrated in different scoring systems for prognosis that could guide clinicians for a better management in patients with neuroendocrine tumors.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Neuroendocrine pancreatic tumors represent the second prevalent entity of malignant tumours of the pancreas and show an overall mortality of about 60%. At the moment surgical resection is the only option of potentially curative therapy, as with the currently available chemo- and radiotherapeutic approaches an inhibition of tumor growth but no regression of the tumor can be achieved. Therefore for about 80% of pNET patients no curative therapy can be offered. To obtain the identification of novel potential target genes for the development of new therapeutic strategies, primary tissues from pNET patients were analyzed. Amongst others Plac8 (Placenta-specific 8) was identified, which

is a small protein of unknown function, showing different forms of cellular localisation depending on the cell type analyzed, indicating at its ability to fulfill a variety of physiological functions.

Aims & Methods: In the course of this study, the function of Plac8 in neuroendocrine pancreatic tumors is to be unveiled to evaluate its value as a potential target for pNET therapy. Therefore primary tumor tissue of about 100 pNET patients were analyzed for Plac8 expression by quantitative realtime PCR and immunohistochemistry. Furthermore established pNET cell lines from human origin where transfected with siRNAs against Plac8 and there proliferative activity and viability where analyzed by BrdU and MTT assay. Changes in these important characteristics of tumor cells were further examined by westernblot analyzes of key regulators of apoptosis and cell growth.

Results: Plac8 is highly expressed in primary human pNET tissues on RNA- as well as on protein level. Functional in vitro analyses show that the siRNA-mediated knockdown of Plac8 not only in human but also in rat cell lines leads to significantly reduced proliferative activity and reduced cell growth. These effects come along with indicative changes in the expression of central regulators of cell cycle while apoptotic pathways seem not to be affected.

Conclusion: Overexpression of Plac8 in neuroendocrine tumors of the pancreas promotes the proliferative phenotype of the tumor cells while the inhibition of Plac8 inhibits cell growth and metabolism. Therefore in the future Plac8 could represent a very interesting target molecule for the treatment of pNETs.

P1448 CLINICAL OUTCOMES OF SUPERFICIAL LARYNGOPHARYNGEAL CANCER WITH LYMPHO-VASCULAR INVASION AFTER ENDOSCOPIC LARYNGO-PHARYNGEAL SURGERY

H. Ishida¹, R. Nakamura¹, T. Omori², S. Mayanagi¹, K. Fukuda¹, K. Suda¹, N. Wada¹, H. Kawakubo¹, Y. Kitagawa¹

¹Surgery, Keio University School of Medicine, Tokyo/Japan

²Department Of Surgery, Kawasaki Municipal Kawasaki Hospital, Kawasaki/Japan

Contact E-mail Address: hishida223@gmail.com

Introduction: Since the majority of laryngopharyngeal carcinomas are detected at an advanced stage, most cases are treated with concurrent chemotherapy and radiation therapy. The key to improving the prognosis and quality of life is early detection of the primary cancer and treatment using minimally invasive surgery. We previously reported the good oncologic outcomes with ELPS (Endoscopic laryngo-pharyngeal surgery) for superficial laryngo-pharyngeal carcinoma. However there is no clinical evidence for an additional treatment nor prognosis about the cases conducted endoscopic resection which were diagnosed to be surficial carcinoma with lympho-vascular invasion histopathologically.

Aims & Methods: This study aimed to investigate the optimal additional treatment and clinical course for the surficial laryngo-pharyngeal carcinoma with lympho-vascular invasion. We analyzed clinicopathological data in 9 patients showed Lympho-vascular invasion receiving ELPS between 2007 and 2014.

Results: Positive lympho-vascular invasion was found in 9 cases. Detected the tumor depth was SEP in 7 lesions and MP in 2 lesions. Mean alcohol consumption is 9.9 abv units. Average smoking history is 38.9 pack years. 5 cases are low-activity ALDH2 heterozygotes and have alcohol flushing reaction. Histopathological findings showed 5 cases with lymphatic invasion (ly1, v0), 2 cases with vascular invasion (ly0, v1), and 2 cases with lympho-vascular invasion (ly1, v1). Two patients underwent an additional chemoradiotherapy without recurrence. Four patients had cervical lymph node or local recurrence, two of them were salvage ELPS cases after chemoradiotherapy. One of two salvage cases also had distant metastasis and was given palliative treatment, and finally died. The other one underwent surgical salvage and remained alive. One case with lymphatic and vascular invasion had no adjuvant therapy and remained no recurrence. And the other 2 cases had no recurrence but died of other cause.

Conclusion: Lympho-vascular invasion is a risk factor for cervical lymph node metastasis, which has a possibility to a very aggressive disease. In those cases, chemoradiotherapy as an additional treatment is recommended as far as possible. If patients already had prior radiotherapy, close follow-up is essential to detect recurrence early. In those cases, chemotherapy or additional surgical resection are also considerable if the general conditions are satisfactory.

Introduction: The positive lateral margin after endoscopic resection (ER) of early gastric cancer (EGC), additional surgery or endoscopic submucosal dissection (ESD) are recommended. However, the additional surgery often difficult due to advanced age or patient's comorbid conditions.

Aims & Methods: The aims of this study is to investigate of appropriate management in patients with positive lateral margin after ER. We analyzed

retrospectively 103 patients with positive lateral margin after ER from January 2005 to December 2015, in single tertiary center. Clinicopathological data were retrieved to assess the local recurrence rate, survival rate, procedure related adverse events.

Results: Of the 103 patients, 27 patients (26.4%) underwent early re-treatment within 3months after initial ER(17 patients in re-do ESD, 10 patients in additional surgery). And 76 patients (73.6%) were observed under close surveillance. Median duration of follow-up period was 45.7(6–132) months. Recurrence rates of early re-treatment group(3.7%, n=1/27) was lower than surveillance group(18.4%, n=14/76; p=0.05). five-year survival rates not significantly different between the two groups, at 100%, 97.4% respectively. In close surveillance periods, 12 patients were confirmed to local recurrence by follow-up biopsy, then delayed re-treatment was performed (7 patients in re-do ESD, 5 patients in surgery, mean time after initial ER=27.5months). Finally, a total of 24 patients were treated with re-ESD, and 17 patients were treated with additional surgery. Among these two groups, there were no significant difference in recurrence rates (8.3% vs. 0%) and five-year survival rates (both 100%). However, adverse events that related to treatment was more frequent in additional surgical group (2 ileus, 1 umbilical hernia).

Conclusion: The additional treatment should be recommended for patients with positive lateral margin after initial ER for EGCs. In addition, re-ESD which have a similar efficacy and a better quality of life, compared to additional surgery is a favorable option for control of recurrence or residual EGCs.

P1450 EFFICACY OF THE FORCED COAGULATION MODE WITH LOW HIGH-FREQUENCY POWER SETTING DURING ENDOSCOPIC SUBMUCOSAL DISSECTION

T. Ishida¹, T. Toyonaga², Y. Ohara², R. Ariyoshi¹, F. Kawara¹, S. Tanaka¹, Y. Morita¹, E. Umegaki¹, N. Hoshi¹, T. Azuma¹

Introduction: Bleeding control is one of the most important factors to success endoscopic submucosal dissection (ESD) in safety. We have reported the endoscopic pre-coagulation technique using soft coagulation mode (S method) is effective¹. This method is useful for the prevention of bleeding when relatively large vessels penetrating between muscle layers are dissected. However we have thought that S method is insufficient especially for large vessels such as more than 2mm, we have to use hemostatic forceps for preventing hemorrhage despite trying S method. However we found that forced coagulation mode with low high-frequency power setting (F1-10 method) can exhibit pre-coagulation function without bursting vessels. It is suggested that F1-10 method is useful for large vessel pre-coagulation.

Aims & Methods: We investigated the deference of hemostatic ability between S method and F1-10 method in clinical study and ex vivo study. In clinical study we analyzed retrospectively their hemostatic ability about consecutive six gastric ESD cases in each groups excluded some cases, which have the risk of affecting data for example taking anticoagulation drugs. The diameter of treated vessels, frequency and duration of the compressed vessel, and bleeding frequency after cutting vessels were noted by the recorded videos. In ex vivo study, to investigate the coagulation mechanism of those two different power settings was evaluated the peak voltage, current elapsed time, and electric energy by using the data recording program (VIO DOKU) and the width and depth of coagulation was measured on macro- and microscopic levels using porcine tissues.

Results: In clinical study, the total number of vessels processed by endoknife pre-coagulation were 49 and 61 vessels in the S and F1-10 methods. The median vessel diameter was 2mm in the S method and 1.5mm in the F1-10 method. The median frequency of the compressed vessel was twice in both methods, and the median coagulation time was 9s and 10s in the S and F1-10 methods, respectively. No significant difference was found between the S and F1-10 methods. The bleeding rate after vessel processing was 18.4% (8/49) and 4.8% (3/62) in the S and F1-10 methods, respectively (P=0.058, odds ratio [OR]: 3.84, 95% confidence interval [CI]: 0.96–15.34). No statistically significant differences were found; however, the F1-10 method strongly showed a trend in preventing bleeding after pre-coagulation compared with the S method (P=0.058). We further investigated the bleeding rates of the large vessels, defined as ≥2mm in diameter. There were 26 and 29 large vessels in the S and F1-10 methods, respectively. The bleeding rates of the large vessels were 26.9% (7/26) and 3.4% (1/29) in the S and F1-10 methods, respectively, which were significantly different (P=0.021, OR: 10.32, 95% CI: 1.17–90.78). In ex vivo study, the median peak voltage was 172 Vp and 560 Vp in the S and F1-10 methods. The median current elapsed time was 0.22s and 1.54s in the S and F1-10 methods. The F1-10 method could keep the electric current longer than the S method. The mean total electrical energy was 6.34 W and 12.5 W in the S and F1-10 methods. F1-10 method was able to achieve to give larger electrical energy in the routine block. And the width and depth of coagulation in F1-10 method spread wider and deeper in macro- and microscopic sections.

Conclusion: F1-10 method is suggested to achieve a stronger hemostatic effect than the S method in clinical procedures and ex vivo models.

P1451 EXPOSURE TO ENDOTHERAPY FOR UPPER GASTROINTESTINAL BLEEDING AT THE POINT OF GASTROSCOPY CERTIFICATION-IS IT SUFFICIENT?

K. Siau, P. Dunkley, J. Anderson, I. Beales, R. Broughton, M. Feeney, A. Haycock, N. Hawkes, R. Valori, C. Wells, S. Thomas-Gibson, B. Mckaig

Contact E-mail Address: keith@siau.org

Introduction: Although certification in diagnostic gastroscopy has been established in the UK, there is no formal process for quality assurance (QA) in endotherapy for upper gastrointestinal bleeding (UGIB). Training opportunities are variable, with 11% of final year UK gastroenterology trainees citing inadequate exposure,^[1] despite an expectation to independently manage UGIB upon achieving specialist status. Data on endotherapy exposure during endoscopy training is limited. We aimed to assess whether trainees are receiving adequate exposure to endotherapy at the time of gastroscopy certification.

Aims & Methods: Trainees awarded certification in gastroscopy between September 2009–2016 were identified from the national trainee electronic portfolio (JETS). Trainee inputs and formative assessments (direct observation of procedural skills - DOPS) for UGIB therapy, up to their certification date, were analysed. Only trainees with >200 procedures were included, which is the minimum procedural number to allow certification within the UK, thereby excluding those who had submitted baseline information which may have contained therapeutic data. Exposure rates from medical endoscopists (physician and surgical trainees) were compared with non-medical endoscopists (NME).

Results: 885 trainee portfolios were analysed (765 medical and 120 NMEs), with a median procedural count of 276 (IQR 124). The median number of therapeutic entries and DOPS were 4 (IQR 11), and 1 (IQR 3) respectively. Overall rates for endotherapy and DOPS were 2.9% and 0.8% per procedure. When stratified by therapy, the median exposure to each therapy was either 0 or 1, with means displayed in Table 1. 25.2% of trainees had no exposure to any type of endotherapy (67.5% of NME and 18.6% of medical endoscopists, p < 0.0001). Of medical endoscopists awarded certification, 37.1% had not performed band ligation, 50.7% had not placed a clip, and 54% had not used heater probe. NME had significantly less exposure to each modality of endotherapy considered (overall odds ratio 0.10, p < 0.0001).

Table 1: Mean procedural counts at the point of UGI certification.

	Total	UGIB Therapy	DOPS	Argon	Banding	Clip	Heater Probe	Injection
Medical	346	10.7	2.6	2.1	4.4	1.6	1.6	4.0
Non-medical	323	1.1	0.29	0.3	0.4	0.1	0.1	0.3
p-value	0.143	<0.0001						

Conclusion: Training on endotherapy prior to certification is limited. The current UGI certification process does not ensure competency in endotherapy for UGIB. In response, the JAG QA team have recently released new DOPS forms specific to UGIB, and are consulting on introducing formal certification in endotherapy for UGIB.

Introduction: Barrett's esophagus (BE) is a known premalignant condition with risk for progression to esophageal adenocarcinoma. Electronic chromoendoscopy with magnification (ECM) is an evolving imaging technology being investigated as a novel imaging tool to identify dysplasia in BE to assist with higher yield BE surveillance and improve the diagnostic yield of esophageal biopsies for BE.

Aims & Methods: This is a single-center study to evaluate the efficacy of ECM (iScan by Pentax) in the detection of BE and dysplastic BE in a screening, average risk population with BE in Northeast Mexico. We conducted a retrospective study of 100 consecutive patients (41 males) with known BE (confirmed by pathology) during surveillance upper endoscopy for dysplastic BE between

March and September of 2016. All patients underwent EC with iScan. The esophagus was inspected with a ECM capable endoscope (EG- 2990-Zi) and deliberate biopsies were taken from tissue identified by ECM that suggested BE. All biopsies were confirmed by a GI pathologist. Primary endpoint was the correlation between visual inspection diagnosis of dysplastic BE by ECM versus pathologic diagnosis of BE as the gold standard.

Table 1: Patient characteristics and outcomes

Characteristics	100
Age (mean)	47.7
Male	41/100
Endoscopic diagnosis: nondysplastic BE	96/100
Endoscopic diagnosis: BE with LGD	4/100
Pathologic diagnosis: nondysplastic BE	94/100
Pathologic diagnosis: BE with LGD	4/100
Pathologic diagnosis: benign gastric mucosa	1/100
Pathologic diagnosis: esophageal ulcer	1/100
Accuracy	98%
Sensitivity	100% [95% CI (96%–100%)]
Specificity	0% [95% CI (0%–84%)]
Positive predictive value	98% [95% CI (93%–99.7%)]
Negative predictive value	NA

Results: In our cohort 41% were male, with mean age of 47.7 years. Endoscopic diagnoses by ECM were divided into nondysplastic BE (96/100) and suspected dysplastic BE (4/100). On pathology nondysplastic BE was found in 94/100 patients, BE with low-grade dysplasia was found in 4/100 patients. Benign gastric mucosa with no alterations (1/100), and ulcerated esophagitis (1/100). The overall accuracy of endoscopic diagnoses using ECM against pathology diagnosis was of 98%, with sensitivity of 100% [95% CI (96%–100%)], and positive predictive value of 98% [95% CI (93%–99.7%)].

Conclusion: Endoscopic diagnosis of BE by directed biopsies of esophageal tissue with use of ECM is highly accurate. Future prospective studies are needed to validate our preliminary findings and assess inter-observer variability.

Introduction: Barrett’s oesophagus (BO) is the main risk factor for oesophageal adenocarcinoma (OAC). International guidelines recommend endoscopic surveillance for early detection of dysplasia (DYS) and/or OAC but current biopsy protocols can miss areas of endoscopically unapparent neoplasia. At present, advanced diagnostic imaging technologies and specific endoscopist and pathologist expertise in detecting the subtle phenotypic changes associated with DYS/OAC are available only in tertiary care referral centres.

Aims & Methods: The aim of this study is to investigate the diagnosis changes after BO assessment in a tertiary care referral centre. 119 consecutive patients [male = 103, female = 16; median age = 58 (50;64)] referred to the Veneto Institute of Oncology (IOV-IRCCS) BO Unit between 01/03/2015 and 01/03/2017 were considered. Patients were divided in 3 groups according to the admitting diagnosis (AD): BO patients without DYS/OAC or visible lesions (Group 1,

n = 82); BO patients with DYS/OAC but no visible lesions (Group 2, n = 33); BO patients with DYS/OAC and visible lesions (Group 3, n = 4). All patients underwent an endoscopy under deep sedation at IOV with HD magnification endoscopes + NBI + acetic acid chromoendoscopy. Target biopsies and/or EMR were obtained in case of endoscopically visible lesions; 4-quadratic biopsies/2 cm were obtained otherwise. All the specimens were diagnosed by two expert GI pathologists, who reached a final diagnosis (FD). In Group 2 patients where FD was BO without DYS/OAC, previous histology was reviewed by two expert pathologist.

Results: Results are summarized in Table 1. Group 1 (n = 82): FD of DYS/OAC with visible lesion was reached in 2 out of 82 patients (2.4%), both treated by EMR + RFA. No one had a FD of DYS/OAC without visible lesions. Group 2 (n = 33): FD of DYS/OAC with visible lesions was revealed in 13 out of 33 patients (39.4%); 11 were treated by EMR + RFA, 1 by surgery and 1 chemio/radiotherapy. In 20 patients the AD was downgraded to uncomplicated BO: in 19 patients (57.6%), a review of previously taken biopsies by expert pathologist excluded neoplasia. In only one patient no lesion was found but the review of original histology slides confirmed a low-grade DYS and the patient was treated by RFA. Group 3 (n = 4): DYS/OAC was confirmed in all the 4 patients (2 treated by EMR + RFA, and 2 by surgery).

Conclusion: When upper endoscopy is performed in a BO reference center where specific facilities and expertises are available (i.e. deep sedation, HD magnification endoscopes, chromoendoscopy, expert endoscopist and pathologist) “invisible” DYS is a very rare diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic full-thickness resection (EFTR) for sub-epithelial lesions (SETs) of GI tract is less frequently described; possibly due to technical challenges involved in dissection and need for resultant defect closure. Current study describes single-center experience of EFTR for treatment of SETs.

Aims & Methods: Prospective database of patients undergoing EFTR for SETs over 6-years (2011–2017) was abstracted. Patient selection for EFTR—endoscopy, endoscopic ultrasound (EUS) and CECT. Inclusion criteria - encapsulated lesions, predominantly endophytic component and absence of features of invasive malignancy. Exclusion criteria—patients unfit for general anesthesia or major invasive procedure, uncorrectable coagulopathy or high risk features for malignancy. All procedures performed under general anesthesia with endotracheal intubation. High-definition endoscope (GIF-HQ-190 or CIF-HQ-190, Olympus Corp., Japan) with distal transparent hood and carbon dioxide insufflation used in all. After submucosal (SM) elevation by Gelofuscin, mucosal incision and SM dissection performed to expose SET. Encapsulated SET enucleated maintaining intact capsule. Adherent and attached muscularis propria (MP) layer fibers divided. IT or Dual-knife™ used for dissection and coag-grasper for hemostasis. Resultant MP layer defect closed endoscopically.

Results: Total N = 18 (M:F=11:7), mean age=53.6 (Range=28–78). Presentation—GI bleed=7 (38%), abdominal pain=4 (22%), non ulcer dyspepsia=1, rectal mass=1 and asymptomatic, incidentally diagnosed=6 (33%). Layer of origin—MP layer in all. Location—stomach=13 (72%), duodenum=2, rectum=2, proximal jejunum=1. Mean size of SET=3.3 cm (range 1–7). Mean procedure time=182 mins (60–345), and mean hospital stay was 4 days. Adverse events—two (11%)—esophageal laceration during specimen retrieval=1 (closed using endoclips), failure=1 (due to undetected large exophytic component—surgical resection). Histopathology with

Abstract: P1453

		Final Diagnosis (FD)		
		BO without DYS/OAC	BO with DYS/OAC but no visible lesions	BO with DYS/OAC and visible lesions
Admitting Diagnosis (AD)	Group 1 BO without DYS/OAC (n = 82)	80	0	2
	Group 2 BO with DYS/OAC but no visible lesions (n = 33)	19	1	13
	Group 3 BO with DYS/OAC and visible lesions (n = 4)	0	0	4

IHC-GIST-9(50%),neuroendocrine tumor-3(16%), leiomyoma-1, schwannoma-1, neuroma-1, duplication cyst-1, parietal cell hyperplasia-1. Closure - 16/18 (2 defects in distal extra peritoneal rectum left open intentionally for healing by secondary intention); techniques-through-the-scope (TTS) clips-7, over-the-scope clip-4, omental patch+clip-2 (TTS- 1, OTS- 1), endoscopic suturing-1, endoloop+clip-1. Mortality-nil. Follow up endoscopy at 4 weeks showed healing in all 17 patients. Median follow up -2 months.

Conclusion: EFTR is safe and effective for resection of SETs. Pre EFTR EUS and CECT may be useful to select appropriate candidates. Secure closure of defect is necessary for intraperitoneal full-thickness defects. Further studies comparing EFTR and surgery are recommended

PI455 PROPHYLAXIS OF VARICEAL BLEEDING IN CIRRHOTIC PATIENTS: EFFICACY AND SAFETY OF ENDOSCOPIC VARICEAL LIGATION IN A TERTIARY CENTRE

E. Soares¹, M. Gravito-Soares¹, A. Henriques¹, N. Almeida¹, L. Tomé¹

¹Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal, Coimbra/Portugal

Contact E-mail Address: es18497@gmail.com

Introduction: In the natural history of chronic liver disease, variceal bleeding represents a life-threatening complication of portal hypertension, with high risk of mortality and recurrence. Current guidelines define vasoconstrictive therapy or endoscopic variceal ligation (EVL) in primary prophylaxis and the combination of both in secondary prophylaxis.

Aims & Methods: We aimed to evaluate the efficacy of EVL therapy in both primary and secondary prophylaxis of variceal bleeding in cirrhosis and to establish the patient's clinical outcome. This was a retrospective observational cohort study of a total of 444 EVL procedures performed in 250 cirrhotic patients, who were admitted in a gastroenterology department of a tertiary centre, between 2004–2016, to receive EVL as prophylaxis of variceal bleeding. Sessions of ligation were repeated every two to three weeks in order to reach variceal eradication. The clinical outcome included the recurrence of bleeding (primary endpoint), the eradication success rate of oesophageal varices, EVL-related complications and overall and bleeding-related mortality.

Results: The mean follow-up period for all 250 cirrhotic patients enrolled in the study was 73.2±41.0months, with mean age of 63.9±10.8years and a predominance of male gender (80.4%;n=201). At initial endoscopy, 237 (53.4%) had portal hypertensive gastropathy, being severe in 168 (37.8%). EVL was performed as primary prophylaxis in 50.9%(n=226) and secondary prophylaxis in 49.1%(n=218). Varices were obliterated in 209 (83.6%) patients with mean number of EVL procedures necessary to eradicate varices of 1.8±0.95 and a maximum of procedures of 6. Recurrent bleeding occurred in 11.2%(n=28) of cases with a mean time to re-bleeding occurrence of 8.1±14.2months. Major and significant complications were verified in 8.1%(n=36) of patients. The main complications were bleeding related to post-banding ulceration (75.0%;n=27) and infection (22.2%;n=8), with mean time between EVL and complication occurrence of 11.1±11.8days (minimum:0;maximum:43). Intra-procedure complications occurred in 11(2.5%) patients with no death, despite of two cases of Sengstaken-Blakemore balloon necessity. The overall mortality was 5.4%(n=24), being 0.4%(n=2) related to variceal bleeding.

Conclusion: EVL seems to be an efficient, safe and relatively simple therapeutic procedure in both primary and secondary prophylaxis of variceal bleeding in cirrhotic patients. Since the main complications occurs over 1 week after EVL procedure, the majority of patients can be safely treated in an ambulatory setting.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI456 THE VALUE OF ENDOSCOPIC FULL-THICKNESS RESECTION FOR GASTRIC AND DUODENAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA LAYER

M. Xu¹, C. Zhang¹, Q. Li¹

¹Endoscopy Center, Zhongshan Hospital, Shanghai/China

Contact E-mail Address: whitelily.chen@aliyun.com

Introduction: Given diminishment of quality of life caused by surgery in the stomach and duodenum, a minimally invasive treatment is desirable for gastric and duodenum submucosal tumors (SMTs).

Aims & Methods: We aimed to assess the value of endoscopic full-thickness resection (EFTR) technique for gastric and duodenal submucosal tumors (SMTs) originating from the muscularis propria (MP) layer. A total of 276 patients with single gastric SMTs originating from the MP layer were performed EFTR between January, 2010 and February, 2014. The tight adhesion of the tumor to gastric or duodenal serosal layer could be seen in every case from endoscopic ultrasound (EUS) before the procedure. The SMTs orientated endoscopically were performed EFTR using a standard ESD technique without laparoscopic assistance under direct endoscopic view. The defect of gastric and duodenal wall was closed after resection.

Results: A total of 276 patients included 94 males and 182 females. Their median age was 57.8 years (range, 30–81 years). Among all the 276 SMTs in our study,

165 located in gastric fundus, 96 located in gastric body, 8 located in the antrum, 1 located in the angle of stomach, and 6 located in duodenum. The median lesion size was 1.7 cm (range 0.7–6.0 cm). The success rate of EFTR was 98.9% (273/276). EFTR was failed in 3 cases: one case was out of control because of bleeding into enterocoelia, two cases required conversion into laparoscopic surgery because of giant lobulations of the tumor outside the cavity. The median operation time was 65 min (range, 14–210 min). En bloc resection rate was 98.1% (268/273), piecemeal resection rate was 1.9% (5/273). The median length of hospital stays was 4.4 days (range, 1–23 days). Pathological outcomes revealed that the lesions included 137 (49.7%) gastrointestinal stromal tumors (GISTs), 103 (37.3%) leiomyomas, 13 (4.7%) schwannomas, 8 (2.9%) calcifying fibrous tumors, 7 (2.5%) glomus tumors, 5 (1.8%) displaced pancreas, and 3 (1.1%) fibroblastomas. The procedure-related complications were as follows. Different degrees of epigastric pain occurred in 168 (60.9%) cases, among which 24 (8.7%) cases required analgesics. Pneumoperitoneum occurred in all the patients and was treated successfully with peritoneocentesis decompression. Seroperitoneum occurred in 15 (5.4%) cases. localized peritonitis occurred in 3 (1.1%) cases, and digestive tract leakage occurred in 1 (0.4%) case. All the cases with above complications recovered spontaneously or after conservative treatments. No massive bleeding or abdominal abscess was found after EFTR. None of the 273 cases developed procedure-related death. No tumor residual or recurrence was found during the follow-up period ranging 3–55 months.

Conclusion: EFTR without laparoscopic assistance is minimally invasive, safe, and effective for treating gastric and duodenal SMTs, which originate from the MP layer and adhere tightly to the serosa. High en bloc resection rate could be achieved. However, a larger number of the cases and long-term outcome deserve further research.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI457 BLUE LIGHT IMAGING AND LINKED COLOR IMAGING FOR DETECTION AND CHARACTERISATION OF CHRONIC GASTRITIS

J. Weigt¹, A. Link¹, A. Canbay¹, P. Malfertheiner¹

¹Gastroenterology, Hepatology & Infectious Diseases, Medizin. Universität Magdeburg Gastroenterologie und Hepatologie, Magdeburg/Germany

Contact E-mail Address: jochenweigt@gmx.de

Introduction: Current standard in the characterization of gastric mucosal changes is the use of virtual chromoendoscopy with magnification to visualize the pit pattern and vascular changes. The most recent development in light emitting technology is the so called Multi Light Illumination, that composes light out of 4 coloured LED. Blue Light Imaging (BLI) is composed of a continuous spectrum with peaks at 410 and 450 nm to enhance surface and vascular structures. Linked Color Imaging (LCI) uses BLI light together with post processing that reallocates colour tones resulting in a high contrast of different red tones. Until now only few data exist about the use of BLI and LCI in chronic gastritis (CG).

Aims & Methods: We aimed to analyse the use of LCI and BLI in detecting and characterization of chronic gastritis and premalignant conditions of the stomach. 24 consecutive patients were investigated. All patients were investigated under conscious sedation. In all cases an endoscope equipped with zoom (Fujifilm EG-760Z) was used. Endoscopic classification was based on the following parameters: normal gastric mucosa was defined as mucosa with visible superficial capillary network (SCN) without any focal lesions; atrophy (AG) was defined by whitening of the mucosa with visible deeper vascular architecture in white light, BLI and LCI; intestinal metaplasia (IM) was diagnosed if mucosa had villous or ridged surface with whitening in LCI or white light or light blue crest sign in BLI; CG was diagnosed in case of loss of SCN or focal lesions not matching the definition of other focal lesions or cancer. Biopsies were sampled according to the updated Sydney classification system and in addition of every visible focal lesion. After endoscopy a prediction of histology was made by the endoscopist.

Results: We investigated 24 patients (15 female, 9 male, age 65 yrs (25–87yrs)). *H. pylori* was detected by histology or urease test in 7 patients. 3 patients showed normal gastric mucosa, 13 patients presented IM or AG either in the antrum or the corpus. According to MAPS criteria 7 patients had extensive disease with premalignant conditions in both, antrum and corpus. The concordance of endoscopic classification and histology was 79.1% (19/24) in the antrum and corpus each. Despite the inconcordance of histology and endoscopic diagnosis in 5 cases the intervals for surveillance according to MAPS guidelines would have been correctly respected with the use of endoscopic assessment in all cases.

Conclusion: LCI and BLI are accurate in detection and characterization of changes in gastric mucosa with an acceptable concordance to histology. These new imaging modalities are a step towards precise endoscopic diagnosis of gastric mucosal changes and have the potential to reduce the number of unnecessary histologic investigations and offer the possibility for more appropriate endoscopic diagnosis.

P1458 LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION(ESD) FOR RELATIVE INDICATION GROUP OF EARLY ESOPHAGEAL SQUAMOUS CELL CARCINOMA (EESCC) IN AGED PATIENTS

Z. Qi¹, Y. Zhong¹, P. Zhou¹

¹Endoscopy Center, Zhongshan Hospital Fudan University, Shanghai/China

Contact E-mail Address: poem001@qq.com

Introduction: According to the Japanese Esophageal Society Guidelines, Early Esophageal Squamous Cell Carcinoma (EESCC) involving the muscularis mucosa or <200µm invasion of the submucosa, and circumferential extent of >2/3 were relative indications (RI) for ESD. Additional treatment (AT, including esophagectomy or chemoradiotherapy) may be needed after ESD. But in aged RI patients, most will refuse AT due to higher rates of debilitating symptom in China.

Aims & Methods: The aim of this study was conducted to evaluate the long-term outcomes of aged RI patients without AT after ESD.

Between January 2008 and December 2013, a total of 158 aged EESCC patients were included in the present retrospective study. Prognosis outcomes were analyzed.

Results: 89 patients included in absolute indication (AI) group and 69 in RI group. The baseline characteristics were balanced between two groups. During the follow-up time (median 56 (1–108) months), short-term adverse events (4.3% vs 1.1%, $p=0.319$) and postoperative stricture rate (31.8% vs 21.3%, $p=0.134$) were higher in RI group than in AI group. 5-year recurrence-free survival rate (85.8% vs. 87.2%, $p=0.561$), metastasis-free survival rate (100% vs. 98.6%, $p=0.437$), overall survival rate (96.6% vs 90.0%, $p=0.613$) and cause-specific survival rate (98.9% vs 98.5%, $p=0.264$) for AI group and RI group were comparable.

Conclusion: Aged RI EESCC patients without AT(esophagectomy or chemoradiotherapy) showed comparable prognosis outcomes with AI group after ESD. So follow up may be recommended, substituted for AT in aged RI group.

P1459 RETROSPECTIVE ANALYSIS ON SUSPICION OF FOREIGN BODY INGESTION AND FOOD IMPACTION ON GASTROENTEROLOGY EMERGENCIES

J. T. Correia De Sousa¹, D. Libanio¹, P. Lago¹, R. Marcos-Pinto¹, I. Pedroto¹

¹Gastroenterology, Centro Hospitalar do Porto, Porto/Portugal

Contact E-mail Address: joao.correia.de.sousa@gmail.com

Introduction: Suspicion of foreign body (FB) and food impaction (FI) are one of the most common motives for endoscopic emergency. This retrospective study reviewed 288 cases of suspicion on FB/FI, by the frequency of endoscopic alterations, predictive factors to presence, types of FB found, and therapeutic approach.

Aims & Methods: Unicentric retrospective cohort study of endoscopies performed during one year of gastroenterology emergency setting.

Results: In 2015, 288 endoscopies were performed on suspicion of FB/FI (22% of total emergency endoscopies, $n=1309$), of them 69.1% ($N=199$) were performed during the night. Patients' median age was 58 years, and 52.8% were women. The presence of FB/FI was confirmed in 71.2% ($n=205$); of them 61.5% ($n=126$) were FI. The most frequently found foreign bodies were meat bones 18% ($n=37$) and fish bones 14.6% ($n=30$). Most FB/FI were found on the proximal esophagus (56.1%, $n=115$). Endoscopic removal was performed on 129 cases (63.4%), endoscopic mobilization in 54 (26.3%), and in 22 endoscopic removal wasn't achieved (10, where referred of otolaryngology; 2 for surgery and 10 were deferred to endoscopy with sedation, in operating room). Endoscopy under sedation was performed in 20 cases (9.7%). About ¼ had associated comorbidities, the most common were esophageal ring in 22 (10.7%) and benign stenosis in 17(8.3%) patients. Major complications were rare: 1 perforation (0.3%) and 3 deep esophageal lacerations (1.5%). Age (>55years), presence of comorbidities, and previous episodes were associated with presence of FB/FI on Endoscopy (Odds Ratio 2.01, 3.39 and 4.63 respectively).

Conclusion: Endoscopy is frequently preformed for suspicion of FB/FI in our emergency setting. Presence is confirmed in the majority of the cases. Predictive factors for presence were identified. Most FB/FI were removed with success with low complication rates. This data favor the endoscopic approach on suspicion of FB/FI.

P1460 LEARNING CURVE FOR ENDOSCOPIC SUBMUCOSAL DISSECTION OF GASTRIC NEOPLASMS; LOW-VOLUME SINGLE-CENTER EXPERIENCE

S.T. Kim, T.H. Kim, S. Na

Internal Medicine, Jeju National University Hospital, Jeju/Korea, Republic of

Contact E-mail Address: panzervor@paran.com

Introduction: Endoscopic submucosal dissection (ESD) has become a standard therapy for early gastric neoplasia. There is no consensus yet about the number of experiences required for performing ESD alone.

Aims & Methods: We aimed to investigate the learning curve of ESD performed by a single beginner endoscopist focusing on developing the performance of dissection, shortening the procedure time, and preventing complications.

Methods: Records of 120 consecutive ESD procedures performed by a single beginner endoscopist with an ESD knife from March 2012 to February 2016 were collected. For analysis of the learning curve, total procedures were divided into four periods, each comprising 30 sequential ESD. The parameters assessed were the en-bloc resection rate, complete resection rate, procedure time, and related complications.

Results: In the procedure time according to the number of experiences, the procedure time decreased from 30 experience. However, there was no statistical difference from the first (63.5 ± 54.0) to the second quarter (44.5 ± 31.4 , $p=0.19$), to the third quarter (40.7 ± 27.8 , $p=0.08$), and to the fourth quarter (40.8 ± 23.1 , $p=0.09$). There was no procedure that exceeded 100 minutes from the third quarter. There were a total of seven perforations, four of which were in the first quarter, two in the second, and one in the third. In the procedure time according to the location of the lesions, upper third lesion (92.0 ± 43.7) showed longer procedure time than middle (46.6 ± 40.2 , $p < 0.01$) and lower third (39.5 ± 27.5 , $p < 0.01$) with statistically significant difference. In addition, in the fibrotic lesions, regardless of size and location, all took a very long time, more than 100 minutes.

Conclusion: It needs accumulate experience with the help of a professional expert up to 30 cases, and to the more advanced level, about 90 procedures are needed. And, the location of the lesion is the important factor in determining the difficulty of the procedure. Therefore, it is best to avoid the upper third lesion as far as possible until experience 90 cases or at least 30 procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1461 COMPARATIVE STUDY OF ESD AND SURGICAL RESECTION FOR GASTRIC SETS ORIGINATED FROM MUSCULARISPROPIA

C.B. Ryu¹, M.S. Lee¹, J.Y. Bae²

¹Digestive Disease Center And Research Institute, Department Of Internal Medicine, SoonChunHyang University School of Medicine, Bucheon/Korea, Republic of

²Department Of Internal Medicine, Seoul Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: ryuchb@gmail.com

Introduction: Endoscopic resection for gastric subepithelial tumors (SETs) originated from the muscularispropria (GSET-PM) has offered less invasive alternatives to surgical resection. The aims of this study were to compare endoscopic submucosal dissection (ESD) with surgical resection for the removal of GSET-PM.

Aims & Methods: This study involved 17 patients with GSET-PM removed by ESD and 76 patients who underwent curative surgical resection. ESD was attempted in GSET-PM with well marginated tumors which was below 5cm and showed an endoluminal growth pattern according to endoscopic ultrasound (EUS) finding.

Results: ESD group were more likely to have upper portion (10/17, 58.8%) and surgery group were more likely to have mid portion (41/76, 53.8%) ($p=0.039$). ESD group were smaller median tumor size (25.6 mm vs 35.9 mm, $p=0.037$) and higher endoluminal ratio ($58.5 \pm 9.1\%$ vs $45.8 \pm 15.4\%$, $p=0.002$). ESD group were mostly to have Yamada type III (10/17, 58.8%) and surgery group were mostly Yamada type I (52/76, 68.4%) ($p < 0.001$). Complete resection by ESD was lower than by surgical resection (82.4% vs 100%, $p < 0.001$). In ESD group, 3 performed surgical resection after ESD (1 incompletely resection and 2 uncontrolled bleeding) and 1 showed perforation was completely resected with endoscopic closure. In surgery group, complications occurred in 6 patients (1 leakage, 1 stricture, 1 hernia and bowel obstruction, 1 wound infection and 2 worsened general condition after surgery). Although surgery group were lower in complication rate than ESD group ($p=0.006$), severity of complications were higher in the surgery group and there were no mortalities in the ESD group compared with 2 in the surgery group. There was no statistical difference of recurrence and the follow-up period between two groups.

Conclusion: Conclusion: ESD can be one of good options for the resection of endoluminal GSET-PM and could be replace treatment by surgical resection in Yamada type III with a high endoluminal ratio.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1462 CAP ASSISTED UPPER ENDOSCOPY VERSUS SIDE-VIEWING ENDOSCOPE FOR EXAMINATION OF THE MAJOR DUODENAL PAPILLA: A RANDOMIZED, BLINDED, CONTROLLED, NON-INFERIORITY CROSSOVER STUDY (CAPPA-II STUDY)

Introduction: Examination of major duodenal papilla (MDP) by standard forward-viewing is limited and the use of side-viewing endoscope (SVE) is mandatory. Cap assisted esophagogastroduodenoscopy (CA-EGD) utilizes a cap fitted to the tip of the endoscope that can depress the mucosal folds and thus might improve visualization of MDP. The aim of this study was to compare CA-EGD to SVE for complete examination of the MDP.

Aims & Methods: Prospective, randomized, blinded, controlled, non-inferiority crossover study. Subjects scheduled for elective EGD were randomized to undergo CA-EGD (group A) or SVE (group B) before undergoing a second examination by the alternate method. Images of the MDP were evaluated, after image processing, by three blinded multicenter-experts. Our primary outcome measure was complete examination of the papilla. Secondary outcome measures were image quality of mucosal pattern, ability to obtain an overview of the papilla and overall satisfaction of the evaluators. For secondary outcomes, a score was given from 1 to 10 (1=poor, 10=excellent).

Results: A total of 62 patients were randomized and completed the study. Complete examination of MDP was achieved in 59 patients using CA-EGD compared to 60 patients using SVE (95 vs. 97%, $p=1.0$). CA-EGD had mean scores of 8.7 ± 1.3 , 7.1 ± 0.86 and 7.9 ± 1 regarding mucosal pattern, overview and overall satisfaction, respectively, versus 5.3 ± 1.6 ($p < 0.001$), 8.3 ± 0.9 ($p < 0.001$) and 7.6 ± 0.6 with SVE ($p=0.01$).

Conclusion: CA-EGD is non-inferior to SVE for complete examination of MDP. CA-EGD had significantly higher scores than SVE regarding the image quality and overall satisfaction, while SVE had a better overview. CA-EGD is a safe and effective method for examination of MDP and can replace the SVE for diagnostic indications.

P1463 (IN)ACCURACY OF CAMBRIDGE PROTOCOL FOR PATIENTS HARBOURING CDH1 MUTATION: A CONSECUTIVE SERIES

R. Castro, D. Libânio Monteiro, T. Pinto-Pais, M. Dinis-Ribeiro, C. Brandão
Department Of Gastroenterology, Instituto Português de Oncologia, Porto, Porto/Portugal

Contact E-mail Address: rui.arrais.castro@gmail.com

Introduction: Hereditary diffuse gastric cancer (HDGC) accounts for 1 to 3% of all gastric cancer and it can be caused by a germline mutation of the gene CDH1. Life time risk for gastric cancer is 80% with a mean age at diagnosis of 40 years. Affected individuals generally present multiple foci of signet ring cell carcinoma (SRCC) scattered throughout the gastric mucosa, difficulty detected by endoscopy.

Aims & Methods: The aim of this study was to access the validity of Cambridge protocol with a high-resolution endoscope in patients with proven pathological germline mutation of the gene CDH1. A prospective cohort study was performed between September 2016 and March 2017 in 11 patients with CDH1 mutation. They perform a base line high-resolution endoscopy (Olympus-GIF-HQ190) with random biopsies according Cambridge protocol and additional targeted biopsies of any visible lesion. The total number of biopsies and the total number and localization of SRCC foci was registered. For those patients submitted to prophylactic gastrectomy, data was compared with surgical specimen histology. To access the validity of Cambridge protocol with a high resolution endoscope in patients with proven pathological germline mutation of the gene CDH1.

Results: During the 11 endoscopies a total of 353 biopsies (329 random biopsies and 24 targeted biopsies; mean of 32.1 biopsies per patient) were performed. Two patients presented 1 SRCC foci in random biopsies, being that one of them presented positive histology in 2 targeted biopsies. It was necessary to perform 165 random biopsies to identify a single SRCC foci. It was necessary 12 targeted biopsies to identify a SRCC foci associated with a visible lesion. Five patients were submitted to total gastrectomy and every surgical specimens presented SRCC foci.

Conclusion: Despite the use of high-resolution endoscopes and the high number of random biopsies, endoscopic evaluation presents many limitations for the diagnosis of HDGC. According to literature, prophylactic total gastrectomy remains the first option in patients carrying CDH1 mutation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic clips are used in a variety of clinical situations in GI endoscopy—for arrest of bleeding or for closure of bowel perforations or chronic fistulae. Conventional through-the-scope clips often cannot provide optimum results; and therefore full-thickness (FT) over-the-scope (OTS) clips have been devised.

Aims & Methods: Current study describes the clinical experience of use of a recently developed FT OTS clip (Padlock™, Aponos Medical, USA). Data from a prospectively maintained database of all patients undergoing the new FT OTS clip was abstracted. Patient demographics, primary diagnosis, history of previous endotherapy, endoscopic procedure, indications for FT OTS clip usage, technical and clinical success and early and delayed adverse events were recorded. The clip—clip is available in two different sizes for use in upper and lower endoscopy. It is supplied preloaded on a cartridge that fits on the distal end of endoscope. The trip-wire travels alongside the endoscope, enabling additional instruments to be passed through the endoscope channel, and special double-channel endoscope is not required for its application. Technique of clip application—the clip was loaded on the distal end of the endoscope and endoscope advanced to site of interest. Bowel wall defect or bleeding point was positioned within the clip and strong suction was applied. Clip was fired by closing the handle on the delivery system. Suction was slowly released and site was inspected.

Results: Total 21 clips used in 19 patients. M: F=12:7, mean age=57.9 years (range –24–84 years). Indications for FT OTS clip use—severe GI bleeding—7 (36.8%) (duodenal ulcer bleed—5, rectal ulcer—1, bleed during ESD for rectal lateral spreading tumor—1); for closure of bowel perforation during endoscopic resections—7 (36.8%) (gastric—3, duodenum—2, rectum—2); and closure of chronic bowel fistulae—5 (26.3%) (esophagus—3, duodenum—1, rectum—1). Previous h/o endotherapy—3/7 of bleeding patients, primary therapy using OTS clip in remaining 16. Technical success was 100%. Two patients needed two clips each due to large size of defect. Clinical success—bleeding arrested in 7/7 (100%), bowel perforation sealed—7/7 (100%); fistula closure successful—4/5 (80%). In one patient of chronic duodenal fistula, fistula reopened 12 weeks after initial sealing of fistula and required surgery. Follow up at 4 weeks revealed no delayed adverse events in any patient.

Conclusion: The new OTS Clip (Padlock™, Aponos) is safe and effective for treatment of severe bleeding and for closure of post ER full-thickness defects and chronic fistulae. Further studies with larger sample size are recommended.

Contact E-mail Address: bmiutescu@yahoo.com

Introduction: Endoscopic resection of ampullary adenomas has increased in the last decade due to the high morbidity with a high mortality in patients undergoing surgical procedures.

Aims & Methods: This study aims to evaluate the outcome of endoscopic ampullectomy (EA) in a tertiary endoscopy department. We included in the study patients that underwent EA between January 2014 - April 2017 at the Regional Institute of Gastroenterology and Hepatology Cluj-Napoca, Romania. All patients had a benign pathological result prior to the EA. Post-procedural complications such as bleeding, perforation, cholangitis, pancreatitis and mortality were analyzed. Data about resection type, post EA histology and 1 year follow-up was also processed.

Results: 19 patients underwent EA, with a mean age of 63.5 ± 17.7 years and a mean size of the tumor of 17.4 ± 7.8 mm. The male to female ratio is 0.7. "En bloc" resection was done in most cases 15/19 (78.9%). Bleeding occurred in 6 cases (31.6%) and two patients (10.5%) developed acute pancreatitis. One patient died due to severe bleeding. The average days of hospitalization after endoscopic ampullectomy were 5.7 with a range from 2 to 25 days. Adenocarcinoma was described in the final histopathological result in 4/19 cases (21.1%). One year follow-up noted a recurrence rate of 15.8% (3/19 cases).

Conclusion: In conclusion, endoscopic ampullectomy is a difficult procedure with an increased risk of complications but performed by experienced endoscopists is safe and surgical interventions can be avoided.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1466 PER ORAL ENDOSCOPIC MYOTOMY: UPDATED RESULTS FROM A UNITED KINGDOM CASE SERIES

S. Gulati¹, A. Emmanuel¹, H. Inoue², A. Haji¹, B. Hayee¹

¹Endoscopy, King's Institute of Therapeutic Endoscopy, RS/United Kingdom

²Digestive Disease Center, Showa University Koto-Toyosu Hospital, Tokyo/Japan

Contact E-mail Address: shraddha.gulati@nhs.net

Introduction: Per-oral endoscopic myotomy (POEM) has been adopted as a minimally invasive treatment option for achalasia and even spastic oesophageal conditions¹. The first case of POEM was performed at the King's Institute of Therapeutic Endoscopy (KITE) in 2013. Here we present our initial case series including the first UK case of diffuse oesophageal spasm (DES).

Aims & Methods: Prospective data was collected for consecutive patients undergoing POEM including demographics, POEM technique, the use of Endoluminal Functional Lumen Imaging Probe (EndoFLIP) and adverse events. Clinical success was defined as a reduction of Eckardt score (ES) to ≤ 2 or a reduction in 4 points from baseline. Follow up data at 3 and 12–24 months (m) post-POEM was analysed using the Wilcoxon signed ranks test to compare pre- and post-POEM ES and 4sIRP and pre and post-treatment GORD-HRQoL score. Repeated-measures ANOVA was used for multiple time-point comparisons.

Results: POEM was performed in 51 patients (22F, age 48.6 ± 13.5 years). Further baseline data is presented in table 1. Median gastric and oesophageal myotomy was 3 cm (2–4) and 10 cm (3–18) respectively with a selective circular myotomy in all cases and a posterior approach in 11. POEM was clinically successful in $n=48/51$ (94%) eligible for review at 3m. Reduction in ES at 3m; 8.5 (5–12) vs 0 (0–6) $p < 0.0001$ was sustained in 31 patients with median follow up of 15 m (3–36); 8.5 (5–12) vs 2 (0–7) ANOVA $p < 0.0001$. Reduction in IRP-4s was observed 24.05 ± 10.47 mmHg vs 7.81 ± 4.91 mmHg ($p=0.001$). Revision of POEM was performed in $n=3$ at 6, 16 and 27 m with clinical success achieved in all cases at 3 m review. Pre and post-myotomy EndoFLIP showed an increase in oesophago-gastric junction diameter from 5.87 mm to 11.27 mm ($p < 0.001$) ($n=11$) and distensibility improved from 1.14 mm²/mmHg to 2.87 mm²/mmHg ($p=0.008$) ($n=8$). Median post-POEM GORD-HRQoL score ($n=50$) was 1 (0–31). 8 patients with scores > 12 improved with medical treatment; 15.5 (13–31) vs 6.5 (1–11, $p=0.0078$) as did 5 cases of acid reflux identified by 24 hr pH testing in $n=19$ at time of analysis. Endoclip displacement was encountered in $n=2$ and replaced endoscopically including readmission of 1 patient for delayed mucosal incision site healing (Clavien-Dindo Grade IIb). There were no cases of mortality, perforation, infection/major bleeding.

Table 1: Baseline characteristics

Patient Demographics	
Age (mean, SD, range) (years)	48.6 ± 13.5 (22–79)
Male (n) (%)	29 (57)
Female (n) (%)	22 (43)
Clinical Data	
Duration of disease (mean, SD, range) (years)	4.4 ± 4.2 (0.25–25)
Eckardt Score (median, range)	8 (4–12)
Chicago Subcategorisation	
Achalasia Type I (n) (%)	4 (8)
Achalasia Type II (n) (%)	42 (82)
Achalasia Type III (n) (%)	2 (4)
DES	1 (2)
Uncategorised (EndoFLIP used)	2 (4)
Non-Sigmoid Oesophagus (n) (%)	45 (88)
Sigmoid Oesophagus (n) (%)	6 (12)
Treatment History	
Prior Achalasia Treatment	27 (53%)
Prior Botulinum Toxin Injection; BTX (n) (%)	9 (18)
Prior Pneumatic Dilatation; PD (n) (%)	13 (25)
Prior Heller Myotomy; LHM (n) (%)	9 (18)

(continued)

Table 1 Continued

Patient Demographics	
Prior POEM (n) (%)	3 (6)
> 2 prior treatments (n) (%)	4 (8)
ASA Physical Status Classification	
ASA grade I (n) (%)	21 (41)
ASA grade II (n) (%)	22 (43)
ASA grade III (n) (%)	8 (16)

Conclusion: This is the largest UK case series of POEM for achalasia including the first successful UK POEM procedure for DES. At our institute, POEM was performed successfully in a potentially more challenging cohort where 52.9% had prior endoscopic/surgical treatment. Our results are in line with international consortia and ASGE findings that POEM is a safe and efficacious procedure for the treatment of achalasia and oesophageal spastic disorders for both short term and sustained symptomatic benefit.

P1467 NEW CHALLENGE FOR SAFER ENDOSCOPIC SUBMUCOSAL DISSECTION USING CO₂ LASER

Y. Morita, R. Ariyoshi

Gastroenterology, Kobe University, Kobe/Japan

Contact E-mail Address: ymorita@med.kobe-u.ac.jp

Introduction: Endoscopic submucosal dissection (ESD) is increasingly accepted as a minimally invasive treatment for the patients with early gastrointestinal cancers. However, ESD demands high maneuverability technique, and the success of the operation is dependent of each operator's skill. We have developed a novel laser surgery system for ESD to overcome such difficulties of ESD, which is composed of a CO₂ laser source and a disposable flexible hollow fiber probe. Compared to conventional ESD (C-ESD) using electric surgical knives, ESD using CO₂ laser (L-ESD) method has an advantage of less risk of perforation and massive thermal damage, because the CO₂ laser is strongly absorbed by water such as saline or sodium hyaluronate. Farther more, the cutting point can be precisely recognized by another visible guide laser. Due to non-contact laser irradiation and adequate visualization of treatment area, the laser system facilitates more precise and safer treatment and provides high quality and stable dissection. We hypothesized that performing ESD using CO₂ laser with a submucosal laser absorber could be a safer and simpler ESD technique.

Aims & Methods: The aim of this study was to evaluate the feasibility of L-ESD and the quality of the resected specimen obtained by L-ESD in living porcine compared with C-ESD. We performed ESD for a total of 14 hypothetical lesions in three porcine stomachs (L-ESD, 7 lesions; C-ESD 7 lesions) under general anesthesia. En-bloc resection rate, procedure time, adverse events, and the quality of the resected specimen were evaluated. To evaluate the smoothness of the cutting surface in the resected specimens, we compared the length of the resected side of the submucosa (LRS) with the length of the muscularis mucosa (LMM).

Results: The en-bloc resection rate was 100% in both groups. Although the mean L-ESD procedure time was 23.3 ± 10.8 minutes, and was significantly longer than in the C-ESD group (9.4 ± 6.6 minutes; $p < 0.05$), there was no uncontrollable bleeding or perforation in either group. The mean ratio of LRS to LMM was $107 \pm 3.3\%$ in the L-ESD group, and was significantly lower than that of the C-ESD group ($138 \pm 28\%$) ($P < 0.005$).

Conclusion: ESD using CO₂ laser might be a feasible and effective method for the treatment of early gastrointestinal cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1468 LONG-TERM OUTCOME OF ACUTE CORROSIVE INGESTION: A PROSPECTIVE SINGLE-CENTER STUDY

S. Dhar Chowdhury, B. Kumar, R. T. Kurien, S. K. Ghatak, D. Sreekar

Gastroenterology, Christian Medical College, Vellore, Vellore/India

Contact E-mail Address: sudipta@cmcvellore.ac.in

Introduction: Acute corrosive ingestion (ACI) is a common and serious medical problem accounting for a number of hospital admissions. ACI causes significant mortality and morbidity. These patients are at risk of developing luminal strictures of the upper gastrointestinal tract in the long term. This is more in patients with high-grade injury.

Aims & Methods: The present study aimed at assessing the long-term outcomes of high-grade (Zargar's grade \geq Grade 2A) corrosive-induced injury of upper gastrointestinal tract (1). This was a prospective study conducted in the Department of Gastroenterology at Christian Medical College, Vellore. The study period was between January 2008 to December 2014. All patients were managed by a standard protocol which included doing a gastroscopy within 24 hours of ACI. In this study we included patients ≥ 15 years with high-grade (Zargar's grade

≥Grade 2A) corrosive-induced injury of upper gastrointestinal tract. Patients in whom gastroscopy could not be done or who had it done at another hospital were excluded from the study. The study was approved by the Institutional Ethics committee and was funded by a fluid research grant received from Institutional Review Board at Christian Medical College, Vellore, India. The data was analysed using SPSS version 17. The parametric continuous variables were expressed as, mean ± SD and the non parametric continuous variables were expressed as median. Comparison between groups was done using Fisher's exact test.

Results: During the study period a total of 112 patients presented with ACI. In all 82 patients were included in the study. Amongst them, 53% of the patients were females and the mean age was 36.5 ± 15.5 years. The intent of corrosive ingestion was suicidal in 70% and accidental in 30%. In majority (50%) of patients the nature of corrosive was not known. Nasogastric tube placement was done in 50%, nasojejunal tube placement in 32% and 8% no tube was placed. Surgery as needed in 19% (tracheostomy or feeding jejunostomy or a definitive surgery). Amongst the 82 patients who were included in the study, 11 were lost to follow up. Follow up was done in 71 patients in whom the median follow up period was 31 months (range 2m–72m) during which 12 (16.9%) patients expired (73% related to ACI). Amongst the 59 patients, that were alive 16(27%) were symptomatic, 12(20%) had dysphagia, 5(6%) had regurgitation, 4(5%) had chest pain, 6(7%) had weight loss and 11(18%) patients required diet modification. In all, 43(73%) patients underwent barium study during follow up and strictures were noted in 21(36%). The site of stricture was esophageal in 11(53%), stomach in 8(38%) and combined esophageal and stomach in 2(9%). Esophageal stricture was seen in all patients with Grade III B esophageal injury, 27% (6/22) with Grade III A injury and 19%(5/27) with Grade II B injury. None of the patients with Grade II A injury developed stricture. Stricture in stomach developed in 25% (2/8) patients with Grade III B injury, 25% (6/24) with Grade III A injury, 10%(1/10) with II B injury and 20% (1/5) with II A injury.

Conclusion: Acute corrosive ingestion is associated with significant morbidity and mortality. There needs to be stringent control on sale, use and storage of such chemicals.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Probe-based confocal laser endomicroscopy (pCLE) provides real-time microscopic visualization with 1000-fold magnification, allowing endoscopic access to the histological evaluation of gastrointestinal lesions. pCLE may thereby be helpful in guidance of endoscopic therapy. However, histopathological assessment still remains a gold standard for histological diagnosis so far, while pCLE-based diagnosis has not been generally accepted yet. Therefore, more studies assessing diagnostic accuracy of pCLE are warranted.

Aims & Methods: The aim of this study was to compare diagnostic accuracy of pCLE with standard biopsies in the diagnosis of macroscopically visible esophageal and gastric lesions.

A single-center, prospective, controlled and pathologist blinded study. We enrolled all consecutive patients with a visible esophageal or gastric lesion. All patients underwent high-resolution endoscopy and the lesion was examined by pCLE. After pCLE, standard biopsies were taken from the lesion and the specimen was sent for standard histopathological assessment. Final diagnosis was determined based on assessment of endoscopic or surgical resection specimen (if possible) or standard biopsies. Some of the patients with an obviously malignant lesion underwent endoscopic resection immediately after pCLE without standard biopsies being obtained. Main outcomes of the study were diagnostic accuracy, sensitivity and specificity of pCLE vs. standard biopsies.

Results: We examined 45 lesions (38 esophageal, 7 gastric) in 41 patients. Definitive diagnoses revealed 28 malignant lesions (21x adenocarcinoma (AC), 7x squamous carcinoma (SCC)) and 17 benign lesions. In summary, pCLE diagnosis was correct in 76% (34/45) and incorrect in 24% (11/45) while diagnosis based on biopsy was correct in 73% (27/37) and incorrect in 27% (10/37). pCLE confirmed malignant diagnosis in 81% (22/27) of cases and biopsy in 65% (10/16) (in 6 patients with a definitive diagnosis of AC and SCC, biopsies showed low- or high-grade dysplasia or necrotic tissue). Benign diagnosis was accurate in 65% (11/17) of lesions based on pCLE vs. 100% of lesions (17/17) based on biopsy. Overall sensitivity, specificity, and diagnostic accuracy of biopsies were 67% CI 95 (49–88%), 100% (54–100%) and 83% (68–94); sensitivity, specificity, and accuracy of pCLE for the correct histological diagnosis were 81% (62–93%), 91% (59–99%) and 84% (70–93), respectively.

Conclusion: pCLE provides satisfactory diagnostic accuracy comparable with standard biopsies in malignant esophageal and gastric lesions in particular.

Introduction: Non-variceal upper digestive bleeding (NV-UDB) represents a significant cause of hospital admission. In order to stratify patients according to the risk of the complications (re-bleeding/death), and to predict the need of clinical intervention and patient's outcome, several risk scores have been proposed by international guidelines and implemented in clinical practice.

Aims & Methods: The aim of the study consisted in the analysis of the accuracy of three risk scoring systems used in non-variceal upper digestive bleeding for assessing patient's prognosis, previously estimated to be predictive for re-bleeding/death after gastrointestinal bleeding. We assessed prospectively a batch of 1872 patients admitted in the Gastroenterology Department of Emergency County Hospital Timisoara in a 12-year period, in which we calculated 3 risk scoring systems, Rockall, Cedars-Sinai and Baylor, based on clinical and endoscopic data. We compared their accuracy for assessing patient's prognosis, expressed as the need of blood transfusions, number of hospitalization days, re-bleeding, surgery and death. Discriminative ability was assessed using the area under the receiver operating characteristic curve (AUROC).

Results: The batch included 1134 (60.6%) male and 738 (39.4%) female, mean age 62 ± 7.8 years. Regarding the need of blood transfusions, the predictive ability of the scores is as follows: Rockall AUROC 0.59 CI(0.55–0.62), sensitivity(Se) = 81.7%, specificity(Sp) = 35.5%, positive predictive value(PPV) = 28.4%, negative predictive value(NPV) = 86.1% (p < 0.0001); Cedars-Sinai AUROC 0.59 CI(0.55–0.63), Se = 72.4%, Sp = 41.3%, PPV = 28.5%, NPV = 82.3% (p < 0.001); Baylor AUROC 0.56 CI(0.49–0.63), Se = 41.9%, Sp = 75.5%, PPV = 40.6%, NPV = 76.5%. Number of hospitalization days: Rockall AUROC 0.66 CI(0.55–0.77), Se = 61.5%, Sp = 65.2%, PPV = 90%, NPV = 25% (p = 0.003); Cedars-Sinai AUROC 0.63 CI(0.50–0.75), Se = 53.1%, Sp = 73.9%, PPV = 89.5%, NPV = 27.4%; Baylor AUROC 0.52 CI(0.51–0.73), Se = 47.06%, Sp = 66.6%, PPV = 84.2%, NPV = 25%. Re-bleeding: Rockall AUROC 0.69 CI(0.66–0.73), Se = 69.1%, Sp = 60.4%, PPV = 14.2%, NPV = 92.8% (p < 0.0001); Cedars-Sinai AUROC 0.73 CI(0.69–0.77), Se = 84.4%, Sp = 49.02%, PPV = 13.7%, NPV = 97%; Baylor AUROC 0.54 CI(0.45–0.63), Se = 35.1%, Sp = 81.2%, PPV = 16.2%, NPV = 92.4%. Surgery: Rockall AUROC 0.67 CI(0.61–0.73), Se = 71.2%, Sp = 59%, PPV = 16%, NPV = 98.1%; Cedars-Sinai AUROC 0.72 CI(0.66–0.78), Se = 58%, Sp = 77.4%, PPV = 9.3%, NPV = 97.9%; Baylor AUROC 0.55 CI(0.41–0.68), Se = 50%, Sp = 66.2%, PPV = 5.1%, NPV = 97.4%. Death: Rockall AUROC 0.85 CI(0.81–0.89), Se = 84.7%, Sp = 76%, PPV = 18.2%, NPV = 99.5% (p < 0.0001); Cedars-Sinai AUROC 0.71 CI(0.66–0.76), Se = 83.1%, Sp = 48.1%, PPV = 10.2%, NPV = 97.6%; Baylor AUROC 0.75 CI(0.67–0.83), Se = 76.09%, Sp = 72.3%, PPV = 19.2%, NPV = 97.2%. There were no statistically significant differences encountered in predicting the need of blood transfusions and surgery between the scores (p > 0.05). Baylor score was superior vs Rockall in estimating the hospitalization period (p = 0.04) and the risk of re-bleeding (p = 0.0009), and Cedars-Sinai proved to be superior to Baylor score in predicting re-bleeding (p = 0.002) and to Rockall score in predicting death (p = 0.006).

Conclusion: On our cohort of patients, Cedars-Sinai score proved to be the best in predicting the re-bleeding and death in patients with NV-UDB in comparison to Rockall and Baylor scores.

Introduction: Dysphagia and malnutrition is a common feature in up to 64% of patients with head and neck, esophagus and gastro-esophageal cancer, and the need of radiotherapy or chemotherapy often worsens these symptoms. Percutaneous endoscopic gastrostomy (PEG) is the preferred route of feeding and nutritional support in these patients. Although generally considered to be a safe procedure, it has been arguable that PEG tube placement complications in cancer patients may be superior when compared to non-cancer patients.

Aims & Methods: The aim of this study was to evaluate the complications rate after PEG tube placement in cancer patients. We did a single-centre prospective database including all patients with PEG tube insertion between March 2014 and June 2016, evaluating the complications during 6 months follow-up.

Results: A total of 265 patients (83% men, mean age 59 years) underwent PEG tube insertion. 224 patients (84.5%) had head and neck cancers and 33 patients

(12.5%) had esophageal cancer; 207 patients (78.1%) had stage IV disease. At the time of PEG tube placement, 138 patients (52%) had grade 3 dysphagia and the mean body mass index (BMI) was 20.9 Kg/m². All the patients underwent antibiotic prophylaxis previous to the procedure. There was an increase on BMI to 23.8 Kg/m² at 6 months follow up. Eight patients (3.8%) had immediate complications after the procedure (bleeding from the PEG tract-6; anesthetic complications - 2). The overall complication rate at the first month of follow up was 14.4%, at the third month 20.5% and at the sixth month 11.7%. The overall peri-PEG infection rate was 14%, and was the main complication at the first month of follow up. Development of hyper-granulation tissue was the most frequent complication at the third month of follow-up. Buried bumper syndrome occurred in 10 patients (3.7%). None of the patients had tumor seeding at the gastrostomy site. Overall mortality was 26.4%, none of the deaths attributable to PEG tube insertion.

Conclusion: PEG placement is a safe and effective technique in cancer patients. The rate of major complications and tube site infection were similar to the results found in literature for non-cancer patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Probe-based confocal laser endomicroscopy (pCLE) has been developed to overcome limitations of the current endoscopic sampling techniques. pCLE allows detailed examination of cellular structures and may examine larger areas compared to standard biopsy. Patients after endoscopic treatment of Barrett's esophagus (BE)-related neoplasia (BORN) should undergo endoscopic surveillance with biopsies to detect persistence or recurrence of intestinal metaplasia (IM) or neoplasia (N).

Aims & Methods: The aim of this prospective study was to evaluate the efficacy of pCLE (vs. standard biopsies) in detection of persistent/recurrent IM/neoplasia in patients after endoscopic treatment of BORN. A single-center, prospective, controlled and pathologist-blinded (still ongoing) study in patients undergoing surveillance endoscopy after endoscopic treatment of BORN. pCLE images were obtained from the neo-Z-line (a few cases including macroscopically visible tongues), the cardia and the esophagus. Thereafter, standard biopsies were taken and sent for histopathological analysis (4 biopsies from macroscopically normal neo-Z-line, 2 biopsies from the cardia and the esophagus and targeted biopsies from visible abnormalities, if present). BE was defined in pCLE as columnar-lined epithelium with dark mucin in goblet cells, a villiform pattern, and regular-shaped capillaries in the mucosa. The dysplastic BE was characterized by black cells with irregular borders and shapes, high dark contrast to the surrounding tissue, and irregular leaking capillaries in the mucosa.

Results: We examined 29 patients, from these 14 patients (48%) had the initial diagnosis of low-grade intraepithelial neoplasia (LGIN), 7 patients (24%) had high-grade intraepithelial neoplasia (HGIN) and 8 patients (28%) had an early adenocarcinoma (EAC). Persistent/recurrent IM was detected at the level of neo-Z-line in 10 patients (34.5%) by both standard biopsies and pCLE. pCLE but not biopsies detected persistent/recurrent IM in 2 patients (6.7%), another 2 patients had IM present in biopsies but not in pCLE. pCLE diagnosed one patient with recurrent LGIN in a macroscopic visible tongue arising from neo-Z-line, which was not confirmed in biopsies. Sensitivity and specificity of pCLE detection of persistent/recurrent IM was 83.3% (95% CI 51.6–97.9) and 89.47% (95% CI 66.9–98.7), respectively, with positive predictive value 83.3% (95% CI 56.1–95.0) and negative predictive value 89.5% (95% CI 70.4–96.8). Agreement of pCLE and histopathological findings was 86%.

Conclusion: pCLE seems to be comparable with standard biopsies in detection of persistent/recurrent IM after endoscopic treatment of BORN. Nevertheless, these results need to be confirmed in a larger cohort of patients. *Supported by a grant from Ministry of Health of the Czech Republic, No. 16–27648A.*

P1473 FLEXIBLE ENDOSCOPIC SEPTUM DIVISION (FESD) OF ZENKER'S DIVERTICULUM: OUTCOMES FROM A SINGLE TERTIARY CENTER USING A NEW SYMPTOMS SCORE

R. Maselli, G. Lollo, M. Di Leo, R. Nicoletti, E. Finati, P.A. Galtieri, L. Poliani, F. Auriemma, R. Semeraro, A. Fugazza, E.C. Ferrara, A. Anderloni, S. Carrara, A. Repici

Humanitas Research Hospital, Rozzano/Italy

Contact E-mail Address: roberta.maselli@humanitas.it

Introduction: Symptomatic Zenker's diverticulum (ZD) can be treated by flexible endoscopic septum division (FESD) as a minimally invasive alternative to surgery or to rigid endoscopic procedure. There is still a lack of standardization of the FESD as well as data on late outcome are scarcely reported. Moreover, FESD outcomes are differently reported in available literature and no specific scores have been yet validated.

Aims & Methods: We aim to report the outcome of all ZD treated by FESD in our institution by using a new symptoms score. We retrospectively reviewed consecutive patients with ZD treated by FESD in a single tertiary-care academic medical center between April 2014 and Feb 2017. All patients were included in a prospectively maintained database. A dedicated new score was created to obtain reliable and objective evaluation of outcome of our patients. This score (Milano-Zenker score, MZ-score) is based on the three main ZD symptoms: dysphagia, regurgitation and weight loss. The ZD score (maximum score, 9) is the sum of the symptom scores for dysphagia, regurgitation (for both: 0, absent; 1, occasional; 2, daily; and 3, each meal), and weight loss (0, no weight loss; 1, <5 kg; 2, 5–10 kg; and 3, >10 kg). The main outcome was clinical success, defined as MZ score ≤2 at the latest follow up. Patient's symptoms were evaluated at 1 month and at every 6 months after the procedure. Adverse events were recorded and classified as intraprocedural, postprocedural (<14 days), and late (15–30 days).

Results: 100 patients underwent FESD, with a mean age of 70.3 ± 11.2 years (range 39–95) and prevalence of male gender (66%). Twenty-nine (29%) of treated ZD were re-intervention: 20 (69%) after previous FESD; 8 (27.6%) after previous surgery; 1 (3.4%) after previous surgery and FESD. Mean initial MZ score was 4.5 ± 1.8 (range 1–8). Intraprocedural bleeding was observed in 5 patients (5%), with all of successfully treated by clips. No postprocedural/late bleedings were recorded. One perforation was observed and treated conservatively. The mean follow up period was 14 months (range 3–35). Overall clinical success was obtained in 78.5% of patients. Mean post treatment ZD score was 1.3 ± 1.5, significantly lower than initial MZ score (p < 0.0001).

Conclusion: FESD represents a safe and effective treatment for symptomatic patients with Zenker's diverticulum. Although it needs to be validated, proposed MZ score could represent a useful tool to monitoring post-procedural symptoms and guide subsequent management.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1474 HOW ACCURATE ARE THE SYMPTOMS IN PATIENTS WITH FOOD IMPACTION AND FOREIGN BODIES INGESTION?

A. Laranjo¹, I. Mocanu², M. M. Carvalho¹, S. Pires¹, N. Veloso¹, L. Gonçalves¹, R. Godinho¹, I. Medeiros¹

¹Gastroenterology Department, Hospital Espírito Santo de Évora, Évora/Portugal

²Hospital Espírito Santo, Évora/Portugal

Contact E-mail Address: anamlaranjo@gmail.com

Introduction: Food impaction (FI) and foreign body ingestion (FBI) remain the most frequent indications for emergency esophagogastroduodenoscopy. The symptoms in these patients are often nonspecific and their location is not always related to the endoscopic findings.

Aims & Methods: The aim of this study was to characterize the symptomatology of the patients with suspected FI and FBI, to correlate the clinical symptoms with the endoscopic findings and to assess its management and complications. This was a retrospective unicenter cohort study including patients with suspected FI and FBI during three years (2013–2016). Statistical analysis was performed using IBM SPSS Statistics 22 with p < 0.05 deemed to be statistically significant.

Results: 198 patients were included (90 patients with FI, 70 patients with FBI, 38 patients without endoscopic findings of FI or FBI): 59.1% men, with a mean age of 60.10 ± 19 years. Patients with FI were predominantly men and were significantly older when compared with FBI patients (p < 0.05). Dysphagia was the most frequent symptom in FI patients, while foreign body perception and odynophagia were more common in FBI. The symptoms in FI group were localized more frequent in the esophagus (83.3%) and FI was identified by esophagogastroduodenoscopy in the distal esophagus in 58.9% of those patients. In comparison, the symptoms in patients with FBI were predominantly localized in oropharynx (65.7%) and FBI was identified in proximal esophagus in 55.7% of those patients. There was more correlation between the location of the symptoms and the endoscopic findings in patients with FI compared with the patients with FBI (FI 65.6% VS 47.1%; p < 0.05). In FI patients, the most frequent esophageal abnormalities were peptic stenosis and Schatzki ring. In FBI patients, the most common foreign bodies identified were meat (47.1%) and fish bones (22.9%). Foreign body forceps was the most used device in FBI patients, while Roth Net was preferred in FI patients. Overall, esophagogastroduodenoscopy was effective in the resolution of FI in 100% of the patients and foreign body extraction was not possible in 4 patients (5.7%). Major complications occurred in 0.5% (1 perforation).

Conclusion: In FI patients, the location of the symptoms has a better correlation with the endoscopic findings compared with FBI patients. The esophagoduodenoscopy is safe and effective in patients with FI and FBI.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1475 GASTROINTESTINAL ENDOSCOPY UNDER SEDATION IS ASSOCIATED WITH PNEUMONIA IN OLDER INPATIENTS—RESULTS OF A RETROSPECTIVE CASE-CONTROL STUDY

C. M. Kollmann, W. Schmiegel, T. Brechmann

Department Of Gastroenterology And Hepatology, Berufsgenossenschaftliches University Hospital Bergmannsheil GmbH, Bochum/Germany

Contact E-mail Address: christopher.kollmann@rub.de

Introduction: Apparent aspiration is a notable adverse event during gastrointestinal endoscopy under sedation (GIES) [1, 2], but data about the incidence and the role of inapparent aspiration is scarce. Furthermore, patients undergoing endoscopies experience respiratory symptoms such as coughing, shortness of breathing, fever and other respiratory adverse events within 24 hours relatively often in more than 5% [3]. Since coughing during endoscopy has been attributed to an increased risk of aspiration-related postprocedural infection [4] respiratory infections might be underreported. Additionally, patients in advanced age are not only determined as a high-risk group for GI adverse events following colonoscopies [5], but are also more likely to develop hospital-acquired pneumonia [2]. Therefore, the aim of the study was to determine the risk of pneumonia, lower respiratory infection (LRI) and systemic inflammatory activation after GIES.

Aims & Methods: A total of 250 consecutive inpatients who had undergone GIES during a hospital stay of at least three days were included in a retrospective cohort study. Age-, gender- and length of hospital stay-matched controls (ratio 1:1) who had not undergone any invasive procedure or sedation served as controls. Laboratory parameters had to be available before and three and/or seven days after endoscopy. Primary objective was the occurrence of pneumonia in general and older patients (≥ 65 years). Secondary objectives were the development of LRI, elevation of inflammatory markers (CRP and WBC), initiation of antibiotic treatment, pathogen detection and pulmonary infiltration. Statistics included χ^2 test, paired t-test, ANOVA, multiple linear regression analysis.

Results: No significant differences for the occurrence of pneumonia (1.6%, GIES group vs. 0.4%, control group, $p=0.178$, χ^2 test) and LRI (4.8% vs. 2.0%, $p=0.084$) in general, but in the older age group (2.6% vs. 0.0%, $p=0.041$, and 7.8% vs. 2.5%, $p=0.034$, respectively) were detected. Inflammatory parameters were significantly increased after GIES, particularly on day three. GIES patients received antibiotic treatment more frequent while pulmonary infiltration did not differ.

Conclusion: This data confirms a higher risk of pneumonia due to GIES in the advanced aged population. In general, patients are more likely to develop inflammation and to receive antibiotic treatment suggesting an increased risk of radiologically non-visible inflammation due to micro-aspiration.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1476 SYMPTOMATIC RESPONSE OF PYLORIC PNEUMATIC DILATION, BOTOX INJECTION OR COMBINATION THERAPY IN PATIENTS WITH GASTROPARSIS OR DELAYED GASTRIC EMPTYING POST-GASTRIC TRANSPOSITION

A. Gupta, M. A. Everson, R. Haidry, M. Banks, S. Bown, D. Graham, R. Ganatra, A. Ramasubramoni, L. Lovat, R. Sweis

Department Of Gastroenterology, University College London Hospital, London/United Kingdom

Contact E-mail Address: abs Gupta@aol.com

Introduction: Therapeutic options for gastroparesis or delayed emptying following oesophagectomy with gastric transposition are limited. Although commonly performed, there have been no studies addressing the relative merits of endoscopic dilatation of the pylorus, botulinum toxin (Botox) injection or combination therapy. We assessed the symptomatic response of patients undergoing non-surgical pyloric intervention at a specialist tertiary centre.

Aims & Methods: 33 patients (13 male; mean age 45, range 17–80) underwent a total of 51 endoscopic procedures over 2 years. Treatments were either 100IU units of Botox injected into 4 quadrants of the pylorus or pneumatic dilation (PD) incrementally up to 16–20 mm (Hercules; Cook Medical). Patients with gastric malignancy, previous pyloric surgery or no documented follow-up were excluded. Post-therapeutic responses were assessed at first follow up post-procedure and graded as 'good', 'partial' or 'none/poor'. Patients were grouped according to type of therapy and indication.

Results: There were no immediate or late complications observed. 31 procedures were performed for gastroparesis with a mean post-procedure follow-up of 11 weeks. Overall, a partial or good response was observed in 81% (25/31). Specific treatment with Botox alone (18 procedures) or as part of combination therapy (10 procedures) led to a good or partial response in 86% (24/28) compared to 33% (1/3) who had PD alone ($p=0.03$). 14 procedures were performed in the post-surgical group with a mean post-procedure follow-up of 10 weeks. Overall, a partial or good response was observed in 93% (13/14); treatment with Botox alone or as part of combination therapy led to a good or partial response in 100% (10/10) compared to 75% (3/4) who had dilatation alone ($p=0.1$). 6 therapies were performed without a defined indication, 2 patients (33%) had a partial or good response, both of which had combination therapy.

Conclusion: Pyloric intervention with Botox, PD or combination therapy are safe and effective treatment options for patients with gastroparesis or delayed gastric emptying following gastric transposition. Subjective treatment without a clear indication shows little improvement.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1477 AN ANALYSIS OF COMPLICATIONS FOLLOWING ENDOSCOPIC SUBMUCOSAL DISSECTION IN A WESTERN SETTING - MAKING THE CASE FOR A SHORTER LENGTH OF STAY

S. Subramaniam¹, K. Kandiah¹, G. Longcroft-Wheaton², P. Bhandari¹

Contact E-mail Address: shar811@googlemail.com

Introduction: Endoscopic submucosal dissection (ESD) is an established technique for the treatment of gastrointestinal (GI) neoplasia in Japan. The high uptake and mastery of the procedure there was in part enabled by the high prevalence of early gastric cancer in Japan. Conventional practice in Japan is to admit patients for 3 to 5 days after the ESD procedure for monitoring in view of the risk of serious complications which is between 1–10%. Cost and resource provision in a publicly-funded Western healthcare setting favours shorter planned stays following ESD.

Aims & Methods: We aimed to identify the type and site of lesions being treated in a Western setting as well as the rate, timing and predictors of complications in order to evaluate current admission practice. An electronic database of all ESD procedures performed in our academic institution from 2012–2017 was analysed. Parameters were the number, type, onset and management of complications following ESD. Significant complications (bleeding and perforation) necessitating hospital admission were categorised as early (within 24 hours) and delayed (24 hours to 28 days) post procedure.

Results: A total of 410 ESDs were performed within the time period (225 colorectal, 117 oesophageal, 52 gastric and 16 duodenal). There were 21 complications. ESD for gastric and duodenal lesions had a higher complication rate (11.5% and 12.5% respectively). The table below stratifies the complications according to type, location and onset.

		Colorectal	Oesophageal	Gastric	Duodenal
Early	Bleeding	3/225	1/117	0/52	0/16
	Perforation	2/225	0/117	2/52	1/16
Total (early)		5/225 (2.2%)	1/117 (0.9%)	2/52 (3.9%)	1/16 (6.3%)
Delayed	Bleeding	5/225	1/117	4/52	1/16
	Perforation	1/225	0/117	0/52	0/16
Total (delayed)		6/225 (2.7%)	1/117 (0.9%)	4/52 (7.7%)	1/16 (6.3%)
Grand total of all complications		11/225 (4.9%)	2/117 (1.8%)	6/52 (11.5%)	2/16 (12.5%)

19 of the 21 total complications (90.5%) were successfully managed endoscopically. 1 patient underwent an emergency right hemicolectomy for a delayed colonic perforation and 1 patient had radiological embolisation for a bleed 7 days following a caecal ESD. 72.7% (8/11) of the patients who experienced delayed bleeding presented 7–10 days following ESD. Of this, 50% occurred following recommencement of anticoagulants/antiplatelets.

Conclusion: ESD in this Western setting was more commonly performed for colonic and oesophageal lesions rather than gastric as seen in Japan. The complication rate is modest and almost all were managed successfully with an endoscopic approach. They occurred more commonly in gastric and duodenal sites. This may be related to the technical difficulties of resection or low volume of procedures performed at these locations. The use of anticoagulants is a risk

factor for delayed bleeding. Given that the majority of delayed complications occurred more than 5 days post procedure, a standardised 5 day inpatient stay would prove futile in our cohort.

P1478 PREDICTIVE FACTORS AND MANAGEMENT OF REFRACTORY BENIGN OESOPHAGEAL STRICTURES

M. Moura, C. Simões, C. Noronha Ferreira, P. Santos, J.P. Freire, J. Lopes, L. Carrilho Ribeiro, J. Velosa
Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, EPE, Lisboa/Portugal

Contact E-mail Address: cmiguelmour@gmail.com

Introduction: The optimal management and the predictive factors of response to endoscopic dilatation of refractory benign oesophageal strictures remains controversial.

Aims & Methods: To evaluate the prevalence and factors predicting response to treatment of benign refractory oesophageal strictures with scheduled endoscopic dilations. Retrospective analysis of 75 patients submitted to scheduled endoscopic dilatation of benign oesophageal strictures between October 2010 and November 2016. Strictures were classified as refractory when ≥ 5 endoscopic dilations were needed with at least one dilation achieving ≥ 15 mm of diameter during the course of management of the oesophageal strictures.

Results: The study sample included 42 (56%) male patients and the mean age was 57 ± 18 years. The dysphagia scale at baseline was: solids (1)–17 (22.7%), semi-solids (2)–23 (30.7%), liquids (3)–23 (30.7%) and complete (4)–12 (16%). Body mass index (BMI) at baseline was 22 ± 5 Kg/m². The aetiology of the benign strictures was: surgical–31 (41.3%), peptic–15 (20%), caustic–10 (13.3%), radiotherapy–10 (13.3%) and others–9 (12%). The location of the oesophageal strictures was as follows: proximal third–34 (45.3%), middle third–12 (16%), distal third–27 (36%) and multiple locations–2 (2.7%). Stricture type: simple–44 (58.7%), complex–31 (41.3%). Patients underwent a median of 4 (1–26) endoscopic dilation over a median period of 19 weeks (1–229). Dilations were done with Savary-Gilliard dilators–35 (46.7%), TTS-balloons–24 (32%) or both–16 (21.3%). The mean diameter of dilation achieved was 15.7 ± 2.2 and a dilatation diameter of ≥ 15 mm was achieved in 56 (74.6%) patients. Local injection of corticosteroid (dexametasone 5mg) was performed at least once in 39 (52%) patients and in $\geq 25\%$ of dilations in 39 (52%) patients. From the study sample, 25 (33.3%) patients fulfilled criteria of refractory strictures. In this subgroup, there was a significant association with post-surgical aetiology ($p=0.042$), lower baseline BMI ($p=0.039$), higher rate of local injection of corticosteroids ($p < 0.001$) and higher dilation diameter ($p < 0.001$). Refractory strictures were significantly associated with the need for local corticoid injection (OR 9.76, 95%CI 0.035–0.46, $p=0.02$) by binary logistic regression analysis. However, none of the other factors were found to be independent predictors of response to therapy.

Conclusion: Surgical aetiology was significantly associated with refractory benign oesophageal strictures and these patients were significantly more likely to require local corticosteroid injections during scheduled endoscopic dilations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1479 LOCAL CORTICOSTEROIDS IMPROVE EARLY CLINICAL OUTCOMES IN PATIENTS UNDERGOING ENDOSCOPIC DILATION OF BENIGN OESOPHAGEAL STRICTURES

M. Moura, C. Simões, C. Noronha Ferreira, P. Santos, J.P. Freire, J. Lopes, L. Carrilho Ribeiro, J. Velosa
Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, EPE, Lisboa/Portugal

Contact E-mail Address: cmiguelmour@gmail.com

Introduction: Locally injected corticosteroids have been shown to improve outcomes in patients undergoing endoscopic dilation of peptic strictures.

Aims & Methods: To evaluate factors predicting early clinical response to endoscopic dilation of benign oesophageal strictures. Retrospective analysis of 75 consecutive patients submitted to scheduled endoscopic dilations between October 2010 and November 2016. Clinical improvement was defined as dysphagia score ≤ 1 . IBM SPSS®21 was used for statistical analysis.

Results: The study sample involved 42 (56%) male patients and the mean age was 57 ± 18 years. Dysphagia scale at baseline: solids (1)–17 (22.7%), semisolids (2)–23 (30.7%), liquids (3)–23 (30.7%) and complete (4)–12 (16%). Body mass index at baseline was 22 ± 5 Kg/m². Stricture aetiology: surgical–31 (41.3%), peptic–15 (20%), caustic–10 (13.3%), post-radiotherapy–10 (13.3%) and others–9 (12%). Stricture location: proximal–34 (45.3%), medium–12 (16%), distal 27 (36%) and multiple–2 (2.7%). Stricture type: simple–44 (58.7%), complex–31 (41.3%). Patients underwent a median of 4 (1–26) endoscopic dilations over a median period of 19 weeks (1–229). Dilations were performed with Savary-Gilliard dilators–35 (46.7%), TTS-balloons–24 (32%) or both–16 (21.3%). The mean diameter of dilation was 15.7 ± 2.2 and dilatation of ≥ 15 mm was achieved in 56 (74%) of patients. Local corticosteroid injection (dexametasone 5mg) was performed at least once in 39 (52%) patients and in $\geq 25\%$ of dilations also in 39 (52%) patients. The rate of complications was 13.3% (perforation (n=9) and

bleeding (n=1)). Surgery was performed in 10 patients (13.3%) (refractory strictures (n=7) and post dilation perforation (n=3)). Improvement of dysphagia symptoms was only associated with the maximum dilation diameter ($p=0.026$) and local injection of corticoids ($p < 0.001$) as was confirmed by binary logistic regression wherein both maximum dilation diameter (OR: 4.92, 95%CI 1.05–2.04, $p=0.027$) and topical injection of corticosteroids (OR: 7.22, 95%CI 0.021–0.55, $p=0.007$) were strongly associated with improved dysphagia scores. **Conclusion:** In our study sample with multiple aetiologies of benign oesophageal strictures, only the maximum dilation diameter and local injection of corticosteroids were associated with improved clinical outcomes in patients undergoing endoscopic dilation of benign oesophageal strictures.

P1480 TRENDS IN CERTIFICATION FOR GASTROINTESTINAL ENDOSCOPY AND VARIATIONS BETWEEN TRAINEE SPECIALTIES: RESULTS FROM THE UK TRAINEE ENDOSCOPY DATABASE

K. Siau, R. Broughton, J. Anderson, I. Beales, M. Feeney, A. Haycock, N. Hawkes, G. Johnson, B. Mckay, R. Pullan, R. Valori, C. Wells, S. Thomas-Gibson, P. Dunkley

**JAG Working Group For The Quality Assurance Of Training, Joint Advisory Group, London/United Kingdom*

Contact E-mail Address: keith@siau.org

Introduction: In the UK, endoscopy certification is overseen by the Joint Advisory Group (JAG). Since 2011, e-certification has been awarded for upper and lower GI endoscopy online via the JAG Electronic Training System (JETS). We aimed to analyse trends in endoscopy e-certification, and assess for differences between trainees in gastroenterology (GI), surgical (GS) and non-medical endoscopists (NME).

Aims & Methods: We prospectively identified trainees awarded certification for gastroscopy, flexible sigmoidoscopy (FS) and colonoscopy from the JETS database. For each specialty, we collected data on lifetime procedural counts, formative assessments, and key performance indicators (KPIs) at the time of certification. Comparisons between specialties were analysed using a combination of χ^2 , Mann-Whitney and median tests.

Results: Between June 2011–Dec 2016, 2857 applications were awarded certification. Numbers of gastroscopy and provisional colonoscopy awarded have been in steady state since 2013, whilst numbers for sigmoidoscopy and full colonoscopy continue to increase. Trainees awarded certification comprised mainly of GI (53.2%), GS (28.5%) and NME (15.8%) trainees. With the exception of FS, most certifications were awarded to GI trainees (Figure 2). Median procedural numbers ($p < 0.001$) and formative DOPS count ($p < 0.001$) pre-certification varied for each modality in the order of NME > GI > GS. Caecal intubation rates (CIR) at full certification were similar between GI (95.6%) and GS (95.6%, $p=0.81$), but lower in NME (93.6%, $p=0.02$ vs. GS, $p=0.006$ vs. GI), despite no differences at provisional certification (median CIR 95.6%, $p=0.32$). Rates of D2 intubation (median 98.7%) varied across groups (GS > GI > NME, $p=0.002$). Certification awarded at first attempt were similar across specialties (mean 89.4%, $p=0.19$), but varied for gastroscopy (NME 95.5%, GS 90.1%, GI 89.7%, $p=0.01$).

Conclusion: Despite variations amongst trainee specialties, endoscopy certification is a transparent and robust benchmark for assessing competency, as evidenced by trainee KPIs. Further studies are required to study the impact of recent changes to certification, and if variations in KPIs exist following certification.

P1481 EFFICIENCY AND SAFETY OF ENDOSCOPIC PAPILLECTOMY FOR TREATMENT OF DUODENAL PAPILLA TUMORS

Y. Chu¹, M. Xu¹, P. Zhou¹, C. Zhang¹

¹Endoscopy Center And Endoscopy Research Institute, Fudan University Zhongshan Hospital, Shanghai/China

Contact E-mail Address: xu.meidong@zs-hospital.sh.cn

Introduction: A duodenal papilla tumor is an uncommon neoplasm in the upper gastrointestinal tract. In the early stage, patients often have no complaints and the tumors are usually occasional found during gastroduodenoscopy examination. Endoscopic papillectomy can be achieved with curative resection for benign adenoma and some early papillary carcinoma. However, some complications are accompanied with the procedure, like pancreatitis and bleeding. This retrospective study is to evaluate therapeutic effect and safety of endoscopic papillectomy on duodenal papilla tumors.

Aims & Methods: From June 2009 to November 2016, the information of patients who received endoscopic papillectomy was recorded, which included basic characteristics and clinical outcomes, such as recurrence rate, bleeding, pancreatitis.

Results: 37 patients (totally 40 cases) received endoscopic papillectomy. The procedure was completed with gastroscope in 32 cases and duodenoscope in 8 case. Endoscopic mucosal resection (EMR), endoscopic piecemeal mucosal resection (EPMR) and endoscopic submucosal dissection (ESD) was performed in 21, 17 and 2 cases respectively. None of the lesions invaded the submucosal layer.

Pancreatic stents and biliary stents were inserted in 9 and 12 patients respectively. In general, 5% (2/40) and 12.5% (5/40) cases had intraoperative and postoperative bleeding respectively. 20% (8/40) cases suffered from pancreatitis, of which mild, moderate and severe happened in 3, 4 and 1 cases. Six patients had tumor recurrence. And 3 patients received repeat endoscopic papillectomy, two received pancreatic-coduodenectomy and one received no other treatments with close follow-up. Two patients died from failures of treatments for papillary tumors and one patient died due to other unrelated cause.

Characteristics and adverse events of endoscopic papillary in cases

Sex	
Male Female	29 8
Age (years, mean \pm SD)	55.1 \pm 10.0
Endoscope type	
Gastroscope Duodenoscope	32 8
Resection method	
EMR EPMR ESD	21 17 2
Pathological results	
LGD, HGD, Tis, Tm, Tsm, Non-tumor	12, 24, 0, 2, 0, 2
Tumor sizes (cm)	
Longer diameter, Shorter diameter	2.02 \pm 0.88, 1.50 \pm 0.69
Biliary Stent	
Yes, No	12, 28
Pancreatic stent	
Yes, No	9, 31
Hospital stays (days, mean \pm SD)	6.7 \pm 13.4
Follow-up time (months, mean \pm SD)	36.6 \pm 28
Adverse events	
Intraoperative bleeding	5%(2)
Postoperative bleeding	12.5%(5)
Perforation	2.5%(1)
Cholangitis	0
Pancreatitis, Mild, Moderate, Severe	20%(8), 7.5%(3), 10%(4), 2.5%(1)
Recurrence	16.2%(6)
Surgery	7.9%(3)
Mortality	7.9%(3)

EMR, endoscopic mucosal resection; EPMR, endoscopic piecemeal mucosal resection; ESD, endoscopic submucosal dissection; LGD, low-grade dysplasia; HGD, high-grade dysplasia; Tis, intraepithelial carcinoma; Tm, intramucosal carcinoma; Tsm, carcinoma with duodenal submucosal invasion.

Conclusion: Endoscopic papillary is proved to be efficient in treating papilla tumors without submucosal invasion. However, adverse events like pancreatitis and bleeding should be taken seriously and managed properly.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1482 CHANGES IN SCORING OF DIRECT OBSERVATION OF PROCEDURAL SKILLS (DOPS) FORMS IN ENDOSCOPY TRAINING AND THEIR IMPACT ON COMPETENCE ASSESSMENT

K. Siau¹, P. Dunckley¹, A. Nevill², J. Anderson¹, I. Beales¹, R. Broughton¹, M. Feeney¹, A. Haycock¹, N. Hawkes¹, B. Mckaig¹, S. Thomas-Gibson¹, R. Valori¹, C. Wells¹, G. Johnson¹

²Faculty Of Education, Health And Wellbeing, University Of Wolverhampton, Walsall/United Kingdom

Contact E-mail Address: keith@siau.org

Introduction: DOPS are validated tools for assessing competence in endoscopy. Previously, DOPS were scored on a 4-point competence-based scale, with scores of 3 and 4 signifying competence. In July 2016, the DOPS rating scale changed to a supervision-based scale that has been shown to be more reliable,^[1] with 4 ratings from maximal supervision, up to competent without supervision. We aimed to assess whether changes to the rating scale have affected distribution of scores and hence demonstrate validity.

Aims & Methods: We used the UK trainee endoscopy database (JETS) to collect DOPS scores for gastroscopy (n = 1934), sigmoidoscopy (n = 517), colonoscopy

(n = 2296) and polypectomy (n = 370) in the 6-months before July 2016 (old DOPS) and after (new DOPS), for trainees at early stages of training (total procedures < 100). To allow analysis, the new DOPS rating scale was aligned to a 4-point scale, hence a score of 4 on new DOPS = Scores 3 or 4 on old DOPS, and scores on the new and old DOPS compared using the Mann-Whitney U-test. **Results:** 5117 DOPS (77.7% new and 22.3% old) were included for analysis. Overall, there were variations in distributions of all scores (p < 0.001) between forms (Figure 1). Compared to new DOPS, scores of 1 were underutilised on old DOPS (0.6% vs 3.0%, p < 0.001). Frequencies of low scores (pooled scores of 1&2) were similar for gastroscopy (p = 0.53) and sigmoidoscopy (p = 0.34), but not for colonoscopy (new 11.9% vs. old 13.9%, p < 0.001) and polypectomy (new 6.8% vs. 19.9%, p < 0.001). Trainees on old DOPS were more likely to be rated as competent (score 3 or 4) compared to new DOPS (86.4% vs. 55.8%, p < 0.001). On subgroup analysis, this was evident for gastroscopy (86.3% vs. 49.1%, p < 0.001), colonoscopy (86.1% vs. 58.2%, p < 0.001), sigmoidoscopy (90.6% vs. 62.0%, p < 0.001), but not polypectomy (80.1% vs. 67.9%, p = 0.12).

Conclusion: Endoscopy assessors are applying a greater range of scores using a new DOPS rating scale based on degree of supervision, in two cohorts of trainees matched for experience. This indicates better construct validity with the new rating scale. Further work is underway to determine the reliability of the new DOPS to inform summative assessment and certification for UK endoscopy trainees.

Introduction: Endoscopic resection of duodenal adenomata carries an increased risk of perforation compared to other locations in the upper or lower GI tract.^{1,2} Additionally in endoscopic resection of widespread adenomata (Spigelman III/IV) at the level of D2/D3 there is an increased risk of secondary perforation due to auto-digestion of the denuded duodenal wall by pancreatic enzymes and bile independent of the primary endoscopic resection method. We recently reported of the successful implantation of a mini-vacuum sponge with extended length of the suction tube and reduced in volume compared to a standard esophageal vacuum sponge.³

Aims & Methods: From September 9th, 2015 to March 20th, 2017 endoscopic resection of wide-spread duodenal or papillary adenomata of >2cm in D2/D3 was performed in five patients. There was a surgical indication for Whipple's resection as primary intervention or in case of failure in all patients. All patients agreed and gave their informed consent to the procedure.

Results: Five patients with widespread duodenal adenomata were included (2x papilla, 3x D2/D3 extrapapillary adenomata; 5x tubular; 3x HGIN, 2x LGIN). The macroscopic mean maximum diameter and perpendicular diameter of the lesions were 4 x 2.8 cm (largest 7.5 x 3.7 cm; smallest 2.2 x 1.8 cm). In all cases the implantation of a protective mini-vacuum sponge (EsoVac reduced in volume to 1.2 x 1.5 cm (dia, length) with extended suction tube; Braun Corp., Melsungen). Continuous suction was applied over several days (-125 mm Hg; ActiVAC, KCI Medical, Wiesbaden) depending on the size of the resection area and healing status (m = 10 days, 4-14 days). An endoscopic/radiologic vacuum sponge exchange was performed every 3-5 days. In 4 cases additional atraumatic over-the scope-clips (OTSC, Ovesco Tuebingen) were placed during the procedure and in 5/5 cases additional hemoclips were applied to secure the wall and for hemostasis. In 5/5 cases (100%) an excellent healing could be observed during follow-up. No patient had to be operated during or following the intervention (FU 2-14 mo.). In all cases the resection was curative with 'en bloc' resection, though in one case the specimen ruptured during retrieval into three parts (4x HGIN, 1x LGD; 4x R0, 1x Rx). In one case 10 days after resection an acute bleeding occurred with the need of endoscopic clipping and prophylactic radiologic coiling of the gastroduodenal artery with uneventful course. In a second case a minor bleeding occurred without necessity of transfusion during ablation of an OTSC three mo after the primary intervention. All patients were asymptomatic during follow-up.

Conclusion: The endoscopic resection of large duodenal adenomata in D2/D3 is feasible and was safe in our collective using the application of a duodenal mini-vacuum sponge for continuous local drainage of bile and pancreatic juice as alternative to Whipple's resection. The results in this first small collective should be reproduced in a prospective multicentric trial.

Introduction: Acute perforations are one of the recognized complications of both diagnostic and therapeutic gastrointestinal endoscopy. For decades, surgical treatment has been the standard of care, but endoscopic closure has become a more popular approach, due to feasibility and the reduction of the burden of surgery, combined with the availability of various endoscopic closure devices.

Aims & Methods: We aimed to assess the technical and clinical success and safety of endoscopic closure, in total, and for each endoscopic device used in closing acute perforations in animal models. Medical literature (Cochrane library, EMBASE, MEDLINE) from 1966 till September 2016 was searched. A systematic review and meta-analysis were performed on studies reporting technical and clinical success of endoscopic closure of acute perforations, according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guidelines.

Results: 46 studies on animal models were identified. 15 studies, including 4 randomized controlled trials, met our inclusion criteria (acute, less than 24 hours, iatrogenic, no fistulas or leaks, clear documentation of the method of closure, and technical and clinical success and 5 cases or more of endoscopic closure per study), were analysed. A total of 214 endoscopic closures were attempted in these studies. The overall technical success rate was 94.8% (n = 201/214, 95% CI: 92%-97.6%), clinical success was 92.3% (n = 189/214, 95% CI: 88.8%-95.8%), and complication rate was 4.2% (n = 6/214, 95% CI: 1.6%-6.8%). Technical success for endoclip closure was 84.9% (95% CI: 71.4%-93.6%), and clinical success was 83.2% (95% CI: 69.5%-92.5%), and complication rate was 2.7% (95% CI: 90.12%-99.88%). For OTSC (Over the scope clip device), technical success was 97% (95% CI: 88%-99.7%), clinical success was 97% (95% CI: 88%-99.7%), and complication rate was 1.87% (95% CI: 91.2%-98.8%). The technical success for endosuturing (endoscopic suturing device) was 92.7% (95% CI: 82% to 98%), clinical success was 87% (95% CI: 74.9%–94.8%), complication rate was 1.9% (95% CI: 91.1%- 98.9%).

Conclusion: Our study suggests that endoscopic closure is a suitable treatment option for acute iatrogenic gastrointestinal perforations with a reasonable technical and clinical success, and low complication rate. Further confirmation from prospective studies in human is needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1486 RISK FACTORS FOR COLORECTAL POLYP IN ASYMPTOMATIC YOUNG ADULTS UNDER THE AGE OF 50

Y. Myung

hyundae UVIS hospital, Incheon/Korea, Republic of

Contact E-mail Address: dittomyung@gmail.com

Introduction: Current guidelines recommend that adults age 50 to 75 be screened for colorectal cancer (CRC). However, CRC incidence rates have increased among young adults and have decreased among older adults.

Aims & Methods: The aim of this study was to investigate the risk factors of colorectal polyps in young adults aged <50 years. From January 2016 to December 2016, we compared the risk factors of colorectal polyp group with non-polyp group in patients aged <50 years who underwent screening

colonoscopy. The risk factors examined included body mass index (BMI), metabolic syndrome, smoking, alcohol consumption, age and gender.

Results: Of the 1862 patients, prevalence of colorectal polyps and adenomatous polyps were 13.1% and 7.8%, respectively. Multivariate analysis revealed that metabolic syndrome (OR, 1.89, 95% CI, 1.13–3.17, P=0.015) was independent predictor for colorectal polyps. Age over 40 years old (OR, 2.47, 95% CI, 1.48–4.14) and metabolic syndrome (OR, 1.59, 95% CI, 0.87–3.30) were independent predictors for adenomatous colorectal polyps.

Conclusion: Metabolic syndrome is risk factor of colorectal polyps in young adults aged <50 years. Age over 40 years old is additional risk factor of adenomatous polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1487 COMPARISON BETWEEN AN ASYMMETRIC (SMALL DOSE IN THE MORNING) AND A SYMMETRIC SPLIT-DOSE REGIMEN OF POLYETHYLENE GLYCOL PLUS BISACODYL FOR BOWEL PREPARATION FOR SCREENING COLONOSCOPY: A RANDOMIZED NON-INFERIORITY CLINICAL TRIAL

Introduction: Bowel cleansing has a critical role to increase the quality and effectiveness of colonoscopy. International guidelines recommend the use of split-dose regimens of PEG solutions. However, the adoption of split dose regimens in clinical practice remains sub-optimal, in particular in early morning.

Aims & Methods: We aimed to compare the efficacy of bowel preparation using an asymmetric split-dose regimen (approximately 25% of the dose is given on the day of the procedure and 75% of the dose is given on the day before) with the standard split-dose regimen in patients undergoing screening colonoscopy. We prospectively enrolled consecutive outpatients undergoing screening colonoscopy. All subjects received a split-dose preparation with a 2L PEG-citrate-simethicone plus Bisacodyl. Patients were randomly assigned to: group A, asymmetric split dose regimen (1.5 L of PEG + bisacodyl the day before and 0.5 L 3 hours before colonoscopy); group B, symmetric split dose regimen (1 L of PEG + bisacodyl the day before and 1 L 4 hours before colonoscopy). Bowel preparation was evaluated using the Boston Bowel Preparation Scale (BBPS) score. The primary endpoints were the proportion of adequate bowel cleansing (BBPS ≥ 2 in each segment of the colon). Moreover, all patients filled in a nurse-administered questionnaire assessing compliance, tolerability and safety of bowel preparation. The threshold for statistical significance in this study was p=0.05 and a 10% margin was used to demonstrate non-inferiority of asymmetric vs. symmetric split-dose regimen.

Results: 179 patients were enrolled (mean age 60 ± 8 years, males 56%), 88 in group A and 91 in group B. Split-dose was taken by 76/88 and by 77/91 patients in group A and B, respectively (85.2% vs 85.5%, p=0.831). Failure of cecal intubation occurred in 1 patients for each group. In the ITT analysis, bowel cleansing was considered adequate in 71/76 (93.4%) and 70/77 (90.9%) patients respectively in group A and B (p=0.765). BBPS total score was similar in group A and B (6.9 ± 1.2 vs. 6.9 ± 1.4; p=0.846). No differences were observed regarding adenoma detection rate [32/76 (42.1%) vs 35/77 (45.4%); p=0.745] and scores of each colon segment. The full amount of product and adjunctive fluids were taken by 68/76 (89.4) and 71/77 (92.2%) (p=0.158) in group A and B, respectively. Tolerability and occurrence of adverse events were similar in the two groups.

Conclusion: An asymmetric (low morning-dose) split-dose preparation with a low volume formulation with additional Bisacodyl is not inferior to the standard split-dose regimen in achieving an adequate bowel cleansing in patients undergoing screening colonoscopy. A lower amount of preparation in the morning allow to the patients to wake up later; this regimen could be thus preferred by patients undergoing colonoscopy early in the morning. Further study are needed to determine the efficacy and tolerability of the asymmetric preparation for colonoscopy scheduled in early morning.

Introduction: Colorectal endoscopic submucosal dissection (ESD) is a technique with remarkably greater difficulty than upper gastrointestinal ESD because of unstable maneuvers and inherited anatomic variability in the colon. Thus, aiming at reducing these restrictions, we have used single balloon (SB) overtube to assist colorectal ESD in cases considered to have difficult operability. In this study, to evaluate the usefulness of a single balloon overtube to assist colorectal ESD.

Aims & Methods: The study included 35 patients with 39 colorectal lesions who underwent the SB guided ESD (group SB). The treatment outcome of the group was compared with that of another group that consisted of patients with 39 colorectal lesions who underwent ESD without SB (group NSB). The backgrounds of the patients in group NSB were corrected by using the propensity score matching method. The application of the combined use of SB was determined when the circumferential access to the lesion was difficult, and paradoxical movement was observed.

Results: The characteristics of the lesions in group SB were as follows: proximal, 28 lesions; distal, 11; rectal, 0; mean size of tumors, 37.6 ± 9.8 mm; gross findings of laterally spreading tumor of granular type (LST-G), 11 lesions; non-granular type (NG) tumors, 28; adenomas, 11; mucosal cancers, 22; and submucosal cancers, 6. The mean procedure time was significantly shorter in group SB (SB group vs non-SB group: 67.36 min vs 106.00 min; $p < 0.05$). No significant differences were found in en bloc resection, complete resection, postoperative bleeding, and perforation rates. No accidental symptom associated with balloon endoscopy was observed.

Conclusion: Using a single balloon overtube can be expected to improve not only access to the lesion but also facilitate scope manipulation for colorectal ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1489 SEDATION IN COLORECTAL ESD: A SYSTEMATIC REVIEW OF WESTERN CLINICAL PRACTICE

Introduction: Endoscopic Submucosal Dissection (ESD) for colorectal lesions is a highly skilled technique which over the last few years has been adopted by Western countries for the management of colorectal neoplasia. There is no consensus in the literature regarding the technique of anaesthesia/sedation method for ESD. We aim to describe current sedation practices used in ESD in Western Hospitals.

Aims & Methods: A systematic literature search was performed to identify all articles describing colorectal ESD procedure performed in Europe, America and Australia. Electronic databases including PubMed, the Cochrane library and Embase were searched. Original articles or abstracts for congress in English were included. A questionnaire was sent to the authors of the identified articles in order to obtain additional information regarding sedation practice, if this was not explicitly detailed in the original articles. All articles were examined independently for eligibility by two reviewers (S.B. and M.S.). Any Disagreements were resolved by consulting a third reviewer (A.P.)

Results: This review resulted in 18 eligible original articles, of which (5/18) 27.8% were prospective studies, (7/18) 38.9% retrospective series and (6/18) 33.3% were abstracts presented at congresses. The mean number of ESD cases described was 68 (range: 11–302). Most institutions opted to admit patients following the procedure (15) 83.3%, with just one managing patients on an entirely outpatient basis. The mean duration of post procedure observation was 2 days (0–4). The Endoscopy department was the chosen location for colorectal ESD in (12) 66.6% of institutions and operating room (OR) for (4) 22.2%. In (2) 11.1% institutions the preference was for OR in selected cases. Deep sedation with propofol or propofol + midazolam +/- fentanyl was used in (8) 44.4% of the institutions. General anaesthesia was used in (4) 22.2%, while conscious sedation was used in (3) 16.7%. In (3) 16.7% of institutions deep sedation, conscious sedation or general anaesthesia was used according to the cases and clinician decision. A designated anaesthesiologist was in charge of sedation in (7) 38.9% of the institutions, with either nurse anaesthesiologist or an anaesthesiologist in (5) 27.8%, a nurse anaesthesiologist alone in (2) 11.1%, the performing endoscopist in (2) 11.1%, endoscopy nurse in (1) 5.5% and a second physician in (1) 5.5% of institutions.

Conclusion: The sedation strategy used in colorectal ESD in Western world is heterogeneous. Most institutions opt for deep sedation administered by anaesthesiologists within the endoscopy room. By and large, patients are admitted post procedure for observation. Greater sharing of experience is required to better understand the optimal method of sedation for this technique within the context of western practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1490 COMPUTER-AIDED POLYP MEASUREMENT OF 78 POLYPS DURING LIVE COLONOSCOPY (CAPME): A PROSPECTIVE STUDY

Introduction: Colonic polyp measurement is an important outcome in current endoscopic practice. Polyp size estimation is mandatory to determine the surveillance interval after polypectomy and useful to anticipate and prevent complications in therapeutic procedures, for it has been proven that polyp size is one of the main risk factor of complications (bleeding, perforation). Nevertheless, a high degree of subjectivity exists (especially overestimation of polyp size) in polyp size estimation because of a lack of validated and reproducible measurement methods. The aim of this study was to compare a computer-aided polyp measurement (CAPME) to an unassisted visual estimation (UVE) and an endoscopic reference measurement (ERM).

Aims & Methods: This prospective monocentric study was led between November 2015 and July 2016 in the University-affiliated Hospital of Clermont-Ferrand, the Blaise Pascal Institut (BPI) and the Image Science For Interventional Techniques (ISIT) research unit of Clermont-Ferrand (France). Video-endoscopic procedures were recorded and secondly used for the CAPME method. The endoscopic acquisition protocol was standardized with a slow back-and-forth movement of the endoscope towards the polyp. A photography of each polyp was taken with an open biopsy forceps placed on the base of the polyp. ERM was then measured thanks to a simple rule of three knowing the fixed size of the open biopsy forceps (8 millimetres, mm). UVE was determined on the same photography without any measurement devices by two different endoscopists. All the measurements were realized blinded of the other results. Accuracy of the CAPME and UVE methods was defined by a variation less than 1 mm with the ERM. We used the Lin concordance correlation coefficient (CCC) to measure the agreement between the variables.

Results: 33 patients and 78 polyps were included in this study. The mean polyp size was 5.3 mm, with 73.1% (n = 57) of polyp less than 5 mm. The Lin CCC with the ERM was 0.972 (95% CI, 0.960–0.983; $P < 0.001$) for the CAPME method, and was greater than the UVE Lin CCC (0.830; 95% CI, 0.797–0.863; $p < 0.001$). Accurate polyp measurement was obtained for 68 polyps with CAPME method (87.2%) versus 56 polyps (71.8%) for UVE assessment ($p < 0.01$). Inaccuracy was increasing proportionally to polyp size (40.9% of inaccurate polyp measurement for polyps greater than 10 mm) and we observed a systematic overestimation of supracentimetric polyps for UVE method. Unlike UVE, CAPME accuracy was not impacted by polyp size variation in our study (11.1%; 14.7% and 10.8% for polyps of > 10 mm; 5–10 mm and < 5 mm respectively).

Conclusion: To our knowledge, this is the first prospective study with significant data analysing a computer-aided polyp measurement in live colonoscopic procedures. In our study, this methods shows more accuracy than the visual estimation, which is the actual gold standard. The main limitation of this study is the endoscopic protocol (back-and-forth movement of the endoscope) that increases the endoscopic procedure. The use of DualFocus might be a solution to overcome this problem.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1491 USING THE MULTI-ASSISTANT RATING SCALE (MARS) FOR ENDOSCOPIC NON-TECHNICAL SKILLS PERFORMANCE AUGMENTS USE OF STANDARD KEY PERFORMANCE MEASURES IN INDEPENDENT COLONOSCOPISTS

N. Hawkes, F. Kokwara, B. Davies, J. Cornish
Gastroenterology, Cwm Taf University Health Board, nr Cardiff/United Kingdom

Contact E-mail Address: neilhawkes@aol.com

Introduction: Endoscopic Non-Technical Skills (ENTS) are an essential component of high-quality endoscopy giving information about performance in a team context however these are not routinely assessed as part of the key performance indicators (KPIs) for independently practising colonoscopists. We have developed a validated 360-degree assessment tool based on assistant ratings for ENTS (MARS tool) with acceptable inter-rater agreement providing an assessment in 4 key ENTS domains. We compared measured performance in these areas against existing key performance indicators which measure aspects of insertion and lesion detection skills.

Aims & Methods: We aimed to add a 360-degree multi-assessor rating scale (MARS) to provide a global assessment of ENTS skills to the existing KPI panel correlating the results against existing caecal intubation rate (CIR) and polyp detection rate (PDR). The validated MARS tool assesses 4 ENTS

domains—Communication (COMM), Situational Awareness (SITA), Leadership (LEAD) and Judgement & Decision-making (J&DM). Each MARS domain was represented by 10 items and is assessed on a 7-point scoring scale - endoscopists should score >90 in each domain (80–90 = need for improvement, <80 = sub-optimal performance). CIR and PDR measures are routinely calculated for all colonoscopists using the HICCS Electronic Reporting System with manual validation of these data. Feedback is presented on a quarterly basis to practitioners—endoscopists are expected to achieve 90% CIR and 20% PDR. Correlation of these factors with practitioners' ENTS scores were measured using the Pearson test.

ENTS, CIR and PDR scores by colonoscopist

Operator	COMM	SITA	LEAD	T&DM	CIR(%)	PDR(%)
1	96	99	97	100	95.2	72.5
2	94	94	87	95	83.6	49
3	99	100	97	98	90.8	51
4	100	100	100	99	91.5	47
5	79	73	73	85	91.7	34.5
6	100	99	99	98	87.5	34.5
7	66	59	62	69	67.4	17
8	100	100	98	99	83.8	20
9	74	83	84	86	87.5	31.5

Results: 9 endoscopists with known variability in standard colonoscopy KPIs consented to an assessment of ENTS using the MARS tool. Their ENTS scores were correlated with existing KPIs for each colonoscopist (Oct 2016–Mar 2017). Scatter plots provided an overall positive correlation between ENTS domains and CIR (COMM 0.58; SITA 0.66; LEAD 0.66; J&DM 0.75) and PDR (COMM 0.49; SITA 0.55; LEAD 0.50; J&DM 0.60). Three endoscopists were identified as having sub-optimal scores in all of the ENTS domains (operators 5,7,9). Taking into account important KPI thresholds 2 out of 3 (33%) of these endoscopists identified were not meeting CIR targets (c.f. 66% of ENTS competent group) and one (33%) did not meet PDR targets (c.f. 0% in ENTS competent group).

Conclusion: The MARS tool is a practical way to measure of ENTS performance designed as a 360 degree feedback and identifies areas for development within independently practitioners that are not currently highlighted by standard colonoscopy KPI measures. There is some correlation with current KPI feedback panels but using a specific validated ENTS assessment tool augments current assessment panels. Both CIR and PDR primarily depend on the colonoscopists' individual skills rather than the team elements required by polypectomy or EMR and these more complex tasks may show stronger correlation with MARS ENTS evaluation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1492 EARLY ECONOMIC MODELLING OF EMI-137 TO IMPROVE THE DETECTION RATE OF POLYPS IN PATIENTS WITH INCREASED RISK OF COLORECTAL CANCER

B. Shinkins¹, A. Smith¹, N. King¹, A. Davies², I. Wilson²

¹Test Evaluation Group, Academic Unit Of Health Economics, University of Leeds, Leeds/United Kingdom

²Edinburgh Molecular Imaging, Edinburgh/United Kingdom

Contact E-mail Address: b.shinkins@leeds.ac.uk

Introduction: Colorectal Cancer (CRC) is the third most common cancer diagnosed in men and second most common cancer in women, affecting 1,361,000 people worldwide each year. CRC is a slow growing tumour that most commonly develops from polyps which form in the inner lining of the colon or rectum. The identification and removal of polyps whilst still in a precancerous state has been shown to be effective in reducing mortality from CRC. Current clinical practice relies on white light (WL) colonoscopy for detecting colorectal polyps, but this is associated with a detection "miss-rate" of up to 26% for small (<10 mm) polyps and 2% for large polyps (van Rijn et al., 2006). Missed lesions (false negative results) puts patients at an unnecessary risk of late stage detection, when management has higher costs and worse clinical outcomes. Recent technological developments have resulted in more accurate technologies for polyp detection becoming available. One such technology is the EMI-137 imaging agent (Edinburgh Molecular Imaging (EMI))) which has demonstrated potential to enhance the sensitivity of colonoscopy.

Aims & Methods: We aimed to evaluate the potential cost-effectiveness of EMI-137 compared to standard WL colonoscopy in patients at high risk of colorectal cancer. A de novo economic model for patients participating in the UK national bowel cancer screening programme referred for colonoscopy as a result of a positive faecal occult blood test was developed. The early economic modelling approach consists of 5 stages: 1) literature review, 2) evidence synthesis, 3) care pathway analysis, 4) decision analytic modelling, 5) sensitivity analysis and value of information analysis. The structure of the models has been determined by current recommended practice. The potential benefits of EMI-137 were identified via interviews with endoscopists across Europe and communication with the manufacturer. Early cost-effectiveness and value of information analysis will be conducted to assess the viability of the EMI imaging technology to enhance current NHS patient care, and to inform the necessity and direction of future investments into the research and development of this intervention.

Results: The addition of EMI-137 fluorescent agent to standard WL colonoscopy results in a lifetime per-patient average additional NHS cost of £426 and an additional 0.04 QALYs, giving an incremental cost-effectiveness ratio (ICER)

of £11,245 per additional QALY. The cost-effectiveness of EMI-137 was sensitive to the time horizon of the model. EMI-137 remained within the NICE recommended cost-effectiveness threshold priced at \$500 or less. Value of information analyses revealed that uncertainty in the cost-effectiveness of EMI-137 is primarily driven by uncertainty in the assumption that EMI-137 reduces the risk of future polyps after polypectomy. The results of this modelling exercise have since been used to inform the design of Phase I/III clinical studies.

Conclusion: The results of this early economic modelling exercise demonstrated that EMI-137 has the potential to be cost-effective for patients participating in the UK National Bowel Cancer Screen Programme. The value of information analyses have highlighted the key parameters for which further evidence is required, and this will be used to inform the design of future clinical studies.

Introduction: Safety and diagnostic accuracy of colonoscopy depend on the quality of colon cleansing. Several factors have been reported to affect the quality of bowel cleansing, one of them being hospitalized.

Aims & Methods: We performed a prospective, randomized endoscopist blinded clinical trial between February 2016 and January 2017 included. Our aim was to investigate whether the association of a visual educational booklet improves the level of cleanliness achieved in hospitalized patients who are undergoing a colonoscopy. Hospitalized patients >18 years undergoing colonoscopy were included. Exclusion criteria were: previous colonoscopy in the last 3 years, previous colectomy, known inflammatory bowel disease, urgent colonoscopy, dementia or refusal to participate in the study. Both groups received 4 L polyethylene glycol solution. The intervention consisted of a visual educational booklet (visual cohort). Demographic data, personal history, reason for admission and for colonoscopy, work shift in which it was performed, and findings at endoscopy were collected. The Boston Bowel Preparation Scale (BBPS) was used to assess the bowel preparation. A BBPS score <6 or with at least one segment <2, was considered a poor preparation.

Results: One hundred and thirty six patients were included, 51.5% were male, with a mean age of 64.3 ± 17.6 years, and 95.59% of Spanish nationality. The mean body mass index was 27.3 ± 5.2 kg/m². Educational attainment was below school education in 71.05%. Most patients were submitted from the internal medicine ward (72.1%), and the gastroenterology ward (21.32%). Anemia (31.62%), abdominal radiographic findings (16.91%), hematochezia/rectal bleeding (15.44%), diarrhea (11.03%), and abdominal pain (8.82%) were the most frequent indications. Patients characteristics, bowel cleansing and endoscopic findings are shown in table 1. The educational booklet did not suppose a difference in the bowel cleansing attained. Factors that impacted on the level of well and poorly prepared patients in the bivariable study were: age (62.1 ± 18.7 vs 70.5 ± 14.8; p = 0.0193), diabetes mellitus (22.33% vs 42.42%; p = 0.024), hypertension (45.63% vs 69.70%; p = 0.016), cardiovascular disease 14.5% vs 36.3%; p = 0.006, and colorectal cancer on colonoscopy (99% vs 81.82%; p = 0.001). In the multivariable analysis the only factors associated with a poor bowel cleansing were cardiovascular disease (OR 3.37 (1.34–8.46); p = 0.010), and colorectal cancer on colonoscopy (OR 3.82 (1.26–11.61); p = 0.018).

Table 1: Baseline characteristics, bowel cleansing and endoscopic findings.

PATIENTS N = 136 (n)	Standard management (n = 70)	Educational booklet (n = 66)	p
Age(year)*	66.2 (56.8–78.4)	63.3 (53.0–78.3)	0.54
Sex(Male)	51.43%	51.52%	0.99
BMI(Kg/m ²)*	26.9 (24.4–29.7)	26.9 (23.5–29.9)	0.85
Diabetes Mellitus (136)	18 (25.71%)	19 (28.79%)	0.69
Hypercholesterolemia (136)	33 (47.14%)	33 (50%)	0.74
Smoking habit (136)	19 (27.14%)	15 (22.73)	0.55
Alcoholism (135)	8 (11.59%)	4 (21.21%)	0.13
Cardiovascular disease(136)	11 (15.71%)	16 (24.24%)	0.21
Chronic kidney disease(136)	5 (7.14%)	9 (13.64%)	0.21

(continued)

Table 1 Continued

PATIENTS N = 136 (n)	Standard management (n = 70)	Educational booklet (n = 66)	P
Chronic Obstructive Pulmonary Disease (135)	6 (8.70%)	5 (7.58%)	0.81

Constipation (135)	14 (20%)	9 (13.85%)	0.34
Antidepressants (136)	13 (18.57%)	7 (10.61%)	0.19
Family history of CRC (132)	7 (10.45%)	8 (12.31%)	0.74
ASA score ≤ 2 (121)	38 (59.37%)	32 (56.14%)	0.81
Need for diaper during admission (128)	9 (13.64%)	10 (16.13%)	0.69
Apendectomy (136)	18 (25.71%)	4 (6.06%)	0.002
Umbilical herniorrhaphy (136)	3 (4.29%)	2 (3.03%)	0.70
Hysterectomy (136)	8 (11.43%)	4 (6.06%)	0.27
Caesarean (136)	1 (1.43%)	4 (6.06%)	0.15
Other gynecological surgery (136)	4 (5.71%)	5 (7.58%)	0.66
Other surgery (136)	21 (30%)	19 (28.79%)	0.88
COLONOSCOPES RESULTS:			
Work shift (morning)	58 (82.86%)	59 (89.39%)	0.27
Cecal intubation rates	67 (95.71%)	62 (93.94%)	0.49
BBPS*	7 (6–9)	6 (5.7–9)	0.17
BBPS Left Colon*	2 (2–3)	2 (2–3)	0.37
BBPS Mild Colon*	2 (2–3)	2 (2–3)	0.10
BBPS Right Colon*	2 (2–3)	2 (2–3)	0.22
BBPS ≤ 5	15 (45.45%)	18 (54.55%)	0.43
Adenoma detection rate	29 (41.43%)	18 (27.27%)	0.40
Advanced Adenomas	9 (12.85%)	5 (7.57%)	0.48
Colorectal cancer	8 (11.43%)	8 (12.12%)	0.90

Conclusion: The use of a visual educational booklet for the preparation of colonoscopies does not provide a significant improvement in hospitalized patients in our health area. Heart disease and/or colon cancer were predictors of poor preparation for colonoscopy. An optimized preparation should be considered for this type of patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1494 STUDY OF ULCERATIVE COLITIS COMPLICATED BY PRIMARY SCLEROSING CHOLANGITIS

S. Murasugi, A. Ito, H. Kambayashi, M. Yonezawa, T. Ohmori, K. Tokushige
 Institute of Gastroenterology, Tokyo Women's Medical University, Tokyo/Japan

Contact E-mail Address: murashun0305@yahoo.co.jp

Introduction: Primary sclerosing cholangitis (PSC) is often associated with autoimmune diseases, and approximately 70% of PSC patients in Europe/United States and 32% in Japan also have ulcerative colitis (UC). While the complication of PSC is confirmed in about 5% of UC patients, the clinical features of UC associated with PSC differ from those of UC without PSC.

Aims & Methods: We investigated the clinical and colonoscopic features of colitis associated with PSC. We retrospectively examined the clinical features, including the clinical course and colonoscopic findings, of 25 colitis patients with PSC attending our hospital between 2000 and 2016.

Results: The male-female ratio was 12:13 and the age at diagnosis of PSC was 49 ± 15 years. PSC was the initial diagnosis in 12 patients (48%), while colitis was the first to be diagnosed in 4 patients (16%), and both diseases were found concurrently in 9 patients (36%). Among the 21 patients with the diagnosis of PSC first or concurrently, 12 patients (57%) had no symptoms of PSC and the latter was recognized by screening. There were 12 patients with UC (52%) and 11 patients with nonspecific colitis (48%). Among the 24 patients in whom the disease extent was assessed, 22 had pancolitis, 1 had left-sided colitis, and 1 had proctitis. Inflammation predominantly affected the right colon in 20/22 patients with pancolitis and also involved the terminal ileum in 9 patients (48%). The Mayo score for colonoscopic evaluation of UC was 1 in 16 patients (64%), 2 in 8 patients (32%), and 3 in 1 patient (4%). There were no rectal lesions in 10 patients (40%). Liver biopsy was performed in 17 patients, and Ludwig's stage was Stage I in 1 patient (6%), Stage II in 12 patients (71%), Stage III in 3 patients (18%), Stage IV in 1 patient (6%). Ludwig's stage did not correlate with the Mayo score. All patients with PSC and enterocolitis received oral

ursodeoxycholic acid (UDCA), including 13 patients with UDCA only (52%), 2 patients with combination of salazosulfapyridine (SASP) (8%), 5 patients in combination with 5-aminosalicylic acid (5-ASA) (20%), 2 patients in combination with prednisolone (PSL) (8%), 1 patient with the combination of SASP + PSL (4%), and 2 patients with 5-ASA + PSL (8%). The UDCA dose was 300 mg in 2 patients (8%), 600 mg in 15 (60%), and 900 mg in 8 (32%).

Conclusion: In colitis patients with PSC, there was no clear association between colonoscopic disease activity and the severity of PSC. There was no sex difference and the age at diagnosis of PSC showed a bimodal distribution (30s and 60s). Pancolitis was very frequent and predominantly affected the right colon, but disease activity was low. Rectal lesions were mild or absent. About half of the patients had inflammation of the terminal ileum.

P1495 COMPETENCY OF ENDOSCOPIC NON-TECHNICAL SKILLS (ENTS) DURING ENDOSCOPY TRAINING

K. Siau, P. Dunkley, J. Anderson, I. Beales, R. Broughton, M. Feeney, N. Hawkes, G. Johnson, B. Mckaig, R. Valori, C. Wells, S. Thomas-Gibson, A. Haycock

*JAG Working Group For The Quality Assurance Of Training, Joint Advisory Group, London/United Kingdom

Contact E-mail Address: keith@siau.org

Introduction: Endoscopic non-technical skills (ENTS), comprising of communication and teamwork, situation awareness, leadership and judgement and decision-making, are recognised indicators of quality endoscopy and patient safety. Since July 2016, electronic assessment forms (DOPS) for UK trainee endoscopists have been updated to include ENTS as an assessable domain. We aimed to assess the uptake and distribution of ENTS scoring in DOPS and their correlation with other endoscopic skills, across all assessable endoscopic modalities.

Aims & Methods: We identified all DOPS submitted between July 2016 and Feb 2017 from the UK endoscopy trainee database (JETS) and acquired data on trainees, procedures and scores. We collated scores for each of the 4 assessable domains (pre-procedural, procedural, post-procedural and ENTs) into overall outcomes of "not competent" (if any domain items required supervision) or "competent", and compared this to the overall competence rating. Statistical analysis was performed using chi2 and regression modelling.

Results: 8601 DOPS were prospectively collected, with ENTS assessed in 99.3%. Competency rates of individual ENTS items are summarised in Table 1. Rates of overall ENTS competency (defined as all items scoring competent) varied across procedures ($p < 0.001$): ERCP 39.8%, EUS 44.1%, gastroscopy 59.6%, colonoscopy 62.3%, PEG 71.1%, gastrointestinal bleed (71.5%), sigmoidoscopy 72.4% and polypectomy 73.2%. Scores by individual ENTS components are displayed in Table 1. Of DOPS awarded overall competency, 5.9% (240/4077) lacked full competence in ENTS ($p = 0.10$ across modalities). Across trainee specialties and endoscopic modalities, competence was greatest for "communication and teamwork" (77.1% overall), but least with "judgement and decision making" (68.3%). Competency in ENTS increased with lifetime procedural count (OR 1.008 per increase in procedure, $p < 0.001$), and correlated strongly with other assessable domains, including overall score ($p < 0.001$). After adjusting for procedural count, factors predictive of ENTS competence included trainee seniority (OR for ST5 level: 1.96, $p < 0.0001$), surgical trainees (OR 1.21, $p = 0.014$), trainees performing polypectomy (OR 2.02, $p < 0.0001$), and higher DOPS count (OR 1.03 per increase in DOPS, $p < 0.001$).

Table 1: Unadjusted ENTS scores by endoscopic modality.

	Communication and Teamwork	Situational Awareness	Leadership	Judgement and Decision Making
Colonoscopy	77%	75%	70%	68%
Dilatation	78%	75%	64%	64%
Polypectomy	82%	83%	81%	77%
ERCP	65%	62%	54%	48%
EUS	71%	71%	47%	59%
Sigmoidoscopy	83%	81%	79%	74%
OGD	73%	70%	67%	64%
PEG	80%	76%	78%	77%
Gastrointestinal Bleed	85%	83%	78%	77%

Conclusion: ENTS is an assessable domain within endoscopy training, with scores that correlate with other procedure-related skills, demonstrating construct validity of the ENTS scoring system. Competency of ENTS develop with procedural count, and vary with trainee seniority and speciality. Longer term data are required to assess the impact of ENTS on certification.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1496 MAKING COLONOSCOPISTS MORE AWARE OF THEIR ENDOSCOPIC NON-TECHNICAL SKILLS-IMPROVING FEEDBACK FORMATS DERIVED FROM THE MULTI-ASSISTANT RATING SCALE (MARS) TOOL

N. Hawkes, F. Kokwara, B. Davies, J. Cornish

Gastroenterology, Cwm Taf University Health Board, nr Cardiff/United Kingdom

Contact E-mail Address: neilhawkes@aol.com

Introduction: The development of Endoscopic Non-Technical Skills (ENTS) is associated with expert performance and high quality endoscopic outcomes. Whilst ENTS domains have been incorporated into Joint Advisory Group (JAG) Direct Observation of Procedural Skills (DOPS) forms, used as training tools, knowledge of ENTS domains amongst independent practitioners varies. To improve performance in this area of practice requires validated measurement tools and specific feedback against which improvement can be measured. We have previously developed a validated 360-degree multi-assessor rating scale (MARS tool) based on experienced endoscopy assistant ratings for ENTS providing data on 4 main domains of ENTS—each comprising 10 related but independent practice points. Providing an optimised feedback format for this data is likely to maximise the potential benefits of measuring ENTS performance.

Aims & Methods: We aimed to provide an optimised format for performance enhancing feedback in the ENTS domains and basis for specific auditable outcomes and performance indicators. Local colonoscopists gave consent to application of the ENTS questionnaire. The validated MARS tool assesses 4 ENTS domains—Communication (COMM), Situational Awareness (SITA), Leadership (LEAD) and Judgement & Decision-making (J&DM). Each MARS domain in the administered questionnaire was represented by 10 items and is assessed on a 7-point scoring scale. We sought to develop 1) a format to illustrate an individual's overall performance in each of the 4 main ENTS domains in comparison to other operators and 2) a detailed domain breakdown highlighting areas of underperformance 3) Collate feedback on the presentation formats.

Results: 9 endoscopists consented to an assessment of ENTS using the MARS tool. The MARS questionnaires were administered during January 2017—relating to the prior 3 months clinical practice. Acceptable performance thresholds were set as >90% good-excellent ratings in each domain. Need for improvement was defined as 80–90% good-excellent ratings (i.e. 10–20% average or poor ratings) and sub-optimal performance as 80% or less good-excellent ratings (i.e. >20% average-poor ratings). Good intra- and inter-rater reliability was demonstrated for these cut-off values during validation of the MARS tool. Scatter plots were used to present the overall domain ratings for COMM, SITA, LEAD and J&DM domains allowing comparison with other endoscopists. To provide more detailed domain-specific feedback to endoscopists an individual report is generated of 4 domain tables summarising the question items and using a 'traffic-light' display to help operators quickly identify those specific skills that require areas for improvement. All endoscopists reported finding the ENTS feedback helpful and indicated that it was 'likely' or 'very likely' to prompt an alteration in practice. A suggestion to add an additional column to the summary table indicated where performance level has changed in subsequent audit rounds is being considered.

Example Feedback table - Situational Awareness Domain for Endoscopist 9

SITA 1	Pre-assessment of potential patient risks	GREEN
SITA 2	Recognises problems in a timely fashion	GREEN
SITA 3	Aware of working environment, minimises disruptions	GREEN
SITA 4	Effectively troubleshoots technical problems that arise	RED
SITA 5	Recognises and assesses pathological findings effectively	GREEN
SITA 6	Reacts flexibly and effectively to unexpected or unforeseen circumstances	RED
SITA 7	Aware of patient safety parameters during procedure, responds well	AMBER
SITA 8	Considers other opinions and guidance when faced with an untoward event	AMBER
SITA 9	Predicts well the likely outcome of a situation and plans for this eventuality	AMBER
SITA 10	Constantly checks patient aiming to minimise procedural discomfort	AMBER

Conclusion: The MARS tool is a practical way to measure ENTS performance alongside other key performance measures as part of a robust quality assurance system. The benefits of providing overall comparative data has been established previously in sharing more established key performance indicators. The feedback format for data derived from the MARS tool has additionally provided detailed domain-specific ENTS performance ratings that brings to attention areas for improvement in a clear and understandable way that can be re-tested as part of an integrated audit cycle.

P1497 OUTCOMES OF ENDOSCOPIC RESECTION OF COMPLEX COLORECTAL LESIONS REFERRED TO A TERTIARY INSTITUTION AFTER FAILED ATTEMPTS AT RESECTION OR EXTENSIVE MANIPULATION

A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji

Endoscopy, King's College Hospital, London/United Kingdom

Contact E-mail Address: aemmanuel@nhs.net

Introduction: Substantial manipulation or sampling of large colorectal lesions prior to endoscopic resection can have significant effects on the feasibility and outcomes of endoscopic treatment. Failed attempts at resection and extensive sampling or tattooing into lesions prior to referral to a specialist centre are common in western practice. However, there are few data defining the scope of the problem and the effects on outcomes following endoscopic resection. We examined the effect of significant prior manipulation on the feasibility and outcomes of endoscopic resection of complex colorectal neoplasms in a UK tertiary referral centre.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥ 2 cm were included. All lesions were assessed with magnification chromoendoscopy supplemented by colonoscopic ultrasound in selected cases. A lesion specific approach was used to decide on resection technique. Patients were grouped according to whether they had previous failed attempts at resection, heavy manipulation (≥ 6 biopsies or tattoo into the lesion), or minimal sampling only (< 6 biopsies). Outcomes included initial successful endoscopic resection, complications, recurrence and the need for surgery.

Results: 426 of 437 lesions were successfully resected (97.5%) using EMR $n=340$ and ESD and Hybrid ESD ($n=97$). The mean lesion size was 5.5 cm ($+/- 3.0$ cm). 225 (51%) lesions had been subjected to failed attempts at resection or heavy manipulation prior to referral. In 97 lesions (22%), an average of 1.5 (range 1–5) previous attempts at resection had been made, including 43 attempts at transanal surgical resection in 25 patients. A further 128 lesions (29%) had been extensively sampled or tattooed. Mean lesion size was 55.6 mm $+/- 30.7$ mm. Initial endoscopic resection was deemed successful in 98% of cases after previous failed attempts, 97% of cases with prior heavy manipulation and 97% of other cases ($p=0.86$). En bloc resection was possible in fewer patients with previous attempts at resection (14%, 31% and 42% respectively, $p < 0.001$). Complication rates were higher for patients with prior heavy manipulation compared to those with failed attempts at resection and minimal sampling (14% versus 5% and 3%, $p < 0.001$). Recurrence rates were 24.1%, 14.6% and 12.2% respectively ($p=0.07$). 95% of patients without invasive cancer who had prior failed attempts at resection were free from recurrence and had avoided surgery at last follow up.

Conclusion: Failed prior attempts at resection or heavy manipulation of lesions reduces the chance of achieving en bloc resection and increases the risk of complications and recurrence. Nevertheless, specialist management in a dedicated tertiary unit results in safe and successful organ preserving endoscopic treatment of these extremely challenging lesions in over 95% of cases with few significant complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1498 NBI VERSUS BLI: WHICH MODALITY IS BETTER FOR OBSERVATION OF MUCOSAL BLOOD FLOW IN THE SMALL AND LARGE BOWEL USING NBI (NARROW BAND IMAGING) OR BLI (BLUE LASER IMAGING)?

M. Yasuda¹, Y. Naito², Y. Itoh²

¹Dept. Of Gastroenterology And Hepatology, Uji-Tokushukai Medical Center, Uji-city/Japan

²Department Of Gastroenterology And Hepatology, Kyoto Prefectural University of Medicine, Kyoto/Japan

Contact E-mail Address: koutoku7@fa2.so-net.ne.jp

Introduction: In recent years, significant advances and innovations have been made in gastrointestinal endoscopy technology. The special light observation using a narrow band light source different from conventional white light is one such innovation. The special light observation with a magnifying procedure has markedly contributed to improving the diagnosis of lesions in the esophagus, stomach, and large bowel; it is particularly useful for differentiating between benign and malignant lesions and evaluating the depth of invasion. The instruments for narrow band imaging (NBI) were developed by Olympus Co., Ltd., and those for blue laser imaging (BLI) by Fujifilm Co., Ltd. These systems are applied to magnifying endoscopy in clinical practice. Studies have examined the usefulness of magnifying observation with NBI (m-NBI), BLI (m-BLI), and new and brighter BLI (m-BLI bright) for the diagnosis of neoplastic diseases, especially for the early detection of gastrointestinal cancers. However, there are relatively few reports describing the application of these techniques to benign diseases.

Aims & Methods: This basic study aimed to explore the potential of magnifying endoscopic observation with special light by evaluating the visualization of mucosal blood flow in the small and large bowel. The subjects were selected from among patients who had undergone colonoscopy since April 2016. They were randomized into three groups: patients undergoing examination with EC-L600ZP, a high-end instrument manufactured by Fujifilm Co., Ltd. (group F), CF-HQ290ZI, a high-end instrument manufactured by Olympus Co., Ltd. (group O1) or PCF-H290ZI manufactured by Olympus Co., Ltd (group O2). Each group consisted of 25 patients. The visualization of mucosal blood flow in the small and large bowel by magnifying endoscopic observation with special light was evaluated and scored as follows: good visualization 2; partial visualization 1, and no visualization 0. The water method and tip attachment were used in all cases.

Results: The respective mean scores for visualization of the small and large bowel were 2 and 2 in group F, 1.32 and 1.24 in group O1, and 1.48 and 1.40 in group O2. The visualization scores for both the small and the large bowel were significantly higher in group F than in groups O1 and O2. Group O2 had higher scores than group O1, although the difference was not statistically significant. The endoscope used in group F has a bright laser light source and maximum optical magnification levels up to 135 times and maximum electronic magnification levels up to 270 times. On the other hand, the endoscopes used in groups O1

and O2 have relatively dark xenon light sources and maximum optical magnification levels up to 80 and 110 times, respectively. Therefore, the differences in visualization of mucosal blood flow in the small and large bowel among the groups were considered to be attributable to differences in instrument efficiency. **Conclusion:** Our results show that magnifying observation with BLI is superior to that with NBI regarding the observation of mucosal blood flow in the small and large bowel. We are planning to conduct a study on the clinical application of magnifying observation with BLI for visualization of mucosal blood flow in the small and large bowel.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1499 MULTIPLE COLORECTAL ADENOMAS WITHOUT APC OR MUTYH GERMLINE MUTATION: A HETEROGENEOUS SUBGROUP OF PATIENTS

L. Sanchez Mete, E. Mannisi, A. Martayan, M. Varanese, V. Stigliano
Gastroenterology And Digestive Endoscopy, Regina Elena National Cancer Institute, Rome/Italy

Contact E-mail Address: lupe.sanchez@ifo.gov.it

Introduction: Multiple colorectal adenomas (MCRA) can be defined as an endoscopic feature of ≥ 10 colorectal adenomas in patients (pts) without APC or MUTYH germline mutation. At present its clinical features, management and the presence of extracolonic cancer are not well studied.

Aims & Methods: The aim of the present study is to better define the clinical characteristics at diagnosis and during follow-up of MCRA affected patients. Forty-eight patients (22 Females, 26 Males) with MCRA (≥ 10 colorectal adenomas), without deleterious mutations of APC or MUTYH genes, were recruited for the study. Clinical features at diagnosis and extracolonic manifestations were recorded. Forty patients underwent annual colonoscopy at our division with a mean follow-up of 8.1 years (range 1 to 38y). Findings from esophagogastroduodenoscopy were also recorded. Eight patients were lost at follow-up.

Results: The mean age at MCRA diagnosis was 50.1 ± 14.6 years (range, 19 to 79 years) and 20 pts (41.6%) had at least a first degree relative affected with colorectal neoplasia. Clinical features at diagnosis: the number of polyps ranged between 10 and 20 in 43.7% of the cases; 21 and 50 in 27.1%; ≥ 50 in 29.2%; 22.9% of pts had one or more adenocarcinomas (ADC); 16.6% had a previously diagnosed extracolonic cancer (breast, endometrial, thyroid, lung, bladder, brain, larynx). Twenty-five pts (52%) needed surgery, ten underwent a subtotal colectomy and fifteen a total colectomy. During follow-up twenty-two (55%) pts developed recurrent adenomas and two (5%) had one or more ADC in the retained colectum; 12.5% of pts developed duodenal adenomas, one had a duodenal adenocarcinoma; we recorded one case of abdominal wall desmoid.

Conclusion: MCRA patients in the present study had similar clinical characteristics to MUTYH associated Polyposis (MAP) affected patients. They were generally diagnosed at a mean age of >50 years, they had more than 20 polyps (56.3%) at diagnosis, associated with ADC in 22.9% of the cases and required surgery in the majority of cases (52%). During follow-up, pts also developed recurrent adenomas. Clinical characteristics and family history in these patients support the hypothesis that pathogenic alterations in yet unknown genes may be involved. Next-generation sequencing is a promising technology aimed at this purpose. However, these patients should undergo a closer surveillance than those with sporadic adenomas.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1500 EVALUATION THE RELATIONSHIP BETWEEN NUMBERS OF BIOPSIES PER CASE AND DEGREE OF FIBROSIS IN COLON

J. Yang¹, Y. Jung¹, I. Chung¹, Y.S. Cho¹, S.J. Han¹, T.H. Lee¹, S. Park¹, H. Cho², Y. Hwangbo³, S. Kim¹

¹Division Of Gastroenterology & Hepatology, Department Of Internal Medicine, Soonchunhyang University College of Medicine, Cheonan Hospital, Cheonan/Korea, Republic of

²Department Of Pathology, Soonchunhyang University College of Medicine, Cheonan/Korea, Republic of

³Department Of Preventive Medicine, Soonchunhyang University College of Medicine, Cheonan/Korea, Republic of

Contact E-mail Address: soufly99@naver.com

Introduction: A degree of fibrosis on targeted lesion is one of the widely known factors which affects the results of Endoscopic mucosal resection (EMR) and Endoscopic submucosal dissection (ESD). Severe fibrosis is associated with complications such as perforation, post-coagulation syndrome and bleeding. Discovering the factors causing fibrosis of tumor could help sorting patients who is suitable for endoscopic removal of colon tumor. Generally a biopsy is performed on a tumor larger than 2 cm in diameter for a diagnose purpose. Fibrosis can be caused by biopsy performed before resection.

Aims & Methods: We conducted a study to evaluate the relationship between numbers of biopsies and degree of fibrosis in colon. We retrospectively enrolled 149 lateral spreading tumors (LSTs) from 145 patients who underwent colon ESD or EMR between January 2005 and May 2016. All LSTs were larger than 2 cm and conducted en-bloc resection. We included elevated or flat type LSTs and excluded lesions of the depressive or ulcerative type. Each data is categorized with prior biopsy status, numbers of biopsies. Degree of fibrosis in resected tumors by EMR or ESD was classified as 0 (no fibrosis), 1 (few), 2 (moderate), 3 (much) by pathologist. Distribution (focal, scattered, and diffuse)

and depth (mucosa, submucosa, mucosa and submucosa) of fibrosis were also analyzed.

Results: The mean age of patients was 62.9 \pm 11.1 years old. Of the total 149 lesions, preprocedural biopsies were performed in 109 lesions (73.2%) and biopsy was not performed in 40 lesions (26.8%). The size of lesions was 54.4% in 20–30 mm, 28.2% in 30–40 mm, and 17.4% in >40 mm and the histologic type of lesions was 60.4% in adenoma, 20.8% of intramucosal cancer, and 18.8% of submucosal cancer, respectively. Signs of fibrosis were present on 45.9% (50/109) of patients with prior biopsy, and 40.0% (16/40) of patients without prior biopsy. ($P=0.326$) There was no significant difference in degree ($P=0.791$), distribution ($P=0.941$) and depth ($P=0.748$) of fibrosis between groups with or without prior biopsy. In relationship between pathologic results and the presence of fibrosis, the percentage of adenoma, intramucosal cancer, SM-1($<1000\mu\text{m}$) cancer and SM-2($>1000\mu\text{m}$) cancer with fibrosis were 32.31%, 66.67%, 87.5% and 90% ($P=0.00$). Additionally, the fibrosis rate for tumors ≤ 3 cm and >3 cm were 44.12% and 58.97% ($P=0.002$). When biopsies were performed two or more times on a same lesion, it showed significant difference comparing to patients who only underwent biopsy just once. (OR 4.98, 1.20–20.51, 95% CI, $P=0.026$)

Conclusion: Degree, distribution and depth of fibrosis were not associated with prior biopsy status. However, the more invasive tumor is, the more presence of fibrosis was found. Moreover, the caution should be needed when performing multiple biopsies because; multiple biopsies are more likely to cause fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1501 ADVANCED NEOPLASIA YIELD IN PATIENTS UNDERGOING COLONOSCOPY AFTER SCREENING FLEXIBLE SIGMOIDOSCOPY: DOES THE DISTAL COLONIC PATHOLOGY PREDICTS THE YIELD IN PROXIMAL COLON?

R. Rameshshanker, F. Purchiaroni, A. Crudeli, A. Rajendran, I. Stasinou, A. Wilson, S. Thomas-Gibson, A. Haycock, A. Humphries, N. Suzuki, B.P. Saunders
Wolfson Endoscopy Unit, St Mark's Hospital, Harrow, London/United Kingdom

Contact E-mail Address: r.rameshshanker@nhs.net

Introduction: Currently patients undergoing a screening flexible sigmoidoscopy (Bowel Scope screening) examination at the age of 55 are referred for colonoscopy if the following polyp criteria are met: polyp >1 cm, villous histology, high grade dysplasia, 3 or more adenomas or >20 hyperplastic polyps (HP).

Aims & Methods: Objective is to assess the proportion of patients who had an advanced adenoma (size >1 cm, villous or high grade dysplasia on histology) in the proximal colon when referred for a colonoscopy after a screening flexible sigmoidoscopy. A retrospective cross-sectional study of patients who underwent Bowel Scope screening between July 2013 - July 2016 at St Mark's Bowel Cancer Screening (BCS) Centre was performed. Epidemiology, procedural and polyp data were retrieved from the endoscopy and Bowel Cancer screening database.

Results: 9960 patients had a screening flexible sigmoidoscopy in the time period. Descending colon was reached in 82% of patients. Advanced adenomas were detected in 351 (3.2%) patients. 520 (5.2%) patients had a colonoscopy following screening flexible sigmoidoscopy as per the BCS protocol. Median age was 55 years (male: female ratio 2:1). Caecal intubation was achieved in 98% (510/520) of cases. At least one adenoma or a sessile serrated adenoma/polyp (SSA/P) was detected, proximal to the extent of flexible sigmoidoscopy examination, in 45% (232/520) of patients (Table 1). Presence of advanced adenoma in the distal colon was an indication for colonoscopy in 351/520 patients (68%). Of these, 52 (14.8%) had a synchronous proximal colonic advanced adenoma and 20 (5.7%) had a synchronous SSA/P. Only 5 (1.4%) patients had an advanced SSA/P (polyp >1 cm or with dysplasia) in the proximal colon. Presence of distal advanced adenoma was associated with proximal advanced adenoma ($p=0.0006$). However, there was no association between presence of distal advanced adenoma and proximal SSA/P ($P=0.47$) or advanced SSA/P ($p=0.4$).

Table 1: Proximal colonic pathology during colonoscopy

(continued)

Table 1 Continued

Indication	Number of patients	Proximal Advanced adenoma	Proximal SSA/P	Proximal advanced SSA/P
Indication	Number of patients	Proximal Advanced adenoma	Proximal SSA/P	Proximal advanced SSA/P
Adenoma > 1 cm	153	14.4%	8.5%	2.6%
Villous features	189	14.3%	3.2%	0.5%
High-grade dysplasia	9	36.4%	8.3%	0%
Others (> 1 cm non adenomatous polyp, > 20 hyperplastic polyps, > 3 adenomas)	169	5.3%	5.8%	1.6%

Conclusion: Distal colonic advanced adenomas are a marker of synchronous proximal colonic adenomas and sessile serrated polyps. When colonoscopies were performed for other indications (non-adenomatous polyp > 1 cm, multiple distal HP polyps) the yield in the proximal colon was significantly smaller. These “soft” indications for colonoscopy accounted for a significant additional workload that appears unjustified.

P1502 LEARNING CURVE FOR OPTICAL DIAGNOSIS OF COLORECTAL POLYPS USING CUMULATIVE SUM ANALYSIS

R. Rameshshanker, A. Wilson, S. Thomas-Gibson, N. Kamperidis, N. O'Shea, B.P. Saunders

Wolfson Endoscopy Unit, St Mark's Hospital, Harrow, London/United Kingdom

Contact E-mail Address: r.rameshshanker@nhs.net

Introduction: Optical diagnosis for diminutive and small colorectal polyps is an attractive option to reduce costs and streamline patient care. The American Society of Gastrointestinal Endoscopy Preservation and Incorporation of Valuable Endoscopic Innovations (PIVI) established a 90% diagnostic threshold for real time endoscopic assessment of the histology of diminutive colorectal polyps. For adoption of optical diagnosis in clinical practice, colonoscopists must be trained and show on-going competence. The learning curve for trainees to achieve the competency has not been fully explored.

Aims & Methods: Aim is to evaluate the minimum number of polyps to achieve and maintain the optical diagnostic thresholds per PIVI standards using an upward CUSUM plot. Four trainees without previous experience in optical diagnosis at our institution participated in this prospective study. Four weeks before the commencement of the study they were given a training module on optical diagnosis (OD). OD was based on NICE and WASP classification.^{1,2} During the study period (January 2016-August 2016), each trainee documented the optical diagnosis of polyps less than 10 mm in size. Confidence levels of OD were noted at the same time. Patient demographics and polyp details (site, size, Paris classification and histology) were collected prospectively. OD of each polyp was compared against the polyp histology. Polyps without the histological confirmation were excluded from the analysis. Every trainee had on-going feedback on their performance.

Results: A total of 708 polyp observations were performed by trainees during the study period. Total number of adenomas, hyperplastic polyps and sessile serrated adenomas/polyps (SSA/P) were 364, 214 and 52 respectively. Trainees OD performance was plotted on an upward CUUM plot.

Table1: Trainees optical diagnostic performance

	Trainee1	Trainee 2	Trainee 3	Trainee 4
Sensitivity	95%	96%	94%	92%
Specificity	91%	87%	83%	91%
Positive Predictive Value	89%	94%	88%	94%
Negative Predictive Value	92%	92%	91%	93%

All 4 trainees achieved sustained accuracy (90% threshold) in OD within 12–58 observations. The number of polyps required to reach the plateau varied between 12 to 58. Every trainee's confidence level improved over time (from 69% to 89%) and the effect was augmented by in-vivo feedback and revision of training module. Table 1 summarises the optical diagnostic performance of all 4 trainees. Negative predictive value for adenomas were above 90% for all trainees.

Conclusion: The CUSUM scores of all 4 trainees in the study reached the PIVI standards plateau by the 58th polyp observation. In-vivo feedback and continued training appears important to maintain the performance. Our preliminary findings could be used as a guide to plan the certification process for implementation of optical diagnosis.

P1503 THE CLINICAL VALUE OF ENDOSCOPIC FULL-THICKNESS RESECTION FOR THE TREATMENT OF COLORECTAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA: A PROSPECTIVE SINGLE-CENTER STUDY

M. Xu, C. Zhang, Q. Li

Endoscopy Center, Zhongshan Hospital, Shanghai/China

Contact E-mail Address: xumeidong@aliyun.com

Introduction: Given diminishment of quality of life caused by colectomy and rectectomy, a minimally invasive treatment is desirable for colorectal submucosal tumors (SMTs).

Aims & Methods: The aim of the current study was to evaluate the clinical efficacy, safety and feasibility of endoscopic full-thickness resection (EFTR) for colorectal SMTs originating from the MP layer. A prospective study was carried out, including a consecutive cohort of 56 patients who underwent EFTR for colorectal SMTs originating from the MP layer between January 2008 and September 2014 in our center. Among these lesions, 21 located in the colon, 9 located in the intraperitoneal rectum and 26 located in the extraperitoneal rectum. The tight adhesion of the lesion to the serosal layer was identified before EFTR in all cases. EFTR was performed using a standard ESD technique under direct endoscopic view. The defect of colorectal wall was closed after resection in all cases. Complete resection rate, complications and lesion recurrence were evaluated.

Results: Successful EFTR was performed in 54 (96.4%) patients. The other 2 patients were transferred to suffer laparoscopic right hemi-colectomy and EFTR combining laparoscopic operation respectively, because the lesions involved the external organs and were too difficult to get en bloc resection endoscopically. The en bloc resection rate and complete resection rate were both 96.4% (54/56). Among 54 cases, 52 of these lesions were performed with EFTR without laparoscopic assistance, while 2 needed laparoscopic assistance to get the defect closed after resection. The median operation time was 45 min (range, 20–130 min). The median maximum diameter of resected tumors was 1.5 cm (range, 0.5–5.0 cm). Accurate histopathologic results were acquired from all the resected lesions, including 18 leiomyomas, 11 gastrointestinal stromal tumors (GISTs), 8 fibrous tumors, 5 schwannomas, 11 granulomas, 2 displaced endometrium, and 1 hamartoma. Three patients had local peritonitis and two patients developed postoperative bleeding. All of them recovered after receiving conservative treatments. No single case developed diffuse peritonitis. No lesion residual or recurrence was found during the follow-up period ranging 2–54 months.

Conclusion: EFTR appears to be a safe, feasible, and effective procedure for providing accurate histopathologic evaluations, as well as a curative treatment for colorectal SMTs originating from the MP layer. However, it should be performed by the very experienced endoscopists.

Introduction: Colonic ESD has been becoming a standard treatment in the world. However, sometimes it is hard to remove the colon tumor during ESD. When we find it difficult to detach the colorectal neoplasm in ESD, we have to consider, the following three points: if we don't have enough experience and skill, we should take the training more. If there are lots of vessels and fibrosis in the submucosal layer, it is necessary to choose adequate tools. And if patients have complicated colon, suitable endoscope need to be selected. In such cases we always use DBE.

Aims & Methods: We evaluated the outcomes of colonic ESD by using DBE (DBE-ESD). Short DBE we used were EC450BI5, EN530BI and EI580BT (Fujifilm Co., Tokyo, Japan). We've performed DBE-ESD on 211 lesions in 184 patients. We analyzed the lesions located in the proximal colon, and the following items were examined: arrival time, procedure time, rate of negative margin, perforation rate, length of hospital stay and recurrence rate in the 5th-year after the ESD.

Results: There were 159 lesions located in the proximal colons. The median arrival time to the lesion was 7.9 min, operation time 51.1 min, negative rate of horizontal margin 99.4%, vertical margin 99.4%, perforation rate 0%, median length of hospital stay 3.1 days., and recurrence rate in patients with more than 5 year follow-up 0%.

Conclusion: Because the balloons and the overtube retained the scope at stable position, we were able to get good working space. Therefore, DBE should be one option for difficult cases in ESD.

Introduction: Adenoma detection rate (ADR) is a quality indicator of screening colonoscopy. Monitoring withdrawal time (WT) and use of full-spectrum endoscopy (FUSE) have been suggested to increase the ADR since allow an accurate evaluation of the hidden areas of the colon.

Aims & Methods: We aimed to evaluate whether monitoring of WT alone or in combination with the use of FUSE would be able to increase the ADR. In a prospective non-randomized observational study, consecutive outpatients, aged 18–85 yr, undergoing colonoscopy with different indications were enrolled. In phase 1, endoscopists performed 660 colonoscopies either with standard forward-viewing endoscope (SFVE) (n = 330) or with FUSE (n = 330) without a dedicated WT protocol. In this phase, colonoscopy WTs were measured without the endoscopists' knowledge of being monitored. In phase 2, endoscopists were informed of being monitored and performed further 660 colonoscopies either with SFVE (n = 330) or with FUSE (n = 330).

Results: No differences were observed among the four arms in terms of demographic, clinical features, and indications to colonoscopy. WT was lower in phase 1 arms compared to phase 2 arms (SFVE: 267 ± 96 vs. 387 ± 65, p = 0.001; FUSE: 293 ± 112 vs. 430 ± 93, p = 0.001). When endoscopists were aware of being monitored and used full-spectrum endoscope we observed a higher ADR [phase 1 SFVE 27.3% (90) phase 1 FUSE 33.0% (109) phase 2 SFVE 33.6% (111) phase 2 FUSE 41.8% (138); p = 0.001] and adenoma per colonoscopy (APC) [phase 1 SFVE 0.43 ± 0.85 phase 1 FUSE 0.56 ± 1.08 phase 2 SFVE 0.65 ± 1.24 phase 2 FUSE 0.71 ± 1.08; p = 0.004]. The detection rate of adenoma located proximally to the splenic flexure was higher in phase 2 arms (phase 1 SFVE 11.2% vs. phase SFVE 16.4%, p = 0.056; phase 1 FUSE: 12.7% vs. phase 2 FUSE 18.9%, p = 0.033), whereas adenoma located distally to the splenic flexure was higher in the FUSE arms compared to SFVE arms, but these differences were not significant (Phase 1 SFVE 20.0% vs. Phase 1 FUSE 24.8%, p = 0.081; Phase 2 SFVE 21.8% vs. Phase 2 FUSE 27.0%, p = 0.147).

Conclusion: Unmonitored endoscopists have a sub-optimal WT, which increases when they are aware to be monitored. Use of full spectrum scopes combined with WT monitoring results in increase of adenoma detection rate. In particular, monitoring WT increases the detection of adenomas in proximal colon, whereas the use of FUSE seems to increase the detection of adenomas in distal colon.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1506 HIGH LEVELS OF "PRESUMED POLYP MISS RATE" AT 1 AND 3 YEARS FOLLOWING INDEX SCREENING COLONOSCOPY: NO ROOM FOR COMPLACENCY

R. Rameshshanker, F. Purchiaroni, A. Wilson, A. Rajendran, S. Thomas-Gibson, A. Humphries, A. Haycock, N. Suzuki, B.P. Saunders

Introduction: Colonoscopy with polypectomy is considered the optimal method of bowel cancer prevention. Despite improvements in colonoscopy training and technology, it remains as an imperfect tool and the adenoma miss rates vary between 6–27%.

Aims & Methods: Aim is to determine the presumed miss rate for adenomas and sessile serrated adenomas/polyps (SSA/Ps) after a complete screening colonoscopy Methodology A prospective observational study was performed at our bowel cancer screening centre over 12 months from July 2015. Patients who underwent a surveillance colonoscopy following an index colonoscopy were included (one and three-year surveillance). All colonoscopies were performed by 6 experienced, accredited bowel cancer screening colonoscopists. Polyp characteristics and procedural data were prospectively recorded and collected. Polyp histology and epidemiology data were retrieved from our endoscopy database. A polyp was considered as "missed" at the index colonoscopy if at 1 year surveillance it was not adjacent to a scar (a recurrence) or at 3 years if > 5 mm in size and not adjacent to a scar.

Results: 241 patients underwent a surveillance colonoscopy (male: female 2:1, median age 65 years). 90/241(37.3%) patients had a one-year surveillance colonoscopy. There was no significant difference in the quality of bowel preparation, caecal intubation rate and total procedure time between index and surveillance procedures. Total number of polyps detected during index and surveillance colonoscopies were 815 and 469 respectively. The presumed miss rate of polyps, adenomas, SSA/Ps and advanced adenomas were 37.8%(469/1241), 22.1%(176/798), 41.7%(20/48) and 15.2%(36/236) respectively. More adenomas were missed in the proximal colon when compared to distal colon (26.64% vs 18.04%, p = 0.01). Table 1 illustrates the distribution of missed adenomas in each segment of colon. Adenoma miss rates per size as follows: < 5 mm, 6–9 mm and > 10 mm were 24.27 and 8% respectively. Higher number of polyps (> 3)

detected during index colonoscopy independently correlated with high miss rates (84.3% vs 72%, p = 0.04).

Table 1: Missed polyps at different colonic segments

Location	Adenoma miss rate (%)	Sessile serrated adenoma miss rate (%)
Rectum	9	33
Rectosigmoid junction	19	0
Sigmoid colon	23	50
Descending colon	10	0
Splenic flexure	26	0
Transverse colon	27	30
Hepatic flexure	30	57
Ascending colon	26	50
Caecum	26	0

Conclusion: Our study highlights that there is likely to be a significant miss rate for adenomas and SSA/Ps even after careful index colonoscopy. Miss rate was higher when multiple polyps are seen at the index examination. This finding appears to justify the current BSG (British Society of Gastroenterology) guidelines for an early, 1 year colonoscopy when multiple polyps are seen. The presumed polyp miss rate at 1 & 3 years may be justified as a new quality metric within screening programmes.

Introduction: Systemic diseases including several types of cancer have been associated with periodontitis, potentially owing to the constant systemic inflammatory state in those patients. Data on a potential association of periodontal disease and colorectal neoplasia is scarce and conflicting.

Aims & Methods: Data from 25,407 patients undergoing healthy check up assessing periodontal disease according to periodontitis-risk classes (PRC 0–healthy gingiva, PRC 1 – tatar or plaque, PRC 2 – redness or swelling) and screening colonoscopy between 2009 and 2012 in Austria were included. Colonoscopy outcomes were compared between patients with and without signs of periodontal disease using multivariate models adjusting for age, sex, smoking, alcohol consumption, diabetes and BMI.

Results: In multivariate adjusted models, patients with periodontal disease had similar odds for the detection of colorectal polyps as those without signs of periodontal disease [adjOR 1.070; 95% CI: 0.918; 1.247]. Regarding the prevalence of adenomas, patients with periodontal disease, likewise, had similar odds as those with healthy periodontal tissue [adjOR 1.010; 95% CI: 0.840; 1.213]. Similarly, those with periodontal disease had comparable odds for colorectal adenomas as those without signs of periodontal disease [1.055 (0.785; 1.418)]. In the table below the adenoma detection rate (ADR) and advanced adenoma detection rate (AADR) divided into the periodontitis-risk classes.

Table 1: ADR (adenoma detection rate) and AADR (advanced adenoma detection rate) according to the periodontitis-risk classes

	PRC 0	PRC 1	PRC 2
Adenoma (ADR)	19,34%	19,56%	20,02%
Advanced adenoma (AADR)	5,42%	6,1%	6,5%

Conclusion: Conclusion: Periodontal disease has no impact on the adenoma and advanced adenoma detection rates in a large screening colonoscopy cohort.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1508 OUTCOMES OF ENDOSCOPIC RESECTIONS OF LARGE NON-POLYPOID LESIONS IN INFLAMMATORY BOWEL DISEASE: A SINGLE UNITED KINGDOM CENTRE EXPERIENCE

S. Gulati, A. Emmanuel, M. Burt, P. Dubois, B. Hayee, A. Haji
Endoscopy, King's Institute of Therapeutic Endoscopy, RS/United Kingdom

Contact E-mail Address: shraddha.gulati@nhs.net

Introduction: Patients with colitis carry an increased risk for the development of dysplasia compared to those without¹. The SCENIC consensus statement recommends endoscopic resection of all visible dysplasia². Due to technical challenges and limited experience in the West of large colitis associated non-polypoid endoscopic resections, such patients are often subjected to colectomy.

The King's Institute of Therapeutic Endoscopy (KITE) is a tertiary centre for endoscopic assessment and resection of large/challenging colorectal polyps. Here we present the largest single-centre case series of large non-polypoid resections associated with colitis.

Aims & Methods: Adults with confirmed colitis (ulcerative colitis extending beyond the rectosigmoid junction and crohn's colitis affecting at least the left colon) with lesions at least 20 mm in size within the colitis segment were included. Data including demographics, clinical history, lesion characteristics, method of resection and post-resection surveillance were collected prospectively in patients from January 2011 to November 2016. Resection techniques included endoscopic mucosal resection (EMR), endoscopic submucosal dissection (ESD) and hybrid ESD. Surveillance of resection site with magnification chromoendoscopy (mCE) was performed at 3 months with pan colonic mCE at 1-year post resection and annually thereafter.

Results: Thirteen lesions satisfied the inclusion criteria in 13 patients. Patient demographics and clinical data are presented in table 1. Mean lesion size was 47.3+/-22.4 (20–90) mm. All lesions were non polypoid with distinct margins and no ulceration. High-frequency mini-probe ultrasound confirmed intramucosal lesions in 5 cases where pit/vascular pattern was distorted due to inflammation. En bloc resection was achieved in 6 cases. 69% lesions were deeply scarred of which 66% had experienced prior instrumentation. Resection of a single lesion was abandoned due to intense fibrosis. Macroscopic evidence of complete resection was achieved in all remaining cases. Endoscopic diagnosis of pre-cancerous lesions of less than 1000 µm submucosal invasion was confirmed histopathologically in 100% of resected lesions. Complete excision was confirmed in all en bloc resections. A single case of small perforation and another with delayed minor bleeding were both managed endoscopically. Mortality/hospital admission within 30 days post resection was 0%. Median follow up was 28 months (12–35) with no recurrence. Alternative site dysplasia was detected in 2 patients. All lesions were sub 20 mm and resected endoscopically. Two patients were referred for colectomy due to a concomitant diagnosis of neuroendocrine tumour and the second with alternate site advanced dysplasia.

Table 1: Baseline characteristics.

Patient Demographics	
Age at time of resection (mean, SD, range) (years)	57.31+/-12.7, 30–81
Male (n) (%)	10 (77)
Female (n) (%)	3 (23)
Clinical Data	
Duration of disease (mean, SD, range) (years)	19.9, 14.2, 1–50
Disease extent	
Splenic Flexure (n) (%)	3 (23)
Pan-colonic/Extensive (n) (%)	10 (77)
Primary Sclerosing Cholangitis	3
IBD Medication	
5-ASA* (n) (%)	11 (84)
Azathioprine (n) (%)	2 (15)
Biologics (n) (%)	1 (7)
ASA Physical Status Classification	

(continued)

Table 1 Continued

Patient Demographics	
ASA grade II (n) (%)	7 (54)
ASA grade III (n) (%)	4 (31)
ASA grade IV (n) (%)	2 (15)

Conclusion: This cohort series demonstrates that endoscopic resection of large non-polypoid lesions in association with colitis is feasible using an array of resection methods, safe and has good long term outcomes in a western tertiary endoscopic centre.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1509 RESEARCH ON APPLICATION OF TRANSANAL TUBE DECOMPRESSION FOR PREVENTION OF COMPLICATIONS IN COLORECTAL MUCOSAL LESIONS AFTER ESD

L. Bing, Z. Qi, Y. Zhong
Endoscopy Center And Endoscopy Research Institute, Zhongshan Hospital, Fudan University, Shanghai, Shanghai/China

Contact E-mail Address: 13564623481@126.com

Introduction: Endoscopic submucosal dissection (ESD) has been widely used in the minimally invasive treatment of early colorectal mucosa and submucosal lesions. This technique has made it possible to resect even large mucosal or submucosal lesions en bloc, and the recurrence rate is lower. However, due to the thinner colorectal wall and more abundant blood vessels, postoperative complications after ESD is higher in this site. As a result, how to prevent complications related to ESD for colorectal lesions has raised widespread concern. In recent years, more and more researchers placed transanal tube for patients with colorectal cancer resection or intestinal obstruction to promote the early discharge of the gas and liquid in the intestine. The efficacy of this method to reduce incidence of complications and to promote recovery of intestinal function have been verified by a number of studies. Based on this, we applied transanal tube to some patients with colorectal ESD, hoping to provide new ideas for the prevention and treatment of complications.

Aims & Methods: We aimed to evaluate transanal tube for prevention of complications in colorectal mucosal lesions after endoscopic submucosal dissection (ESD). Data of 61 patients with colorectal mucosal lesions undergoing ESD from January to December 2016 were reviewed. All patients were followed up and we analyzed the incidence rate of complications after ESD within one month.

Results: The median age of 61 patients was 61(32~83) years. 21 of all lesions were located at right-half colon, 9 at left-half colon and 31 at rectum. The mean diameter of the lesions was 3.26 ± 2.27 (0.8–12.0) cm. There were not intraoperative complications including serious bleeding and perforation. Delayed bleeding on the eighth post-ESD day was detected in 1 (1.6%) patient who was cured by transfusion. 3(4.9%) patients suffered post-ESD electrocoagulation syndrome and perforation did not present in all cases. In this group with transanal tube for decompression, the rates of perforation, delayed bleeding and post-ESD electrocoagulation syndrome were all lower than others which was 1.4~8.2%, 0.5%~9.5% and 12.1%~40.2% respectively in literature reports.

Conclusion: The application of transanal tube in colorectal mucosal lesions after ESD could effectively reduce the incidences of complications. However, we should do more research to know whether transanal tube need to be placed routinely after ESD or not.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Underwater endoscopic mucosal resection (UEMR) is an alternative to traditional EMR for the resection of colonic polyps. With this technique, water insufflation is used in place of air or CO₂, and submucosal lifting is usually not required, as water-immersed submucosa cushions itself from the muscularis propria.^[1] Theoretically, this reduces the risk of diathermy-induced injury,^[1] and allows for more complete resection margins.^[2]

Aims & Methods: In this prospective dual-centre study, we aim to evaluate the safety and efficacy of UEMR for clinically significant (>10mm) colonic polyps. Studied outcomes included: 1) completeness of UEMR, 2) intraprocedural and 30-day complication rates, 3) percentage requiring submucosal lift, and 4) rates and predictors of polyp recurrence. Procedures were performed by two screening endoscopists accepting tertiary referrals at St. Mark's Hospital, London, and Russell's Hall Hospital, Dudley, UK. Recurrence was defined as the presence of any polyp tissue at the resection site. Endoscopy records were examined and correlated with histology. Univariate analyses were performed using Pearson's chi² to identify predictors of measured outcomes.

Results: Between June 2014 and March 2017, a total of 85 patients (median age 69.5 years, interquartile range [IQR] 11, 50.6% male) underwent UEMR of 97 colonic polyps (median size 25 mm, IQR 25 mm, range 10–160 mm). 13 (13.4%) were recurrences following previous conventional EMR. Polyps were predominantly left sided (66%) with flat (63.5%) or sessile (35.4%) morphology. 43.8% of polyps were removed *en bloc*, whilst argon plasma coagulation (APC) was used in 13.7%. Histology comprised of: low-grade dysplasia (80.2%), high-grade dysplasia (12.5%), adenocarcinoma (3.1%) and non-dysplastic sessile serrated lesion (4.2%). Overall, resection at index UEMR was deemed endoscopically complete in 97.9%. Submucosal lift was required in 27.8% and positively correlated with polyp size >30 mm (OR 3.58, 95% CI 1.37–9.38, p=0.01), but not morphology (flat vs. sessile, p=0.99). The 30-day complication rate was 4.1% (n=4), consisting of intraprocedural bleeding (n=2, average diameters: 35 mm) and delayed rebleeding (n=2; average diameter: 57.5 mm), with haemostasis achieved for all cases. No cases of perforation or mortality were identified. Of the 60.8% (n=59) who attended for repeat endoscopy post-UEMR, the rate of recurrent or residual polyp was 14.8% (8/54) at 4 months and 13/59 (22.0%) within 1 year. Significant predictors of post-UEMR recurrence included: piecemeal vs. *en bloc* resection (OR 5.50, 95% CI 1.10–27.6, p=0.03) and recurrent polyp (OR 4.17, 95% CI 1.02–17.05, p=0.04), but not polyp size, site, morphology, dysplasia status, use of submucosal lift, APC, patient age, or study centre. **Conclusion:** UEMR is a safe alternative to conventional EMR for the management of clinically significant colonic polyps. However, our post-UEMR recurrence rate of 22.0% appears higher than other studies,^[2] but may be skewed by the tertiary nature of referrals. Although randomised trials are awaited, our data suggest that those performing UEMR should attempt *en bloc* resection where possible, and consider wider resection margins for recurrent polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1511 WATER-AIDED COLONOSCOPY - RESEARCH FOCUS IN THE PAST DECADE AND CURRENT CLINICAL PRACTICE

F. W. Leung

Medicine, Sepulveda Ambulatory Care Center, VAGLAHS; David Geffen School of Medicine at UCLA, North Hills/United States of America/CA

Contact E-mail Address: felixleung@socal.rr.com

Introduction: Water-aided techniques have forged a paradigm shift in endoscopic diagnosis and therapy. The inauguration (10/22/2014) of the International WATERS with memberships worldwide attested to participants' commitment to advance clinical, educational and research missions. To aid planning of future work in each of these areas, a descriptive study of water-aided colonoscopy was performed.

Aims & Methods: The aims of this study were two-folds. Study 1: To assess the focus of investigations in the past decade. Study 2: To obtain a cross-sectional snapshot of current clinical practice. Study 1: Studies registered at Clinicaltrial.gov were searched for using the search term "water colonoscopy". Study 2: Members of International WATERS voluntarily participated in a survey. After indicating the proportion of patients with different modes of sedation, respondents selected yes (1) or no (0) responses to each of 16 questions related to their practice of water-aided colonoscopy.

Results: Study 1: In the past decade, 48 trials of water-aided colonoscopy were registered at Clinicaltrial.gov. They aimed at evaluation of insertion pain in unsedated, minimally sedated, or on demand sedation patients; assessment of efficacy in difficult colonoscopy; study of the impact on adenoma detection; and underwater mucosal resection or polypectomy. Study 2: Questionnaire

responses are summarized in Table 1. Respondents: n=23. Water-aided colonoscopy is used in patients sedated with propofol, minimal sedation or on demand sedation (3–16%); but more commonly in patients with moderate or no sedation (30–34%). During insertion 95.5% use infusion of water and only 36.4% leave the air/CO₂ pump on. 42.9% and 33.3% record volumes infused and suctioned upon arrival to the cecum. 52.4% remove almost all infused water during insertion. 71.4% and 59.1% performed polypectomy (<20 mm and >20 mm, respectively) underwater during withdrawal.

Table 1A: % of respondent's patients

	Mean	SD
Sedated with propofol	16	30
Receive minimal sedation	11	19
Are unsedated	34	35
Receive on demand sedation	3	5
Receive moderate sedation	30	39
Table 1B: Proportion of respondents using the following approaches (%)		Mean
Infuse water during	insertion	95.5
	withdrawal	36.4
Leave air/CO ₂ pump on during	insertion	36.4
	withdrawal	90.0
Keep track of volume of water	infused at different insertion locations	19.0
	suctioned at different insertion locations	14.3
Keep track of volume of water	infused upon arrival to the cecum	42.9
	suctioned upon arrival to the cecum	33.3
Keep track of volume of water	infused when colonoscopy is finished	33.3
	suctioned when colonoscopy is finished	28.6
Perform polypectomy (<20 mm) underwater during	insertion	31.8
	withdrawal	71.4
Perform polypectomy (>20 mm) underwater during	insertion	13.6
	withdrawal	59.1
Remove almost all infused water during	insertion	52.4
	withdrawal	57.1

Conclusion: The variable modes of application amongst respondents who profess to use water-aided colonoscopy reflect the versatility and strength of the paradigm-changing approach, which is easily adaptable to meet the diverse needs of individual colonoscopists. Standardization based on results of randomized controlled trials appears to be prudent to permit further assessment of water-aided colonoscopy in clinical, educational and research settings.

Introduction: Endoscopic submucosal dissection (ESD) is a suitable technique used for the endoscopic management of selected early gastrointestinal neoplasms (EGN).

Aims & Methods: This is a prospective study of patients with EGN eligible for ESD in three tertiary hospitals. The main goal was to evaluate initial therapeutic results and learning curve of ESD. Initial Technical success rates, procedure speed, en-bloc & R0k resection, R0, speed and complications rates were prospectively evaluated. The results of the learning curve were analyzed by chronological order of blocs of 50 cases. Perforation was established as any disruption of the muscular layer, regardless of size or identification of peritoneal fat. Time of procedure was considered from initial submucosal injection to final detachment of the specimen.

Results: ESD was attempted in 183 lesions from January 2012 to April 2017. Majority of procedures were performed at Puerta de Hierro University Hospital (160/87.4%). Mean age was 67 (SD 10.6) years, with male proportion 55.2%. Most common location was colorectal (77.8%), followed by gastric (12.8%) and esophageal (9.4%). Success was observed in 96.2% of patients with en-bloc and R0 resection of 93.9% and 92.3% respectively. Mean lesion size was 46.5 mm (range 8–130) with a mean speed of 9.01 min/cm² (range 1–209). Perforation was

the main complication (48 (26.2%) events), requiring surgery in 5 (10.4%) cases. Perforation was related statistically significant to location ($p=0.05$) and LST morphology ($p=0.05$). Most frequent location of perforation was transverse colon (OR 88.3; SE 137), followed by descending colon (OR 13.5; SE 19.4) and splenic flexure (OR 6.3; SE 11.8). Perforation was more common in LST-NG lesions vs LST-G (OR 14.1 SE = 19.3 vs 11.6 SE 15.6). Perforation rates were not statistically associated with the presence of severe submucosal fibrosis compared to absence of fibrosis (0.8 SE 0.6 vs 1 SE 1; $p=0.9$). Post-ESD complications were observed in 15 (8.2%) patients (delayed perforation(7), bleeding(4), electrocoagulation syndrome(1), severe esophageal stricture(1), haemoperitoneum(1) and splenic rupture(1)). Six cases (40%) were managed with surgery. Results from the learning curve progression according to consecutive chronological blocs of 50 cases (33 last bloc) are summarized in table 1. Initial success increased from 94% to 100%; speed of ESD decreased after the first 50 cases (15.5 cm²/min), up to 6.7 and 6.5 cm²/min in the last 2 blocs. A high perforation rate in the first period (32%) was reduced to 18–30.3% the following periods. Endoscopic treatment was successful in most cases of perforation (89.6%). Surgery was required for severe complications, incomplete ESD and/or perforation (n, %) (16 cases, 8.7%).

Conclusion: On clinical ESD, high rates of success and en-bloc and R0 resection can be achieved along the learning curve. Perforation is the most common complication and is still a challenge for Western countries. However, increasing experience reflects a high success in endoscopic management of perforation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1513 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR COLORECTAL NEOPLASIA: THE EXPERIENCE OF A UK TERTIARY REFERRAL CENTRE

A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King's College Hospital, London/United Kingdom

Contact E-mail Address: aemmanuel@nhs.net

Introduction: Despite the advantages of endoscopic submucosal resection (ESD) demonstrated in large series from the far east, the procedure is not commonly practiced in the west and its role in standard practice is still debated. Although limited evidence regarding its efficacy in European practice is emerging, very few centres in the United Kingdom perform ESD regularly, if at all. We report the experience of a UK tertiary referral institution using ESD as part of a lesion specific, pragmatic approach to endoscopic resection in a complex patient cohort.

Aims & Methods: Patients who underwent ESD of colorectal lesions were included. Lesions were assessed with magnification chromoendoscopy supplemented by colonoscopic ultrasound in selected cases. A lesion specific approach was used to decide on resection technique, which included assessment of morphology, pit pattern, risk of submucosal invasion, and presence of submucosal fibrosis or scarring. ESD was used where en bloc resection was deemed essential, or as part of a hybrid procedure to ensure resection of a dominant nodule or suspicious area of a lesion in one piece, or where fibrosis or scarring would make standard EMR impossible. A resection was designated a hybrid procedure if ESD was used to effect submucosal dissection, circumferential incision alone to assist snare resection was not included.

Results: 116 lesions (mean size 58.8 mm) were resected using ESD (n = 58) and hybrid ESD (n = 58). 82 (70.7%) had been subjected to prior attempts at resection (n = 58) or extensive sampling. Only 11 lesions had no prior biopsies performed. En bloc resection was achieved in 93.1% where ESD was used alone, with a recurrence rate of 4.7% after a mean follow up of 12.4 months. There were 6 microperforations treated with either endoscopic clips or antibiotics alone with no adverse sequelae, and one clinically significant perforation requiring surgery. However, the resected lesion in this case contained an invasive adenocarcinoma with deep submucosal invasion—there was no residual tumour in the surgical

resection specimen. Post- procedure bleeding occurred in 6 patients, none of whom required additional interventional therapy. 71% of cases were successfully performed as day case procedures. 97% of patients without invasive cancer were free from recurrence and had avoided surgery at last follow-up.

Conclusion: Colorectal ESD can be used as part of a standard lesion specific approach in a western referral centre to deliver safe and effective organ conserving treatment to patients with large challenging lesions. Knowledge regarding lesion assessment and selection in western practice should be improved to reduce the incidence of prior heavy manipulation and guide appropriate referral.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1514 RISK OF STENOSIS AND OUTCOMES FOLLOWING ENDOSCOPIC RESECTION OF LARGE COLORECTAL LESIONS INVOLVING MORE THAN 75% OF THE LUMINAL CIRCUMFERENCE

A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King's College Hospital, London/United Kingdom

Contact E-mail Address: aemmanuel@nhs.net

Introduction: Little is known about the risk of stenosis and outcomes following endoscopic resection of lesions in the colorectum which leave extensive mucosal defects. A limited number of studies suggest significant stenosis rates, although reports on outcomes and suggested management are conflicting. We determined the risk of stenosis and outcomes of endoscopic resection of colorectal lesions leaving mucosal defects $\geq 75\%$ of the circumference.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥ 2 cm were included. Resection technique included EMR, ESD and hybrid techniques involving ESD. Patients were grouped according to circumferential extent of the mucosal defect after resection. Surveillance colonoscopy was performed at 3 and 12 months. Clinicopathological characteristics and outcomes were compared between groups.

Results: 435 colorectal lesions ≥ 2 cm were resected using EMR (n = 342), ESD (n = 45) or hybrid techniques (n = 48). Circumferential extent of the resulting mucosal defect was $\geq 75\%$ in 41 patients. 8 lesions were fully circumferential: 1 caecal lesion and the rest in the recto-sigmoid and rectum. 3 of these circumferential lesions contained deeply invasive adenocarcinoma and 1 benign lesion ultimately required surgery. The 41 lesions with a mucosal defect $\geq 75\%$ of the circumference had a mean size of 100.5 mm vs 49.0 mm for other lesions ($p < 0.001$). These patients had significantly more complications (16.7% vs 4.7%, $p < 0.001$), including a higher rate of perforation (8.3% vs 2.3%, $p = 0.02$), although none required surgery, and a significantly higher rate of recurrence (44.8% vs 9.2%, $p < 0.001$). 79% of patients without cancer were free from recurrence and had avoided surgery at last follow-up compared to 97% of patients with mucosal defects $< 75\%$ ($p < 0.001$). Stenosis occurred in 7 patients: 4 lesions extensively involving the rectum and recto-sigmoid and 2 lesions involving the sigmoid colon extending to the rectosigmoid. 1 of these involved a mucosal defect of only 50% of the circumference and 3 were fully circumferential. 1 patient had a symptomatic anorectal stenosis requiring dilatation under anaesthesia, 1 patient was asymptomatic but underwent early dilatation after the first surveillance endoscopy at 3 months. The remaining patients were asymptomatic and managed expectantly. In all these latter cases spontaneous improvement in the stricture was noted at the subsequent surveillance colonoscopy.

Conclusion: The majority of patients with these extensive complex lesions can successfully be treated with endoscopic resection and avoid surgery. However, these patients have a significantly greater risk of complications and recurrence and should be managed in a tertiary institution. Although there is a significant risk of stenosis, it appears that most cases are asymptomatic and spontaneously improve with expectant management.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1515 RISK OF HIGH-GRADE DYSPLASIA AND SUBMUCOSAL INVASION IN DIFFERENT MORPHOLOGICAL SUB-TYPES OF LARGE COLORECTAL NEOPLASTIC LESIONS RESECTED AT A UK TERTIARY REFERRAL UNIT

Introduction: Although it is well recognised that the risk of invasive carcinoma in apparent benign colorectal neoplastic lesions differs according to morphology, the incidence of invasive cancer varies between studies and there is limited data from large western series to inform practice. The importance of appropriate resection techniques, including the use of ESD, is increasingly recognised in western practice. It is therefore imperative that the risk of submucosal invasion is assessed as accurately as possible to prevent inappropriate attempts at resection. We determined the risk of submucosal invasion and high-grade dysplasia (HGD) in different morphological sub-types of large colorectal lesions subjected to endoscopic resection.

Aims & Methods: Colorectal lesions ≥ 2 cm subjected to endoscopic resection were included. Lesions were assessed with magnification chromoendoscopy. Clinicopathological data recorded included morphological type according to Paris classification, sub-types of laterally spreading tumours (LST), degree of dysplasia, presence of submucosal invasion and outcomes following resection.

Results: 435 colorectal lesions ≥ 2 cm were resected. Mean lesion size was 55.2 mm (range 20 mm–160 mm). The frequency of and the incidence of high-grade dysplasia and invasive adenocarcinoma in the different morphological sub-types are shown in Table 1. The incidence of high-grade dysplasia (8.6%) and invasive adenocarcinoma (1.2%) was very low in LST granular homogenous lesions.

Morphology	Mean size (mm)	High-grade dysplasia (%)	Invasive adenocarcinoma (%)
Is	36.7	2 (33.3)	1 (16.7)
Isp	37.8	21 (27.6)	7 (9.2)
IIa	27.2	5 (10)	0 (0)
IIa + IIc	35.0	3 (100)	2 (66.6)
LST G H	54.3	15 (8.6)	2 (1.2)
LST G MN	83.3	49 (43.0)	12 (10.0)
LST NG	45.0	4 (36.4)	2 (18.2)

LST G H = LST granular homogenous LST G MN = LST granular mixed nodular LST NG = LST non-granular ESD or hybrid ESD was used to resect 97 lesions. 53% of lesions had been subjected to previous failed attempts at resection, ≥ 6 biopsies or had tattoo injected at their base prior to referral. Of 29 invasive adenocarcinomas, 9 were deemed to be cured by endoscopic resection (superficial submucosal invasion with no adverse prognostic features). Of the remaining 20, 5 patients refused surgical resection, 5 were unfit for major surgery and 10 had surgery. 2 had residual tumour in the surgical resection specimen, 5 had none and 3 had surgery at their referring institution. Only 3 patients with initially benign lesions developed adenocarcinoma in subsequent lesions—all of these were early cancers without nodal metastases at surgical resection.

Conclusion: In one of the largest European series reporting the incidence of invasive carcinoma in different morphological sub-types of colorectal neoplastic lesions, we confirm that LST granular homogeneous type lesions have a very low incidence of invasive carcinoma and that care should be taken in the choice of resection technique for other sub-types of LSTs which more frequently harbour malignancy. Accurate endoscopic assessment and classification to aid meticulous lesion selection is essential to this process.

P1516 POLYP DETECTION INCREASES WITH COLONOSCOPY WITHDRAWAL TIME

K. Agar, L. Hamzaoui, M. Medhioub, B. Bouchabou, M.M. Azouz
Gastro-enterology, Med Taher Maamouri Nabeul, Nabeul/Tunisia

Contact E-mail Address: khaledagar27@gmail.com

Introduction: Polypectomy of adenomatous polyps during colonoscopy has been shown to decrease the incidence of colorectal cancer (CRC). Withdrawal time during colonoscopy is thought to improve polyp detection. A minimal withdrawal time of six minutes is recommended.

Aims & Methods: The aim of this study is to evaluate the role of colonoscopy withdrawal time in adenomatous polyp detection. It is a retrospective, descriptive and analytic study collecting all consenting patients who had a colonoscopy in Mohamed Taher Maamouri Hospital of Nabeul, between January 2016 and March 2017. Incomplete colonoscopies or those performed in patients having had segmental colectomy were excluded. We defined two groups of patients: - G1: withdrawal time ≥ 7 minutes - G2: withdrawal time < 7 minutes Two parameters were evaluated: -Polyp Detection Rate (PDR): the percent of colonoscopies with one or more adenomatous polyps detected -Mean Number of polyps detected per colonoscopy (MNP).

Results: A total of 1059 patients were screened for enrollment; 749 total colonoscopies were studied: 383 men (51.1%) and 366 women (48.9%). Colic preparation was good (Boston score > 6) in 49.4% of patients. Colonoscopy was normal in 434 cases (57.9%). Colonic polyps were detected in 197 patients (26.3%). The mean number of polyps detected per colonoscopy (MNP) was 2.31 (min: 1, max: 25). The mean polyp diameter was 6.8 millimeters (1 to 50 mm). The mean withdrawal time was 8.2 minutes (4 to 20 minutes). Overall PDR was 26%. G1 included 599 colonoscopies and G2 included 150 colonoscopies. PDR in G1 was 28.04% versus 20% in G2, the difference between the two groups was not significant (p: 0.7). As for the MNP, it was significantly higher in G1: 2.29 versus 1.86 in G2 (p: 0.049).

Conclusion: In our study, a withdrawal time exceeding seven minutes was significantly associated with the number of polyps detected in colonoscopy. Further studies may be helpful to confirm these results ideally by comparing these parameters in the same patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1517 OUTCOMES OF ENDOSCOPIC RESECTION OF RECURRENT COLORECTAL LESIONS TREATED AT A UK TERTIARY REFERRAL CENTRE

A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King's College Hospital, London/United Kingdom

Contact E-mail Address: aemmanuel@nhs.net

Introduction: Endoscopic resection of large colorectal lesions, especially by piecemeal EMR, carries a significant risk of recurrence. Although several series examine the outcomes and risk of recurrence following endoscopic resection, few focus on the outcomes of patients being treated for recurrence after initial expert resection, and these mostly focus on one technique to deal with recurrence. We evaluated the outcomes after recurrence of colorectal lesions after apparent successful endoscopic resection in a specialised UK tertiary institution employing a range of resection techniques.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥ 2 cm were included. All lesions were assessed with magnification chromoendoscopy supplemented by colonoscopic ultrasound in selected cases. A lesion specific approach was used to decide on resection technique. Outcomes were evaluated for patients treated for recurrent lesions.

Results: Of 396 colorectal lesions ≥ 2 cm initially resected, recurrence occurred in 48 patients. 36% of these patients had already had a mean of 1.6 previous failed attempts at resection prior to referral to our institution, and 66% had had either a failed attempt at resection or extensive sampling involving ≥ 6 biopsies or tattoo placed under the lesion. 69% of patients were successfully treated with further endoscopic resection and avoided surgery. 27 recurrent lesions larger than 20 mm were treated with endoscopic resection, with a mean lesion size of 48.3 \pm 19.1 mm. Techniques used were EMR (n=16), ESD (n=2), Hybrid ESD and EMR (n=9). The remaining lesions < 2 cm were resected using EMR. A mean of 1.4 \pm 0.75 procedures were required to achieve successful endoscopic treatment of recurrence. Of 23 patients who were ultimately successfully treated with endoscopic resection, 15 required a single further endoscopic resection after recurrence, 8 patients required 2 or more further resections. 8 patients required surgery, 3 as a result of developing invasive adenocarcinoma with the recurrence. There were no perforations as a result of endoscopic resection of recurrent lesions and only 1 patient was readmitted with post-procedural bleeding which was managed conservatively.

Conclusion: These data demonstrate the challenges of an advanced endoscopic resection service in much of western practice where patients with recurrent lesions represent a particularly complex cohort, most of whom have already had extensive prior manipulation or attempts at resection. Familiarity with a range of resection techniques and appropriate equipment is essential to successfully treat recurrent lesions in this group with endoscopic resection, which can be achieved in the majority of patients without significant complications.

P1518 THE EFFECTIVENESS OF NEW TECHNIQUE WITH SELF-EXPANDABLE METALLIC STENT INSERTION IN TREATING RIGHT-SIDED COLONIC OBSTRUCTION

C.B. Ryu¹, M.S. Lee¹, J.Y. Bae²

¹Digestive Disease Center And Research Institute, Department Of Internal Medicine, SoonChunHyang University School of Medicine, Bucheon/Korea, Republic of

²Department Of Internal Medicine, Seoul Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: ryuchb@gmail.com

Introduction: Self-expandable metallic stent (SEMS) is widely used to treat malignant colonic obstruction. However, most reports about SEMS insertion have concentrated on the left colon and very tough to insert SEMS on the right colon, especially distal ascending colon.

Aims & Methods: This study aimed to (1) investigate the effectiveness of new insertion technique with SEMS for right-sided colonic obstruction and (2) compare the safety and technical success of SEMS insertion. The data from ten patients who underwent SEMS with a new technique for malignant obstruction of ascending colon in our hospital were analyzed retrospectively. Initially, we tried to insert with the straight type guiding tube and wire for obstructed area of ascending colon under CO₂ insufflation. It defined by difficult cannulation more than 20 minutes manipulation. For difficult cannulation, we change to curved type guiding tube (CleverCut2V/CleverCut3V Double and Triple Lumen sphincterotomes). All cases were difficult cannulation and change to curved type. Cannulation time between straight and curved type guiding tube, technical and clinical success, complications, and technical difficulties were analyzed. We compared the results between SEMS insertion and decompression tube placement in right colons and the outcomes of SEMS insertion between right- and left-sided colonic obstructions.

Results: Cannulation time with a curved type guiding tube decreased of all cases (20 min vs 8.5 min). For ascending colons, the technical and clinical success rate of SEMS insertion with new technique significantly 100% (10/10). There was no

complication (0/10). Concerning SEMS insertion, the technical difficulty and safety of SEMS insertion were similar between right- and left-sided colonic obstructions.

Conclusion: A new technique of curved type guiding tube with SEMS insertion for right-sided colon, especially distal ascending colon is significantly more effective than straight type guiding tube, and this procedure was safer and less technically challenging than expected. SEMS insertion should be considered for treating right-sided malignant colonic obstruction.

Introduction: Endoscopic full-thickness resection (EFTR) in the colon using the FTRD kit is a recent technique that allows en-bloc resection of colonic lesions that are poor candidates for resection by endoscopic mucosal resection (EMR). It does not require the injection of a solution into the submucosa and allows an en-bloc resection of colonic lesions up to approximately 30 mm. We present results of the initial experience in 3 centers of Catalonia.

Aims & Methods: We retrospectively analyzed the clinical, endoscopic and anatomopathological data of all cases of EFTR performed in 3 centers in Catalonia using the FTRD kit (Ovesco Endoscopy, Tübingen, Germany) during the period between June 2015 and January 2017. All patients underwent the procedure under deep sedation with propofol, all patients were duly informed of the technique and potential complications derived from the procedure, obtaining written informed consent prior to the procedure. All EFTR resections in the colon were performed using the FTRD kit (Ovesco Endoscopy, Tübingen, Germany), grasping and pulling the lesion inside the cap, deploying the OTSC and resecting the tissue over the OTSC with the preloaded snare. Clinical assessment was performed before and after procedures with a complete blood test before procedure. Blood test was not routinely used after procedures. Demographic, clinical, endoscopic and histologic data were collected from each patient, and analysed with STATA software.

Results: 16 endoscopic full-thickness resections of the colon were performed. The mean age of the patients was 69 years (53–79), with men being 88%. The indications were recurrent/residual lesions with non lifting sign (75%) and untreated lesions with non lifting sign (25%). The locations were juxtavalvular (n=2), hepatic flexure (n=3), transverse colon (n=4), descending colon (n=3), sigma, stump or anastomosis (n=2). The mean diameter of the resected samples was 20.8 mm (13–33 mm). The histology of the lesions was adenoma with low grade dysplasia (50%), adenoma with high grade dysplasia (25%), sessile serrated polyp without dysplasia (6%) and three lesions were adenocarcinoma with deep submucosal invasion (19%). There were no clinically relevant complications or emergency surgery. 1 patient had mild self-limited hemorrhage, 6 patients had mild abdominal pain (38%) and 3 patients developed postpolypectomy syndrome (19%).

Conclusion: Endoscopic full-thickness resection is a safe and feasible technique for selected cases in colon.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Lynch syndrome (LS) is an autosomal-dominant disease, with increased risk of colorectal cancer (CRC), hence annual surveillance colonoscopy is recommended, do not recommend one over the other.

Aims & Methods: We aimed to compare the diagnostic yield (DY) of different endoscopic modalities for detection of colorectal neoplasia in patients with LS by performing a meta-analysis of existing literature. We searched Pubmed for prospective studies. For each modality, we performed comparative total per-adenoma analysis and sub-analyses for flat lesions and location (right/left colon).

Meta-analysis was performed using pooled rate ratios (RR) with fixed effects model due to low heterogeneity within the subgroups.

Results: Five studies compared white light endoscopy (WLE) to chromoendoscopy. In four studies compared WLE to chromoendoscopy directly (one study used a "back-to-back" design but lesions were resected only after chromoendoscopy and the other study compared two different sets of patients). Chromoendoscopy (n=75) identified more adenomas in the right colon than WLE (n=73 patients) RR 3.27 (95%CI 1.83–5.87). Overall detection of adenomas or flat lesions was not statistically different between the two methods.

Conclusion: Chromoendoscopy is superior to WLE for detection of adenomas in Lynch syndrome, especially flat lesions and adenomas in the right colon.

Introduction: Endoscopic mucosal resection (EMR) has been shown to be useful in the removal of large colorectal adenomas. These lesions are often resected by using a piecemeal technique, which a risk of recurrence in 10% to 30% of cases. Recently, hot avulsion technique (HA) has shown promising results in the resection of residual fragments of large colorectal adenomas, with lower recurrence rate.

Aims & Methods: The aim of this study was to evaluate the efficacy and safety of HA at index EMR and at EMR local recurrence. We did a retrospective study based on all the HA performed between June 2015 and February 2017. The endoscopic characteristics, complications and recurrence rate after the initial HA were evaluated.

Results: 33 HA were performed among 29 patients (16 men and 13 women) with an average age of 69 years. The average follow up time was 11 months. HA was used to remove residual adenomatous tissue at 17 index EMR (mean size of the lesion 30 mm) and to remove recurrent fibrotic adenomatous tissue at EMR scar in 12 cases (mean size of recurrence tissue 14 mm). HA was successful in removing residual/recurrent adenomatous tissue in all patients. There were no immediate or long term adverse events. Comparing the two groups, local recurrence after initial HA occurred in one case at the index EMR group (1/17) and in 2 cases at the local EMR recurrence group (2/12). The overall recurrence rate in patients with a minimum 6 months follow up was 15% (3/20).

Conclusion: HA is a safe and effective technique to eradicate both residual tissue in large colorectal adenomas and recurrent fibrotic adenomatous tissue at EMR site, with low recurrence rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Quality of bowel preparation and adenoma detection rate (ADR) are routinely assessed in screening colonoscopy. However, data on patient experience are scarce.

Aims & Methods: This prospective non-interventional study compared bowel preparation quality according to the Harefield Scale, performance quality measures and patients satisfaction in screening colonoscopies performed within an Austrian quality assurance program.

Results: 5000 screening colonoscopies performed by 20 endoscopists were included in this study. 50.3% of screened individuals were women. Because of the unequal patient count using CitraFleet® (CF, n=261), Picoprep® (PP, n=2678), Klean-Prep® (KP, n=804) and Moviprep® (MP, n=1252), PC and CF were grouped as low volume (LV) purgatives. Age and gender adjusted success rates and ADR per purgative were 97.0% and 23.3% for LV, 97.5% and 32.5% for KP and 93.5% and 26.0% for MP. Women had higher success rates than men (p=0.073) and success rate decreased with patients' age (p=0.008). The compliance regarding consumption of the entire volume was best with LV (89.2%, KP 87.6%, MP 87.3%), which had a significant effect on success rate p=0.027. 93.5% of patients in the LV group would use the same purgative again compared to 68.4% in the KP and 73.2% in the MP group.

Conclusion: All investigated purgatives met the required quality standards of ≥90% rate of adequate bowel preparation according to the current ESGE guidelines. Success rates were higher in women and younger patients. Although only <90% of patients consumed the whole volume, the majority of patients would use the same purgative again.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1523 DIFFERENCES BETWEEN BOWEL PREPARATION QUALITY OF SURVEILLANCE AND SCREENING COLONOSCOPY

A. K. Hinterberger, D. Penz, E. Waldmann, B. Majcher, A. Dokladanska, A. Szymanska, M. Trauner, M. Ferlitsch

Department Of Internal Medicine III, Division Of Gastroenterology & Hepatology, Medical University of Vienna, Austria, Vienna/Austria

Introduction: Adequate bowel preparation is necessary for a successful and complete colonoscopy. Minimum of adequate rate (excellent + good + fair) should be 90% according the actual ESGE guidelines (Kaminski et al, *Endoscopy* 2017). The aim of study was, to verify if there is a difference at quality of preparation between screening and surveillance colonoscopy. It might be that there is an improvement at surveillance colonoscopy due to better knowledge.

Aims & Methods: 107,614 examinations from 288 endoscopists were analysed between 2012 and 2017 within the Austrian certificate of screening colonoscopy. For the calculations six different categories were used: excellent, good, fair, poor, unsatisfactory, poor only in the right colon. Data are shown as Mean and SD.

Results: 8578 surveillance colonoscopies (43.88% female, mean age 66.67) and 99271 screening colonoscopies (51.04% female, mean age was 62.31) were included. Within screening colonoscopy 37.59% (SD = 31.50) were excellent prepared vs. 34.60% (SD = 33.98) within surveillance colonoscopy, good 47.43 (SD = 27.28) vs. 45.61% (SD = 31.28), fair 11.39% (SD = 11.58) vs. 14.39% (SD = 21.69), poor 2.38% (SD = 3.06) vs. 3.68% (SD = 9.75), unsatisfactory 0.77% (SD = 1.20) vs. 0.89% (SD = 3.69), poor only in the right colon 0.69% (SD = 1.81) vs. 0.39% (SD = 1.22). Calculations revealed no significant differences among screening and surveillance colonoscopies relating the following categories: excellent (p=0.4357), good (p=0.5911), unsatisfactory (p=0.6282) and poor only in the right colon (p=0.1457). Bowel preparation varies significantly between screening and surveillance in groups of fair (p=0.0454) and poor (p=0.0497). Bowel preparation influences the adenoma detection rate (ADR). Mean ADR in excellent preparation was 22.16% (SD = 16.36%), in good 25.41% (SD = 17.30%), in fair 24.63% (SD = 19.44), in poor 19.94% (SD = 25.57), in unsatisfactory 12.08% (SD = 22.77) and in poor only in the right colon 24.22% (SD = 30.89%). Adequate rate in screening colonoscopy was 96.22% (SD = 3.98%) vs. 95.07% (SD = 10.45%) in surveillance

colonoscopy. Rates correspond to ESGE guidelines and do not differ significantly (p=0.1265).

Conclusion: Data showed distinctions between fair and poor, whereas there were more fair and more poor prepared patients at the surveillance colonoscopy, than at the screening colonoscopy. Age of patients at surveillance colonoscopy was higher, hence patients need improved enlightenment. ADR in excellent, good and fair bowel preparation was adequate. In poor, unsatisfactory was low and ADR at poor only in the right colon is high due to low count (N=374).

P1524 DIFFERENCES IN QUALITY OF BOWEL PREPARATION AT SCREENING COLONOSCOPIES IN PRIVATE PRACTICES AND HOSPITALS

B. Majcher, D. Penz, E. Waldmann, A. Hinterberger, A. Dokladanska, A. Szymanska, M. Trauner, M. Ferlitsch

Department Of Internal Medicine III, Division Of Gastroenterology & Hepatology, Medical University of Vienna, Wien/Austria

Contact E-mail Address: barbara.majcher@meduniwien.ac.at

Introduction: Bowel preparation influences the adenoma detection rate and is therefore an important quality parameter in screening colonoscopy. According to actual ESGE guideline "Performance measures for lower gastrointestinal endoscopy: a European Society of Gastrointestinal Endoscopy (ESGE) Quality Improvement Initiative", 90% of colonoscopies should have adequate bowel preparation. The aim of this study was to investigate whether there is a difference in quality of bowel preparation between private practices and hospitals.

Aims & Methods: Data from screening colonoscopies performed within quality certificate in Austria (2012- 2017) provided by 245 endoscopists were evaluated. The recording of the quality of the bowel preparation was described as one of the following categories: excellent, good, fair, poor, poor only in the right colon and unsatisfactory.

Results: From the 125,127 screening colonoscopies included in this study, 72.93% were performed in private practices, (50.66% female, mean age 60.7) and 27.07% in hospitals (49.35% female, mean age 60.35). Significant difference was found between the average values of screening colonoscopies with excellent bowel preparation (38.00% (SD = 30.36) in private practices vs. 27.92% (SD = 23.11) in hospitals, p=0.0215), fair (10.68% (SD = 10.89) vs. 15.18% (SD = 9.93), p=0.0001) and unsatisfactory (0.66% (SD = 0.96%) vs. 1.43% (SD = 1.76), p=0.0003) while there was no statistical significance among the average values from participants with good bowel preparation quality (47.40% (SD = 26.38) in private practices vs. 51.78% (SD = 19.28) in hospitals, p=0.6428), poor (2.57% (SD = 2.93) vs. 2.89 (SD = 2.89), p=0.2987) and poor only in the right colon (0.69 (SD = 1.74) vs. 0.80% (SD = 1.15, p=0.7721). The mean ADR did not show any statistical difference between private practices and hospitals (23.98% (SD = 10.89%) vs. 25.80% (SD = 12.80%), p=0.7652).

Conclusion: More excellent bowel preparation was found in private practices while the screening colonoscopies in hospitals showed a higher rate of fair and unsatisfactory bowel preparation.

²Institute Of Biostatistics And Analyses, Masaryk University, Faculty of Medicine, Brno/Czech Republic

Contact E-mail Address: Nadiya.Brodyuk@uvn.cz

Introduction: Laterally spreading tumors (LSTs) are important precursors of colorectal carcinoma. They are usually removed by endoscopic mucosal resection (EMR). However, local residual neoplasia (LRN) may occur during follow-up. The aim of the study was to evaluate the occurrence of LRN and the risk factors for its presence.

Aims & Methods: This retrospective study in a high-volume tertiary-referral center examined patients who had undergone EMR between 2013 and 2015 and who had had at least 1 surveillance colonoscopy after the initial treatment. LRN was defined histologically as the presence of neoplastic tissue in the post-EMR site.

Results: 160 laterally spreading tumors were diagnosed in 138 patients (62% men, mean age 67 years). Mean follow-up interval for surveillance colonoscopy was 6 months. Residual neoplasia at surveillance endoscopy was present following 21% of colonic EMRs. Single variate analysis showed evidence of an increased risk of residual neoplasia for LST ≥ 20 mm (p=0.006), villous adenomas (p=0.001), piecemeal resection (p=0.011) and G-type morphology (p=0.003). In multi-variate analysis, only size of the lesion (p=0.080) and villous component (p=0.043) were found to be a significant risk factor of LRN.

Conclusion: This retrospective study shows that the occurrence of LRN is frequent. Careful colonoscopic surveillance after EMR and the use of new methods to further reduce residual neoplasia are needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1526 ENDOSCOPIC SURVEILLANCE AFTER SURGERY ON FAMILIAL ADENOMATOUS POLYPOSIS PATIENTS: IT IS EFFECTIVE BUT INTERVALS CAN BE WIDENED

J. Pinho¹, J. Lage², M. Dinis-Ribeiro², C. Brandão²

¹Gastroenterology, Tondela - Viseu Hospital Center, Viseu/Portugal

²Gastroenterology, Instituto Português de Oncologia do Porto, Porto/Portugal

Contact E-mail Address: julianapinho18@gmail.com

Introduction: Familial adenomatous polyposis (FAP) is an autosomal dominantly inherited syndrome, associated with a lifetime risk for colorectal cancer close to 100%. Thus prophylactic colectomy is recommended for patients with FAP. Colectomy with ileorectal anastomosis (IRA) is the surgical option of choice in the majority of patients, given the complications and morbidity associated with ileal pouch-anal anastomosis. Therefore, annual endoscopic surveillance is recommended after surgery to prevent cancer in the rectal remnant (CRR).

Aims & Methods: The aim of this study was to determine the impact of endoscopic surveillance on CRR prevention in FAP patients after surgery. We did a retrospective single center study on findings of follow up endoscopies and determination of the cumulative risk of adenomas and prevalence of high risk adenomas (HRA) (villous histology, high-grade dysplasia and ≥ 10 mm) and CRR.

Results: 30 patients submitted to IRA were included (50% women), with a mean age of 43 years, 2 patients with attenuated phenotype. Nine patients had adenocarcinoma in the resected colon. Six patients started chemoprophylaxis after surgery (sulindac-4; celecoxib -1). The median time to adenoma appearance was 5 years (95% CI 3.4–6.6) and to HRA/CRR 12 years (95% CI 5.2–18.8), with a decreased median time to both adenomas and HRA/CRR in patients under chemoprophylaxis. The cumulative risk of adenomas was 20% at 1 year after surgery, 34.1% at 3 years and 57.4% at 5 years. During the follow up period, HRA/CRR developed in 17 patients (56.7%): HRA–12 patients (40%); intramucosal carcinoma–2 patients (6.7%); invasive adenocarcinoma–3 patients (10%). None of the patients died with CRR. The cumulative risk of HRA/CRR was 21.8% at 5 years, 46.1% at 10 years and 66.3% at 15 years. All the patients with HRA/CRR had rectal involvement prior to surgery ($p=0.008$) and a higher number of adenomas resect in the rectal remnant ($p=0.017$).

Conclusion: The FAP endoscopic surveillance program allowed detection of HRA/CRR in a high percentage of patients. Based on these results, an intensive surveillance program should be suggested but endoscopic surveillance intervals widen in the first 5 years after surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1527 BOWEL PREPARATION FOR FLEXIBLE SIGMOIDOSCOPY: COMPARISON OF POLYETHYLENE GLYCOL ELECTROLYTE SOLUTION (PEG-ES) AND PHOSPHATE ENEMA IN 4,949 PATIENTS AT TWO UK HOSPITALS

A. Yusuf, S. Paranaheewa, A. Jeevagan, P. Mayhead

¹Gastroenterology, East Sussex Healthcare NHS Trust, Eastbourne/United Kingdom

Contact E-mail Address: abdyus12@nhs.net

Introduction: Flexible sigmoidoscopy is increasingly used to examine the left side of the bowel for diagnostic and surveillance purposes, and is now part of the UK bowel cancer screening programme. It is crucial to achieve adequate bowel cleansing in order to optimise the diagnostic yield of the test, and also to minimise the number of repeat procedures. However, the optimum bowel preparation for this procedure has consistently been debated^{1,2,3}.

Aims & Methods: Both phosphate enema and (PEG-ES) are commonly used for bowel preparation in flexible sigmoidoscopy at both hospitals participating in this study. We therefore wanted to compare the outcomes for these two methods. We retrospectively reviewed all the patients who underwent flexible sigmoidoscopy from January 2014 to December 2016 using each hospital's electronic endoscopy reporting system. We analysed their demographics, type of bowel preparation used in each case, and the quality of their individually achieved bowel preparation, subjectively graded as "Excellent, Adequate or Inadequate" by the endoscopist performing the procedure. A chi-squared test was used to calculate p-values.

Results: In total 6196 patients underwent flexible sigmoidoscopy during the study period (males 2885 (46.56%), mean age 62.80 years, range 16–101 years). 1247 (20.13%) patients were excluded from further analysis for the following reasons: No bowel preparation given ($n=451$), no documentation of the quality of the bowel preparation ($n=657$), and non-(PEG-ES) oral preparation used ($n=139$). A total of 4949 patients were included in the study, of whom 2103 had (PEG-ES) (42.49%) (males 986 (46.89%), mean age 60.97 years, range 18–95 years) and

2846 (57.50%) (males 1269 (44.59%), mean age 63.98 years, range 17–101 years) had phosphate enema. The results are summarised in the table below.

Type of bowel preparation	Excellent	Adequate	Total Adequate and Excellent	Inadequate
(PEG-ES) ($n=2103$)	1126 (53.54%)	770 (36.61%)	1896 (90.16%)	207 (9.84%)
Phosphate enema ($n=2846$)	624 (21.93%)	1297 (45.57%)	1921 (67.50%)	925 (32.50%)
Total ($n=4949$)			$P < 0.0001$	

Conclusion: Our large retrospective study showed that oral preparation with (PEG-ES) gave significantly better results than phosphate enema, which gave acceptable results in only 67.5% of the patients. As a result of this study, PEG-ES is now the preferred option at our hospitals, if there is no contraindication for this.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic resection of large colonic lesions (LCLs, > 20 mm) is effective and it is associated with an acceptable incidence of incomplete resection and complications when performed by appropriately trained endoscopists in resourced centers^{1,2,3}. Scanty data on the management of these lesions outside referral centers are reported in the literature.

Aims & Methods: Aim of present study is to evaluate the management of endoscopic resection of LCLs and intra-procedural complications in a real-life setting. In a prospective, multicenter, observational study in 20 centers, data from consecutive endoscopic resections of LCLs performed over a 6-month period were collected by a web-database. All patients undergoing LCLs resection were enrolled at procedure-time and followed-up at 15 days for adverse events and at 6 months for endoscopic/histological recurrence.

Results: 1452 LCLs (mean size 30.6 mm, SD 12.4; 41.4% lateral spreading tumor, 28.1% sessile, and 30.5% pedunculated) removed in 1329 patients (58% males, mean age 66 ± 11.4 years) were analysed. An endoscopic mucosal resection (EMR) was performed in 57.9%, snare polypectomy in 34.7%, underwater EMR in 1.2% and endoscopic submucosal dissection in 6.2% of the lesions. Of patients with LCLs, 19.4% were on ATT (62.5% aspirin, 12.2% thienopyridines, 4.8% dual antiplatelet, 15.4% vitamin K antagonists [VKAs], 5.1% direct oral anticoagulants [DOACs]). Aspirin and/or thienopyridines were withheld before resection in 53.6% and 91.7% of patients, respectively. Overall, intra-procedural bleeding requiring endoscopic therapy occurred in 8.1% of patients; 28% of them were on ATT, which had always been withheld, but in 48% of patients on aspirin. At multivariate analysis, intra-procedural bleeding was correlated with increasing polyp size (Odds Ratio 1.02 95% Confidence Interval 1.01–1.04), and inversely with execution of pre- and post-resection prophylaxis maneuvers (Odds Ratio 0.55 95% Confidence Interval 0.37–0.82 and Odds Ratio 0.55 95% Confidence Interval 0.37–0.82 respectively). As concerns

complications, delayed bleeding occurred in 4.5% of the subjects, whereas perforation occurred in 1.5% (0.9% early and 0.6% delayed) of patients, 86.7% of whom were successfully managed endoscopically. At the moment, 6-months follow-up is available for 35% of the patients, with a positive endoscopic and/or histological recurrence documented in 22.8%.

Conclusion: The management of resection of LCLs varies widely. The incidence of intra-procedural bleeding correlates with polyp size and prophylactic maneuvers, and its endoscopic management is successful in most of cases. Overall, complication rate is marginal and efficacy is good, even in a real-life setting.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The incidence and mortality of colorectal cancer (CRC) can be decreased through the removal of precancerous adenomas. Endoscopic removal of polyps over 2 cm is considered a high-risk procedure both for complications and malignant transformation.

Aims & Methods: The aim of this study was to evaluate the outcome and complication rate after endoscopic removal of polyps over 2 cm. In this retrospective study clinical and demographic data of patients undergoing polypectomy due to colorectal adenoma over 2 cm between 2012 and 2017 were collected. Data on endoscopic procedures, complications of polypectomy and histological assessments of the removed polyp were obtained.

Results: Data of 100 patients (male/female: 58/42) was analyzed in the study. Forty-seven of the 106 removed polyps proved to be pedunculated, 21 were sessile and 34 flat. Six patients had more than one large polyp (>2 cm). The locations of the removed polyps were rectum in 33, sigmoid colon in 38, cecum in 12 and other parts of the colon in 23 patients. In 65 cases, polyps were excised with endoscopic mucosa resection (EMR) or hybrid endoscopic submucosa dissection (ESD). In 41 cases snare was used to remove the polyps in one or more pieces. Based on histological findings 54 (50.9%) polyps were shown to be low-grade adenomas, 34 (32.07%) high-grade adenomas, 1 (0.9%) polyp was hyperplastic, and 17 (16.03%) proved to be malignant among which complete endoscopic removal was achieved in 9 patients (52.9%). Additional smaller polyps were found in 39 patients and a synchronous cancer in 7. During polypectomies 91 hemoclips were deployed to close suspected perforation (8 cases) to cease bleeding (19) or for prevention. Postpolypectomy syndrome developed in 8 cases. Second-look colonoscopy was required in 8 cases due to bleeding within a mean of 4 days after the first examination. Hemoclip insertion was needed in 5 cases and epinephrine injection in 1 case. The bleeding stopped spontaneously in 2 cases. Blood transfusion was required in 3 patients. Surgical intervention was not needed in any case.

Conclusion: Malignant transformation was revealed in 16% of the polyps over the size of 2 cm. Complete endoscopic removal of these polyps was successfully performed in half of the patients. Endoscopic removal of high-risk polyps is safe in experienced hand.

PI530 WHAT IMPROVED AND WHAT REMAINS TO BE ACHIEVED IN ORDER TO COMPLY WITH THE NEW RECOMMENDATIONS OF POLYPECTOMY BY THE EUROPEAN SOCIETY OF GASTROINTESTINAL ENDOSCOPY

J. P. Rodrigues¹, R. Pinho², L. Alberto², A. Rodrigues², L. Proença², T. Freitas², A. P. Silva², S. Fernandes², S. Leite², J. Silva², A. Ponte², M. Sousa², J. C. Silva², J. Carvalho²

Introduction: The choice of polypectomy technique differs according to regional preferences and availability. This year, in order to standardize the approach to this techniques, the European Society of Gastrointestinal Endoscopy (ESGE) published recommendations for colorectal polypectomy and endoscopic mucosal resection (EMR).¹

Aims & Methods: We aimed to evaluate the recent years evolution of the adherence to the recommendations of colorectal polypectomy and EMR at a tertiary center. We conducted a unicentric analysis of polypectomy and mucosectomy techniques performed consecutively between January and June of 2011 and 2016 at a tertiary center. According to the recommendations, the excision of sessile and flat polyps is considered adequate when performed with cold biopsy forceps or cold snare for polyps ≤3 mm, cold snare if 4–9 mm, cold or hot snare if 10–19 mm and EMR if ≥20 mm. Polypectomy of pedunculated polyps is considered adequate when performed with a diathermic loop in polyps <20 mm, always in association with any prophylactic therapy when polyp size ≥20 mm.

Results: We included 1721 endoscopic procedures of polypectomy and EMR, concerning 696 patients (64.5% male; mean age = 64.2 ± 11.0 years). 1381 (80.2%) sessile polyps, 153 (8.9%) flat lesions and 187 (20.9%) pedunculated polyps were identified, with a mean size of 7.9 ± 7.0 mm. Regarding sessile and flat polyps, one of the recommended excision techniques was performed in: 84.6% (n=270) of ≤3 mm polyps (75.7% in 2011 vs. 95.8% in 2016; p < 0.001); 22.2% (n=109) of 4–5 mm polyps (12.5% vs. 36.5%; p < 0.001); 13.4% (n=59) of 6–9 mm polyps (5.4% vs. 23.8%; p < 0.001); 100% (n=206) of 10–19 mm polyps; and 100% (n=88) of ≥20 mm lesions. For pedunculated polyps, the resection technique was adequate in: 99.3% (n=134) of polyps of size <20 mm (100% vs. 97.6%; p > 0.05) and in 84.6% (n=44) of those ≥20 mm (82.6% vs. 86.2%; p > 0.05). Overall, 52.3% (n=900) of endoscopic procedures of polypectomy or EMR were performed as recommended; 42.7% (n=410) in 2011 vs. 64.5% (n=490) in 2016; p < 0.001.

Conclusion: Even before publication of the European recommendations, there has already been an increase in the proportion of polypectomies performed adequately in the different groups of lesions. There is still a need to adjust clinical practice in some subgroups, especially in polyps of size 4–9 mm, in order to strictly comply with the recommendations.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic resection of superficial neoplasms at the perineal rectum is difficult due to pain sensibility, narrowness of the anal canal, presence of internal rectal plexus, whereas that of at the ileocecal valve (ICV) due to the variable morphology of the ICV itself and ileal involvement.

Aims & Methods: Aim was to assess the feasibility and outcomes of ESD in these locations. Prospectively collected database in a single nonacademic center. From 1.2010 to 11.2016, all consecutive patients scheduled to ESD for a superficial neoplasm in the perineal rectum (distal margin <30 mm from the dentate line) and at the ICV were compared to those in the pelvic rectum and in the cecum and ascending colon, respectively. ESD was performed with the standard technique. Follow-up was scheduled at 3 and 6 months within the first year and then yearly. Biopsies were taken from the scar of the resection site if a residual tissue was detected.

Results: A total 16 neoplasms at ICV were compared to 110 neoplasms in the cecum and ascending colon; 30 neoplasms in the perineal rectum were compared to 58 cases in the pelvic rectum (Table). Features of neoplasms in the perineal and pelvic rectum were no different as well as neoplasms at the ICV and cecum and ascending colon. ESD en bloc rates were lower in the perineal rectum and at the ICV, but no significant differences were found with the respective control groups (P = 0.490 and 0.404, respectively). ESD R0 rate was significantly lower at the ICV (P = 0.021). Adverse events were not different, although 3 perforations occurred in the cecum and ascending colon. During follow-up (median 36 months; range 24–84): residual tissue was diagnosed at the ICV in 2 (13%) cases, in the cecum and ascending colon in 2 (2%) cases (P = 0.078); in the perineal rectum in 4 (13%) cases and pelvic rectum in 2 (3%).

	IC valve (n.16)	cecum & Ascending (n.110)	perineal rectum (n.30)	Pelvic Rectum (n.58)
size, mm median (range)	44 (20–85)	35 (15–80)	48 (23–180)	35 (12–70)
morphology: LST-G/NG	12/4	81/22	23/3	39/7
scar positive	0	19	8	10
ESD en bloc	12 (75)	91 (83)	22 (73)	48 (83)
ESD R0	7	81	15	41
ESD R1 (HM/VM)	5/0	10/0	6/1	4/1

Conclusion: The ESD of neoplasms at the ICV and perineal rectum is feasible and effective. The complete resection rate is low due to the challenging anatomy of

that precludes conducting a mucosal incision far from tumor margins. A careful endoscopic follow-up is mandatory to detect residual neoplasms.

Introduction: Colorectal cancer (CRC) is one of the most common malignancies in developed countries, with associated occlusive disease being relatively common. Endoscopic placement of self-expandable metallic stent (SEMS) is the first-line palliative treatment for malignant bowel obstruction.

Aims & Methods: Evaluate the outcome of endoscopic SEMS placement in CRC obstruction. Retrospective analysis of patients CRC submitted to endoscopic placement of SEMS from 2009 to 2016 in the Gastroenterology Department of Centro Hospitalar do Algarve. Statistical analysis was performed with SPSS version 24.

Results: The study included 23 patients with CRC obstruction, who were submitted to endoscopic SEMS placement, with a mean age of 75.2 ± 13.47 years. The stents were placed with a palliative purpose in 69.6% of cases ($n = 16$) and a transitory procedure before surgery in 30.4% of cases ($n = 7$). Technical and clinical success was found in 91.3% of the patients, without any recorded death during the procedure. In patients whose goal was palliative treatment (75% men and 25% women) they had a mean age of 81.6 ± 9.28 years. In 43.8% of the patients the tumor was located in the rectum, 31.6% in the sigmoid region and 25% in the recto-sigmoid transition. Being the majority (75%) well differentiated. There was a need for dilatation in 31.3%, most of the stents were uncovered (56.3%). 25% of the patients had complications. After stent placement, about 25% of the patients did chemotherapy. There was a 75% mortality rate (37.5% died by 6 months and 37.5% died by 12 months of follow-up). The use of chemotherapy after SEMS placement influenced the complications associated with the procedure ($p < 0.05$) but none of the other variables had a statistically significant influence on early death (up to 6 months).

Conclusion: SMES is an effective and safe palliative option for unresectable tumors, although the use of chemotherapy after the placement of prostheses may have an influence on the appearance of complications. Malignant colon occlusive of the colon can be treated effectively with the use of endoscopic techniques.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: julianapinho18@gmail.com

Introduction: Endoscopic mucosal resection (EMR) has been shown to be a safe and effective technique for removal of large colorectal adenomas. However, local adenoma recurrence remains a significant limitation, with prior published data describing recurrence rates of 10% to 30% post EMR.

Aims & Methods: This study aimed to evaluate the outcomes of EMR for large colorectal adenomas and identify the risk factors for adenoma recurrence. We did a retrospective analysis of the colorectal EMR performed between June 2009 and December 2016. Resected lesions larger than 20 mm in diameter with at least 3 months follow up were included. Patients referred for surgery were excluded.

Results: During the study period, 201 colorectal lesions ≥ 20 mm in size were removed in 198 patients (118 men and 80 women, mean age 68 years). Mean lesion size was 35 mm and 137 (68.2%) were located in the rectum and left colon. 66 lesions (32.8%) were larger than 40 mm in diameter. Piecemeal resection was performed in 171 lesions (85.1%). Local adenoma recurrence occurred in 44 cases (21.9%) after a mean time of follow up of 7.6 months, and the majority was managed with polypectomy or new EMR. The cumulative risk of adenoma recurrence was 7.5% at 3 months, 15.5% at 6 months and 17.1% at 12 months. In the multivariate analysis, the variables associated with a high risk

of recurrence were lesions ≥ 40 mm in size ($p = 0.0001$) and intra-procedural bleeding ($p = 0.020$). The recurrence rate was higher in the patients treated with argon plasma coagulation ($p = 0.046$).

Conclusion: After EMR of large colorectal adenomas, local recurrence rate was 21.9%. The risk factors for adenoma recurrence include lesions ≥ 40 mm and intra-procedural bleeding. Argon plasma coagulation was not associated with lower recurrence rate.

Introduction: European colorectal screening guidelines have modified the follow-up interval times based on baseline colonoscopy findings in recent years. In addition, the waiting list and individual conditions may modify the real follow-up times and this could impact in advanced adenoma detection rate in follow-up and patients outcome.

Aims & Methods: The aim of the present study was to comparatively analyse the risk of advanced lesions (advanced adenoma, invasive cancer) in high-risk patients included in a colorectal cancer screening program with different real follow-up times. One-thousand one-hundred and sixty-six patients (mean age: 60.66 ± 5.86 years, 69.1% men) who underwent a baseline colonoscopy with ≥ 3 adenomas and/or ≥ 10 mm between 2007–2012 were included. A Kaplan-Meier regression and a comparative subgroup analysis by Long-Rank test were carried out to detect the impact of real times within patients of the same risk. An adjustment for baseline covariates (high-grade dysplasia, villous component) by Cox analysis was also performed.

Results: The real follow-up times in ≥ 3 adenomas ($n = 853$, 73.16%) and ≥ 1 adenoma ≥ 10 mm ($n = 779$, 66.81%) were 38.54 ± 11.57 and 38.66 ± 11.68 months. The risk of advanced lesions were 0.26%, 1.46%, 2.83%, 9.09% and 10.38% ($n = 121$ advanced lesions) in 12, 24, 36, 48 and ≥ 60 months respectively. The most important increase was at 3–4 years ($+0.52\%$ /month). The proportion of advanced lesions within 1–2 adenomas and ≥ 3 adenomas subgroups at 48 months were 5.43% and 10.43% ($p < 0.001$), with no differences in small adenomas < 10 mm ($p = 0.478$).

Conclusion: The risk of advanced lesions in high-risk patients increased significantly at 36–60 months after baseline colonoscopy, being more important in ≥ 3 adenomas subgroup. There were no differences for 1–3 years interval.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1535 CLINICAL OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION OF MALIGNANT NON-PEDUNCULATED COLORECTAL LESIONS

Introduction: Conventional endoscopic resection, such as snare polypectomy and endoscopic mucosa resection (EMR) of benign polyps in colon and rectum reduces colorectal cancer (CRC) incidence and mortality but the role of endoscopic resection in the management of patients with early CRC (i.e. submucosal invasion) remain elusive. Large sessile and flat lesions are difficult to remove en bloc with EMR, resulting in a high level of tumor recurrence. Thus, endoscopic resection of large (> 2 cm) sessile and flat malignant lesion with snare or EMR is not recommended. Endoscopic submucosal dissection (ESD) results in high en bloc resection rates of large (≥ 2 cm) benign lesions resulting in low numbers of recurrences. However, there is limited data in the literature on the potential role of ESD in the treatment of patients with early CRC. In the present study, we present our results on performing ESD in patients with large sessile and flat malignant lesion in the colon and rectum in a large European center.

Aims & Methods: Our aim was to investigate the potential role of ESD in treatment of early colorectal cancer. We retrospectively reviewed medical records of

254 patients that underwent colorectal ESD at the endoscopy unit at Skåne University Hospital in Malmö, Sweden Jan 2014 to Dec 2016. Indications for ESD were flat and sessile lesions larger than 20 mm in diameter with low or high graded dysplasia (251 cases). Moreover, three patients with known colorectal adenocarcinoma underwent ESD due to significant comorbidity excluding surgery. In total, we identified and included 29 cases of histologically verified submucosal invasive CRC in this study.

Results: This study included 29 patients with median age of 69 years (range 44–89 years). Median tumour size was 40 mm, ranging from 20–70 mm. Tumours were either flat (Paris classification IIa, 6 cases), sessile (Paris classification Is, 19 cases) or a combination of flat and sessile (4 cases). Half of the lesions were located in the rectum and half in the colon. En bloc resection was achieved in 24 cases (83%), piecemeal resection in 4 cases (14%) and ESD was incomplete in one case. Median time to complete the procedure was 89 min (Range 18 to 594 min). Macroscopic complete resection was obtained in 26 cases (90%). R0 resection was found in 20 specimen (69%), RX was found in 3 cases (10%) and R1 was found in 5 cases (17%). Lymphovascular involvement was seen in 6 cases (21%). Depth of invasion was as follows; Sm1: 15, Sm2: 7, Sm 3: 7. In total four suspected immediate perforations occurred, three of these were managed conservatively (clips, fasting and antibiotics) and in one case, ESD was aborted and the patient was taken to emergency surgery. Pathological assessment of the resected sigmoid segment revealed T3N0. No acute significant bleeding occurred during the procedures. One patient sought emergency care 12 days after the procedure with rectal bleeding, no colonoscopy was performed to determine the site of bleeding. Five patients underwent additional surgery since the pathological report stated that the resection was R1. Tumour residue was only found in one of the five resected specimens. 18 patients have undergone endoscopic follow up, to this date without any sign of recurrence. Two patients await surgery and three patients await endoscopic follow up.

Conclusion: We herein present our findings on performing ESD on 29 patients with early CRC. Our results indicate that colorectal ESD is a safe and effective treatment in meticulously chosen patients even with malignant lesions. Further studies with longer follow up is needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1536 ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) VS HYBRID DISSECTION: WHICH TECHNIQUE TO FAVOR IN LARGE COLORECTAL LESIONS?

M. Guillaumot, S. Leblanc, H. Soliman, B. Briean, M. Barret, R. Coriat, F. Prat, S. Chaussade

Gastroenterology, Cochin Hospital, Paris/France

Contact E-mail Address: marie-anne.guillaumot@aphp.fr

Introduction: Large colorectal lesions (>20 mm) can be removed endoscopically by endoscopic mucosal resection (EMR), often in a piecemeal fashion resulting in low en bloc and radical (R0)-resection rates. In this indication, submucosal dissection (ESD) allows en bloc resection whatever the size, but still remains technically difficult and time consuming. A hybrid endoscopic technique has been developed, called simplified or hybrid dissection. The aim of our study was to evaluate the results and complications of endoscopic dissection by hybrid technique compared to classical endoscopic submucosal dissection.

Aims & Methods: Our study was carried out from January 2013 to June 2016 from a prospective database. The 40 lesions removed by hybrid technique were compared to the control group of 109 ESD. The hybrid dissection procedure was performed as follow: submucosal injection around the lesion of macromolecules, circumferential mucosal incision and submucosal dissection using the tip of a single-strand snare by endo-cut Q mode, central submucosal injection of the lesion and final resection with the single-strand snare, if possible in en-bloc. Patient characteristics, tumor location and size, dissection characteristics, "block" resection rate, R0 resection rate (healthy margins), procedure and hospitalization time, and complications were identified and compared with the so-called "classical" ESD technique.

Results: Lesions were more frequently located in the colon (vs rectum) in the hybrid dissection group compared to the ESD group (72.5% versus 28.5%, $p < 0.001$). The lesions were type IIc according to Paris classification in 10% of the hybrid dissection group and 13.1% in the ESD group ($p = 0.8$). The mean size of the lesions was lower in the hybrid dissection group than in the ESD group ($32.4 \text{ mm} \pm 13 \text{ mm}$ compared to $54.4 \text{ mm} \pm 26.7 \text{ mm}$, $p < 0.001$). An en bloc resection was performed in 52.5% and 84.4% in the hybrid dissection and ESD group, respectively ($p < 0.001$). The procedure time (including general anesthesia time) was lower in the hybrid dissection group compared to the ESD group ($103 \text{ min} \pm 62 \text{ min}$ vs $191 \text{ min} \pm 73 \text{ min}$, $p < 0.001$, respectively). The hospitalization time was lower in the hybrid dissection group than in the ESD group ($1.1 \text{ days} \pm 1.13 \text{ days}$ vs $2.8 \text{ days} \pm 1.8 \text{ days}$, $p < 0.001$). R0 resection rates were lower in the hybrid dissection group than in the ESD group (47.5% and 61% respectively, $p < 0.001$). Hybrid dissection was performed for adenocarcinoma, adenoma with high grade dysplasia and adenoma with low grade dysplasia in 12.5%, 42.5% and 40%, respectively. The rate of adenocarcinoma was lower compared to the ESD group (12.5% versus 30.8%, $p = 0.009$). In the hybrid dissection group, the rate of perforation was lower than the ESD group (5% versus 20%, $p = 0.04$). There was no significant difference in the rate of bleeding (1.8% in the hybrid dissection group and 2.5% in the ESD group). In case of complication, there was no need of surgical treatment in the hybrid dissection group, but was needed in one patient in the ESD group.

Conclusion: Hybrid dissection is less effective in terms of en bloc resection of large colorectal tumors. Classical endoscopic submucosal resection should be preferred, especially in case of suspected adenocarcinoma despite longer procedure and hospitalisation time.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1537 TRENDS IN STATISTICS REGARDING ELECTIVE ERCP PROCEDURES IN THE VENETO REGION: A RETROSPECTIVE STUDY BASED ON ADMINISTRATIVE DATABASES

M. Saia¹, E. Rosa-Rizzotto¹, E. Guido¹, D. Caroli¹, A. Frasson², B. Germanà³, P. Pilati², F. De Lazzari¹

³*San Martino Hospital - Ulss1, Gastroenterologic Unit, Belluno/Italy*

Contact E-mail Address: d.caroli@libero.it

Introduction: Since its introduction in 1968, Endoscopic retrograde cholangiopancreatography (ERCP) has become a commonly performed endoscopic procedure used to diagnose and to treat conditions associated to the pancreatobiliary system. It is nevertheless associated to the highest risk of complications of all routine endoscopic procedures. It is important to have a thorough understanding of the potential complications and the adverse events that may be associated to ERCP procedures so that these may be managed appropriately should they occur. The aim of this study was to examine the trends in ERCP usage here in the Veneto Region (Northeastern Italian area) and, in particular, the complications and mortality rate associated to it.

Aims & Methods: Utilizing an anonymous database of hospital discharge records referring to the period between 2007 and 2015, a retrospective study was carried out to examine the complications associated to ERCP. All of the elective hospitalizations for gallstones in the bile duct during which the procedure was carried out within two days of being hospitalized were examined. Hospitalizations for neoplasms were not considered. The study considered the onset of complications or death as outcome indicators as well as the patients' post-procedure status; the threshold value that was utilized was 2 days and the patients who later underwent surgery (e.g. cholecystectomy) were excluded from our analysis; the associations between the type of hospital where the patients were being assisted both with regard to the type of organization (Hub or Spoke model) and the type of management (public/private) were also evaluated.

Results: A total of 3,136 admissions out of total of 14,626 hospital days ($\text{SD}: 4.6 \pm 5.8$ days) were identified in a total of 40 hospitals, 6 (15%) of which private. The sex ratios were overlapping and the mean age, which was equal to 68.3 ± 14.2 (range 6–98 yrs), was higher in the females (69.1 ± 14.9 vs. 67.5 ± 13.5); significant deviations during the period examined were not noted. A total of 212 complications (6.8%) were registered: these included acute pancreatitis (4.5%), cholangitis (1.3%), sepsis (0.4%), acute cholecystitis (0.3%), cardiopulmonary complications (0.2%), perforations and hemorrhage (0.2%). The complications that presented, which were significantly higher in the female sex (7.3% vs. 6.2%; $p < 0.05$), besides a greater average hospital stay in those subjects (10.9 ± 13.9 vs. 4.2 ± 4.4 days), the within hospital mortality was 4.1% (13 cases) and there was a 6.1% of deaths due to complications. As far as the post-procedure hospital stay was concerned, in 55% of the cases, the discharge of patients within a two day period was more frequent in those assisted in public hospitals ($\text{OR}: 1.55; \text{IC}95\%: 1.21-1.89; p < 0.05$) in which 90% of the activities were carried out and no differences linked to their characteristics. The stratification of complications according to the type of hospital (range 2–17%) did not uncover any significant differences during the period examined.

Conclusion: Study findings uncovered that pancreatitis was the most common post-procedure ERCP complication in the patients studied; the total complication rate was in line with that reported in the literature. That result and the fact that no correlation was found between the type and percent of complications and the type of hospital can be attributed to the effective regional hospital organization characterized by a capillary network of specialists capable of performing complex endoscopic procedures throughout the region limiting the need to transfer patients from one hospital to another.

Introduction: Risk factors for post-endoscopic retrograde cholangiopancreatography pancreatitis (PEP) have been widely investigated. Nevertheless, studies focusing in metabolic conditions especially obesity, dyslipidemia and diabetes mellitus (DM) are still limited.

Aims & Methods: The aim of our study was to evaluate the effect of these factors on the frequency of PEP. We retrospectively analyzed all ERCP performed over a 12 months period [January 2015- December 2015] and carried out at the gastroenterology unit of our hospital. All patients were evaluated prospectively for the frequency of PEP based on the consensus criteria. The patients with obesity (Body mass index $\text{BMI} \geq 30 \text{ kg/m}^2$), dyslipidemia (triglyceride $> 2 \text{ g/L}$ or LDL-cholesterol $> 1.6 \text{ g/L}$) and DM (history of DM or fasting glucose level

>1.26 g/l) were found out before the procedure. The rate of PEP compared separately between patients with and without of these metabolic conditions.

Results: Two hundred twenty three procedures were performed during the study period. The rate of obesity, dyslipidemia and DM was 23.7%, 8.1% and 19.7% respectively. A PEP occurred in 13 patients with an overall incidence of 5.8%. The rate of PEP was 3.8% in patients with obesity, 11.1% in patients with dyslipidemia and 9.1% in patients with DM. Although PEP was more frequent in dyslipidemia (11.1% vs 5.3%) and DM (9.1% vs 5.3%) groups, results did not reach a statistical significance ($p=0.30$, $p=0.31$ respectively). This could be explained by the small effective of patients. In the other hand, PEP was less frequent in the obesity group (3.8% vs 6.9%) but there was no statistical significance $p=0.28$.

Conclusion: In our study, metabolic conditions were not associated with an increased risk of PEP. It seems to be wise to evaluate the role of these conditions in larger prospective studies since the expanded prevalence of metabolic syndrome in general population.

P1539 PLACE OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) IN THE MANAGEMENT OF HEPATIC HYDATID DISEASE

H. Hassine, M. Sabbah, N. Bibani, D. Trad, H. Elloumi, D. Gargouri, A. Ouakaa, J. Kharrat

Gastroenterology, Habib Thameur Hospital, Tunis/Tunisia

Contact E-mail Address: hajer.hassine@gmail.com

Introduction: Hepatic hydatid disease (HHD) is a major endemic health problem in certain areas of the world such as Tunisia. Intrahepatic rupture of a hepatic hydatid cyst is a common complication ranging between 3 and 17%. Furthermore, biliary leakage is the most frequent postoperative complication following surgery for hydatid cysts of liver. Both conditions require per endoscopic biliary drainage.

Aims & Methods: The aim of this study was to assess the results of ERCP in patients with HHD. We retrospectively analyzed the results and complications of all ERCP performed for HHD whether before or after surgical treatment over a 10 years period [January 2007 - December 2016] and carried out at the gastroenterology unit of our hospital.

Results: Sixty seven procedures were included (mean age 40.4 years [15–82] and sex ratio male/female 31/36). Of the 67 procedures, 58 (86.5%) were performed in patients who had undergone previous surgery. The indications of the ERCP were persistent external biliary fistulae in 77.6%, overcome obstruction or cholangitis due to residual materials within bile duct in 20.7% and secondary biliary strictures in 1.7%. In patients who had not undergone previous surgery (13.4%), the indications of the ERCP were cholangitis due to intra-biliary rupture of hydatid cyst in 44.4% associated with acute pancreatitis in 55.6%. The cannulation of the papilla was impossible in 6 cases (8.9%) and the endoscopic sphincterotomy (ES) could not be performed. When papilla cannulation was obtained, per endoscopic cholangiographic findings were: dilation of the biliary tract (21.3%) with filling defects of varying size and shapes (52.5%), leakage of contrast medium into the cyst cavity (41%) and distal stenosis (3.3%). ES was then performed in all cases with satisfactory results. Thus, hydatid membranes (36%) or daughter cysts (1.6%) encountered in bile ducts have been emptied out in 93.4% by biliary occlusion balloon and/or Dormia basket. Nevertheless, two patients required biliary stenting due to stricture of the bile duct and two others required nasobiliary drainage. One patient presented post ERCP pancreatitis (1.5%).

Conclusion: ERCP is a safe and effective way to manage biliary complications of HHD. In most patients, ES is the most efficient treatment of postoperative external biliary fistulas, jaundice and accompanying cholangitis. In some cases, biliary stenting or nasobiliary drainage may be required.

P1540 QUALITY INDICATORS AND POST OPERATIVE OUTCOME OF ERCP PERFORMED IN A LOW RESOURCE SETTING; CAN QUALITY INDICATORS FROM DEVELOPED SETTINGS BE APPLIED?

I. Kongala Liyanage¹, E. Thalagala¹, S. Kulatunge¹, R. Peiris¹, N. Nawarathne¹

Contact E-mail Address: Isurujith@gmail.com

Introduction: Endoscopic Retrograde Cholangiopancreatogram (ERCP) is a complex and invasive procedure. Quality control and monitoring for complications is an important part of ensuring patient safety. Gastroenterology and Hepatology unit of the National Hospital of Sri Lanka performs the most number and variety of ERCP procedures in Sri Lanka. Although facilities are limited, detailed patient records and logs were maintained since commencement of ERCP procedures in this unit.

Aims & Methods: A retrospective analysis was carried out on quality indicators and complications of the ERCP procedures performed in this unit since 2006. Data from written records were entered into an electronic database and analysis was done using STATA version 13. Quality indicators and standards published by the American Society of Gastrointestinal Endoscopy and American College of Gastroenterology in 2015 were used.

Results: A total of 3780 ERCP procedures were performed. Females consisted of 54% of the patients ($n=2041$). Mean age in years was 57.6 (SD=8.4). Male

patients were older with a mean age of 61.2 years whereas the mean age of females was 54.6 years ($P < 0.05$). Cholelithiasis was the commonest indication (85%) and 68% out of these patients had active cholangitis at the time of the procedure. Chronic pancreatitis, benign and malignant strictures requiring stenting, postoperative bile duct damage the other common indications. Data were available on 19 out of the 24 quality indicators. A total of 15 quality standards were met (7/9 pre procedure, 4/5 intra procedure and 4/10 post procedure). Most prevalent major complications were Post ERCP Pancreatitis (PEP) and post ERCP Cholangitis (PEC) complicating 2.22% and 4.78% procedures respectively. Mortality was less than 0.1% ($n=3$). Cardiorespiratory complications and complications of anesthesia were seen in 16 patients (0.41%) resulting in one mortality. These were significantly associated with older age and the total number of medical comorbidities the patients had ($p < 0.05$). Deficiencies practices and information gathering were noted mostly in postoperative care and includes documentation of patient satisfaction rate and long-term complication rates. After the quality review data on all quality indicators are gathered for future quality control purposes.

Conclusion: This supports the fact that centers with minimal resources can monitor quality standards and maintain satisfactory patient safety levels. Low numbers of postoperative complications were noted in this review. Old age and having multiple medical comorbidities were associated with a higher complication risk. Quality checkups help to identify deficiencies in practice as well as documentation and help to adjust future practices, even in low resource settings.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1541 USE OF MICROCATHERETERS IN ECHOENDOSCOPY-GUIDED BILIOPANCREATIC RENDEZ-VOUS—INITIAL EXPERIENCE

J. Pinto, C. Saldaña Dueñas, C. Leitão, I. Fernández-Urién Sainz, J.J. Vila
Endoscopy Unit, Biliary And Pancreatic Diseases Unit, Complejo Hospitalario de Navarra, Pamplona/Spain

Contact E-mail Address: jsdiaspinto@gmail.com

Introduction: EUS-guided pancreatic or biliary rendezvous is a technically demanding procedure, and the intraductal manipulation of the guidewire remains the most challenging step. Passing the guidewire through the needle may cause its fragmentation on the sharp metallic bevel. We have described the method of using a microcatheter for EUS-guided rendezvous, which allows easier handling and exchange of the guidewire, while avoiding both the risk of fragmentation and the need of injection of contrast to achieve a complete ductogram.

Aims & Methods: We aimed to evaluate the early experience of the microcatheter method in EUS-guided rendezvous procedures in the biliary and pancreatic tracts. During EUS-guided biliary or pancreatic rendezvous, initial puncture of the duct of interest was attempted with a 19G needle without stylet and

previously flushed with contrast. A 0.025" guidewire was then inserted through the needle into the duct and advanced anterogradely to the papilla. If further manipulation was necessary to entry the duodenum, movements were performed with caution in order to avoid fragmentation of the guidewire. Whenever the passage through the papilla was not achieved or the guidewire movements were hampered by the needle bevel, we performed a microcatheter technique. After removing the needle, leaving the guidewire in situ, a 3F, 150 cm long microcatheter was inserted over the guidewire into the duct. Then, manipulation of the guidewire, guidewire exchange and contrast injection were performed according to the discretion of the endoscopist. We reviewed the cases of EUS-guided pancreatic or biliary rendezvous performed in our unit using microcatheters from September 2015 to March 2017. Technical success was considered when the rendezvous could be completed.

Results: Nine patients with previous unsuccessful manipulation of the guidewire with the needle during EUS-guided biliary or pancreatic rendezvous underwent a microcatheter-guided attempt on the same procedure. Pancreatic rendezvous was attempted in 5 cases (2 chronic pancreatitis, 2 pancreas divisum and 1 pancreatic cancer) and biliary rendezvous in the other 4 (3 biliary stenosis and 1 ampulloma). Technical success was achieved in 7 patients (78%) with the microcatheter technique. Technical failure occurred in 1 patient with biliary stenosis in whom a EUS-guided hepaticogastrostomy was performed in the same procedure and in 1 patient with chronic pancreatitis with symptomatic pancreatic duct stenosis. There were no adverse events after the procedure, irrespective of technical success.

Conclusion: In our series, using a microcatheter for the indructual manipulation of the guidewire increases the EUS-guided rendezvous technical success without increasing the complication rate, irrespective of technical success.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Biliary tract complications (BTC) are the leading problem in patients after orthotopic liver transplantation (LT). The present study analysed the results and predictors of treatment outcomes in patients with biliary stenoses undergoing endoscopic retrograde cholangiopancreatography (ERCP) and/or percutaneous transhepatic cholangiodrainage (PTCD) at the University Medical Centre Hamburg-Eppendorf.

Aims & Methods: All adult patients who received ERCP or PTCD for BTC after LT between 2009 and 2015 were retrospectively analysed. Remission of BTC was defined as no need of intervention for at least 12 months. To identify predictors of endoscopic treatment outcome in patients with biliary stenoses, a multivariate logistic regression analysis was performed after univariate variable selection. Laboratory parameters that were significant in the multivariate analysis, were dichotomised stepwise according to the most informative cut-off predicting outcome. Furthermore, endoscopic techniques were analysed in both the ERCP- and PTCD-subgroup.

Results: Of 144 patients with BTC after LT, 116 were diagnosed with biliary stenoses. Among these, 86 received ERCP, 17 PTCD and 13 both techniques. Long-term remission was achieved in 55 patients (47% overall; 53% in ERCP alone and 30% when PTCD was applied). Patients with non-anastomotic strictures (NAS) (odds ratio [OR] 0.25, 95% confidence interval [CI] 0.10–0.57; p=0.001), requirement of PTCD (OR 0.30, 95% CI 0.10–0.79; p=0.018) and higher pre-interventional serum-bilirubin levels (OR 0.88, 95% CI 0.76–0.98; p=0.037) were less likely to achieve remission. The most informative bilirubin cut-off to predict the outcome was 5 mg/dl. This cut-off maintained a significant association with outcome in the multivariate model (OR 0.30, 95% CI 0.08–0.95; p=0.049). In the ERCP-subgroup, dilation with a higher maximal balloon-diameter was associated with a favourable outcome (p=0.043).

Conclusion: Both ERCP and PTCD can provide long-term benefit in patients with BTC after LT. However, patients with NAS and requirement of PTCD had less favourable outcomes. The pre-interventional bilirubin level could be a valuable parameter to identify patients at risk of treatment failure. Larger ERCP balloon diameters may benefit remission.

Introduction: Confocal endomicroscopy is an endoscopic imaging technique permitting the microscopic analysis of the digestive mucosa in real time (esophagus, stomach, duodenum, colon, biliary tract and pancreas) due to injection of fluorescein which is an intravenous contrast. The aim of this national observational study under the guard of SFED is to evaluate the practice of confocal endomicroscopy in France, specifically its indication, histologic correlation, therapeutic benefits depending on the operator and complications.

Aims & Methods: We executed a multicentric observational prospective study from September 2013 to February 2015. Collection of data was based on a standardized collection sheet. All operators were trained on performing confocal endomicroscopy. The intravenous injection of fluorescein was given either in bolus or in a perfusion method at a dilution of 1 or 10%. Demographic, clinical, endoscopic and endomicroscopic data were collected. For each act the correlation between the confocal endomicroscopy and histology and the outcome of the ECM depending on the operator was reported.

Results: In total 399 procedures of confocal endomicroscopy were done on 399 patients (median age was 59 +/- 14.5, males were 52%) and these were performed in 12 centers. The main indications were: diagnosis and monitoring of Barrett esophagus 28% (111/399), surveillance of gastritis 4% (16/399), characterization of colorectal polyp and searching for dysplasia in IBD patients 17% (68/399), undetermined biliary stenosis 11% (42/399), pancreatic cysts 30% (123/399) and other rare cases (lymph nodes characterization, pancreatic mass, ampulloma, GIST, celiac disease, control post mucosectomy of gastric and duodenal polyps) 10% (39/399). The quality of imaging was good in 83% of cases (331/399), average in 16% (64/399) and poor in 1% (6/399). The correlation with histology was measured by using Cohen's kappa coefficient. The results were respectively k=0.9, 0.78, 0.82, 0.7, 0.94, 0.93 for Barrett's esophagus, gastritis, IBD, colorectal polyps, undetermined biliary stenosis and pancreatic cysts. The outcome of the procedure according to the operator was beneficial for three main indications: Barrett's esophagus (82% especially for targeting biopsies), serous pancreatic cysts (100% of cases), and undetermined biliary stenosis (90% of cases and especially for real time therapeutic decision). One major side effect was seen during the study, which was an anaphylactic choc after a bolus injection of 2.5cc of fluorescein 10% in a 69y old patient who didn't have any previous history of allergies. This patient was hospitalized for surveillance for three days.

Conclusion: In conclusion, confocal endomicroscopy is an in vivo microscopic imaging technique that is easily performed throughout the digestive tube with a good histologic correlation especially for Barrett's esophagus, undetermined biliary stenosis and pancreatic cysts. Its importance in the management of patients remains to be clarified with the advent of new endoscopic magnification techniques.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1544 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH SURGICALLY MODIFIED GASTRO-ENTERIC-BILIARY ANATOMY: RESULTS FROM A TERTIARY CENTER

E. Soares, M. Gravito-Soares, N. Almeida, D. Gomes, E. Camacho, S. Mendes, R. Ferreira, L. Tomé

Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal, Coimbra/Portugal

Contact E-mail Address: es18497@gmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) represents a crucial procedure in the management of biliopancreatic pathology. However, its performance in patients with surgically modified gastro-enteric-biliary anatomy (SMGA) is a challenging issue.

Aims & Methods: We aimed to evaluate the efficacy of this advanced endoscopic technique in patients with SMGA. This was a retrospective observational cohort study of all patients with surgical modification of biliary/pancreatic access undergone ERCP, between 01/2002 and 02/2017. Demographic variables, indications, the breakdown of surgical procedures and technical success rate were evaluated as well as potential predictive factors of therapeutic efficacy rate. Compared patients with successful technique(G1) and therapeutic failure by ERCP

requiring surgical and/or radiological therapy(G2), regarding recurrence of biliary-pancreatic pathology, major complications and post-procedure 30-days mortality.

Results: A total of 153 ERCP procedures were carried out in 103 patients with SMGA (mean age:75.4±11.3years, men:80.6%). The breakdown of surgical procedures was: Billroth II-77.7%(n=80); Billroth I-10.7%(n=11); Roux-en-Y-8.7%(n=9); post-duodenopancreatotomy-2; gastric sleeve-1. The forward-viewing endoscope was used in 79.8%(n=122), duodenoscope in 19.6%(n=30) and colonoscope in 0.6%(n=1). The success rate was: technical-62.1%(95/153); therapeutic-93.7%(89/95). The success rate by type of surgical reconstruction was: gastric sleeve-100%; Billroth I-94.4%; Billroth II-60.5%; post-duodenopancreatotomy-50%; Roux-en-Y-18.2%. After multivariate analysis, poor papillary orientation/localization (OR = 5.618;p = 0.006) was the only independent predictor of technical failure. On the other hand, high values of total bilirubin (OR = 1.339;p = 0.024) and benign etiology of obstructive jaundice (OR = 1.789;p = 0.017) were independent predictors of therapeutic success. In 25 patients with no endoscopic technical/therapeutic success, surgical (n = 14) or radiological approach (n = 11) was performed. Comparing G1vsG2, there were no differences in the recurrence rate of biliary-pancreatic disease (23.1%vs36.0%;p = 0.205) or mortality (9.0%vs8.0%;p = 1.000). However, G2 group had a high rate of major complications (12.8%vs36.0%;p = 0.016).

Conclusion: The technical and therapeutic success rates of ERCP in patients with SMGA were 62.1% and 93.7%, respectively (lower in Roux-en-Y). Given the increased number of patients with SMGA and the high rate of complications associated with radiological and surgical therapies, it is essential to optimize ERCP technique rather than conventional endoscopy/duodenoscopy, including the use of balloon-assisted enteroscopy.

P1545 NEWLY DEVELOPED BASKET FOR DIGITAL, SINGLE-OPERATOR CHOLANGIOSCOPY FOR MANAGEMENT OF RESIDUAL STONES AFTER LITHOTRIPSY

J.H. Moon, Y.N. Lee, H.J. Choi, H.W. Lee, T.H. Lee, M.H. Choi, S. Cha, Y.D. Cho, S. Park

Digestive Disease Center And Research Institute, Department Of Internal Medicine, SoonChunHyang University School of Medicine, Bucheon and Seoul/Korea, Republic of

Contact E-mail Address: jhmoon@schmc.ac.kr

Introduction: Detection of residual or fragmented stones after lithotripsy for retained common bile duct stones can be improved by digital, single-operator cholangioscopy (SOC) by high resolution imaging quality. However, therapeutic intervention for the removal of residual CBD stones is limited by lack of appropriate accessories.

Aims & Methods: We evaluated the role of SOC and newly developed dornia basket for the evaluation and removal of residual stones after lithotripsy. From March to October 2016, 34 patients who had undergone lithotripsy for retained CBD stones with no evidence of filling defects in occluded balloon cholangiography were included. After balloon cholangiography, the bile duct was evaluated by SOC for the complete evacuation of stones. Detected residual CBD stones were directly retrieved with newly developed dornia basket inserted into the working channel of SOC. The incidence of residual stones detected by SOC, and the success rate of residual stone retrieval under SOC were investigated.

Results: DPOC was successfully performed in all patients. Of these, 11 patients (32.4%) had residual CBD stones. The residual stones were successfully removed in 10 patients (90.9%) by dornia basket under SOC. (84.6%) except residual stones on Lt. hepatic duct. There were no complications associated with SOC or direct stone removal.

Conclusion: Digital SOC combined with newly developed dornia basket is useful for the detection and extraction of residual stones after lithotripsy for retained CBD stones expanding therapeutic intervention of SOC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1546 ASSOCIATION BETWEEN PREDICTIVE FACTORS AND RADIATION EXPOSURE DURING ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY

S. Dong, C.H. Oh, J.R. Moon

Kyung Hee University College of Medicine Dept. of Internal Medicine, Seoul/Korea, Republic of

Contact E-mail Address: gidrdong@hanmail.net

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) relies on the use of ionizing radiation in the form of fluoroscopy. Because use of fluoroscopy has positive relationship with radiation exposure, it makes a risk of the development of cancer and other radiation toxicity. The increasing exposure of patients and endoscopists to radiation is concerning.

Aims & Methods: The aim of our study was to evaluation of predictive factors of radiation exposure to the patients and endoscopists during endoscopic retrograde cholangiopancreatography. A cross-sectional retrospective analysis of 892 ERCPs performed at tertiary academic hospital over 48-month period by on expert endoscopist was conducted. The primary outcomes of interest were the radiation exposure of patients and endoscopists during procedure as determined by radiation dose in dose area product (DAP), absorbed dose (AD) and fluoroscopy time. And we correlated them with age, sex, body mass index, diagnosis, duration of procedure, procedure name and procedure complexity.

Results: As a result of analysis of the 892 ERCPs performed during 4 years, the mean duration of fluoroscopy time was 5.52 mins (95% CI, 5.15–5.93). Mean radiation duration were as follows: CBD stones (n = 511, 5.76 mins); malignant stenosis of bile duct (n = 189, 5.78 mins); pancreatic disease (n = 95, 5.28 mins); benign stenosis of bile duct (n = 51, 5.32 mins); and periampullary stenosis (n = 46, 4.89 mins). Multivariate analysis revealed that prolonged duration of fluoroscopy time was related with specific factors of patient included age, BMI, diagnosis and procedure complexity (all p < 0.05). Among the parameters, procedure complexity was the most significant relation with radiation dose. In addition, the following three procedures made prolonged procedure duration: two more procedures performed during ERCP and mechanical lithotripsy (all p < 0.05)

Conclusion: ERCPs are associated with significantly higher radiation exposure to patients on the specific procedure. The endoscopists should be aware of the increased dose of radiation required when performing ERCP in patients with increased BMI, old age, and who need two more ERCP procedure.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1547 DEVELOPMENT OF AN ERCP REGISTRY FOR QUALITY CONTROL AND BENCHMARKING

Introduction: To obtain representative information about invasive endoscopic procedures is a principal goal to monitor efficacy and safety. A web-based, online central registry can serve this aim allowing structured data collection and usage of universally accepted terminology.

Aims & Methods: We decided to develop a web-based registry which is easy to use and captures relevant procedure related information. The primary aim of the registry is to monitor relevant outcome data of ERCP.

Results: Hungarian experts in ERCP were invited at the initiation of the registry for discussion and consensus. Detailed data collection form was initially developed based on internationally recommended quality parameters. The prospective observational research project was approved by the Scientific and Research Ethics Committee (Budapest, Hungary). A web-based case report form was developed after finalisation and tested from January 2017 at our department. ERCP related data of consecutive patients were collected prospectively after consenting the patients. The data from the first 100 procedures were analysed to demonstrate the usability of the registry. Ninety-two patients (51 females, 41 males) were involved in this preliminary evaluation with an average age of 69.2 years (23–93 years). The number of elective and urgent examinations were almost equal. The indication of ERCP were the following: bile duct disorder based on laboratory or imaging data was the indication in 45%, obstructive jaundice in 31%, cholangitis in 16%, acute biliary pancreatitis in 5%, pancreatic disorder in 3%. The difficulty of procedures was evaluated: grade 1–22%, grade 2–45%, grade 3–30%, grade 4–3%. Fifty-nine procedures were performed in patients with intact papilla of Vater, bile duct access was not successful in one case (1.7%). Precut procedure was applied in 14 cases (23.3%), all of them resulted successful biliary access at the same procedure. Immediate complications were observed in 8 cases (8%), 6 of them (6%) were bleeding. All were successfully controlled, and none of the patients required blood transfusion or repeated endoscopy. Mild post-ERCP pancreatitis was developed in one patient (1%). Cholangitis was observed in 2 cases (2%). Follow up was conducted 30 days after the ERCP by a telephone call and/or reviewing health care documentations to observe long term outcome. Four patients (4%) died during this period, but only 1 death was related to the procedure, caused by unresolved cholangitis.

Conclusion: The ERCP registry is an essential tool for measuring quality indicators. The universal usage will allow benchmarking at individual, institutional and national level and will help in quality improvement. Efficacy, safety and impact on different pancreatobiliary disorders will be also measurable.

P1548 DOUBLE-BALLOON ENTEROSCOPY FOR ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH SURGICALLY ALTERED UPPER GASTROINTESTINAL ANATOMY

C. Ghaoui¹, E. Samaha¹, G. Rahmi¹, G. Perrod¹, H. Benosman¹, A. Vienne¹, C. Savale¹, S. Khater¹, L. Abbes¹, J. Danset¹, G. Malamut¹, C. Cellier¹

Contact E-mail Address: celineghaoui@hotmail.com

Introduction: Double-balloon enteroscopy-assisted endoscopic retrograde cholangiopancreatography or DBE-ERCP allows access to the biliary ducts of patients with surgically altered Upper Gastrointestinal (GI) anatomy. We studied the feasibility and efficacy of DBE-ERCP at our institution.

Aims & Methods: This is a retrospective study of all patients with surgically altered GI anatomy who underwent DBE-ERCP at our institution between February 2011 and March 2017. The primary endpoint was the global success rate of DBE-ERCP. The secondary endpoints were (1) the success rate of enteroscopy defined as reaching the desired post-surgical anatomic target, (2) the diagnostic success rate defined as successful cannulation of the native papilla or

anastomosis, and (3) the therapeutic success rate. We used a 2.2 m DBE with a 2.8 or 3.2 mm of operating channel (EN 450 T5, or EN580T Fujinon inc Saitama Japan).

Results: A total of 12 patients (sex ratio 1/1) with a mean age of 65 [47–82] underwent 14 DBE-ERCP. 7 patients had Roux-en-Y gastro-jejunostomy with a bilio-jejunostomy, 4 patients had Roux-en-Y with a native papilla, and 1 patient had a Billroth II gastric bypass. Enteroscopy success rate was 93% (13/14 procedures). The diagnostic success rate was 85% (11/13 procedures) with 4/5 of native papillae. Therapeutic interventions including sphincterotomy (n=4), biliary stone extraction (n=4) and biliary dilation (n=2) were needed in 8/11 procedures and their success rate was 100%. The global success rate of DBE-ERCP was 78% (11/14 procedures). Our results were comparable to those of the literature (global success rate of 82%). The only complication was one case of superficial intestinal lacerations without perforation (complication rate 7%).

Conclusion: DBE-ERCP in patients with surgically altered upper GI anatomy is a safe and efficient procedure with a global success rate of 78%. Using shorter enteroscopes with wider operating channel in the future might improve the success rate of this technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Biliary cannulation may be difficult in 10–15% of patients (1) and needle-knife sphincterotomy is more often used as a rescue treatment. A more recent technique for difficult cases is transpancreatic sphincterotomy. Both situations are well known as Post-ErCP pancreatitis risk factor (2). To best of our knowledge only few studies compared success rate and adverse events in these techniques (3–7).

Aims & Methods: We aimed to compare the efficacy and safety of NKS comparing to TPS in difficult biliary cannulation. We conducted a bibliographic search using PUBMED, EMBASE including 2 RCTs and 4 non randomized trials from January 2000 to December 2016. OR using the Mantel-Haenszel method was used for dichotomous variables. Quantitative synthesis was performed using Review Manager version 5.0. Primary outcome was success rate. Secondary outcomes were rate of overall complications, and pancreatitis. Clinical heterogeneity was assessed by I² value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity.

Results: Success rate was higher in NKS group compared to TPS (OR 2.98 95%CI 1.01–8.85, p=0.05). Complications and risk of pancreatitis were similar in both group (OR 0.74 95%CI 0.51–1.09 p=0.13; OR 1.09 95%CI 0.68–1.75 p=0.71)

Conclusion: NKS is associated with higher success rate with equal risk of complication and pancreatitis risk compared to TPS. Further and well design RCTs are needed before a firm conclusion could be made

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Transpancreatic Sphincterotomy (TPS) involves wire-guided cannulation of the main pancreatic duct (MPD) followed by standard pull-type sphincterotomy cutting towards the main channel. Typically a MPD stent insertion should follow TPS to prevent post-ERCP pancreatitis (PEP). ESGE [1] recommends that in patients with a small papilla that is difficult to cannulate, TPS should be considered if unintentional wire guided MPD cannulation occurs. A previous study had suggested that TPS might be as effective as double guide wire (DGW) technique in achieving biliary cannulation in difficult cases and has a lower pancreatitis rate. [1]

Aims & Methods: The aim of this study was to review the practice, complications and outcomes of TPS in University Hospital of North Tees (district general hospital in the north-east of UK). All ERCP procedures between January 2014 and October 2016 were reviewed. Endoscopy reports, blood results and discharge letters were used for data collection.

Results: 1365 ERCP procedures were performed in the study period. Overall CBD cannulation rate was 91.3%. 105/1365 (7.7%) wire guided TPS procedures were carried out. Mean age in the TPS group was 67 years (range: 20–91) - 64/105 (61%) male and 41/105 (39%) females. 3 senior consultants and a senior endoscopic fellow performed TPS. TPS was used as the initial strategy in the event of MPD cannulation and without using alternative methods such as DGW. Cholelithiasis was the commonest ERCP indication in TPS group (58/105). Other indications include pancreatic cancer, biliary stricture, cholangiocarcinoma and bile leak post cholecystectomy. CBD cannulation was achieved in 96/105 (90.5%) of cases - 81/105 (77.1%) during the first ERCP and 15/105 (14.2%) at second ERCP [where CBD cannulation was achieved at second attempt, TPS had been done at the first ERCP]. In 9/105 patients CBD cannulation was not achieved. 8/105 (7.6%) had a complication. 6/105 (5.7%) patients had PEP - 5/6 had a prophylactic MPD stent. 1/105 had a post sphincterotomy bleed which was controlled with endoscopic therapy. 1/105 had a perforation and a subsequent long hospital stay. There were no procedure-related deaths.

Conclusion: This study demonstrates that TPS is a safe and effective way of gaining CBD access. Our data suggests that experienced operators in a DGH setting can safely carry out TPS. Our study is the second largest cohort in the literature and the largest cohort in the UK. We would suggest early adoption of TPS if wire access to the pancreatic duct is achieved, this will likely reduce complication rate as a result of less engagement with the papilla and overall reduced time at CBD cannulation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cholelithiasis is a relative frequent condition in patients with gallbladder stones (prevalence of 3–16%). Endoscopic sphincterotomy and stone extraction is the recommended treatment of bile duct stones. In the case of failed endoscopic therapy, cholecystectomy combined with bile duct exploration or intraoperative endoscopic retrograde cholangiopancreatography should be performed.

Aims & Methods: The main objective of this study was to evaluate the efficacy of endoscopic extraction methods in patients who presented cholelithiasis. We conducted a retrospective single center study over 7 years from Jan 2009 to Dec 2015. Patients with single or multiple bile duct stones submitted to endoscopic retrograde cholangio-pancreatography (ERCP) were included. We analyzed each technique by considering the following parameters: mean diameter of the stone(s), mean diameter of CBD and success rate defined by number of cases solved endoscopically vs. cases of residual lithiasis/referred to surgery. Every ERCP was performed using Olympus® side-viewing endoscopes. Stone size, number and CBD diameter were documented on the initial diagnostic cholangiogram. Stones were removed using retrieval balloon catheter, Dormia extraction basket, mechanical lithotripter and CRE™ Balloon Dilator (DASE). In case of residual lithiasis, a biliary 10Fr/7Fr Amsterdam plastic stent was placed and a second ERCP was planned within 2–4 weeks. The efficacy endpoint was the success rate regarding complete clearance of the bile duct. Statistical analysis

was performed using SPSS version 20.0. A P-value of less than 0.05 was considered statistically significant.

Results: We included 1976 patients who presented choledocholithiasis and underwent different endoscopic extraction techniques. Mean diameter of stone(s) extracted using only the basket (Group A) was 6.8 mm with a mean CBD diameter of 11.6 mm for patients with complete clearance of the bile duct compared to 11.8 mm (mean stone diameter) with 14.3 mm (mean CBD diameter) for patients solved eventually by surgery ($P < 0.001$). Only 3.2% of cases had to be referred to surgery. Stones removed using only a retrieval balloon (Group B) had a mean diameter of 7.6 mm with a mean CBD of 13 mm among patients solved endoscopically, significantly lower than those with residual lithiasis: 15.5 mm (mean stone diameter) with 16 mm (mean CBD diameter) ($P < 0.001$). 9% of cases were referred to surgery. The lithotripter alone (Group 3) was efficient for a mean stone diameter of 12.3 mm with a mean CBD diameter of 13.3 mm. By associating the basket with a retrieval balloon (Group 4) we obtained a 100% success rate of endoscopic removal for a mean stone diameter of 9.6 mm with a mean CBD diameter of 12.9 mm. We also analyzed the parameters in patients who underwent endoscopic extraction by using a retrieval balloon combined with balloon dilator (Group 5). The success rate in this group was 90% for a mean stone diameter of 14.8 mm with a mean CBD diameter of 12.4 mm. In Group 6 we included cases which required combined techniques ($> = 3$). We observed a mean stone diameter of 9.4 mm with a mean CBD diameter of 13.8 mm in patients solved endoscopically, compared to those referred to surgery who had a mean stone diameter of 14.2 mm with a mean CBD diameter of 14.3 mm ($P < 0.001$). In this group the success rate was 67.2%. Overall, we had a success rate of 91.3% for endoscopic removal of choledocholithiasis with a mean stone diameter of 7.1 mm and a mean CBD diameter of 12.1 mm, compared to 3.8% of cases referred to surgery with a mean stone diameter of 13.6 mm and a mean CBD diameter of 14.3 mm ($P < 0.001$).

Conclusion: The most successful endoscopic method to remove large stones ≥ 15 mm was balloon dilator combined with retrieval balloon. Intermediate stones 7–15 mm can be successfully removed by using retrieval balloon or lithotripter or a combination of basket with retrieval balloon \pm balloon dilator. Most CBD stones < 7 mm were successfully removed by using basket. In conclusion, any diameter > 7 mm will most probably require more elaborate techniques.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Diclofenac and indomethacin are the most studied drugs for preventing post-ERCP pancreatitis (PEP), but their use is controversial.

Aims & Methods: Our aim was to evaluate of all trials published in full text and studied efficacy of diclofenac or indomethacin prospective controlled with placebo or non-treatment for the prevention of PEP in adult patients undergoing ERCP. Systematic search of databases (PubMed, Scopus, Web of Science, Cochrane) for relevant studies published from inception to 30 June 2016.

Results: Our meta-analysis of 4741 patients from 17 trials showed that diclofenac or indomethacin significantly decreased the risk ratio (RR) of PEP to 0.60 (95% confidence interval/CI/0.46–0.78, $P = 0.0001$), number needed to treat (NNT) was 20, and the reduction of RR of moderate to severe PEP was 0.64 (95% CI 0.43–0.97, $P = 0.0339$). The efficacy of indomethacin compared to diclofenac was similar ($P = 0.98$). The efficacy of indomethacin or diclofenac did not differ according to timing ($P = 0.99$) nor between patients with average-risk and high-risk for PEP ($P = 0.6923$). The effect of non-rectal administration of indomethacin or diclofenac was not significant ($P = 0.1507$), but rectal route was very effective ($P = 0.0005$) with a NNT of 19. The administration of indomethacin or diclofenac was avoided in patients with renal failure. Substantial adverse events were not detected.

Conclusion: The use of rectally administered inexpensive and safe diclofenac or indomethacin before or closely after ERCP is recommended in every patient (without renal failure) undergoing ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1553 RECTAL DICLOFENAC AND PANCREATITIS AFTER ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY

L. Del Olmo Martínez¹, B. Velayos², M. Ruiz-Rebollo²

¹Gastroenterology, Hospital Clínico, Valladolid/Spain

²Hospital Clínico Universitario, Valladolid/Spain

Contact E-mail Address: ldelolmo@yahoo.es

Introduction: Rectal diclofenac or indomethacin reduces the risk of pancreatitis after endoscopic retrograde cholangiopancreatography (ERCP). Most studies of its efficacy included high-risk cohorts and excluded low-risk patients. We investigated the potential of rectal diclofenac to prevent post-ERCP pancreatitis (PEP) in a variety of patients.

Aims & Methods: A cohort of 1534 ERCPs performed at the Hospital Clínico of Valladolid between 2009 and July 2016 was collected. The median age of the patients was 75 years old (between 12 and 102 years). 54% were male and 45.9% female. There were 93 procedures in which cannulation of the desired pathway was not achieved but the papilla had been manipulated so they are patients who have been included in the study. After May 2012, with a few exceptions, patients received diclofenac before their procedure. 730 patients did not receive Diclofenac. PEP was defined by consensus criteria.

Data regarding the factors predisposing to the development of PEP have been collected both in relation to the technique itself and to patient-related factors. A comparative study has been made between both groups using Chi square.

Results: The two groups were similar in age, sex, suspicion of Oddi sphincter dysfunction, recurrent acute pancreatitis, chronic pancreatitis, cannulation time-10m, use of pre-cut, previous PEP, dilation without sphincterotomy. There were differences in the number of sphincterotomies in which it was greater in the Diclofenac group (p.004). There was also a greater number of Wirsung cannulations in the group treated with Diclofenac (p.004). There were a total of 47 PEP (3.1%), being 78.3% mild acute pancreatitis.

Taken as a whole the patients had no difference in the number of PEP between the two groups, since in those treated with Diclofenac there was 3.4% and in the non-treated patients 2.8%.

When taking only patients with de novo sphincterotomy, there was no difference between the number of PEP between the two groups being 4.4% in those treated with Diclofenac versus 4% in the untreated patients. In those patients who were cannulated Wirsung, an incidence of PEP of 8.2% was observed in the group without Diclofenac, compared with 6.6% in the treated group (p.006). There were no differences between those treated with Wirsung's prosthesis and those not treated in both groups. There was no PEP in patients treated with pancreatic prosthesis.

There was a higher incidence of PEP in women in both groups and a trend towards greater number of PEP among those treated with Diclofenac, although without statistical significance. There was also a greater number of PEP in patients under 40 years of age treated with Diclofenac compared to those not treated with 14.3% versus 7.1% (p.024).

No differences were found between the groups treated and not treated with Diclofenac when crossing with sphincter dysfunction of Oddi, previous PEP, number and sizes of choledocholithiasis and sizes with the appearance of PEP.

Conclusion: In this retrospective cohort study of patients undergoing ERCP that included low-risk patients, rectal diclofenac was not associated with a significant decrease in the absolute rate of pancreatitis. In our study, diclofenac decreases the impact of PEP in those patients who are cannulated the pancreas.

P1555 A PILOT STUDY OF PROBE-BASED CONFOCAL LASER ENDOMICROSCOPY FOR COMPUTER-AIDED DIAGNOSIS OF BILE DUCT CANCER BY USING THE DEEP LEARNING TECHNOLOGY

K. Furukawa¹, N. Yokoyama², H. Hashidate³

¹Dept. Of Gastroenterology, Niigata General Hospital Dept. of Gastroenterology, Niigata/Japan

²Niigata City General Hospital Dept. of Digestive Surgery, Niigata/Japan

³Pathology, Niigata City General Hospital, Niigata/Japan

Contact E-mail Address: furukawa@hosp.niigata.niigata.jp

Introduction: The confocal laser endomicroscope (CLE) is of two types, an endoscope-based CLE (eCLE), which is integrated in the tip of the endoscope, and a probe-based CLE (pCLE), which goes through the accessory channel of the endoscope. The biliary tract, which cannot be reached by using eCLE, is observable with pCLE by using cholangioscopy. pCLE has the advantage of obtaining a magnification image that is like taking a biopsy tissue specimen but noninvasively, without the interference of bleeding and mucus secretion. However, it is sometimes difficult because only few gastroenterologists can achieve the required level of conventional diagnostic accuracy.

Aims & Methods: We developed a computer-aided diagnosis (CAD) system based on pCLE imaging using deep learning technology. The purpose of this study was to determine the usefulness of this CAD system for the diagnosis of bile duct cancer. We prepared the classifier of the extracted features of the bile duct cancer pCLE images by using the deep learning framework presented by Kyocera communication system Co. Ltd. Japan. The pCLE images by Cellvisio (Mauna Kea Technologies, France) were obtained through the SpyGlass DS (Boston Scientific Corporation, USA). They were compared with the pathological examination results from the surgical specimen and biopsy using SpyBite (Boston Scientific Corporation, USA). Learning sets were constructed by using 49 images of normal area and 23 images of cancer lesion. The test sets of the pCLE images were constructed using 6 images of normal area and 14 images of cancer lesion, separately from the learning set.

Results: The accuracy, sensitivity for cancer diagnosis, specificity, negative-predictive value, positive-predictive value of our CAD system by test set were 69.8%, 50%, 100%, 53.8%, and 100%, respectively. The 7 false-negative diagnoses reduced the sensitivity and negative-predictive value. The images of 6 of the false-negative diagnoses, indicating a 1.0 probability, did not show signs of cancer at all. A constant diagnosis was possible while being extremely small learning sets. The specificity and positive-predictive value were good, and the pCLE image was thought to have a characteristic suitable for CAD by using deep learning technology. However, many false-negative diagnoses with a probability 1.0 may have occurred owing to deflection and the lack of learning sets. To improve precision, a teaching set of adequate quality and quantity is necessary.

Conclusion: Automated diagnosis of bile duct cancer can be achieved by using the deep learning technology of pCLE imaging. Our CAD system will be improved with the appropriate learning sets.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1556 COMPARISON OF EUS-GUIDED FINE NEEDLE BIOPSY TECHNIQUES FOR CORE TISSUE ACQUISITION AND DIAGNOSTIC PERFORMANCES IN PANCREATIC SOLID LESIONS

C. Cho¹, S.J. Yeo¹, A.N. Seo², H.I. Bae²

¹Internal Medicine, Kyungpook National University Medical Center, Daegu/Korea, Republic of

²Pathology, Kyungpook National University Medical Center, Daegu/Korea, Republic of

Contact E-mail Address: cmcho@knu.ac.kr

Introduction: The acquisition of core tissue in endoscopic ultrasound-guided tissue sampling (EUS-TS) is necessary for histologic diagnosis and immunohistochemical staining in the diagnosis of some solid mass lesions. Although recent studies revealed the superiority of core biopsy needle in the specimen adequacy, controversy still remains that which EUS-TS techniques would result in better acquisition of core tissue and diagnostic accuracy.

Aims & Methods: The aim of our study was to evaluate EUS-TS techniques with a ProCore needle using suction and slow pull suction for solid pancreatic lesions without an on-site cytopathologist. Patients who referred to EUS-TS for pancreatic mass lesion were enrolled. We performed EUS-guided fine needle biopsy (EUS-FNB) using a ProCore needle (Cook Medical, Limerick, Ireland) with two needle passes and applied each pass of different techniques (suction or slow pull suction) which were randomly allocated. EUS-TS specimens were evaluated by one experienced cytopathologist who was blinded to applied techniques. The acquisition of core tissue and diagnostic performances were compared between two techniques.

Results: From Aug. 2014 to Dec. 2016, 94 patients with pancreatic mass were enrolled and 12 patients were excluded due to no final diagnosis (n=5), cystic lesion (n=5) and loss of follow up after EUS-TS (n=2). Finally, 82 patients (48 males; median age, 63 years) with 164 needle passes were included without

technical failure and procedure-related adverse events. The median size of the lesion was 26 mm (range, 11 to 80 mm). There were 68 malignant and 14 benign lesions. Overall core tissue acquisition and diagnostic accuracy was 84.8% (139/164) and 73.2% (120/164), respectively. There was no significant difference between suction and slow pull suction in the acquisition of core tissue (85.4% vs. 84.1%, p=1.000) and diagnostic accuracy (72.0% vs. 74.4%, p=0.860).

Conclusion: Although our study revealed no differences between EUS-TS techniques in the core tissue acquisition and diagnostic accuracy for pancreatic solid lesions, further prospective study including variable lesions and sizes of needle is needed to validate for optimal application and sequences of EUS-FNB techniques.

Introduction: Gallbladder drainage, performed by EUS-guided positioning of specially designed fully covered metal stents, may be considered a valid option in patients with cholecystitis unfit for surgery. We describe the first case series of patients with diagnosis of acute cholecystitis treated conservatively using a silicone-covered nitinol stent with bilateral anchor flanges (NAGI-stent).

Aims & Methods: Our aim was to evaluate the feasibility and clinical impact of EUS-guided drainage with NAGI-stent in patients with acute cholecystitis unfit for surgery. Sixteen consecutive patients (9 males; Mean age: 84 years) with diagnosis acute cholecystitis according to Tokyo guidelines criteria, not suitable for surgical approach, were conservatively treated and drained with EUS-guided short flared stents positioning. The procedure was performed in 2 tertiary endoscopic centers by 4 experienced endoscopists (>500 EUS/ERCP performed yearly), by using the NAGI-stent. Each attempt to access the gallbladder was firstly performed from the transduodenal position and resulted successful in 13 (81%) patients, whilst a transgastric approach was preferred in the remaining 3 patients. Two different approaches were performed for the EUS-guided gallbladder puncture: a) a 0.035-inch wire was advanced through a 19G-needle into the gallbladder and dilation of the access was achieved with a 10 Fr cystenterostome; b) a 0.035-inch wire was advanced through a 10 Fr cystenterostome directly used in order to achieve gallbladder access. At the end of the procedure, a fully covered metallic stent, 12–16 mm of diameter and 20–30 mm of length with bilateral anchor flanges (NAGI-stent) was advanced on the wire by using the fluoroscopy guide. Technical success, clinical success, adverse events, and long-term outcome were assessed.

Results: Technical success was achieved in all cases, clinical success was observed in 15 (94%) patients, whilst in 1 case the procedure failed due to stones impaction into the stent but it resolved with a new stent positioning. Symptoms relief occurred in all patients, 1 day after the procedure in 12 (75%) cases and 2 days later in remaining 4 (25%) patients. A bleeding episode occurred in 2 (12.5%) patients, in one case such complication was intra-procedural and it was successfully stopped during the same endoscopic session, in the other case it was a delayed adverse events requiring arterial embolization but the patient died 10 days later. At follow-up, two patients died due to myocardial infarction at 2 and 6 months, one for acute renal failure after 6 months, two for pancreatic cancer after 7 months and one for cholangiocarcinoma after 5 months. In the remaining patients no cholecystitis recurrence or biliary obstruction were observed at median follow-up of 112 days (range 49–180 days).

Conclusion: Our data showed that EUS-guided gallbladder drainage with NAGI-stent is feasible and successful in patients with acute cholecystitis unfit for surgery. Since this type of stent is cheaper compared to others, the use of such device may result more attractive as a further endoscopic option for these selected patients.

Introduction: Endoscopic ultrasound guided-fine needle aspiration (EUS-FNA) is considered the gold standard method for assessment solid pancreatic masses. The needles for aspiration currently available are 19G, 22G and 25G and there is no concrete evidence to prove the benefit of one against another.

Aims & Methods: We aimed to compare the efficiency in the diagnosis of solid pancreatic lesions through the EUS-FNA with 25G and 22G needles. Studies were analyzed from five databases (Medline, Scopus, Cochrane, LILACS and CINAHL), without year or language restriction, using an extensive search strategy. Only randomized trials comparing 22G and 25G needles were included. Two independent reviewers went through the literature search and the results were analyzed by fixed and random effects. The diagnostic characteristics were calculated for a 95% confidence interval.

Results: 504 studies were found in the search, of which 21 were read and then finally 04 randomized studies were selected to be included in the analysis. Thus, a total of 462 patients were evaluated (233: 25G needle/229: 22G needle). The sensitivity of the 25G needle was 93% (CI, 89–96%; I2 0.0%), and for the 22G needle was 91% (CI, 85–94%; I2 19.9%). The specificity of the 25G needle was 87% (CI, 73–96%; I2 41.1%), and for the 22G needle was 83% (CI, 70–93%; I2 81.1%). The positive likelihood ratio of the 25G needle was 4.57 (CI, 2.08–10.03, I2 0.0%), and for the 22G needle was 4.26 (CI, 0.43–41.88, I2 94.7%). The post-test probability of the 25G needle in the study population was 93.85% and for the 22G needle was 91.30%. The area under the sROC curve of the 25G needle was 0.9705 and for the 22G needle 0.9795, also showing no statistically significant correlation between them ($p=0.497$).

Conclusion: Based on randomized studies, this systematic review and meta-analysis did not demonstrate a significant statistical difference between the 22G and 25G needles used during EUS-FNA in the diagnosis of solid pancreatic lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: EUS-guided gallbladder drainage (EGBD) is gaining popularity as an alternative method for drainage of the gallbladder in patients suffering from acute cholecystitis that are at high-risk for cholecystectomy. However, the long-term outcomes and the learning curves of the procedure is uncertain.

Aims & Methods: This was a retrospective review of all patients that received EGBD in the Prince of Wales Hospital between June 2012 to March 2017. All procedures were performed or supervised by a single operator. EGBD was performed in patients that are at high-risk for cholecystectomy and suffering from acute cholecystitis or on long-term cholecystostomy tube drainage. Outcome parameters included demographics, technical and clinical success, procedural characteristics, adverse events and follow-up duration.

Results: 50 patients were recruited during the study period. The mean (S.D.) age was 82.34 (9.3) years old and 22 patients were male. 42 patients were American Society of Anesthesiologist grading of ≥ 3 and the mean (S.D.) age-adjusted Charlson comorbidity index was 5.96 (1.82). The mean (S.D.) size of the gallbladder was 9.94 (9.83) cm. The hospital stay was 6.78 (5.36) days and follow-up duration was 664.65 (541.58) days. The overall technical success and clinical success rates were 96% and 86% respectively. Clinical success was not achieved in 7 patients as they suffered from 30-day mortality. 6 were due to uncontrolled sepsis and multi-organ failure even after adequate gallbladder drainage. 1 patient had aspiration pneumonia resulting in death. 15 patients (30%) suffered from 30-day adverse events with 6 of these being attributable to the procedure. Maldeployment of the stent occurred in 6 patients and this was managed by placement of an additional metallic stent to bridge the gallbladder to the gastric or duodenal lumen. Recurrent cholecystitis occurred in 1 patient (2%) during follow-up.

When comparing the first 25 procedures to the subsequent 25 procedures, significant differences were observed in the procedural time [29.21 (10.65) vs 15.6 (1.66) minutes, $P < 0.001$], the need of an additional stent [24% vs 0%, $P = 0.022$] and hospital stay [7.76 (5.13) vs 5.75 (5.50) days, $P = 0.009$]. Whilst no differences were observed in the technical and clinical success rates and adverse events.

Conclusion: EGBD is a safe and effective method for achieving gallbladder drainage in patients that are at high-risk for cholecystectomy. Performance of 25 procedures are required to gain competency in the procedure.

Introduction: Despite advances in radiotherapy for pancreatic cancer, local gastrointestinal (GI) toxicity still remains one of the major limitations to effective dose delivery and further dose escalation due to the close proximity of the GI wall to the pancreas, particularly in the head region. One potential method to reduce local GI toxicity would be to increase the physical distance between the head of the pancreas and the duodenal wall. A novel, injectable hydrogel, synthesized as iodinated polyethylene glycol microparticles, has been FDA-approved for use as a soft tissue fiducial marker. The hydrogel remains stable for 3 months and is absorbed by 7 months. To date, there has been no reports on the technical feasibility of endoscopic ultrasound (EUS)-guided hydrogel injection into the interface between the head of the pancreas and the duodenal wall to increase the peri-pancreatic space for the course of radiotherapy.

Aims & Methods: We aimed to evaluate the technical feasibility of EUS-guided hydrogel injection into the interface between the head of the pancreas and the duodenal wall in a cadaveric model. Baseline CT was performed on three unfixed cadaveric specimens. Using a linear EUS scope, the interface between the duodenal wall and the head of the pancreas was identified in a cadaveric model. A 19-gauge FNA needle was used to inject the hydrogel into the peri-pancreatic space with creation of a visible separation between the duodenal wall and the pancreatic parenchyma. The procedure was repeated along the length of the head and uncinate of the pancreas. CT was performed post procedure to confirm location and to measure the distance created between the duodenum and pancreas. Gross dissection of the pancreas and duodenum was performed to evaluate localization of the hydrogel.

Results: All three cadavers underwent successful EUS-guided injection of the hydrogel. Cadaver 1 received a total injection volume of 9.5cc with creation of peri-pancreatic space along the head of the pancreas measuring 11.77 mm in maximal diameter. Cadaver 2 received a total injection volume of 27cc with creation of peri-pancreatic space along the head and uncinate of the pancreas measuring 13.20 mm in maximal diameter. Cadaver 3 received a total injection volume of 10cc with creation of peri-pancreatic space along the head of the pancreas measuring 12.89 mm in maximal diameter. The hydrogel was clearly visualized during EUS with hyperechoic echogenicity and on post-procedure CT images without any artifacts in all cases.

Conclusion: EUS-guided delivery of hydrogel is feasible and results in an increase in the peri-pancreatic space in a cadaveric model. The hydrogel is clearly visualized on EUS and CT without significant artifacts. Further studies are warranted to evaluate feasibility, effectiveness and safety in a clinical model.

Contact E-mail Address: rossi.gemma@hsr.it

Introduction: There are few published studies about the use of a novel radiofrequency (RF) system (EUSRA RF needle; VIVA RF generator; STARmed Co. Ltd; Koyang, Korea), with poor standardization of the procedure in terms of ablation powers and ablation times, resulting in great heterogeneity of the results.

Aims & Methods: To standardize the radiofrequency ablation (RFA) procedure using this new system performing ex-vivo tests on porcine liver in order to find the best ablation power and ablation time to produce the maximum size of coagulative necrosis at histological examination. The system consists in a radiofrequency generator delivering electric energy, a 19 Gauge needle (150 cm in length with a 10 mm monopolar electrode), a peristaltic pump (to perfuse the needle with chilled saline solution, maximizing the ablation volume without tissue charring), an isolating plate and a pedal to deliver RFA. Liver samples were treated at different powers: 10, 20, 30 and 40 Watts (W); each ablation power was applied for a duration of 1, 3, 5, 7 and 15 minutes, according to Fibonacci escalation dose scheme, used in phase I studies. We registered macroscopically: the size (millimeters) of the global treated area and the size of the central necrotic core. Microscopically an expert pathologist, blinded about ablation powers and times applied, gave the report of the histological examination (millimeters of coagulative necrosis and surrounded zone).

Results: The lower ablation power (10 W) produced the maximum macroscopic ablated area. RF ablation time at 10 W showed a good linear correlation with both the sizes of total macroscopic ablated area ($R=0.92$) and central macroscopic ablated area ($R=0.89$). Histologically the pathologist described two different injured zones by thermal effect: a central small and well-demarcated coagulative necrotic area around the needle insertion point (A zone) with a maximum diameter of 4 millimeters and a surrounded larger area of "diaphanization" (B zone), showing mild signs of cellular alterations (cytoplasmic hypochromia) without cellular necrosis. A zone sizes didn't change among different ablation times (mean size: 3.25 mm) while B zone diameter increased with the increase RF application at the fixed power of 10 W. At the microscopic analysis the pathologist didn't see any difference in size of coagulative necrosis among the different ablation powers ($R=0.24$).

Conclusion: RFA with this new system is feasible and effective to produce very small areas of coagulative necrosis (millimeters) well-demarcated in respect to the surrounding parenchyma and could be useful, in the future, to treat, with multiple passes and higher precision, target lesions with a flexible needle. Moreover, the system can produce larger zones of mild cellular alterations at lower ablation powers (10 W), increasing with the increase of ablation times, but it needs future in-vivo animal studies in order to assess the evolution of these zones (evolving into fibrosis? necrosis? recovering?).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1565 THROMBOEMBOLIC DISEASE DIAGNOSED BY ENDOSCOPIC ULTRASOUND IN PANCREATIC CANCER: A CASE SERIES

C. Atalaia Martins¹, P. Pinto-Marques¹, I. Mocanu¹, J. Cortez-Pinto¹, D. Serra²
¹Gastroenterology, Hospital Garcia de Orta, Almada/Portugal
²Gastroenterology, Hospital da Luz, Lisboa/Portugal

Contact E-mail Address: catarinatalaiamartins@gmail.com

Introduction: Malignant associated thromboembolic disease (TED) has a complex multifactorial pathogenesis. Tumor cells activate platelets and express procoagulant factors including tissue factor and thrombin; in addition, normal host tissues may express procoagulant activity in response to the tumor. Thrombotic risk varies substantially according to cancer location and pancreatic cancer is one of the leading causes. The clinical spectrum includes migratory superficial thrombophlebitis, arterial thrombosis, deep venous thrombosis, portal vein thrombosis and disseminated intravascular coagulation. We ought to assess the role of endoscopic ultrasound (EUS) diagnosing TED in pancreatic cancer patients.

Aims & Methods: We perform a retrospective review of all EUS cases for pancreatic cancer in two centers and assess all TED events diagnosed.

Results: In a period of 6 months, a total of 55 EUS for pancreatic neoplasms were performed in two centers. TED was present in 5 patients (9%): 3 were male and the mean age was 70 (range, 46–81). In 1 patient the EUS indication was a large abdominal mass whose origin was not clear, in the remaining 4 the indication was

the pancreatic neoplasm. In all of them was performed EUS with fine-needle aspiration. EUS identified 4 arterial pulmonary embolism (PE) and 1 inferior vena caval thrombosis (IVCT) with right atrial extension: 2 (3,6%) had recently been diagnosed by computed tomography (CT) but 3 (5,4%) were not previously known. In all these, CT confirmed diagnosis.

Table 1: Demographic, clinical and ultrasonographic characteristics of the patients.

	Gender (F/M)	Neoplasm Age location	Cytology results	Thromboembolic disease	Thromboembolic disease previously known? (Yes/No)	CT confirmation? (Yes/No)
Case 1 F	81	Isthmus	Leiomyosarcoma EP metastasis		Yes	Yes
Case 2 M	70	Tail	Adenocarcinoma EP		No	Yes
Case 3 M	81	Head	Not available yet EP		No	Yes
Case 4 F	46	Tale	Neuroendocrine tumor	IVCT	Yes	Yes
Case 5 M	72	Uncinate process	Adenocarcinoma EP		No	Yes

Conclusion: To the best of our knowledge, this is the first case series of EUS-based TED diagnosis in pancreatic cancer patients. This series underlines importance of a systematic, station approach EUS technique, namely in the mediastinum regardless the clinical indication. TED is a common complication of pancreatic cancer and has major therapeutic and prognostic implications.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Choledocholithiasis is the most common cause of biliary pain, leading to cholangitis and gallstone pancreatitis. Patients affected by choledocholithiasis presents an incidence of choledocholithiasis ranging from 8% to 20%. When the suspicion of choledocholithiasis is confirmed, stones should be removed by ERCP, but this operative measurement is associated with high rates of adverse events as post-ERCP pancreatitis, bleeding or perforation. A correct diagnosis of choledocholithiasis, before ERCP, is mandatory to decrease the operative risk and health care costs. Endoscopic ultrasound (EUS) has a high sensitivity and specificity in the diagnosis of CBD stones and could substitute other imaging modalities as CT-scan or MRCP, when indicated.

Aims & Methods: The aim of our study was to assess the role of early EUS (<48 hours), in patients undergone US in emergency room for suspected biliary colic. We retrospectively evaluated all the patients arrived at first aid for suspected biliary colic (i.e. right upper quadrant pain and/or epigastric region, associated with an elevation in serum ALT, AST, GGT, ALP, or total bilirubin, but in absence of amylase or lipase elevation). All patients, irrespective of the finding at the US, performed an EUS within 48 hours since admission. Data are presented as proportions with 95%CI and mean \pm standard deviation (SD). Correlation between categorical variables was evaluated by computing the "phi" coefficient. We computed the number needed to misdiagnose, i.e. the number of patients who need to be tested in order for one to be misdiagnosed by the test, as 1/(1-diagnostic accuracy). All the analyses were run with R statistical software.

Results: Overall, from January 2016 to December 2016, 88 patients (56% female; mean age 64 ± 17 years) were admitted to our hospital for suspected biliary colic. All of these subjects underwent abdominal ultrasound (US) at admission, which identified gallstones in 47 patients (71%); further, US documented common bile duct (CBD) stones in 58 (65%) patients, CBD sludge in 4 (5%) subjects, whereas no choledocholithiasis was found in 26 (30%) patients. At EUS examination CBD stones were found in 70 (80%) patients. Comparing US to EUS, US gave false negative results in 16 (18%) cases and false positive findings (i.e. identifying CBD stones not documented by EUS) in 8 (9%) patients. The two diagnostic procedures showed little correlation ($\phi=0.289$). The number of

patients needed to be tested by US in order to provide an incorrect diagnosis was 3.7 (95%CI: 2.6–5.5).

Conclusion: US performed in the emergency room has a low diagnostic performance compared to EUS, but remains a first-step-approach in patients with right upper quadrant pain and/or in epigastric region, associated with an elevation in liver enzyme. Based on the results of our study, EUS performed within 48 hours from the admission allows an immediate correct endoscopic treatment with significant spare of unnecessary operative procedures, reducing possible related complications and costs.

P1567 BILIOPANCREATIC RADIOFREQUENCY ABLATION: COMPARISON OF THE THREE CURRENTLY AVAILABLE DEVICES IN A PIG MODEL

M. Barret¹, S. Leblanc¹, B. Bordačahar¹, A. Rouquette², S. Chaussade¹, F. Prat¹

¹Gastroenterology, Cochin Hospital, Paris/France

²Pathology, Cochin Hospital, Paris/France

Contact E-mail Address: maximilien.barret@aphp.fr

Introduction: Three devices are currently available to perform radiofrequency ablation (RFA) of biliopancreatic lesions. Data from animal models are scarce. **Aims & Methods:** Radiofrequency ablation was performed in four live pigs on the common bile duct and the liver parenchyma using an endobiliary probe (endoHBP), on the liver and pancreatic parenchyma using an RFA catheter through an echoendoscope and biopsy needle (EUS RFA) and using a needle-shaped RFA catheter (EUSRA) through an echoendoscope. Radiofrequency ablation time and power were allowed to vary. The animals were sacrificed 2 hours after the procedure. Histopathological assessment of the maximal depth of thermal lesions was performed on three representative slides for each RFA impact.

Results: In the common bile duct, the depth of ablation ranged from 215 ± 47 (Power = 8 W, Time = 90 s) to 330 ± 43 µm (Power = 10 W, Time = 30 s), suggesting that power is the most important parameter in this location. Conversely, depth of ablation in the liver parenchyma using the endoHBP probe ranged from 947 ± 237 µm (Power = 10 W, Time = 30 s) to 1960 ± 20 µm (Power = 10 W, Time = 180 s), suggesting that time is the most important parameter for RFA in the liver. The EUS RFA probe in the liver parenchyma showed a tissue necrosis increasing with the power setting used, ranging from 1903 ± 451 µm (Power = 8 W, Time = 120 s) to 2457 ± 1047 µm (Power = 12 W, Time = 120 s). This was not observed in the pancreatic parenchyma, where tissue damage ranged from 3108 ± 373 (Power = 8, Time = 120 s) to 2305 ± 78 µm (Power = 12, time = 120 s). The EUSRA ablation of the liver parenchyma resulted in tissue damage from 1573 ± 245 µm (Power = 30 W, Time = 11 s) to 1545 ± 120 µm (Power = 70 W, Time = 9 s). In the pancreas, ablation depth ranged from 3616 ± 475 µm (Power = 30 s, Time = 15 s) to 3805 ± 446 µm (Power = 70 W, Time = 11 s).

Conclusion: Power and time of ablation have different effects on the extent of tissue necrosis in the common bile duct, the hepatic and pancreatic parenchyma, depending on the type of catheter used to perform RFA. As indications for hepatobiliopancreatic RFA tend to expand, specific ablation protocols should be developed for each tumor location and device.

Introduction: Endoscopic ultrasound (EUS)-guided rendezvous techniques facilitate common bile duct (CBD) access during subsequent endoscopic retrograde cholangiopancreatography (ERCP) in a single session. Cases of initial ERCP failure mainly comprise malignant biliary or ampullary infiltration and altered anatomy of the papilla, the former accounting for the majority of reports in the literature.

Aims & Methods: We aimed to evaluate the efficacy and safety of EUS-guided rendezvous in a series of distal CBD obstruction with failed initial ERCP, due to inaccessible intra-diverticular papilla. Consecutive patients with distal CBD obstruction, in whom selective biliary cannulation at ERCP was unsuccessful due to large duodenal diverticula, underwent EUS-guided rendezvous. CBD puncture was performed via the transduodenal approach and the guide wire was advanced antegradely across the papilla. The echoendoscope was then exchanged for a duodenoscope and a sphincterotome was inserted through the papilla alongside or over the wire, to allow further manipulations.

Results: In a total of 2480 ERCPs performed over a 4-year period, 18 cases were selected to undergo EUS-guided rendezvous due to the presence of a large ampullary diverticulum. Primary indication for ERCP was CBD stones in 15 patients, pancreatic head cancer in 2 patients and cholangiocarcinoma in 1 patient. Mean age of the patients was 77 years (range 62–91) and mean diameter of the CBD was 16 mm (range 8–21). Successful CBD puncture with antegrade passing of the wire into the duodenum and subsequent ERCP, in the same session, was achieved in 2/3 (66.6%) cases of malignant obstruction and in 13/15 (86.6%) cases of

lithiasis. Retrograde biliary cannulation during ERCP was performed over the wire in 6 cases and alongside the wire in 12. The mean procedural time was 80 minutes (range 55–115). A case of inadvertent CBD wall penetration by the sphincterotome, with contrast extravasation, occurred during an over-the-wire cannulation. No major complications, i.e. perforation (extra-luminal air or bile leakage), bleeding and pancreatitis occurred. Three cases of amylaseemia and transient fever were noted.

Conclusion: EUS-guided rendezvous is an effective salvage technique for failed CBD cannulation via standard ERCP, in cases of inaccessible papilla due to large ampullary diverticula. Along the guide-wire biliary cannulation may prevent inadvertent CBD wall trauma, compared to the over-the-wire approach.

Introduction: The preoperative differentiation of the solid pancreatic neoplasms by endoscopic ultrasound fine needle aspiration (EUS-FNA) remains around 90% and different needles or techniques of sampling has been used for improving the results. Data about the progress in diagnosis when the contrast harmonic enhanced EUS-FNA (CH-EUS-FNA) is used are scarce.

Aims & Methods: We aimed to assess the role of contrast-enhanced EUS-FNA compared to standard EUS-FNA in diagnosing the solid pancreatic neoplasms.

Methods: Patients from one tertiary medical center with visible solid pancreatic mass on CT scan were included. EUS-FNA (one pass) and CH-EUS-FNA (one pass) were performed randomly in each patients by using a standard 22G needles, an Olympus-Aloka equipment and Sonovue as contrast agent. Core histology was assessed separately for each pass by the same pathologist blinded from the randomization process. The final diagnosis was based on the results of EUS-FNA and surgery, or the findings after 9 months' follow-up.

Results: The final diagnosis of 40 patients included was adenocarcinoma (n = 36), neuroendocrine tumors (n = 2), chronic pancreatitis (n = 2). The lesions were located in the head of the pancreas (60%), body (32%) and tail (8%). The diagnostic sensitivity and specificity based on core histology was 89% and 94% in the CH-EUS-FNA passes and 86% and 91% in the EUS-FNA passes and the diagnostic value was significantly better in the CH-EUS-FNA group (p = 0.0046, t-test). The visual core size was not significant for the true-positive diagnosis of malignancy.

Conclusion: In a randomized control trial, CH-EUS-FNA improved significantly the diagnosis of solid pancreatic neoplasms over standard EUS-FNA. These techniques are complementary, not competitive, and they can be performed in the same session, resulting the increasing of the diagnostic rate with a minimum of passes.

P1570 EARLY CAPSULE ENDOSCOPY PROVIDES BETTER BLEEDING LOCALIZATION VALUE IN PATIENTS PRESENTING WITH NON-HEMATHEMESIS GASTROINTESTINAL BLEEDING WHEN COMPARED TO CLINICAL SYMPTOMS ALONE

S. Jawaid¹, N. Marya², A. Foley¹, C. Marshall¹, K. Bhattacharya¹, D. Cave¹

Introduction: Traditionally, clinical symptoms such as melena were used as strong predictors for an upper GI bleeding source with primary evaluation with an EGD (esophagogastroduodenoscopy). Little consideration was given to the small bowel. It has been known for decades that melena can originate from the nose to the right colon and hematochezia can originate from the proximal gut to the rectum. Thus, current endoscopic approaches have limited localization value and diagnostic yields. We hypothesize capsule endoscopy (VCE) provides better localization of bleeding when compared to clinical symptoms alone.

Aims & Methods: In this study, we compare the efficacy of localizing the source of bleed in early VCE versus SOC (standard of care) tests chosen based on clinical symptoms alone. This was a prospective single center randomized trial of 73 consecutive patients presenting to the University of Massachusetts Medical Center with NHGIB (melena, hematochezia/anemia, or guaiac-positive stools/anemia). Exclusion criteria included presence of pacemaker, dementia, non-English speaking, hemodynamically significant bleeding. Patients were randomized to SOC arm versus early capsule (EC) deployment. The EC group received a primary diagnostic procedure based on clinical symptoms that was dictated by the gastroenterologist on service, who was at liberty to choose the procedure sequence as they felt appropriate.

Results: Of the 218 patients screened, 73 were included. 2 patients from the initial included group were excluded (one due to technical capsule failure and one was transferred from an outside hospital). Baseline characteristics were similar and depicted in Table 1. The EC group (n=34) had localization of presumed source of bleeding in 67.6% (n=23) of patients at the time of the first diagnostic procedure compared to 48.4% (n=16) in the SOC group (p=0.02). Active bleeding or stigmata of recent bleeding at the time of the first procedure was seen in 64.7% (n=22) of patients in the EC groups compared to only 30% (n=11) in the SOC group (p=0.003). However, when melena was the presenting symptom in the SOC (n=26) group, EGD was the most commonly chosen primary diagnostic procedure (n=23), but was only diagnostic 52% of the time. After complete diagnostic evaluation in the SOC group, patients presenting with melena had lesions located in the esophagus (3.8%), stomach/duodenum (46.2%), small bowel (11.5%), colon (11.5%), but 27% had no source identified. EC group had lesions localized to the esophagus (2.9%), stomach/duodenum (35.2%), small intestine (8.8%), colon (20.5%), and 32.3% did not have lesions identified. When hematochezia/anemia were the presenting symptom (n=7), EGD was never diagnostic as a primary procedure, colonoscopy (COLO) had a 50% diagnostic rate, and VCE was diagnostic 100% of the time.

Conclusion: VCE used as the first test in patients with NHGIB detects active bleeding significantly more often than the SOC approach, since it examines much more of the GI tract than EGD and COL alone. Detection of the anatomic site of bleeding allows for better therapeutic decisions.

Introduction: Data regarding mucosal healing (MH) of isolated small bowel Crohn's Disease (CD) induced by anti-tumor necrosis factor alpha agents are scarce.

Aims & Methods: 1) To evaluate MH rates by capsule endoscopy (CE) in patients with symptomatic CD and active isolated small bowel (SB) disease treated with adalimumab (ADA). 2) To correlate MH with clinical and biological indices of remission. This was a prospective observational, single center study. CD patients with isolated (per CE) active (CDAI > 220) SB disease, who were recommended ADA by their treating physician were consecutively recruited; first CE was performed prior to commencing ADA, and the second -14-week after starting ADA. All enrollees underwent a patency capsule study to confirm patency. Disease severity was assessed by the capsule endoscopy Crohn's Disease activity index (CECDAI) score. MH was defined as CECDAI score < 3.

Results: Out of 31 patients screened, 24 were eligible, and 22 completed the study (as two patients developed an allergic reaction to ADA and were withdrawn) Females: 12 (54.5%), median disease duration: 3 years (IQR 1-7), biologic experienced (Infliximab) -3 patients. After 14 weeks of ADA therapy MH was detected in 8/22 patients (36.4%), CDAI < 150 in 11/22 patients (50%), normalization of CRP in 7/22 patients (31.8%), and normalization of fecal calprotectin in 8/22 patients (36.4%). Inflammatory indices significantly decreased within 14 weeks of ADA treatment compared with baseline: median CECDAI 5 (1-16) vs 15 (10-20), p=0.001; median CDAI 150.8 (109.8-211.5) vs 256 (240.5-320.2), p<0.001; median CRP 0.14 (0.07-0.5) vs 1.1 (0.2-1.5) mg/dl, p=0.002; median fecal calprotectin- 83 (80-139) vs 128 (61.5-266.5), µg/gram, p=0.014. MH

detected by CE did not correlate with normalization of either CDAI < 150, CRP or fecal calprotectin levels.

Conclusion: ADA induced MH in 36% of CD patients with isolated active SB disease. MH did not correlate with either clinical or biological remission. Thus, further evaluation should be performed after 52 weeks of maintenance therapy.

Introduction: Capsule endoscopy (CE) is widely used to investigate the small bowel (SB). However, patients with inflammatory bowel disease (IBD) are considered to be at higher risk for capsule retention. The ESGE recommends using dedicated cross-sectional imaging to assess SB patency in patients with known Crohn's Disease (CD) prior to CE. Evidence suggests that a combination of SB magnetic resonance imaging (MRI), faecal calprotectin (FC) and CE together may be more effective in assessing SB inflammation compared to an individual modality alone. We aimed to assess the effectiveness of this approach.

Aims & Methods: Retrospective, multicentre study; consecutive patients who had undergone both SB MRI and CE within 6 months of each other were included. Data collected: patient demographics, indications for CE and MRI, CE and MRI findings, and FC levels closest to the time of CE. Continuous data is presented as means ± standard deviation; comparisons were made using T-test (p < 0.05 taken to be significant).

Results: 82 patients (28M/54F, Mean age 41.4yrs) underwent both CE and SB MRI at 4 centres in the United Kingdom, Israel and Portugal. Indications included suspected SB inflammation (n=61), IBD reassessment (n=21). Overall, there were 3 incomplete CEs, but no case of SB capsule retention. Of 82 SB MRIs, 4 patients had evidence of SB obstruction, 10 had SB thickening and/or inflammation, 3 had other findings (SB pneumatosis, polyps). 64/82 cases were normal and 1 study had poor contrast, precluding any conclusion. Of the 4 patients with SB MRI evidence of obstruction, only 1 had strictures seen on CE. The other 3 patients had insignificant or normal CE findings. Of the 10 patients with SB thickening and/or inflammation seen on MRI, 6 had corresponding CE findings; in particular, there were 2 cases with strictures on CE and 4 cases with mucosal inflammatory changes. 64 patients had normal SB MRI and 35 (54.7%) had a normal CE. 18/64 (28.1%) patients had mucosal inflammatory changes on CE; 2 of them had strictures which were eventually traversed by the capsule. 10 patients had other non-inflammatory findings on CE. Of 18 patients with normal SB MRI but SB inflammation on CE, 9 had a raised FC (FC > 150 µg/g), 5 had borderline FC levels (50-100 µg/g). None of the patients in this group had normal FC levels; the mean FC was 637.5 ± 844.4 µg/g. In the group of patients with both normal SB MRI and CE, 16/35 had raised FC; 7 patients had borderline FC levels. The overall mean FC for these patients was 266.3 ± 221.9 µg/g. The mean FC between patients with SB inflammation seen on CE and patients with normal SB MRI and CE was significantly different (p=0.04).

Conclusion: A significant proportion (28.1%) of patients with normal SB MRI to investigate possible SB inflammation had CE findings showing SB inflammation, including 2 patients with strictures. However, no retention occurred in this group. Raised FC was significantly associated with CE findings despite normal SB MRI.

Introduction: The interpretation of small bowel capsule endoscopy (SBCE) requires a high level of concentration. An abnormality may be present on just a few of the many thousands of images presented for interpretation. It is

unknown whether fatigue affects the accuracy of SBCE reporting and how many SBCE studies can be read in one session.

Aims & Methods: Thirty-two participants (16 experienced SBCE readers and 16 novices) were invited to participate in this study. Each participant was asked to read 6 pre-selected SBCE studies consecutively. These studies were presented in a random order. All readings took place using the single view mode, readers were able to choose the frames per second viewed from a range of speeds. Fatigue was measured subjectively using a Likert scale and objectively using a computer-based psychomotor vigilance test. These measures were performed at prior to commencing the study and after every second capsule read. Accuracy in lesion detection was determined by comparison with a gold standard reading derived from the non-consecutive readings of two expert capsule readers. Accuracy was plotted against the order in which SBCE studies were read. The aim of this study was to determine whether fatigue influences the accuracy of SBCE interpretation and how many cases can be read before accuracy declines.

Results: In keeping with existing literature, high intra-observer variability amongst the participants was observed, with experienced readers reaching kappa values of 0.51 with the gold standard and 0.08 amongst novices. As progressive SBCE studies were read the mean speed increased for both experts and novices, with a mean reduction of 10 minutes between the first and the last study read. This was associated with faster reading speeds selected in progressive studies read. Where accuracy was analyzed with respect to the reading speed chosen, a negative correlation between increasing speed and accuracy was demonstrated, with 31% of lesions detected when read at 6–10 frames per second, compared to 15% when using the 22–28 speed. There was no significant change in accuracy with progressive capsule read when the group was analyzed as a whole. The accuracy of experienced readers declined after just one study read, from 38% to 27% and plateaued thereafter. Novice readers demonstrated no significant change across the time points, with a trend towards improvement, perhaps indicating skills acquisition during the study.

Conclusion: The accuracy of SBCE reporting declines after one study reporting in a given period of time by expert SBCE readers. The optimal time interval between study reporting needs to be explored. This does not affect novice readers perhaps demonstrating skill acquisition.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1574 FEASIBILITY OF SAME-DAY COLON CAPSULE ENDOSCOPY (CCE) IN PATIENTS WITH INCOMPLETE COLONOSCOPY

M. Hussey¹, G. Holleran², C. Tersaruolo², D. McNamara¹

¹Gastroenterology, Tallaght Hospital, Dublin/Ireland

²Trinity Academic Gastroenterology Group, Trinity College, Dublin/Ireland

Contact E-mail Address: husseyma@tcd.ie

Introduction: Rates of incomplete colonoscopies (IC) range from 2–19%, requiring repeat procedures or radiological imaging which can often lead to diagnostic delays as well as increased inconvenience for the patient. Same-day CCE may offer a more convenient and cost-effective mode of colonic examination post IC.

Aims & Methods: We aimed to determine the feasibility of same-day CCE post incomplete colonoscopy. A prospective pilot study was performed. Any patient without a contraindication to CCE with an IC for reasons other than poor bowel prep was offered the test following an appropriate recovery time of 1-hour post IC. Informed consent was obtained from all subjects. Upon ingestion of the capsule, where feasible, 10 mg of IV metoclopramide was given to overcome the antimotility effects of fentanyl given during routine colonoscopy. Standard booster protocol for CCE was administered. Patient demographics, procedure indication, sedation levels along with key CCE data including preparation quality, completion, positivity rates and adverse events were all recorded.

Results: To date, 40 same-day CCE have been completed. The mean age was 57 yrs. (22–83 yrs.) and 65% (26) were female. Indications for OC were: altered bowel habit 33% (n=13), Iron deficiency anaemia 30% (n=12), Inflammatory Bowel Disease Assessment 15% (n=6), PR bleeding 5% (n=2), abdominal pain 5% (n=2), polyp surveillance 5% (n=2), positive family history of CRC 5% (n=2) and abnormal imaging 2% (n=1). OC were incomplete due to excessive looping 40% (n=16), patient intolerance 30% (n=12) and severe diverticular disease 30% (n=12). The mean sedation used during OC was 5 mg midazolam (range 3–10 mg) and 75 mcg of fentanyl (range 50–100 mcg). In all 84% (n=34) of CCE were complete, however full colonic views were obtained in 94% (n=37). Mean colonic passage time was 222 minutes and overall image quality was deemed to be excellent in 16% (n=6), good in 31% (n=12), adequate in 44% (n=18) and poor in 9% (n=4) of participants. Overall findings were normal 25% (n=10), polyps 38% (n=15), inflammation 22% (n=9), diverticular disease 25% (n=10), angiodysplasia 3% (n=1). Amongst the patients who had polyps, 8 required polypectomies and the remaining 7 were put on a surveillance programmes. Based on the CCE findings, 4 of the IBD patients required treatment escalation. In terms of adverse events one patient reported abdominal pain during the procedure and one patient retained the capsule due to an inflammatory stricture.

Conclusion: CCE would appear to be feasible in the majority of patients and significantly detects colonic pathology.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1575 DEDICATED DIFFUSION WEIGHTED MR IMAGING FOR STAGING PERITONEAL METASTASES IN COLORECTAL CANCER; AN ACCURATE PREOPERATIVE SELECTION TOOL FOR CYTOREDUCTION SURGERY (CRS/HIPEC) CANDIDATES

I. Jansen¹, D.M. Lambregts¹, S. Chandrasegaram-Shanmuganathan¹, N. Kok², G.L. Beets², R. G.h. Beets-Tan¹, A. Aalbers², M. Lahaye¹

Contact E-mail Address: M.Lahaye@nki.nl

Introduction: Peritoneal carcinomatosis (PC) is a well-known mechanism of spread of cancer; it is the second-most frequent cause of death in colorectal cancer patients. However, the prognosis of PC patients has dramatically improved in recent years. Nowadays, selected patients benefit from extensive cytoreductive surgery and hyperthermic intraperitoneal chemotherapy (CRS-HIPEC). 5-year survival rates of up to 50% are reported after CRS-HIPEC. Despite this survival gain, CRS-HIPEC has a considerable morbidity rate of 49% with a severe complication rate of 21%. Obviously, it is important for patients with a limited life expectancy to avoid pointless and costly aggressive surgical procedures. Hence, recognizing patients with a maximum risk-to-benefit ratio for the procedure is imperative. To select patients who could benefit from CRS-HIPEC the Peritoneal Cancer Index (PCI) is used. The PCI combines the location/size of peritoneal tumours found at surgery at 13 abdominal regions. Each of the 13 regions is scored for implant size on a scale of 0–3 (0 = no visible tumor implants; 1 = implants < 0.50 cm; 2 = 0.50–5.0 cm; 3 = > 5.0 cm). The PCI is the sum of the lesion scores from all 13 areas, and thus can vary between 0–39. The PCI is widely validated and is a quantitative prognostic indicator for long-term outcome. However, with this surgical staging procedure it is not always feasible to inspect all relevant intra-abdominal regions due to formation of adhesions and/or tumour. So, there is a desperate need for a non-invasive imaging tool that could select those patients who will benefit from CRS-HIPEC. However, currently there is no validated imaging tool that can accurately predict the PCI.

Aims & Methods: Therefore, the aim of this study was to estimate the PCI preoperatively with diffusion weighted MRI (DW-MRI) and compare this with the PCI found at surgery to assess whether DW-MRI can be used to select CRS/HIPEC candidates. In this ongoing study twenty-four consecutive patients (April 2016–April 2017) with histologically proven peritoneal carcinomatosis from colorectal origin were included. Patients were scheduled for exploratory laparoscopy and/or CRS/HIPEC and underwent preoperative dedicated DW-MRI (scantime = 30 min).

Two independent readers prospectively determined the PCI on DW-MRI. Patients were categorized as low-risk (PCI 0–21) versus high-risk (PCI 22–39); in our center considered operable versus non-operable. Reference standard was PCI found at surgery. Furthermore both readers evaluated whether a R1 resection could be achieved on a 5-point scale combining PCI and other risk factors for an incomplete surgery, like invasion in hepatic hilum, mesenteric vessels, extensive pelvic invasion of liver metastases. Sensitivity and specificity of the test were calculated and receiver-operating characteristic curves (ROC) were constructed. The area-under-the-curve (AUC) was calculated for each reader. Quadratic weighted kappa was used to evaluate the interobserver agreement.

Results: At surgery the mean PCI was 13.8 (range 0–34). For reader 1 the mean PCI was 13.4 (0–29) and for reader 11.9 (0–34). Both readers categorized 23 out of 24 patients correctly (accuracy 96%) when compared to surgical findings. Both readers understaged the same patient. The sensitivity and specificity for selecting patients with a PCI < 22 was for both readers 100% and 75%, respectively. The interobserver agreement was perfect (k = 1.0). The UAC for predicting overall operability was 0.99 for reader 1 and 0.95 for reader 2.

Conclusion: These data suggest that DW-MRI is a robust and highly accurate selection tool to noninvasively select colorectal cancer patients who could benefit from CRS/HIPEC. Interestingly, no overstaging occurred with DW-MRI; this means that DW-MRI did not deprive patients from potential curative surgery. In addition, due to the lack of large studies concerning this subject, our 'pilot study' is one of the largest DW-MRI study in PC literature.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: During colonoscopy, clinicians perform visual inspection of the polyps to predict histology. Kudo's pit pattern classification is one of the most commonly used for optical diagnosis. These surface patterns present a contrast with respect to their neighboring regions and they can be considered as bright regions in the image that can attract the attention of computational methods.

Aims & Methods: We aimed to assess the accuracy of a new computational system based on the segmentation and characterization of bright regions as

cues to obtain an automatic histological classification of colonic polyps. Our automatic histology prediction system is based on the segmentation of textural elements from polyp surface and their correlation with Kudo's pit pattern classification. Textural elements are identified as bright regions in polyp surface and there are characterized according to their shape into tubular and circular: a high presence of tubular patterns is associated to an adenomatous histology whereas the absence of prominent tubular structures is associated to non-adenomatous. Taking this into account, we characterized segmented bright regions using a tubularity metric (*Tub*) designed to obtain low values for circular shapes and high values for tubular regions of the same area. We tested our method in high definition (HD) white light polyp images which were obtained with a colonoscope Olympus CIF-H190 at Hospital Clinic in Barcelona. Neither conventional nor virtual chromoendoscopy were used. These images were selected to show as much variability in polyp appearance as possible. We used the mean of all *Tub* values for an image to classify it into two classes: Adenoma and Non-Adenoma. A ROC curve was constructed to select the optimal threshold value of *Tub*. Then, we compared the histology prediction provided by our system and the actual histology obtained after lesion removal.

Results: 51 polyp images were analyzed: 38 (74.5%) adenoma and 13 (25.5%) non-adenoma. Mean size of polyps was 14 ± 13 (range 1–40) and had the following morphology based on Paris classification: 5 (9.8%) 0-Ip, 27 (52.9%) 0-Is and 19 (37.3%) 0-IIa. Mean *Tub* values were different for adenoma compared to Non-adenoma (19.5 ± 6.5 vs 14.1 ± 6.3; $p=0.013$). An optimal threshold value of *Tub* = 13.14 to separate adenoma vs. non-adenoma was selected from the operating point of the ROC curve. With this value, our method was able to provide an accurate histological diagnosis in 44 out of 51 images (86%) (table) with a Sensitivity, Specificity, PPV and NPV for the diagnosis of adenoma of 95%, 61%, 88% and 80%, respectively. On the other hand, processing of a single HD image took 2.7 seconds making feasible its use in the endoscopy room.

		Histological Gold standard		
		Non-adenoma	Adenoma	total
Automatic prediction	Non-adenoma	8	2	10
	Adenoma	5	36	41
	total	13	38	51

Conclusion: A computer vision system based on bright regions in the image has a high accuracy for on-line prediction of polyp histology during colonoscopy. Though the use of shape characterization is promising, the inclusion of other polyp characteristics (i.e. shape, color, vessels...) as well as enlarging the validation database could improve the robustness of our methodology.

P1577 COLORECTAL LATERALLY SPREADING TUMORS DETECTED AT CT COLONOGRAPHY

M. Iwabuchi, M. Sugimura, S. Toda, K. Ukai
Gastroenterology, Sendai Medical Center, Sendai/Japan

Contact E-mail Address: s7856@snh.go.jp

Introduction: Laterally spreading tumors (LSTs) of the colorectum are classified into the following two subtypes according to their morphology; granular type (LST-G), and non-granular type (LST-NG). Meanwhile, CT colonography (CTC) is a relatively new radiological technique for imaging the entire colorectum and its sensitivity for detecting polyps more than 1 cm has been reported to be greater than 90%. However, the detectability of LST in CTC has not been fully delineated.

Aims & Methods: The aim of this study was to determine the detectability in CTC of LSTs focusing on their subtypes. We retrospectively reviewed and matched data on endoscopic and CTC reports in 33 patients (35 LSTs) who received a multidetector CT scan using contrast media immediately after total colonoscopy at the Sendai Medical Center, Japan, between May 2012 and December 2016. LSTs were classified into the following two categories: LST-Gs (24 lesions) and LST-NGs (11 lesions).

Results: 35 pathologically proven LSTs were evaluated. Histology included adenomas in 18, intramucosal cancers in 14, and submucosal cancer in 3. The mean diameter of the LSTs was 24.5 mm. Of the 35 LSTs detected on colonoscopy, 30 were observed and matched by CTC (85.7%). 23 out of 24 (95.8%) LST-Gs were detected, while 7 out of 11 (63.6%) LST-NGs were detected. The detectability of LST-Gs was significantly higher than that of LST-NGs ($p < 0.05$). The detectability of adenoma (77.8%; 14/18) was lower than that of intramucosal (92.9%; 13/14) and submucosal (100%; 3/3) cancer. Furthermore, the detectability of LSTs tended to increase with increasing tumor size.

Conclusion: CTC can effectively detect LST-Gs, while the detection of LST-NGs is still challenging.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1578 ANALYSIS OF CT COLONOGRAPHY MISS RATE OF LARGE NEOPLASTIC LESIONS DETERMINED BY COLONOSCOPY ON JAPANESE NATIONAL CT COLONOGRAPHY TRIAL (JANCT)

M. Hirayama¹, T. Takayama², R. Fujii¹, T. Minagawa¹, S. Ohiwa², K. Sakata¹, M. Yoshida¹, Y. Okagawa¹, H. Ihara¹, T. Sumiyoshi¹, Y. Tsuji², N. Yoshizaki¹, H. Kondo¹, K. Nagata³

Introduction: CT colonography (CTC) may be readily used for imaging of the colon in elderly or poor risk patients with colon polyps and cancer because of its non-invasiveness and relatively short inspection time. But, the drawbacks to make a misdiagnosis may be inevitable. Therefore, analysis of misdiagnosis case is crucial on the new modality for the colon cancer screening examination.

Aims & Methods: We evaluated the misdiagnosed case of large neoplastic lesions determined by colonoscopy (CS) from JANCT by CTC with radiologist and gastroenterologist interpretations¹. Out of 1257 cases enrolled in JANCT, 1181 cases were actually studied, omitting 76 cases according to the exclusion criteria. More than 16 DAS CT were used for CTC, respectively. Images were retrospectively reconstructed by using a 0.5mm section index. The CTC examination was prepared by PEG-C solution before scanning. CO₂ gas as an effervescent agent was then administrated just before scanning. This was used for the contrast medium. CTC images were analyzed by AZE Virtual Place software. The CTC and CS were independently analyzed by endoscopist and radiologist in blind fashion. We investigated misdiagnosed lesions with CTC more than 10 mm detected by CS. We considered the pseudo-negative lesions misdiagnosed with CTC interpretation (PNL) by radiologist or gastroenterologist and also considered the true pseudo-negative lesions misdiagnosed with CTC interpretation (true PNL) by radiologists and gastroenterologists. Because we conceived true PNL showed the limitation of CTC interpretation instead of PNL involved a human error.

Results: PNL was diagnosed by CS at 0-Ip (8 cases, 8 lesions), 0-Is (10 cases, 12 lesions) and 0-IIa (17cases, 19 lesions), respectively according to the criteria of the Paris classification. True PNL was also diagnosed at 0-Ip (1 case, 1 lesion), 0-Is (5 cases, 6 lesions) and 0-IIa (11 cases, 13 lesions), respectively. True PNL/PNL ratio was 0-Ip 12.5%, 0-IIa 50% and 0-IIa 68.5%, respectively. There was no PNL at 0-Ilc, Type I, II and III on this study. Most of all true PNL were so called flat lesion not only 0-IIa lesion.

Conclusion: CTC was proven to be a reasonably useful approach to obtain the image of colon diseases without any invasiveness to the patient. On CTC interpretation, lower protruded lesion was considered less detectivity than highly protruded lesion like 0-Ip.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The formation of fibrotic tissue in intestinal wall of Crohn's Disease (CD) patients is transmural and mucosal biopsies are unrepresentative of real intestinal damage. Magnetic Resonance Enterography (MRE) allows a transmural study of the bowel loops. Recently the percentage of gain of contrast medium has been proved useful to study fibrosis in CD patients. Diffusion Weighted Imaging (DWI) through the restriction of the apparent diffusion coefficient (ADC) allows an accurate evaluation of disease activity in CD patients avoiding contrast agents.

Aims & Methods: The aim of this study is to investigate if DWI sequence of MRE was able to identify intestinal fibrosis in CD patients candidate to surgery, using the histopathology specimens and percentage of gain as gold-standard. Thirty ileocolonic CD patients candidates to surgery for stricturing disease were consecutively enrolled from October 2010 to November 2015. All patients underwent MRE before the surgery. The histopathological examination was performed using an histological score for inflammation (AIS) and fibrosis in the stenotic segment and in the ileum before the stenosis.

Results: All population had an active disease at MRE. ADC value had a significant correlation with fibrosis score ($r = -0.648$; $p < 0.0001$), AIS ($r = -0.763$; $p < 0.0001$) and percentage of gain ($r = -0.687$; $p < 0.0001$). A strong correlation emerged between wall thickness and fibrosis score ($r = 0.671$; $p < 0.0001$). The

threshold of wall thickness for fibrosis was >6.3 mm (specificity 100% and sensitivity 69.23% with AUC 0.89). The cut-off of ADC value for fibrosis was $<1.1 \times 10^{-3} \text{ mm}^2 \times \text{s}^{-1}$ with a sensitivity of 71.79% and specificity of 94.44% (AUC = 0.83).

Conclusion: The DWI sequence with ADC value can identify fibrosis in intestinal wall of CD patients avoiding the use of contrast medium.

P1580 MOLECULAR IMAGING OF C-MET IN THE CLINICAL MANAGEMENT OF GASTROINTESTINAL CANCERS

N. McDonald, C. Portal, I. Wilson

Edinburgh Molecular Imaging, Edinburgh/United Kingdom

Contact E-mail Address: i.wilson@edinimage.com

Introduction: The primary indication for c-Met targeted optical imaging agent EMI-137 is enhanced endoscopic detection of lesions during colorectal cancer screening, including flat lesions that are difficult to detect by normal white light endoscopy. We have evaluated the potential benefit of EMI-137 and analogues beyond colorectal cancer screening since c-Met is up-regulated in many other cancers.

Aims & Methods: We have synthesised analogues of EMI-137 where the fluorescent reporter was replaced by a radionuclide chelating moiety for PET imaging. The use of this agent alongside EMI-137 could enable the PET localization of the lesions prior to surgery guided by fluorescent signals. Through a systematic analysis of scientific literature databases, and the Human Protein Atlas, we have identified more than 13 different types of solid cancer that are amenable to optical imaging for which there is evidence for c-Met as a target. We believe that imaging of c-Met with EMI-137 in these indications has the potential to positively impact critical problems in the existing patient care path and reduce morbidity, mortality, and healthcare costs. We have assessed: 1) the healthcare problem, the impact on patient care path, and the likelihood of adoption by clinicians 2) the hardware landscape; whether imaging hardware required is commercially available or is being developed, and feedback from clinicians in the US and EU 3) our confidence in c-Met as a valid imaging target to address the healthcare problem

Results: We have identified a number of promising applications within Digestive Oncology; gastric cancer, locally-advanced rectal cancer, and bile duct cancer surgery are all life-threatening indications with urgent healthcare problems that could be improved by utilising imaging of c-Met with EMI-137. Compatible imaging systems are commercially available for these indications. There is also strong evidence for c-Met as a biomarker in stratification in Barrett's oesophagus (BO), a potentially precancerous lesion with the risk of progression to oesophageal cancer. Progression rates are low and overall survival rates in BO patients are similar to the general population. However, due to the poor prognosis of oesophageal cancer, patients with BO lesions are managed by regular endoscopic surveillance and biopsy. This means that there is arguably a disproportionate healthcare burden relative to the level of risk.

Conclusion: Gastric cancer, locally advanced rectal cancer, and bile duct cancer surgery all have strong evidence for c-Met as a valid target, and the healthcare problems are clear and widely recognized, with EMI-137 having the potential to have high impact and improve curative procedures in serious, life-threatening conditions. An imaging agent that enabled more accurate risk stratification of BO patients would lead to a change in patient management, with the potential to remove unnecessary biopsy and to reduce the frequency of surveillance.

P1581 HOMEMADE FIXATION OF FULLY-COVERED SELF-EXPANDING METAL STENT

C.M.P.S. Pennacchi, E. H.G. Dominguez, E. Q. Mendonça, J. F.D. Oliveira, B. D.C. Martins, G. De Paulo, F. Kawaguti, C. C. Gusmon, U. Ribeiro Jr., R. A.A. Sallum, F. Maluf-Filho

Endoscopy, ICESP Sao Paulo Dept. of Endoscopy, Sao Paulo/Brazil

Contact E-mail Address: ktpennacchi@yahoo.com.br

Introduction: Esophageal self-expandable metal stents are currently used as an alternative for surgical treatment in esophageal neoplasia, benign strictures, fistulas and anastomotic leaks. Migration is a common complication after stent placement and have higher rates when fully covered stents are employed. Covered stents prevent tumor ingrowth and can be removed easily, they can be used in the closure of fistulas and leaks. External fixation of the stent with Shim's technique seems to be efficient in preventing stent migration, but has a high cost and is not always available. Fixation by clipping or sutures has similar limitations. We developed a homemade technique for external fixation of the stent using dental floss to prevent stent migration. We present the results of this technique in a small cohort.

Aims & Methods: The present study enrolled sixteen patients with esophageal malignancies, anastomotic leaks, esophageal fistulas and extrinsic compression. The stents used in these patients were five partially covered and ten fully covered. We developed a homemade technique using dental floss for external fixation of the stent which prevent stent migration. We pull stripes of dental floss into the stent mesh and using a method similar to exchange of a nasobiliary drainage catheter, the dental floss is drawn out through the nose, tied a knot into it and its loose end is fixed to the patient's earlobe.

Results: Upper gastrointestinal endoscopy was performed after two weeks and the proximal uncovered flange of the stent was evaluated. If it was embedded in the esophageal mucosa and did not separate from the esophagus with air insufflation, the external fixation was removed. Otherwise, the fixation was kept for another 2-4 weeks when a new endoscopic evaluation was performed. Patients were evaluated 15-30-60 days after stent placement. In cases of migration of the entire length of the stent into the stomach, the patient received a new stent and the same fixation method was employed. In cases of stents partially migrated through the cardia, the same stent was repositioned and fixed with dental floss stripes as previously described.

Conclusion: According to the results we believe this homemade technique using dental floss for external fixation of stents is a simple and cheap method that can be applied and used to prevent stent migration.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1582 CLINICAL OUTCOME WHEN USING SELF EXPANDING METAL STENT IN OBSTRUCTIVE COLORECTAL CANCER IN 248 PATIENTS; 7 YEARS EXPERIENCE FROM A TERTIARY CENTER

M. Shafazand, T. Radomski, L. Alkelin, N. Papachrysos

Gastroenterology, Sahlgrenska University Hospital, Gothenburg/Sweden

Contact E-mail Address: morteza.shafazand@vgregion.se

Introduction: The reported incidence of colorectal cancer in Sweden in 2014 was 60-65/100,000 inhabitants and caused 25-30 deaths/100,000¹. Of all colorectal cancer, approximately 15-20% debuts with acute obstructive symptoms. Conventional acute surgical procedures in these conditions (open surgery) have been shown to lead to mortality risk up to 20% and morbidity risk of 45-50%, followed by increased need for intensive care and more infections and stoma complications². Self-expanding Metal Stent (SEMS) for relieving malignant colon obstruction is a treatment option for non-curative cases or for bridging the patient for later surgery. Studies have shown "clinical success" of SEMS at 90%. An article from 2007 concludes that SEMS in acute colon obstruction has better results regarding sickness and side effects compared with acute open surgery³.

Aims & Methods: Our compilation covers the years 2010-16, when 248 SEMS interventions (53% men, 47% women, age 28-97) were performed at SU/Östra Hospital. In 78% of cases, the obstruction was located below the left flexure. In 80%, SEMS was made for palliative purposes.

Results: Technically, SEMS succeeded in 98% of cases and had clinical success in 90% of cases (absence in need of emergency surgery). Complications (colony perforation) occurred in 6% of the cases. Mortality within 30 days was 11% and within 90 days 22%. For all performed interventions, the difference with regard to 90-day mortality for the indication was palliative vs. bridging, 29 resp. 3%. Based on the clinical outcomes "success" vs "failure", the 90-day mortality rate was 19 resp. 55%.

Conclusion: Our interpretation is that SEMS is an effective method of acceptable safety regarding complications in acute malignant colon obstruction. The method is suitable for both intended intestinal relief for palliative purposes, as well as awaiting later curative measure (bridge to surgery).

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: bucur.denisaa@gmail.com

Introduction: Tracheoesophageal fistulas are severe complications which commonly occur secondary to malignant tumors of the esophagus. Other causes include mediastinal or respiratory tract tumors, surgery, radiotherapy and trauma. Without treatment they often lead to pulmonary and gastroenterological complications, such as pneumonia, acute respiratory distress syndrome and poor nutrition. The purpose of this study was to assess the efficacy of endoscopic treatment performed in our clinic for esophageal fistulas.

Aims & Methods: We performed a retrospective study on 43 patients admitted in our clinic between January 2015 and April 2017 for esophageal fistulas.

Results: The average age of the patients included in the study was 54 years old. The causes leading to the tracheoesophageal fistulas were the following: esophageal malignancy in 18 cases (41.8%), surgery in 8 cases (18.6%), respiratory tract malignancy in 6 cases (14%), gastric sleeve in 5 cases (14%), radiotherapy in 3 cases (7%) and trauma in 2 cases (4.6%). In every case, the treatment of choice was placement of fully-covered metallic stents. A number of 16 patients needed reintervention, with a mean of 2 reinterventions per patient. Regarding recurrent fistulas, endoclips were used in one case (2.3%), additional stenting in 11 cases

(25.5%) and repositioning of the stent in 4 cases (9.3%). All cases resulted in fistula closure without additional surgical intervention.

Conclusion: Fully covered metallic stents offered effective treatment for esophageal fistulas, regardless of the cause. Recurrent fistulas were successfully treated by additional stents and in rare cases endoclips.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1584 LONG-TERM OUTCOME OF ENDOSCOPIC TREATMENT OF SYMPTOMATIC ENTERIC STRICTURES IN CROHN'S DISEASE

E. Aichinger, M. Koch, K. Rothfuss, C. Schäfer, K. Grün, M. Schneider, J. Peveling-Oberhag, N. Lubomierski, J. Albert

Department Of Gastroenterology, Hepatology And Endocrinology, Robert Bosch Hospital, Stuttgart/Germany

Contact E-mail Address: e.aichinger@alumni.pmu.ac.at

Introduction: Endoscopic treatment of enteric strictures in patients with Crohn's disease (CD) is well established; however, long-term outcome is unknown.

Aims & Methods: All patients with CD, who had undergone endoscopic therapy of symptomatic strictures at Robert-Bosch-Hospital Stuttgart from 2008–2017, were included in this retrospective cohort study. A follow-up was available for 131/135 (97%) patients with a mean of 30.1 months (SD: 0 to 103).

Results: A total of 452 endoscopic interventions (mean 3.4 per patient, median 2 per patient, range 1–69 treatments) were performed in 135 patients (female n=67/male n=68, mean age 47.5 years, BMI: $22.8 \pm 4.98 \text{ kg/m}^2$, duration of illness: median 25.1 months). In 165 cases, the dominant stricture was located in the ileocecum, in 105 in the colon, esophagus (90), duodenum (54), upper intestine (26), lower intestine (11) or stomach (1). In 166 and 286 cases, there was an anastomotic and non-anastomotic stricture present, respectively. Treatment consisted of hydrostatic balloon dilatation (n=447); bougienage (4), and cSEMS (1). Dilatation was performed to a mean of 14 mm (SD: 2.4, range 7 to 24 mm). In seven cases complications occurred after endoscopic treatment (bleeding: n=5; infection: n=1; perforation: n=1) which resulted in an extension of the hospital stay (n=5), antibiotic therapy (1) and surgery (1). Immediate clinical success was observed in 438 of 452 of cases (96.9%). A single intervention was performed in 61/135 patients (45.2%), two interventions in 36 (26.7%), and three or more in 38 (28.1%). In 41 of 135 patients (30.4%), surgical treatment of the stricture was required in the course of disease.

Conclusion: Endoscopic treatment of symptomatic stricture in CD is safe and effective. Repetitive dilatation is feasible with a significant reduction of clinical symptoms, and surgery was required in about 30% of patients at long-term follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1585 ENDOSCOPIC INTRALESIONAL STEROID INJECTION IS EFFECTIVE IN THE TREATMENT OF BENIGN REFRACTORY OESOPHAGEAL STRICTURE, A META-ANALYSIS

L. Szapáry¹, N. Farkas², K. Márta¹, P. Hegyi¹, B. Eross¹

¹Centre For Translational Medicine, University of Pécs Faculty of Medicine, Pécs/Hungary

²Institute Of Bioanalysis, University of Pécs, Pécs/Hungary

Contact E-mail Address: lacika.szapary0701@gmail.com

Introduction: Endoscopic dilation is an effective treatment in oesophageal strictures, but recurrences may require frequent and repeated dilations in the long term. Several trials have been conducted to determine the efficacy of intralesional steroid injection in the treatment of benign refractory oesophageal strictures, since the first pediatric case series was published in 1969. However, a meta-analysis has not been carried out yet.

Aims & Methods: The aim of the analysis is to summarise the results and establish evidence in support or against the complementary treatment.

A meta-analysis was performed using the preferred reporting items for systematic review and meta-analysis protocols (PRISMA-P). Two reviewers conducted a comprehensive search on databases from inception to February 2016, to identify trials, comparing the efficacy of dilatation to dilatation combined with intralesional steroid injection. A meta-analysis was conducted on the data using the random-effects method by DerSimonian and Laird, because of the high level of the heterogeneity.

Results: There were 45 articles found in Embase, 55 in PubMed, and 6 in the Cochrane database. Altogether 11 articles were suitable for analyses, after exclusion of duplicate articles, case reports, results from non-human and pediatric studies. These studies involved 373 patients in total. The periodic dilation index was comparable in 4 studies, where the pooled result showed, that it decreased in the intralesional steroid plus dilation group (standardized mean difference: -0.717 , 95% CI: -1.191 ; -0.242 , p-value: 0.003). The total number of repeat dilations was comparable in 5 studies, where the standardized mean difference was -0.465 as compared to the dilation alone group (95% CI: -0.777 ; -0.153 , p-value: 0.004). The dysphagia score was comparable in 5 studies, but in this case no significant difference could be observed between the two groups (standardized mean difference: 0.274, 95% CI: -1.822 ; 1.165, p-value: 0.510).

Conclusion: Our meta-analysis showed a significant improvement in the periodic dilation index and total number of repeated dilations in the patients treated by intralesional steroid injection as well. We recommend the use of intralesional steroid injection for benign refractory oesophageal strictures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1586 EFFICACY AND COMPLICATIONS IN PALLIATIVE OESOPHAGEAL STENTING, EXPERIENCES OF A TERTIARY REFERRAL CENTER IN THE UK

C. Clisby¹, C. Gordon², B. Eross²

¹Endoscopy, Royal Bournemouth Hospital, Bournemouth/United Kingdom

²Gastroenterology, Royal Bournemouth Hospital, Bournemouth/United Kingdom

Contact E-mail Address: c.clisby83@gmail.com

Introduction: Palliative stenting is now established as a major treatment for dysphagia resulting from incurable malignant stricture of the oesophagus. There are multiple possible complications after oesophageal stent insertion; most of these present with increasing dysphagia; however pain, bleeding, and reflux are also common. Although data on rates of various complications are available, there are no agreed standards to audit performance against, nor any requirement to do so. As this is a palliative procedure, success in symptom control is paramount; if this is not being achieved, then the appropriateness of the procedure must be questioned. As with any invasive procedure, complication rates are affected by multiple variables: technique, type of stent, length and site of stricture, operator experience, patient co-morbidities and performance status. As a result of these variables, stated complication rates also vary. Only one study reported a rate of dysphagia (29%); migration occurred in 5–15% of cases, tumour ingrowth/overgrowth 5–20%, and food bolus obstruction in 5–15%. Quoted median survival ranged from 61–104 days, with a 30-day mortality of 20–28%.

Aims & Methods: Our aim was to scrutinise the efficacy and the safety of our palliative oesophageal stenting work. A retrospective study of all patients undergoing oesophageal stent insertion at our unit, between 01.01.2012 and 01.04.2016 was undertaken, looking for evidence of complications, repeat interventions, and for survival statistics after stent insertion. Patients who had undergone stent insertion for reasons other than oesophageal malignancy were excluded.

Results: Between 01.01.2012 and 01.04.2016, 152 stents were inserted in 125 patients for dysphagia in palliative oesophageal cancer; 104 patients had stent inserted once, 16 patients had twice, 4 patients had 3 times and 1 patient had 4 stent insertions. 69.6% were male and the median age at death was 79 years (SD 10.94). The reported histology for the 125 patients revealed, 85 (68%) adenocarcinoma, 30 (24%) squamous cell carcinoma, 5 (4%) Lung cancer causing external compression of the oesophagus, 2 (1.6%) mesothelioma, 1 (0.8%) externally compressing spindle cell sarcoma, 1 (0.8%) metastatic adenocarcinoma from the colon, 1 (0.8%) externally compressing signet ring adenocarcinoma. Of these stent insertions 52 (34.2%) were documented to have on going or recurrent dysphagia after the procedure, of which the causes were: tumour over- or ingrowth in 9 (5.9%); stent migration in 15 (9.9%); distal obstruction due to gastric folds 2 (1.3%); dysfunction of the anti-reflux valve in 3 (2.0%); and food bolus obstruction in 7 cases (4.6%), stent occlusion of unspecified cause 2 (1.3%) and stent disintegration in 1 (0.7%) case. In 13 (8.6%) cases cause for dysphagia was not found or not investigated. 100 (65.8%) stent insertions resulted in complete resolution of the dysphagia. Repeat endoscopy was necessary in 34 (27.2%) patients, who had 98 repeat gastroscopies in total, to deal with minor complications of the stent insertion or to investigate dysphagia. In total there were 13 (8.7%) significant complications caused by the stent insertion of which 7 (4.6%) were bleeding, 2 (1.3%) were tracheo-oesophageal fistula formations, 1 (0.7%) was delayed perforation, 1 (0.7%) was a too short stent, 1 (0.7%) was a disintegrating stent and 1 (0.7%) was a compression of the bronchi. Median survival of the 125 patients after stent insertion was 96 days (SD 128) and 30-day mortality was 11.2% (14 patients). It is important to note that with retrospective data analysis, some data is not available, due to variations in recording at the time and a reliance on the patient to report symptoms to a clinician. Currently 2 patients are still alive.

Conclusion: Palliative stenting at this centre continues to be an effective treatment for patients with dysphagia from oesophageal cancer. On the whole, outcomes from stenting at this unit compare favourably with published data in terms of dysphagia, other complications, and mortality. Steps to improve post-procedure monitoring in the form of a "stent registry" with prospective collection of data by telephone or face-to-face follow-up could be useful in future service development.

P1587 LONG-TERM RESULTS: WHEN RE-STENOSIS COMES AFTER ESOPHAGEAL STENTING?

D. Gusev, S. Kashin, N. Akhapiin

Endoscopy, Yaroslavl Regional Cancer Hospital, Yaroslavl/Russian Federation

Contact E-mail Address: denis_gusev83@mail.ru

Introduction: Self-expanding metallic stents (SEMS) is a well-established form of palliative treatment for dysphagia in esophageal cancer. Progression of the tumor after stenting with re-stenosis is a serious problem in patients with better prognosis and longer survival.

Aims & Methods: The aim of this study was to assess the timing and probability of esophageal re-stenosis after stenting by tumor growth. We performed a retrospective analysis of patients with advanced esophageal cancer who was underwent stenting, as a palliative treatment, for the last 5 years in the Yaroslavl Regional Cancer Hospital. We installed partially covered SEMS of one design from one manufacturer. The length of stents was 80, 100, 120, 140 mm, diameter - 20 mm. Patients with follow-up of more than 60 days were included in this study.

Results: Of the 165 patients from the database, 97 patients were selected, whose follow-up period was more than 2 months. There was a predominantly of male patients (78.5%), mean age of 72 years. To each patient was inserted a same partially covered stent, which is 4 cm longer than a tumor stenosis. The stent was placed 2 cm distal and 2 cm proximal of the stenosis. Of 97 patients, 18 (18.5%) patients had tumor overgrowth with recurrence of dysphagia. Tumor overgrowth was verified as malignancy. Tumor localization before stenting: the upper and middle part of the esophagus - 6 patients, the lower part and the cardia - 12 patients. In 12 cases tumor growth spread out in the proximal direction, in 6 cases - in the distal. Interestingly, the distal tumor overgrowth after stenting was predominant (66.6%) in cases of localization in middle and upper part of the esophagus, while the proximal tumor spread (83.3%) was noted in cases of localization in the lower part of the esophagus or cardia. Period of re-stenosis was from 2 to 12 months, an average of 5.7 months. The period of re-stenosis in the upper and middle part of the esophagus is 4 months, while in cases of tumor localization in the lower part of the esophagus or cardia is 6.1 months. In almost cases palliation was successfully achieved with re-intervention. Five patients required several sessions of argon-plasma coagulation an average one time in 3-4 weeks.

Conclusion: The use of SEMS in patients with advanced esophageal cancer, with an expected long-term survival, is associated with an increased risk of re-stenosis by tumor overgrowth. Period of re-stenosis was an average of 5.7 months. The direction of spread tumor after stenting and the time of dysphagia recurrence could depend from localization of the tumor. This complication is not fatal and managed by endoscopic methods.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1588 SELF-EXPANDABLE METAL STENTS ARE A VALID OPTION IN PATIENTS WITH LONG-TERM SURVIVAL FROM ADVANCED ESOPHAGEAL CANCER

E. Rodrigues-Pinto¹, P. Pereira², T.H. Baron³, G. Macedo¹

Introduction: Self-expandable metal stents (SEMS) are often used for palliative treatment of dysphagia in patients with advanced esophageal cancer, with anticipated limited survival. However, due to previous reports of high adverse event (AE) rates when used long-term, concerns have been raised with the use of SEMS in patients with survival longer than 3 months.

Aims & Methods: We aimed to the role of esophageal SEMS in patients with advanced esophageal cancer and expected survival longer than 6 months. Technical success was defined as successful deployment of the stent in the correct position. Clinical success was defined as relief of dysphagia 1 week after placement.

This was a retrospective study of patients with clinical dysphagia and advanced esophageal cancer who underwent SEMS placement with a stent dwell time of greater than 6 months. In all patients the indication for stent placement was dysphagia due to esophageal malignancy.

Results: Forty-two patients were followed for 298 days (183-861 days). At the end of follow-up the mortality was 93%. The majority of lesions were located at the proximal/middle esophagus (55%), and were traversable using an ultrathin gastroscope in 79% of patients; in no patient could a standard upper endoscope pass. Twenty-nine patients (69%) underwent further therapy (chemotherapy and/or radiotherapy) with SEMS *in situ*; however, only 14 began therapy before development of an AE (4 patients underwent further therapy after AE). Clinical improvement occurred in all patients, however 59% of patients (n=25) experienced an AE (15 migrations, 8 overgrowth/ingrowths and 2 stent-induced fistulae). The median stent patency was 236 days (19-513). Two AEs occurred within 30 days of stenting, 7 occurred between 30-90 days, 7 occurred between 90-180 days, and 9 occurred after 180 days. Endoscopic management was attempted in every SEMS-related AE (20 patients required a second SEMS, 2 had successful SEMS repositioning and 1 was treated with argon plasma; 2 SEMS were removed without the need for further therapy), with a clinical success of 100%, however, in 7 patients the previously treated AE recurred (4 in/overgrowths and 3 migrations). Multivariate analysis showed that strictures traversable with an ultrathin gastroscope were associated with a higher risk of AEs (OR 11.7, 95% CI [1.2-114.6], p=0.035).

Conclusion: Long-term esophageal stenting in patients with advanced esophageal cancer is associated with a high prevalence of AEs without an impact on mortality, and most could be managed endoscopically. Strictures traversable only using an ultrathin gastroscope are a risk factor for AEs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The incidence of iatrogenic bile duct injury (BDI) remains high despite increased awareness of the problem with significant impact on patient's well-being and even survival despite seemingly adequate therapy. Over the past years, endoscopic and percutaneous biliary interventions became readily

available in many centers and have revolutionized the management of iatrogenic biliary or concomitant vascular injuries.

Aims & Methods: Evaluate the role of intervention radiology procedures to manage different post-cholecystectomy complications focusing on the novel techniques to improve the final outcome. From June 2014 to June 2016, 30 patients presenting with post cholecystectomy complications were referred to interventional radiology unit in our university hospital. They were 9 males and 21 females (age range: 18–66 years). Patients presented with biliary leaks (n=12), benign biliary strictures with intrahepatic biliary dilatations (n=21), postoperative hernia (n=2), bleeding related to hepatic artery pseudo-aneurysm (n=1). Different types of interventional procedures were performed, including: Percutaneous trans-hepatic drainage (PTD) (n=16), sequential dilatation of benign stricture with increasing catheter calibers over 6 months followed by manometric studies before catheter withdrawal (n=6), biliary stenting with plastic stent (n=2), Insertion of pigtail catheter (n=15), preoperative progressive pneumo-peritoneum for their adhesiolysis effect to manage post-operative huge incisional hernias before their surgical repair (n=1), and selective embolization of bleeding related hepatic artery pseudo-aneurysm (n=1) using tissue adhesive (n-Butyl 2 Cyanoacrylate).

Results: All percutaneous procedures were technically successful. No recorded early or late complications. After manometric studies, all managed cases with benign strictures did not show any clinical evidence of restenosis during 6 months follow-up. Overall, 14 out of 30 patients (46.7%) were only managed by different interventional radiology procedures. Second step surgical repair was needed for 13 patients (43.3%) and endoscopic managed for 3 patients (10%) with biliary leaks.

Conclusion: Minimally invasive interventions were valuable techniques in the management of different post-cholecystectomy complications. In fully equipped centers, expert multidisciplinary teams would achieve high cure rates for iatrogenic biliary injuries.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1590 WHAT IS THE ROLE OF ANGIOGRAPHY IN ACUTE COLONIC AND SMALL BOWEL BLEEDING?

R. Vale Rodrigues¹, P. Amaro¹, M. Ferreira¹, M. Barros¹, P. Donato¹, L. Tomé¹
¹Gastroenterology, Centro Hospitalar e Universitário de Coimbra, Coimbra/Portugal

Contact E-mail Address: rita.vale.rodrigues@gmail.com

Introduction: Angiography is a diagnostic and therapeutic modality that is widely available for upper gastrointestinal bleeding but is used less frequently when the source of bleeding is placed distally to the Treitz angle.

Aims & Methods: To assess the usefulness of angiography in the diagnosis of colonic and small bowel bleeding and to determine the efficacy and complications of therapeutic procedures. Retrospective study; we included all patients with colonic and small bowel bleeding that were submitted to arteriography with or without embolization, admitted to the gastroenterology department of a tertiary hospital between February 2006 and November 2016. Statistics: Chi-square/Fisher exact test, T-student.

Results: Sixty-six patients were evaluated, 63.6% male, mean age = 75 years (29–95). Angiography was done for: bleeding recurrence (36.2%), hemodynamic instability (33.3%), both (27.3%) or failure to endoscopic hemostasis (3%). The aetiology after angiographic study was: presumed diverticular (n=28), angiectasis (n=8), confirmed diverticular (n=6), tumoral (n=5), post-mucosectomy/polypectomy (n=4), unclarified (n=12), others (n=3: Dieulafoy, ileum ulcers, radiation proctitis). Angiography showed additional clinical information in 25.8% of patients (n=17). Twenty-three patients (34.8%) underwent arterial embolization, all with technical success, with bleeding recurrence in 3, of which only one was submitted to surgery; there were 2 cases of bowel ischemia. The reasons for deciding not to embolize were: absence of active bleeding (90.7%) and end-vessel bleeding (9.3%). There were no differences between the groups in demographic data, comorbidities, mortality, source of bleeding, haemoglobin at admission/discharge and creatinine (p > 0.05); Arterial embolization was more frequent if hemodynamic instability (p=0.029); The average time of hospitalization was lower in the group submitted to embolization (8.8 vs 11.5 days, p=0.014). Overall, 11 patients died, due to: re-bleeding/hypovolemic shock (n=5), exacerbation of comorbidities (n=3), hospital acquired infection (n=2) or post embolization complication (n=1).

Conclusion: Arteriography was a valid option for the diagnosis of colonic and small bowel bleeding; allowed therapeutic intervention in more than one third of patients, with 87% of clinical success and reduction of hospitalization time.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Surgery for radical treatment of oesophageal cancer carries significant inherent risk. Objectively Identifying patients that are high risk of complications is of importance. The aim of this study was to assess the prognostic value of physical fitness variables determined objectively by cardiopulmonary exercise testing (CPET) in patients undergoing potentially curative surgery for oesophageal cancer (OC) within an enhanced recovery programme.

Aims & Methods: Consecutive 180 OC patients (106 ACA, 11 SCC, 3HGD) underwent preoperative CPET with prospective recording of morbidity and survival. Non-parametric receiver operating characteristic (ROC) curves and logistic regression were used to assess the relationship between CPET variables and post-operative morbidity severity score (MSS).

Results: Of 180 patients, 120 were included for analysis (median age 65 yr., 100 male, 75 neoadjuvant therapy); 60 did not proceed to surgery and were excluded. Postoperative morbidity and mortality occurred in 83 (69%, CD ≥ 3 in 27, 22.5%) and 4 (3.3%) patients respectively. ROC curve analysis showed oxygen uptake (peak V02) gave an area under the ROC of 0.66 (95% CI 0.55 to 0.77, p=0.009) and optimum cut-off of 17.0 ml/kg/min (sensitivity 70%, specificity 53%). Anaerobic Threshold (AT) gave an area under the ROC of 0.62 (95% CI 0.51–0.74, p=0.048) and optimum cut-off of 10.5 ml/kg/min (sensitivity 60%, specificity 44%). Multivariable analysis revealed peak V02 to be the only independent factor to predict morbidity severity CD ≥ 3 (OR 0.85, 95% CI 0.75–0.97, p=0.018). Cumulative survival was associated with operative MSS (Chi² 4.892, DF 1, p=0.027) but not with CPET variables.

Conclusion: CPET is a significant predictor of morbidity after oesophagectomy with peak V02 the most important factor.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1592 PROPENSITY SCORE ANALYSIS OF 18-FDG PET/CT ENHANCED STAGING IN PATIENTS UNDERGOING SURGERY FOR OESOPHAGEAL CANCER

N. Patel¹, K. Foley², D. Chan², C. Brown¹, A. Powell¹, T. Abdelrahman¹, P. Fielding², A. Roberts², W. Lewis¹

¹General Surgery, University Hospital Wales, Cardiff/United Kingdom

²Radiology, University Hospital Wales, Cardiff/United Kingdom

Contact E-mail Address: neilrama@hotmail.com

Introduction: PET/CT has become an integral part of the staging pathway for potentially curable oesophageal cancer (OC), primarily used to identify occult distant metastases unseen by conventional radiological modalities. The aim of this study was to analyze the effect of PET/CT introduction on overall survival and assess patterns of recurrence after oesophagectomy.

Aims & Methods: Consecutive 496 patients undergoing oesophagectomy for cancer [median age 63 (31–80) yr., 395 male, 425 ACA, 71 SCC, 325 neoadjuvant therapy] were studied. Two hundred and twenty-three patients underwent PET/CT enhanced staging protocols and the primary outcome measure was overall survival based on intention to treat.

Results: Overall 3-year survival pre-PET/CT was 42.5% compared with 57.8% post-PET/CT (Chi² 6.571, df 1, p=0.004). On multivariable analysis, pT stage (HR 1.486 [95% CI 1.27–1.74] p < 0.0001), pN stage (HR 1.116 [95% CI 1.05–1.20] p=0.001) and PET/CT (HR 0.689 [95% CI 0.53–0.89] p=0.004) were independently associated with duration of overall survival. Recurrent cancer was observed in 125 patients (51.4%) pre-PET/CT; compared with 74 patients post-PET/CT (37.8%, p=0.015), and was less likely to be distal in location after PET/CT inception (39.5 vs. 27.0%, p=0.006).

Conclusion: PET/CT enhanced staging is an important and independent factor associated with improved survival in patients undergoing oesophagectomy for cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1593 PREDICTION OF LYMPH NODE METASTASIS FOR SUPERFICIAL ESOPHAGEAL CANCER WITH USING RANDOM FOREST ANALYSIS

Contact E-mail Address: masaty871222@gmail.com

Introduction: Although surgical techniques and perioperative management for esophageal cancer has been developed, it cannot be still safe to be performed esophagectomy. Therefore, endoscopic submucosal dissection (ESD) for the superficial cancer have been increased. We also need to consider the risk of lymph node metastasis before treatment in each patient and the aim of this study is to predict lymph node metastasis for superficial esophageal cancer.

Aims & Methods: Seventy patients who was diagnosed as clinical T1a-MM, T1b-SM1 or T1b-SM2 and underwent esophagectomy at the Keio University, Tokyo, Japan between July 2000 and June 2016 were enrolled in this study. Patients who underwent esophagectomy as additional resections after ESD were included. We used random forest analysis to predict lymph node metastasis.

Results: There were 62 men and 8 women in this study. The mean age of all patients was 62.8 ± 8.2 years. The main location of the tumor was in the middle thoracic esophagus (Upper: Middle: Lower, 13: 39: 18, respectively). 14 patients had lymph node metastasis in pathological findings; 2 patients (25%) were diagnosed as clinical T1a-MM, 2 patients (6.6%) were T1b-SM1 and 10 patients (31.3%) were T1b-SM2. Random forest technique (2000 trees) resulted in an estimate of error rate of 25.7%. Lymph node metastasis was most associated with the factor of pathological T (relative importance 100%) followed by lymphatic invasion (96.3%), clinical T (89.7%) and multifocal tumor (72.2%).

Conclusion: Random forest analysis confirmed the predictors for lymph node metastasis such as pathological T and lymphatic invasion.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1594 PROGNOSTIC SIGNIFICANCE OF CARDIORESPIRATORY FITNESS, BODY COMPOSITION ANALYSIS, AND SYSTEMIC INFLAMMATORY RESPONSE IN UPPER GASTROINTESTINAL CANCER

N. Patel¹, P. Blake¹, J. Wheat¹, C. Brown¹, A. Powell¹, T. Abdelrahman¹, W. Lewis¹

¹General Surgery, University Hospital Wales, Cardiff/United Kingdom

Contact E-mail Address: neilrama@hotmail.com

Introduction: Malnutrition is associated with higher rates of operative morbidity and therefore represent potentially reversible prognostic risk factors. Bioelectrical Impedance Analysis (BIA) is a non-invasive, easily reproducible and simple means of accurately measuring body composition.

Aims & Methods: The aim of this study was to assess the prognostic value of body composition variables determined objectively by bioelectrical impedance analysis (BIA) in patients undergoing potentially curative surgery for oesophageal (OC) and gastric cancer (GC) within an enhanced recovery programme (ERP). Consecutive 168 OG patients [median age 65 (24–86) yr., 131 male, 105 OC, 64 GC, 157 ACA, 8 SCC, 3 Neuroendocrine] underwent preoperative measurements of systemic inflammatory response [SIR, including FBC, CRP, Albumin, and modified Glasgow Prognostic Score (mGPS)]. Patients underwent multi-frequency (0.5 kHz, 50 kHz and 100 kHz) BIA assessment using a Maltron Bioscan 920 (Maltron International Ltd, Essex, UK), and Cardio Pulmonary Exercise (CPX) assessment was performed selectively (70 OC, 27 GC). Primary outcome measure was Clavien Dindo (CD) morbidity severity score (MSS) of ≥ 3 .

Results: Oesophagectomy was performed in 106, gastrectomy in 64, and laparotomy only in 25 patients. Postoperative morbidity and mortality occurred in 75 (45%, CD ≥ 3 in 35, 21%) and 4 (2%) patients respectively. On univariable analysis, MSS ≥ 3 was associated with anaerobic threshold ($p=0.011$), CRP ($p=0.001$), mGPS ($p=0.011$), intra-cellular water (ICW, $p=0.041$), and extra-cellular water content ($p=0.015$). Multivariable binary logistic regression revealed ICW content [LQ vs. UQ CD ≥ 3 , 5 vs. 39%, OR 1.22 (95% CI 1.06–1.41) $p=0.006$] and CRP [LQ vs. UQ CD ≥ 3 , 7 vs. 37%, OR 1.03 (0.99–1.06) $p=0.076$] to be independently associated with MSS.

Conclusion: Seven-fold variability in morbidity severity was observed after OG cancer surgery and ICW and SIR were the most important prognostic indicators.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1595 COPING AND QUALITY OF LIFE AFTER ESOPHAGECTOMY FOR CANCER

²Esophageal And Digestive Tract Surgical Unit, Regional Centre For Esophageal Disease, Veneto Institute of Oncology (IOV-IRCCS), Padova/Italy

Contact E-mail Address: luca.saadeh@gmail.com

Introduction: Esophagectomy is one the most challenging and burdening operation for its length and the variety of anatomical districts involved. Nowadays, as consequence of the improved postoperative mortality, effects of esophagectomy are chronic and quality of life (QoL) has become one of the main outcome measure to evaluate treatment. Coping is the ability of managing stressful situations such as postoperative conditions. At present, there are no studies focusing on coping after esophagectomy for esophageal cancer

Aims & Methods: The aim of this study is to describe coping styles and QoL after esophageal resection. EORTC QLQ-C30 was used to assess QoL while the COPE-NVI (New Italian Version) was used to measure the coping ability. They are both self-reported questionnaires, validated in Italian language. EORTC C30 functional scales are: PF2 (physical functioning), RF (role functioning), EF (emotional functioning), CF (cognitive functioning) and SF (social functioning). COPE-NVI considers five dimensions: Social Support (SS), Avoidance Strategies (AS), Positive Attitude (PA), Orientation to the Problem (OP), Transcendent Orientation (TO). Non-parametric statistics was used.

Results: Fifty-one EC patients participated in the study and completed the C30 and COPE-NVI questionnaires. Thirty-two patients completed the questionnaires after surgery. Mean COPE-NVI scales were: SS=22.3 (SD 9.5), AS=23.2 (SD 4.8), PA=30.8 (SD 7.9), PO=22.5 (SD 8.8), TO=22.1 (SD

5.0). Overall, mean C30-QL2 was 72.9 (SD 16.3). Mean C30 functional scales were: PF2=80.8 (SD 16.6), RF=85.0 (SD 20.7), EF=81.5 (SD 17.0), CF=87.4 (SD 14.0) and SF=90.0 (SD 14.0). Avoidance Strategies score was negatively correlated with Social Function ($\rho=-0.60$, $p=0.004$). The remaining correlations between COPE-NVI scales, C30-QL2 and C30 functional scales were statistically not significant. Nineteen patients completed the questionnaire twice, with 3–6 months between the two fillings. The mean differences of the COPE-NVI scales were not statistically significant.

Conclusion: In our series, patients used Positive Attitude to manage everyday life changing. Whenever avoidance strategies (i.e. emotional indifference or drugs) were used, social abilities were compromised. Moreover, after surgical intervention coping seemed to be a stable feature. Therefore, in the early follow-up after surgery multidisciplinary team can identify and the coping features of patients in order to improve them to prevent QoL worsening.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1596 A RELIABLE AND ACCURATE ALGORITHM TO QUANTIFY THE TUMOR STROMA QTS AMONG TUMOR ENTITIES: HIGH INFILTRATION OF CD3⁺ AND CD8⁺ LYMPHOCYTES CORRELATES WITH IMPROVED SURVIVAL IN HEPATOCELLULAR CARCINOMA AND PANCREATIC CANCER

Introduction: The tumor micro environment plays a vital role in the growth of malignancies. Through for example tumor-infiltrating lymphocytes (TILs) it influences overall and disease free survival of patients in various cancer entities. There are many studies in the literature that investigate TILs. However, there is great heterogeneity about how to quantify these cells in the tumor tissue. Therefore, we present a novel Quantification of the Tumor Stroma (QTS) Algorithm to reliably and accurately quantify cells of the tumor stroma and to perform a correlation with survival after resection of patients with hepatocellular carcinoma and pancreatic cancer.

Aims & Methods: Immunohistochemical staining of CD3 and CD8 antigens in frozen sections of metastatic colorectal cancer (mCRC) and ovarian cancer (OvCa) as well as in paraffin sections of hepatocellular carcinoma (HCC) and pancreatic cancer (PCa) was performed. For each entity 10 slides per antigen were examined ($n=80$). In these different entities reliability and accuracy of computed quantification was tested in order to develop a general algorithm (Figure): First, reliability of identification of hot spots was investigated using two blinded observers. Hot spots were defined as regions with the highest density of TILs. The absolute amounts of cells were compared with the intraclass-correlation coefficient (ICC). Second, accuracy was tested. To examine whether quantification of 1 vs 3 hot spots yields accurate results CD8⁺/CD3⁺ ratio as well as the absolute cell numbers were compared with the ICC respectively. Third, computed counting methods (1) ZEN 2 software counting (ZC), (2) ImageJ software with subjective threshold (ISC) and (3) ImageJ with colour deconvolution (IAC) were compared to a manual counting (gold standard) using a linear regression analysis. Finally, 60 resected tumor tissues of HCC and 30 of PCa were retrieved. 3 hot spots have been selected for every slide and groups of high/low infiltration of CD3⁺ and CD8⁺ Lymphocytes have been created according to the median value. Then, statistical correlation with overall survival (OS) and disease free survival (DFS) was performed.

Comparison of manual counting to the computed methods showed mostly excellent accuracy of the obtained results using intraclass correlation with reliability analysis (ICC) and coefficient B with linear regression (B):

mCRC	OvCa	HCC	PCa
ZC ICC = 0.926, B = 0.868	ICC = 0.987, B = 0.968	ICC = 0.869, B = 0.621	ICC = 0.601, B = 1.280
ISC ICC = 0.973, B = 0.851	ICC = 0.992, B = 1.030	ICC = 0.990, B = 1.060	ICC = 0.934, B = 0.914
IAC ICC = 0.986, B = 0.945	ICC = 0.990, B = 1.060	ICC = 0.955, B = 0.723	ICC = 0.932, B = 1.327

Results: Quantification results from 2 blinded observers for reliable detection of hot spots were 0.949 in mCRC, 0.843 in OvCa, 0.805 in HCC and 0.957 in PCa. The ICC for the ratio of CD8/CD3 in 1 hot spot compared to the average from 3 hot spots was consistent in all groups. The absolute cell count in 1 vs 3 hot spots did differ reaching ICC scores reflecting a poor accuracy. ZC in PCa yielded inconsistencies. ISC reached excellent results in all groups. IAC reached excellent reliability in frozen sections and HCC but not in PCa (Table). High infiltration of CD3⁺ Lymphocytes correlated significantly with improved DFS in HCC ($p=0.016$) and PCa ($p=0.001$) as well as improved OS in PCa ($p=0.046$). High infiltration of CD8⁺ Lymphocytes correlated significantly with improved DFS in HCC ($p=0.028$) and OS in PCa ($p=0.006$).

Conclusion: In this we introduce a systematized way to count tumor stroma cells in frozen and paraffin sections. Some rules should be observed: First, subjective selection of hot spots by 1 observer is accurate. Second, if a ratio is to be determined, quantification of 1 hot spot is sufficient. If the absolute cell count is to be determined, quantification of 3 hot spots is recommended. Third,

computed counting methods achieve mostly excellent accuracy. ISC is accurate for sections with high background staining. IAC can be used in sections with low background staining. With the QTS Algorithm quantification of cells in the tumor stroma is reliable and accurate. Furthermore, clinical correlations after the use of this algorithm show results according to the literature: High infiltration of CD3⁺ and CD8⁺ Lymphocytes correlates with favorable prognosis in HCC and PCa. The future use of immunoscore systems may help to predict prognosis after resection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Lifestyle-related disease has been recognized as a risk factor for hepatocellular carcinoma (HCC). On the other hand, there are few reports concerning liver resection (LR) in obese patients.

Aims & Methods: We performed curative LR in 471 patients with HCC between 2001 and 2015. In this study, we defined an obesity as no less than 25 of body mass index (BMI). We compared clinicopathological findings, operation details, and surgical outcomes of the obese and non-obese patients. Furthermore, we assessed the safety and the benefit of laparoscopic partial hepatectomy and left lateral segmentectomy in the obese patients.

Results: Among 471 patients, 123 patients (26.1%) were defined as obese. Among them, 20 patients (4.2%) showed no less than 30 of BMI. Diabetes, hypertension, and hyperlipidemia were significantly more common, and the patients with hepatitis virus positive were less in the obese patients group than in the non-obese patients group ($p < 0.05$). The two groups showed no differences in the liver function tests except the indocyanine green retention rate at 15 minutes. There were no significant differences between the two patients group in the number of tumors, diameter of tumor, prevalence of cirrhosis, frequency of portal invasion, the operative procedure, operative duration, blood loss, incidence of postoperative complications, postoperative hospital stay, and in-hospital mortality (3.3% vs. 1.4%). No significant difference was found in relapse-free survival rate, or overall survival rate between the two groups, too. Thirteen patients underwent laparoscopic surgery, and 34 patients had open surgery. The two groups showed no difference in the background, including BMI. However the operation time (265 min vs. 397.5 min) and the postoperative hospital stay (14 days vs. 18 days) were significantly shorter, and the blood loss (50 ml vs. 600 ml) was less in the laparoscopic surgery group than in the open surgery group ($p < 0.05$).

Conclusion: Liver resection in the obese patients with HCC was safe, and laparoscopic liver resection might be more useful for reducing the surgical stress and reducing the hospital stay.

P1599 TIMING OF ELECTIVE CHOLECYSTECTOMY AFTER ACUTE CHOLECYSTITIS - A POPULATION-BASED STUDY

A. Popowicz, G. Sandblom

Department Of Clinical Science, Intervention And Technology, Karolinska Institute, Stockholm/Sweden

Contact E-mail Address: agnieszka.popowicz@ki.se

Introduction: Acute cholecystectomy as treatment of acute cholecystitis is standard of care. However, many patients are still treated conservatively and undergo elective surgery. Often 6–12 weeks following the primary admittance is postulated as a good timing for an elective surgery but there are no studies on the optimal timing for delayed cholecystectomy.

Aims & Methods: The aim of our study was to determine when it is most advantageous to perform an elective cholecystectomy after an episode of acute cholecystitis. All patients treated for acute cholecystitis in Sweden during the years of 2006 and 2013 were identified through the Swedish Inpatient Register. This cohort was cross-linked with the Swedish register for gallstone surgery, GallRiks where information on surgical outcome was retrieved. The impact of time from admission to surgery with regards to operative time, percentage of procedures completed with minimally invasive technique, peri and postoperative complications and bile duct injury or bile leakage were analysed with logarithmic transformation of time and multivariate logistic regression adjusting for gender and age.

Results: During the years 2006 to 2013, 31091 patients were treated for acute cholecystitis in Sweden. After exclusion of patients that did not perform surgery, were not registered in GallRiks and patients that were treated with acute cholecystectomy 8532 patients were identified that underwent planned surgery. In multivariate linear regression analysis with adjustment for gender and age the risk for peri- and postoperative complications, bile duct injuries and bile leakage

and amount procedures not completed with minimally invasive technique decreases with time from the last hospitalization to surgery. All p-values < 0.05 .

Conclusion: For those patients undergoing elective cholecystectomy after an acute cholecystitis the safety increases if surgery is performed later than 30 days after discharge.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1600 MIXED REALITY SURGERY USING CT-BASED PATIENT-SPECIFIC IMMERSIVE 3D HOLOGRAMS ENHANCED SPATIAL AWARENESS IN HEPATO-PANCREATO-BILIARY AND GASTROINTESTINAL SURGERY

M. Sugimoto

Graduate School Of Health Welfare Science, International University of Health Welfare, Tokyo/Japan

Contact E-mail Address: sugimotomaki@mac.com

Introduction: We developed a CT-based patient-specific holographic surgical simulation navigation system of immersive mixed reality (MR).

Aims & Methods: The aim of this study is to identify its benefit of simulating, analyzing and evaluating operative surgical treatment options in gastrointestinal and hepato-pancreato-biliary surgery.

We used our original immersive MR application using HoloLens, that is a pair of MR smartglasses built-in head-mounted display. By reconstructing the patient-specific 3D surface polygons of each organ out of the patient's MDCT images, MR anatomy was displayed on the grasses three-dimensionally during actual surgery. The HoloLens features an inertial measurement unit which includes an accelerometer, gyroscope, and a magnetometer for environment understanding sensors, an energy-efficient depth camera, a 2.4-megapixel photographic video camera, and an ambient light sensor. We performed 10 gastrointestinal and hepato-pancreato-biliary surgeries.

Results: The accurate surgical anatomy of size, position, and depth of the cancers, surrounding organs, and vessels during surgeries could be measured using build-in dual infrared light sensors. The exact location between surgical devices and patient's anatomy could be traced on the pair of MR smartglasses by satellite tracking. The gesture controlled manipulation by surgeons' hands with surgical grooves was useful for intraoperative anatomical references of tumors and vascular position under sterilized environment. It allowed the user to manipulate the spatial attributes of the virtual and real anatomies, which can enhance spatial awareness. The use of our systems reduced the length of the operation and discussion time.

MR navigation assistance could support complex procedures with the help of pre- and intra-operative imaging with better visualisation of the surgical anatomy and spatial awareness with visualisation of surgical instruments in relation to anatomical landmarks.

Conclusion: We report illustrative benefits of the immersive MR in surgical planning, simulation, education, and image-guided navigation. These could overcome the limitations of the conventional image-guided surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Post-surgical leaks are the first complication after non-bariatric oeso-gastric surgery in terms of frequency and morbidity. Anastomotic fistula change the prognostic of the operated patient increasing the length of stay, increasing costs, increasing mortality and increasing risks of oncological recurrence. Surgery is still a possibility of treatment in particular in case of severe sepsis but the role of endoscopy has evolved with development of a new armamentarium of endotherapy dedicated to such complications. In cases of post laparoscopic sleeve gastrectomy leaks, a shift is ongoing between closure or diversion methods (Ovesco, clips, covered self expandable metal stents (SEMS)) and internal drainage (double pig tail stents). Two large studies have just reported a high efficiency and a low complication rate with internal drainage with double pig tail stents for post sleeve gastrectomy leaks. No data are available for such an endoscopic internal drainage in fistulas of the upper digestive tract non-linked to bariatric surgery. Here we report the results of a pilot bi-centre retrospective study.

Aims & Methods: A retrospective study of all upper digestive tract leaks non linked to bariatric surgery and treated by double pig-tail stent (DPTS) in two

tertiary centers has been performed. DPTS are traced by the pharmacies of our two hospitals and all cases of DPTS were analysed thanks to the database of the pharmacies of our two hospitals since May 2014 (first DPTS used for non bariatric upper digestive tract fistula) 7 or 10 french DPTS have been used according to the size of the fistula and the choice of the physician. Technical success was defined as the possibility to place the DPTS within the fistula. Clinical success was a composite endpoint combining clinical amelioration of the patient and healing of the fistula allowing the removal of the DPTS.

Results: 17 patients have been treated by DPTS from May 2014 to March 2017 for an upper digestive tract leaks non linked to bariatric surgery. Fistulas were linked to a lewis-santy surgery in 8 patients (47%), total gastrectomy in 4 (23.5%), boerhaave syndrome in 2 (11.8%), endoscopic perforation in 2 (11.8%) and aortic surgery in 1 (5.9). An infected collection was present in 16 patients (94%) and 11 (64.7%) suffer from a clinical sepsis. The mean delay between surgery and the diagnostic of fistula was 10 days and the delay of the diagnosis of fistula and the endoscopic drainage by DPTS was 16.4 days. DPTS were used alone in first intention in 11 cases (64.7%), in first intention in combination with a SEMS in 11.7% and in second intention after failure of a SEMS in 3 (11.7%). All patients had a technical success and 15 patients (88.8%) had a clinical success. The mean delay for refeeding after DPTS was 17 days. The mean ablation time of the DPTS was 73 days. 3 patients presented a complication (1 stenosis, 1 bleeding and 1 migration).

	N = 17
AGE	55 (25–77)
ETIOLOGY	
Lewis Santy	8 (47%)
total gastrectomy	4 (23,5%)
Boerhaave	2 (11,8%)
Endoscopic perforation	2 (11,8%)
Aortic surgery	1 (5,9%)
ASA score	2,3 (1–4)
Associated collection	16 (94%)
Clinical sepsis	11 (64,7%)
Biological sepsis	14 (82,3%)
Delay surgery-diagnosis	10 days
Delay Diagnosis-DPTS	16,4 days
Endoscopic procedure	
DPTS alone in first intention	11 (64,7%)
DPTS + SEMS in first intention	2 (11,7%)
DPTS in second intention	4 (23,5%)
Technical success	17 (100%)
Clinical success	15 (88,8%)
Delay for refeeding	17 (4–52)
Delay for ablation of DPTS	73 (36–157)
Complications	
Stenosis	1 (5,9%)
Migration	1 (5,9%)
Bleeding	1 (5,9%)

Conclusion: Endoscopic internal drainage using DPTS seems to be an interesting therapeutic option for upper digestive tract leaks non-linked to bariatric surgery. DPTS are effective, safe, cheap and could replace SEMS not always well tolerated and with a high rate of migration. Prospective multicenter studies are needed to confirm these preliminary results.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Abdominal compartment syndrome (ACS) is serious complication of big number of surgical interventions. According the data of the World Society of the Abdominal Compartment Syndrome (WSACS), rate of mortality without treatment is more than 90%, after treatment from 25% to 75% [1]. Patients with ruptured abdominal aortic aneurysms (RAAA) are the group of high risk regarding this complication. Rate of incidence ACS at these patients is between 8% to 25%[2]. According to data of various authors, from one third to one half of them have died [3]. One of the main cause of this is the absence of good monitoring of intraabdominal pressure in this group of patients[4]. Currently, we have one effective way of treatment for this pathology: decompressive laparotomy[5]. But prophylaxis becomes more important point, if we take to attention mortality after start the develop of abdominal compartment.

Aims & Methods: We aimed to investigate the impact of implantation polypropylene mesh in abdominal wall on rate of development ACS and it severity for patients after open repairing of ruptured abdominal aortic aneurysm. Patients with rAAA (total amount n=87 patients) were operated in standard volume. Before finish of surgery in study group (n=49, 34 males, 15 females, average age 63 years +/- 14 years) was performed implantation of polypropylene mesh ('inlay' type) and was sutured skin and subcutaneous tissue only. In control group (n=38, 26 males, 12 females, average age 61 years +/-15 years) surgery was finished by standard way. In all patients had infrarenal type of rAAA. Middle laparotomy or thoracophrenodiaphragmal access was used. After surgery intraabdominal pressure was controlled by intravesical method during first seven days after operation. We fixated rate of complication and mortality in both groups. We followed-up patients after surgery and controlled far outcomes too. First mesh implantation was performed at 24 February 2014, last at 03 March 2017.

Results: In study group we fixated 5 cases of ACS (10.2%), including 3 cases of light ADS (intraabdominal pressure (IAP) –12–15mmHg), 1 case of moderate ADS (IAP 16–20 mmHg), and 1 case of severe ADS (IAP 21–25 mmHg).Decompressive laparotomy was performed in one case with satisfactory result. In general, mortality in study group was 18.4% (9 cases).In control group we fixated 9 cases of ACS (23.7%), including 3 cases of light ADS (intraabdominal pressure (IAP) –12–15mmHg), 2 cases of moderate ADS (IAP 16–20 mmHg), and 3 cases of severe ADS (IAP 21–25 mmHg) and 1 case with very severe ADS (IAP more than 25 Hgmm).Decompressive laparotomy was performed in three cases, satisfactory result was achieved in 1 case, in two cases patients have died from polyorgan insufficiency. In general, mortality in control group was 28.9% (11 cases). We did not find any specific complication, related with implantation of polypropylene mesh during all three years of follow-up.

Conclusion: 1. Impantation of polypropylene mesh is a safe and effective procedure for prophylaxis of ACS for patient with rAAA. 2. Impantation of mesh allows to avoid ACS for patient with rAAA and related with it complication and outcomes. 3. It is possible to implantate polypropylene mesh for other diseases, not only for rAAA, but this point requires further investigations.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Peritoneal collections and abscess after Bariatric Surgery (BS) leaks are dreaded complications. Laparoscopic or open surgery and percutaneous CT drainage are the current indications. Endoscopic management of pancreatic collections is a rationale for Endoscopic Peroral Drainage (EPOD) approach in cases of BS leaks with abdominal collections.

Aims & Methods: The aim of this study is to evaluate utility and safety of EPOD to treat peritoneal collections and abscesses secondary to BS leaks. Methods: This retrospective study included 65 consecutive patients from 2007 to 2015 at a single center (40 Sleeve gastrectomy, 25 gastric bypass) after 5 to 21 days from

surgery. Patients presented heart rate over 120 bpm. Images from CT showed left sub-phrenic, peri-gastric or free abdominal collections. An Upper GI endoscopy was performed to localize the leak opening and enter to peritoneal cavity. Either 9.8 or 5.8 mm diameter gastroscope were used. In 10 patients with orifices smaller than 5.8 mm balloon dilatation of the leak opening allowed peritoneal access. The fluid content was suctioned out (100 to 700 ml). Sample was taken for bacterial cultures. The cavity was flushed and suctioned out with sterile saline solution (200 ml to 1000 ml). In cases of inadequate location surgical drains catheters were repositioned or replaced using endoscopic forceps and snares. Fifteen patients had malfunctioning latex drains. Replacement for drainage catheters was performed advancing with endoscopes through the leak all the way down to the skin. Once the tip of the endoscope was outside the peritoneum the latex drains were removed. Catheters were snared or grasped and pulled back into the peritoneum leaving the proximal end close to the fistula opening. In 5 patients without surgical drainage systems one laparoscopic port was localized inside peritoneum and re-opened under endoscopic vision to allow drainage catheters placement. In 8 patients peritoneal adhesions were endoscopically liberation with endoscopic forceps or knives to facilitate peritoneal navigation.

Results: Heart rate returned to normal within 24 hours and leukocytosis improved after 72 hours. In 50% of patients heart rate returned to normal immediately. Average time for the whole procedure was 45 minutes. Abdominal catheters were removed between 7 and 18 days once full resolution of the drainage was achieved. Twenty patients were discharged within the first 24 hours. The rest were discharged between 3 and 8 days. Partially covered SEMS were placed for 6 to 8 weeks leading to complete closure of leaks. There were no adverse events related.

Conclusion: EPOD for peritoneal collections and abscesses secondary to BS leaks is feasible, safe and highly effective.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1605 CLINICAL ASSESSMENT OF THE FAILING TO REVERSE A DIVERTING ILEOSTOMY

Introduction: A diverting loop ileostomy with procedure of intestinal resections and intestinal anastomosis decreases morbidity from anastomotic leaks and may even reduce the risk of anastomotic leak as shown in recent studies. Reversal of a temporary ileostomy is considered a simple surgical procedure presenting with a low morbidity and mortality rates. However, ileostomy reversal may be associated with number of complications requiring reoperation, with anastomotic leak (AL) being most critical often leading to failure in restoration of digestive tract continuity.

Aims & Methods: The study aimed at evaluating the results of restoration of intestinal continuity in patients primarily operated on for colorectal cancer and inflammatory conditions. We assessed the frequency of failure following the surgical procedure of diverting loop ileostomy closure. The study was conducted at a tertiary referral center. 147 adult patients (89 men, mean age 50.5y ± 16.71y and 58 women, mean age 49.3y ± 16.99y) were enrolled to this study. All included patients underwent surgical closure of a temporary loop ileostomy at the Department of General and Colorectal Surgery, Lodz, Poland, between 2004 and 2015. The medical data was collected in a retrospective manner basing on hospital records. The analyzed parameters included length of hospitalization, gender, age, BMI, concomitant conditions, American Society of Anesthesiologists classification score (ASA) and the character of postoperative complications. Statistical analysis was used to evaluate the correlation between the variables and postoperative complications.

Results: AL as a postoperative complication with the need to create a new ostomy occurred in 15 patients (10.2%). Higher values of BMI and older age have been noted compared to noncomplicated surgeries (27.54 ± 2.36 vs. 23.02 ± 3.98; $p < 0.001$; 54.53 ± 12.3 vs. 50.25 ± 15.95; $p = 0.029$ respectively). There was no significant correlation between patients' gender and the incidence of AL ($p = 0.087$). The number of prior surgical procedures and ASA scale positively correlated with the prevalence of AL ($p = 0.038$; $p = 0.003$ respectively). There were no significance difference between patient with colorectal cancer and inflammatory conditions ($p = 0.534$). The average time interval from prior surgery to reversal of the stoma and AL occurrence were not related and did not reveal statistical significance (8.5 ± 4.41 vs. 7.24 ± 4.47; $p = 0.25$). Univariate logistic regression demonstrated that a BMI levels, patients' age and average time interval from prior surgery to reversal procedure were significantly associated with failure of restoration of intestinal continuity.

Conclusion: AL as a critical postoperative complication is still a major issue related with failure of intestinal continuity restoration in patients undergoing loop ileostomy clouser. Patients with elevated BMI, older age and shorter average time interval from prior surgery to reversal procedure present higher risk of failure in restoration of digestive tract continuity. The incidence rate of AL was similar in patients operated primarily on for inflammatory conditions and colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1606 BODY COMPOSITION AS A PREDICTOR OF MORBI-MORTALITY FOLLOWING BILIOPANCREATIC CANCER SURGERY

M.P.C. Santos¹, S. Velho², C. Cunha², F. Costa³, L. Agostinho², R. Cruz², R. Maio², M. Cravo¹

Introduction: The impact of body composition on the outcomes following pancreaticoduodenectomy is still unclear.

Aims & Methods: The aim of this study was to analyze the association between body composition and postoperative complications and 90-day mortality in patients undergoing biliopancreatic cancer surgery. Retrospective study of patients with pancreatic, ampullary or bile duct carcinoma that underwent surgery between March 2012 and October 2016. Body composition (skeletal muscle area, visceral fat area, subcutaneous fat area and muscle radiation attenuation) was assessed in diagnostic or staging computed tomography (CT), in axial images at the level of the 3rd lumbar vertebra. Postoperative complications were recorded according to Clavien-Dindo classification and categorized as minor (grade I–IIIa) and major (grade IIIb–V).

Results: Fifty-nine patients were analyzed and 11 were excluded due to unavailable CT scan at our institution. Forty-eight were included, 28 were men, with a mean age of 70.9 ± 8.5 years. The incidence of major complications was 25% and 90-day mortality was 8.3%. On simple logistic regression of factors associated with major complications skeletal muscle area (OR 0.97, 95% CI 0.94–1.00, $P = 0.09$) and index (OR 0.91, 95% CI 0.81–1.00, $P = 0.09$) showed a trend for a protective effect. On multiple logistic regression skeletal muscle index was a protective factor (OR 0.89, 95% CI 0.79–0.99, $P = 0.05$) and longer surgery (OR 1.01, 95% CI 0.99–1.03, $P = 0.07$) was associated with higher incidence of major complications. The receiver-operator characteristic (ROC) curve showed an acceptable power of discrimination of major complications using a model with skeletal muscle index and surgery duration as independent variables (area under the curve of 0.736). On simple logistic regression surgery duration (OR 1.02, 95% CI 1.00–1.06, $P = 0.05$), visceral fat area (OR 1.02, 95% CI 1.00–1.04, $P = 0.02$) and index (OR 1.05, 95% CI 1.01–1.12, $P = 0.04$) were associated with higher 90-day mortality whereas muscle radiation attenuation had a protective effect (OR 0.88, 95% CI 0.76–0.99, $P = 0.05$).

Conclusion: These results suggest that low values of skeletal muscle and muscle radiation attenuation, as well as high values of visceral fat and longer surgery are associated with worse clinical outcomes following biliopancreatic cancer surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1607 GASTROSCHISIS: A 16-YEAR STUDY

Introduction: Gastroschisis is a ventral body wall defect through which protrude mainly large and small intestines. The disease's clinical course and prognosis depend on both surgical techniques, severity of the defect, accompanying anomalies and complications.

Aims & Methods: We performed a retrospective study based on the analysis of patients records admitted to our hospital Neonatal Intensive Care Unit between January 2000 and December 2016. The aims of this study were to evaluate defect's incidence, management and outcome of patients with gastroschisis in our institution.

Results: During the period 2000–2016 the overall incidence of gastroschisis in our NICU was 5.23% (140 cases-all transferred from other units). The average birth gestational age was 35.5 weeks and the average birth weight was 2270 g. The abdominal wall defect was identified in antenatal period only in 15.4% of cases. Also, 23 patients (16.4%) presented other associated anomalies: 12 cases with atresia or stenosis of various intestinal segments, 6 cases with renal anomalies and 5 cases with cardiac defects. Surgical techniques performed for abdominal defect closure were: primary closure in 35 cases (25%), staged closure in 12 cases (8.57%), Gross technique in 44 cases (31.4%) and manual reduction and closure (Bianchi procedure) in 49 cases (35%). The average period of digestive pause was 12.9 days and the mean length of stay in NICU was 30.4 days. Patients were also mechanically ventilated for an average period of 4.6 days. The most frequent complication was late-onset sepsis (37.8%); also 26 neonates (18.5%) underwent unplanned reoperation and 7 neonates (5%) remained with short bowel. The average mortality in our group was 33% but it constantly decreased over the years (from 84% in 2000 to 11% in 2016). Sepsis, prematurity, low birth weight and associated defects were identified as major risk factors for the unfavorable outcome (death).

Conclusion: The management of neonates with gastroschisis depends on several factors including the status of herniated organs, the size of abdominal cavity, the presence of other associated congenital anomalies and last but not least on the resources and experience of the neonatal interdisciplinary team. Significant changes occurred in the management of gastroschisis in our Unit and as consequence, the outcome of patients with gastroschisis has dramatically improved during the studied period.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Urinary metabolic profiling has been shown to distinguish patients with inflammatory bowel disease (IBD) from healthy controls (HC), and also separate ulcerative colitis (UC) from Crohn's disease (CD) in Caucasian (Cau) cohorts (1). Diet and lifestyle also have an effect on metabolic profiles (2), and these differ in patients from different ethnic backgrounds. Moreover, clinical phenotype varies between Caucasians and South Asians (SA)(3), however discriminatory metabolites have not been studied in different ethnic populations. The aim of this study was to compare the urinary metabolic profiles of IBD patients and healthy controls from Caucasian and South Asian backgrounds.

Aims & Methods: Samples from 405 IBD patients (283 Caucasian and 122 South Asian) and 137 healthy controls (98 Caucasian and 48 South Asian) were analysed by ¹H-NMR spectroscopy. Clinical and dietary data were collected. Orthogonal partial least squares discriminant analysis (OPLSDA) was performed to examine whether there were differences in metabolic data between Cau and SA. R² (variance), Q² (quality assessment) and p values (validity) for each model were described.

Abstract: P1608

*Montreal classification

⁺OPLSDA model examining the differences in urinary metabolic profiles between these cohorts

⁺⁺p value cannot be calculated if OPLSDA model has negative Q² values

OPLSDA models also separated South Asian healthy controls from Caucasians healthy controls, and South Asian Crohn's disease from Caucasian Crohn's disease, but in UC no robust model could be made.

Results: The phenotype of South Asian Crohn's disease was not significantly different to Caucasian Crohn's disease in this cohort. In the South Asian UC group there was more pancolitis (p = 0.051) and less proctitis (p = 0.008). There were more vegetarians in the South Asian group. OPLSDA was able to separate patients with IBD from healthy controls, and also UC from Crohn's disease, in the Caucasian cohort, but this separation could not be replicated in South Asians (negative Q² values).

Conclusion: The separation between Caucasian and South Asian healthy controls may reflect differing lifestyles including diet. Caucasian IBD patients could be separated from healthy controls, and Crohn's disease from UC, replicating previous studies. South Asian IBD patients could not be separated from healthy controls which may be due to lower numbers of South Asian patients in this study, and specifically less Crohn's disease patients where stronger discriminating models have been shown in Crohn's disease in previous studies. In Crohn's disease, Caucasians and South Asians could be separated, but Caucasian and South Asian patients could not be distinguished in the UC cohort, possibly suggesting the metabolic milieu in Crohn's disease is stronger and less influenced by the impact of ethnicity.

Introduction: Reduced saccharolytic fermentation has been described in patients with quiescent ulcerative colitis (UC). Such defects may differ across colonic regions along with acute variations in dietary fibre intake. These aspects deserve further study.

Aims & Methods: We aimed to define regional colonic fermentation by direct intestinal pH-transit profiling in patients with quiescent UC following acute variations in fermentable fiber intake. A randomized, double-blind, crossover trial was performed. Patients with quiescent UC (Partial Mayo Score ≤1; faecal calprotectin <150 µg/g) and healthy controls who were not taking any

antibiotics (including sulfasalazine), probiotics or fiber supplements were recruited. After a 7-day run-in, subjects were fed study meals high (11 g oligo-saccharides, 2 g resistant starch) or low (<1 g) in fermentable fiber over a 12-h period before ingesting the pH-motility capsule, subjects then crossed over to the other diet 3 days after passage of the capsule. Endpoints were diet-associated differences in overall, caecal and distal colonic pH, and colonic transit time (CTT), taken as time between the ileo-cecal junction and capsule exit. Caecal pH was defined as the minimum pH following passage through the ileo-cecal junction whereas maximum pH was arbitrarily used as distal colonic pH.

Results: 15 UC patients (aged 24–72 y; 9 males) and 9 controls (aged 22–69 years, 4 males) were studied. A decrease in overall and distal colonic pH was observed in controls with high vs low fiber diet (Table 1). In UC patients, a high fermentable fiber intake reduced caecal pH but paradoxically tended to increase distal colonic pH. A significant association was observed for UC extent and changes in overall ($r=0.81$; $p<0.001$, Spearman's correlation) and caecal pH ($r=0.53$; $p=0.04$) after a high fermentable fiber diet (Figure 1). No differences in CTT were observed between diets in either cohorts but subgroup analysis in the UC cohort showed highly heterogeneous responses to a high fermentable fiber diet. 64% patients had slower CTT whilst 36% had unchanged or faster CTT. In contrast, majority (63%) of controls had no changes in CTT after a high fiber diet.

Table 1: Colonic pH and transit responses to acute changes in fermentable fiber intake

		Overall mean pH (95% CI)	Mean caecal pH (95% CI)	Mean distal colonic pH (95% CI)	Median [IQR] CTT (h)
UC n = 15	Low fiber	6.4 (6.2–6.8)	5.6 (5.3–5.7)	7.9 (7.6–8.2)	17 [9–23]
	High fiber	6.3 (6.0–6.5)	5.2 (5.0–5.4)	8.1 (7.6–8.4)	21 [16–39]
	<i>p</i> -value	0.20	0.001	0.09	0.13
Healthy n = 9	Low fiber	6.9 (6.5–7.2)	5.5 (5.2–5.8)	8.2 (8.0–8.5)	16 [15–37]
	High fiber	6.3 (6.0–6.5)	5.2 (4.9–5.5)	7.7 (7.4–8.0)	18 [15–32]
	<i>p</i> -value ¹	0.02	0.15	0.04	0.58 ²

¹paired t-test or ²Mann-Whitney test

Conclusion: A high fermentable fiber diet partially increased colonic fermentative activity in patients with quiescent UC compared to controls. Moreover, contrary to controls, UC patients exhibited an increase in distal pH and heterogeneous colonic transit responses after a high fermentable fiber intake. Our findings suggest that abnormalities in motility and regional defects in the function of the colonic microbiota exist despite quiescent disease.

P1610 FECAL MICROBIAL DYSBIOSIS IN CHINESE PATIENTS WITH INFLAMMATORY BOWEL DISEASE

H. Ma, H. Zhang

Department Of Gastroenterology, First Affiliated Hospital of Nanjing Medical University, 300 Guangzhou Rd, Nanjing 210029, China, Jiangsu/China

Contact E-mail Address: mahaiqin2010@163.com

Introduction: Microbial dysbiosis in the gut has been suggested to play an important role in the pathogenesis of inflammatory bowel disease (IBD).

Aims & Methods: In this study, we aimed to analyze the fecal microbiota in Chinese patients with IBD. Fecal samples from 15 patients with Crohn's disease (CD), 14 patients with ulcerative colitis (UC) and 13 healthy individuals were subjected to 16S rDNA sequencing. The V4 hypervariable regions of 16S rDNA were sequenced by the Illumina MiSeq2500 platform. Quality control and operational taxonomic units (OTUs) were calculated with QIIME software.

Results: Significant differences in community richness and microbial structure were observed both in CD and UC compared with normal controls. At the phylum level, analysis of the microbial compositions revealed that the Proteobacteria percentages, were significant higher in IBD than in controls. While at the genus level, we found that the abundance of 8 genera in CD and 23 genera in UC, particular the *Escherichia* genus, were significantly different when comparing with controls. We next surveyed the taxonomics composition distribution between different phases of disease, detecting that the abundance of the Bacteroidetes was significant decreased in active CD group compared with inactive CD group. However, the Proteobacteria was only nominally increased in active CD relative to inactive CD, which did not hold significance after correction. Furthermore, the relative abundance of the Bacteroidetes, especially the

Bacteroides, was negatively correlated with the calculated Crohn's disease activity index (CDAI) scores of patients.

Conclusion: Our findings showed the specific characteristics and dysbiosis of fecal microbiota within Chinese IBD patients. In addition, the abundance of the Bacteroidetes was significant lower in active CD group than in inactive CD group and it was negatively correlated with CDAI, indicating that the Bacteroidetes could be related with the disease activity.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1611 HYPOXIA-MEDIATED IRON UPTAKE PREVENTS INFLAMMATORY GENE EXPRESSION IN THE INTESTINAL EPITHELIUM THROUGH THE REGULATION OF NF-KB BINDING ACTIVITY

S. Simmen, J. Cosin Roger, C. De Valliere, M. Scharl, J. Zeitz, S. Vavricka, G. Rogler, P. A. Ruiz-Castro

Aims & Methods: In the present study, we sought to elucidate the effects of iron supplementation on hypoxia-mediated responses in the intestinal epithelium. For this purpose, serum starved Caco-2 monolayers were subjected to normoxia (21% O₂) or hypoxia (0.2% O₂) in the presence and absence of ferric ammonium iron citrate (FAC) and the iron chelator deferoxamine (DFO). Total RNA was isolated and changes in the expression of tumor necrosis factor (TNF), interleukin (IL)-1 β , DMT-1, FPN and ferritin was assessed by real-time quantitative PCR. Western blot analysis was performed with antibodies against ferritin, p-NF- κ B, HIF-1 α , p-mTOR, p62 and LC3. mRNA synthesis in Caco-2 cells under hypoxia was blocked using actinomycin D. Chromatin immunoprecipitation experiments were carried using antibodies against NF- κ B and primers for promoter binding regions of TNF and IL-1 β . Healthy volunteers (n = 10) were subjected to hypoxic conditions resembling an altitude of 4,000 m above sea level for 3 h using a hypobaric chamber. Serum samples were collected the day prior to hypoxia, and one day, one week and one month after hypoxia.

Introduction: Environmental hypoxia has been established to influence the development of inflammatory bowel disease (IBD). Adaptive responses to low oxygen-tension are mediated through hypoxia inducible factor (HIFs), which are tightly regulated by oxygen and iron levels through the action of hydroxylases. Dietary iron is mainly absorbed by duodenal enterocytes through the divalent metal transporter (DMT)-1. Once iron is inside the enterocytes, it is either sequestered into ferritin or transported out of the enterocyte into the circulation by ferroportin (FPN). Regulation of uptake, storage and export of iron is mediated by signals reflecting oxygen and intracellular iron levels in enterocytes, and systemic iron requirements. Central to systemic iron regulation is the liver hormone hepcidin, which regulates and is regulated by systemic iron levels. Hepcidin expression is induced by cytokines and results in anemia of inflammation.

Results: Hypoxia induced the mRNA expression of TNF and IL-1 β concomitantly with the iron transporters DMT-1 and FPN in Caco-2 cells under iron-starving conditions, thereby promoting iron uptake. The iron chelator deferoxamine (DFO) induced HIF-1 α stabilization and TNF mRNA expression under both normoxic and hypoxic conditions. Conversely, iron supplementation induced ferritin protein accumulation under normoxic and hypoxic conditions, and reduced TNF and IL-1 β mRNA expression. Interestingly, neither iron chelation nor iron supplementation reduced hypoxia-mediated p-NF- κ B. Iron induced p-mTOR and blocked autophagy. Iron overload enhanced decay of TNF, but not IL-1 β mRNA. Iron also prevented binding of NF- κ B to the promoter of TNF and IL-1 β . Healthy volunteers presented reduced serum levels of iron, as well as transferrin saturation. Ferritin levels were unchanged indicating anemia of inflammation and suggesting enhanced intracellular iron accumulation in enterocytes following hypoxia.

Conclusion: Our results suggest that hypoxia-mediated iron uptake is crucial to counteract hypoxia-induced pro-inflammatory gene expression, and identify iron intracellular uptake and storage as a hypoxia protective mechanism to reduce mucosal inflammation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1612 OGR1 (GPR68) EXPRESSION IS INCREASED IN INTESTINAL INFLAMMATION AND CORRELATES WITH DISEASE ACTIVITY IN PATIENTS WITH IBD

J. Cosin Roger¹, K. Baebler¹, S. Bengs¹, S. Lang¹, M. Turina², A. Rickenbacher², M. Scharl¹, K. Seuwen³, P. A. Ruiz-Castro¹, B. Misselwitz¹, G. Rogler¹, C. De Valliere¹

Contact E-mail Address: katharina.baebler@usz.ch

Introduction: In both forms of inflammatory bowel disease (IBD), Crohn's disease (CD) and ulcerative colitis (UC), inflammation of the gut wall is associated with extracellular tissue acidification. Low extracellular pH stimulates the family of proton-sensing G-protein coupled receptors (GPCRs); ovarian cancer G-protein coupled receptor 1 (OGR1), T-cell death-associated gene 8 (TDAG8 or GPR65) and G-protein coupled receptor 4 (GPR4), which activate second messenger signaling cascades. Recent studies reported a link between IBD and this family of pH-sensing receptors; in genome-wide association studies (GWAS), TDAG8 has been identified as an IBD-risk gene. The mechanism behind the increased risk of developing IBD remains unclear. OGR1 and TDAG8 are alleged to act in opposition by regulation of the inflammatory response; enhancing or inhibiting inflammatory pathways respectively, however the interplay between OGR1 and TDAG8 is unclear.

Aims & Methods: In this study we aim to investigate the role of OGR1 in IBD patients. Expression of OGR1 in surgical specimens from non-IBD (n=5), CD (n=10) and UC (n=10) patients was determined by immunohistochemistry, RT-qPCR and Western blotting. Clinical disease activity was assessed by the Harvey Bradshaw Index (HBI) and the Modified Truelove and Witts activity index (MTWAI) for CD and UC patients, respectively. Nonparametric Spearman's rank correlation analysis was performed.

Results: OGR1 immunostaining of human surgical samples from non-IBD patients revealed OGR1 expression mainly in lamina propria cells, with weaker staining in epithelial cells. OGR1 staining in IBD patients was stronger compared to controls; however, in IBD patients OGR1 is highly expressed in both epithelial cells and cells in the lamina propria. Further, paired samples taken at the same time, from non-inflamed and inflamed intestinal tissue from IBD patients showed stronger OGR1 staining in the inflamed mucosa compared to the non-inflamed mucosa. Accordingly, mRNA and protein expression of OGR1 was significantly increased in patients with IBD compared to non-IBD patients. Additionally, a significant positive correlation was observed between OGR1 expression and the clinical score in both the non-inflamed (rs 0.7311, p=0.0069) and the inflamed mucosa (rs 0.7698, p=0.0034).

Conclusion: The expression of OGR1 is significantly increased in patients with IBD. OGR1 expression correlates with IBD disease activity, suggesting an active role of OGR1 in IBD pathogenesis. OGR1 appears to be a therapeutic target among the pH-sensing receptors involved in IBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI613 MICROBIAL PROFILING OF NEWLY DIAGNOSED PATIENTS WITH ULCERATIVE COLITIS DIFFERS WITH ETHNICITY; RESULTS OF AN INCEPTION COHORT TIME SERIES ANALYSIS

⁶Imperial College London, London/United Kingdom

Contact E-mail Address: rm399@imperial.ac.uk

Introduction: Ulcerative colitis (UC) phenotype in South Asian (SA) migrants differs to Caucasians with a predominant pan-colonic extent.¹ A separate study showed different microbial profiles with lower bacterial diversity in the SA group.² The significance of these findings is unclear due to small sample size (n=30) and single time point analysis.

Aims & Methods: We aimed to examine microbial profile of SA and Caucasian UC patients. Faecal samples were collected from 48 UC patients recruited in a prospective inception cohort study at diagnosis (time point 1; months 0–3) and 2 further time points over one year (time point 2: months 4–8, time point 3: months 9–12). Patients were stratified by ethnic group (SA, Caucasian, Other), treatment (none, 5-ASA, Azathioprine and Steroids) and disease duration. Healthy controls (HC) were recruited locally among the staff at St. Marks Hospital. For 16S pyrosequencing the hypervariable region (V1) of the 16S rRNA gene was amplified by PCR. The amplicons were subjected to sequencing using Illumina MiSeq technology. The sequences were loaded onto the QIIME pipeline. Statistical analysis was performed using STAMP 2.1.3 software with Welch's two-sided t-test for comparing two groups. Microbial richness was calculated based on Chao1 index. Weighted Unifrac metrics were applied to construct Principle Coordinate Analysis (PCoA) plots.

Results: Ninety-four faecal samples were collected. Sample collection for all time points included SA (n=13), Caucasian (n=9), healthy SA (n=11) and healthy Caucasian (n=12). There was no significant difference in relative abundance of bacteria between treatment groups (5-ASA, Azathioprine, Steroids, None) and time points (1 vs 3). Comparing healthy SA and healthy Caucasians, there was only one significant difference in relative abundance of Clostridiales at the family level. (Increased in SA group). The Chao1 diversity index showed a trend towards lower diversity in the SA group compared to Caucasians although there was no significant difference. There were significant increases in *Bifidobacterium*, *Rikenellaceae*, *Lactobacillus* and *Streptococcus* (Table 1) and significantly decreased relative abundance in *Barnesiellaceae*, *Anaerostipes* and *Ruminococcus*.

TABLE 1: Summary of Bacterial Taxonomic Findings in South Asians (SA) and Caucasians with ulcerative colitis. *Increase or decrease in SA relative to Caucasians

Phylum	Change*	Family	Change*	Genus	Change*
<i>Actinobacteria</i>	Increased	<i>Bifidobacteriaceae</i>	Increased	<i>Bifidobacterium</i>	Increased
					Increased
<i>Bacteroidetes</i>	Decreased	<i>Bacteroidales</i>	Decreased	<i>Barnesiellaceae</i>	Decreased
				<i>Rikenellaceae</i>	Increased
<i>Firmicutes</i>		<i>Lactobacillaceae</i>	Increased	<i>Lactobacillus</i>	Increased
				<i>Streptococcus</i>	Increased
		<i>Clostridiales</i>	Increased		Decreased
		<i>Lachnospiraceae</i>	Decreased	<i>Anaerostipes</i>	Decreased
				<i>Unclassified</i>	Decreased
<i>Proteobacteria</i>		<i>Ruminococcaceae</i>	Decreased	<i>Ruminococcus</i>	Decreased
		<i>Veillonellaceae</i>	Increased		
		<i>Pasteurellaceae</i>	Decreased		

Conclusion: Increased *Bifidobacteria* and *Lactobacillus* in the SA group is consistent with the previous study.² A possible explanation is the consumption of fermented foods in the SA group although there was no difference between healthy SA and Caucasian controls. There is a trend towards lower diversity in the SA group and reduced *Bacterioides* which are consistent with the UC dysbiosis described in the literature. Functional analysis of this unique microbial profile through metagenomic and metabonomic techniques may explain the different disease behaviour in the SA group.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI614 VITAMIN D SUPPLEMENTATION REDUCES FAECAL CALPROTECTIN AND ALTERS INTESTINAL MICROBIOTA COMPOSITION IN PATIENTS WITH ACTIVE ULCERATIVE COLITIS

M. Garg¹, P. Hendy¹, S. Shaw², N. S. Ding¹, G. Hold², A. Hart¹

¹Ibd Unit, St Mark's Hospital, Harrow/United Kingdom

²School Of Medicine, University of Aberdeen, Aberdeen/United Kingdom

Contact E-mail Address: philiphendy14@gmail.com

Introduction: There is evidence for vitamin D as an immunomodulator in patients with IBD, but results from clinical trials to date are inconclusive. It is uncertain whether vitamin D supplementation may affect the intestinal microbiota.

Aims & Methods: This study aimed to assess the effect of vitamin D replacement in deficient patients with and without ulcerative colitis (UC) on inflammation and faecal microbiota. Vitamin D was replaced over 8 weeks to patients with active UC, inactive UC, and non-IBD controls with baseline 25(OH) vitamin D < 50 nmol/L, and markers of inflammation and stool collected for microbiota analyses by next generation sequencing.

Results: Eight patients with active UC, 9 with inactive UC and 8 non-IBD controls received 40,000 units of vitamin D weekly over 8 weeks. No demographic differences were noted across the groups. Mean baseline 25(OH) vitamin D levels were 34 (range 12–49) nmol/L. Vitamin D supplementation increased mean 25(OH) vitamin D to 111 (range 71–158) nmol/L (P < 0.001), and reduced parathyroid hormone levels from mean 4.3 to 3.3 pmol/L (p=0.017). No change in baseline medications for UC took place in patients with UC, except for one patient with active UC who ceased his 5-aminosalicylate. Faecal calprotectin levels reduced from median 275 to 91 µg/g (p=0.023) in patients with active colitis, but did not change in patients with inactive colitis or non-IBD controls. Similar improvements in albumin, platelet count and symptomatic disease activity indices were noted. No changes in overall bacterial diversity were noted. There was a trend towards an increase in abundance of *Ruminococcus gnavus* post vitamin D supplementation in active UC patients, but this did not reach statistical significance.

Conclusion: Vitamin D supplementation was associated with reduced intestinal inflammation in patients with active UC. A randomised controlled trial evaluating vitamin D in IBD is required, along with further investigation of potential mechanisms by which vitamin D may alter specific microbial composition.

Introduction: Attack by commensal microbiota is one component for induction of inflammatory episodes in ulcerative colitis (UC). In UC, the mucus layer is intrinsically devoid of phosphatidylcholine (PC) resulting in low hydrophobicity which facilitates bacterial invasion. Colonic ectophospholipase-carrying bacterial strains are likely candidates to break the PC mucus barrier. Therefore we aimed to evaluate the effect of phospholipase A₂ (PLA₂) inhibitors on inflammation in a genetic UC mouse model.

Aims & Methods: Attack by commensal microbiota is one component for induction of inflammatory episodes in ulcerative colitis (UC). In UC, the mucus layer is intrinsically devoid of phosphatidylcholine (PC) resulting in low hydrophobicity which facilitates bacterial invasion. Colonic ectophospholipase-carrying bacterial strains are likely candidates to break the PC mucus barrier. Therefore we aimed to evaluate the effect of phospholipase A₂ (PLA₂) inhibitors on inflammation in a genetic UC mouse model.

Results: Luminal UDCA-LPE reduced the PLA₂ activity in stool by 36 ± 8%. Concomitantly no inflammatory phenotype was observed when compared to kindlin 2^(-/-) mice not treated with UDCA-LPE. The improvement was documented in regard to stool consistency, calprotectin levels in stool, and macroscopic/endoscopic as well as histologic features of the mucosa. The pattern of colonic microbiota distribution obtained in the UC phenotype mice was reversed by UDCA-LPE to the control mice pattern.

Conclusion: The inhibition of the bacterial ectophospholipase A₂ activity improves mucosal inflammation in a genetic mouse model of UC. It is assumed that the remaining mucus PC shield is better preserved when luminal PLA₂ is suppressed.

Introduction: Inflammatory bowel diseases (IBDs), Crohn's disease (CD) and ulcerative colitis (UC) are typically associated with a decrease in local pH. Genome-wide association studies (GWAS) identified over 240 non-overlapping single-nucleotide polymorphisms (SNP) associated with IBD. G-protein-coupled receptor 65 (GPR65) or T-cell death associated gene 8 (TDAG8) has recently been reported to be a genetic risk factor for IBD. The T genotype of the lead GPR65 SNP (rs8005161) within the GPR65 gene confers increased IBD risk. In response to extracellular acidification, GPR65 activates second messengers: cAMP, via the Gs signaling pathway, and G12/13/Rho signaling.

Aims & Methods: In this study, we analyzed the functional relevance of SNP rs8005161 as well as the association of this GPR65 variant with IBD. Discovery: 2064 IBD patients from the Swiss IBD Cohort Study (SIBDCS) were genotyped for IBD risk SNPs by MALDI-TOFF mass spectrometry. Validation: 1138 individuals (591 non-IBD, 203 UC, 344 CD) were genotyped for risk SNPs, GPR65 (rs8005161, rs3742704) and GALT (rs1805078), with Taqman SNP Genotyping Assays. 10 IBD patients of each genotype GPR65 rs8005161 TT, CT and wild type/CC (WT/CC) from the SIBDCS and 10 non-IBD controls (CC) were recruited for functional studies. CD14⁺ cells were isolated from blood samples and subjected to an extracellular acidic pH shift (pH 6.6 vs. pH 7.6) in functional assays and tested for cAMP and RhoA GTPase activation.

Results: Sequenced genotype frequency of rare homozygote rs8005161 in the SIBDCS was 1.17%, minor allele frequency (MAF) - 10.3%. The variant rs8005161 was more frequent in UC patients (MAF 14.53% vs 10.05% in the non-IBD group), whereas no statistically significant association with IBD, UC or CD was found for the other variants (GPR65 rs3742704, GALT rs1805078) by Taqman genotyping. No significant differences were observed in the cAMP production between IBD (WT/CC, CT, TT) and non-IBD (WT/CC) genotype carriers upon pH shift from 7.6 to 6.6. A decreased activation of GTPase RhoA was seen in IBD (WT/CC, CT, TT) patients after an acidic pH shift, but no differences between rs8005161 TT, CT and CC patients was observed.

Conclusion: The minor T allele of the GPR65 associated SNP rs8005161 was significantly enriched in UC patients. RhoA signaling was reduced in IBD patients indicating differential activation of Rho signaling in patients versus controls. However, no differences in cAMP signaling in IBD TT/CT/CC subjects compared to healthy CC subjects were observed. Our results suggest impaired RhoA signaling in IBD patients upon a pH shift, indicating a mechanistic explanation for increased IBD risk with GPR65 polymorphisms.

Introduction: Macrophages contribute to fibrosis through the release of different mediators and the pattern of secretion may vary according to their phenotype. Recent evidences have identified Wnt pathway as an emerging modulator of fibrosis.

Aims & Methods: The aim of the present study is to analyze the pattern of expression of macrophage markers and Wnt ligands in surgical resections from Crohn's disease (CD) patients with different disease behavior. CD patients were categorized according to Montreal classification (age at diagnosis, location and behavior). mRNA was isolated from resections of patients presenting an stricturing (B2) or a penetrating (B3) behavior or from patients with colorectal cancer (control). The expression of macrophage markers (CD206, CD86, iNOS, Arginase), Wnt ligands (Wnt1, Wnt2, Wnt2b, Wnt3, Wnt3a, Wnt3b, Wnt4, Wnt5a, Wnt5b, Wnt6, Wnt7a, Wnt7b, Wnt8a, Wnt8b, Wnt9a, Wnt9b, Wnt10a, Wnt10b and Wnt16) and DKK1 (inhibitor of Wnt signaling) was analyzed by RT-PCR.

Results: B3-patients seem to present a higher infiltration of macrophages since increased expression of markers classically used to detect pro-inflammatory (CD86) and regulatory/pro-resolving/pro-fibrotic phenotypes (CD206, ARG) was detected in this group. These patients also presented a generalized overexpression of Wnt ligands together with augmented DKK1 mRNA levels. B2-patients showed a more complex situation with ligands that present increased (Wnt3), reduced (Wnt2B) or unchanged expression in the absence of significant variations in the levels of macrophage markers (Table). Table. Relative (Gene/b-actin) mRNA expression (fold induction vs control group) of genes with detectable levels. Data are expressed as Mean ± SEM with n ≥ 7 in all groups and analyzed by ANOVA + Kewman-Keuls test. (*p < 0.05 vs control; #p < 0.05 vs B2).

Conclusion: Crohn's disease patients presenting a stricturing (B2) or a penetrating (B3) behavior undergoing surgical resection differ in the pattern of macrophage infiltration and Wnt signaling.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1618 CD16 POSITIVE CELLS EXPRESS TGFB AND MEDIATES MURINE INTESTINAL FIBROSIS

Introduction: M2 macrophages play a key role in injury repair and fibrosis. We have reported that STAT6-dependent macrophages mediate mucosal repair after TNBS-induced acute colitis¹ and that, in a chronic model, STAT6-deficient animals accumulate macrophages expressing the CD16 marker that promote intestinal fibrosis².

Aims & Methods: We aim to analyze whether the expression of the pro-fibrotic mediator TGFβ is related with this macrophage phenotype and the relevance of these cells in murine intestinal fibrosis. Murine peritoneal macrophages obtained from both WT or STAT6 (-/-) mice were treated with IL-4 (20 ng/ml), IL-10 (50 ng/ml) or vehicle and the mRNA expression of CD16 and TGFβ was analyzed 72h later by qPCR. WT or STAT6 (-/-) mice were weekly administered with TNBs (0.5, 0.5, 0.75, 0.75, 1, and 1 mg, intrarectally) or saline and were sacrificed 7 weeks after the first TNBs administration. The mRNA expression of CD16, TGFβ, Vimentin, Colla1, α-SMA, MMP2 and TIMP1 was evaluated in murine intestinal mucosa by qPCR. In all cases results were expressed as fold induction vs vehicle and the correlation between different measurements was analyzed using Pearson's correlation coefficient (r).

Results: A positive and significant correlation between CD16 mRNA and TGFβ mRNA was observed in isolated macrophages from WT mice (r=0.637, P=0.03) and STA6 (-/-) mice (r=0.677, P=0.002) receiving different treatments. In the mucosa of WT and STAT6 mice the expression of TGFβ showed a positive and significant correlation with CD16 mRNA (r=0.601, P<0.001), and with the expression of several fibrotic markers (vimentin: r=0.6537, P<0.0001; Colla1: r=0.5101, P=0.0003; α-SMA: r=0.4126, P=0.0048; MMP2: r=0.5729, P<0.0001; and TIMP1: r=0.3958, P=0.0071).

Conclusion: The expression of TGFβ is associated with CD16 positive cells and is involved in murine intestinal fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The intestinal inflammation is reduced by electrical stimulation of the efferent vagus nerve. Cholinergic output may be a target to minimize tissue damage in autoimmune disease. Cholinergic neural output can modulate innate immune responses through stimulation of $\alpha 7$ nicotinic acetylcholine receptors ($\alpha 7$ nAChR). GTS-21, a selective $\alpha 7$ nAChR agonist, has previously demonstrated to inhibit the inflammation associated with rheumatoid arthritis (RA). In this study we investigate whether GTS-21 protects against DSS-induced colitis and its potential mechanism.

Aims & Methods: Male BABL/c mice (8–10 weeks old, n=32) were randomly divided into 4 groups: normal control group, DSS-induced group, GTS-21 treatment control group (DSS-induced mice treated with GTS-21), α -BGT group (DSS-induced mice treated with α -BGT and GTS-21) (n=8, each group). DSS group was given final concentration of 3.5% DSS drinking water, the treatment group was treated with GTS-21 (20 mg/kg intraperitoneal injection) per day, α -BGT group was pre-treated with α -BGT (0.1 mg/kg/day, intraperitoneal injection) for 30 min prior to GTS-21 injection, and the control group received saline. Caco2 cells were randomly divided into 4 groups: normal control group, TNF- α -induced group, GTS-21 treatment control group, α -BGT group. TNF- α group of Caco2 cells were exposed by 25 ng/ml TNF- α . GTS-21 group were given 100 ng/ml GTS-21 for 30 min prior to TNF- α ; α -BGT group pre-treated with α -BGT (50 ng/ml) for 30 min prior to GTS-21 injection. BAY 11-2028 (NF- κ B inhibitor) group were given 50 ng/ml BAY-11-2028 for 30 min prior to TNF- α . Disease activity index, macroscopic scores, and colonic damage were determined. The intestinal permeability of mice was measured by fluorescein-isothiocyanate-dextran (FITC-Dextran) method. Western blot was used to detect the tight junction protein and NF- κ B associated protein expression.

Results: Compared with DSS-induced mice, DAI score decreased and colon length improved after administration of GTS-21 (9.13 \pm 0.74 cm vs 6.85 \pm 0.53 cm, P < 0.01), HAI score decreased (1.25 \pm 1.32 vs 10.5 \pm 2.64, P < 0.05). The $\alpha 7$ nAChR antagonist α -BGT can eliminate those protective effects (Figure 1). 2. The intestinal permeability improved after administration of GTS-21 compared with DSS-induced mice (49.52 \pm 28.59 ug/ml vs 157.40 \pm 32.40 ug/ml P < 0.05); whereas α -BGT can block this protection (115.50 \pm 6.10 ug/ml vs 49.52 \pm 28.59 ug/ml P < 0.05) (Figure 2, 3). 3. The expressions and distribution of tight junction protein in DSS-induced mice were enhanced after treatment with GTS-21 (p < 0.05) (Figure 4, 5). 4. GTS-21 attenuated the NF- κ B activation (p < 0.05). α -BGT administration reversed the inhibitory effect of GTS-21 (p < 0.05) (Figure 6). 5. GTS-21 improves the distribution of tight junction proteins in the intestinal epithelial cells induced by TNF- α (Figure 7). 6. GTS-21 reduces nuclear translocation of NF- κ B in Caco2 cells induced by TNF- α (Figure 8).

Conclusion: The $\alpha 7$ nicotinic acetylcholine receptors agonist GTS-21 can attenuate the intestinal inflammation in DSS-induced mice, which may be due to improving intestinal mucosal barrier function by enhancing the expression of tight junction protein.

Introduction: Intestinal fibrosis is a common complication of IBD and macrophages can contribute to fibrosis through the release of different mediators. We have recently reported that Wnt10b increase the deposition of collagen and promotes intestinal fibrosis in TNBs-treated mice (P015 ECCO 2017).

Aims & Methods: The aim of the present study is to analyze the pattern of expression of macrophages and the expression of Wnt10b in human macrophages from surgical resections from Crohn's disease (CD) patients with a B2-stricturing and B3-penetrating behavior according to Montreal classification (age at diagnosis, location and behavior) as well as from non-inflamed tissue from cancer patients. Resections were immediately processed and lamina propria mononuclear cells characterized by flow cytometry. Macrophages were identified within singlet viable leukocytes as CD45 + CD14 + CD64+. The percentage of CD206, CD16, CD163, CD86 and Wnt10b positive cells was analyzed in macrophages. Data are expressed as Mean \pm SEM % with n \geq 5 in all groups (P < 0.05* vs control, Student's t test).

Results: The percentage of macrophages identified as CD45 + CD14 + CD64+ constituted the 0.22 \pm 0.03% of total events in the control mucosa while represented the 1.35 \pm 0.40% in the mucosa from CD patients (p < 0.05). A high proportion of mucosal macrophages expressed CD206 in both, control (83.3 \pm 4.8%) and CD (89.6 \pm 3.9%). In these CD206+ cells, an increased expression of CD16 in CD mucosa was observed (Control: 34.5 \pm 6.8%; CD: 59.7 \pm 6.4%*) while that of CD163 was similar in both groups (control: 72.8 \pm 8.4%; CD: 85.2 \pm 7.3%). The analysis of Wnt10b in CD206+ showed a significantly higher expression in CD patients (56.6 \pm 4.2%) than in control samples (30.1 \pm 10.4%). Additionally, CD86+ macrophages were more abundant in CD mucosa (Control: 8.2 \pm 1.1%; CD: 29.3 \pm 10.2%*).

Conclusion: The mucosa of CD patients accumulate pro-inflammatory macrophages measured as CD86+ cells while those macrophages expressing the M2-marker CD206 alter their phenotype increasing the expression of both, CD16 and the profibrotic mediator Wnt10b.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1621 ANAEMIA PREVALENCE AND TREATMENT APPROACH FOR INFLAMMATORY BOWEL DISEASE

G. Bengi¹, H. Keyvan², H. Akpınar¹

¹Gastroenterology, Dokuz Eylul University Hospital, Izmir/Turkey

²Internal Medicine, Dokuz Eylul University Hospital, Izmir/Turkey

Contact E-mail Address: drgokselbengi@hotmail.com

Introduction: For inflammatory bowel disease (IBD), anaemia is the most frequently observed extra intestinal finding, prevalence of which varies from 6% to 74%. It's of great importance to determine and treat anaemia as it lowers patients' life quality and leads to labour loss. The main causes of anaemia in IBD are iron deficiency anaemia (IDA) and anaemia of chronic disease (ACD). In this study, we aim to specify the type and prevalence of anaemia along with a treatment approach for inflammatory bowel disease (IBD).

Aims & Methods: In this study, we aim to specify the type and prevalence of anaemia along with a treatment approach for inflammatory bowel disease (IBD). We conducted a retrospective study on 465 patients, who were diagnosed with IBD and followed up at our hospital from June 2015 to June 2016 (male: 254, female: 211, average age: 47 \pm 14.4, Crohn disease (CD): 257, Ulcerative Colitis (UC): 208). According to WHO criteria, anaemia occurs when haemoglobin value is below 13 g/dL in men and 12 g/dL in women.

Results: In our study, we determined that 50.3% of total 465 patients had anaemia, which was more frequent in women than men (64% vs. 39%, p < 0.001). Anaemia frequency was higher in CH cases (57%) than in UC cases (41%) (p=0.001). CD involvement were as follows: 54.5% in ileal involvement, 60.4% in colonic involvement and 58.5% in ileocolonic involvement. Furthermore, 27.5% of UC patients had proctitis (E1) involvement while 41% of them had involvement in left colitis (E2) and 31.5% had pancolitis involvement. There was no significant relation between anaemia frequency and duration of disease (p=0.216). We specified the following types of anaemia: IDA only 32.9% (77), ACD only 5.5% (13), IDA and ACD combination 6.8% (16), anaemia stemming from B₁₂/folic acid deficiency 6.4% (15), multiple anaemia 17.8% (41) and anaemia with no etiology 30.7% (72). 50% of patients with anaemia received treatment; 23% of IDA patients had oral iron intake and 41% of them had parenteral iron treatment while 53% of patients who were suffering from megaloblastic anaemia got B₁₂/folic acid treatment.

	CD206	ARG	CD86	Wnt2	Wnt2B	Wnt3	Wnt9A	Wnt10B	DKK1
CONTROL	1.9 \pm 0.4	1.5 \pm 0.3	2.7 \pm 0.6	2.3 \pm 0.6	1.4 \pm 0.2	1.4 \pm 0.2	1.3 \pm 0.2	1.2 \pm 0.3	1.7 \pm 0.2
B2	3.1 \pm 0.8	1.4 \pm 0.4	3.4 \pm 0.7	3.3 \pm 0.7	0.4 \pm 0.1*	2.7 \pm 0.6*	2.7 \pm 0.6	0.6 \pm 0.2	2.1 \pm 0.7
B3	7.7 \pm 1.6*#	3.2 \pm 0.8*#	7.0 \pm 1.8*#	5.1 \pm 1.2	1.7 \pm 0.3#	6.0 \pm 1.0*#	3.9 \pm 1.7*	2.3 \pm 0.4*#	6.1 \pm 1.7*#

Conclusion: We found out that almost half of all IBD patients (50.3%), whom we followed up, had anaemia, the most frequent reason of which was IDA. Almost half of these patients received anaemia treatment. We should increase the treatment rate in our IBD patients that have anaemia.

Introduction: IBD is a chronic disorder of the gastrointestinal tract characterized by disruption of epithelial barrier function and gut inflammation. Evidence supports a relevant role of succinate, an intermediate of the tricarboxylic acid cycle¹, in inflammation and the succinate receptor, SUCNR1, has been recently related with rheumatoid arthritis².

Aims & Methods: To analyze the role of SUCNR1 in a murine model of colitis induced by TNBS. WT or SUCNR1^{-/-} mice received TNBS (3.5 mg/20g mice, intrarectally) or vehicle (EtOH 40%) and were weighed daily (results are expressed as percentage vs the weight at day 0) and mice were sacrificed 2 and 4 days after TNBS administration. Colon length and mucosal histology were evaluated according to Wallace Score (1–10). The mRNA expression levels of *iNOS*, *Arginase 1*, *COX-2*, *TNF-α*, *IL-1β*, *IL-6* and *IL-10* was analysed by qPCR. **Results:** Treatment of mice with TNBS induced a loss of body weight that peaked 2 days after treatment. Subsequently, mice began to recover and, four days after treatment, body weight reached similar values to those of control animals. In TNBS-treated SUCNR1^{-/-} mice compared with TNBS-treated WT mice: a) the loss of body weight was significantly ($P < 0.05$) attenuated ($96.99 \pm 0.7\%$ vs $91.78 \pm 1.1\%$); b) the reduction in colon length was prevented (6.6 ± 0.2 vs 5.2 ± 0.2 cm); c) damage score was significantly reduced (3.5 ± 0.2 vs 4.8 ± 0.5) two days after TNBS treatment. d) The increase in the expression of pro-inflammatory molecules was significantly prevented ($P < 0.05$) (table 1) while no significant differences were detected in the expression of *COX-2* (Table 1).

Table1: mRNA expression of different molecules detected in the colon of TNBS-treated mice. Results are expressed as fold induction vs the value obtained in WT mice.

	iNOS	ArgI	COX-2	TNFα	IL-1β	IL-6	IL-10
WT	2.6 ± 0.6	1.6 ± 0.7	1.1 ± 0.2	2.6 ± 0.6	1.7 ± 0.2	4.2 ± 1.0	0.8 ± 0.1
KO	1.5 ± 0.4	2.8 ± 1.0	1.3 ± 0.3	1.3 ± 0.2	1.2 ± 0.1	1.7 ± 0.3	1.4 ± 0.2

Conclusion: Activation of the succinate receptor SUCNR1 mediates murine colitis. These findings highlight the biological significance of SUCNR1 and open the door to novel approaches for IBD treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1623 ZIP7 INDUCES DISRUPTION OF THE INTESTINAL BARRIER THROUGH ACTIVATION OF ENDOPLASMIC RETICULUM STRESS IN INFLAMMATORY BOWEL DISEASE

J. Sun, Q. Zhan, F. An

Wuxi People's Hospital, Nanjing Medical University, wuxi/China

Contact E-mail Address: jingdianjing99@126.com

Introduction: Inflammatory bowel disease (IBD) is a chronic intestinal inflammatory disease with a tendency to recurrence, and intestinal barrier disorders play a key role in its development. The deficiency of zinc is a clinical manifestation and can promote the development of IBD. Zinc Transporter Member 7 (ZIP7) is a gate keeper protein in the intracellular release of zinc in cells. Recent studies revealed that ZIP7 helps to maintain the intestinal mucosal integrity. In addition, ZIP7 can regulate endoplasmic reticulum stress.

Aims & Methods: Our aim was to investigate the role of ZIP7 in IBD initiation and progression. We investigated the expression of ZIP7 in the intestinal mucosa of IBD patients and in interleukin-10-gene-deficient (IL10^{-/-}) mice, and assessed the relation between ZIP7 and disease activity. ZIP7 upregulated/downregulated lentivirus was used to infect IEC6 and HIEC cells, then we evaluated the expression of inflammatory factors, mucosal tight junction proteins (Occludin and ZO-1), and proteins related with endoplasmic reticulum stress (IRE1, XBP1, TRAF2, ASK1 and p-JNK). In addition, we used siRNA to silence IRE1 and SP600125 to

inhibit the JNK pathway respectively, then evaluated the effect of endoplasmic reticulum stress on mucosal tight junction proteins.

Results: We found that ZIP7 was downregulated both in the intestinal mucosa of IBD patients and in IL10^{-/-} mice, which was associated with disease activity. In IEC6 and HIEC cells, the expression of mucosal tight junction proteins was consistent with the level of ZIP7, but the expression of inflammatory factors and endoplasmic reticulum stress associated proteins were on the contrary. After the silence of IRE1 and the inhibition of JNK pathway, the expression of mucosal tight junction proteins was partly resumed in ZIP7 downregulated cells.

Conclusion: ZIP7 induces disruption of the intestinal barrier, which was associated with activation of endoplasmic reticulum stress in IBD. It is expected to provide a novel mechanism of IBD and provide a new target for the treatment of IBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1624 EFFECT OF T CELL ACTIVATION AND INFLAMMATION ON THE INTERACTION BETWEEN T CELLS AND ENTERIC GLIAL CELLS

Introduction: The accumulation of immune cells around the enteric neuronal ganglia of patients affected by Crohn's disease is predictive of disease recurrence after post-operative resection. As cells of the enteric nervous system could be implicated in the formation of these myenteric and submucosal plexitis in chronic inflammatory digestive diseases, inter-relationship between T cells and enteric glial cells (EGC) was investigated.

Aims & Methods: To analyse the interactions between immune and enteric neural cells, EGC isolated from the myenteric plexus of the rat digestive tract were co-cultured with CFSE-labeled T cells. Impact of T cell activation on neuro-immune interactions was investigated by treating T cells with anti-CD3/anti-CD28 antibodies. To determine whether inflammatory conditions favored the contacts between glial and immune cells, EGC were treated with LPS or TNF/IL1 prior their exposition to T cells. After 2 hours, non-adherent cells were removed and the T cells interacting with EGC (SI00⁺) were counted. Immunocytochemistry were also used to characterize the subpopulations of T cells (CD4⁺, CD8⁺) that contact glial cells.

Results: Analyses reveal that non-activated T lymphocytes are capable of interacting with EGC. They also show that activation of T cells with anti-CD3/anti-CD28 antibodies increases the number of T lymphocytes interacting with EGC. Interestingly, an increased number of EGC-T cell interactions was observed after pretreatment of EGC with inflammatory stimuli. This phenomenon was also noted with activated T cells. Characterization of T cells show that both CD4 and CD8 cells are capable of contact with EGC.

Conclusion: Our present data reveal that EGC interact with T cells. These contacts are favored by T cell activation but also by EGC exposure to inflammatory cytokines. Further experimentations are required to characterize these neuro-immune interactions but they suggest that EGC-T cell contact may play a crucial role in case of inflammatory bowel diseases. This work is supported by the Association François Aupetit.

Introduction: Enteric glial cells (EGC) are essential to intestinal epithelial barrier (IEB) homeostasis. In healthy intestines, EGC reduce IEB permeability and promote mucosal healing. In inflammatory bowel disease (IBD) such as Crohn's Disease (CD) and Ulcerative Colitis (UC), both EGC phenotype and IEB functions are altered, but putative involvement of EGC in IBD pathogenesis remains unknown. If the astrocyte reactivity is well studied, the reaction of EGC to chronic inflammation is not well documented. We investigated whether EGC impact on IEB permeability was altered in an inflammatory environment and in EGC from IBD patients.

Aims & Methods: Rat EGC as well as human EGC from control, CD and UC patients were stimulated with the cytotoxic TI (TNFα+IL1β; 1 to 100 ng/ml) or LPS for 2 or 4 days. Reactive EGC phenotype where characterized and reactive EGC functional impact on IEB permeability was studied (i) *in vitro* using human intestinal epithelial cells (IEC) in a non-contact co-culture model, or (ii) *in vivo* by grafting the treated rat EGC in colon wall of Sprague Dawley rats.

Results: Rat and human control EGC induced a significant reduction of IEB paracellular permeability after TI treatment when compared with untreated or LPS treated EGC. LPS or TI treatment had no significant effects on IEC alone. *In vivo* colon wall grafting with control EGC did not modified the permeability whereas colon wall grafting with EGC preconditioned by TI significantly reduced

the permeability when compared to control animals. Human EGC from control or UC patients treated with TI induced a decrease in IEB permeability too, but EGC from CD patients did not.

Conclusion: This work is not only the first evidence showing that reactive EGC can have beneficial effects upon IEB permeability, but also shows that EGC from CD but not UC patients have lost these reactivity. This could define EGC as active players in CD pathogenesis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1626 PROSTACYCLIN REVERSES COLITIS THROUGH THE DOWN REGULATION OF INTESTINAL EPITHELIAL PERMEABILITY

Introduction: In inflammatory bowel disease (IBD) both intestinal epithelial barrier (IEB) permeability and PTGIS expression are altered. Nevertheless the role of the lipid mediator PGI₂ produced by PTGIS in IEB regulation is unknown. The present study concerns the control of IEB permeability by PGI₂ and its involvement in the development of colitis.

Aims & Methods: PGI₂ production from control or IBD biopsies was established using high sensitivity liquid chromatography tandem mass spectrometry. Consequences of flolan PGI₂ analogous supplementation were evaluated in a DSS-induced mice model of colitis, measuring disease activity index (DAI), inflammation (pro-inflammatory cytokine mRNA) and IEB permeability (sulfonic acid flux). Molecular mechanisms involved were assessed by quantification of junctional and pro-proliferative vs pro-apoptotic protein expression (western blot and immunostaining). Eventually PGI₂ impact on reversing IEB breakdown was assessed *ex vivo* measuring permeability of mice or human mucosal explants treated with staurosporine apoptosis inducer, or permeability of IBD biopsies both treated or not with flolan.

Results: Biopsies from IBD patients had lower PGI₂ production compared to control patients, and addition of flolan reduced their permeability. *In vivo* PGI₂ supplementation significantly reduced DAI, and inflammation (Interferon mRNA) as well as reduced IEB permeability. DSS-induced cleavage of Caspase 3 is normalized by flolan. *Ex vivo*, staurosporine-induced permeability of mice or human mucosal explants is entirely inhibited by flolan.

Conclusion: This study not only presents a role of PGI₂ in controlling IEB permeability through the regulation of apoptosis mechanisms, but also reveals that increased permeability in IBD patients can be fixed by PGI₂ supplementation.

Introduction: 7 α -hydroxy-4-cholesten-3-one (7HCO) is a reliable method to diagnose bile acid malabsorption (BAM). Since 7HCO is an intermediate metabolite in the bile acid synthesis, increased levels reflect bile acid production, which is the case in BAM.

Aims & Methods: We evaluate retrospectively, prospectively collected clinical data during the first year after implementation of a new test using ultrahigh performance liquid chromatography coupled to mass spectrometry to measure 7HCO (see reference). In adult patients with clinical suspicion of BAM, unexplained diarrhea and a subgroup with obesity 7HCO was measured. Levels <30 ng/ml are considered as normal values. The decision to treat with cholestyramine was at the discretion of the treating physicians.

Results: We performed 126 7HCO analysis in 112 patients (62% female, mean age 51+/-16 years) with a mean level of 84+/-91 ng/ml. Cholestyramine treatment was more likely initiated in patients with Crohn's disease (RR 1.8; 95%CI 0.9-3.7) or after ileocecal resection (RR 3.1; 95%CI 1.7-5.7). Diarrhea improved in 60% of patients with a 7HCO level above 40 ng/ml. Thresholds of 60 or 100 ng/ml do not improve prediction of response to cholestyramine treatment.

7HCO measurement in subgroups

Subgroups	Number	Mean [ng/ml]	SD	Range#
Diarrhea	79	94*	96	<5 - >300
No diarrhea	33	59*	71	<5 - >300
Cholestyramine treated	27	167§	105	11 - >300
Cholestyramine untreated	85	57§	67	<5 - >300
Crohn's disease (CD)	18	182	105	13 - >300
Ileocecal resection (IR)	26	197	105	28 - >300
CD + IR	13	214	95	41 - >300
Obese (mean BMI 39.1 kg/m ²)	21	62	49	6-244

*p < 0.05; §p < 0.001; #Validation Range 5-300 ng/ml

Conclusion: A 7HCO measurement above 40 ng/ml seems to be associated with a good response to cholestyramine treatment, which suggests clinical bile acid malabsorption. However, most patients have higher levels, particularly in Crohn's disease after ileocecal resection. These preliminary results warranted confirmation on a larger scale.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Ulcerative colitis (UC) is a clinical type of inflammatory bowel diseases. The pathogenesis of UC remains unclear. Nowadays the role of T-helper type 17 (Th17) as well as cytokines they release is discussed in pathogenesis of autoimmune inflammation in UC.

Aims & Methods: The aim of study is to analyze the serum levels of following cytokines: interleukin (IL)-17A and F, 21, 22, 23, 10 in UC patients both in the acute stage of disease and remission. Forty eight UC patients in the acute stage and twenty patients in remission were included into the study. Serum cytokine levels were analyzed using multiplex immunoassay for Th17 cytokines (Bio-Rad, USA). Statistical analysis was performed using STATISTICA 6.0 Software Package. The control group consisted of 11 healthy volunteers.

Results: Statistically significant increase of IL-17A level (15 pg/ml [12.11;23.38]); 14.68 pg/ml [11.29;17.19] respectively) was observed in patients with UC both in acute stage and remission compared to controls (7.36 pg/ml [5.18;8.06], p=0.00007, p=0.00029 respectively). The same trend was observed regarding IL-21, which median values were higher both in acute stage (156.51 pg/ml [133.44;233.53]) and remission (144.02 pg/ml [133.44;154.43]) compared to control group (98.31 pg/ml [89.14;124.86]), and showed statistically significant differences (p=0.00077, p=0.0054 respectively). Besides it was revealed that IL-17F and IL-22 were also higher in acute stage (136.5 pg/ml [68.25;228.185] and 3.76 pg/ml [1.5;5.83], respectively) compared to controls (48.7 pg/ml [38.7;87.6]; and 2.6 pg/ml [1.7;3.2], respectively), however differences were not statistically significant (p=0.06; p=0.172, respectively). Increase of described cytokines levels could be a sign of Th17 functional overactivity suggesting autoimmune type of inflammation. Statistically significant increase of IL-10 in remission (27.99 pg/ml [17.53;33.55]) compared to controls (4.36 pg/ml [3.26;15.25], p=0.0046) was found as well. IL-10 was also higher in patients with acute stage (21.93 [3.61;35.35]) compared to controls, however differences were not statistically significant (p=0.065). IL-10 as an anti-inflammatory cytokine characterizes the activity of regulatory T-cells which suppress autoimmune inflammation. In addition, it was revealed that the level of IL-23 which stimulates Th17 differentiation was higher both in acute stage (258.4 pg/ml [55;367.49]) and remission (244.93 pg/ml [200.26;301.93]) compared to controls (124.3 pg/ml [107.9;296.04]), however differences were not statistically significant.

Conclusion: Increase of IL-17A, IL-17F, IL-21, IL-22 levels could be a sign of Th17 functional overactivity suggesting autoimmune type of inflammation. IL-17A and IL-21 produced by Th17 cells might be considered as markers of active autoimmune inflammation in UC patients.

Introduction: The steroid-refractoriness is a common complication of ulcerative colitis (UC), which appears unpredictably. Several mechanism of action (MoA) has been implicated in corticosteroid failure. However, there are no conclusive studies on the molecular functions involved in UC steroid-refractoriness.

Aims & Methods: Therefore, we decided to know in depth the MoA related to the steroid failure, exploring transcriptomic data from a cohort of patients with UC treated with glucocorticoids. RNA from rectal biopsies was obtained before and on the 3rd day of glucocorticoid treatment. Then, whole-genome expression using microarrays (Illumina, USA) and profiles microRNA by sequencing (Illumina, USA) were analysed. After quality control, omics data were compared between phenotypes. The results of these comparisons were integrated into mathematical models generated by means of Systems Biology.

Results: These models reproduce the updated molecular interactions on glucocorticoids and UC, and integrating our experimental data, we identified a potential MoA that includes 64 key proteins, 18 of them capable of perfectly classifying patients with a good response to glucocorticoids and the non-responders. The biological functions of these proteins have been associated with inflammation (e.g. RelA), glucocorticoid receptor transcription (e.g. NR3C1 and NCOA3) and angiogenesis (e.g. VEGF), mainly. But among these 18 proteins, the ANP32e has never been related to either steroid-refractoriness or ulcerative colitis. ANP32e is a chaperone linked to H2A-H2A.z exchange (H2A.z is part of the nucleosomes flanking DNA regions recognized by the glucocorticoid receptor). Additional WB and immunofluorescence assays confirm differences in the intestinal levels of ANP32e and in the nuclear localization at baseline, between patients with different responses to glucocorticoids.

Conclusion: In conclusion, this study has identified a potential new MoA related with UC steroid-refractoriness involving chromatin remodeling modifications.

Introduction: The intestine is populated with myriads of bacteria, which form a complex ecosystem and have tremendous impact on our health. In inflammatory bowel disease (IBD), shifts in microbiota composition and a reduction in overall diversity have been described. There are attempts to therapeutically transfer the microbiota from healthy subjects to persons suffering from intestinal disease. While in case of *Clostridium difficile* infections, this approach proves to be very efficient; the therapeutic value of fecal microbial transfer (FMT) in IBD is still unclear. In mouse models of intestinal inflammation, the effect of FMT has been studied poorly and if so, germ-free or antibiotic-treated animals have been used—models that poorly reflect the situation in human IBD patients. Here, we addressed how transmission of microbiota from healthy to diseased mice affects recovery from acute colitis.

Aims & Methods: Acute colitis was induced in 12–14 week old C57B6 mice by administration of 2% DSS in the drinking water for 7 days. Mice with colitis were co-housed with healthy mice after removal of DSS. Due to coprophagy, this results in fast transfer of the microbiota between co-housed mice. To analyse changes in the composition of microbiota over time, stool samples were taken every second day and sequenced for the V4 hyper-variable region in the bacterial 16S DNA.

Results: As expected, DSS treatment resulted in severe weight loss, and even 7 days after withdraw of DSS (day 15), histology confirmed severe colitis. Intestinal inflammation was accompanied by an overall reduction of microbial diversity (decreased Shannon index, $p < 0.01$), and a marked shift in the composition of the microbiota (increased abundance of Verrucomicrobia, Cyanobacteria and some families of Firmicutes [mainly Clostridiaceae], although overall abundance of Firmicutes was decreased [$p < 0.01$ for all]). However, on day 15, these changes were less pronounced, indicating a normalization of the microbiota composition upon recovery. DSS-treated mice which were co-housed with healthy littermates after colitis induction, showed faster recovery (earlier weight gain, reduced histological scores, reduced levels of the infiltration marker myeloperoxidase (MPO), less pronounced shortening of the colon, $p < 0.01$ for all) and an earlier normalization of the microbiota composition.

Conclusion: Our results indicate that co-housing of DSS-treated mice with healthy mice results in transfer of healthy microbiota to diseased mice, and promotes recovery from colitis. This indicates that introduction of a “healthy” microbiota might have beneficial effects during intestinal inflammation and

opens the possibility to systematically study the effect of genetic alterations in donor and/or recipient on the efficacy of FMT.

Introduction: In Crohn's Disease (CD), colonic phenotype of the ileum has been reported in severe lesions, but not in CD ileum with no lesions or with early post-operative recurrence (1).

Aims & Methods: In a prospective study at 5 years, we aimed to address whether colonic phenotype of the ileum may represent a subclinical marker of clinical postoperative recurrence in CD. At this purpose, clinical recurrence was assessed yearly for 5 years in a cohort of CD patients with colonic phenotype of the ileum already defined at surgery, 6 and at 12 months after ileo-colonic resection (1). A cohort of CD patients with clinical and endoscopic recurrence already assessed and reported at 6 and 12 months after ileo-colonic resection (1), was clinically followed up for additional 4 years. In the 5 years follow up, indication for treatments, haematochemical, radiological and/or endoscopic assessments was given according to current European guidelines (2). Haematochemical assessments included whole blood count, ESR, serum CRP evaluation yearly for 5 years, with possible additional assessments, according to clinical indications. Clinical recurrence (CDAI > 150) was assessed yearly for 5 years. Colonic phenotype of the ileum was already reported at surgery, at 6 and 12 mos, according to the expression of sulfomucins (colon mucin-type) and sialomucins (small intestine mucin-type) (1). In the present study, correlation between the percentage of expression of sulfomucins and clinical recurrence was evaluated yearly for 5 years. Statistical analysis: results expressed as median (range), correlations were assessed by the Spearman correlation test, differences between groups by the unpaired T test.

Results: After ileo-colonic resection, clinical follow up at 5 years was completed by 17/19 (89.4%) CD patients enrolled (12 males, age 41 [17–57]). The percentage of expression of sulfomucins (colon phenotype) as assessed in the ileal surgical specimens was significantly correlated with the CDAI score at 4 years ($r = 0.62$; $p = 0.007$) and at 5 years ($r = 0.6$; $p = 0.010$). Differently, in the ileal biopsies at 6 months, colonic phenotype of the ileum, evaluated by the expression of sulfomucins was significantly correlated with the CDAI score at 6 months ($r = 0.68$; $p = 0.003$). The percentage of expression of sulfomucins in the ileal biopsies at 12 months was significantly correlated with the CDAI score at 6 months ($r = 0.57$; $p = 0.015$) and at 2 years ($r = 0.53$; $p = 0.02$). The ileal expression of sulfomucins in the surgical specimens at surgery was higher in patients with vs without clinical postoperative recurrence at 2 years (40 [10–99] vs 5 [0–50]; $p = 0.04$). The expression of colon mucin-type in the ileal biopsies at 12 months was higher in patients with vs without clinical recurrence, both at 12 months (30 [1–40] versus 0 [0–35]; $p = 0.02$) and at 2 years (30 [0–40] versus 0 [0–35]; $p = 0.029$). No correlations were observed between the percentage of expression of sulfomucins at surgery, at 6 or at 12 months and the haematochemical parameters considered.

Conclusion: In CD, colonic phenotype of the ileum as assessed by the expression of ileal sulphomucins, may represent a predictive marker of clinical recurrence after ileo-colonic resection for CD.

Introduction: Immunization of a quadrivalent influenza vaccine (A/California/7/2009(H1N1) pdm09, A/Switzerland/9715293/2013(NIB-88) (H3N2), B/Phuket/3073/2013, and B/Texas/2/2013) began in the 2015/2016 season. We assessed the immunogenicity and booster effect of quadrivalent influenza vaccine for adult inflammatory bowel disease patients treated with immunosuppressive drugs and/or anti-TNF- α agents.

Aims & Methods: Single vaccination group and booster group were randomly assigned to adult patients with crohn's disease or ulcerative colitis, and quadrivalent influenza vaccine was administered subcutaneously. Serum samples were collected at 3 points (before vaccination, 4 weeks after vaccination and after the end of influenza season) in the single group and 4 points in the booster group (before vaccination, 4 weeks after the first vaccination, 4 weeks after the second vaccination and after the end of the influenza season). Antibody titer against each influenza strain was measured by inhibition of hemagglutination.

Results: A total of 132 patients with IBD were randomly assigned to single vaccination and booster groups. Eighteen patients received immunomodulatory monotherapy and 20 received anti-TNF- α single agent therapy. Nineteen patients received combination therapy of immunosuppressant and anti-TNF- α agents. No significant difference between the single vaccination group and booster group was observed (geometric mean titers: H1N1: p=0.81; H3N2: p=0.79; B/Phuket: p=0.82; B/Texas: p=0.84). In patients treated with infliximab, seroprotection rate (SP%) and seroconversion rate (SC%) tended to be lower in influenza A strains in patients who maintained blood concentrations (SP%: H1N1: OR 0.37 (0.11–1.21); H3N2: OR 0.22 (0.07–0.68), SC%: H1 N1: 0.23 (0.06–0.91); H3N2: 0.19 (0.06–0.56)).

Conclusion: Serological response rate to influenza vaccination was low in IBD patients receiving immunosuppressant therapy, especially infliximab, even with a quadrivalent influenza vaccine.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The global incidence of inflammatory bowel disease (IBD) is increasing. Migration may influence disease epidemiology. The UK demographics are affected by sustained migration from South Asia. The incidence of UC in South Asians (SA) was previously reported as higher than the Caucasian population.^{1,2} These single centre studies were done over 20 years ago. The current epidemiology of IBD in the multiethnic UK is unknown.

Aims & Methods: We aimed to describe the UK incidence of IBD and distribution within ethnic groups. Census data (2011) was used for background population size, ethnic groups and to identify areas with high SA populations where Indian and Pakistani were the predominant groups. The incidence was calculated by using the number of subjects in each ethnic group in the background population as the denominator. Adult patients (>16 years) with newly diagnosed IBD (fulfilling Copenhagen diagnostic criteria) were prospective recruited over one year in 7 catchment areas with high SA population. Data including demographics ethnic codes and disease phenotype (Montreal classification) was collected onto the Epicom database. Chi-squared test was used to detect differences in IBD incidence between ethnic groups. A p value <0.05 was considered significant.

Results: Over 1 year IBD was diagnosed in 351 cases; 219 ulcerative colitis (UC), 107 Crohn's disease (CD) and 26 Inflammatory bowel disease unclassified (IBDU). Collective crude incidence rates were 15.54/100,000 for IBD, 9.69/100,000 for UC, 4.80/100,000 for CD and 1.01/100,000 IBDU. (Table 1) Crude IBD incidence rates varied between populations: lowest was 6.81/100,000 in Pennine, North Manchester and highest 26.11/100,000 in Leicester. Overall incidence of UC was higher than CD (9.69/100,000 vs 4.80/100,000) and was consistent for all populations except Pennine (3.31/100,000 for CD and 2.76/100,000 UC) Of the total number of IBD cases recruited 298/351 were coded as Caucasian, Indian or Pakistani. IBD, UC and CD incidence was similar between Pakistani and Caucasian groups. UC incidence was significantly higher in the Indian population compared to Caucasians and Pakistanis (p < 0.001). Data for disease phenotype was available for 160/219 patients with UC (24% E1, 42% E2 and 34% E3). There was no significant difference in disease extent between ethnic groups.

Conclusion: The incidence rates for IBD in seven urban populations in England are similar to recent data from Western Europe (IBD 18.5/100,000, UC 9.8/100,000 CD 6.3/100,000 and IBDU 2.4/100,000). Ethnic-adjusted incidence rates showed that Indians have higher incidence of UC than Caucasians and Pakistanis with highest observed incidence in Northwest London. These findings are consistent with previous data suggesting that Indians have a higher predisposition for UC. Genetic, environmental and dietary factors may be responsible for differences and further analyses are underway. Better understanding of the susceptibility of Indians to UC may lead to the underlying cause of UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Inflammatory bowel diseases (IBD-Crohn's disease (CD); ulcerative colitis (UC)) are lifelong inflammatory conditions of the gastrointestinal tract. IBD-associated colorectal cancer (CRC) accounts for approximately 1–2% of all cases of CRC. Although data on mortality rates in IBD patients are controversial, CRC has been shown to account for approximately 10–15% of all deaths among IBD patients. The aim of our nationwide registry was to prospectively collect IBD-related mortalities and all types of malignancies diagnosed in the Hungarian IBD population.

Aims & Methods: Data on all death and malignancies developed between 2015 and 2016 in IBD patients were recorded. Each members of the Hungarian Society of Gastroenterology were prospectively interviewed 3 monthly by personal emails to report both death and malignancies observed in their patient population. Demographic and clinical data including previous immunosuppressive and biological therapy were also collected.

Results: Fifty-five newly diagnosed malignancies were reported (mean age: 49.3 years old, mean disease duration was 16.9 years; male/female ratio was 34/21): 30 CRC (mean age: 52.5 years, mean disease duration: 19.9 years, male/female ratio was 22/8) one of them had 1 pouch cancer previously colectomized because of sigmoid tumor, 4 skin, 3 lung, 2 breast, 2 cervix, 2 pancreas, 2 liver, 1 gallbladder, 1 prostate, 1 esophageal, 1 salivary gland, 1 thyroid, 1 central nervous system, 1 tonsil, laryngeal cancer, 1 B-cell lymphoma and 1 retroperitoneal sarcoma throughout the examined period. Twenty-two of the 30 CRC cases were associated with UC, 60% with pancolitis. Twenty of the 30 cases were located on the rectosigmoid region, 2 had multiple localization. Nineteen deaths were reported during the examined period. Ten fatal cases were related to IBD (6 males 4 females; 1 CD patient with rectal cancer, 1 patient with pouch cancer, 1 CD patient with pancreas, 1 CD patient with interstitial pneumonia, 1 UC and 2 CD patients with septic complications, 1 UC patient with meningitis, 1 UC patient with hemorrhagic shock, 1 CD patient with intestinal perforation). Age of death was significantly lower in case of IBD-related mortality compared to the other patients and general population (51.9 vs. 65 vs. 73.4 (data from Central Statistical Office 2013, Hungary) years, $p < 0.05$). Immunosuppressive and/or biological therapy was ever given for 4/10 patients with IBD-related mortality.

Conclusion: The most frequently observed IBD-related malignancy is CRC, which can be multifocal and mainly involved the distal part of the colorectum typically in UC patients with pancolitis and chronic activity. Malignancy and septic complications were the leader causes of IBD-related mortality characterized by earlier death than in the rest and in the non-IBD population.

Introduction: The increasing incidence of anal canal (AC) carcinomas in men and women requires better knowledge on Human papillomavirus (HPV) infection at this site and its risk factors. Higher incidence of AC cancers in Crohn's disease (CD) patients is strongly suggested in the literature, without knowledge on HPV involvement. A gastroenterology population offers the opportunity to study a mixed and non-sexually at risk selected population and to study anal HPV infection in CD patients.

Aims & Methods: The aim of the study was to assess AC HPV infection prevalence and its risk factors in a gastroenterology population. The 'Human PAPILLomavirus ANal infection' - PAPILLAN- study took place in a French university hospital gastroenterology unit. Consecutive patients were prospectively recruited at the occasion of a colonoscopy, whatever the indication. On the colonoscopy day, under general anesthesia, AC smear was sampled with a dedicated brush for molecular analysis. HPV detection and genotyping was performed with the INNO-LiPA assay. Risk factors for any HPV, and high risk (HR) HPV infection were assessed by bivariate and multivariate analysis after logistic regression.

Results: A total of 469 consecutive patients (median age 54 years, 52% women) had suitable anal samplings for HPV DNA detection. Among them 101 had inflammatory bowel disease (IBD), 70 had CD. 112 patients had at least one immunosuppressive treatment for IBD or another condition. Overall 34% of the population had a detection of any HPV type in AC smears. HR HPV prevalence was 18%, LR HPV prevalence was 9% and HPV16 prevalence was 7%. Most prevalent HR HPV types were, by decreasing order: HPV16, HPV51, HPV52 and HPV39. Among all patients with HPV positive or HR HPV positive samples, 65.6% and 65.9% were women, respectively ($p < 0.0001$; $p = 0.0035$, compared to men). Regarding medical history, HR HPV and HPV16 prevalence were significantly higher in Crohn's disease patients (30%, $p = 0.0051$; 14%, $p = 0.0072$, compared to the rest of the study population). Eleven/12 patients (50%) with perianal CD had an AC infection with any HPV. Multivariable analysis associated female gender and history of sexually transmitted disease with the presence of any HPV in AC; and female gender, history of sexually transmitted disease, lifetime and past year number of sexual partners, active smoking and immunosuppressive treatment (OR 5.3) with the presence of HR HPV.

Conclusion: We demonstrated that CD patients harbor more frequent AC infection with HR HPVs and that immunosuppressive treatment is an independent factor for HR HPV infection at this site. These findings strongly support prophylaxis with vaccination and adequate screening in our patients.

Introduction: Extended spectrum beta-lactamase producing Enterobacteria (ESBL-E) are the most frequently found multi-drug resistant bacteria colonizing the gut of inflammatory bowel disease (IBD) patients.¹ Changes in the microbiome may act as a trigger in IBD inflammation process.

Aims & Methods: The aim of the study was to analyze whether gut colonization with ESBL producing Enterobacteria is associated with clinically relevant disease activity increase in ulcerative colitis (UC) and in Crohn's disease (CD). All consecutive patients with confirmed UC and CD diagnosis, previously hospitalized in two largest tertiary medical care centres in Riga, Latvia during a 7-year period (2010–2016) were included in the study, interviewed, rectal swabs were collected, Enterobacteria were cultured and analyzed for ESBL presence according to EUCAST guidelines. To clinically evaluate disease activity UC patients were evaluated according to Mayo score, Montreal classification, adapted Truelove and Witt's criteria and CD patients according to Crohn's disease activity index (CDAI), suggested by ECCO IBD guidelines (2016).

Results: A total of 101 patients with UC and 47 patients with CD were tested for gut colonization with ESBL-E. We found that 12 (11.9%) of the UC patients and 5 (10.6%) of the CD patients were colonized with ESBL-E. Statistically significant differences were found in all UC clinical disease activity scores between patients with and without gut colonization with ESBL-E and showed tendency towards statistical significance in CD. The mean disease activity according to Mayo score in UC patients without ESBL-E colonization was 3.44 (SD = 2.07), whereas in patients with ESBL-E colonization it was 5.08 (SD = 2.84) ($p = 0.015$). Most of the UC patients without ESBL-E colonization ($n = 63$; 70.8%) were in clinical remission, whereas half of the patients with ESBL-E colonization ($n = 6$;

50%) had mild to moderate to severe disease activity, according to Montreal classification disease severity section ($p=0.037$). Most of the UC patients without ESBL-E colonization ($n=81$; 91%) had mild disease activity, whereas half of the patients with ESBL-E colonization ($n=6$; 50%) had moderate disease activity, according to modified Truelove and Witt's criteria ($p < 0.001$). Most of the CD patients without ESBL-E colonization ($n=38$; 90%) had moderate disease activity, whereas most of the patients with ESBL-E colonization ($n=3$; 60%) had severe disease activity, according to CDAI ($p=0.05$).

Conclusion: Gut colonization with ESBL-E might increase disease activity in out-patients with IBD. Such finding could be clinically relevant and help to improve diagnostic and treatment protocols for IBD patients, because eradication of ESBL producing bacteria might reduce IBD disease activity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Smoking has a differential effect on inflammatory bowel diseases (IBD); deleterious for Crohn's disease (CD) and protective for ulcerative colitis (UC). Thickness of the mucus layer, immune system (cytokines production), microvasculature and intestinal microbiome are potential mechanistic factors influenced by the nicotine and numerous other substances. It has been hypothesized that smoking cessation is associated with the second peak of diagnosis in UC patients after 50 years old. Our aim was to confirm this hypothesis using data on smoking status at IBD diagnosis.

Aims & Methods: Adult IBD patients included in the Swiss IBD cohort from November 2006 to November 2015 were asked about their smoking status at diagnosis. We compared the proportion of former smokers in 10-year groups of UC and CD patients.

Results: 2361 IBD patients (1366 CD, 995 UC) were included in the analysis. Among them 52% of CD and 24% of UC patients were smokers at diagnosis (proportion of smokers in Switzerland (2014): 29%). The higher proportion (66%) of former smokers at diagnosis was in the 50 to 60 years old group of UC patients compared to only 26% in CD patients between 40 to 50 years old ($p < 0.001$). On a gender basis, the higher proportion of former smokers is particularly significant high among male 50–60 years old with UC (68%) and persists among them over 60 years old (52%).

Conclusion: The proportion of former smokers at diagnosis increases dramatically and significantly over years in UC patients compared to CD patients. A peak was reached over 50 years old suggesting an indirect impact of smoking cessation on the second peak of diagnosis in ulcerative colitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In aetiology of inflammatory bowel disease (IBD) role of micro-organisms including those from the oral cavity is taken into account. Oral bacteria are known for biofilm formation and enamel demineralisation leading to the formation of caries cavities.

Aims & Methods: The aim of the study was to determine the state of hard teeth tissues measured by DMFT index in adult patients with ulcerative colitis (UC) and Crohn's disease (CD). The study involved 119 UC and CD patients aged from 18 to 72 (mean 34.45). Disease phenotype at diagnosis was classified

according to the Montreal classification and only the patients who had conducted a complete diagnostic workup of the entire gastrointestinal tract were included. Following, the data on the occurrence of extraintestinal symptoms, the incidence of IBD in the family, type of treatment, including surgery, were also collected. The complete assessment of the hard teeth tissues based on the DMFT index (decayed, missing, filled teeth) was performed.

Results: The study population was characterized by a high DMFT index with mean value 19.35. There was a significantly higher number of filled (F) and lower number of lost teeth (M) among patients who underwent respective surgery. Noticed incidence of IBD in the family was similar in both groups of patients. Type of treatment has no significant impact on DMFT index values. There were no statistically significant differences between UC and CD group in DMFT index, M and F values. However, it has been found that these groups differ in D values which averaged 4.5 and 3.2 for CD and UC groups ($p < 0.05$). The analysis of both patients' groups with regard to gender showed statistically significant differences in D and F values. The lowest mean D value was noticed in UC females group (2.8) and the highest in CD males (5.2); average F values were opposite—11.4 for UC females and 7.8 for CD males. Statistical analysis of DMFT index among patient from CD and UC groups according to disease phenotype showed no significant differences in DMFT, D and M in both groups. Average DMFT varied from 18.14 for L1 to 20.50 for L4 patients in CD group and from 17.30 for E1 to 20.55 for E2 in UC group. However, significant difference in F values was observed in CD patients: L1 and L2 have lower average F than those with L3 and L4 (6.66, 7.46, 10.25 and 14.00 respectively; $p=0.0215$). D values were significantly higher for patients with none or one extraintestinal symptoms ($p < 0.05$). Results of D values obtained in our study were higher than for healthy population aged 35–44 in Poland (mean D ~2).

Conclusion: The results of preliminary POLIBD study among two groups of IBD patients showed similar values in DMFT index and higher average number of carious teeth in CD patients, especially in men.

Introduction: Crohn's disease (CD) is a chronic inflammatory disease that can affect any section of the gastrointestinal tract. Malnutrition is a common sequel in these patients and many pathogenic mechanisms could be involved such as poor dietary intake, altered energy expenditure, nutrient malabsorption and/or losses.

Aims & Methods: This cross-sectional study aimed to evaluate the resting energy expenditure (REE) in CD patients, in accordance with clinical status of disease, compared to a control group.

Methods: All consecutive adult CD women were prospectively enrolled, while a group of healthy women, matched for age and weight, served as control group (C). CD women were classified in clinically active disease (CD-A) and clinical remission (CD-R) according to Crohn's Disease Activity Index (CDAI) (>150 and <150 , respectively). All subjects underwent REE measure by indirect calorimetry with a canopy system, while body composition variables, such as fat-free mass (FFM) and fat mass (FM), were assessed by bio-impedance analysis (BIA).

Results: Finally, forty-two women with CD, 23 with clinically active disease (CD-A; CDAI = 219 ± 53) and 19 in clinical remission (CD-R; CDAI = 83 ± 41) were recruited for the study, while 40 matched-healthy women were enrolled as control group (C). We found that body weight, FFM and phase angle (PA) differed among groups; but age, height and FM did not. Post-hoc analysis revealed that body weight was significantly lower for CD-A in comparison with C (CD-A: 55.7 ± 9.23 kg vs C: 64.5 ± 6.3 kg; $p=0.02$). FFM was reduced in women with CD than C (CD-A: 39.6 ± 4.32 kg and CD-R: 39.5 ± 6.68 kg vs C: 44.4 ± 4.68 kg; $p < 0.01$) while PA was lower for CD-A compared to both CD-R and C (CD-A: 5.5 ± 0.6 vs CD-R: 6.0 ± 0.5 and C: 6.1 ± 0.5 ; $p < 0.001$). REE did not differ among groups; nevertheless when it was adjusted for FFM, we observed that REE/FFM increased for both CD-A and CD-R groups compared to C (CD-A: 35.9 ± 4.17 kcal/kg, CD-R: 35.1 ± 4.96 kcal/kg vs C: 30.2 ± 3.38 kcal/kg; $p < 0.01$).

Conclusion: These preliminary results show that REE, when adjusted for FFM, is increased in women with CD, unrelated to disease activity, compared to healthy subjects and this could negatively affect the energy balance and contribute to weight loss.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1640 MAGNETIC RESONANCE CHOLANGIOGRAPHY ABNORMALITIES IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

A. Belle¹, A. Lopez¹, V. Laurent², C. Baumann³, H. Rousseau³, X. Orry², J. Bronowicki¹, L. Peyrin-Biroulet¹

Introduction: Primary sclerosing cholangitis (PSC) is a rare and devastating complication of inflammatory bowel disease (IBD). There is no standard for the screening of primary sclerosing cholangitis (PSC) in patients with IBD. Magnetic resonance cholangiography (MRC) may replace liver biopsy in this clinical situation. The main objective of this prospective observational study was to assess the frequency of MRC-detected liver diseases, including PSC, in adult IBD patients with liver function abnormalities and to identify clinical and biological characteristics associated with these findings.

Aims & Methods: From June 1, 2009 to January 31, 2017, 421 patients were included and screened with MRC: cohort 1 included 206 IBD patients with liver abnormalities; cohort 2 included 28 IBD patients without liver abnormalities; and cohort 3 included 187 non-IBD patients with liver abnormalities. Two senior radiologists independently evaluated MRC findings.

Results: MRC abnormalities were observed in 18% of patients in the cohort 1; 3.6% in the cohort 2; and 31% in the cohort 3 (Table 1). Based on MRC, we found respectively 11.2%, 0%, and 7% of PSC in cohorts 1, 2, and 3. 29.2% of IBD patients with liver abnormalities had infra-clinical PSC. A history of intestinal resection ($P = .0357$), abnormal gamma-glutamyl transferase values ($P = .0064$), and abnormal alkaline phosphatase values ($P = 0.021$) were significantly associated to suspected PSC.

Table 1: MRC abnormalities in cohorts 1, 2 and 3

Results of MRC	Total	Normal	Ductopenia	Doubt	PSC	Others
Cohort 1	206	150 (72.8%)	28 (13.6%)	9 (4.4%)	23 (11.2%)	0
Cohort 2	28	27 (96.4%)	1 (3.6%)	0	0	0
Cohort 3	187	116 (62.0%)	0	0	13 (7.0%)	58 (31.0%)

Conclusion: Using MRC in patients with IBD, we found a higher prevalence of PSC than based on clinical symptoms. Systematic screening for PSC using MRC could be recommended in routine practice for IBD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1641 TRUECOLOURS ULCERATIVE COLITIS (TCUC): WILL PATIENTS WITH UC COMPLETE DIGITAL QUESTIONNAIRES IN REAL-TIME?

Introduction: TCUC is a comprehensive real-time web-based programme for patients with UC. It monitors multiple parameters via electronic questionnaires: symptoms, quality of life (QoL), outcomes (eg emergency department visits) and demographics. Medications are entered and personalised treatment guidance formulated. This information, graphically displayed on a traffic light system, is available to the patient and clinical team via the TCUC website, which is housed on a secure National Health Service server.

Aims & Methods: A prospective, non-randomised 6-month pilot study recruited patients from the Oxford Inflammatory Bowel Disease service. The aims were to assess feasibility, usability and adherence. Recruitment rate (number recruited/ expression of interest) and retention rates were calculated. At registration, questionnaires were scheduled either daily (simple clinical colitis activity index, SCCAI), fortnightly (QoL, IBD-Control-8, CUCQ-8 and EQ5D-5L), or once only (outcomes). Patients then received email prompts linked to scheduled questionnaires. Monthly home IBDoc® faecal calprotectin (Fcal) measurements were incorporated, monthly blood tests collected and flexible sigmoidoscopy performed at entry and after 6 months. Adherence to all questionnaires and samples was calculated. Usability was assessed via the System Usability Scale (SUS) ($n = 59$) and qualitative interviews ($n = 28$). SUS broadly classifies usability of a system from poor (< 70) to superior (> 90). A deductive approach was used for the qualitative coding and analysis.

Results: Sixty-six patients were recruited (recruitment rate 66/240 invitations delivered, 28%). Of 66 patients, 29 (44%) were male, median age 40.7 yrs

(IQR 17.0, range 18–65), median duration of disease 5.6 years (IQR 10.7, range 0–30), distribution of disease (E1 18%, E2 38%, E3 33%, unknown 11%), activity of disease at entry (remission 38%, mild 35%, moderate 26%, severe 1%), tertiary education 58%, biologic use 47%. Retention rate 57/66, (86%). Main reason for withdrawal (5/9, 55%) was the need for sigmoidoscopy and monthly blood tests during the trial.

Table 1: Adherence to Questionnaires

Questionnaires	Adherence over 6 months	First 3 months	Last 3 months
Daily symptom (SCCAI) questionnaire	76%	81%	72%
Fortnightly QoL questionnaires (IBD-Control 8, CUCQ8 and EQ-5D)	95%	96%	94%
Once only demographic and outcome questionnaires	100%	100%	100%

Uptake of Fcal home testing was 73% (48/66), median tests 4 (IQR 3, range 1–6). Median SUS score was 92.5 (IQR 15, range 45–100) which corresponds to a 'superior product'. Qualitative interviews confirmed that TCUC was efficient, effective, easy to learn and well liked. Improvements suggested included optimisation of the graphical display on smartphones and decreasing the number of QoL questionnaires from three to one, with a preference for IBD-Control.

Conclusion: Patients with UC will collect digital data in real-time, with good adherence to symptom, QoL, outcome questionnaires and Fcal home testing. Usability was classified as 'superior' but further improvements are possible. Larger studies are required to determine cost effectiveness.

Disclosure of Interest: A. Walsh: An unrestricted educational grant from Abbvie Pharmaceuticals was received for this work. Buhlmann laboratories provided all IBDoc kits for this study. All other authors have declared no conflicts of interest.

P1642 BODY COMPOSITION AS A PREDICTOR FACTOR OF DISEASE OUTCOME IN INFLAMMATORY BOWEL DISEASE- RESULTS OF 3-YEAR FOLLOW-UP

Introduction: Malnutrition and altered body composition can develop in patients with inflammatory bowel diseases (IBD) for a variety of reasons. Malnutrition and sarcopenia may worsen disease outcome in chronic disorders, raise the risk of infections and hospitalisation.

Aims & Methods: We followed 198 IBD outpatients (144 CD and 54 UC) for 3 years to identify potential risk factors of unfavourable disease outcome. Baseline body composition were measured by bioelectrical impedance analysing (BIA) method to evaluate nutritional status. Penalized logistic regression was used for the multivariate modelling of the outcome, with two sets of - prespecified - predictor variables age, sex, CU/CD, BMI, FFMI.

Results: According to our results 19.2% of the patients ($n = 38$) were underweight (had BMI $< 18.5 \text{ kg/m}^2$) and 29.8% ($n = 59$) had alarming low fat-free mass index (FFMI) and were at risk of sarcopenia. Overall 31.5% ($n = 62$) of the patients needed steroid therapy and 53.5% ($n = 106$) was given anti-TNF. Almost third of the participant (30.8%, $n = 61$) were hospitalized due to disease flare or its complication at least once during the follow-up time. The mean period of hospitalization was 19.14 ± 32.7 days. 20.2% ($n = 40$) of all participants have undergone intestinal surgery. Hospitalization was positively associated with sarcopenia risk: alarming low FFMI was associated with an OR of 1.81 (95% CI: 1.03–3.20, $p = 0.04060$). The risk of operation was higher in patients with lower BMI: OR = 1.55 (95% CI: 1.05–2.29, $p = 0.02778$) for 5 units decrease; no other association was significant in the models.

Conclusion: Our results suggests that low BMI is a risk factor of surgery in inflammatory bowel disease patients. Furthermore alarming low FFMI is a predictor of need of hospitalization and that suggests more serious flares. Identification of malnutrition and altered body composition has notable importance in disease outcome among IBD patients.

Introduction: The majority of Crohn's disease (CD) develop stricturing complications of the disease at some point. The proper selection of patients with potential benefit of therapy escalation is crucial in order to avoid unnecessary bowel damage. Rapid contrast uptake in the affected bowel segment at intravenous contrast-enhanced ultrasound (CEUS) has been shown to correlate with disease activity but there are no data available on the benefit of CEUS for the therapeutic decision making in this clinical setting.

Aims & Methods: The aim of the study was to evaluate the clinical outcomes of CD patients with stricturing disease managed based on the CEUS findings. CD patients with stricturing disease were recruited from two IBD centra between June 2015 and February 2017. Patients with penetrating disease complications were excluded. CEUS was performed using 2.4 mL of intravenous contrast (SonoVue, Bracco Imaging). Patients having rapid uptake (within 20 second after injection) were indicated for therapy escalation, patients without uptake with obstructive symptoms were referred for surgery; patients without uptake and no obstructive symptoms remained at the stable medication. In patients with the minimal follow-up of one year clinical and endoscopic remission was evaluated.

Results: In total, 27 patients were included (10 men; median age 37 yrs, range 23–67; 22 pts with ileo-coecal localization, 3 pts with multiple small bowel segments involvement, 2 with colonic disease). Seventeen patients (63%) had rapid uptake at the CEUS; 13 of these patients had therapy escalation (3 pts intensification or switch of another biological; 10 pts had therapy step-up to antiTNF or immunosuppression). Remaining three pts improved subsequently on stable therapy with antiTNF and one patient with longstanding symptomatic colonic stricture was referred for surgery. Ten patients (37%) had no rapid uptake at the CEUS; seven out of these patients had symptomatic stricturing disease and were referred for surgery. Three patients had no symptoms and no therapeutic changes were made. Twenty-five patients had follow-up longer than 12 months (median 18 months, range 13–23). In the group of patients with rapid uptake, all but two patients achieved sustained remission after therapy escalation. Two patients initially responded to therapy but have lost response and eventually needed surgery. In the group with no rapid uptake, patients without surgery remained in remission without any changes in the medication. Patients who underwent surgery in this group had no changes in therapy after surgery and none of these patients had recurrence at the surveillance colonoscopy at 12 months.

Conclusion: Contrast-enhanced ultrasound might be helpful in guiding the therapeutic decision making between surgery and therapy intensification in patients with stricturing Crohn's disease.

Introduction: Inflammatory bowel disease (IBD) commonly affects patients during their reproductive years, making the interaction between fertility, pregnancy, and IBD an important issue for both genders. As these are the reproductive years, patients and physicians often have concerns regarding the interaction between IBD, medications and surgery used to treat IBD, and reproduction, pregnancy outcomes, and neonatal outcomes.

Aims & Methods: We aimed to determine IBD patient's reproductive behaviour and evaluate the factors that affect fear of family planning. Finally we investigated the correlation of disease activity and pregnancy outcome. 207 patients from our IBD population (142 with Crohn's disease, 65 with ulcerative colitis) were reviewed by personal questionnaires.

Results: In all, 53% of participants were female (the mean age was 31.9 years with mean duration of disease activity of 10.7 years). 47% of patients were male, (the mean age was 32.5 years with disease duration of 10.2 years). 62 patients (32 female and 30 male) have children (39 and 42) after diagnosing IBD (mean age of childbearing was 30 years. 81% of reviewed female and 79% of male patients plan to have more children, although approximately one-third of patients (33% of female and 29% of male patients) reported having fewer children than planned up till now secondary to disease activity, surgical and ongoing medical treatments. The main patient-related reasons for "voluntary infertility" were fear of congenital abnormality secondary to medications of IBD (68%) and concern about genetic risk of IBD in child (56%). 50% of male and 75% of female patients got adequate information and education from conception do delivery. Pregnancy was planned in 77% of cases, the childbearing and delivery was without any complication. Prematurity and low birth weight occurred in 6–6 cases (10%-10%). IBD was in remission in most cases, during pregnancy 25% of the patients had flare. 40% of women could breastfeed their baby after 6 months.

Conclusion: The management of IBD in women during their reproductive years should include consideration of their family planning decisions, and education counseling regarding the overall safety of medications and the importance of

medication adherence should occur prior to conception. Disease control prior to desired conception and throughout pregnancy is the most important factor to keep in mind when caring for the IBD patients. Educating the patients will help to achieve successful outcomes both for patients and babies.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1645 DIAGNOSTIC DELAY AND PREDICTIVE FACTORS FOR CROHN'S DISEASE IN AN ALGERIAN POPULATION

Y. Chelbi, R. Boulares

Constantine, Ben Badis Hospital, Constantine/Algeria

Contact E-mail Address: Yacinechelbi4@yahoo.fr

Introduction: Crohn's disease (CD) is a chronic inflammatory bowel disease whose diagnostic delay (DD) is highly variable. A delay in diagnosis of MC may be detrimental to the patient, delaying appropriate therapeutic management. Factors Influencing SD may be a function of the country's health system, but also linked to the particular clinical and evolutionary profile of the disease. The objective of this study was to measure the DD of CD, to describe its distribution and evolution over time and to The factors associated with a long DD (>Q3).

Aims & Methods: All patients with certain or probable CD between 2004 and 2016 identified by The department's inflammatory disease hospital registry was included. The socio-demographic characteristics collected included: the patient's residential area at the time of diagnosis in urban, rural or semi-urban, distance from the nearest hospital (CH). Clinical symptoms and phenotype of CD to diagnosis according to the Montreal classification were collected

Results: Among 247 patients with CD; 90 had a median SD of 03 months. A DD ≥ 7 months was considered a diagnostic delay observed in most patients is 157. In univariate and multivariate analysis at diagnosis, the female sex (54.25%), young age (37.24%), absence of emaciation (27%), presence of extra-digestive manifestations (25.91%) and Isolated lesions (L1) (34%) and penetrating phenotype (B3) (22.67%) were associated with anopenal lesions (27.12%). Diagnostic delay. Socio-demographic characteristics were not associated with delayed diagnosis.

Conclusion: This study shows that most of the patients, 63.56% have a diagnostic delay significantly associated with the female sex. The young age, the absence of weight loss and a localization of the disease limited to the hail the penetrating phenotype of disease. No socioeconomic variables or reflective of access to care were found to influence.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1646 TUBERCULOSIS IN INFLAMMATORY BOWEL DISEASE UNDER TUMOUR NECROSIS FACTOR ALPHA ANTAGONIST-THE RISK BEYOND SCREENING

L. Carvalho, M.A. Túlio, J. Carmo, J. Rodrigues, T. Bana, E Costa, C. Chagas

Gastroenterology, Centro Hospitalar Lisboa Ocidental, Lisboa/Portugal

Contact E-mail Address: lilipcarvalho@gmail.com

Introduction: Tumour necrosis factor alpha antagonist (anti-TNF α) has revolutionized the treatment of the inflammatory bowel disease (IBD). Considering that it plays a central role in immune-mediated modulation, there are some obvious concerns about safety. There is evidence that it increases the risk of opportunistic infections such as tuberculosis, particularly latent infection reactivation. Due to global high incidence of tuberculosis and its commonly severity in immunocompromised patients (extrapulmonary and disseminated pattern), the exclusion of latent tuberculosis (LT) infection is currently part of the screening prior to starting biologic therapy. Despite negative screening, the risk of tuberculosis infection remains active during the immunomodulation therapy. However, only a few cases of life-threatening disseminated tuberculosis have been reported in immunocompromised patients probably related to the increased use of higher accuracy screening tests, such as interferon-gamma release assays (IGRA). Negative screening cases with IGRA are not described.

Aims & Methods: We intend to know the incidence of tuberculosis in IBD patients under anti-TNF α therapy in a single tertiary referral centre, analyzing the tuberculosis screening methods and demographic characteristics. IBD patients treated with anti-TNF α therapy between January 2000 and December 2016 were retrospectively analyzed.

Results: During this period 166 patients received anti-TNF α therapy. Before anti-TNF α treatment, screening for LT was performed through medical history, chest X-ray, tuberculin skin test (TST) and/or IGRA. Forty-two patients (25%) had positive screening and received tuberculosis prophylaxis prior anti-TNF α therapy. Seven patients (4.2%) developed tuberculosis while under anti-TNF α treatment (four women, mean age 44 \pm 7 years and mean IBD duration 10 \pm 8 years). Six of them had a negative LT screening (methods: 4 TST and 2 IGRA) and one patient had positive TST screening, been treated with isoniazid before starting anti-TNF α therapy. During screening three patients were under immunosuppressive and one under corticosteroid therapy. In the IGRA negative screening patients, the diagnosis of tuberculosis occurred within the first 10 weeks after starting anti-TNF α . There were five cases of miliary tuberculosis and two of pulmonary disease. Despite difficult diagnosis, all patients were treated successfully, six of whom needed hospitalization.

Conclusion: In our centre the incidence of tuberculosis in IBD patients under anti-TNF α therapy was 4.2% and most of them presenting with a severe disease pattern. The therapeutic regime of tuberculosis was effective and no mortality was recorded. All this patient had a previously negative screening, two of them with IGRA, been considered a high sensitivity and specificity screening method. Therefore, a surveillance strategy for IBD patients with anti-TNF α therapy is needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The MediCrohn study was designed to evaluate the level of agreement between the Harvey Bradshaw Index (HBI) translated into a patient-based questionnaire completed through a mobile app, and the original HBI questionnaire assessed by the clinician (considered as reference).

Aims & Methods: Patients completed the HBI score through a mobile app designed for both Android and iPhone devices and thereafter (<48 h later), the questionnaire was completed onsite by the gastroenterologist who was blinded for the patients' responses. We assessed agreement between HBI scores of the clinician and patient on the total sum score and per item. HBI score <5 was considered as inactive disease.

Results: 135 patients participated in the study and completed the HBI through a mobile app (mean age: 36 \pm 8 years, 58% women). The proportion of agreement between clinician and patient assessment, both evaluating CD as active or in remission was 91.1%. Only in 12 cases (11%), the patient classified CD as active, whereas the physician evaluated it as inactive. No active cases remained undetected by the patient evaluation. Sensitivity, specificity, positive and negative predictive values are shown in Table. The highest agreement was seen for the

questions: "abdominal mass" and "general well-being" whereas "number of liquid stools per day" was the item with the lowest agreement.

Patient Rate	Clinician Assessment	Clinician Assessment	Total	
	Active	Remission		
Active	26	12	38	
Remission	0	97	97	
Total	26	109	135	
Sensitivity (%)	Specificity (%)	PPV(%)	NPV (%)	Agreement
100	89	68	100	91.1% CI(95%)

Conclusion: The HBI score self-administered by the patient through a mobile app resulted in a high percentage of agreement with the gastroenterologist evaluation, and high negative predictive value for disease activity. Results of the MediCrohn study encourage the use of this mobile app and gives some hints on its conditions of use as a support for the involvement of patients in the management of their disease. Future studies will help to define its precise role in clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Histological remission (HR) has become an important treatment target in ulcerative colitis (UC). However, limited data exist on reliability of histological scoring in daily practice, when it comes to assess minor histological abnormalities. We investigated the reproducibility and reliability of UC histological scores in colonic biopsies assessed as HR by a general pathologist in daily practice. Next, we investigated correlations between the initial histological assessment and the expert review by expert gastrointestinal (GI)-pathologists.

Aims & Methods: We performed a retrospective single-centre study in a tertiary IBD referral centre. Colonic biopsies of UC patients with mucosal healing (MH) throughout the examined colon were included. All biopsies were re-assessed by three blinded GI-pathologists using three histological scoring indexes (Geboes score (GS), Riley score (RS), Harpaz (Gupta) Index (HGI)) and a global visual scale (GVS). We evaluated inter- and intraobserver variation and correlations between scores and initial histological assessment using Cronbach's alpha and Spearman's rho analysis.

Results: We included 270 biopsies from 39 UC patients. The interobserver concordance for all histological indexes was substantial to almost perfect (GS 0.84; RS 0.91, HGI 0.61GVS 0.74). The correlation between the RS and GS was almost perfect (R=0.86), but no correlation was found between the primary histological assessment and the GS (0.00), the RS (-0.01), the HGI (0.03) and the GVS (-0.04) as scored by expert GI-pathologists.

Conclusion: Available histological scores for UC are reliable with strong mutual correlations in case of limited histological abnormalities. However, the discrepancy between daily practice histological assessment and dedicated GI-pathologists is significant and this may have important implications for the selection process of a unified histological disease activity score in UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1649 EVALUATION OF MODIFIED MAYO ENDOSCOPIC SCORE AND DUBLIN, NEW ENDOSCOPIC SCORES THAT INCORPORATE ULCERATIVE COLITIS EXTENSION, IN THE PREDICTION OF RELAPSE

J. P. Rodrigues¹, R. Pinho², S. Fernandes², J. Silva², A. Ponte², M. Sousa², J. C. Silva², S. Leite², T. Freitas², L. Proença², A. P. Silva², L. Alberto², A. Rodrigues², J. Carvalho²

²Gastroenterology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova De Gaia/Portugal

Contact E-mail Address: jaimepereirarodrigues@gmail.com

Introduction: Current endoscopic activity scores for Ulcerative Colitis (UC) do not take into account the extent of mucosal inflammation. Recently, two endoscopic scores that combine the assessment of severity and disease extension were developed, the Modified Mayo Endoscopic Score (MMES)¹ and Degree of Ulcerative Colitis Burden of Luminal Inflammation (DUBLIN)².

Aims & Methods: We aimed to evaluate the relation of the scores with disease activity and as predictive factors of clinical relapse. Patients with UC in clinical remission (partial Mayo score [pMS] ≤1) who underwent colonoscopy between January/2010 and December/2013 were included. MMES and DUBLIN scores were calculated. Analytical and histological activity (defined by Geboes score ≥3.1 and Nancy score=2-4) as well as predictive factors of relapse and relapse-free time were evaluated. Relapse was defined as pMS ≥2, therapy to induce remission, hospitalization and/or colectomy.

Results: 82 patients were selected, 51.2% (n=42) female, mean age=49.4 ± 13.7 years. MMES ranged between 0-13.8 and DUBLIN between 0-9. MMES and DUBLIN scores presented good correlation (r=0.945, p < 0.001). MMES was higher in patients with histological activity defined by Nancy (3.7 ± 4.0 vs. 0.8 ± 1.5; p < 0.001) and Geboes (4.0 ± 4.2 vs. 1.3 ± 2.4; p=0.005). DUBLIN was also higher in patients with histological activity defined by Nancy (1.9 ± 2.1 vs. 0.5 ± 0.8; p=0.001) and Geboes (2.0 ± 2.3 vs. 0.7 ± 1.2; p=0.008). There was no significant correlation between both scores and analytical activity. Relapse occurred in 36.6% (n=30) of patients, with a cumulative risk of 9.8, 18.4, 25.9, 31.5 and 42.0% at 12, 24, 36, 48 and 60 months, respectively. Mayo Endoscopic Subscore (MES) (p < 0.001), MMES (p < 0.001), DUBLIN (p < 0.001), Geboes (p=0.03) and Nancy scores (p=0.001) presented a significant association with relapse. In multivariate analysis, MES (OR=2.32; p < 0.001), MMES (OR=1.19; p < 0.001) and DUBLIN (OR=1.36; p < 0.001) were predictive of relapse independently from histology. Areas under the ROC curve were 0.71 (MES, p < 0.001), 0.75 (MMES, p < 0.001) and 0.74 (DUBLIN, p=0.001) for prediction of relapse, with MMES significantly higher than MES by a difference of 0.037 (0.002-0.072); p=0.03.

Conclusion: MMES and DUBLIN scores correlate with each other and with histological activity and are independent predictors of relapse. MMES was superior to MES in the prediction of relapse.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Magnetic resonance enterography (MRE) is an imaging technique recommended to determinate and confirm the extension and activity of Crohn's disease (CD) in the small bowel and discriminate penetrating disease and complications. MRE diagnosis allows to optimize medical treatment in IBD patients.

Aims & Methods: The aim of this study is to evaluate the impact of MRE on medical decision making in IBD patients and determinate the maintenance of this new treatment along the time. Consecutive MRE studies performed in patients

with confirmed or suspected Crohn's disease between January 2011 and August 2014 were included in three tertiary centers. Medical charts were retrospectively reviewed. MRE indication, demographic and IBD data were collected at time of MRE. Three months after MRE, medical decision (conservative approach with maintenance therapy, significant change in medical therapy or surgery) was assessed. After twelve months of follow-up, the treatment decided after MRE was reviewed.

Results: A total of 474 MRE studies were performed and indications for MRE were: assessment of small bowel involvement in 40 (8.3%) patients with indeterminate colitis (IC) and 20 (4.2%) with suspected-IBD patients or evaluation of severity and extension of the disease in 414 (87.5%) CD patients (232 F; mean age 37 ± 13 years). Only 4 patients with suspected-IBD (4/20;20%) had involvement of small bowel on MRE confirming the CD diagnosis. Twenty-one patients with IC (21/40;52.5%) changed the diagnosis to CD. In 199/474 (40.5%) MRE determined a change on medical decision and 140 (70.3%) patients modified maintenance treatment because of MRE findings. Of them, 127 (63.8%) underwent "set-up" treatment by prescribing immunosuppressants (IS) (n=45), anti-TNF agents (n=22), anti-TNF escalation (n=8), adding IS to anti-TNF agents (n=9) and changing anti-TNF agents (n=5). In addition, 13 (9.2%) patients underwent "top-down" therapy due to stop IS (n=7), anti-TNF (n=3) or anti-TNF de-escalation (n=3). Surgery was indicated on 62 (62/199;31.1%) patients after MRE. After one year of follow-up, the medical decision was maintained on 65.4% (288/440) of patients.

Conclusion: RE is a very helpful tool for the medical management of CD patients. MRE provides major information to optimize treatment in the long-term of patients with active CD.

Introduction: Crohn's disease (CD) is a chronic progressive destructive disease, resulting in cumulative structural bowel damage, which may predict long-term disability. The Lémann Index (LI) has been developed to measure CD-related bowel damage, including bowel surgery, presence of stricturing and penetrating lesions (Pariente and al. *Gastroenterology* 2015). The first Inflammatory Bowel Disease - Disability Index (IBD-DI) has recently been validated (Gower-Rousseau, *Gut* 2015).

Aims & Methods: The aim of the present study was (1) to identify factors associated with bowel damage and with disability in CD and (2) to evaluate the correlation between the LI and the IBD-DI. We performed a prospective study in the tertiary referral center of the Claude Huriez Hospital in Lille, from September 2016 to November 2016, including all consecutive CD outpatients. Bowel damage was assessed by the LI calculated according to the published LI protocol. Abdominal and pelvic Magnetic resonance imaging (MRI)s were reviewed and red by the same couple of one gastroenterologist and one radiologist. The IBD-DI was also calculated for all patients. Factors associated with LI and IBD-DI levels were identified by means of bivariate analyses of variance.

Results: 130 patients were prospectively and consecutively included. Median age was 34.0 (interquartile range [IQR]: 26.0-46.0) and median disease duration was 10.0 (IQR: 5.0-17.0) years. 65 patients (50%) underwent at least one resection surgery. The median LI was 10.8 (IQR: 0.6-17.5). Disease duration (p < 0.0001), cumulated anal location (p < 0.0001) and CD activity (p < 0.0001) were associated with higher LI scores. Median IBD-DI was 25.0 (IQR: 14.7-41.1). Female gender (p=0.02), CD activity (p < 0.0001) and current anoperineal lesions assessed by clinical examination and pelvic MRIs (p=0.001) were associated with higher IBD-DI scores. The correlation coefficient between the LI and the IBD-DI was 0.12 (-0.05, 0.29; p=0.154).

Conclusion: In a large cohort of CD patients from a tertiary referral CD center, disease duration, anal location and CD activity are associated with bowel damage assessed by the LI, while female gender, disease activity and current anoperineal lesions are associated with disability assessed by the IBD-DI. Correlation between the LI and the IBD-DI was low.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The aetiology of Crohn's disease (CD) and ulcerative colitis (UC) is not known. Recent data suggest a different cytokine profile between CD and UC. **Aims & Methods:** The aim of this study was to analyse the expression of mRNA of proinflammatory, regulatory anti-inflammatory cytokines, chemokines and their ligands (IL-6,-8,-10,-12, IL-23, TNF α , CCR1,- 2-5,-9, IL-10,TLR2,-4,-5, CD 207, -206), and transcription factor FoxP3 in the inflamed and non-inflamed intestinal biopsy samples of mucosa in IBD patients. We performed a cross-sectional study. The cohort consisted of 87 consecutive IBD patients (47 CD and 40 UC) who underwent colonoscopy at the IBD centre of University Hospital Bratislava. We took biopsies from non-inflamed and if present also from inflamed mucosa from sigma (CD, UC) and terminal ileum (CD). mRNA was extracted from mucosal biopsy samples, isolated by a RLT buffer and reversely transcribed. We normalized the expression of the target genes to the expression of the house-keeping gene (GAPDH). Finally, we compared the expression of cytokines in inflamed and non-inflamed mucosa separately for CD and UC patients.

Results: In UC patients, we observed higher expression of IL-8(p=0.04), IL-23 (p=0.019) TLR2 (p=0.002), CCR1 (p=0.007), CCR2 (p=0.037), CCR5 (p \leq 0.001), CD206 (p=0.011), TNF α (p=0.002) and IL-6 (p=0.006) in the inflamed mucosa from sigma. In CD patients, we observed increased expression of chemokines of CCR1 (p=0.005) and IL-8 (p \leq 0.001) in the inflamed mucosa of a terminal ileum and decreased expression of CCL5. Also, in group of patients with CD we did not observe the difference of the expression of mRNA cytokines between the inflamed and non-inflamed mucosa of sigma.

Conclusion: There was a significant difference in the mRNA cytokine profiles between CD and UC patients.

Introduction: The various methods of disease monitoring for Crohn's disease (CD) are available however the quality of those methods differ. High accuracy, low cost, patients-friendly and also physicians-friendly methods are needed. Balloon-assisted enteroscopy (BAE) is labour-intensive method. However, DBE enable a detail inspection and therapeutic capabilities, and could not be substituted for any other modalities. The surgical intervention is one of the poorest outcome in the disease history of CD patients. There is little knowledge whether the monitoring of disease activity and the endoscopic intervention using BAE contribute the preferable outcome of CD.

Aims & Methods: We conducted a retrospective single-centre cohort study to elucidate whether the on-demand BAE and Endoscopic balloon dilation (EBD) therapy leads to the decreasing of surgery rate for the small bowel and better outcomes for CD patients. Double balloon endoscopy (DBE) examinations were conducted when the attending physicians of each patients were needed. EBD therapy was undergone at the stenosis where the endoscope could not pass and was not contraindication regardless of the presence of symptoms. The 181 examinations of DBE for 55 CD patients since 2004 were enrolled in this study. The primary endpoint is the comparing the differences of surgical rates between using endoscopic balloon dilation therapy and not. The secondary endpoints are cumulative non-surgery rate of CD patients using DBE monitoring and EBD therapy by Kaplan-Meier method.

Results: Subjects were 55 patients, genders were 9 females and 46 males, mean age was 42 years old (SD, 13.0, median 44 range, 22-77). 50 (28%) antegrade, 131 (72%) retrograde DBE and 58 (32%) EBD therapy were undergone. EBD was performed in 17 (31%), mean 3.4 times per patient) patients. In 17 patients who underwent EBD therapy, only one (6%) patient underwent surgery after EBD and the other 16 (94%) of patients did not undergo surgery during follow-up periods (mean 1719 days). In 38 patients who did not undergo EBD therapy, 7 (18%) patients underwent surgery during the follow-up periods (mean 1659 days). The surgery rate of EBD group was approximately three times lower than non-EBD group. Cumulative non-surgery rate of CD patients who were monitored using DBE in on-demand manner were 85% in 3 years and 82% in 5 years. These results may mean that non-EBD group consist of two major subgroups that one was the patients who had complex strictures that did not meet the indication for EBD and the early surgery was needed, and the other was the patients whose small bowel lesions were mild.

Conclusion: In patients who underwent EBD, the necessity for surgery was smaller. Furthermore, in patients who underwent DBE monitoring, the cumulative non-surgery rate was relatively higher than historical control. DBE may show the

future necessity for surgery and discriminate the necessity for the strict monitoring from mild or moderate monitoring that leads to better quality of life for CD patients. The scheduled monitoring using enteroscopy would be a further issue to clarify.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Neutrophil gelatinase-associated lipocalin (NGAL) is a protein that is secreted by neutrophils in increased amounts in inflammatory disorders and its level reflects neutrophilic activity. Endoglin is the receptor and modulator of endothelial TGF- β and it is responsible for the endothelial activation secondary to inflammation. Although the increase in endoglin expression with the inflammation in the colonic mucosa of mice was shown before, its relationship with the disease activity in inflammatory bowel disease (IBD) is not searched yet. The relationship of serum NGAL and serum and colonic endoglin levels in ulcerative colitis (UC) and Crohn's disease (CD) patients were investigated in this study.

Aims & Methods: Eighty-six UC, 63 CD, 36 non-IBD (screening, irritable bowel syndrome) and 52 healthy controls who were followed up in Gastroenterology Department of Sisli Hamidiye Etfal Education and Research Hospital between years 2015-2016 were enrolled. Patients were evaluated by endoscopic (Rachmilewitz index for UC, simple endoscopic score for CD (SES-CD) for CD) clinical (clinical colitis activity index (CCAI) for UC and CD activity index (CDAI) for CD), and pathologic activity scores and immunohistochemical staining.

Results: There were no differences between UC and CD patients in terms of serum endoglin and NGAL levels. NGAL and endoglin levels were significantly higher in endoscopically active UC group (n=59) (142.8 \pm 68.7 ng/mL and 546.0 \pm 148.8 pg/mL) compared to inactive UC (n=27) (119.7 \pm 26.3 ng/mL and 476.9 \pm 134.2 pg/mL), to non-IBD (115.8 \pm 27.2 ng/mL and 460.6 \pm 103.2 pg/mL) and to controls (116.7 \pm 31.7 ng/mL and 457.2 \pm 114.1 pg/mL). Although there were limited number of inactive CD patients (n=11), serum NGAL and endoglin levels were significantly higher in endoscopically active CD group (n=52) (135.0 \pm 28.9 ng/mL and 555.6 \pm 133.6 pg/mL) compared to inactive CD (115.2 \pm 35.9 ng/mL and 458.7 \pm 132.8 pg/mL), to non-IBD and to controls (Figure). Stricturing and fistulizing CD groups had significantly higher endoglin levels compared to inflammatory CD (p<0.001 and p=0.001). NGAL levels were significantly increasing with the increasing disease extension in UC and CD (p=0.012 and p<0.001). While the clinical activity subgroups were evaluated, there were significant difference in UC and CD patients in terms of endoglin levels but not NGAL levels (Endoglin: p=0.002 p=0.574, NGAL: p=0.020, p=0.171). Endoglin levels were more strongly correlated with the pathologic activity scores in both UC and CD groups compared to NGAL levels (Endoglin: r=0.443, p<0.001; r=0.453, p<0.001 NGAL: r=0.274, p=0.011; r=0.409, p=0.001) The immunohistochemical staining index of endoglin showed positive correlation with the immunohistochemical staining of vascular endothelial growth factor (VEGF) (UC r=0.486, p<0.001; CD r=0.383, p=0.002). The immunohistochemical staining index of endoglin in the colonic mucosa was correlated with the serum levels of endoglin in both UC and CD patients (UC r=0.641, p<0.001; CD r=0.437, p<0.001)

Conclusion: The present study highlights significant associations between endoglin and NGAL and IBD presence and activity, and demonstrates elevated serum and colonic endoglin levels in patients with active IBD as a novel finding.

Introduction: Although thiopurine-induced myelotoxicity and hepatotoxicity rarely occur during maintenance thiopurine therapy for inflammatory bowel disease (IBD), current guidelines advise laboratory monitoring every 3 months. This study was performed to assess the current laboratory monitoring regime in thiopurine maintenance therapy with regards to consequences of myelotoxicity and hepatotoxicity.

Aims & Methods: In this multicenter cohort study, we evaluated adult IBD patients with quiescent disease who were on maintenance thiopurine therapy between 2000–2016. Data collection started after 12 consecutive months of thiopurine treatment. The primary outcome was therapy adjustment, i.e. therapy cessation or dose reduction, due to myelotoxicity (leukocyte count $<4.0 \times 10^9/l$, platelet count $<150 \times 10^9/l$) and/or hepatotoxicity (alkaline phosphatase (AP), gamma-glutamyltransferase (γ -GT), alanine aminotransferase (ALT) and/or aspartate aminotransferase (AST) above the upper limit of normal (ULN)). The secondary outcomes were prevalence of myelotoxicity and hepatotoxicity and additional diagnostic procedures due to this toxicity.

Results: This study included 223 IBD patients (55% female, 64% with Crohn's disease, mean age at diagnosis 27.2 years (SD 11.5)). Median follow-up was 3.2 years (IQR 1.9–4.7). The mean monitoring frequency was 3.3 assessments per treatment year (SD 1.8). Toxicity was observed in 445/2402 laboratory assessments (18.5%) in 120 patients. In total, 20 (0.8%) therapy adjustments were performed and 25 laboratory assessments (1.0%) led to additional diagnostic procedures. Myelotoxicity, observed in 244 assessments, led to 11 dose reductions and in 3 patients therapy was stopped. For hepatotoxicity, observed in 201 assessments, 2 dose reductions were performed and in 4 patients therapy was stopped. Ninety percent of observed toxicity were mild leukopenia (leukocyte count $3.0\text{--}4.0$) or mild hepatotoxicity (<2 ULN), primarily in the first years of treatment. Dose adjustments were more often associated with moderate leukopenia (leukocyte count <3.0) than with mild leukopenia ($p < 0.01$). In total, 2 complications were recorded, 1 patient was hospitalized because of pancytopenia and received red blood cell transfusion, and 1 patient was treated for a CMV infection. Both patients presented with symptoms in clinic with preceding normal laboratory values. No mortality due to thiopurine-induced toxicity was observed.

Conclusion: Although mild toxicity is common during maintenance thiopurine therapy, adjustments based on laboratory assessments are rare. Therefore, a less intensive regime to monitor thiopurine-induced toxicity should be considered.

Introduction: Intestinal fibrosis represents one of the main sources of morbidity for patients with Crohn's disease (CD), as its onset is associated with the development of CD-related complications which increase the likelihood of hospitalization and surgery¹. Ultrasound elasticity imaging (UEI) is a non-invasive ultrasonographic technique developed to evaluate tissue fibrosis by measuring tissue strain after application of a force². We have recently demonstrated that UEI can reliably detect severe ileal fibrosis in patients with Crohn's disease³. We therefore hypothesized that a more severe range of fibrosis might influence the therapeutic response to anti-tumor necrosis factor (TNF) treatment.

Aims & Methods: The aim of this explorative study was to assess the ability of UEI to predict therapeutic outcome in active CD patients treated with anti-TNF antibodies. 30 patients with ileal or ileocolonic CD (20 males, age 38.8 ± 14.5) initiating anti-TNF treatment were enrolled in the study. All patients completed the induction phase and underwent scheduled maintenance therapy with anti-TNF for 16.1 ± 8.5 months. Patients underwent bowel ultrasound and UEI at baseline and 14 weeks after initiation of anti-TNF. Bowel wall stiffness at UEI was quantified by calculating the strain ratio (SR) between the bowel wall and the surrounding mesenteric tissue. Receiver operating characteristic curve analysis was used to identify the best SR cut off able to predict surgery/bowel obstruction. Transmural healing at 14 weeks was defined as a bowel wall thickness ≤ 3 mm. Frequency of CD-related surgeries or hospitalizations due to bowel obstruction was recorded during the follow-up. The data are given as mean values \pm standard deviation

Results: Five patients (16.6%) underwent surgery or hospitalization for bowel obstruction during the follow up. Frequency of CD-related surgeries or hospitalizations was significantly greater in patients with $SR \geq 2$ at baseline than in patients with $SR < 2$ ($p = 0.02$). A significant reduction in bowel thickness was observed after 14 weeks of anti-TNF treatment (from 5.8 ± 1.5 mm to 5.1 ± 1.7 mm, $p < 0.005$), while SR values remained unaltered (1.5 vs 1.3 , $p = 0.5$). A significant inverse correlation was observed between values of strain ratio at baseline and thickness variations following anti-TNF therapy ($p = 0.007$). Eight out of 30 patients (27%) achieved transmural healing at 14 weeks. Baseline SR was significantly lower in patients with transmural healing than in patients not achieving this endpoint (1.06 ± 0.16 vs 1.67 ± 0.17 , $p < 0.05$).

Conclusion: This explorative study shows that UEI is able to predict therapeutic outcomes, including CD-related surgeries and transmural healing, in patients with Crohn's disease treated with anti-TNF therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1657 CLINICAL CHARACTERISTICS OF RECTAL-SPARING ULCERATIVE COLITIS

A. Ito, O. Teppei, T. Katutoshi

Dept. Medicine, Inst. Gastroenterology, Tokyuu Womens Medical University, Tokyo/Japan

Contact E-mail Address: itoayumi@ige.twmu.ac.jp

Introduction: Ulcerative colitis (UC) generally involves the entire large intestine extending from the rectum to the ileocecal junction. However, some patients with moderate or severe UC lack any obvious rectal involvement (known as rectal-sparing [RS]-UC).

Aims & Methods: In this study, we evaluated the differences in the clinical characteristics and disease course between patients with refractory UC with or without RS. Of the 437 inpatients with refractory UC who achieved remission between April 2001 and September 2016 (follow-up period: 915 ± 53 days, mean ± SD), 57 patients were classified as RS-UC and 340 patients without RS (standard [S]-UC group). Patients of the two groups were compared for gender, age at onset, site of involvement, disease duration, pretreatment clinical activity index (CAI, Lichtiger score), Hb, C-reactive protein (CRP), total dose of prednisolone (PSL) before the achievement of remission, duration of hospitalization, endoscopic scores (Mayo and UCEIS), and relapse rates (at 100, 300, 500, and 1000 days post-remission). Patients with RS were defined as those without any detectable rectal inflammation despite not receiving local treatment, such as rectal enema/infusion or suppositories. Remission was defined as CAI of ≤4. Relapse was defined as the need to restart remission induction therapy, such as intensive intravenous PSL, initiation of treatment with biological agent, or re-administration and dose escalation of tacrolimus to achieve a high blood trough level (≥10 ng/dl).

Results: RS was observed in 57 (10.4%) patients. There were significant differences in CRP (RS-UC: 5.1 ± 6.02, S-UC: 2.3 ± 3.4 mg/L) and pretreatment endoscopic scores (Mayo: RS-UC: 2.7 ± 0.3, S-UC: 2.4 ± 0.5; UCEIS: RS-UC: 6.1 ± 1.3, S-UC: 5.7 ± 1.4) between the two groups (P < 0.05). There was no significant difference in the relapse rate at 100 days after remission (RS-UC: 18%, S-UC: 15%). However, the two groups showed significant differences in the relapse rates at 300 days (RS-UC: 38%, S-UC: 17%), 500 days (RS-UC: 57%, S-UC: 48%), and 1000 days (RS-UC: 77%, S-UC: 62%) after remission.

Conclusion: Our results showed that RS is not an uncommon finding among patients with UC. Based on the higher CRP, endoscopic score, and relapse rates in the RS group, than the standard UC group, we recommend aggressive treatment of UC patients with RS.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1658 EVALUATION OF COLONIC MUCOSA WITH FLEXIBLE SPECTRAL IMAGING COLOR ENHANCEMENT (FICE) IN PATIENTS WITH LONG TERM ULCERATIVE COLITIS DURING DYSPLASIA SCREENING

G. Bengi¹, S. Kaya Özding¹, H. Akpınar¹

¹Gastroenterology, Dokuz Eylül University Hospital, İzmir/Turkey

Contact E-mail Address: sedozdinc@yahoo.com

Introduction: Ulcerative colitis (UC) associated colorectal cancer risk (CRC) is related to the age of onset and duration and anatomic extent of the disease. The risk of malignancy increases with the duration of the disease (1). Current guidelines recommend beginning the surveillance colonoscopy after eight to ten years of disease; random biopsies should be obtained from 4 quadrants of every 10 cm of the entire colon. In addition, any suspicious areas should be biopsied (2). Recent endoscopic imaging technologies provide a more detailed visualization of the superficial microstructure of the mucosa and vascularity. Thus it is possible to get targeted biopsies. The purpose of this study is; to evaluate the image patterns of dysplastic changes in ulcerative colitis, and their histopathological correlation, by using a virtual chromoendoscopy technique, FICE and to investigate the effectiveness of this technique.

Aims & Methods: The purpose of this study is; to evaluate the image patterns of dysplastic changes in ulcerative colitis, and their histopathological correlation, by using a virtual chromoendoscopy technique, FICE and to investigate the effectiveness of this technique. Eighteen follow-up patients of our inflammatory bowel disease polyclinic, with UC at least 8 years of disease history and who are in clinical remission are included to this study. Screening colonoscopy was performed to the patients included in the study. Entire colon and especially dysplasia suspected areas visualised with standart endoscopy first, and then with FICE; random and targeted biopsies were taken. Image patterns were compared with histopathologic diagnosis. Normal, colitis and polyps images acquired by FICE, were evaluated by seven endoscopists and statistical analysis was performed.

Results: In a total of 18 patients, by evaluating 123 colonic segments, 1831 images were taken. 1652 image acquired by FICE, and 179 were white light images. Images taken by FICE separately, from each areas of normal colonic mucosa, polypoid lesions and colitis. A total 584 biopsies were taken, 492 (84.2%) random and 92 (15.7%) targeted biopsies. While there were no dysplasia in random biopsies, low-grade dysplasia was detected in 3 diminutive polyps taken as targeted biopsy. The analysis of the FICE images by voting by seven endoscopists showed that, the best imaging channels are; 2, 6, 9 for normal mucosa; 3, 7, 9 for polyps; and 2, 3, 9 for colitis. When all the images are analyzed, channels 2 and 9, were found to be significantly different from other channels. When the most rated channels, 2 and 9, were compared to the WLE, the FICE image is better for evaluation of the mucosal and vascular structure. However, there were no significant difference between channels 2 and 9.

Conclusion: There were no significant superiority of FICE, in dysplasia screening. Consistent with the literature, this study showed us that FICE is effective in detecting diminutive polyps, and evaluating surface patterns without magnification. In clinical remission in patients with UC, FICE can have a role in the assessment of the severity of inflammation. For this purpose, more clinical trials are needed. Our study is the first study with FICE in UC. Channels 2 and 9 are the best image channels of FICE in UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The gut microbiome is thought to be relevant to the pathogenesis of inflammatory bowel disease (IBD). We aimed to explore associations between measures of gut microbiota and clinical as well as inflammatory disease activity in an inception cohort of treatment-naïve IBD patients as well as with inflammatory activity in symptomatic non-IBD patients and healthy controls. The term 'dysbiosis' expresses alterations in the gut microbial community.

Aims & Methods: Patients were diagnosed according to international criteria, including endoscopic and histopathologic assessment. Clinical disease activity in Crohn's Disease (CD) patients was measured by the Harvey-Bradshaw index (HBI), and in ulcerative colitis (UC) patients by the Simple Clinical Colitis Activity Index (SCCAI). Inflammatory activity was assessed by CRP and faecal calprotectin (Fcal), (fCAL® ELISA, Bühlmann laboratories AG). Stool samples were collected within 60 days prior to and 14 days after the diagnosis, and stored at -80°C. Antibiotic treatment within the last two months was an exclusion criterion. Faecal microbiota profiles were generated by 16S rRNA analyses, using the GA-map™ Dysbiosis Test. Dysbiosis was defined as non, mild or severe (1). Differences in disease activity between levels of dysbiosis severity were analysed using ANOVA at a significance level of p < 0.05, and univariate associations between inflammatory activity and log-transformed microbiota profiles were analysed using ANCOVA. P-values corrected for multiple testing, using Benjamini-Hochberg correction, are presented.

Results: Data on dysbiosis, bacteria profiles, and Fcal were available in 57 CD, 80 UC, 12 IBD-U patients and 100 symptomatic non-IBD patients, and 45 healthy controls. CRP was available for 52 CD, 74 UC, 10 IBD-U patients, and 88 symptomatic non-IBD patients. HBI was available for 50 CD patients, while SCCAI was available for 77 UC patients. Disease activity: No association was found between Fcal and dysbiosis in UC patients (P=0.08), CD patients (P=0.22), and healthy controls (P=0.57). However, an association was found between Fcal and dysbiosis in symptomatic non-IBD patients (P=0.04) and in IBD-U (P=0.005). An association was found between CRP and dysbiosis in CD patients (P=0.02), while not for UC and symptomatic non-IBD patients. No association was found between HBI and dysbiosis in CD patients (P=0.23), and between SCCAI and dysbiosis in UC patients (P=0.32). Microbiota: Increasing dysbiosis severity in UC, CD and non-IBD patients yielded lower abundance of *Faecalibacterium prausnitzii*, and higher abundance of Proteobacteria, a profile typically observed in gut inflammatory conditions. In addition, the commensal bacteria *Bifidobacterium* yielded lower abundance with increased dysbiosis severity in UC and non-IBD patients, and in combination with elevated levels of Fcal and/or CRP in UC patients. In the healthy controls, increasing dysbiosis severity yielded higher abundance of Proteobacteria.

Conclusion: In conclusion, a relationship between faecal dysbiosis in sub-groups of IBD and non-IBD was found, in CD patients also with CRP. Accordingly, gut bacteria profiles and abundance may potentially be used to differentiate between severity in UC and CD patients, as a non-invasive tool to monitor disease activity in IBD.

Introduction: Crohn's disease (CD) is a lifelong inflammatory bowel disease. Evaluating the extent and severity of the disease is critical to determine appropriate therapeutic strategies in patients with Crohn's disease. MR imaging is one of the most recommended technique for detection of large and small bowel lesions of CD. The aim of this study is to establish clinical utility of the 5-point MR enterocolonography (MREC) classification for assessing CD activity based on endoscopic findings.

Aims & Methods: A total of 120 patients (70 for derivation cohort and 50 for validation cohort) with CD was enrolled and undergone MREC and ileocolonoscopy or balloon-assisted enteroscopy (BAE). MREC was evaluated for each bowel segment: rectum, sigmoid, descending, transverse, ascending colon, terminal, proximal ileum, and jejunum, according to the consensus of two observers in the derivation phase, and independently by three observers in the validation phase, using a 5-point MREC classification based on a lexicon of MR findings. The conventional MR score, or MaRIA, was evaluated simultaneously. Areas under the receiver operating characteristic curves (AUCs) were obtained to assess the accuracy of discriminating deep ulcers. Inter-observer reproducibility was assessed using weighted Kappa coefficients.

Results: BAE was performed in 49 (70%) and 37 (74%) patients in the derivation and validation cohorts. The AUCs of MREC classification were 89.0% in the derivation phase and 88.5, 81.0, and 77.3% for three observers in the validation phase. The AUCs of MREC classification were statistically non-inferior to those of MaRIA ($p < 0.001$). The cross-validation accuracy was 81.9% in the derivation and 81.5% in the validation phase. The MREC classification showed good.

Conclusion: For clinical use, radiological reporting systems should be simple and provide appropriate levels of accuracy and reproducibility. The 5-point MREC classification meets these requirements, and is useful for evaluating CD activity in the large to deep small bowel segments.

Introduction: Metabolic Syndrome (MetS) is a combination of biochemical and anthropometric disturbances and a recognized risk factor for cardiovascular disease. A higher prevalence of this condition has been previously reported in IBD patients, correlating to age as in the general population.

Aims & Methods: The aim of this study was to assess the effect of individual disease activity-related putative risk factors for MetS in a group of IBD patients, as well as any protective effects of treatment on MetS or its components. Consecutive IBD patients and age- and sex-matched controls were included during a 1-year period. MetS was diagnosed according to the "harmonized" criteria as the presence of >3 criteria among elevated waist circumference, blood pressure, blood glucose, serum triglycerides, or reduced HDL levels. All subjects underwent colonoscopy; endoscopic disease activity was assessed according to SES-CD and Mayo endoscopic scores. CRP, fecal calprotectin (FC), hemoglobin and ferritin levels were also measured.

Results: We enrolled 145 consecutive IBD patients (53 Crohn's disease and 92 ulcerative colitis; 58 M/87 F; mean age 51 ± 18 ys) and 250 age- and sex-matched controls. Overall MetS prevalence was 37% in IBD and 21.6% in controls (OR = 2.1, 95%CI: 1.32–3.39). Prevalence according to sex or disease type did not show significant differences. At multivariate analysis, age and BMI >25 were associated to an increased probability for a positive MetS status both in IBD (respectively, OR = 3.41 and OR = 6.0) and controls (respectively, OR = 3.47 and OR = 3.74). In patients under 50 years, age (OR = 1.24), CRP (OR = 1.9) and FC (OR = 1.35) positivity were associated to MetS status, while a BMI >25 increased risk at any age (<50 ys OR = 3.8, >50 ys OR = 1.56). Endoscopic activity did not associate to MetS status at any age. Interestingly, anti-TNF α treatment was protective in both groups, but reached statistical significance only in older subjects (>50 ys OR = 0.08). Regarding individual MetS components, in the <50 ys subgroup, age and CRP positivity associated with an impaired glycemic (respectively, OR = 1.15 and OR = 2.28) and lipidemic status (respectively, OR = 1.23 and OR = 2.3). In older patients, CRP positivity only associated to impaired HDL status (OR = 5.41). Importantly, anti-TNF α treatment favourably associated to HDL status (OR = 0.2).

Conclusion: MetS prevalence is increased in IBD compared to healthy controls at any age. Subjects with increased BMI and/or inflammatory markers are at higher risk for MetS, while anti-TNF α agents appear to be protective. The components associated to MetS are differently distributed according to age, with the inflammatory ones prevailing in subjects <50 years and metabolic disturbances in older patients. These results indicate that, while in the short term appropriate treatments may reduce MetS occurrence and associated risks in subjects >50 years, in younger patients more effective inflammation control measures may prevent MetS and its related long-term neoplastic and cardiovascular complications.

P1662 C-REACTIVE PROTEIN/ALBUMIN RATIO IS A GOOD PREDICTOR OF RESPONSE TO INTRAVENOUS CORTICOSTEROIDS IN ACUTE SEVERE ULCERATIVE COLITIS

S. Monteiro¹, T. Cúrdia Gonçalves¹, F. Dias De Castro², S. Leite¹, M.J. Moreira², J. Cotter²

Contact E-mail Address: sara.s.o.monteiro@gmail.com

Introduction: Patients with acute severe ulcerative colitis (ASUC) have a high risk of rescue medical therapy or colectomy. Recently, the C-reactive protein (CRP)/albumin ratio at the 3rd day of treatment, with intravenous corticosteroids, has been shown to be a predictor of early colectomy in patients with ASUC.

Aims & Methods: To evaluate the accuracy of CRP/albumin ratio on admission, to predict response to intravenous corticosteroids in patients with ASUC. Retrospective assessment of systematically hospitalized patients with first episode of ASUC, who required intravenous corticosteroids. Demographic, clinical, laboratory and endoscopic variables were evaluated on admission. The response to intravenous corticosteroids on day 3 was based on Oxford criteria. In unresponsive patients, rescue medical therapy with infliximab or cyclosporine has been instituted. The accuracy of CRP/albumin ratio in predicting non-response to intravenous corticosteroids was assessed by the area under the ROC curve (AUC).

Results: 51 patients were included, 30 (58.8%) of them female, with a mean age 34.3 ± 14.5 years. Twelve patients (23.5%) required medical rescue therapy. No patient underwent colectomy. The presence of deep ulcers and a shorter evolution of the disease were associated with a lack of response to intravenous corticosteroids, $p < 0.001$ and $p = 0.008$, respectively. Patients with no response to intravenous corticosteroids had higher CRP admission values and lower albumin values, compared to patients with response, 111 vs 67.5 (mg/L), $p = 0.028$, 2.8 vs 3.5 (g/dL), $p = 0.005$, respectively. The CRP/albumin ratio was also higher in unresponsive patients 40.06 vs 22.14, $p = 0.022$, showing a good accuracy for predicting no response to intravenous corticosteroids with an AUC of 0.746, $p = 0.01$.

Conclusion: A high value of CRP/albumin ratio was significantly associated with the absence of response to intravenous corticosteroids, at the 3rd day of treatment. This index may allow a better risk stratification on admission, of patients with acute severe ulcerative colitis.

Introduction: The MCV flow study confirmed the association Δ MCV ≥ 7 fl at week 26–28 of Azathioprine monotherapy (mAzA) with favourable outcomes in a Portuguese IBD population.

Aims & Methods: For this work, our aims were to evaluate the need for step-up therapy in those under mAzA with Δ MCV <7 and to identify predictors of combined deep remission outcomes (DeepRem), at the same timepoint, for the patients who subsequently began combination therapy with Anti-TNF (AzaExperienced + Anti-TNF). Evaluation of patients under mAzA with Δ VGM <7 at key timepoint week 26–28 treatment, included for *The MCV flow study*. Demographic characterization and severity of pre-treatment disease was evaluated (Montreal classification, previous surgery status, Mayo score and Crohn's disease activity index [CDAI]). Δ MCV's association with DeepRem [Steroid-free clinical remission (CDAI <150 , Mayo <2) + mucosal healing (MH) + C-reactive protein (CRP) <10] and need for biological therapy at the key-timepoint was verified. Evaluation of DeepRem and its independent predictors in patients who subsequently started combination therapy. Statistic: Chi-square test; Binary logistic regression.

Results: A total of 106 IBD patients were evaluated [56.6% women, mean age 39 ± 15.2 years; 58 ad, 14% operated] at week 26–28 of mAzA. Identified strong association between an average Δ VGM ≥ 7 ($n=70$; 66%) with DeepRem ($p < 0.05$), while a Δ VGM <7 was associated with biological therapy need ($p < 0.05$). 45 patients were later started with Anti-TNF therapy

(Aza + Infliximab 46.7%; Aza + Adalimumab 53.3%) and only 44% achieved DeepRem at the key-timepoint. A Crohn's A3L2B3 + p phenotype ($p=0.045$), steroid therapy in the last year ($p=0.009$) and $\Delta\text{VGM} < 7$ ($p=0.036$) were identified as the variables that best explained the difficulty reaching DeepRem. **Conclusion:** This study confirms the prognostic value of ΔVGM in our population. For mAza patients, $\Delta\text{VGM} \geq 7$ was associated with DeepRem and $\Delta\text{VGM} < 7$ was found to be associated with biological therapy need. However, even after starting Anti-TNF, $\Delta\text{VGM} < 7$ was identified as a predictor of the difficulty reaching DeepRem.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1664 FECAL CALPROTECTIN PREDICTS SHORT-TERM RELAPSE IN INFLAMMATORY BOWEL DISEASE PATIENTS IN DEEP REMISSION

Introduction: Most inflammatory bowel disease (IBD) patients with clinically successful treatment seem to have some degree of residual mucosal inflammation. Elevated fecal calprotectin (FC) concentrations can be found despite clinical remission and may indicate relapse risk in asymptomatic IBD.

Aims & Methods: The aim of this prospective study was to evaluate whether elevated FC values can predict short-term clinical and/or endoscopic relapse. We enrolled 60 IBD patients (30 ulcerative colitis - UC, 30 Crohn's disease - CD) who were in clinical and endoscopic remission. FC was measured using quantitative immunochromatographic point-of-care test (Quantum Blue® Calprotectin, Bühlmann Laboratories AG, Switzerland). Patients were followed-up by FC examination and clinical activity assessment every second month until relapse or up to 24 months. Ileocolonoscopy was performed at inclusion and at the time of clinical relapse.

Results: During the follow-up 36 (60%) relapsed and 24 (40%) remained in remission. The mean time to relapse in all patients was 13.9 (range 2–20) months. Significant increase in median FC levels was seen 2 months ($p < 0.001$) before endoscopic relapse. ROC analysis indicated that a cut-off of $> 90 \mu\text{g/g}$ (OR 24, 95% CI = 5–117, $p < 0.001$) in mean FC values 2 months before relapse could predict relapse in UC patients with 83.3% sensitivity and 82.9% specificity. In CD patients a cut-off of $> 155 \mu\text{g/g}$ (OR 193, 95% CI = 22–1682, $p < 0.001$) could predict relapse within two months with 91.7% sensitivity and 94.6% specificity. Constantly normal FC values during the follow-up were predictive for deep remission.

Conclusion: It seems that FC elevates two months before clinical and/or endoscopic relapse. FC is a suitable marker for predicting relapse and building a follow-up strategy for IBD patients in clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1665 GLYCEMIC CONTROL AND INSULIN RESISTANCE IN PATIENT WITH INFLAMMATORY BOWEL DISEASE - PRELIMINARY RESULTS FROM THE POLIBD STUDY

Introduction: Hyperglycemia associated with critical illness - also called stress hyperglycemia or stress diabetes - has been demonstrated with much higher prevalence of severe ill patients. It is connected with many factors, including increased cortisol level, catecholamines uptake, glucagon production, gluconeogenesis, insulin resistance and inflammatory markers. It is not considered as an adaptive response anymore. Furthermore uncontrolled hyperglycemia is associated with poor outcomes and significantly increases mortality rates. That is why stress hyperglycemia and insulin resistance may be a marker of severe illness.

Aims & Methods: We analysed the data (glycemia, insulin level, HOMA IR level, C-reactive protein level, HbA1C) of 62 patient aged 18 years and older (20 women and 42 men, 32.26 ± 13.8 years of age) with IBD hospitalized in our clinic from 2016 to 2017. 16 patient were with Ulcerative Colitis (UC) and 48 patients with Crohn's Disease.

Results: The analysis of patients with Ulcerative Colitis showed that only one of the patients had hyperglycemia within the range of 140 mg–200 mg (the patient had type 2 DM) but interestingly 37.5% of the patients had fasting hyperglycemia over 100 mg. Over 86% of these patient were submitted to our clinic with the exacerbation of the disease and had abnormal level of C-reactive protein, calprotectin (> 1800) and fasting insulin level over 10 IU/ml. The analysis of the group of patients with Crohn's Disease showed different results which may be connected with different metabolic profile of these patients. Most of the patients

with fasting hyperglycemia (only 12.5%) had elevated C-reactive protein level but not fasting insulin level - it was within normal range. The highest level of the fasting insulin (over 10 IU/ml) in this group was observed in 3 patients who had to undergo immediate surgical treatment - two of them because of the bowel obstruction and one of them because of the perforation.

Conclusion: In our opinion there is a strong connection between fasting glucose, CRP level and exacerbation of the disease in CU patients but not in case of the Crohn's Disease. In this group the elevated fasting insulin may be a marker of severe illness.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1666 THE ROLE OF MR IMAGING IN ASSESSMENT OF LEMANN INDEX IN THE COURSE OF CROHN'S DISEASE

J.M. Pienkowska, O. Kozak, T. Nowicki, E. Szurawska

Radiology, Medical University of Gdansk, Gdansk/Poland

Contact E-mail Address: oliwiak@gumed.edu.pl

Introduction: Crohn's disease (CD) is a progressive, chronic and destructive inflammatory bowel process which, during its course, can lead to complications such as strictures and penetrating lesions (fistulas and abscesses), which may consequently require operative treatment. In some patients, bowel damage is present at the moment of diagnosis. The aim of the study is to assess the initial Lemann Index (LI), which comprehensively evaluates the entire gastrointestinal tract damage in patients with newly diagnosed Crohn's disease.

Aims & Methods: In 209 patients with clinical suspicions of Crohn's disease MR imaging, endoscopic examination and histopathology were performed. In 151 patients with confirmed active/chronic CD the Lemann Index has been calculated on the basis of radiological and clinical information for initial assessment of cumulative digestive tissue damage. To create the Lemann Index the gastrointestinal tract was divided into 4 organs: upper digestive tract, small bowel, colon/rectum and anus. Each organ was divided into segments (3 for the upper digestive tract, 6 for the colon/rectum and 1 for anus). Strictures and penetrating lesions were assessed at each segment on 4-degree scale (0–3) according to the severity of lesions.

Results: Based on the findings of the initial radiological examination, active inflammation process was found in 76 patients and chronic process in 75 patients. The baseline study demonstrated such complications as strictures in 14 patients, fistulas in 15 and abscesses in 4 patients. For all patients the LI was calculated. The obtained values were within the range from 0 to 22.

Conclusion: Over the years, the progression of Crohn's disease leads to an increase in the value of Lemann Index, therefore, it seems that the evaluation of this repetitive parameter already in the first, baseline study and in all following control MR examinations will allow for a more complete assessment of patients in terms of progressive bowel damage and modification of the therapeutic process.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Optical imaging is being increasingly advocated for characterization of polyps during colonoscopy. The accuracy of these techniques during surveillance colonoscopy in colonic inflammatory bowel disease (IBD-C) is unclear and with variable results reported. We aimed to perform a systematic review and meta-analysis of the diagnostic accuracy of optical imaging techniques including dye based and virtual chromoendoscopy, magnification endoscopy and confocal laser endomicroscopy.

Aims & Methods: We searched Medline and Embase for relevant papers. Full articles or abstracts were eligible when characterization performance of dye-based chromoendoscopy (DCE), virtual chromoendoscopy (VCE) (narrow-band imaging [NBI], i-scan, Fujinon intelligent chromoendoscopy [FICE]), magnification endoscopy and confocal laser endomicroscopy (CLE) had been compared with histopathology, as the reference standard. Enough information had to

be required to obtain a 2x2 contingency table. Pooled analysis was done using a random-effects model. Sub-group analysis was performed at real-time Kudo pit pattern based and real-time CLE for characterization of visible lesions. Heterogeneity was assessed using Chi squared and I² statistics.

Results: Our search strategy identified 172 studies of which only 20 met the inclusion criteria. The pooled results are outlined in the table.

Conclusion: Real-time CLE and magnification endoscopy had the best performance characteristics. However there was a lot of heterogeneity in the results. Most CLE and magnification studies were single centre, single expert user which could explain these results. CLE studies were also affected by attrition bias with some studies reporting non-interpretable images in a significant proportion.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The need to stratify patients with Crohn's disease (CD) according to the risk of developing complications is essential to delineate therapeutic approach. A score that evaluates the severity of DC (Siegel et al, Gut 2016) has recently been developed and published, taking into account intestinal lesions, disease activity and complications during the course of the disease, ranging from 0 to 100.

Aims & Methods: We aimed to evaluate the performance of the aforementioned score at the time of diagnosis and its relation to the need for surgery and hospitalizations in patients with CD. We performed a retrospective study that included patients diagnosed with DC in our hospital between 01/2012–12/2015. The score was calculated at the time of diagnosis and information on the course of the disease was collected. Statistical analysis was performed in SPSS (v23).

Results: A total of 57 patients (52.6% women) with a mean age of 33.74 ± 15.8 years were included. The median severity score at diagnosis was 16 ± 16.5 ranging from 4 to 50. Twenty-four patients (40.7%) required surgery and 29 (49.2%) were hospitalized for reasons associated with the disease. At diagnosis, the score was higher in A1 patients (26 vs 19.2 and 13.7, p=0.05), with a penetrating phenotype (25.5 vs. 19 and 12, p=0.02), and in patients requiring surgery during the course of their disease (21 vs 14, p=0.1). There was a positive correlation between the score at diagnosis and the number of surgeries during follow-up (r=0.43; p=0.05). Survival analysis showed a trend towards shorter time for surgery or hospitalization in patients with a score above the median at diagnosis (p logrank = 0.09).

Conclusion: The new severity score seems to be a promising tool for stratification and prognosis of patients with CD at diagnosis, and its utility should be validated in prospective studies.

Introduction: Microscopic colitis (MC) is a clinical syndrome of severe watery diarrhoea with few or no endoscopic abnormalities. The incidence of MC is reportedly similar to that of other inflammatory bowel diseases. The need for histological confirmation of MC frequently guides reimbursement health policies. With the advent of high-definition (HD) colonoscopes, the incidence of distinct endoscopic findings reported in MC has risen. This has the potential to improve diagnosis times, increase cost-effectiveness of MC management and diminish the workload and costs of busy modern endoscopy units.

Aims & Methods: Publications on distinct endoscopic findings in MC available until 31st March 2017 were searched systematically (electronic and manual) in PubMed. The following search terms/descriptors were used: collagenous colitis(CC) OR lymphocytic colitis(LC) AND endoscopy, colonoscopy, findings, macroscopic, erythema, mucosa, vasculature, scars, lacerations, fractures. An additional search for MC AND perforation was made.

Results: Eighty (n=80) articles, predominantly single case reports (n=45), were retrieved. Overall, 1,582 (1,159 female; 61.6 ± 14.1 years) patients(pts) with MC and endoscopic findings were reported. The majority of articles (n=62) were on CC (756 pts; 77.5% female). We identified 16 papers comprising 779 pts (68.9% female) with LC and 7 articles describing 47 pts (72.3% female) confirmed to have MC. The youngest patient was 10 and the oldest 97 years old. Aside from diarrhoea, symptoms included abdominal pain, weight loss, bloating, flatulence and oedema. In the study group we found 616 (38.9%) pts with macroscopic findings. The most common colonoscopic findings were non-ulcerous lesions i.e. pseudomembranes, a variable degree of vasculature pruning & dwindling, mucosal lacerations & abnormalities such as erythema/edema/nodularity, or surface textural alteration (n=537; 87.2% pts). Isolated linear ulcerations were identified in 5 pts(0.8%) and in conjunction with non-ulcer lesions in 74 pts(12.0%). The location of endoscopic findings was not reported in 26 articles. Distinct endoscopic findings were described in the left (descending, sigmoid, rectum –23/20/10 studies), right (cecum, ascending–7/21 studies) & transverse colon (14), as well as duodenum (4), and terminal ileum (2). Colonic perforation was reported in 9 patients (0.57%).

Conclusion: Endoscopic findings are recognized with increased frequency in pts with MC. This could improve MC diagnosis by prompting a more extensive biopsy protocol in such cases and an earlier initiation of treatment. Procedure-related perforation has been reported in this group; therefore, cautious air insufflation is advisable when endoscopic findings are recognised.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: It is well recognized that patients with inflammatory bowel disease (IBD) are at risk for nonalcoholic fatty liver disease (NAFLD). Our aim was to evaluate the prevalence and to quantify hepatic steatosis in IBD patients using the controlled attenuation parameter (CAP).

Aims & Methods: We prospectively recruited all IBD patients presenting for a disease flare or follow-up visit in our clinic, during a 18 month period. Patients who reported chronic alcohol intake more than 20 g/day and those with coexisting viral hepatitis were excluded from analysis. Clinical characteristics and laboratory data were recorded. Hepatic steatosis was evaluated by conventional ultrasound, hepatic steatosis index (HSI) and transient elastography with CAP (Fibroscan, Echosens, Paris). Significant steatosis ($S \geq 1$) was defined for a CAP value over 236 [1], and the cut-off of HSI for detecting NAFLD was set at ≥ 36 [2].

Results: Altogether 62 IBD patients (35 ulcerative colitis, UC and 27 Crohn's disease, CD), mean age 45 ± 15 years, 50% female, were included in the analysis. The two groups (UC, CD) were similar regarding disease activity (remission/flare-48.5/51.4% in the UC group, 55.6/44.4% in the CD group), BMI (24.1 and 24.4 respectively) or inflammatory markers (ESR 21 and 21.1 mm/h, fibrinogen 498 and 513 mg/dl). UC patients had higher mean cholesterol values (205.9 vs. 176.4 mg/dl) and 11% of them were diabetic (compared to none in the CD group). Mean CAP was higher in CD compared to UC-246 vs. 225 dB/m, while HSI was similar among the two groups 34.9 ± 4.9 and 34.6 ± 5.4 , respectively. US identified 18/62 (29%) patients with fatty liver, HSI detected 3 more patients (21/62, 33.9%) and CAP even 2 more (23/62, 37.1%), yielding an extra 8% detection rate. NAFLD-IBD patients were more likely to have CD phenotype, history of resection, steroid use and longer disease duration.

Conclusion: In our cohort, about one in three IBD patients had fatty liver disease, as quantified by CAP. Diagnostic performance of CAP was better than conventional ultrasound and HSI in detecting fatty liver in IBD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Irritable Bowel Syndrome (IBS) is a common gastrointestinal disorder that affects around 11% of global population. Despite the high prevalence of IBS, the cause of this disorder remains unknown and the criteria used to diagnose IBS are still unclear. In recent years, disturbances in the intestinal microbiota have been associated to the pathophysiology of IBS. Recently, two accurate biomarkers: *Faecalibacterium prausnitzii* (Fpra) and *Escherichia coli* (Eco) have been shown to discriminate between Inflammatory Bowel disease (IBD) and Healthy subjects (H). Therefore, the purpose of this study was to verify the capability of Fpra and Eco abundances to distinguish among healthy subjects, IBS, and IBD patients, in order to create a non-invasive system of diagnostic support for IBS patients.

Aims & Methods: A cohort consisting of 33 H and 14 IBS was enrolled. IBS patients were separated by subtypes: IBS with constipation (C-IBS), IBS with diarrhea (D-IBS), and alternate IBS (A-IBS). Rome IV criteria were used to diagnose IBS patients. Moreover, 29 ulcerative colitis (UC) and 15 Crohn's disease (CD) patients were also included. All subjects were recruited by the Gastroenterology Services of the Hospital Universitari Dr. Josep Trueta (Girona, Spain) and Hospital Universitari de Bellvitge (Hospitalet del Llobregat, Spain). Fpra total and Eco abundances were quantified by qPCR.

Results: We found lower abundance values of Fpra in IBS patients when compared with H ($P = 0.005$). In contrast, Eco abundance was higher in IBS patients, although the differences observed were not significant ($P = 0.221$). When comparing among subtypes of IBS (C-IBS, D-IBS, and A-IBS) no significant differences were observed, although Fpra abundance was lower in C-IBS. We also used Fpra in combination with Eco as a complementary indicator of dysbiosis (Ratio

Fpra/Eco). This ratio allows a good discrimination between H and IBS ($P = 0.041$). When it comes to discrimination between IBS and IBD patients, significant differences were observed in Fpra/Eco ratio between UC and IBS patients ($P = 0.008$), but not between IBS and CD patients ($P = 0.775$). Concerning disorders different to IBS, significant differences were also observed between H and CD ($P > 0.001$), between H and UC ($P = 0.037$), and between CD and UC ($P = 0.027$).

Conclusion: Fpra abundance is a good biomarker to discriminate between healthy subjects and IBS patients. The use of Fpra/Eco ratio allows to distinguish IBS from H and UC patients. In contrast, none of the used biomarkers was able to differentiate IBS and CD patients. These results show that IBS and CD patients share similar dysbiosis parameters opening the need of further study to established any eventual pathogenic link.

Introduction: Inflammatory bowel disease (IBD) and irritable bowel syndrome (IBS) may present in a similar manner [1] [2]. Measuring faecal calprotectin concentration is often recommended to rule out inflammatory bowel disease, however, there are no tests to positively diagnose irritable bowel syndrome and invasive tests are still used to rule out other pathologies [3, 4]. There is a chance; therefore, for novel, non-invasive diseasespecific biomarkers. Volatile organic compounds (VOCs), originating from physiological metabolic processes in the human body, are excreted as waste products through stool samples. For this reason, several biological, non-invasive, simple and low-cost biological markers of inflammation that are useful in clinical practice for both diagnostic screening and therapeutic or course response monitoring are being evaluated in recent years. Evolution of the disease. In this sense, stool markers, and especially calprotectin, have become of great importance in recent years as screening to select patients requiring more diagnostic studies and as a marker of activity for therapeutic follow-up [5]. Can the VOCs from stool samples show differences between ulcerative colitis and Crohn's disease?

Aims & Methods: Five healthy individuals (control group- CON) and nineteen patients diagnosed with IBD were selected for the analysis of their stool VOCs. Healthy participants Healthy control samples (Control) (n=5) were collected from healthy volunteers workers in the Digestive Diseases Area and they reported no illnesses related to the gastrointestinal tract and had not undergone antibiotic treatment in the 3 months before sampling. Active patients were defined as a Mayo Clinical score of 3 or more for ulcerative colitis (UC) and a Harvey Bradshaw clinical index of 4 or more for Crohn's disease (CD). In both cases with a calprotectin >300 micr/gr or relevant endoscopic lesions. Patients were classified according Montreal and ECCO criteria. This preliminary study is based in a group of CD-UC-CON where was analyzed 10 CD patients, 9 UC patients and 5 controls with 455 samples. Data from stool samples was obtained using eNose MOOSY32 [6].

Results: Figure 1 shows the scatter 3D plot with three voltage parameters for the group CD-UC-CON. These parameters mean the voltage from the eNose's signals on saturation slope (vB) and late saturation (cV) and the number of sensor from the MOOSY32. Table 1 shows the comparative between relative error absolute and classification.

Table 1: Different algorithms test for matrix classification by WEKA software. Classification Relative absolute error

MLP Cross	10	92.0%	16.5%
MLP	30%Train + 70%Test	94.1%	12.2%
BayesNet Cross	10	89.8%	5.8%
BayesNet	30%Train + 70%Test	86.0%	22.1%
J48 Cross	10	89.6%	16.7%
J48	30%Train + 70%Test	89.7%	17.1%

Conclusion: In this preliminary research to distinguish between Ulcerative Colitis and Crohn's Disease, the best algorithm for patient's classification was the MLP with 30% to train and 70% to test. Although the high classifications result it is hopeful is necessary continue working to understanding how the eNose's signals affect to the relative absolute error and improving the algorithms to decrease the error.

Introduction: Czech Registry of Inflammatory Bowel Disease (IBD) Patients on Biological Therapy (CREdIT) was launched in March, 2016 in order to collect and analyze the data from Czech centers appointed to provide biological therapy to IBD patients.

Aims & Methods: The objective is to provide information on the CREdIT registry after its first year of operation. Basic demographic data (sex, age, diagnosis, Montreal classification or disease extent) were collected together with information on disease activity, therapeutic regimen, concomitant medication and adverse events. Patients who begun biologic therapy prior to enrolment into the registry as well as those who start their treatment are included, and labeled as "retrospective" and "prospective" cohort, respectively.

Results: Among 30 centers providing biological therapy to patients with Crohn's disease (CD) and ulcerative colitis (UC) in the Czech Republic, 24 participated as of the end of March 2017. The centres enrolled 2129 IBD patients (CD, 1595, 74.9%; UC, 505, 23.7%; IBD-U, 29, 1.4%), with median of 63 (range 4–528) patients per center. Majority belong to the retrospective cohort (65%), the remaining 35% represent the prospective cohort. According to the latest data check, patients are treated with infliximab (1273, 59.8%), adalimumab (739, 34.7%), vedolizumab (73, 3.4%), and golimumab (42, 2%). Treatment intensification (at any time of therapy) was used in 348 patients (19.1%). Infliximab was the most frequently used drug in the first line of biological treatment of both diseases, while adalimumab and vedolizumab were the most used drugs in the second and third line, respectively. When started with biological therapy, majority of CD patients was on concomitant azathioprine (55.4%), while UC patients used most frequently mesalazine (72.7%). Among CD and UC patients, the proportion of patients on concomitant corticosteroids decreased from 42.7% and 67.9% to 10.2% and 24.5%, respectively. 76 (3.5%) patients experienced at least one adverse event while on biologic treatment.

Conclusion: The new Czech national registry collects and provides data on IBD patients treated with biological therapy. Majority of patients enrolled have Crohn's disease, and the mostly used drug is infliximab. Therapy is effective with low frequency of adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI674 THE DIAGNOSTIC VALUE OF MIRNA-320A AS A BIOMARKER IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

F. Cordes¹, C. Ruhs¹, M. Brückner¹, T.M. Nowacki¹, F. Lenze¹, M.A. Schmidt², C. Cichon², D. Bettenworth¹

Introduction: In patients with inflammatory bowel diseases (IBDs), comprising Crohn's disease (CD) and Ulcerative colitis (UC), a patient-tailored therapy is an unmet need that requires accurate monitoring of the intestinal disease activity. We demonstrated recently, that the expression of microRNA (miR)-320a follows the disease activity in murine colitis models¹. In this prospective study we evaluated the potential of miR-320a as a biomarker to monitor the disease activity in IBD patients as well as its potential to distinguish UC/CD from infectious colitis.

Aims & Methods: The miR-320a was measured by qRT-PCR analysis in peripheral blood samples from 36 CD und 34 UC patients with acute flare of disease (n = 51) and in remission (n = 37) as well as in healthy control patients (n = 20) and in patients with infectious colitis (n = 9). Disease activity was assessed clinically applying the Crohn's disease activity index (CDAI) and the partial Mayo score (pMayo) for UC patients as well as the simple endoscopic score Crohn's disease (SES-CD) and the endoscopic Mayo score (eMayo) to score endoscopic disease activity.

Results: Both in CD and in UC patients, miR-320a expression in remission was significantly increased as compared to healthy controls (49 ± 8/87 ± 17 vs. 17 ± 3; both p < 0.001) but distinctly lower as in CD/UC patients with acute flare (1718 ± 488; p = 0.006; 531 ± 107, p = 0.001). In CD patients with clinical acute flare (CDAI > 220), miR-320a expression level were significantly increased as compared to CD patients in clinical remission (CDAI < 150; 2677 ± 637 vs. 57 ± 9; p < 0.001) and showed a strong correlation with endoscopic disease activity (r² = 0.70). Similarly, in UC patients, miR-320a also revealed a significant increase in patients with low (pMayo 3–4), moderate (pMayo 5–6) and severe clinical disease activity (pMayo > 6) as compared to UC patients in remission (259 ± 47; 281 ± 26; 1090 ± 204 vs. 76 ± 13, all p < 0.001). Furthermore, we detected a significantly enhanced miR-320a expression with increasing endoscopic disease activity (eMayo 1: 89 ± 14 vs. eMayo 2: 301 ± 50, p = 0.006; vs. eMayo 3: 775 ± 245; p = 0.02). Most importantly, miR-320a expression in CD and UC patients with acute flare of disease was significantly increased as compared to patients with infectious colitis (53 ± 12, p < 0.001).

Conclusion: The miR-320a expression in peripheral blood from IBD patients follows the clinical and endoscopic disease activity and may distinguish between IBD and infectious colitis. Therefore, miR-320a might serve as biomarker to non-invasively assess the disease activity in IBD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI675 COST EFFECTIVENESS OF IBD OC FAECAL CALPROTECTIN AS A SURROGATE MARKER OF MUCOSAL HEALING POST INDUCTION OF BIOLOGICAL AGENTS IN INFLAMMATORY BOWEL DISEASE

G. El-Safi, K. Sugrue, D. Fitzgerald, C. Byron, L. Barry, M. Farman, A. Alhanaee, M. Buckley, J. McCarthy
Dept. Of Gastroenterology, Mercy University Hospital, Cork/Ireland

Contact E-mail Address: jafaralsafi@hotmail.com

Introduction: Traditionally in our unit all IBD patients started on anti-TNF therapy are followed up at 3 months in the clinic and we aim to do a colonoscopy at 6 months to assess for mucosal healing. Recently we have started using a relatively new technology, called IBDoc, which allows testing the faecal calprotectin at home using a smart phone application and the results are automatically updated in our database.

Aims & Methods: We aimed to evaluate the cost effectiveness of using IBDoc faecal calprotectin post induction of biological agents. The data was collected retrospectively from our IBDoc data base. All patients that were commenced on anti-TNF therapy for IBD and trained in using IBDoc at home were included. IBDoc faecal calprotectin was tested at 3 and 6 month post induction of biological agents.

Results: Total number included in the study was 131 patients. 40% had normal calprotectin at 3 month saving 53 follow up clinic visits (cost of clinical visit 128 euro), and 75% had a normal faecal calprotectin at 6 months saving 40 routine colonoscopy (cost of colonoscopy 337 euro). 78 patients had a raised faecal calprotectin at 3 month, of which 28% had a normal faecal calprotectin at 6 month saving 22 follow-up colonoscopy. In total 53 clinical visits and 62 colonoscopies were avoided.

Conclusion: This study demonstrate a significant cost effectiveness of using IBDoc faecal calprotectin post induction of anti-TNF therapy, as well as reducing the waiting time for both clinic visits and colonoscopies.

Introduction: Infliximab (IFX) levels have been associated with clinical and endoscopic outcomes in patients with inflammatory bowel disease (IBD). Therapeutic drug monitoring (TDM) and a treat-to-target therapeutic approach may arise as a clinical strategy to optimise infliximab efficacy, safety and cost. The current IFX assay test and the cut-off levels used in practice, are based on a high time consuming ELISA procedure, processed in a batch-like method (technical delay) and requiring high expertise. An easy to use, rapid point-of-care test would dramatically reduce the turnaround time for results, allowing a faster decision. The aim of this work is to compare a newly developed point-of-care diagnostic test (Quantum Blue® assay) with the standard ELISA method (Promonitor® assay) determining a correlation factor that permits therapeutic management in a similar way.

Aims & Methods: A total of 135 serum sample from patients with CD and UC. IFX concentration in serum samples were determined using a well established IFX-specific ELISA assay (Promonitor®) and the tested assay Quantum Blue®. According to the manufacturer, the lower and upper limits of quantification are: In the Quantum Blue assay 0.4 µg/ml and 20 µg/ml, respectively. In the Promonitor assay 0.035 µg/ml and 14.4 µg/ml, respectively. All statistics were carried out using the statistical programs IBM SPSS statistics 21 and Epidat version 4.2.

Results: The IFX levels measured by the point-of-care method were higher than those measured by established ELISA (Promonitor level: mean 4.67, median 3.2 s.d. 4.39 (0.035–14.4)); Quantum Blue level mean 6.31; median 3.7 s.d. 6.27 (0.4–20). The intraclass correlation coefficients were 0.81 ($p < 0.001$). The standard ELISA had a high ($r = 0.89$) and significant ($p < 0.001$) correlation with the Quantum Blue® assay. A Bland-Altman analysis showed a bias of 1.88% confirming the overall excellent correlation of the two methods. The results for each method were stratified according to a commonly accepted therapeutic range (3–7 µg/ml; lower than 3 and higher than 7) with a high agreement. We estimated a simplified score to convert the “point-of-care” level into “Promonitor” level and facilitate dose management: “Nivel de Promonitor = 0,793 + 0,615 * Nivel QB”.

Conclusion: Quantum Blue® assay is a really useful technique enabling the fast and friendly quantitative determination of IFX levels to ensure correct dosing in IBD.

Introduction: The significance of established risk factors for colorectal cancer in inflammatory bowel disease remains debated.

Aims & Methods: Our aim was to evaluate how individual disease variables contribute to the development of colorectal cancer. A population-based inception cohort of patients with ulcerative colitis patients diagnosed between 1990–1994 have been prospectively followed at one, five, 10 and 20 years after inclusion. In total we identified 517 patients, 266 (51.5%) were males, aged median 37.4 (min 4, max 88) years at inclusion. The following variables were analyzed: age at ulcerative colitis diagnosis, gender, presence of low or high grade dysplasia, use of azathioprine and 5-amino salicylic acid, extent of mucosal inflammation, first-grade relative with colorectal cancer.

Results: We identified 10 patients diagnosed with colorectal cancer after being diagnosed with ulcerative colitis. Age at ulcerative colitis diagnosis and low grade dysplasia were significantly associated with higher risk of CRC (HR = 1.06, 95%CI [1.02–1.11], $p = 0.003$ and HR = 86.4 95%CI [10.1–740.3], $p < 0.001$ for age and low grade dysplasia respectively). Patients who were older than 40 years at diagnosis had 4 times higher risk of developing colorectal cancer compared to patients diagnosed with ulcerative colitis at a younger age. HR = 4.08, 95%CI [1.02,16.39], $p = 0.047$. Male gender (HR = 1.949, use of azathioprine (HR = 2.50), use of 5-amino salicylic acid (HR = 2.92) and extent (HR = 1.78) were also associated with higher risk of CRC, however the estimates did not reach the level of statistical significance. Males diagnosed with UC when older than 40 years and with extent of inflammation had 8.4% probability of developing CRC within 20 years after their diagnosis.

Conclusion: Our results show that the presence of low grade dysplasia significantly increases the risk of colorectal cancer. The study was limited by the sample size.

P1678 MANAGEMENT OF COMPLEX PERIANAL FISTULAE: WHEN TO SUSPECT INFLAMMATORY BOWEL DISEASE?

M. F. Cardoso¹, J. C. Branco¹, A. M. Oliveira¹, C. G. Rodrigues¹, L. Santos¹, C. Carneiro², J. Reis¹

¹Gastroenterology, Hospital Professor Doutor Fernando Fonseca, Amadora/Portugal

²Surgery, Hospital Professor Doutor Fernando Fonseca, Amadora/Portugal

Contact E-mail Address: marianafcardoso@gmail.com

Introduction: Perianal fistulae are a frequent manifestation of inflammatory bowel disease (IBD) often associated with significant morbidity, which may

precede or appear simultaneously with intestinal disease.¹ The approach to patients with perianal fistulae and no intestinal symptoms is poorly defined, and it remains to elucidate if there is a subgroup of patients in whom a more extensive search for IBD is warranted.

Aims & Methods: Unicentric retrospective cohort study including patients evaluated between 2012 and 2016 for complex perianal fistulae, defined according to the American Society of Colon and Rectal Surgeons². Patients with known IBD, malignancy or history of pelvic radiation were excluded. Patients in whom the diagnosis of IBD was established were compared to the others.

Results: 124 patients were included (mean age 48.2 ± 17.8 years; 71.0% men), with a mean follow-up of 26 months. 18 patients (14.5%) were diagnosed with IBD, namely Crohn's disease. The classification of the fistulous tracts was as follows: intersphincteric (71.8%), transsphincteric (38.7%), extrasphincteric (7.3%), suprasphincteric (5.6%), horseshoe (24.2%) and with an abscess (44.4%). The majority of patients with IBD presented intestinal symptoms (15/18), in 8 cases preceding the perianal disease but not motivating investigation in the past. In 3/18 (16.7%) patients diagnosed with IBD, perianal fistula was the sole clinical manifestation of the disease. Patients with IBD were younger (30.1 vs 51.4 years, $p < 0.001$), had a higher incidence of perianal abscesses (88.9% vs 36.8%, $p < 0.001$), more persistent/recurrent disease (88.9% vs 50.6%, $p = 0.003$) and a tendency to a higher number of fistulous tracts (38.9% had ≥ 5 tracts vs 17.9% in the group without IBD; $p = 0.059$).

Conclusion: In this cohort of patients with complex perianal fistulae, although in the majority of cases the diagnosis of IBD was suggested by the presence of intestinal symptoms, these were absent in 16.7% patients. There should be a higher suspicion of IBD in young patients and in those who have perianal disease of greater complexity.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1679 THE ADDITION OF AN IMMUNOSUPPRESSANT IS AN EFFECTIVE OPTIMIZATION STRATEGY AFTER LOSS OF RESPONSE TO ANTI-TNF ALPHA MONOTHERAPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A TWO-YEAR STUDY

F.S. Macaluso¹, C. Sapienza¹, M. Ventimiglia¹, S. Renna¹, G. Rizzuto¹, R. Orlando¹, M. Di Pisa², M. Affronti¹, E. Orlando¹, M. Cottone¹, A. Orlando¹

Introduction: In patients with inflammatory bowel disease (IBD) the addition of an immunosuppressant (IM) after loss of response to anti-TNF alpha monotherapy is regarded as an emerging strategy of therapeutic optimization. However, few clinical data have been reported to date.

Aims & Methods: The aim of this study was to evaluate efficacy and tolerability of this “selective” combination therapy in patients with IBD. All consecutive patients with loss of response to anti-TNF alpha monotherapy despite an intensive dose optimization who added an IM from October 2014 to October 2016 were entered in a prospectively maintained database. The steroid-free remission and the clinical response, this latter defined as a clinical improvement (reduction of Harvey-Bradshaw Index ≥ 3 for Crohn's disease and of Mayo Partial Score ≥ 2 for ulcerative colitis compared with baseline) with a concomitant reduction of steroid dosage compared with baseline and discontinuation within twelve weeks, were set as clinical end points.

Results: Among 630 patients treated with biologics during the study period, 46 (33 Crohn's disease and 13 ulcerative colitis) were included (table 1). A total of 31 patients (67.4%) were treated with an intravenous anti-TNF α (infliximab, as originator product or biosimilar), while 15 (32.6%) with a subcutaneous anti-TNF α agent (10 adalimumab and 5 golimumab). The mean doses of thiopurines used in combination therapy were below those regarded as therapeutic in IBD, methotrexate was mostly employed at a dose of 15 mg/week, and all patients treated with mycophenolate mofetil were able to tolerate the target dose of 1500 mg/day. The mean duration of follow-up was 12.8 ± 7.3 months. Twenty-one patients (45.7%) remained on combination therapy at the end of follow-up: 15 (32.6%) maintained a steroid-free remission, and 6 patients (13.0%) achieved a clinical response. In patients who experienced a treatment success, median value of C-reactive protein decreased from the baseline to the end of follow-up (13.2 vs. 3.0, $p = 0.01$; normal values < 5 mg/L). Adverse events leading to treatment discontinuation were reported in 8 out of 46 patients (17.4%).

Table 1

Contact E-mail Address: mattiacrespi4@gmail.com

Introduction: Extra-Intestinal Manifestations (EIM) are frequently (up to 40%) encountered in patients with Crohn's Disease (CD). Commonly, their presence is associated to a more severe degree of luminal disease and lower response to

conventional therapy (i.e. immunosuppressants). Drug trough levels are associated with biological drug response, while the role of Anti-drug Antibodies (AAA) is still debated. Moreover, the predicting factors associated with AAA development have not been thoroughly studied yet. To the best of our knowledge, there are no studies correlating the presence of EIM and AAA development.

Aims & Methods: The aim of our prospective study was to identify an association between the presence of EIM and the development of AAA in CD patients treated with biological therapy. We prospectively enrolled 60 CD patients (32 males, median age = 46y, range = 21–72) treated either with adalimumab (ADA n = 39, 65%; IFX n = 21, 35%) with a median follow-up of 80 (range 14–206) weeks. Blood samples were drawn at standardized time points assessed using an homogenous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States). **Results:** AAA were detected in 27 (45%) patients and their development has proved to be more frequent in subjects treated with IFX rather than those in therapy with ADA (n = 14, 66.6% vs 13, 33.3%, $P = 0.017$). EIM were observed in 26 (43.3%) patients, without any significant difference between ADA and IFX patients (n = 17, 51.5% vs n = 9, 42.9%, $P = 1$). We found that ADA treated patients with EIM were more likely to develop AAA (n = 9, 52.9% versus n = 4, 18.2%, $P = 0.039$) while no statistically significant association between EIM and AAA development was observed in IFX treated patients (n = 5, 55.5% versus n = 9, 75%, $P = 0.4$).

Conclusion: We found that ADA-treated patients with EIM tend to develop more frequently AAA. Assuming that the presence of AAA reduces the effectiveness of biological therapy, the presence of EIM may be considered a predictive factor for loss of response to biological therapy with anti-tumor necrosis factor alpha drugs.

Introduction: Patients with microscopic colitis (MC) often present with abdominal pain and diarrhoea¹, and small cross-sectional surveys suggest that up to one-third may meet diagnostic criteria for irritable bowel syndrome (IBS)². However, the impact of IBS-type symptoms in patients with MC, in terms of their effect on psychological health and quality of life has not been assessed.

Aims & Methods: We conducted a cross-sectional survey of individuals with MC. We analysed demographic data, symptoms that met the Rome III criteria for IBS, mood (via hospital anxiety and depression scale (HADS)) and somatoform-type behaviour (via patient health questionnaire-15 (PHQ-15)), and quality of life (QOL) (via SF-36) in order to examine risk factors for, and impact of, IBS-type symptoms in patients with MC.

Results: In total, 157 individuals with MC returned completed questionnaires, 53 (36.6%) of whom met the Rome III diagnostic criteria for IBS. The commonest histological subtype of MC was collagenous colitis (52.9%, n = 83), followed by lymphocytic colitis (38.2%, n = 60), and MC-not otherwise specified (8.9%, n = 14). Individuals meeting the Rome III criteria for IBS had significantly higher levels of anxiety (HADS-anxiety score 8.6 vs. 5.0, $P < 0.001$), depression (HADS-depression score 6.1 vs. 3.5, $P = 0.001$), and somatoform-type behaviour (PHQ-15 score 12.5 vs. 7.9, $P < 0.001$) compared with individuals who did not. Individuals meeting the Rome III criteria scored significantly worse on all domains of the SF-36, except for physical functioning. There were also trends towards these individuals being younger (65 years vs. 69.2 years, $P = 0.011$) or taking proton-pump inhibitors (58.5%, n = 31 vs. 42.4%, n = 39, $P = 0.062$).

Conclusion: More than one-third of individuals with MC met diagnostic criteria for IBS and these individuals reported higher levels of anxiety, depression, and somatisation plus impaired quality of life. Management strategies for these symptoms are required.

Introduction: Anaemia is one of the most common extraintestinal manifestations in inflammatory bowel disease (IBD), with iron deficiency being the most frequent cause.

Aims & Methods: To characterize anemia in a population of patients with IBD and to evaluate the efficacy of anti-TNF and carrier therapy. We retrospectively analyzed 169/1166 patients with IBD followed in a tertiary center between 2010–2016. All the patients received replacement therapy with ferric carboxymaltose, ferric saccharum or transfusional support. We analyzed the effect of immunosuppressive therapy with and without anti-TNF: group 1 and 2 respectively. Active disease was defined as C-reactive protein (CRP) ≥ 0.5 mg/dl, faecal calprotectin (FC) ≥ 50 μ g/ml or presence of ulcers in colonoscopy. Anaemia was defined according to ECCO criteria (iron deficiency anaemia (IDA), anaemia of chronic disease (ACD) and mixed anaemia (MA). Multifactorial anaemia (MFA) was diagnosed when there was also vitamin B12 or folate deficiency.

Results: 169 patients were included: 111 with Crohn's Disease (CD), 54 with Ulcerative Colitis (UC) and 4 with unclassified IBD. 44.4% were male and the mean age was 32.2 years (range 7–82). 98.2% had anemia and 1.8% had only iron deficiency; 3.5% and 18.3% had a deficit of vitamin B12 and folate. The most common etiologies of anemia found in CD and UC were IDA (54.1% and 46.3%), followed by MFA (19.8% and 24.1%), ACD (15.3% and 24.1%) and MA (8.1% and 5.6%). Female gender (OR 3.743 95% CI 1.554–9.018, $p=0.003$), previous surgery (OR 2.845 95% CI 1.111–7.284, $p=0.02$) and penetrating pattern in CD (OR 8.252 95% CI 1.289–52.919, $P=0.026$) were predictors of normal hemoglobin (Hb). CRP was associated with highest ferritin values (294.85 \pm 302.00 vs 102.10 \pm 127.75, $p<0.001$). Hb and CRP had a negative correlation ($p<0.176$, $p=0.022$). In UC, CRP and FC normalization was associated with higher Hb and transferrin saturation (13.63 \pm 1.66 vs 12.47 \pm 1.38, $p=0.005$ and 51.33 \pm 26.50 vs 27.63 \pm 9.96, $p=0.048$). There was no difference in the parameters evaluated comparing groups 1 and 2. There was also no significant difference in the variation of Hb and iron values after treatment with ferric saccharum or ferric carboxymaltose.

Conclusion: In a population of patients with IBD, iron deficiency was the main cause of anaemia and the two forms of intravenous iron replacement were equally effective. In the group of patients with UC, elevated CRP was associated with anaemia.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Ustekinumab (UST) has been shown to be effective in refractory Crohn's disease (CD) in phase III trials. The aim of the present study was to prospectively evaluate the association between UST trough levels and anti-ustekinumab antibodies, with the response and the remission to induction and maintenance UST treatment in CD patients.

Aims & Methods: We performed a prospective study including all CD patients refractory to anti-TNF who received subcutaneous UST from September 2015 to November 2016 in the tertiary French referral center of Gastroenterology in Claude Huriez hospital in Lille. During induction patients received 90 mg of SC UST at week 0, 4 and 12. During the maintenance phase patients received 90 mg of SC UST every 8 weeks that could be optimized by shortening injection interval to every 4 weeks in case of loss of response. Clinical response was defined by a decreased Harvey Bradshaw Index (HBI) by 3 points, clinical remission by HBI <5 , loss of response by new increase of HBI. UST trough levels and antibodies were dosed at 12 weeks, and at a single time-point for patients who had received more than 3 months of UST. The results of dosage were obtained by enzyme-Linked ImmunoSorbent Assay technique. We evaluated the correlation between clinical and biological response and remission to UST, and UST trough levels and antibodies concentrations. Differences between independent groups were traced with the use of the Mann–Whitney exact test.

Results: Forty-eight patients with active disease received at least three UST injections and were prospectively included. At time of ustekinumab introduction 77% of patients received concomitant immunosuppressant and 42% received corticosteroids. At the end of the induction phase (week 12) clinical response was observed in 57% patients. There was no significant difference in mean UST trough levels in patients who responded to UST induction (median 1160 ng/ml; IQR: 603–1644) as compared to patients who did not respond (median 1556 ng/ml; IQR: 494–2758, $p=0.24$). Forty-three (90%) patients received at least 4 injections of UST, with 12 patients who were optimized at the time of dosages. Clinical response was observed in 30/43 (70%) patients. Median UST concentration in clinical responder was 1359 ng/ml (IQR: 554–2068) and 2392 ng/ml in non-responder (IQR: 1496–3494), with no significant difference between the two groups of patients ($p=0.20$). UST antibodies were undetectable for the 48 patients.

Conclusion: We confirmed that UST treatment is effective in the majority of CD patients refractory to anti-TNF agents. Median trough levels to UST are not correlated to response and remission to UST induction and maintenance treatment, with no antibodies developed against UST.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1684 ECONOMIC IMPLICATIONS IN INFLAMMATORY BOWEL DISEASES: RESULTS FROM A RETROSPECTIVE ANALYSIS IN AN ITALIAN CENTRE

A. Massella¹, A. Variola¹, R. Tessari², T. Zuppin², R. Ravasio³, A. Geccherle¹

Introduction: Inflammatory bowel diseases (IBDs) are chronic conditions characterized by elevated costs (both direct and indirect). Over the last years also a significative healthcare burden associated with IBD has emerged, due to an increasing use of biological therapies and hospitalization costs. Despite the creation of local or regional databases in Italy data regarding healthcare expenditure are lacking.

Aims & Methods: The aim of this study was to evaluate costs comprehensive of biological treatments and hospitalizations in a series of patients with ulcerative colitis (UC) and Crohn's disease (CD) and their correlation with demographic and clinical variables. Disease severity was evaluated by clinical scores (partial Mayo score for UC, Harvey Bradshaw Index for CD). We analyzed retrospectively patients treated by biologics referred to our IBD Unit between May 2015 and April 2016 who underwent at least six months follow-up (last visit October 2016). As regards biological therapies costs burdened by our Centre pharmacy for each drug (Infliximab, Adalimumab, Golimumab, Vedolizumab) and for single patient were evaluated. About hospitalizations the average costs of hospital care specific for a department through fares for homogeneous groups of patients i.e. Diagnosis-Related Group (DRG) were collected. The mean overall monthly expenditure for each case was then evaluated.

Results: We collected clinical-economical data of 142 patients in biological treatment in the selected period (52 UC, mean age 44.3 years and male 40.4%; 90 CD, mean age 38.8 years and male 56.7%). About half of CD patients (48.9%) underwent previous intestinal surgery. The disease severity was higher in UC group vs CD one. In UC group Infliximab was the most prescribed biologic (51.9%), followed by Golimumab (29.9%) and Adalimumab (21.2%). While CD patients were treated with Adalimumab in 54.4% and Infliximab in 45.6%. The average cost for month of treatment was 1235.41 \pm 358.38 € for UC and 1148.92 \pm 337.36 € for CD (no statistical differences between the groups). In both groups expenditure due to biologics amounts for more than 80%. We analyzed costs in groups different for sex, age and disease activity (only the last one was associated with increased costs with $R^2=0.84$ for UC and 0.95 for CD). The cost increases in patients with more lines of therapy in UC (not in CD) but the difference wasn't significative.

Conclusion: In our study the main cost is due to biological therapy but the subjects enrolled were the most severe in comparison to the whole IBD population under conventional therapy. No differences were found between the type of biologic administered and the way of administration (intravenous or subcutaneous) so the therapeutical choice could be driven by clinical reasons and not only economic ones.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The monitoring of appropriateness, costs, and clinical outcomes of biological therapy in inflammatory bowel disease (IBD) is a relevant need.

Aims & Methods: We aimed to evaluate all these issues in Sicily through a web-based network of all prescribing centers. The Sicilian Network for Inflammatory Bowel Disease (SN-IBD) is composed by a super Hub coordinator centre and five Hub plus ten Spoke centres. From January 2013, all IBD patients starting a biological agent (incident cases) or already on treatment (prevalent cases) were entered in a web based software. Herein we report data of incident cases about the efficacy of biological therapy after twelve weeks and one year of treatment. As clinical end-point, we set remission (corresponding to a Mayo Partial Score <2 for UC, and to a Harvey-Bradshaw Index <5 for CD), and response (reduction of Harvey-Bradshaw Index ≥ 3 for CD and Mayo Partial Score ≥ 2 for UC compared with baseline).

Results: From January 2013 to January 2017, 1578 patients were included. Incident cases were 1151 (808 Crohn's disease [CD], 335 ulcerative colitis [UC], 8 unclassified colitis). Considering that 22.2% of patients experienced more than one line of therapy, a total of 1407 treatments were reported. CD: there was a higher proportion of patients naive to biologics among those on adalimumab (ADA) compared with infliximab (IFX) and vedolizumab (VDZ) (89.3% vs. 53.3% vs. 30.6%, $p < 0.001$). At week 12, there was a higher rate of response/remission for adalimumab (ADA) compared with infliximab (IFX) and vedolizumab (VDZ) (79.8% vs. 71.8%, $p = 0.005$, and 79.8% vs. 47.2%, $p < 0.001$, respectively), and a higher efficacy of IFX compared with VDZ (71.8% vs. 47.2%, $p = 0.004$). The superiority of ADA over IFX remained significant in naive patients (81.5% vs. 73.7%, OR 1.581, $p = 0.026$), but not in non-naive. At week 52, ADA had a higher rate of response compared to IFX (65.4% vs. 56.0%, $p = 0.018$). However, there was no statistical difference between the two drugs when patients were stratified in naive and non-naive, while ADA was superior over IFX in patients with ileo-colic disease (68.8% vs. 48.4%, OR 2.282, $p = 0.001$). UC: there was a higher proportion of patients naive to biologics among those on IFX compared with GOL and ADA (91.6% vs. 44.1% vs. 55.4%, $p < 0.001$). At week 12, there was a higher rate of response/remission for IFX compared with golimumab (GOL) (71.8% vs. 56.6%, $p = 0.034$), but this difference was lost when patients were stratified in naive and non-naive. At week 52, IFX had a higher rate of response/remission compared to GOL (58.2% vs. 38.2%, $p = 0.039$) and ADA (58.2% vs. 33.9%, $p = 0.002$). However, IFX was superior to GOL in naive patients only (60.2% vs. 26.7%, OR 4.165, $p = 0.018$; interaction test: $p = 0.02$), but non in non-naive, and IFX was superior to ADA in naive patients only (60.2% vs. 37.8%, OR 2.650, $p = 0.029$). For both CD and UC, no significant difference in efficacy was observed between IFX originator and biosimilars. Several factors were identified as predictor of response -

independently of the drug employed - at multivariable logistic regression analysis (table 1).

Table 1

DISEASE-TIME POINT	VARIABLE	OR	p
CD-12 WEEKS	Naive to biologics	1.989	<0.001
	Age (continuous variable)	0.982	<0.001
	Upper GI tract involvement	0.388	0.002
	Perianal disease	0.650	0.029
CD-52 WEEKS	Naive to biologics	2.262	<0.001
	Upper GI tract involvement	0.394	0.005
UC-12 WEEKS	Naive to biologics	2.188	<0.001
UC-52 WEEKS	Naive to biologics	2.338	<0.001
	Current smoking	1.562	0.007

Conclusion: In one of the largest "real-life" series of IBD patients on biological therapy reported to date, ADA in CD had a higher success compared to IFX at both 12 and 52 weeks; however, this results could be influenced by the preference of ADA as first-line anti-TNF drug in CD. IFX in UC was superior to GOL and ADA at 52 weeks; once again, this result could be influenced by the preference of IFX as first-line anti-TNF agent in UC; no difference was found between GOL and ADA in UC. Being naive to biologics is a relevant predictor of response in both CD and UC at any time point. No significant difference in efficacy was observed between IFX originator and biosimilars.

P1686 SINGLE-CENTRE EXPERIENCE WITH BIOLOGICAL TREATMENT IN BUDESONIDE-REFRACTORY MICROSCOPIC COLITIS PATIENTS

N. Daferera¹, S. Ignatova², A. Münch²

¹Gastroenterology, University Hospital of Linköping, Linköping/Sweden

²Gastroenterology, Dept. of Gastroenterology, Linköping/Sweden

Contact E-mail Address: andreas.munch@regionostergotland.se

Introduction: Microscopic colitis (MC) is a common cause of chronic watery diarrhoea which is effectively treated with budesonide. However, in rare cases patients are refractory to budesonide leading to a severely deteriorated quality of life. Data on treatment options for budesonide refractory MC patients are sparse. We retrospectively evaluated the outcome of MC patients who have received biological therapy at our centre

Aims & Methods: All patients with MC treated with biological therapy at the Department of Gastroenterology, University hospital Linköping, Sweden were selected and the outcome recorded. Patients were investigated according to sex, age, disease subtype, clinical remission (defined as < mean 3 and no watery stools/day/week), clinical response (defined as 50% reduction of mean stool frequency/day/week), side effects and long-term outcome.

Results: 14 patients (10 women) with mean age at diagnosis of 49 years (range 19–76), thereof 12 with collagenous colitis and 2 with lymphocytic colitis were investigated. All 14 patients had received anti-TNF agents (11 adalimumab (ADA), 3 infliximab (IFX)). ADA was given as induction treatment (160–80–40 mg) and IFX 5 mg/kg at week 0, 2 and 6. Six patients achieved clinical remission. Of these, 2 patients maintained clinical remission for several years after induction treatment, 2 patients are on maintenance treatment with 40 mg ADA/eow, one patient on 400 mg INF every 8 weeks and one patient had loss of response and did not gain clinical remission despite the use of a third anti-TNF agent (certolizumab). Four patients had a clinical response but stopped treatment due to side effects (vomiting, anxiety, fatigue and eczema—all reversible). Four patients had no effect on anti-TNF despite the fact that 2 patient had even tested both anti-TNF agents. Of these 4 patients who failed anti-TNF, 3 patients received treatment with vedolizumab (300 mg week 0, 2 and 6) without effect. One patient had further treatment with rituximab (1000 mg twice) and another patient tested ustekinumab (390 mg once); both did not achieve any clinical improvement.

Conclusion: Budesonide refractory MC patients can achieve clinical remission or response on anti-TNF agents. In the cases that failed anti-TNF, further treatment with vedolizumab (n=3), rituximab (n=1) and ustekinumab (n=1) did not improve the clinical condition. Prospective studies with long duration are necessary to evaluate the efficacy of various biological treatments in budesonide-refractory MC.

Introduction: Recent studies have shown that FODMAPs (Fermentable Oligosaccharides, Disaccharides, Monosaccharides, and Polyols)-free diet is effective in subjects with Irritable Bowel Syndrome (IBS). Patients with Inflammatory Bowel Diseases (IBD), and celiac disease (CD) can experience functional gastrointestinal symptoms unrelated to inflammation, but data about the use of low FODMAPs diet in these settings is still scarce.

Aims & Methods: To evaluate the usefulness of a low FODMAPs diet on patients with IBS, non-active IBD, and CD on strict gluten-free diet (GFD), we performed a dietetic interventional prospective study evaluating the effect of a low FODMAPs diet on subjects affected by IBS, CD following at least a 1-year-GFD and IBD who had been experiencing abdominal symptoms without signs of active inflammation. Each subject was put on a low FODMAPs diet after being evaluated by filling out questionnaires concerning on quality of life and symptoms experienced (IBS-SSS and SF-36), and was re-evaluated twice, first after 1 month and second after 3 months.

Results: 127 subjects were enrolled: 56 with IBS, 30 with IBD and 41 with CD. The analysis of the IBS-SSS survey showed that abdominal symptoms improved after 1 month and 3 months of low FODMAPs diet in all subjects, with statistically significant difference within each group at T0 (average score in IBS: 293±137 SD, average score in IBD: 206±86 SD, average score in CD: 222±65 SD, $p < 0.001$). Furthermore, by analysing the SF-36 questionnaire, while we did not observe any significant difference between the three groups, in terms of response to diet ($p = \text{NS}$), we observed a clinical improvement from T0 to T3, after the start of the diet, for most of the questionnaire's domains.

Conclusion: A low FODMAPs diet could be a valid option to counter abdominal symptoms in patients with IBS, non-active IBD or CD on GFD, and, thus improve their quality of life and social relations.

Introduction: Vedolizumab (VDZ) is a new biologic agent approved for the treatment of adult patients with moderately to severely active ulcerative colitis (UC) and Crohn's disease (CD).

Aims & Methods: The Sicilian Network for Inflammatory Bowel Disease (SN-IBD) is a group composed by all Sicilian centres prescribing biologics. These centres continuously enter in a web based software all real-life data about prescriptions and outcomes of biological therapy in patients with inflammatory bowel disease (IBD). Herein we report data on efficacy of VDZ on intestinal and articular symptoms after 10 and 24 weeks of treatment. As clinical end-point, we set steroid-free remission (corresponding to a Mayo Partial Score < 2 for UC, and to a Harvey-Bradshaw Index < 5 for CD), and clinical response (reduction of Harvey-Bradshaw Index ≥ 3 for CD and Mayo Partial Score ≥ 2 for UC compared with baseline with a concomitant reduction of steroids dosage at week 10, and complete discontinuation at week 24).

Results: From July 2016 to April 2017, 163 patients (84 with CD and 79 with UC) were included (table 1). At week 10, a steroid-free remission was obtained in 71 patients (43.6%), while a clinical response in 37 (22.7%). Out of 71 patients reaching 24 weeks of follow-up, 29 (40.8%) were in steroid-free remission, and 10 (14.1%) had a clinical response. No significant difference in terms of clinical benefit (rate of remission plus clinical response) among patients with UC and CD was reported at week 10 (68.4% vs. 64.3%, respectively; $p = 0.58$) and at week 24 (54.3% vs. 55.6%, respectively; $p = 0.91$), and no difference was observed comparing naïve and non naïve patients, neither at week 10 (61.5% vs. 67.7%, respectively; $p = 0.48$) nor at week 24 (30.0% vs. 59.0%, respectively; $p = 0.11$). At multiple logistic regression analysis, a longer duration of disease (OR 0.961, $p = 0.047$) and presence of steroid-dependence (OR 0.189, $p = 0.033$) were predictors of reduced rates of clinical benefit at week 10, while a low serum level of C-reactive protein at baseline (OR 0.950, $p = 0.031$) was predictor of clinical

benefit at week 24. An improvement of articular symptoms was reported in 39.5% of patients with active spondyloarthritis at baseline at week 10, and in 45.4% of patients at week 24. The only factor associated with articular response was the coexistence of clinical benefit on intestinal symptoms, both at week 10 (OR 8.471, $p = 0.05$) and week 24 (OR 5.600, $p = 0.08$). Three inductions or flares of spondyloarthritis during treatment with VDZ were reported.

Introduction: Combined immune suppression of anti-tumour necrosis factor (antiTNF) biologicals and thiopurines is superior to respective monotherapies in remission induction and maintenance of response in inflammatory bowel disease (IBD). One of the putative mechanism of this clinical benefit is mutually positive pharmacokinetic effect of thiopurines on antiTNF levels and vice versa. It has been suggested that for this synergistic effect, reduced dose of thiopurines might be sufficient but the data supporting this hypothesis are still limited.

Aims & Methods: The aim of the study was to assess the differences of infliximab trough levels according to the dose of concomitantly used thiopurines. All IBD patients treated with infliximab (Remicade®) in two IBD centra between November 2015 and April 2017 were eligible. Infliximab trough levels were routinely measured in all patients with maintenance infliximab therapy using commercially available ELISA kit (Ridascreen®, R-Biopharm). All patients in remission with stable dose regimen of 5mg/kg every 8 weeks at the time of the first assessment of infliximab trough levels were identified retrospectively from the medical records. The differences in the proportion of patients with adequate trough levels (3–12 µg/mL) between patients on infliximab monotherapy, reduced (below 2mg/kg) azathioprine (AZA) dose vs. full (2 to 2.5 mg/kg) AZA dose were analyzed statistically.

Results: Out of a total of 214 IBD patients treated with infliximab, there were 154 in remission at the time of the first assessment of infliximab trough levels. After excluding patients with previously intensified dose regimen, 125 patients were further analyzed. Among these 125 pts, 41 pts (33%) were on infliximab monotherapy, 58 pts (46%) were using combined immune suppression with a reduced dose of AZA and 26 (21%) were using the full AZA dose concomitantly with infliximab. Both groups, patients with infliximab monotherapy as well as patients using a reduced AZA dose had significantly lower percentage of patients with therapeutic levels of infliximab compared with the group using the full dose AZA co-medication (41% vs. 64% vs. 81%; infliximab monotherapy, reduced AZA dose and full AZA dose, respectively; $p < 0.001$ for both comparisons, infliximab monotherapy vs. AZA full dose and reduced AZA dose vs. full AZA dose).

Conclusion: The proportion of patients with adequate infliximab trough levels is significantly higher in patients with full dose of concomitant azathioprine compared with the patients using a reduced dose of azathioprine. Thus, in order to maximize the chances for sustained benefit from infliximab maintenance treatment, the combined immune suppression should comprise full dose of azathioprine.

P1690 C₆₀ FULLERENES ATTENUATE THE INTENSITY OF COLON DAMAGE AND EXTRAINTestinal MANIFESTATIONS ON RAT ACUTE ULCERATIVE COLITIS MODEL

H. Kuznietsova¹, I. Byelinska², N. Dziubenko¹, O. Gurniak¹, O. Lynchak¹, Y. Prylutska¹, V. Rybalchenko¹

Introduction: The primary drugs used for inflammatory bowel disease (IBD) treatment have some adverse effects and often are ineffective, so the need for more potent and more reliable medications is clear. A significant role at all the stages of the inflammatory process is attributed to reactive oxygen species, therefore the use of antioxidants is a promising direction of the IBD therapy.

Aims & Methods: C₆₀ fullerenes are the effective free radicals scavengers [1], therefore the evaluation of possible protective properties of water-soluble pristine C₆₀ fullerenes using the simulation of acute ulcerative colitis (UC) in rats was aimed to be discovered. The pristine C₆₀ fullerene aqueous colloid solution (C₆₀FAS; initial concentration 0.15 mg/ml) was prepared according to the protocols developed before [2]. UC was simulated by acetic acid intracolonic instillation. C₆₀FAS was intraperitoneally or intrarectally applied at dose of 0.5 mg/kg C₆₀ daily for 2 times after UC induction. The colon injury was estimated semi-quantitatively on macro- and light microscopy levels using 10- and 14- grade scales respectively, and the grade of total injury (GTI) was calculated, permeability of colon epithelium was estimated by phenol red dye daily excretion. The states of the colon, liver, pancreas and spleen were assessed by histological (hematoxylin-eosin staining) and biochemical (plasma blood liver enzymes activity) methods, quantitative blood indices were calculated and leucograms were analyzed.

Results: Colon wall edema, hyperemia and hemorrhage on bowel internal surface, ulcers of different size, epithelium desquamation and inflammatory features

manifested by submucosa lymphoid and histiocytic infiltration and extravasation appeared under UC condition. GTI was equal to 12 (GTI_{control} = 0). Rat diurnal phenol red dye excretion exceeded the control one 6.6 times suggesting the damage of colon epithelial barrier. Degenerative features of exocrine pancreas and liver injury were also observed in UC rats. Anemia features manifested by hemoglobin concentration and red blood cell count decrease, reticulocytes volume, hematocrit and the platelet count increase could be caused by intestinal hemorrhages and subsequent erythro- and megakaryocytopoiesis following active release of "young" erythrocytes (reticulocytes) and platelets into the blood. The last could be confirmed with histological assay (rise of the erythroblastic islets and megakaryocytes numbers in the spleen). Increase the number of neutrophils and spleen lymphatic follicles suggested the inflammatory process in the organism. The application of C₆₀FAS by both ways caused GTI drop down to 6 points, restored the mucosa epithelial barrier integrity, attenuated the signs of anemia and normalized the platelet and neutrophils counts, AST and the state of spleen. In addition, C₆₀FAS intraperitoneally restored the state of the pancreas but increased liver functional upload (as evidenced by elevated ALT activity), whereas its rectal application normalized both ALT and AST activities but didn't affect the pancreas. Moreover, C₆₀FAS rectally increased monocytes number, which could be explained by involving the latest in mucosa healing process.

Conclusion: C₆₀FAS corrects local and systemic morphofunctional changes, conditioned by the induction of acute UC. The protective properties of C₆₀ fullerenes against bowel, hematopoietic system and liver due to its local application are more expressed compared to their systemic one, but their impact on pancreas is controversial. Thus, water-soluble pristine C₆₀ fullerenes could be used as efficient therapeutic agents at ulcerative colitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1691 EARLY CLINICAL REMISSION BY WEEK 2 PREDICTS GOOD SHORT- AND LONG-TERM EFFICACY OF TACROLIMUS THERAPY IN PATIENTS WITH MODERATE TO SEVERE STEROID-REFRACTORY ULCERATIVE COLITIS

N. Oshima, S. Ishihara, K. Kawashima, H. Sonoyama, N. Yamashita, N. Fukuba, Y. Mishima, I. Moriyama, T. Yuki, Y. Kinoshita
Gastroenterology And Hepatology, Shimane University School of Medicine, Izumo/Japan

Contact E-mail Address: si360405@med.shimane-u.ac.jp

Introduction: Tacrolimus, a calcineurin inhibitor, has been shown to be safe and effective when used as salvage therapy for steroid-refractory ulcerative colitis (UC). Its pharmacological effect has been reported to be dependent on trough level in blood, though little is known regarding predictive factors in relation to the clinical efficacy of tacrolimus in UC patients.

Aims & Methods: The aim of this study was to identify factors related to prediction of short- and long-time efficacy of tacrolimus for UC. We retrospectively reviewed the medical records of patients with moderate to severe steroid-refractory UC who were treated with tacrolimus as induction therapy at Shimane University Hospital between January 2010 and March 2016. Oral tacrolimus was administered at a whole-blood trough level of 10–15 ng/mL to induce remission and then 5–10 ng/mL to maintain remission. Following tacrolimus therapy for 3 months, patients in clinical remission were given azathioprine for maintenance at an appropriate dosage. Using the Rachmilewitz clinical activity index (CAI), clinical remission was defined as a score of ≤ 4 . Predictive factors associated with short- and long-term tacrolimus efficacy were analyzed by evaluating various clinical parameters.

Results: Thirty-six patients received oral tacrolimus for induction, of whom 22 (61.1%) and 27 (75%) experienced clinical remission at 2 and 12 weeks, respectively, after starting therapy. In patients showing short-term efficacy, the clinical remission rate at 2 weeks was significantly associated with CAI at 12 weeks. Interestingly, of the 22 patients in clinical remission within 2 weeks, 21 (95.5%) remained in remission at 12 weeks. In contrast, only 6 of 14 (42.9%) who did not achieve clinical remission at 2 weeks were not in clinical remission at 12 weeks. For evaluating the long-term efficacy of tacrolimus induction therapy, relapse-free periods were assessed using the Kaplan-Meier method. The relapse-free rate at 48 weeks was higher in patients who achieved clinical remission within 2 weeks as compared to those without remission at that time point (79.0% vs. 60.0%).

Conclusion: Tacrolimus induction therapy was effective for patients with moderate to severe steroid-refractory UC. Our results clearly indicate that clinical remission achievement within 2 weeks is useful for predicting both short- and long-term outcome in UC patients treated with that therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1692 INFLIXIMAB (IFX) IN MODERATE TO SEVERE ULCERATIVE COLITIS (UC): COMPARISON BETWEEN SCHEDULED TREATMENT STRATEGY AND BRIDGE STRATEGY

A.M. Sambuelli¹, A. H. Gil¹, S. M. Negreira¹, M. I. Bellicoso¹, S. Goncalves¹, S.P. Hueros¹, P.R. Tirado¹, P. Chavero¹, A. Cabanne²

¹IBD Section - Medicine, Bonorino Udaondo Hospital, Buenos Aires/Argentina

²Pathology, Bonorino Udaondo Hospital, Buenos Aires/Argentina

Contact E-mail Address: alicia.sambuelli@gmail.com

Introduction: UC is a potentially severe disease that carries an increased risk of complications and colectomy. Immunosuppressant and biological therapies are relevant tools for complex patients. The ACCENT study showed that in Crohn's disease (CD), scheduled IFX infusions vs. episodic are associated with greater efficacy. In UC, historical difficulties of economic access had conditioned to our IBD center, to use IFX in moderate to severe UC as a bridge to thiopurines in pts 6mp/aza naïve. In UC, the mentioned strategy was insufficiently compared with a regimen of scheduled IFX treatment, that currently we use.

Aims & Methods: Our aim was to compare (retrospectively) in moderate to severe UC the results of induction with IFX (in thiopurine naïve pts.) continuing with 6mp/aza maintenance vs. similar induction followed by scheduled IFX maintenance strategy.

We included a cohort of moderate to severe UC treated with IFX in an IBD center (2006 to 2015) comparing results between IFX bridge followed by thiopurines (re-induction when available for moderate to severe relapse) vs. scheduled IFX (induction 0,2,6 wks and 8 wks' interval infusions maintenance). Optimization (by frequency of intervals) was allowed in both modalities. Comparisons: Kaplan Meier/Log rank test: a) Cumulative incidence of colectomy, b) survival times relapse free, c) survival times corticosteroid free.

Results: We identified 135 UC patients receiving IFX for moderate to severe UC (M 60, F 75, Age (mean \pm SD) 35.9 \pm 13.2, UC duration 5.8 \pm 5.9 yrs, Extent: extensive 58.5%, Left-sided 41.5%, Activity: severe 78.5%, moderate 21.5%, mean Mayo score: 10.1 \pm 1.8. Primary no responders at week 12 (n 25: 18.5%) were not considered in maintenance comparisons, which were performed in 110 out of the 135 pts. (Follow-up 37.5 \pm 24.0 months) Groups: IFX bridge (n=51) and scheduled IFX (n 59), which were not different in extent, and mean age, UC duration, Mayo score. Cumulative incidence of colectomy was significantly lower in the scheduled strategy (HR: 6.8805, 95% CI 1.7207 to 27.5133, p=0.0349), survival times free of relapse (HR 3.1026, 95% CI 1.8368 to 5.2405, p<0.0001) and free of corticosteroids (HR 2.6057, 95% CI 1.5516 to 4.3757, p=0.0003). A proportion of UC significantly higher within the re-induced pts (IFX bridge) required a shift of biological drug compared with the scheduled strategy (p=0.016, Fisher), despite of similar rates of optimization. Infusion reactions needing definitive IFX suspension were more frequent as a trend (p<0.06) in re-induced pts.

Conclusion: Similarly to was described for CD pts, in the CU, the scheduled IFX treatment strategy regimen, after a moderate-severe outbreak, seem to be associated with better long-term outcome regarding colectomy requirement, relapses, and need for corticosteroids, compared with a bridge IFX strategy followed by thiopurines

Introduction: Arthropathies are the most common extra-intestinal manifestation (EIM) in patients with inflammatory bowel disease (IBD). Psychological and behavioural factors, including illness perceptions and coping strategies, perceived by IBD patients with arthropathies may differ from patients without arthropathies and may change during follow-up. Understanding these differences and changes over time, creates knowledge for health care professionals about interventions that may be effective in IBD patients with arthropathies.

Aims & Methods: This longitudinal follow-up study evaluates the differences in illness perceptions (individual cognitions and emotions about a disease), coping strategies (behavioral efforts and strategies to deal with a chronic disease) and illness outcomes between IBD patients with and without arthropathies, and examines the changes of these variables in IBD patients with arthropathies after 12 months.

In total, 204 IBD patients with (n=123) and without (n=81) arthropathies completed questionnaires at baseline and after 1 year follow-up to assess illness perceptions (Revised Illness Perception Questionnaire), coping strategies (Coping with Rheumatic Stressors Questionnaire) and illness outcomes including quality of life (Short Form-36), and activity and work impairment (Work Productivity Activity Index). Linear regression analyses were used to assess the impact of arthropathies on illness perceptions, coping and illness outcomes compared

with IBD patients without arthropathies. Mixed model analyses were used to evaluate the change of these factors in IBD patients with arthropathies over time.

Results: Linear regression models demonstrated that arthropathies in IBD were associated with the illness perceptions strong 'illness identity' (B 1.15 (95%CI 0.31-1.98), p=0.007), strong 'cyclical timeline' (B 1.33 (95%CI 0.33-2.34), p=0.010), more 'consequences' (B 2.00 (95%CI 0.60-3.42), p=0.006), stronger 'emotional representations' (B 1.58 (95%CI 0.08-3.08), p=0.039) and a low 'coherence' (B -1.29 (95%CI -2.45-(-0.14)), p=0.029). In addition, the coping strategies increased 'diverting attention' (B 1.34 (95%CI 0.02-2.66), p=0.047) and increased 'consideration' (B 1.18 (95%CI 0.10-2.27), p=0.033), as well as the illness outcomes low physical (B -7.22 (95%CI -9.68-(-4.77)), p<0.001) and mental (B -3.10 (95%CI -5.99-(-0.23)), p=0.035) health and increased activity impairment (B 0.15 (95%CI 0.07-0.23), p<0.001) were related with arthropathies in IBD. After 12 months follow-up, lower scores on the illness perception dimension 'treatment control' (p=0.001) and increased scores on the coping strategy 'pacing' (p=0.03) were found in IBD patients with arthropathies compared with baseline scores.

Conclusion: Suffering from arthropathies in IBD is strongly associated with different illness perceptions, coping strategies and illness outcomes and changes of these factors over time. As a gastroenterologist, addressing the maladaptive illness perceptions, coping strategies and related poor illness outcomes in these patients, may provide an important target for behavioural and physical interventions including cognitive behavioural therapy (CBT) or physical exercise.

Introduction: CT-P13, the first biosimilar monoclonal antibody to infliximab (IFX) has previously been confirmed to be efficacious in inducing mucosal healing in ulcerative colitis (UC) patients.

Aims & Methods: The aim of this study was to evaluate the efficacy of CT-P13 therapy in maintaining mucosal healing in UC. Patients diagnosed with UC, who were administered CT-P13 from June 2014 at 4 Hungarian and one Czech IBD Centre were prospectively enrolled. Sigmoidoscopy was performed at week 14 and week 54 to assess mucosal healing. Mucosal healing was defined as Mayo endoscopic subscore of 0 or 1. Complete mucosal healing was defined as Mayo endoscopic subscore of 0. CT-P13 trough levels, antibody positivity, serum inflammatory markers as CRP level, fecal calprotectin at weeks 14 and 54, concomitant steroid and azathioprine therapy at the time of induction therapy and at weeks 14 and 54, previous use of anti TNF drug and the need of dose intensification as possible predictive factors for mucosal healing at week 54 were evaluated.

Results: Seventy-five UC patients were included in the study of which 74 patients completed the induction therapy and 54 patients had already completed the 54-week treatment period. Mucosal healing was shown in 55.4% of the patients at week 14 and in 61.7% at week 54 (p=0.33). Complete mucosal healing was present in 24.3% at week 14, but in 36.2% at week 54. The median values of CRP (p=0.017), leukocytes (p=<0.001), thrombocytes (p=<0.001), and albumin (p=0.002) showed significant difference at baseline and week 54. Mean trough level of CT-P13 was 5.02 µg/ml and 4.4 µg/ml at week 14 and 54. Serum antibody positivity was proved in 7.7% and 26.2% of cases at week 14 and 54, respectively. Dose escalation was necessary in one third of patients. None of the patients need surgery who completed week 54, however 4 subjects who stopped CT-P13 therapy after induction regimen required colectomy.

Conclusion: Mucosal healing was revealed in two-third of the patients during CT-P13 maintenance therapy. Our study confirmed the long-term efficacy of CT-P13 therapy on mucosal healing in UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1695 THE USE OF ANTI-TNFS IN INDUCING CLINICAL RESPONSE AND REMISSION IN ULCERATIVE COLITIS: A COMPARATIVE ANALYSIS IN THE REAL-LIFE EXPERIENCE OF A SINGLE REFERRAL CENTER

Introduction: Anti-tumor necrosis factor (anti-TNF) agents, infliximab (IFX) and more recently adalimumab (ADA) and golimumab (GOL), have been shown effective and safe in the treatment of moderate-to-severe ulcerative colitis

(UC). Lack of head-to-head RCTs makes the choice among the three anti-TNFs difficult and indirect comparisons by network meta-analyses lead to discrepant results.

Aims & Methods: Our aim was to compare efficacy of IFX, ADA and GOL in inducing clinical response and remission in a prospective cohort of patients with moderate to severe UC. From June 2015 to October 2016, 61 consecutive UC patients were treated with anti-TNFs: 19 with IFX, 25 with ADA and 17 with GOL. Disease activity was assessed by Mayo Score. Clinical response and/or remission were evaluated at week 8 and at week 16. We also recorded: indications to biologic therapy, previous immunosuppressive or anti-TNF therapy and rate of anti-TNF discontinuation.

Results: Among the 61 patients, 36 were males; mean age was 43.6 ± 15 , no significant difference was present in baseline characteristics (extent and disease activity); 39 patients were thiopurine failure; 38 were naïve to anti-TNFs, most were treated with IFX ($p=0.001$). ADA and GOL were more often used as a second-line or third-line. The principal indication for steroid resistance patients was IFX. No significant difference was observed between IFX and ADA both at week 8 (response $p=0.28$; remission $p=0.68$) and at week 16 (response $p=0.5$; remission $p=0.97$), though there was a trend towards a higher rate of response at week 8 with IFX (79% vs 64%). IFX and ADA were more effective than GOL at week 8 (response: IFX vs GOL $p=0.020$; remission: ADA vs GOL $p=0.027$). At week 16 only IFX seems to be more effective than GOL in inducing clinical response ($p=0.048$) but not remission. No significant difference among the three drugs was observed in patients naïve to anti-TNFs. Treatment was discontinued in 2 patient in IFX group and in 6 patients in GOL group and in 6 patients with ADA because of persistent disease activity.

Conclusion: This single-center study shows that IFX is more effective than GOL both in the induction (8 weeks) and in the maintenance of response (16 weeks). ADA is more effective than GOL in inducing remission at 8 weeks but no significant difference is observed in the medium-term. However, GOL was used mainly as a second or third-line. In naïve patients, efficacy among anti-TNFs is comparable. Our results may help clinicians in the choice of an anti-TNF in UC: IFX should be preferred in steroid-resistant patients to get a faster response, ADA and GOL should be the first option in steroid-dependant patients naïve to anti-TNFs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Vedolizumab (VDZ), a gut-selective monoclonal anti- $\alpha_4\beta_7$ -integrin antibody, is used for treatment of Crohn's disease (CD) and ulcerative colitis (UC). Data from large real-world cohorts can further characterise safety events not fully elucidated in a clinical trial setting, such as the risk of serious infections, as identified with anti-tumour necrosis factor- α (TNF α) therapy in the TREAT¹, GISEA² and ENCORE³ registries.

Aims & Methods: We conducted a systematic review and meta-analysis of real-world safety outcomes reported for VDZ in UC and CD. MEDLINE, Cochrane, and EMBASE-indexed publications and conference abstracts ($n \geq 10$) from May 1, 2014–January 10, 2017 were searched for studies reporting real-world VDZ safety outcomes. Reports for patients <18 years of age or for off-label VDZ use were excluded. A meta-analysis was conducted using the DerSimonian–Laird random effects method to obtain a weighted mean of adverse event (AE) rates.

Results: Two hundred and eighteen published studies were identified, with 33 reporting safety rates on 2857 VDZ-treated patients (CD: 1532; UC: 829; unspecified/other: 36; three studies [$n=460$] did not report individual UC/CD data) over a VDZ exposure/follow-up period ranging 0.5–18 months (20 studies). Among included studies, the mean age of patients ranged from 21 to 67 years, with mean disease duration ranging from 7 to 16 years. Most VDZ-treated patients (62–100%) had prior exposure to ≥ 1 anti-TNF α therapy and 6–64% of VDZ-treated patients were receiving concomitant corticosteroids and immunomodulators. The most common non-infectious AEs were acne or acne-like lesions (7%; 95% confidence interval [CI] 5–11%), fatigue (6%; 95% CI 3–15%) and arthralgia (5%; 95% CI 3–10%) (Table 1). The most common infectious AEs were upper respiratory tract infections (6%; 95% CI, 3–11%) and sinusitis (4%; 95% CI <1–19%) (Table 1). Infusion-related reactions occurred in 2% (95% CI <1–4%) of patients ($n=811$), and malignancies were reported in <1% of patients (<1–4%; 2 studies). Overall, the pooled AE rate reported in VDZ-treated patients was 21% (95% CI 14–32%); 10% (95% CI 6–16%) for infections, 8% (95% CI 6–10%) for serious AEs and 7% (95% CI 3–13%) for serious infections (Table 1).

Table 1: Pooled real-world adverse event rates of vedolizumab in inflammatory bowel disease

Non-infectious adverse events ($\geq 2\%$ of patients)			
Event	n	Rate, %	95% Confidence Interval (CI)
Acne or acne-like lesions	290	7.2	4.8–10.9
Fatigue	569	6.3	2.6–14.6
Arthralgia	1356	5.2	2.7–9.9
Exacerbation of IBD symptoms	674	4.9	2.1–11.1
Muscle pains	147	4.8	2.3–9.7
Headache	937	4.7	3.0–7.2
Dizziness	222	4.5	1.4–13.6
Cough	185	4.0	0.3–39.7
Other skin and subcutaneous-related ^a	900	3.7	1.6–8.0
Nausea	623	3.2	1.2–8.5
Paraesthesia	526	2.9	1.0–7.9
Respiratory, thoracic and mediastinal-related ^b	70	2.9	0.7–10.7
Hives	146	2.1	0.7–6.3
Liver-related ^c	468	2.0	0.1–23.9
Memory impairment	136	2.0	0.4–10.2
Other musculoskeletal and connective tissue-related ^d	498	2.0	0.3–12.5
Infectious adverse events ($\geq 2\%$ of patients)			
Event	n	Rate, %	95% CI
Upper respiratory tract infection	960	6.0	3.2–10.8
Sinusitis	576	4.2	0.8–19.1
Other respiratory infections ^e	328	3.1	1.7–5.7
Genitourinary tract infections	409	3.0	1.1–8.0
Flu or flu-like infection	450	2.8	0.8–8.8
Perianal abscess	284	2.5	1.1–5.6
Clostridium difficile	1101	2.1	1.2–3.6
Folliculitis	146	2.1	0.7–6.3
Any adverse events	n	Rate, %	95% CI
Event	n	Rate, %	95% CI
Adverse events	1243	21.3	13.7–31.6
Serious adverse events	832	7.7	6.1–9.7
Infections	906	9.9	6.2–15.5
Serious infections	832	6.7	3.3–13.0

^aIncludes paradoxical skin manifestations, acute generalised exanthematous pustulosis, dry skin, erythema nodosum, palmar erythema ^bIncludes spontaneous nose bleed ^cIncludes liver test abnormalities (transient transaminitis), drug-induced liver injury (not specified) ^dIncludes severe musculoskeletal syndrome, exacerbation of pre-existing enteropathic arthritis ^eIncludes pneumonia, lower respiratory tract infections, respiratory tract infection (not specified)

Conclusion: Pooled analysis of AE rates across multiple studies support the favourable, long-term benefit–risk profile of VDZ in real-world clinical practice, with low rates of infusion-related reactions, serious infections and malignancies reported, and no identification of new safety signals. These results are consistent with integrated safety data reported for VDZ in six clinical trials (>4000 patient-years),⁴ despite the selection of complex patients failing previous immunosuppressive or biologic therapies. Limitations of incidental reporting in real-world studies include potential underestimates of AE rates and the reporting of AEs not regularly observed in clinical trials;³ for example, due to the variability in medication use and sub-optimal screening of prior infections.

P1697 COST-UTILITY ANALYSES OF BIOLOGICS FOR REFRACTORY ULCERATIVE COLITIS

S. Campbell Davies¹, C. Inserra¹, R. Salerno², A. Cassinotti², G. Muserra¹, M. Piacenza¹, S. Ardizzone²

¹Pharmacy, ASST Fatebenefratelli Sacco, Milan/Italy

²Gastroenterology, ASST Fatebenefratelli Sacco, Milan/Italy

Contact E-mail Address: secampbelldavies@gmail.com

Introduction: Although many biologics (Bs) have been approved for the treatment of moderate-to-severe Ulcerative Colitis (UC) in patients who have responded inadequately to conventional therapy, the selection of Bs is controversial due to the lack of head-to-head trials. Indirect economic comparisons of these costly drugs are available from National Healthcare perspectives that are not the Italian ones.

Aims & Methods: The objective is to evaluate cost-utility of Bs for the treatment of refractory moderate-to-severe UC both in Italy and in the Lombardy Region. A Markov model (considering 3 transition states: remission, clinical response, relapse) was constructed using the software R 3.3.1 markovchain-package to evaluate incremental cost-utility ratios (ICUR) of adalimumab (ADA), infliximab (IFX), infliximab biosimilar (IFX-B), golimumab (GOL) and vedolizumab (VED) treatments of patients over a 10-year time horizon from the perspective of the Italian (N) and Lombardy Region (R) healthcare system. Clinical parameters were derived from clinical trials. Costs (actualised by -1.5%) were obtained from the National database and Regional public tender. Utility was expressed as QALY (Quality Adjusted Life Years).

Results: Costs per treatment were different from a N and R perspective (ADA -55%; IFX -16.7%; IFX-B -29.6%; GOL -9.6%; VED -10%). Direct healthcare costs (treatment cost, visits, lab tests, hospital admissions) were calculated over 10 years of treatment per patient: ADA (N: €114,227, R: €68,314, -40.2%), IFX (N: €130,595, R: €103,081, -21%), IFX-B (N: €110,438, R: €78,852, -28.6%), GOL (N: €118,602, R: €96,922, -18.3%), VED (N: €113,852, R: €102,932, -9.6%) with associated QALY respectively of 6.68, 6.66, 6.66, 6.70, 7.02. From a N perspective, IFX-B was dominating compared to all other treatments. The ICUR of VED/IFX-B was €9,483 for 10 years (willingness to pay €948/QALY). From a R perspective, ADA was dominating compared to all other treatments. The ICUR of VED/ADA was €101,818 for 10 years (WTP €10,182/QALY).

Conclusion: National and Regional cost-utility analyses produced different results. As Regional price discounts can occur, local analysis is needed to estimate the economic impact of therapies to ensure optimal choice.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1698 ENDOSCOPIC SUBMUCOSAL DISSECTION OF ULCERATIVE COLITIS-ASSOCIATED DYSPLASIA: A SINGLE CENTER-BASED EXPERIENCE

D. Yang, S. Lee, K. Chang, E.M. Song, S.W. Hwang, S.H. Park, B.D. Ye, J. Byeon, S. Myung, S. Yang

Contact E-mail Address: gi.dr.yang@gmail.com

Introduction: Dysplasia is considered as the precursor of colitis-associated cancer in the long standing ulcerative colitis (UC). Although endoscopic submucosal dissection (ESD) has been suggested as an endoscopic resection technique for non-polypoid dysplasia, only a few studies investigated the feasibility of ESD as a treatment option of non-polypoid dysplasia.

Aims & Methods: We aimed to investigate the feasibility of ESD for the resection of visible, non-polypoid dysplasia in UC. From August 2009 to January 2017, 19 UC patients with low grade dysplasia (LGD), high grade dysplasia (HGD) or early colon cancer were admitted for ESD and their medical records were retrospectively reviewed.

Results: Mean age of the 19 patients was 55.5 ± 15.4 years and mean duration between UC diagnosis and dysplasia detection was 13.7 ± 6.5 years. Nine were male. Five of 19 patients directly underwent colectomy without ESD trial due to non-lifting sign (n = 4) or surface ulceration (n = 1). Of these, preoperative single HGD (n = 3) or ECC (n = 1) patients showing non-lifting sign were diagnosed as invasive cancer and a single preoperative LGD case with non-lifting sign had multifocal LGDs in the colectomy specimen. As a result, ESD was performed for 14 of 19 patients. Major and minor axes of the lesion was 23.4 ± 9.0 mm and

18.1 ± 9.1 mm, respectively. The lesions were located at the rectum (n = 9), sigmoid colon (n = 2), descending colon (n = 1), and transverse colon (n = 1). The gross morphology showed Paris IIa (n = 7), IIb (n = 4), Is (n = 1), and IIb + Is (n = 2). No lesions contained ulcerations. The borders were distinct in 6 and vague but endoscopically assumable in 8 cases. Mean UC endoscopic index of severity scores of the surrounding mucosa was 0.3 ± 0.5. Mean resection time was 54.8 ± 25.7 minutes. En bloc resection and R0 resection rates was 92.9% and 71.4%, respectively. There was no perforation or clinically significant bleeding. Mean hospitalization period after ESD was 1.14 ± 0.36 days. Final histology of ESD specimens revealed 1 indefinite for dysplasia (IND), 1 sessile serrated adenoma/polyp, 7 LGDs, 3 HGDs, and 1 intramucosal adenocarcinoma. Synchronous lesions were present in 5 patients. Synchronous dysplasia in 4 patients were removed endoscopically. However, colectomy was done in one patient having synchronous adenocarcinoma and endoscopically unresectable dysplasia diagnosed by the surveillance biopsy specimens taken during ESD. Metachronous or recurrent dysplasia was identified in 2 of 9 patients who underwent follow-up colonoscopy after ESD (median follow-up period 12.3 months, range 6.3–38.2 months). One developed metachronous LGD at 18 months after ESD and the other developed both metachronous and recurrent LGDs at 8 months after ESD.

Conclusion: According to our ESD series for dysplasia, ESD seems to be feasible for the endoscopic resection of UC-associated dysplasia. However, meticulous surveillance colonoscopy is mandatory to monitor local recurrence and metachronous dysplasia. Non-lifting sign and surface ulceration are highly suggestive of invasive colitic cancer.

Introduction: Biological therapies are effective treatments for inflammatory bowel disease (IBD) but represent an important economic burden to the healthcare system. Adherence surveillance is necessary to optimize the efficacy of treatment and its costs. This issue has been evaluated just in a few studies.

Aims & Methods: We aim to describe the adherence to infliximab in patients with IBD and identify causes and factors associated with poor adherence. We identified all IBD patients treated with infliximab in a single center since 2009. Fulfillment of the prescribed schedule was assessed for every single infliximab infusion. For every patient, we grouped infusions in "courses of treatment" defined as the administration of infliximab at the same dose and schedule for a minimum of six months. Therefore, restarting the treatment after a holiday of more than 4 months, or changing the interval of doses were considered as a new course of treatment. We defined "infusion well administered" when it was done within seven days before or after the date prescribed.

Results: We included a total of 147 courses of treatment, administered to 100 patients. Seventy-four per cent of courses were Crohn disease patients, and 25% in ulcerative colitis patients. In 89% of courses combo therapy with immunosuppressants was used. The prescribed regimes were: every 8 weeks (76.2%), every 10 weeks (7.5%), every 6 weeks (8.8%), every 12 weeks (5.4%) or every 4 weeks (2%). The mean duration per course was 23 months (range: 6–103). Only 69 out of 1714 infusions (4%), were not properly administered. The reported causes for that included: 36 "unknown" (52%), 18 "change requested by patient" (26%), 15 "due to logistic reasons" (15%) and 4 "other" (5.7%). In 107 courses (73%) all the infusions were well administered; in 143 (97%) >80% of infusions were well administered and only 4 courses (2.7%) had less than <80% of adherence. In more than an half of the infusions the cause could not be identified, for that reason analysis of predictive factors could not be performed.

Conclusion: The adherence to the scheduled infliximab regime was very high and it would contribute to maintain the drug efficacy. The reasons for changing the date of administration should be indicated in the clinical history to identify associated factors and minimize the lack of adherence.

P1700 TNF-EXPRESSION OF MONOCYTES IS A PREDICTIVE MARKER FOR RESPONSE TO INFLIXIMAB TREATMENT

D. Lissner, B. Jessen, E. Sonnenberg, F. Schmidt, A. Kuehl, B. Siegmund
 Department For Gastroenterology, Infectious Diseases And Rheumatology, Charité-Universitätsmedizin Berlin, Campus Benjamin Franklin, Berlin/Germany

Introduction: One-third of all patients with inflammatory bowel diseases (IBD) do not respond to initial treatment with the anti-TNF-antibody Infliximab. Thus, predictive markers for response to anti-TNF-treatment are required.

Aims & Methods: The study's aim was to investigate whether levels of TNF produced by peripheral blood mononuclear cells (PBMCs) can predict response to anti-TNF-treatment. Fourteen patients with proven Crohn's disease (CD) or ulcerative colitis (UC) without treatment with biologicals in the past six months were included prior to first Infliximab infusion. Disease activity was measured by the use of Harvey-Bradshaw-Index (HBI) or partial Mayo Score, C-reactive protein (CRP) and ultrasound (Limberg Score). TNF-expression of LPS-stimulated PBMCs was measured by ELISA before treatment. Additionally PBMCs'

intracellular TNF-expression was analysed by flow cytometry. According to a cut-off of 300 pg/ml, patients were divided into low- and high-TNF-producers. Primary endpoint was clinical response, secondary endpoints were decrease in CRP and Limberg Score. Clinical response was defined as a decline in Score of ≥ 2 (HBI) or ≥ 3 (partial Mayo Score). A HBI < 5 or a partial Mayo-Score < 2 was defined as remission. Results were analysed using the Fisher's exact test.

Results: Nine patients reached the endpoint at week 6 and were available for further analysis (5 patients with CD, 4 patients with UC). The median TNF-expression was 653.84 pg/ml (49.53–1154.78 pg/ml). TNF was mainly produced by CD14⁺ monocytes. Four patients were identified as low-producers and five as high-producers. All high-producers responded well to the treatment regarding clinical scoring as compared to only half of the low-producers, but statistical significance was not reached due to the small number of patients (*high*: 100% vs. *low*: 50% clinical response, $p=0.167$). However, remission rates after 6 weeks were significantly higher in high-producers compared to low-producers (*high*: 80% vs. *low*: 0% remission; $p=0.048$). Secondary endpoints showed no significant difference in the two groups.

Conclusion: Quantification of TNF-expression in PBMCs and the resulting classification in low- and high-producers could be a potential predictive marker for response to anti-TNF-treatment in IBD patients.

Introduction: Corticosteroids (CS) are often used concomitantly with biologics in treatment of inflammatory bowel disease (IBD). However, their side-effect profile causes significant clinical and economic burden in long-term treatment. In this study, we investigated the impact of concomitant CS use on vedolizumab treatment persistence in patients with Crohn's disease (CD) and ulcerative colitis (UC).

Aims & Methods: This was a nationwide (Finland), retrospective, non-interventional, multi-center chart review. From 27 centers, we included adult (≥ 18 years of age) IBD patients who received at least one vedolizumab infusion since 2014. Data were collected from medical charts in a standardized case report form. The key data collection points were at baseline, week 14 and month 6 of vedolizumab treatment. The main aim of the study was to analyze vedolizumab treatment persistence among IBD patients using CS in real-world clinical setting.

Results: 247 patients (CD 108, UC 139) were included. At baseline, 47 (43.5%) CD and 84 (60.4%) UC patients were using CS. Higher percentage of patients using CS at baseline discontinued vedolizumab during the 6-month follow-up compared to CS non-users (CD, 14/47 (29.8%) vs. 13/61 (21.3%); UC, 31/84 (36.9%) vs. 16/55 (29.1%)). CS users had less vedolizumab discontinuations due to primary inefficacy ($p=0.04$) and more discontinuations due to adverse events ($p=0.04$), than CS non-users. Over half of the patients on CS at baseline and who persisted on vedolizumab were able to discontinue CS before 6 months timepoint (CD, 18/33 (54.5%); UC, 37/53 (69.8%)). Among CD patients, CS users had higher baseline disease activity than non-users. Such difference was not observed in UC. CS users had shorter disease duration in both CD and UC. There was no difference in the number of prior TNF-alpha inhibitors between CS users and non-users.

Conclusion: Use of CS at the time of initiating vedolizumab treatment was more common in UC than in CD. Vedolizumab treatment persistence was lower in CS users than in non-users in both CD and UC. The data suggests that CS users have less vedolizumab discontinuations due to primary inefficacy and more discontinuations due to adverse events, than CS non-users. The majority of patients on CS at baseline who persisted on vedolizumab were steroid-free by 6 months, potentially relieving the burden of CS-induced side-effects for both patients and society.

Introduction: Vedolizumab is an alpha4beta7 integrin antagonist for the treatment of inflammatory bowel disease (IBD). The role of Vedolizumab drug monitoring, based on the assessment of Vedolizumab trough levels (VTL) and anti-Vedolizumab antibodies (AVA) has not been clarified yet. In this study we investigated the correlation between VTL and AVA and clinical response.

Aims & Methods: Consecutive IBD patients who started therapy with Vedolizumab at our centre were prospectively enrolled. Each patient underwent 300 mg infusion at weeks 0, 2, 6 and 14; additional doses at week 10 and then every 4 weeks were given to non-responders at week 6. Clinical activity was evaluated at baseline and week 6, 14 and 22 by Harvey Bradshaw Index (HBI) and partial Mayo score (pMayo). C-reactive protein (CRP) was measured at weeks 6, 14, 22. VTL and AVA were assayed by ELISA (Theradiag, Marne La Vallée, France) at weeks 6, 10 and 14. Limits of detection for VTL and AVA were 2 ug/ml and 35 ng/ml, respectively. Clinical response was defined as at least 30% reduction of activity scores from baseline and remission was defined as HBI < 5 or pMayo < 2 . Statistics was performed by Mann Whitney test, Spearman's rho, receiver operating characteristic (ROC) curve analysis.

Results: We included 50 patients (mean age 45.5 y; male 56%) with Crohn's disease (CD, n=28) and Ulcerative colitis (UC, n=22). 44 (88%) IBD patients had previous anti-TNF α therapy. Baseline median HBI was 8 (5–16) and median pMayo was 6 (5–7). Median VTL (Interquartile range, IQR) at weeks 6, 10 and 14 were 38.6 (20.3–53.5), 25.4 (13.4–45.6) and 17.7 (10.1–33.7) ug/ml, respectively. VTL measured at week 6 were significantly higher in clinical responders as compared to non-responders: median (IQR) 50.7 (31.8–56.8) vs 33.1 (19.4–42) ug/ml, $p=0.04$. Week 6 VTL were also higher in CRP responders (< 5 mg/l): median (IQR) 48.1 (32.5–55.8) vs 32.8 (19.7–44.3) ug/ml, $p=0.04$. Week 6 VTL were inversely correlated with CRP ($\rho = -0.39$, $p=0.006$). By ROC curve analysis we identified a cut off value for VTL of 44.3 ug/ml for clinical response at week 6 (AUC 0.677, sensitivity 61.9%, specificity 79.3%, $p=0.02$). Week 6 VTL were significantly higher in patients in clinical remission at their last follow-up (mean 20 weeks) compared to non-remitters: median (IQR) 55.8 (46–64.1) vs 33.3 (25.9–40.4) ug/ml, $p=0.0035$. The ROC curve analysis identified a cut off of 44.3 ug/ml (AUC 0.813 sensitivity 88.9%, specificity 73.2%, $p=0.0006$). Week 14 VTL were also significantly higher in patients in clinical remission at 22 weeks compared to non-remitters: median (IQR) 38.3 (20.5–49.8) vs 13.4 (8.4–20.6) ug/ml, $p=0.0035$. The cut off identified by ROC curve analysis for this outcome was 16.4 ug/ml (AUC 0.820 sensitivity 100% specificity 63%, $p=0.0019$). AVA were detected in 2% of patients at week 6, in 5.9% at week 10 and in 4.5% at week 14 and were not correlated with clinical response.

Conclusion: These preliminary data suggest that obtaining a VTL of 44.3 ug/ml after the first 2 Vedolizumab infusions is correlated with early clinical and biological (CRP) response and with clinical remission at a mean follow-up of 20 weeks. Week 14 VTL are correlated with clinical remission at week 22 and the identified cut off is 16.4 ug/ml. Immunogenicity of Vedolizumab is low in these patients.

Introduction: Strictures in Crohn's disease (CD) may occur in different segments along the gastrointestinal (GI) tract. In contrast to ileocecal strictures, endoscopic balloon dilation (EBD) for CD-associated strictures of the upper gastrointestinal (UGI) tract is rarely reported. We therefore performed a combined efficacy and safety analysis of EBD for UGI CD-associated strictures in this multi-centre cohort study.

Aims & Methods: Individual patients characteristics were retrieved from electronic case report forms. Upper GI tract was defined as esophagus, stomach and duodenum up to the ligament of Treitz. Time-to-event analysis was performed to assess symptom recurrence, re-dilation or surgery. Kaplan-Meier estimates were used to calculate event rates. For the multivariable Cox regression models, all variables that were available for at least 85% of subjects were considered for inclusion and the score method was used to choose the best model with two factors for each outcome.

Results: A total of 73 CD patients and 127 performed dilation procedures were included. Stricture locations were: duodenum n=46, stomach n=14; esophagus n=9; stomach and duodenum n=4. Technical success rate was 94.1% resulting in clinical efficacy in 88.9% of patients. Major complications, defined as perforation, bleeding or dilation-related surgery, occurred in 2.9% of all procedures. During a median follow up period of 36 months, 89.4% of patients underwent re-dilation and 29.8% required surgical intervention. The multivariable Cox regression analyses indicated that a younger age at diagnosis was associated with symptom recurrence (HR 0.82 (0.71, 0.95), p=0.008), mucosal inflammation with need for re-dilation (HR 2.7 (1.4, 5.2), p=0.003) and use of anti-TNF with need for surgery (HR 4.8 (1.8, 12.4), p=0.001).

Conclusion: EBD for CD-associated strictures of the upper gastrointestinal tract has a high rate of short-term technical and clinical success with moderate long-term efficacy and acceptable complication rates.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1704 POST-MARKETING SAFETY EXPERIENCE OF VEDOLIZUMAB IN PATIENTS WITH PRE-EXISTING VIRAL HEPATITIS

D. Wu¹, I. N. Hilmi², S. Adsul³, A. Blake⁴, F. Bhayat⁴

¹Chung-ho Memorial Hospital, Kaohsiung Medical University, Kaohsiung/Taiwan

²University Malaya Medical Centre, Kuala Lumpur/Malaysia

⁴Takeda Development Centre Europe, London/United Kingdom

Contact E-mail Address: Fatima.Bhayat@takeda.com

Introduction: Systemic immunosuppressive treatment, such as anti-tumour necrosis factor- α (TNF α) therapy, can reactivate latent hepatitis virus.¹ Vedolizumab (VDZ), a humanised monoclonal antibody, blocks gut-specific lymphocyte trafficking by binding to $\alpha_4\beta_7$ integrin and is approved in moderately to severely active ulcerative colitis or Crohn's disease. The gut selectivity of VDZ may be associated with a lower risk of virus reactivation than anti-TNF α agents. The VDZ European Product Label advises caution regarding VDZ use in patients with controlled chronic severe infection or a history of recurring severe infection.² As VDZ clinical trials excluded patients with chronic viral hepatitis B or hepatitis C infection, there are no clinical trial data available in this population.

Aims & Methods: Here, we describe the safety experience of VDZ use in patients with pre-existing hepatitis B or hepatitis C in the post-marketing setting. Adverse events (AEs) were identified from the VDZ Global Safety database (data-cut May 20, 2014 to Nov 19, 2016) and included if patients' medical history or concurrent conditions included a Medical Dictionary for Regulatory Activities (MedDRA) preferred term suggestive of hepatitis B or hepatitis C infection.

Results: In the context of ~77.382 patient-years of VDZ exposure and a total of 30.470 AEs in the VDZ database, 51 events (n=13 serious [non-fatal]; n=38 non-serious) occurred in 15 patients with pre-existing viral hepatitis B (n=5, including 2 chronic cases) or hepatitis C (n=10). Of the 15 patients, six had ulcerative colitis, seven had Crohn's disease, and in two the indication was not reported (NR). Eight patients received prior/concomitant anti-TNF α therapy; NR n=2. Events reported were reflective of the general VDZ safety profile in patients without viral hepatitis. Liver-related events were reported in two patients with hepatitis C—one patient who was a smoker reported hepatic neoplasm; the other reported hepatic mass and had a history of skin cancer, cholecystectomy, bladder tumour removal and right radical orchiectomy. Both events resulted in VDZ discontinuation. Of events with a reported outcome, 22/26 (84.6%) were resolved or resolving at the time of reporting and 4/26 (15.4%) were unresolved; NR n=25. VDZ treatment was continued in 10/14 (71.4%) patients and discontinued in 4/14 (28.6%); NR n=1.

Conclusion: In the post-marketing setting, there was no evidence of increased risk of viral reactivations in patients with hepatitis B or hepatitis C receiving VDZ. Limitations associated with post-marketing safety reporting (e.g. voluntary nature of reporting and incomplete patient medical history) and currently limited availability of VDZ in regions with endemic hepatitis B and hepatitis C infection should be considered when interpreting these results.

P1705 AMINOSALICYLATES FOR MAINTENANCE THERAPY IN ULCERATIVE COLITIS: IS THE ADHERENCE REALLY IMPORTANT?

D. Martí, M.P. Ballester, M. Fullana, P. Navarro, M.M. Boscá, J. Tosca, F. Mora, M. Minguez

Digestive Disease, University Clinic Hospital of Valencia, Valencia/Spain

Contact E-mail Address: mapibafe@gmail.com

Introduction: The goal of maintenance therapy in Ulcerative Colitis (UC) is to keep clinical and endoscopic steroid-free remission. 5-aminosalicylate (5-ASA) represents the first line maintenance therapy¹. Non-adherence to 5-ASA is associated with an increased risk of disease relapse, colorectal cancer and worsening of quality of life²⁻³. Adherence rate has been analysed in several studies with controversial results⁴⁻⁵.

Aims & Methods: The aim of this study is to quantify the prevalence of adherence to 5-ASA, to identify risk factors to non-adherence and its correlation with the course of the disease. Observational, analytical, retrospective, single tertiary centre, cohort study of all UC patients followed-up in our IBD unit, until January 2016, with 5-ASA maintenance treatment prescribed by an electronic management program. Adherence was considered when 80% of the prescribed 5-ASA was dispensed at pharmacy, during one year (2016), assuming that dispensed 5-ASA is equivalent to medication intake. The study analysed, according to the existence and degree of 5-ASA adherence, UC phenotypic expression (age, sex, smoking habit, Montreal classification, extraintestinal manifestations, complications), disease course (moderate-severe relapse rate that require corticosteroid therapy), 5-ASA properties (dose, administration regime, formulation), consumption of other UC and non-UC chronic drugs. A multivariable logistic regression was applied to discriminate adherent subjects including the risk factors of the univariable analysis. A Spearman's rank coefficient analysis was performed to correlate percentage of adherence with relapse rate.

Results: The study cohort included 433 patients, 55% males with a median age at the first 5-ASA prescription analysed of 49 years (IQR 39–61). 17% had a proctitis, 31% a left-side colitis and 52% an extended disease. 30% of patients suffered from extraintestinal manifestations and 8 from a complication. The mean dose of 5-ASA taken was 2.6 g/day (range 0.7–4.8) distributed in a daily dose in 61% of the patients. Adherence prevalence to 5-ASA was 63%. Adherent group had a higher median age (52 (±11) vs 43 (±13), p=0.001) and received more non-UC chronic drugs (OR = 2.3, 95CI = 1.5–3.4, p=0.001). The independent variables, age and intake of other non-UC drugs, included in the multivariate analysis reached a predictive capacity of 65% outcomes of adherence. There was no significant reduction in the risk of moderate-severe flares that required corticosteroid therapy when comparing both adherent and non-adherent groups and rank correlation showed no relationship between adherence to 5-ASA and relapse rate (r = 0.06; p = 0.2). Patients treated with adjuvant maintenance therapy (bitherapy with thiopurines or antiTNF or triple therapy with both) presented a significant reduction of flares (OR = 0.6, 95CI = 0.7–0.9, p = 0.019).

Conclusion: Adherence to 5-ASA in our population is low. Older patients that take other non-UC chronic treatments show higher adherence. With a one year prescribed and dispensed analysis, non-adherence to 5-ASA is not related with a higher risk of flares that require corticosteroid therapy. Patients treated with adjuvant maintenance therapy, show better results throughout the course of the disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Randomized controlled trials provide efficacy data of novel IBD drugs. The majority of patients included in these trials however, especially for novel biologics, are highly selected patients from referral centres and are included in a variety of countries with very different health care systems. Inclusion criteria and follow-up protocols are strict and do not reflect routine care. Long-term country specific effectiveness and safety data for novel drugs are therefore warranted. Development and implementation of a novel protocol and electronic case reporting registry for every new compound is however time consuming and expensive. Therefore, the Initiative on Crohn and Colitis (ICC) aimed to develop a web-based registry suitable for capturing, managing, and reporting data for all drugs and all IBD phenotypes in everyday practice in all centres.

Aims & Methods: Here, we aim to test the feasibility of the web-based registry in patients starting vedolizumab. With a structured iterative process with IBD-specialist from the ICC, case report forms and lab-evaluation forms were developed to assess key elements of disease activity, safety and a PROM. Furthermore the ICC decided on a uniform follow-up protocol reflecting everyday practise. A web-based registry for capturing, managing and reporting follow-up data of IBD patients starting a new drug was developed (ICC-case series). The registry automatically reminds the treating physician or nurse prior to novel follow-up visits. Feasibility of the ICC-case series was assessed in 6 centres in the Netherlands in patients who started vedolizumab. To test data extraction and reporting, the baseline characteristics of the first cases were assessed. The characteristics were compared to baseline characteristics of subjects in the vedolizumab registration studies.

Results: A total of 230 IBD (4 IBD-U) patients starting vedolizumab were included. All users found the ICC-case series easy to use and received the reminder mails for follow-up visits. Baseline characteristics were successfully extracted and are reported in table 1.

Table 1: Baseline characteristics of ICC cohort and GEMINI trials

Characteristic	ICC cohort CD (N = 146)	GEMINI 2(1) (N = 1115)	ICC cohort UC (N = 80)	GEMINI 1(2) (N = 895)

Prior TNF antagonist therapy (%)				
≥1	145 (99.3)	645 (57.8)	69 (86.3)	367 (41.0)
≥2	114 (78.1)	398 (35.7)	37 (46.3)	-
Prior IBD surgery (%)	72 (49.3)	466 (41.8)	-	-
Perianal surgery (%)	27 (18.5)	-	-	-
IPAA (%)	-	-	3 (3.8)	-

Conclusion: The ICC developed a uniform web-based registry to study post-marketing safety and effectiveness of novel IBD-drugs. A feasibility study with 230 patients starting vedolizumab showed successful data-capture, managing, and reporting with the ICC-case series in 6 centres. Table 1 shows clear differences between baseline characteristics of real-life Dutch patients and patients in the GEMINI studies underlining the importance of country specific post-marketing data.

P1707 SIX-YEAR EFFICACY AND SAFETY OF AZATHIOPRINE TREATMENT IN THE MAINTAINANCE OF STEROID-FREE REMISSION IN INFLAMMATORY BOWEL DISEASE PATIENTS

C. Cassieri¹, R. Pica¹, E. V. Avallone¹, G. Brandimarte², M. Zippi¹, P. Crispino¹, D. De Nitto¹, G. P. Lecca², P. Vernia¹, P. Paoluzi¹, E. S. Corazzini¹

Contact E-mail Address: claudio.cassieri@libero.it

Introduction: Azathioprine (AZA) and thiopurine are widely used for induction and maintenance of remission in patients steroid-resistant or dependent with inflammatory bowel disease (IBD). The treatment must be withdrawn in 5–30% of patients due to the occurrence of adverse events.

Aims & Methods: Aim of this study has been to investigate its efficacy and safety in maintaining steroid-free remission in steroid dependent IBD patients six year after the institution of treatment. Data from consecutive IBD outpatients referred in our Institution, between 1985–2015, were reviewed and all patients treated with AZA were included in this retrospective study. AZA was administered at the recommended dose of 2–2.5 mg/kg. Blood chemistry was analysed before administration of the drug, every 10–15 days for the first 3 months and then every 1–2 months following the institution of treatment.

Results: Out of 2722 consecutive IBD outpatients visited in the index period, AZA was prescribed to 415 patients, 227 (54.7%) were affected by Crohn's disease (CD) and 188 (45.3%) by ulcerative colitis (UC). One hundred and fifty-eight patients with a follow-up <72 months were excluded from the study. Two hundred and fifty-seven patients were evaluated, 143 (55.6%) with CD and 114 (44.4%) with UC. One hundred and forty-two (55.2%) were male

and 115 (44.8%) female (average age of 35.68 ± 14.22 SD years, range 14–74 y.). Six year after the institution of treatment, 130 (50.6%) patients still were in steroid-free remission (85 CD vs 45 UC, 59.5% and 39.5%, respectively, $p=0.0017$), 71 (27.6%) had a relapse requiring retreatment with steroids (29 CD vs 42 UC, 20.3% and 36.8%, respectively, $p=0.0048$), 56 (21.8%) discontinued the treatment due to side effects (29 CD vs 27 UC, 20.2% and 23.7%, respectively). Loss of response from 1st to 6th year of follow-up was low, about 20%.

Conclusion: Six years after the onset of treatment 56% of patients did not require further steroid courses. After the first year loss of response was low in five subsequent years. In the present series the maintenance of steroid-free remission was significantly higher in CD than in UC patients. The occurrence of side effects leading to the withdrawal of AZA treatment has been low.

P1708 CLINICAL EFFICACY AND SAFETY OF ANTI-TNF THERAPY IN INFLAMMATORY BOWEL DISEASE IN THE ELDERLY: A UK TERTIARY REFERRAL CENTRE EXPERIENCE

J. Digby-Bell

Dept. Of Gastroenterology, St. Thomas' Hospital, London/United Kingdom

Contact E-mail Address: jdigbybell@doctors.org.uk

Introduction: Many patients, especially the elderly or those with comorbidities, are excluded from clinical drug trials and little real-life data exists on the safety and efficacy of anti-TNF.

Aims & Methods: We aimed to compare the clinical efficacy and safety of anti-TNF therapy in patients over 60 years in a tertiary IBD centre in London, UK. We interrogated our IBD biologics database from January 2009 to November 2015 and performed retrospective data analysis until end of follow up in April 2017. Data was collected on demographics, endoscopy, calprotectin, CRP, clinical scores, serious infections, malignancy, drug levels and anti-drug antibodies. Patients with an age of '≥60' when starting anti-TNF therapy were identified and '<60' comparators were selected at random in a 2:1 ratio. Primary endpoints: week 14 and week 54 steroid free clinical remission (Harvey Bradshaw Index <5 or Simple Colitis Activity index <3) Secondary endpoint: proportion of patients remaining on anti-TNF at the end of follow up

Results: See table.

Conclusion: Only a small number of '≥60' patients started anti-TNF (29 out of greater than 650). This may reflect our local population or that clinicians favour non anti-TNF therapies in this older group. Overall there was similar clinical efficacy at weeks 14 and 54 of anti-TNF therapy between the 'young' and 'old' groups. There was a higher discontinuation rate after 1 year of therapy in the older group ($p=0.043$). There were more adverse events in the older group (7/29) including 3 new cancer diagnoses compared with the younger group (3/58). 4 patients had detectable anti-drug antibodies in the older group despite 2 of them having therapeutic thiopurine suggesting that the elderly may have more

immunogenicity than the young. Further studies with more patients across multiple sites are required to clarify safety and efficacy in the elderly.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1709 TACROLIMUS IN REFRACTORY ULCERATIVE COLITIS-12 MONTH OUTCOME IN A SINGLE-CENTRE UK DISTRICT HOSPITAL

N. Jayasooriya, L. Everson, S. Mann

Gastroenterology, Barnet and Chase Farm Hospital, Royal Free Trust NHS, Barnet/United Kingdom

Contact E-mail Address: nishani.jayasooriya@nhs.net

Introduction: Rescue therapy is required for patients with moderate - severe ulcerative colitis (UC) who have failed to respond to steroids and thiopurines. Anti-Tumour Necrosis Factor agents (Anti-TNFs) are widely used before considering a colectomy. Calcineurin inhibitors such as ciclosporin and Tacrolimus may be considered as alternatives to biologics. There have been some case series in assessing the use of Tacrolimus in such patients although the United Kingdom experience is limited. (1, 2)

Aims & Methods: We aimed to review the outcome of patients who received Tacrolimus as rescue and subsequent maintenance therapy for refractory symptoms of UC. This was a retrospective single-centre case review series. All patients who were refractory to standard medical therapies and being considered for a colectomy were reviewed by a Gastroenterologist with an interest in Inflammatory Bowel Disease. Demographic data, indications for treatment, clinical course and outcomes were reviewed from Electronic Patient Records (EPR).

Results: Fourteen patients (F=6; mean age of 54 years) received Tacrolimus. 8 patients (57%) had evidence of pancolitis and six patients (43%) had distal colitis. All patients had previously received thiopurines and 11 patients (78.6%) had also received anti-TNFs. Three patients declined Anti-TNF treatment. All patients were steroid-dependent prior to commencing Tacrolimus. One patient received ciclosporin before the switch. The remaining 13 patients were initiated on Tacrolimus in the out-patient setting at a starting dose of 0.1 mg/kg/day in 2 divided doses. Patients took Tacrolimus for a mean period of 18.8 months (range: 2 months to 49 months). Eight patients (57%) achieved a steroid-free remission within 6 months. An additional 3 patients (23%) had a clinical response within 6 months, but required one course of steroids during this time period. Three patients (23%) failed to respond to Tacrolimus; 1 patient remains steroid-dependent and does not wish to proceed to surgery, 1 patient was switched to infliximab and 1 patient proceeded at 10 months to have an elective sub-total colectomy. Tacrolimus was withdrawn in all 3 non-responders. Of the 11 (78.6%) initial responders, 12-month outcome included withdrawal of Tacrolimus in 7 patients (63.6%). Reasons for withdrawal included: n=1 renal impairment; n=1 started on infliximab; n=3 referred for leucapheresis; n=1 restarted on Azathioprine and n=1 referred for proctocolectomy. Three patients (21.4%) remain in steroid-free clinical remission with a good quality of life and

Abstract No: P1708

	< 60 years	≥60 years
Total	n = 58	n = 29
Week 14 steroid free remission (HBI <5, SCCAI < 3)	28/41 (68.3%)	8/16 (50%)
Week 54 steroid free remission (HBI <5, SCCAI < 3)	24/40 (60%)	8/15 (53.3%)
Remain on anti-TNF at week 54	46/58 (79.3%)	23/28 (82.1%)
Reasons for stopping anti-TNF before week 54	7 primary non-response 2 secondary loss of response with detectable anti-drug antibodies 1 infusion reaction 1 clinical & endoscopic remission	2 primary non-response 2 secondary loss of response with detectable anti-drug antibodies 1 infusion reaction
Remain on anti-TNF at end of follow up (April 2017)	38/58 (65.5%)	12/29 (41.4%) p < 0.05
Reasons for stopping biologic during study period	8 primary non-response 4 secondary loss of response 3 secondary loss of response with detectable anti-drug antibodies 1 infusion reaction 1 clinical and endoscopic remission 2 infections (skin and respiratory) 1 stopped attending	4 primary non-response 2 secondary loss of response 3 secondary loss of response with detectable anti-drug antibodies 1 infusion reaction 1 clinical and endoscopic remission 1 infection (ophthalmic) 1 new diagnosis cancer (colorectal) 1 severe fatigue 1 peripheral neuropathy 1 moved away 1 stopped attending
Length of time on anti-TNF if stopped (months)	Range: 3–73 Median: 12	Range: 3–63 Median: 18
Anti-drug antibodies detectable during follow up	3/58 (5.2%)–3 infliximab weeks 14, 34 and 76 2 no concomitant 1 subtherapeutic TGNs 1 prior exposure to infliximab	4/29 (13.8%) -3 infliximab, 1 adalimumab weeks 14, 48, 52 and 54 2 concomitant with therapeutic TGNs 2 no concomitant 0 prior exposure to anti-TNF
Adverse events throughout follow up	1 new diagnosis cancer (testicular) 1 infusion reaction 1 infection (dental abscess)	3 new diagnosis cancer (prostate, colorectal & thyroid) 1 spontaneous ileal perforation requiring emergency surgery 1 infusion reaction 2 infections (chest infection and shingles)

no adverse effects on maintenance treatment with Tacrolimus. 11 patients (78.6%) have avoided a colectomy during the first 12-months of follow-up.

Conclusion: Tacrolimus should be considered as an alternative treatment for patients with refractory UC in the out-patient setting. This is particularly useful if the patient is unwilling to consider a colectomy. With close monitoring and adherence to protocols, it is safe and effective allowing patients an alternative immunosuppressant which may either avoid the need for a colectomy or, give some time to adjust to its implications.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Adalimumab (ADA) and golimumab (GOL) are effective in the induction and maintenance treatment of moderate-to-severe ulcerative colitis (UC). No comparable data between the 2 drugs are available up to now.

Aims & Methods: We reported the Sicilian Network experience on the comparative efficacy of ADA and GOL in patients (pts) with moderate-to-severe UC. From June 2015 until April 2017, 197 consecutive pts with moderate to severe UC were treated with ADA or GOL. The efficacy was evaluated at 8 week and at the end of the follow up considering "clinical response" (reduction of at least 2 points of Partial Mayo Score with concomitant steroid reduction or discontinuation) and "clinical remission" (Partial Mayo Score <2 without steroids). The presence of clinical response or clinical remission was defined as "clinical benefit". Endoscopic Mayo Score was evaluated at the end of the follow up in pts who underwent colonoscopy.

Results: 118 pts were treated with ADA and 79 with GOL for a median follow up of 40.21 [20.32, 69.14] weeks for ADA and 34.00 [17.43, 54.79] weeks for GOL (p=0.08). Eighty-eight pts were naïve to anti-TNFα (59 ADA, 29 GOL, p=0.09). No difference in Mayo Score value was observed between the 2 groups at the time of first drug injection (p=0.92). After 8 weeks clinical benefit was achieved in 93/118 (78.8%) pts treated with ADA and 50/79 (63.3%) pts treated with GOL (p=0.026). Clinical remission was achieved in 48/118 (40.7%) pts treated with ADA and 20/79 (25.3%) pts treated with GOL (p=0.038). At the end of the follow up clinical benefit was achieved in 79/118 (66.9%) pts treated with ADA and 37/79 (46.8%) pts treated with GOL (p=0.008). Clinical remission was achieved in 50/118 (42.4%) pts treated with ADA and 23/79 (29.1%) pts treated with GOL (p=0.082). No difference was observed in clinical outcomes at 8 weeks and at the end of the follow up between naïve and non naïve pts (p=0.187). At the end of the follow up the median Endoscopic Mayo Score was 3.00 [0.00, 5.00] in pts treated with ADA and 4.00 [1.00, 7.00] in pts treated with GOL (p=0.025). Univariable analysis revealed that age > 40 years at the time of first drug injection and age < 40 years at the diagnosis were associated with higher remission rate in pts treated with ADA respect to pts treated with GOL at 8 weeks and at the end of the follow up (p=0.034 and p=0.016 respectively). Disease duration > 5 years was associated with a higher remission rate in pts treated with ADA respect to pts treated with GOL at 8 weeks and at the end of the follow up (p=0.017).

Conclusion: This is the first study where the comparable efficacy of ADA and GOL was evaluated. These real life data confirmed the efficacy of subcutaneous anti-TNFα in the treatment of moderate to severe UC. ADA resulted to be more effective than GOL in inducing and maintaining clinical benefit.

Larger prospective studies with longer follow up are warranted to confirm this data.

Introduction: The efficacy of golimumab for the induction and maintenance of clinical remission in adult subjects moderately to severely active Ulcerative Colitis (UC) has been studied in two completed clinical trials.¹⁻² However, patients enrolled in clinical trials are not entirely representative of those encountered in the clinical practice setting. In Italy, golimumab is on the market for treating UC from March 2015. The aim of our study is to evaluate the durability and safety of golimumab in the context of real-life clinical practice.

Aims & Methods: An observational, multicenter, retrospective-prospective, phase IV study, enrolling all patients starting golimumab from March to December 2015, from 21 IG-IBG centers. This study consists of two different parts: 1) retrospective, regarding data until December 2016 and 2) a prospective one, still ongoing, that will be concluded at the end of 2017. The co-primary outcomes were the overall durability of treatment with golimumab, defined as persistence on golimumab therapy because of sustained clinical benefit, and safety. Results for the first 54-weeks period are reported.

Results: 121 patients (47% female), with mean age of 45.7 years (±SD 14.3) and a median duration of disease of 8 years, (range 0–28) were included. Sixty-seven patients (55.4%) had severe endoscopic activity (Mayo 3). Clinical activity was defined as moderate (Partial Mayo Score (PMS) 5–6) in 55 patients (45.5%) and severe (PMS 7–9) in 66 patients (54.5%). Previous exposure to anti TNF-α was reported in 52% of patients (38 Infliximab, 4 Adalimumab, 21 both). Steroid-dependence and refractoriness were reported in 78.5% and 16.5% of patients, respectively. After 54 weeks, the cumulative persistence on golimumab therapy was 31%. Seventy-seven patients withdrew from treatment, without significant difference among anti TNF-α naïve vs exposed patients (55.2% vs 71.4%, p=0.11 Chi-Square test). Among 90% of patients who completed week 8, 48% of patients were still on golimumab therapy at week 54. Thirty patients (39%) withdrew within the first 14 weeks. Among the remaining patients, at week 54 the persistence on golimumab therapy was 57.1%. Ten patients reported an adverse event, but only 6 of them withdrew from treatment. Four patients reported paradoxical skin lesions, unresponsive to topical therapies. Fifteen patients (12.4) underwent surgery within the first 54 weeks, with a greater percentage among anti TNF-α exposed (20.6% vs 3.4%, p=0.02 Chi-Square test).

Conclusion: This preliminary real-life data study endorses golimumab's promising results, showing 57.1% of durability treatment at week 54 in those patients

who completed first 14 weeks of treatment and confirming it as a safe drug. Anti TNF- α naïve patients were more likely to avoid colectomy.

Introduction: Ciprofloxacin is one of the most frequently used antibiotics in hospitalized inflammatory bowel disease (IBD) patients. Also discrepancies between clinical guidelines and real clinical situations are observed in terms of antibiotics use in patients with IBD. In the last few years an emerging resistance to ciprofloxacin, ranging from 43% to 82%, has been described in extended spectrum beta-lactamase producing bacteria (ESBL-E) colonizing the gut.^{1,2}

Aims & Methods: The objective of this study was to evaluate the gut colonization with ESBL-E in IBD patients, determine the resistance to ciprofloxacin and bacterial plasmid genes associated with that. Rectal swabs were collected from all consecutive patients with confirmed ulcerative colitis (UC) and Crohn's disease (CD) hospitalized in two largest tertiary medical care centres in Riga, Latvia during a 7-year period (2010–2016). Enterobacteria were cultured and analyzed for ESBL presence according to EUCAST guidelines, resistance to ciprofloxacin and bacterial plasmid genes CTX-M, TEM and SHV were detected.

Results: A total of 148 patients with confirmed IBD diagnosis were included in the study—101 (68%) with UC, 47 (32%) with CD. We found that 12 (12%) of the UC patients and 5 (11%) of the CD patients were colonized with ESBL-E. The isolated ESBL producing strains from UC patients included *Escherichia coli* (n = 10), *Klebsiella oxytoca* (n = 1) and *Escherichia hermannii* (n = 1). The isolated ESBL producing strains from CD patients included only *Escherichia coli* (n = 5). The isolated bacterial plasmid genes associated with ESBL production in UC included CTX-M (n = 11; 92%), TEM (n = 4; 33%), SHV (n = 1; 8%), in CD—CTX-M (n = 4; 80%) and TEM (n = 3; 60%). In UC 6 (50%) and in CD 1 (20%) of the isolated ESBL-E were resistant to ciprofloxacin. In 1 case of the ciprofloxacin resistance CTX-M, TEM and SHV gene combination was observed, in 1 case CTX-M and TEM gene combination was observed, in 4 cases only CTX-M gene was present and in 1 case only TEM gene was present.

Conclusion: 1. Higher gut colonization rate with ESBL-E in IBD patients, mostly with *E. coli*, expressing CTX-M gene was found comparing with the literature. 2. Higher resistance to ciprofloxacin was found in ESBL-E isolated from UC patients, comparing to UC patients. 3. CTX-M and TEM genes are associated with resistance to ciprofloxacin.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Anti-TNFs are well-established in therapeutic management of Crohn's disease (CD). Real-life data on their pattern of use in a French clinical setting are, however, limited to this day.

Aims & Methods: The objective of this study was to examine for characteristics of CD patients and anti-TNF use in a real-life setting in France through the general sample of health insurance beneficiaries (EGB database) which includes reimbursement data from a sampled 1/97th of the French population. A cohort of 1280 patients with CD in the EGB database between 01/01/2010 and 31/02/2014 was retrospectively constituted, of which 189 (14.8%) initiated an anti-TNF treatment (infliximab, adalimumab) during that period and were studied for the analysis. An additional analysis was performed based on French hospital discharge data (medical information systems program [PMSI]) from 8142 CD patients to compare results from the EGB database but only support infliximab use due to its exclusive hospital availability in France (adalimumab can be prescribed in both hospital and retail markets).

Results: 48.7% of anti-TNF treated patients were male and the mean age at the initiation of an anti-TNF treatment was 38. The mean duration between diagnosis (measured through the assignment to an ALD [Long Term Illness]) and start of anti-TNF treatment was 6 years. Concomitant treatments such as corticosteroids and immunosuppressants were prescribed at least once in 63% and 47% of patients respectively. Around 57% of patients initiated a treatment with infliximab and 43% with adalimumab. Results at 12 months after anti-TNF initiation are presented in the table below:

Table 1: Anti-TNF use in patients initiating an anti-TNF treatment with at least 12 months of follow-up At 12 months, 13.6% of patients underwent surgery. Results from the hospital discharge database confirmed some of our observations. Optimization rate for infliximab 12 months after initiation was similar (33.1% at 12 months for infliximab). Treatment discontinuation rates were also within the same range observed and stable over time, with 10% of patients discontinuing infliximab treatment each year and a discontinuation rate after 12 months of treatment of 27.2%.

Anti-TNF use at 12 months after initiation	N	Results
Drug survival rate for the first line anti-TNF	108	69.8% [62.3–76.1]
Survival rate for first line adalimumab	47	71.7% [59.9–80.6]
Survival rate for first line infliximab	61	66.3% [55.9–74.8]
Anti-TNF dose optimization rate	85	41.5% [34.5–49.3]
Dose optimization rate for adalimumab	53	33.6% [25.2–43.8]
Dose optimization rate for infliximab	63	38.2% [30.1–47.8]
Switch rate to another anti-TNF	126	17.5% [12.6–24.1]
Switch rate from adalimumab to infliximab	70	13.6% [8.1–22.4]
Switch rate from infliximab to adalimumab	88	14.9% [9.6–23.0]
Anti-TNF treatment discontinuation rate	108	31.4% [25.0–38.9]
Discontinuation rate for adalimumab	47	28.2% [19.4–40.0]
Discontinuation rate for infliximab	61	33.7% [25.2–44.0]

Conclusion: The general sample of health insurance beneficiaries' database provides a unique representative sample to analyze and describe real-life usage of anti-TNF in Crohn's disease patients in France.

P1714 PREDICTIVE FACTORS OF RESPONSE TO ANTI-TNF A TREATMENT OF COMPLEX ANO-PERINEAL FISTULAS IN CROHN'S DISEASE

M. Hafi¹, M. Fekih¹, A. Laabidi¹, N. Ben Mustapha¹, J. Boubaker¹, A. Filali¹

¹Gastroenterology, la rabta hospital, tunis/Tunisia

Contact E-mail Address: maroua.hafi@gmail.com

Introduction: Ano-perineal fistulas (APF) are a common location of Crohn's disease (CD). Their treatment is still disappointing. Identifying the predictive factors of response could guide the practitioner to adapt the anti-TNF α treatment of each patient.

Aims & Methods: We performed a descriptive, longitudinal and retrospective study over a period of 14 years. We included all patients with a definite diagnosis of complex APF of CD treated with anti-TNF α with a minimum follow-up of one year. Patients less than 16 years of age or over 70 years were excluded and non-observing patients were also excluded. A univariate and multivariate statistical analysis was then carried out using the SPSS software to identify the predictive factors of response to the treatment.

Results: A total of 49 patients had complex APF treated with anti-TNF α . 10% of the patients had also recto-vaginal fistulas. The mean age was 31 years. The sex ratio women/men was 1.35. All of the patients had an MRI at diagnosis. Patients had concomitant antibiotics and seton drainage in all cases. 76% of the patients received azathioprine. After the induction phase, 53% of the patients

achieved clinical remission, 31% a partial clinical response and 12% a primary failure. 53% of the patients maintained a clinical remission after a year of maintenance therapy. After a mean time of 13 months, 42% of the patients had a loss of response. The analytical study found that the absence of recto-colic involvement, CRP negativity and normalization of platelet count under treatment and achievement of clinical remission after the induction phase were predictive factors of long term good response to anti-TNF α treatment. Clinical remission after the induction phase was the only independent predictive factor of long-term remission under maintenance treatment after multivariate analysis. However, partial clinical response was predictive of loss of response as well as the presence of a recto-vaginal fistula and young age at diagnosis.

Conclusion: According to our results, the type of response obtained after the induction phase seems to be closely related to the subsequent development of our patients. Prospective studies assessing early therapeutic adaptations could better evaluate this perspective in the event of a partial clinical response. In addition, rectal involvement and recto-vaginal fistulas are factors of poor response for which aggressive and specific treatment is essential.

Introduction: The management of chronic inflammatory bowel disease (IBD) has experienced significant advance with the development of biologic therapy. Infliximab (IFX) was the first monoclonal antibody approved for IBD. The patent expiry of biologics and their relatively high costs that result in a significant economic burden on the healthcare system, had led to the development of biosimilar agents. The biosimilar IFX has been authorised for use in all the indications as the reference IFX. The demonstration of biosimilar IFX efficacy and safety equivalence was based on two pivotal clinical trials in rheumatic diseases. As a result of the extrapolation to IBD, there is growing controversy regarding the appropriate use of biosimilar IFX. The efficacy and safety of infliximab reference in inducing and maintaining remission in IBD has been extensively proven in clinical trials. However, the role of biosimilar IFX, has not been systematically investigated in clinical practice.

Aims & Methods: We aimed to compare the safety and efficacy in inducing and maintaining remission in IBD, between the reference IFX group and biosimilar IFX group. This retrospective, multicenter study was carried out at 4 tertiary hospitals, from January 2013 to December 2016. The analysis included 2 cohorts of consecutive IBD patients. One cohort composed of patients who were treated original IFX since 2013. The second cohort included patients who were treated from the introduction of biosimilar IFX. Adverse events (AEs), demographic, clinical, endoscopic and laboratory data were collected on all patients. Efficacy was assessed according to response and remission at 14th, 54th week. For CU, response was defined as a decrease in partial Mayo score of 2 or more from baseline and a partial Mayo score of 1 or less was used to remission. For CD, response was defined as a decrease in Harvey-Bradshaw score of 3 or more from baseline, and a Harvey-Bradshaw score of 4 or less was used to remission. We used Student's t test for independent samples and Chi-square test. Time to withdrawal due to adverse effects was estimated using Kaplan-Meier survival analysis, and the log rank test was used to test for treatment group differences.

Results: The analysis included 346 consecutive IBD patients, 104 treated with original IFX and 242 with biosimilar IFX. 103 patients were diagnosed with CU, 238 with CD and 5 with indeterminate colitis. Overall median follow-up was 21 months. Baseline clinical activity scores were not significantly different among the 2 groups. Frequency of concomitant azathioprine and systemic steroids were not different among both groups. Patients in biosimilar infliximab group were more likely to experience previous biologic treatment failure (29.2% versus 20.2% in the original IFX, $p=0.0163$). There were no significant differences in patients achieving response and remission at weeks 14 and 54. There were no significant differences in rate of withdrawals among the 2 groups (37.1% versus 38.8% for biosimilar IFX, $p=0.811$). There were no significant differences in cumulative discontinuation rate due to AEs in original IFX and biosimilar IFX (42.42, (95% CI 39.49–45.34) months versus 44.61 (95% CI 42.66–46.56) months, log-rank test $p=0.292$).

Conclusion: Our clinical experience showed similar efficacy and safety profile of biosimilar IFX compared to original IFX.

Introduction: Acute severe Colitis (ASC) is a severe complication of inflammatory bowel disease (IBD), for which there is no consensus definition. Its diagnosis is based on clinico-biological and/or endoscopic criteria. Low endoscopy is essential for the positive diagnosis of ASC as well as for the diagnosis of IBD

Aims & Methods: The objective of this study is to describe the endoscopic aspect of ASC and its interest in therapeutic management in our series of 48 cases it is a prospective descriptive and analytical study of a series of 48 cases of acute severe colitis (ASC) collected during a period of 3 years (2014–2016) in the gastroenterology department.

Results: The average age of our patients is 39.8 years with extremes ranging from 14 to 65 years, a female predominance was found with a sex ratio, M/F of 0.77. The ASC was inaugural in 20 (41.66%), while 28 cases (58.33%) are known to have IBD, with 24 cases of UC (85.7%). Initial endoscopy was performed in all patients. The average time to perform endoscopy (from the onset of symptoms) was 37 days (2 to 75 days). Severe endoscopic aspects were present in 30 patients: deep ulcer (29 cases), spontaneous bleeding (4 cases), friability (4 cases). Other endoscopic lesions found were erythema (12 cases), erosions (5 cases), superficial ulcer (25 cases), pseudo polyps (14 cases), contact bleeding (27 cases). Biopsy was performed in all patients, histology was in favor of UC in 64.58% cases. CMV viral inclusions were found in 2.08% of cases. First-line medical treatment is based mainly on parenteral corticosteroid therapy, has been established in all patients. A second-line treatment with anti-TNF was introduced in 5 cases (10.41%) while surgical treatment was indicated in 15 cases (31.25%) of which 12 cases had severe endoscopic colitis. steroid refractory disease was associated with endoscopic severe colitis ($p=0.04$). In mono-varied analysis, endoscopic severe colitis was found in males more than females (53.6 vs 43.3) With a statistically significant difference $p=0.020$

Conclusion: Endoscopy in ASC occupies an important place to specify the morphological severity and thus make the positive diagnosis, the severe endoscopic colitis constitutes one of the predictive elements of steroid refractory disease requiring the use of a second therapeutic pallium.

Introduction: Response to biological drugs in ulcerative colitis (UC) is variable with induction response rates of 64.5% (vs 29.3% for placebo), 50.4% (vs 34.6% for placebo), 51.0% (vs 30.3% for placebo), 47.1% (vs 25.5% for placebo) for infliximab, adalimumab, golimumab and vedolizumab, respectively. Apart from prior exposure to anti-tumour necrosis factor (anti-TNF) agents and concurrent immunomodulatory therapy, predictors of clinical response and remission to biological drugs have not been identified. We sought to investigate the utility of baseline faecal calprotectin (FC) and early change in FC in predicting clinical response and remission to biological therapy in UC.

Aims & Methods: Patients who were commenced on any biological therapy for UC and had a baseline FC at the time of commencement were included in this retrospective study. Disease activity was monitored serially by calculation of Simple Clinical Colitis Activity Index (SCCAI) or by Physician global assessment (PGA) or by treatment persistence. Clinical response was defined as decrease in SCCAI ≥ 3 or a decrease in PGA score from baseline to follow up. The ability of FC and fold change in FC to predict response and remission at 6 months was estimated using Mann-Whitney test.

Results: A total of 94 patients were commenced on biological therapy of whom 70 commenced anti-TNF therapy and 24 commenced vedolizumab with a mean age of 41.8 (SD: +18.2). Fifty-one (72%) and 39 (55%) patients commencing anti-TNF therapy were on concurrent immunomodulators (IM) and steroids respectively compared to 9 (38%) and 16 (67%) patients respectively for vedolizumab. Sixteen (67%) patients treated with vedolizumab had prior exposure to anti-TNF agents compared to 4 (6%) in the anti-TNF treated group. The 6-month response among patients treated with vedolizumab and anti-TNF agents was 77.2% and 73.5% respectively. The calprotectin values were similar for responders (428.5 (72, 2100) [n=16]) and non-responders (600 (107, 2100) [n=5]) to vedolizumab ($P=0.56$). Similarly, responders (909 (13, 2100) [n=28]) and non-responders (850 (240, 2100) [n=13]) to anti-TNF agents had comparable calprotectin values at baseline, $P=0.93$.

Conclusion: In a single-centre series of biologic treated UC patients, baseline FC did not predict clinical response at 6 months.

Introduction: The prevalence of Crohn's disease is important for planning of health care and allocation of clinical resources. In 2005, a National Patient's Registry in Poland was established to collect demographic and clinical data. To quantify efficacy of medications in real-life treatment during the study period, data regarding medical treatment were collected from Registry.

Aims & Methods: The aim of the study was assess the efficacy and tolerance of different medications in reference to demographic data and disease location and behaviour. 6030 of patients have been enrolled to the Polish National CD Patient's Registry, conducted in 95 gastroenterology centers in Poland. Patient's phenotype according to: Montreal classification, demographics, smoking, alcohol consumption, extraintestinal manifestation and medical treatment have been evaluated. The impact of demographic factors on the use of drugs from different groups (mesalamine, prednisone, azathioprine, methotrexate, anti-TNF), and medications efficacy and tolerance was assessed. The efficacy assessment was evaluated according to subjective 4-step scale. Similarly treatment tolerance was assessed according to 2-step scale.

Results: No gender effects were observed on the use or efficacy of individual drug classes, although greater tolerability of prednisone and azathioprine was observed in men (respectively 95.56 vs 93.82 and 93.94 vs 91.65, both $p < 0.05$). Smoking did not affect the effectiveness and tolerability of the used medications. However surprisingly fewer smokers were treated with azathioprine, methotrexate, and anti-TNF in comparison to non-smokers (38 vs 45%, 0.5 vs 1.55%, 6.5 vs 11%, all $p < 0.05$). In patient's declaring casual alcohol use, the efficacy and tolerability of prednisone was significantly better than in patient's declaring abstinence (89 vs 84 and 96 vs 93%; $p < 0.05$). Referring to the Montreal classification, efficacy of mesalamine, prednisone and azathioprine was significantly higher in A1 group with the lowest in A2 patients (A1: 90, A2:83, A3: 86 for prednisone, $p < 0.05$). Regarding relation to localization of the disease, the efficacy of treatment with immunosuppressive agents (azathioprine and methotrexate) in L3 was significantly lower compared with L1 and L2, despite of increased use of immunosuppressive drugs in L1 (76 vs 82%, $p < 0.05$). As predicted, the use of immunosuppressive and anti-TNF drugs was higher in complicated disease behavior (B2 and B3) than in B1, however efficacy of infliximab was similar in B1 in comparison to others (B3: 15.5% B1: 7% of infliximab use).

Conclusion: This is the first study comparing efficacy and tolerability of treatment methods used in "real-life" practice in Poland during last 8 years. Most observations are in compliance with data from clinical trials. Positive effect of casual alcohol consumption on efficacy of medications requires further observation. Interestingly some unexpected relationships, concerning similar efficacy of infliximab in different disease behavior was found. This effect requires also further observations in regards to more frequent use of anti-TNF drugs in last years.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1719 EFFICACY OF VEDOLIZUMAB INDUCTION THERAPY IN PATIENTS WITH SEVERE, THERAPEUTIC RESISTANT INFLAMMATORY BOWEL DISEASE

Introduction: Vedolizumab (VDZ) is the first gut-specific monoclonal antibody alternative to anti-tumor necrosis factor alpha therapy in patients with moderate-to-severe inflammatory bowel disease (IBD). It has been registered since 2016 in Hungary, but currently the high treatment costs are considerably limiting the availability of VDZ. All newly initiated VDZ therapy is individualized, it should be approved by the steering committee of five Hungarian IBD-specialists. This results in that VDZ therapy is available exclusively for patients in whom conventional treatment was ineffective or contraindicated.

Aims & Methods: The aim of our non-interventional retrospective study was to assess the efficacy of induction VDZ therapy. 41 patients (16 with Crohn's disease (CD) and 25 with ulcerative colitis (UC) received VDZ induction therapy between September 2016 and April 2017 in Hungary. Efficacy of induction therapy was assessed based on the changes of activity indices on week 14.

Results: 40 of 41 enrolled IBD patients were therapeutic failure or intolerant for infliximab and/or adalimumab therapy. The mean age was 38.6 years (range 18–67; median 40) and the average disease duration was 11.7 years (range 1–36; median 10). In 16 cases moderate and in 25 cases severe disease activity was observed. Extra intestinal manifestations occurred in 6 patients, and in 6 cases the IBD was associated with primary sclerosing cholangitis (PSC). Rate of the therapeutic responders for VDZ induction therapy was 80.49% (N=33). Complete clinical remission was observed in 19 cases (46.34%) 8 cases (19.51%) of which were steroid-free remission. In one case VDZ therapy had to be interrupted due to development of IBD associated colorectal cancer and in one case due to MCV infection.

Conclusion: Our results suggest that induction VDZ therapy is effective and it is a safe therapeutic option in anti-tumor necrosis factor alpha failure or intolerant IBD patients with moderate or severe disease activity.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1720 OUTCOMES OF TREATMENT FOR LATENT TUBERCULOSIS INFECTION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE RECEIVING BIOLOGIC THERAPY

Introduction: Tuberculosis (TB) reactivation is of particular concern in patients with inflammatory bowel disease (IBD) treated with biologic therapies. Screening for latent tuberculosis infection (LTBI) is indicated prior to initiating treatment. Despite the reduction of TB reactivation following treatment for LTBI the risk of reactivation still exists. The efficacy of LTBI treatment in IBD patients receiving biologic therapy and the timing of biologic therapy initiation has not been extensively studied.

Aims & Methods: In order to evaluate the effectiveness of LTBI treatment in IBD patients receiving biologic, we conducted a retrospective review of all IBD patients diagnosed with LTBI following a tuberculin skin test (PPD) or interferon gamma release assay (IGRA) and who received biologic therapy between January 1996 and August 2016. Data extracted included patient demographics, TB risk factors, chest x-ray findings, biologic agent used, prior and concomitant therapies, and LTBI treatment regimen. TB reactivation after completion of LTBI treatment was the primary outcome of the study. Risk of TB reactivation was calculated using McGill University's "The Online TST/IGRA Interpreter."

Results: A total of 35 IBD patients (27 Crohn's; 8 ulcerative colitis) were included in the study. Their mean age was 38.3 ± 14.4 years and 68.6% were male (Table 1). The median time from diagnosis of IBD to LTBI was 9 years (0–48 years). Prior IBD therapies included corticosteroids (86%), aminosalicylates (83%), other immunosuppressants (69%). At least 43% of patients have been previously exposed to at least 1 biologic agent. The most common LTBI treatment regimen was isoniazid (INH) for 9 months (n=26, 74%). Biologic therapy used were infliximab (n=14, 40%), adalimumab (n=10, 29%), vedolizumab (n=7, 20%), and certolizumab pegol (n=4, 11%). Combination therapy with an immunomodulator and a biologic agent was administered in 57% of cases (n=20). All patients were treated for LTBI and the majority (83%) was treated prior to

starting biologic therapy. The median time from initiation of LTBI treatment to biologics was 43 days (4–3653). The mean duration of follow-up was 2.9 ± 3.3 years. The median calculated annual risk of developing active TB without treatment was 0.52% (0.08%–1.3%). Of the cohort studied, only one patient taking adalimumab monotherapy after completing 6 months of INH therapy developed reactivation of TB. The estimated TB reactivation rate in our cohort was 0.98 cases per 100 patient-years of follow up.

Table 1: Cohort Characteristics and Estimated Post-treatment Tuberculosis Reactivation Rate

Mean Age	38.3 (± 14.4) years
Male Sex	24/35 patients
Type of Inflammatory Bowel Disease (IBD)	Ulcerative Colitis (23%) Crohn's Disease (77%)
Mean Time since IBD Diagnosis	9 years (range: 0–48)
Type of Biologic Therapy	Infliximab (40%) Adalimumab (29%) Vedolizumab (20%) Certolizumab (11%)
Type Latent Tuberculosis Therapy	Isoniazid (INH) for 9-months (74%) INH for 6-months (11%) Rifampin 4-months (9%) INH + Rifampin for 3-months (3%) Others (3%)
Median time to initiate biologic therapy	43 days (range: 4–3653)
Mean duration of follow-up	2.9 ± 3.3 years
Mean Pre-treatment Risk of Development of Active Tuberculosis	0.52%/year (range: 0.08%–1.3%/year)
Estimated Post-treatment Tuberculosis Reactivation Rate	0.98 cases per 100 patient-years

Conclusion: Treatment for LTBI in patients with IBD treated with biologics is effective, but does not eliminate the risk of reactivation, which occurred at a rate of 0.98 cases per 100 patient-years in our cohort. Additional studies with extended follow-up are warranted to further characterize the efficacy of LTBI treatment in these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1721 CLINICAL CHARACTERISTICS AND MANAGEMENT OF CROHN'S DISEASE IN PATIENTS WITH RESIDUAL DISEASE AFTER SURGERY COMPARED WITH CURATIVE SURGERY. RESULTS FROM PRACTICROHN STUDY

Introduction: Resection in Crohn's disease (CD) intends to be a curative surgery, but sometimes it is not possible to remove completely the lesions of the damaged gut. The aim of our study was to describe the characteristics and management of patients with residual disease after surgery (RD) and to compare these with patients with curative surgery (CS) in post operative CD patients.

Aims & Methods: PRACTICROHN was a retrospective study that included adult patients from 26 Spanish hospitals who underwent CD-related ileocolonic resection with ileocolonic or ileorectal anastomosis between January 2007 and December 2010. Clinical data was retrospectively collected from clinical charts. RD was defined when lesions were still present after surgical resection. Postoperative recurrence (POR) was defined by clinical symptoms (diarrhea, abdominal pain) and endoscopic Rutgeerts score ≥ 2 , and/or CT or MRI confirmation of disease activity. Categorical variables were compared with the χ^2 test or Fisher's exact test Kaplan-Meier method was used to assess time to clinical recurrence and a log-rank test to obtain statistical significance.

Results: Three hundred and sixty-four patients were analyzed (mean age 40 years [SD 13], 50% men). Of these, 27 (7.5%) had RD after surgery. Median age at diagnosis was shorter in patients with RD than CS: 23 (IQR 19–34) years vs 29 (IQR 23–40), $p=0.02$. At the time of resection B1(+p) behavior was more frequent in RD than in CS: 6 (22%) vs 26 (8%), $p=0.05$; and location was mainly L1(\pm L4) in CS (190, 57%) and L3(\pm L4) in RD (19.70%), $p=0.02$. Four (16%) patients in RD were receiving immunomodulators at the time of surgery vs 132 (41%) of CS, $p=0.02$. More patients in RD vs CS presented postoperative complications (12 (44%) vs 87 (26%), $p=0.06$) as well as hospitalizations the first year after surgery (10 (37%) vs 42 (12%) $p=0.001$). No differences in

smoking habit, perianal disease or length of resection were found between the two groups. More patients were performed an endoscopy within the first year after surgery in the RD vs CS: 16 (59%) vs 122 (36%), $p=0.03$ but no difference in prophylactic treatment were found in RD vs CS groups. POR was more frequent among patients with RD (69% vs. 29%, $p=0.001$). Median time to POR was longer in patients who received prophylaxis vs those who didn't received it (698 vs 392 days; $p=0.4$). 81/275 (29%) in the CS presented POR with median time to POR being longer in patients who received prophylaxis (no median found vs 1529 days) $p=0.04$. Table 1.

Table 1

					CI 95%		
Residual disease patients		N	Events	Median time to POR	LL	UL	p-value
Prophylaxis	Yes	15	8	698	217	—	0.4
	No	8	8	392	287	—	
Curative surgery patients		N	Events	Median time to POR	CI 95%		p-value
					LL	UL	
Prophylaxis	Yes	187	48	—	—	—	0.04
	No	88	33	1529	839	—	

Conclusion: Residual disease is a rare situation after intestinal resection in CD. Patients with residual disease after surgery, are more likely followed-up endoscopically within the first year. Conversely, similar proactive recurrence prevention was observed compared to curative surgery. In the case of residual disease although prophylactic treatment is useful, most of the patients will present POR. RD is a factor of poor prognosis in post-operative CD patients.

P1722 SEVERITY OF BILE ACID MALABSORPTION CORRELATES WITH LENGTH OF ILEAL RESECTION IN CROHN'S DISEASE

T. Skouras¹, Y. Prasad², S. Dodd², S. Subramanian²

¹Gastroenterology, Royal Liverpool University Hospital, Liverpool/United Kingdom

²Royal Liverpool University Hospital, Liverpool/United Kingdom

Contact E-mail Address: Thomas.skouras@nhs.net

Introduction: Bile acid malabsorption (BAM) is a common cause of diarrhoea in Crohn's disease (CD) patients with ileal resection and can lead to complications such as renal and biliary stone disease. BAM is usually diagnosed by selenium labelled homotaurocholic acid test (⁷⁵SeHCAT) but its availability is limited. Thus, a large proportion of resected CD patients either remain underdiagnosed or subject to empirical therapy. There is a paucity of studies examining the correlation between length of ileal resection and severity of BAM which will be of particular use to clinicians with no recourse to diagnostic testing for BAM.

Aims & Methods: We identified all CD patients with a prior surgical resection who underwent ⁷⁵SeHCAT testing at our institute. Testing was based on the treating clinician's discretion. The length of resected ileum was recorded from histopathology report. We conducted a Spearman's correlation test to check for correlation between length of resected ileum and percentage retention on ⁷⁵SeHCAT. Response to treatment with bile salt sequestrant and ⁷⁵SeHCAT retention values was tested using Mann-Whitney test.

Results: A total of 97 patients were identified with a mean age of 46.4 (SD 14.5). The median length of resected ileum was 22.5 cms (range 1.5–95 cms) with a median of 1 resection (range 1–4). Overall, 90 patients (92.8%) had ⁷⁵SeHCAT retention values of <5%, 5 (5.2%) patients between 5–10% and only 2 patients had values of >15%. There was moderate correlation between ⁷⁵SeHCAT retention and length of ileal resection (Spearman's rho: 0.4041, $P < 0.001$). Data on response to treatment was available for 60 patients, of who 41 (42%) responded and 19 (19%) failed to respond to bile salt sequestrants. The ⁷⁵SeHCAT retention values was comparable among responders (median 0.02%, range 0.1–6.6) and non-responders (median 0.02%, range 0.1–6.6, Mann-Whitney test, $P=0.72$).

Conclusion: There was moderate correlation between length of ileal resection and severity of BAM as defined by ⁷⁵SeHCAT retention values. Response to bile salt sequestrant therapy was not dependent on ⁷⁵SeHCAT retention values.

OTHER LOWER GI DISORDERS III - HALL 7_

P1723 A MICROBIAL SIGNATURE OF PSYCHOLOGICAL DISTRESS IN IRRITABLE BOWEL SYNDROME

J. Peter, C. Fournier, L. Knoblich, B. Keip, G. Moser

Internal Medicine III Dept Gastroenterology And Hepatology, Medical University of Vienna, Vienna/Austria

Contact E-mail Address: gabriele.moser@meduniwien.ac.at**Introduction:** Irritable Bowel Syndrome (IBS) is associated with alterations along the brain-gut-microbiota axis. Previous studies have suggested a parallel segregation of microbial features with psychological burden in IBS (1,2,3).**Aims & Methods:** The study aimed at examining microbial correlates of psychological distress, anxiety, depression and stress perception. 16s rRNA faecal microbial analyses (Illumina MiSeq, V1-2 amplified from total DNA) in 48 IBS patients (Rome-III criteria, mean age 42 years, 35 female subjects, 25 diarrhoea-dominant, 5 constipation-dominant and 18 alternating-type IBS). Assessment of psychological and clinical variables with validated questionnaires, microbial analysis via QIIME. Machine learning to predict psychological distress through a composite model of bacterial features. Correlational analysis and comparisons in bacterial abundance between subgroups defined by thresholds in psychological variables.**Results:** Thirty-one patients (65%) showed psychological distress, 22 (31%) anxiety, and 10 depression (21%). Psychological distress was uncorrelated with IBS severity (Spearman's $\rho=0.05$, $p=0.736$). Microbial beta diversity was significantly associated with distress and depression $q=0.044$ each. A random forest model using 148 microbial estimators was able to correctly classify patients regarding presence of psychological distress (AUROC=0.98). Patients exceeding thresholds of distress, anxiety, depression and stress perception showed significantly higher abundances of *Proteobacteria* (LDA=2.5). Patients with anxiety were characterized by higher abundances of *Bacteroidaceae* (LDA=3.0). Depression correlated inversely with *Lachnospiraceae* ($\rho=-0.58$, $q=0.018$), anxiety positively with *Anaerotruncus* ($\rho=0.65$, $q=0.001$).**Conclusion:** A microbial signature accurately predicted the presence of psychological distress. Psychological variables significantly segregated gut microbial features, underscoring the role of brain-gut-microbiota interaction in IBS. Supported by Austrian Society of Gastroenterology and Hepatology (ÖGGH) and funds of the Österreichische Nationalbank. Fund project number: 16506**Disclosure of Interest:** All authors have declared no conflicts of interest.

P1724 SACCCHAROMYCES BOULARDII CNCM I-745 LOWERS FECAL CHOLIC ACID CONCENTRATIONS DURING ANTIBIOTHERAPY IN HEALTHY VOLUNTEERS: A NEW POTENTIAL MECHANISM IN THE PROTECTION AGAINST CLOSTRIDIUM DIFFICILE INFECTION

H. Duboc¹, C. Chong Nguyen¹, T. Kabbani², D. Rainteau¹, L. Humbert¹, S. Dowd³, L. Palmieri¹, B. Coffin¹, K. Pallav⁴, A. Bado¹, C. Kelly⁵¹Department of Hepato Gastro Enterology and University Paris Diderot, Sorbonne Paris Cité, INSERM UMR 1149, Louis Mourier Hospital, APHP, Colombes, France, Colombes/France²BIDMC & Harvard Medical School, Boston/United States of America/MA³Molecular Research, Shallowater, TX, USA, Shallowater/United States of America⁴Harvard School of Public Health, Boston, MA, USA, Boston/United States of America⁵Division of Gastroenterology, Department of Medicine, Beth Israel Deaconess Medical Center, Boston, MA, USA, Boston/United States of America**Contact E-mail Address:** henri.duboc@gmail.com**Introduction:** *Saccharomyces boulardii* (SB) CNCM I-745 demonstrated clinical efficacy in the secondary prevention of post-antibiotic *Clostridium difficile* infection (CDI), but the mechanism remains unclear. Cholic acid (CA) is a primary bile acid (BA), synthesized by the liver which triggers the germination of *C. difficile* spores in the intestine. Physiologically, the gut microbiota transforms primary BAs (cholic acid and chenodeoxycholic) into secondary (deoxycholic and lithocholic). CA loses its germinating properties after transformation and appears to become protective against CDI. The goals of this work in healthy volunteers (HV) were to: A) Describe the effect of antibiotics on the quantity of 'pro-germination' primary BA including CA in human stools B) Describe whether SB enhances transformation to 'protective' secondary BA in human.**Aims & Methods:** This work was an ancillary of a previous study conducted in 4 groups of HV at Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, Massachusetts. The previous results of this work showed that SB CNCM I-745 can modulate shifts in the microbiota and reduces diarrhea during an antibiotic therapy. Group 1 (n = 12) received SB CNCM I-745 500 mg twice

daily for 14 days. Group 2 (n = 12) received Amoxicillin-Clavulanate (AC) (875/125mg, twice daily) for 7 days. Group 3 (n = 12) received AC for 7 days and SB for 14 days. Group 4 (n = 12) did not receive any treatment. Groups 1, 2, 3 had successive stool samples at D-28, 0, 3, 7, 10, 13, 21. Group 4 had stool samples at D0, 7 and 21. The fecal concentrations of 28 BAs were measured by HPLC/MS, and expressed as % of total BA concentration.

Results: AC alone (group 2) significantly reduced the rate of fecal secondary BA at day 7 compared to control (group 4) (54.8 ± 10.1 vs $83.1 \pm 7.4\%$, $p=0.017$). In group 3 (AC plus SB), the decrease in secondary BA rate was significantly less than for AC (71.23 ± 7.4 versus $54.20 \pm 9\%$, $p=0.04$), and this difference was prolonged over time. Similarly, the AC + SB group showed a significantly lower (and sustained) increase in CA than in the AC alone group.**Conclusion:** Antibiotics alter the transformation of BA by microbial enzymes into the intestine. This increases primary BA while reducing secondary BA in feces. Cholic Acid rates, a primary BA which facilitates *C. difficile* spore germination in vitro, increases in stool during antibiotic therapy. The concomitant administration of SB during AC treatment significantly reduces this CA peak. These results highlight new human data on a potential mechanism for post-antibiotic CDI: alteration of the microbiota can encourage germination of *C. difficile* spores via increased CA concentrations and reduced concentrations of secondary BAs. The effectiveness of SB in preventing recurrent CDI may be explained, in part, through modulation of microbiota changes that influence the balance of pro- and anti-germination BA concentrations**Disclosure of Interest:** H. P1725 ASSOCIATION OF FUSOBACTERIUM NUCLEATUM IN ORAL CAVITY AND COLORECTAL CARCINOMAS

Y. Komiya¹, T. Higurashi², A. Nakajima²¹Gastrointestinal Medicine, Yokohama City University, Yokohama/Japan²Department Of Gastroenterology And Hepatology, Yokohama City University, Yokohama/Japan**Contact E-mail Address:** komiyacoco@yahoo.co.jp**Introduction:** While particular imbalances in the gut microbiota have been linked to colorectal adenomas and cancers, some specific bacterium have been identified as a related factor. Recent studies have reported a high abundance of *Fusobacterium nucleatum* (*F. nucleatum*) in colorectal cancer (CRC) subjects compared to normal subjects^{1,2}. *F. nucleatum* is also known as a pathogenic species of oral microbiota, but it is not known if *F. nucleatum* plays a role in other part of the digestive tract. *F. nucleatum* may affect metabolic pathways for the carcinogenesis³. We examined whether there is relationship between *F. nucleatum* oral cavity and CRC.**Aims & Methods:** We assessed the abundance of *Fusobacterium* in CRC, colorectal mucosa and saliva. We extracted DNA from mucosal biopsies and measured bacterial levels by quantitative PCR of the 16S ribosomal RNA gene. We also investigated the homology of *F. nucleatum* in oral cavity and CRC.**Results:** In 51 CRC cases, *Fusobacterium* positivity was significantly higher in CRC compared to controls ($p < 0.05$). *Fusobacterium* was more detected in CRC (12.9%) than in normal tissues (3.9%) respectively. The detection rate of *F. nucleatum* was 96% in saliva and 93% in CRC by next-generation sequencer. A total of 15 patients with CRC were included to check the homology of *F. nucleatum* in saliva and CRC. From the 15 patients, 9 were *F. nucleatum*-positive in CRC. 8 of 9 from these patients were *F. nucleatum*-positive in saliva. From these patients who were *F. nucleatum*-positive in saliva and CRC, we next looked for the results of AP-PCR and 6 patients have shown common band patterns.**Conclusion:** The results support a link between the abundance of *F. nucleatum* in oral cavity and CRC. Our data also indicate that there may be a route from the oral cavity to the CRC in *F. nucleatum* positive cases. We are now identifying DNA sequences, specific for the objective strains.**Disclosure of Interest:** All authors have declared no conflicts of interest.

P1727 HUMAN MILK OLIGOSACCHARIDES; A NEW STRATEGY AGAINST POST-ANTIBIOTIC CLOSTRIDIUM DIFFICILE INFECTION?

L. K. Vignsnaes

Business Development, Glycom A/S, Horsholm/Denmark

Contact E-mail Address: louse.vignsnaes@glycom.com

Introduction: Human Milk Oligosaccharides (HMOs) are a family of complex carbohydrates found in high concentrations in human milk and which are now becoming commercially available. In clinical studies, in both infants and adults, HMOs powerfully and specifically modulate the gut microbiota by increasing bifidobacteria and reducing certain pathogenic bacteria (1,2). Also, HMO bacterial consumption results in the production of beneficial metabolites such as short chain fatty acids and the lowering of pH. Hence, the selective growth of bifidobacteria on HMOs can create an ecological niche that is more colonization resistant against pathogens. Bifidobacteria may also have a direct impact on microbial toxins by reducing their level and cytotoxic effect (3). Antibiotics, especially broad spectrum antibiotics, dramatically impact the microbiota and its balance, and have been implicated in the pathogenesis of many health conditions including gastrointestinal symptoms such as diarrhoea (4). The most commonly cited mechanism for antibiotic-associated diarrhoea is intestinal overgrowth of the pathogenic bacterium, *Clostridium difficile*.

Aims & Methods: The aim of this study is to investigate, in *in vitro* models of *C. difficile* infection, (i) the impact of HMOs on the microbial community and activity (e.g. bacterial metabolites and pH), and (ii) the anti-pathogenic activity of HMOs against *C. difficile*, with a focus on preventing recurrence of the infection. Two *in vitro* models, each using human faecal microbiota infected with *C. difficile*, were used to examine the impact of HMOs on bacterial metabolite production and *C. difficile* infection. One model is a 48 hour batch fermentation while the other is a simulated gut model, run for 3 weeks post infection, which simulates the infection cycle of *C. difficile* after antibiotic treatment.

Results: The study revealed that the HMOs increase the level of bifidobacteria, increase the concentration of beneficial metabolites such as short chain fatty acids and decrease pH compared to a control with no added HMOs. Additionally, HMOs reduced the level of *C. difficile*; in some cases completely eradicating *C. difficile* below detection limits. This antimicrobial effect of HMOs on *C. difficile* was pH-independent, hence another mechanism is causing the anti-pathogenic activity of HMOs.

Conclusion: Conclusively, the results show that HMOs can impact *C. difficile* infection in an *in vitro* system, which suggests HMOs as a potential approach to reduce risk of antibiotic associated diarrhoea and post-antibiotic *C. difficile* infection.

Disclosure of Interest: L.K. Vignsnaes: I am a Glycom A/S employee working as Preclinical Development Manager in the Business Development department.

P1728 CHANGES IN GUT MICROBIOTA ASSOCIATED WITH AGING IN OBESE INDIVIDUALS

R. Tanaka¹, M. Matsuzaka¹, S. Nakaji², Y. Sasaki¹

¹Medical Informatics, Hirosaki University, Hirosaki/Japan

²Hirosaki University, Hirosaki/Japan

Contact E-mail Address: r-tana@hirosaki-u.ac.jp

Introduction: It has been reported that the composition of human gut microbiota changes with aging, body mass index (BMI), diet and other environmental factors. In particular, the relationship between gut microbiota and obesity has been underlined frequently because intervention in the microbiota may reduce body fat. In this study, we investigated the relationship between obesity and composition of gut microbiota in healthy Japanese population.

Aims & Methods: Participants were 1,082 healthy Japanese adults (410 males, 672 females) who participated in the Iwaki Health Promotion Project in 2014. Faecal samples were analysed by 16S rRNA gene-targeted sequencing to determine family composition of gut microbiota. They were classified into obese group (BMI ≥ 25) and normal weight group (BMI < 25) according to Japanese standard and were stratified into 7 age groups, 19–29, 30–39, 40–49, 50–59, 60–69, 70–79 and 80–90. The family composition of gut microbiota in each age group was compared between obese and normal group.

Results: There were 235 obese participants, and 847 normal ones. The proportion of Bacteroidaceae decreased substantially, and Ruminococcaceae increasing slightly with aging in obese group. The proportion of Bifidobacteriaceae, Lachnospiraceae and Porphyromonadaceae decreased gradually with aging in both groups.

Conclusion: Changes in composition of gut microbiota with aging were different between obese and normal group. Some previous researches observed differences of composition of gut microbiota between them, but many of the researches did not take aging into consideration. Our study indicated that different intervention stratified with age could be needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1729 BACTERIOCIN PRODUCTION BY MUCOSAL BACTERIA IN COLORECTAL NEOPLASIA

D. Kohoutova¹, M. Forstlova², P. Moravkova¹, S. Rejchrt¹, D. Smajs³, J. Bures¹

³Department Of Biology, Masaryk University, Faculty of Medicine, Brno/Czech Republic

Contact E-mail Address: darina.kohoutova@seznam.cz

Introduction: Due to its high incidence, sporadic colorectal cancer (CRC) remains a huge medical and socioeconomic burden in many countries worldwide including the Czech Republic. The exact contribution of large intestinal bacteria to the pathogenesis of CRC has not been elucidated yet, still the mucosal, not the luminal, microbiota seem to play the crucial role. Bacteriocins are small proteins, which are produced by the *Enterobacteriaceae* bacteria, especially by *Escherichia coli*. Bacteriocins are divided into more groups, colicins and microcins are the most important ones. Bacteriocins possess antibacterial, antineoplastic, proapoptotic and probiotic effect.

Aims & Methods: The aim of this prospective study was to evaluate bacteriocin production by mucosal large intestinal bacteria in colorectal neoplasia. We used an original methodology reported by our group (1). Mucosal biopsies were taken in the caecum, transverse colon and rectum within the colonoscopy in patients with non-advanced colorectal adenoma, non-a-A (11 men, 10 women, mean age 63 ± 10), advanced colorectal adenoma, a-A (which was defined as neoplasia larger than 10 mm and/or containing villous component and/or containing high grade dysplasia; 13 men, 7 women, mean age 65 ± 9), sporadic colorectal carcinoma, CRC (12 men, 10 women, mean age 70 ± 10) and in the controls (average risk population with normal findings on colonoscopy and with negative history of colorectal neoplasia and/or inflammatory bowel disease; 7 men, 13 women, mean age 57 ± 14). After appropriate microbiological culture bacteriocin production by each strain was investigated by PCR methods.

Results: A total of 249 mucosal biopsies were taken (60 controls, 63 non-a-A, 60 a-A, 66 CRC,) and samples were further investigated. Colicin producing strains were isolated in 22% (13/60) controls, 59% (37/63) non-a-A, 55% (33/60) a-A and in 76% (50/66) CRC. Significantly higher production of colicins was observed in non-a-A, a-A and CRC group when compared to controls, $p < 0.001$. Significantly higher production of colicins was confirmed in patients with CRC compared to patients with a-A, $p = 0.016$. Microcin producing strains were isolated in 23% (14/60) controls, 56% (35/63) non-a-A, 78% (47/60) a-A and in 62% (41/66) CRC. Significantly higher production of microcins was observed in non-a-A compared to controls, $p = 0.002$, in a-A and CRC group when compared to controls, $p < 0.001$. Microcins were produced more frequently in patients with a-A compared to those with non-a-A, $p = 0.008$.

Conclusion: Strains isolated from large bowel mucosa in patients with colorectal neoplasia produce bacteriocins more frequently compared to those with normal findings on colonoscopy. We presume, that mucosal large intestinal microbiota with their products including bacteriocins play an important role during the development of colorectal neoplasia.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The production of bacteriocins is considered as the key metabolic function of gut microbiota and as the inherent property of probiotic strains. Bacteriocins and metabolites of probiotic microorganisms (metabiotics) can optimize host-specific physiological functions related to human health.

Aims & Methods: This study aims to: (a) detect the bacteriocin genes of probiotic strains *Lactobacillus helveticus* D75 (NCBI Reference Sequence NZ_CP020029.1) and *Lactobacillus helveticus* D76 (NCBI Reference Sequence NZ_CP016827.1) and (b) evaluate *in vitro* effects of the carboxylic and amino acids mixture identical to the metabolites of the probiotic *Escherichia coli* strain M17 (components of Actoflor®-S dietary supplement). The antagonistic activity of *Lactobacillus helveticus* D75 and *Lactobacillus helveticus* D76 strains was estimated by the deferred antagonism method. The identification of bacteriocin genes was performed by PCR using *helveticin J* gene primers. Amplified fragments were sequenced using ABI PRISM® 310 Genetic Analyzer and were analyzed using NCBI/BLASTX.

Results: The identical sequences of 537 bp homologous to gene fragment of *helveticin* of *Lactobacillus helveticus* DPC 4571 (*lhv_1632* gene) were detected

in DNA of both probiotic strains. Sequencing of these fragments showed difference in three nucleotides compared to the reference DNA of DPC 4571 strain (A instead of G at position 46, C instead of T at position 249 and A instead of T at position 537), but all these replacements do not lead to changes in the amino acid sequence of a bacteriocin. For *Lactobacillus acidophilus* D76 another bacteriocin gene fragment of 283 bp was identified (in addition to 537 bp fragment). The latter had 95% homology with the helveticin J gene of *Lactobacillus helveticus* R0052 (R0052_09025 gene). In NCBI/BLASTX database the sequences homologous to the helveticin gene of *Lactobacillus helveticus* DPC 4571 were found in 11 microorganisms related to *Lactobacillus acidophilus*, *Lactobacillus amylovorus*, *Lactobacillus crispatus*, *Lactobacillus gallinarum*, *Lactobacillus helveticus* and *Lactobacillus kitasatonis*. The addition of the carboxylic and amino acids mixture (Actoflor®-S) results in 2-2.5-fold enhanced antimicrobial activity of both tested probiotic strains against test pathogens *Escherichia coli* O75 and *Salmonella Enteritidis* 209, most likely due to an increase in bacteriocin gene expression.

Conclusion: Study shows that there are at least two bacteriocins in *Lactobacillus helveticus* D76 and one bacteriocin in *Lactobacillus helveticus* D75. Carboxylic and amino acids mixture identical to the metabolites of the probiotic *Escherichia coli* strain M17 probably induces bacteriocin synthesis in probiotic strains *Lactobacillus helveticus* D75 and *Lactobacillus helveticus* D76 and enhances their antimicrobial activity against test pathogens *Escherichia coli* O75 and *Salmonella enteritidis* 209. However, the true potential of gut microbial metabolites mixture and identified probiotic bacteriocins for human health has yet to be realized.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Fecal microbiota transplantation (FMT) has been shown to be effective treatment for recurrent *Clostridium difficile* infection. Concern has been raised about the long-term safety of FMT.

Aims & Methods: The aim of this study was to determine the long-term safety of fecal microbiota transplantation (FMT), and its effect on gastrointestinal symptoms (GI) in *Clostridium difficile* (CDI) patients. We studied 84 patients of which 45 received an FMT treatment via colonoscopy and 39 served as controls receiving antibiotic treatment (AB) for the recurrent CDI and followed their recovery on average of 3.8 yrs. All together 130 patients (55 patients in the FMT group and 75 patients in the AB group) were sent a 45-item questionnaire collecting information about the patient demographics, their physical and mental health, including allergies, infections, gastroenterological conditions such as IBD and IBS, diabetes, autoimmune diseases, neurological disorders, mental wellbeing and malignancies. Response rate for the questionnaire was 64.6%.

Results: There were no differences in the incidence of severe diseases between the groups including the incidence of IBD, diabetes, diseases of the nervous system, autoimmune disease, incidence of colon polyps and cancer. Change of weight was neither different between groups (kg;SD): FMT + 2.5 (5.6) and AB + 1.3 (5.6), $p=0.51$. The AB treated subjects recorded more frequently that their bowel function had become worse and more irregular after the treatment (AB = 35.9%, FMT = 11.1%, $P=0.001$) compared to FMT group. 77.8% of the patients treated with FMT experienced GI symptoms related to IBS whereas 92.3% of antibiotic-treated patients recorded these symptoms ($P=0.06$). AB patients experienced more symptoms of the upper intestinal tract than the FMT-treated patients (AB = 51.3%, FMT = 31.1, $p=0.045$). In this cohort 97.6% of the FMT-treated patients and 60% of AB treated patients would prefer in the future that their initial treatment to be FMT instead of antibiotics.

Conclusion: FMT is a rational, durable, safe, and acceptable treatment option for patients with recurrent CDI. No severe diseases appeared after FMT and FMT seem to relieve GI symptoms better than antibiotic treatment. FMT and AB treated patients would prefer in the future that their initial treatment for recurrent CDI to be FMT instead of antibiotics.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: *Clostridium difficile*-associated disease (CDAD) is an infection caused by *Clostridium difficile*, gram-positive, anaerobic, spore-forming and toxin-producing bacteria. Infection is recognized as the leading cause of diarrhea associated with health care services in the developed countries. In Portugal epidemiological data are limited.

Aims & Methods: Characterize *Clostridium difficile*-associated disease episodes in a Portuguese Hospital Center. Retrospective analysis of 250 hospitalized patients with CDAD, in Centro Hospitalar do Algarve, between 2011 and 2015. The data was obtained from clinical processes and statistical analysis was performed with SPSS version 23.

Results: The patients were mostly women (52%). The mean incidence of CDAD was 0.21% and the patients had an associated mortality of 28%. The year with the highest incidence was 2015 (0.53%) but with a lower associated mortality rate. CDAD was mostly acquired at the hospital level (75.6%) and the mean length of hospital stay was 33 days. About 82.4% of the cases were first occurrences and the remaining (18.6%) were recurrences of CDAD. The majority of the population under study performed Proton Pump Inhibitors-IBP (52.8%) and antibiotic therapy (74.4%) (26.8% made a single antibiotic, and 23.6% 2 or more distinct antibiotics). Penicillin antibiotic class was the most used, followed by Cephalosporins (21.5%), Fluoroquinolones (11.4%) and Macrolides (10.1%).

Conclusion: A significant increase in the incidence of CDAD was observed in this study. This increase may be related to several factors, such as the improvement of laboratory diagnostic methods, increased antibiotic prescription, hospital contamination with *Clostridium difficile* spores or with the appearance of new and more virulent Ryotypes.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colonic diverticular bleeding is the most common cause of lower gastrointestinal bleeding. Persistent bleeding or acute massive bleeding of presenting with hemodynamic disorders requires an interventional treatment. The question of what is the best treatment for acute diverticular bleeding remains

unanswered. In our institution, we gastroenterologists perform interventional radiology for. Retrospective study of transarterial embolization (TAE) for colonic diverticular bleeding was performed.

Aims & Methods: The aim of this study is to clarify the efficacy of TAE for colonic diverticular bleeding. 229 patients were diagnosed as diverticular bleeding from Jan 2010 to Dec 2016 in our institution. Bleeding stopped spontaneously in 126 patients. 103 patients were performed colonoscopy. Overt bleeding occurred in 8 patients after colonoscopy, and those were eligible for this study who underwent TAE. Conservative management or endoscopic procedure were not successful in all the patients. 7 patients were male and 1 was female with a median age of 62.6 years (range 39–85 years). The average opportunity for enhanced CT was 2.1, 7 patients were in shock, and all of 8 the patients were treated with blood transfusion. Those who were extravasation-positive in enhanced CT underwent angiogram from vasa recta near the extravasation at least 3 times. In case radiopaque clips were placed at the bleeding site via colonoscopy to mark embolization site, regardless of whether or not active extravasation was identified on angiogram, coil embolization was performed using 0.010inch coils in vasa recta. Technical success rate and complications were evaluated. Technical success was defined as immediate complete cessation of bleeding confirmed by digital subtraction angiography showing no further contrast extravasation at the end of each TAE. Clinical success was defined as no recurrent bleeding in observation period.

Results: Technical success rate was 88%(7/8), and clinical success was also 88%(7/8). 6 patients were extravasation-positive in enhanced CT, and 5 patients were extravasation-positive in angiogram. Although 3 patients were extravasation-negative in angiogram, 2 patients underwent TAE. After TAE, no recurrence of bleeding was observed. Severe adverse events such as bowel infraction did not occur in all cases.

Conclusion: As the microcatheter technique has recently improved further, adverse events are rare. Therefore superselective coil embolization could be first choice for diverticular bleeding with extravasation-positive in enhanced CT.

PI734 ACCURACY OF THE NASOGASTRIC TUBE AND THE BUN/CREATININE RATIO FOR DISTINGUISHING BETWEEN UPPER AND LOWER SOURCES OF GASTROINTESTINAL BLEEDING. A SYSTEMATIC REVIEW

S. Machlab, E. Martinez-Bauer, P. Garcia-Iglesias, A. Lira, C. Marmol, G. Llibre, J.P. Da Costa, M. Gallach, L. Melcarne, V. Puig-Divi, F. Junquera, R. Campo, E. Brullet, X. Calvet
Gastroenterology, Hospital Universitari Parc Tauli, Sabadell/Spain

Contact E-mail Address: stmachlab@tauli.cat

Introduction: The insertion of a nasogastric tube (NGT) and assessment of the BUN/creatinine ratio were recommended as initial measures to distinguish between upper and lower gastrointestinal bleeding (American College of Gastroenterology 2016). As the nasogastric tube is one of the most bothersome interventions for the patient, we evaluated the evidence supporting these recommendations.

Aims & Methods: The aim of the study was to identify the diagnostic accuracy (sensitivity, specificity, positive predictive value, negative predictive value and likelihood ratios) of the NGT and the BUN/creatinine ratio for distinguishing between upper and lower sources of gastrointestinal (GI) bleeding. We conducted a systematic review of the literature in order to identify studies assessing the diagnostic accuracy of the NGT or BUN/creatinine in patients with melena, hematochezia or rectorrhagia without hematemesis. The search was performed in November 2016 in five data bases (Pubmed, Scopus, Web of Science, Cochrane Plus Library and OpenGrey).

Results: Four studies met the selection criteria (two evaluating the NGT, one BUN/creat and one both). The two methods had a low sensitivity for detecting upper GI bleeding source. Both a positive NGT aspiration and BUN/creatinine ratio above 30 markedly increased the probability of an upper GI source with a positive likelihood ratio ranging from 2 to 11. Unfortunately, the sensitivity of both tests for upper GI bleeding was very low (negative likelihood ratios around 0.6). Characteristics and results of the studies selected are shown in table 1.

Conclusion: For patients with gastrointestinal bleeding without hematemesis, BUN/Creat ≥ 30 indicates a high probability of an upper GI source. Nasogastric tube aspiration provides little additional information and so is not indicated. Neither test reliably rules out an upper GI source of bleeding.

Abstract No: PI734

Table 1: Characteristics and results of the studies

Estudy (year)	Design/Period	Sample size/Testee	Sensitivity (%)	Specificity (%)	Predictive positive value (%)	Predictive negative value (%)	Negative Likelihood ratio	Positive Likelihood ratio
Richards 1990	Retrospective 1981–1990	126 BUN/creat (Cut off ≥ 36)	37	100	100	53	0.63	+++++
Aljebreen 2004	Retrospective 1999–2001	520 NGT	68	54	41	78	0.61	1.44
Witting 2006	Retrospective 1997–2002	325 BUN/creat (Cut off ≥ 30) NGT	39 42	94 91	81 81	70 61	0.65 0.56	6.4 11.1
Kessel 2016	Retrospective 2011–2014	386 NGT	28	86	99	2	0.84	2

Therefore, in cases of uncertainty, an upper GI endoscopy will be necessary to reliably rule out an upper GI source.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI735 GLASGOW-BLACHFORD SCORE ACCURATELY PREDICTS THE NEED OF TRANSFUSION IN ACUTE LOWER GASTROINTESTINAL BLEEDING. A DIAGNOSTIC ACCURACY EVALUATION STUDY

S. Machlab¹, E. Martinez-Bauer², P. Garcia-Iglesias¹, A. Lira¹, C. Marmol¹, G. Llibre¹, J.P. Da Costa¹, M. Gallach¹, L. Melcarne¹, V. Puig-Divi¹, F. Junquera², R. Campo¹, X. Calvet¹, E. Brullet¹

Introduction: The incidence of acute lower gastrointestinal bleeding (LGB) is increasing in Western countries, but the predictors of its outcome are not well studied and defined.

Aims & Methods: The aim of this study was to compare the accuracy of Glasgow-Blachford score (GBS) with three available risk scores (State, Velayos and Newman) for predicting the need of any clinical intervention (endoscopic therapy, vascular embolization, surgery and need of transfusion) in patients admitted for acute LGB. Retrospective study from January 2013 to December 2015 in a university tertiary care hospital. Patients with acute LGB were identified using the International Classification of Diseases (9th Revision) and Clinical Modification codes for admission diagnosis. Scores were retrospectively calculated according to clinical reports data. Area under the receiver operating characteristic curve (AUROC), sensitivity, specificity, positive and negative predictive values were calculated for four scores. Also the best cut-off of each score was chosen from using the AUROC curve values.

Results: A total of 298 (51% men) consecutive patients with acute LGB were identified. Median age was 76.1 years (range 25.4–96.5), 201 (67.4%) of patients were older than 70 years. Five patients (1.7%) died, 18 (6%) developed recurrent bleeding, 89 (29.9%) needed transfusion, 30 (12.1%) received endoscopic therapy, and 3 (1%) underwent transcatheter arterial embolization. No patient required any surgical intervention. AUROC of GBS score was 0.87 (95%CI:0.82–0.91) for the need of transfusion, and 0.82 (95%CI:0.76–0.87) for the need of any clinical intervention. AUROC for the need of transfusion and clinical intervention were 0.68 (95%CI:0.61–0.74) and 0.67 (95%CI:0.60–0.73) for the Strate score, 0.77 (95%CI:0.71–0.83) and 0.74 (95%CI:0.68–0.80) for the Velayos score and 0.78 (95%CI:0.72–0.85) and 0.74 (95%CI:0.68–0.81) for the Newman score, respectively. GBS was significantly more accurate than LGB risk scores for predicting the need of transfusion. Although AUROC of GBS was also numerically better for predicting the need of any clinical intervention, the difference was only significant when comparing with the Strate score. All the risk scores were more accurate for determining the need for transfusion than for the need of clinical intervention. Sensitivity, specificity and negative and positive predictive values for each score are shown in table 1.

Table 1: Sensitivity (S), specificity (Sp), Positive (PPV) and negative (NPV) predictive values of the different scores for detecting the need of transfusion (TRF) or clinical intervention (CI). *Best cut-off scores for Blachford score were 6 for transfusion and 4 for clinical intervention. Values are expressed as%.

Score	TRF	S TRF	Sp TRF	PPV TRF	NPV TRF	CI	S CI	Sp CI	PPV CI	NPV CI
Blachford*	80	78	61	90	89	59	50	91		
Strate > 1	69	58	41	81	66	58	86	78		
Velayos > 0	95	46	41	96	90	46	44	90		
Newman > 1	92	40	39	93	89	40	32	88		

Conclusion: The GBS was superior to the 3 LGB risk scores for predicting the need for transfusion and clinical intervention. The GBS may be an useful tool for risk stratification in acute LGB.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute lower gastrointestinal bleeding (ALGIB) occurs in patients taking anticoagulants either warfarin or non Vitamin K oral anticoagulants (NOACs). The use of NOACs has been increasing compared with warfarin in recent years. We investigated patients with ALGIB on anticoagulation therapy and we analyzed characteristics, management and clinical outcome in patients treated with NOACs versus warfarin.

Aims & Methods: All patients with ALGIB on anticoagulation therapy treated in our hospital during a seven year period were evaluated. Characteristics and clinical outcome were compared between patients on warfarin and patients on NOACs.

Results: Out of 587 patients with ALGIB, 43 (7.3%) were on NOACs and 68 (11.6%) on warfarin with an age 75.9 ± 9.5 vs 77.1 ± 7.9 . The bleeding site was in the small bowel in 2/43 and 6/68 respectively. Causes of bleeding were not different between two groups except for polyps/neoplasia (8/43 vs 6/68, $p=0.003$). Endoscopic hemostasis was more commonly needed in patients on NOACs 17/43 vs 14/68 ($p=0.049$), while they required less hospitalisation days (6.1 ± 4.2 vs 4.5 ± 3.6 , $p=0.04$). Blood transfusions and need for other interventions (embolization and/or surgery) were not different. Also recurrence of bleeding (4/43 vs 11/68) and mortality (3/43 vs 0/68) were low and not statistically different between the two groups.

Conclusion: ALGIB in patients on NOACs although presents some differences it has a similar clinical outcome to patients with ALGIB on warfarin.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1737 NOBLADS - THE NEW RISK SCORE TO PREDICT THE SEVERITY OF ACUTE LOWER GASTROINTESTINAL BLEEDING

M. Patita, G. Nunes, R. Barosa, L. Ramos, C. Fonseca

Gastroenterology, Hospital Garcia de Orta, Almada/Portugal

Contact E-mail Address: martapatita21@gmail.com

Aims & Methods: We aimed to evaluate the accuracy of the NOBLADS score to predict severe LGIB and the outcome of patients admitted by LGIB. We performed a retrospective, observational and unicentric study. Including patients admitted for acute LGIB and submitted to endoscopic evaluation between January/2015 and March/2016. LGIB was classified as severe if ≥ 2 units of erythrocyte concentrate (UCE) were required and/or if hematocrit drop

$> 20\%$. Total score ranges from 0–8; when total score is ≥ 2 , it is considered high risk for severe LGIB.

Introduction: A new risk score for acute lower gastrointestinal bleeding (LGIB) has recently been validated, based on 8 admission criteria—nonsteroidal anti-inflammatory drugs use, absence of diarrhea, absence of abdominal tenderness, systolic blood pressure ≤ 100 mmHg, antiplatelet drugs use, albumin level < 3 g/dL, disease score ≥ 2 (Charlson comorbidity index) and syncope (NOBLADS).

Results: 173 patients were included (male: 50.3%, mean age: 69 ± 17 years), with LGIB manifested by hematochezia (91.9%) or melena. Endoscopic evaluation was performed 1.7 ± 2 days after admission, with the most frequent findings being diverticular hemorrhage ($n=53$) and ischemic colitis ($n=29$); no lesions were found in 8.3% of cases. Thirty-three patients required intervention (endoscopic $n=27$, radiological $n=2$, surgical $n=4$) and 36 (20.8%) repeated endoscopic evaluation. 28.9% of patients presented severe LGIB and the NOBLADS score determined the severity of LGIB with an area under the curve value of 0.92 ± 0.018 . Overall, higher score values were associated with a requirement for transfusion support, intervention and longer hospitalization ($p < 0.001$ for trend test). Patients at high risk for severe LGIB (score ≥ 2 , $n=39$) presented a significantly higher number of transfused UCEs (3.6 vs 0.08 , $p < 0.001$), intervention (38% vs 13%, $p < 0.001$) and days of hospitalization (12.8 vs 3 days, $p < 0.001$).

Conclusion: The NOBLADS score is simple and quick to apply. It predicts with high accuracy the risk of severe LGIB and allows to identify patients that are more likely to require transfusional support, intervention and prolonged hospitalization. In clinical practice, NOBLADS score may be useful to select on admission patients who will benefit from hospitalization or from earlier intervention.

Disclosure of Interest: All authors have declared no conflicts of interest.

¹Fukuyama City Hospital, Fukuyama/Japan

²Okayama University Hospital, Okayama/Japan

Contact E-mail Address: sayo44@hotmail.co.jp

Introduction: The management of antithrombotic agents during the peri-endoscopic period concerns the risks of bleeding and thromboembolism. The Japan Gastrointestinal Endoscopy Society (JGES) guidelines revised in 2012 emphasizes the risk of thromboembolism rather than bleeding. So heparin bridge of anticoagulants is recommended at high-bleeding-risk procedure such as endoscopic mucosal resection (EMR). However heparin bridge in colorectal EMR raises the bleeding rate to approximately 20%, that is very high-rate incident compared with the bleeding rate of 0.3–6.1% generally. It is doubtful whether heparin bridge is appropriate.

Aims & Methods: The aim of this study to clarify the safeness of colorectal EMR under taking anticoagulants without a heparin bridge in anticoagulated patients. This is a prospective intervention study in our hospital and other nine multi-centers (UMIN000021416). The subjects are colorectal polyps resectable by EMR. Inclusion criteria of patient is good performance status (ECOG) 0–1, without severe organ failure. Warfarin is continued as usual if PT-INR is less than 2.6, and direct oral anticoagulants (DOAC) is continued until an evening of the day before and is discontinued only on the day. Primary endpoint is post-EMR bleeding required any interventions (major bleeding). Major bleeding is defined as active bleeding or adherent clot on the resection site by emergent colonoscopy, or conservative treatment required blood transfusion. Conservative bleeding with no intervention (minor bleeding), thromboembolism, and comparison between warfarin and DOAC are clarified as secondary endpoint. The procedure-related period is defined as up to 30 days after EMR or is finished for two weeks after hemostasis.

Results: 41 patients (154 lesions) were performed EMR from February 2015 to March 2017. Patients' characteristics were as follow, the median age was 74 years (range 61–88) and the average of polyp size was 11.6 (range 5–22) mm in diameter. Anticoagulants were divided into 19 cases of warfarin and 22 cases of DOAC. The incidence of major bleeding was none in all cases. On the other hand, minor bleeding which did not require any intervention was recognized at 14.6% (6/41), but there was no case to interrupt anticoagulants. The rate of minor bleeding is no difference between warfarin and DOAC. There was no correlation between minor bleeding and PT-INR value in three cases of warfarin. All three cases of DOAC were medicine once a day. Thromboembolism was not observed.

Conclusion: In colorectal EMR, we clarify the safeness with continuation of warfarin and short discontinuation of DOAC on that day, compared with heparin bridge. We expect to lead to reconsideration of current guideline for safer treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1740 RISK OF COLORECTAL CANCER IN ASYMPTOMATIC INDIVIDUALS WHOSE FIRST DEGREE RELATIVES WERE AFFECTED BY CRC AT DIFFERENT AGES OF ONSET: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 9.28 MILLION SUBJECTS

J.L. L. Huang, M. C. Wong, C. Chan, J. Lin, W. W. Cheung, M. Liang, Y. Fang, C. Yu, D. Fung
Chinese University of Hong Kong, Hong Kong/Hong Kong Prc

Contact E-mail Address: martin_wong@cuhk.edu.hk

Introduction: The current literature is mixed regarding whether first-degree relatives (FDRs) of patients who suffered from colorectal cancer (CRC) at much earlier age are at substantially increased risk of CRC.

Aims & Methods: The present systematic review and meta-analysis examined the CRC risk conferred by family history of CRC in FDRs according to their age of onset. We searched Ovid Medline, EMBASE and grey literature from their inception to December 2016, and included all screening studies that investigated the relationship between family history of CRC in FDR and incidence/prevalence of CRC. Two reviewers independently worked on selection, assessment and data extraction of eligible articles. A random effects meta-analysis was employed to pool relative risks (RR) and odds ratios. Subgroup analyses were performed according to the age of onset of CRC in FDRs of asymptomatic subjects (<40 vs. ≥40; <50 vs. ≥50; <60 vs. ≥60 years). Statistical heterogeneity was assessed by the I² statistics. Publication bias was evaluated by an inverted funnel plot analysis with Begg's regression model.

Results: Fifty-six case-control and seven cohort studies involving 9.28 million subjects were included in the analysis. A family history of CRC in FDRs of asymptomatic subjects conferred a significantly higher risk of CRC (RR=1.76, 95% CI=1.57–1.97; p<.001, I²=95.7%). Earlier age of onset of CRC in FDRs was associated with significantly higher risk of CRC in index subjects (RR=3.29, 95% C.I. 1.67–6.49 for <40 years vs. RR=1.42, 95% C.I. 1.24–1.62 for ≥40 years, p=0.017; RR=2.81, 95% C.I. 1.94–4.07 for <50 years vs. RR=1.47, 95% C.I. 1.28–1.69 for ≥50 years, p=0.001). The Begg's regression test did not identify any publication bias (Kendall's tau=0.122, p=0.159).

Conclusion: A family history of CRC in FDRs whose age of onset is earlier than 40 or 50 years conferred a significantly higher risk of CRC to asymptomatic individuals, implying that age of onset could potentially enhance the discriminatory capability of CRC prediction scores.

P1741 IS THERE ANY DIFFERENCE IN RISK OF COLORECTAL CANCER AMONG ASYMPTOMATIC SUBJECTS WHOSE SIBLINGS VS. PARENTS WERE AFFECTED? A SYSTEMATIC REVIEW AND META-ANALYSIS

J.L. L. Huang, M. C. Wong, C. Chan, J. Lin, W. W. Cheung, M. Liang, Y. Fang, D. Fung, C. Yu
Chinese University of Hong Kong, Hong Kong/Hong Kong Prc

Contact E-mail Address: martin_wong@cuhk.edu.hk

Introduction: Few studies compared the risk of colorectal cancer (CRC) among individuals with probands who were parents, siblings, and those with two or more probands.

Aims & Methods: This systematic review and meta-analysis tested the hypothesis that the risk of CRC conferred by family history of CRC in parents vs. siblings vs. ≥2 first-degree relatives (FDRs) was similar. The Ovid Medline, EMBASE and grey literature were searched from their inception to December 2016, and all screening studies that examined the association between detection of CRC and family history of CRC in FDR were included. Two reviewers independently searched, assessed and extracted data from eligible studies. The relative risks (RR) and odds ratios were pooled based on a random effects meta-analysis. We conducted subgroup analyses according to the identity of FDRs affected (parents vs. siblings vs. ≥2 FDRs), and examined statistical heterogeneity by the I² statistics. Potential publication bias was explored by funnel plot analysis with Begg's regression test.

Results: We identified 56 case-control and 7 cohort studies, consisting of 9.28 million subjects who were finally included in the meta-analysis. Asymptomatic individuals with siblings affected (RR=2.44, 95% CI=1.90–3.13); parents affected (RR=2.18, 95% CI=1.95–2.45) and ≥2 FDRs affected (RR=2.68, 95% CI=1.92–3.74) had statistically similar risk of CRC. We did not identify any publication bias based on the Begg's regression test (p=0.159).

Conclusion: The risk of CRC was similar among subjects whose siblings; parents or ≥2 FDRs were affected by CRC. Information on the identity of the FDRs

affected does not seem to be necessary when the risk of CRC in asymptomatic individuals is predicted.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1742 GILBERT SYNDROME IS NOT THAT INNOCENT!

N. Arber¹, M. Menachem¹, L. Ari², G. Lior¹, B. Ezra¹, H. Gil¹, H.G. Amira¹, J. Maayan¹, S. Shapira¹

Contact E-mail Address: nadira@tlvmc.gov.il

Introduction: Gilbert's syndrome is considered to be entirely benign. Some studies have shown a reduced risk for cardiovascular disease (CVD). There is conflicting data regarding cancer risk among these patients

Aims & Methods: We aimed to evaluate the association of Gilbert syndrome with CVD and cancer. Clinical and epidemiological data was obtained from consecutive healthy subjects undergoing annual screening at the Integrated Cancer Prevention Center in Tel Aviv. The annual check-up includes: thorough examination by specialists in internal medicine, surgery, dermatology/plastic surgery, OBGYN, urology, oncology, oral surgery, gastroenterology. Blood work (smac 24, blood count, TSH, CRP, PSA), vaginal US, PSA and mammography (>40yrs), LDCT in heavy smokers and all needed imaging when clinically indicated. Peripheral blood DNA was extracted from all subjects. Gilbert syndrome was determined by clinical criteria (normal liver function tests but to mild elevation in unconjugated bilirubin <3 mg/dl without any hemolysis). In the majority of the cases the diagnosis was confirmed genetically by the homozygous mutation (TA)7TAA in the promoter region of UGT1A1 enzyme. Prevalence of CVD and cancer were compared between subjects with/without Gilbert syndrome. Mortality data was obtained from the Israeli ministry of health and cancer incidence from the Israeli registry.

Results: A total of 6258 (49%) men and 6461 (51%) women, mean age 47.0±11.5 years, were included of which 1,019 had clinical gilbert. Gilbert was significantly more common among men (11.5% versus 4.6% P<0.001). The rate of gilbert disease was equal in Sephardic and Ashkenazi Jews. Malignancy and CVD were diagnosed in 678 (5.3%) and 1,837 (14.4%) subjects respectively. The prevalence of any CVD was significantly higher in the Gilbert group (OR 1.23 95% CI 1.04–1.46 p=0.017), as well as hypertension (OR 1.37 95% CI 1.12–1.68 p=0.003) and CVA (1.1% versus 0.6% p=0.06). Higher rate of kidney and bladder cancers (OR 2.64, 1.22–5.70, p=0.019) was also observed in the gilbert group. In contrast, the prevalence of breast cancer was much lower among patients with Gilberts (OR 0.36, 0.13–0.97, P=0.034).

Conclusion: In Israel Gilbert syndrome is not that innocent. In a large cohort it seems to be associated with increased risk of hypertension, CVD and CVA. Bladder cancer is higher but females are protected from breast cancer. Further studies are mandated in order to better understand these findings and determine proper screening and surveillance practices in Gilbert disease.

P1743 CHARACTERISTICS AND PREDICTORS OF INTERVAL CANCER: A CASE-CONTROL STUDY

I. Laish¹, J. Mizrahi², F. Konikoff¹

¹Meir Medical Center, Kfar Saba/Israel

²Stony Brook University Hospital, New York/United States of America

Contact E-mail Address: ido.laish@gmail.com

Introduction: Interval colorectal cancer is largely related to a poor endoscopic performance (missed lesions, incomplete polyp resection) or different biology in the development of the polyp (accelerated growth). Thus, quality endoscopic measures and Lynch syndrome were highly investigated for their association with interval cancer. However, most reports came from the Western world and not the Middle East, and differences in ethnicity or environmental factors might potentially have impact on the biology of tumor progression. In addition, patient-related factors were less investigated for their association with interval cancer. The aim of this study was thus to assess tumor and patient characteristics and predictors of interval cancer in a population from Israel.

Aims & Methods: This retrospective cohort study included all patients that were diagnosed with colon cancer in our institution between 2005–2014. Cases included patients with a previous colonoscopy within 1–10 years before the diagnosis of cancer, with either negative findings or benign polyps. Only full colonoscopies with at fair or good preparation were included. Interval cancer was defined on an individual basis, when cancer occurred within the recommended surveillance interval according to accepted guidelines. Cases were further stratified according to time since index colonoscopy (<3 years, 3–10 years). "Positive" controls were cancer patients without previous colonoscopy, and "negative" controls were sex- and age-matched patients with two negative colonoscopies within the study period who were randomly selected on a 5:1 ratio. Tumor characteristics (location, staging) and patient-related features (age, gender, positive family history of colon cancer, aspirin use, diabetes, diverticulosis) were compared between cases and control groups.

Results: 845 patients were diagnosed with a colon cancer within the study period, and 83 cases (9.8%) were found to have interval cancer. Among them, 51 patients (61.5%) had negative findings at index colonoscopy, while 22 (38.5%) had either non-advanced adenomas (12%) or advanced adenoma (26.5%). Compared to "positive" controls with primary cancer (575 patients with full data), patients with interval cancer were older (84% above 60y vs. 65%, $p=0.03$) and had proximal (cecal to splenic flexure) tumor location (57% vs. 34%, $p=0.0001$), but gender (47% vs. 53% males) and tumor staging (78% vs. 70% in stage 0–2, $p=0.12$) were not different. Compared to "negative" healthy controls (255 patients), cases with interval cancer and negative findings at index colonoscopy (51 patients) had higher prevalence of diabetes (33% vs. 15%, $p=0.002$) but the same rate of family history, aspirin use and diverticulosis. There were no significant differences in all these characteristics between patients with interval cancer <3 years and 3–10 years.

Conclusion: Patients with interval cancer tend to be older and have proximal tumor location than patients with primary colon cancer, and have higher prevalence of diabetes. A close surveillance or the use of better endoscopic techniques (e.g. use of NBI, longer retrieval time) should be considered for patients with these characteristics.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1744 THE RELATIONSHIP BETWEEN QUANTITATIVE FIT RESULTS AND NEOPLASTIC FINDINGS

J.S. Mcgrath, M. Borgaonkar, D. Pace, S. Antle, S. Stone, E. Randell, J. Quinlan
Dept. Of Gastroenterology, Memorial University, St. John's/Canada

Introduction: Fecal Immunochemical Testing (FIT) is currently used in most Canadian provinces to screen for colorectal cancer. Newfoundland and Labrador has implemented a provincial population based colon cancer screening program over the past five years. Newfoundland and Labrador selects patients for colonoscopy if one of two FIT values ≥ 100 ng/mL.

Aims & Methods: The goal of this study is to assess the effectiveness of different FIT cut-offs and number of FIT tests for detecting adenomas and colorectal cancer.

Results: Data for this study were obtained in a prospective fashion using the Newfoundland and Labrador Colon Cancer Screening Program. 21,371 patients enrolled in the study were between the ages of 50–74 and at average risk for colon cancer between July 1, 2012 and June 30, 2016. 16,152 participants returned their FIT tests. 1831 were positive on at least one FIT kit and underwent colonoscopy. The positive FIT values ranged from 100.0 to 54,017. The mean FIT was 942.3 (25th percentile: 145, 50th percentile: 260, 75th percentile: 576). Of the 1831 participants who had a colonoscopy 73 (4.0%) were found to have colorectal cancer and 1092 (59.6%) were found to have an adenoma. By using only one FIT test at a cut off of 100, our program would have missed 8.2% of cancers. An additional 541 colonoscopies were required to detect these cancers. If we stratified patients according to number of FIT tests we found that 83.5% of colon cancers detected were positive on both FIT kits at a quantitative cut off of 100. If a FIT cut off of 200 was used and applied to our patients our program would have missed 9.6% of cancers based on one of two tests being positive, 24.7% of cancers is only one FIT kit were supplied to patients and 38.4% of cancers based on both FIT kits being positive. An additional 1133 colonoscopies were required to detect the additional cancers by using two FIT kits as opposed to one. There was a substantial decline in detection of cancer, advanced adenoma and simple adenoma as FIT cut off was increased and with a reduction in FIT kits completed from two to one. The positive predictive value for cancer increased as the quantitative FIT cutoff was increased but this came at the expense of case detected.

Conclusion: Two FIT tests are more effective than one at screening. Patients with two FIT positive results are more likely to have: colon cancer, an advanced adenoma and a simple adenoma. Further triaging of colonoscopy wait lists could be considered based on quantitative FIT values and number of positive tests. Provinces and health authorities need to be cautious when determining the number of FIT kits a participant should complete as well as setting the quantitative cut off. Increasing the FIT cut-off results in a higher probability of colon cancer or adenoma but there are overall less cancers detected.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1745 METABOLIC RISK FACTORS AND THEIR IMPACT IN COLORECTAL CANCER SCREENING: MULTICENTER PROSPECTIVE STUDY

Introduction: Screening of colorectal cancer is focused on the population with average risk of this disease. Individuals with metabolic syndrome represent a population with a higher risk of developing colorectal cancer, but they are not included in colorectal cancer screening standards.

Aims & Methods: To identify the metabolic risk factors associated with colorectal neoplasia (advanced adenomas and cancers) and evaluated their impact in colorectal cancer screening. Prospective, multicenter study was performed from January 2013 to December 2015 at eight high-quality colonoscopy centers. Demographic characteristics, anthropometric measurements, metabolic risk factors, and colonoscopic pathologic findings were assessed in patients with metabolic syndrome (target group) who underwent preventive colonoscopy (FIT positive or screening colonoscopy). This data was compared with consecutive patients without metabolic syndrome (control group). All patients meet the screening population criteria (asymptomatic, without family or personal history of colorectal neoplasia).

Results: 1500 individuals were enrolled; 726 persons (494 men, 68%) in the target group (metabolic syndrome) and 774 persons (353 men, 46%) in the control group (without metabolic syndrome). The significantly higher prevalence of advanced adenomas was observed in the target group (18%; 95% CI 15–21%) comparing to the control group (9%; 95% CI 7–11%); OR 1.8; $p=0.002$. Similarly, the prevalence of all adenomas was higher in the target group (48%; 95% CI 44–51%) than in the control group (35%, 95% CI 32–38%); however, the difference was not statistically significant ($p=0.179$). Individuals with isolated high cardiovascular risk (SCORE $\geq 10\%$) had higher prevalence of both, non-advanced adenomas (51%, 95% CI 46–56%; $p=0.327$) and advanced adenomas (22%, 95% CI 18–26%; $p=0.049$) comparing to the individuals with isolated DM2. Advanced adenomas were more likely in patients aged 65–75 years.

Conclusion: Colorectal neoplasia is positively associated with metabolic syndrome. Cardiovascular risk factors (SCORE $\geq 10\%$) is a stronger risk factor than the presence of diabetes mellitus type 2. Individuals with SCORE $\geq 10\%$ should be considered as a risk group of colorectal carcinomas, and therefore colonoscopy as the primary screening method is appropriate. This project has been supported by the Czech Ministry of Health grant NT 13673 and MO 1012.

P1746 PREVALENCE OF SERRATED POLYPOSIS SYNDROME IN AVERAGE-RISK SCREENING COLONOSCOPES IN GERMANY

C. Schramm¹, K. S. Janhsen², J. Dinter¹, F. Kuetting¹, T. Goesser¹, H. Steffen¹

¹University Hospital Cologne, Cologne/Germany

²St.-Katharinen-Hospital, Frechen/Germany

Contact E-mail Address: christoph.schramm@uk-koeln.de

Introduction: Serrated polyps (SPs) have been recognized as precursors of colorectal cancer (CRC), accounting for up to 30% of CRCs via the serrated neoplasia pathway. SPs are classified into hyperplastic polyps (HPs), sessile serrated polyps (SSPs) with or without dysplasia and traditional serrated adenomas (TSAs).¹ The serrated polyposis syndrome (SPS) is characterised by multiple SPs throughout the colon.¹ It is associated with an increased risk of developing CRC.² Published data on prevalence of SPS ranged from 0.03 in the UK to 0.8 in Spain.³

Aims & Methods: The aim of the study was to determine the prevalence of SPS in average-risk individuals participating in the German CRC screening programme. We retrospectively analyzed screening colonoscopies performed by 11 gastroenterologists in 4 medical practices and 1 tertiary academic hospital between 01/01/2011 and 14/12/2016. Individuals <50 years, with an increased risk for CRC (i.e. inflammatory bowel disease, history of CRC, cancer syndromes), and with previous or incomplete colonoscopy (i.e. procedures not reaching the cecum) were excluded. SPS diagnostic criteria according to the WHO definition from 2010 were: I) ≥ 5 SPs proximal to the sigmoid colon, of which two are ≥ 10 mm, II) any number of SPs proximal to the sigmoid colon in an individual who has a first-degree relative with SPS, or III) ≥ 20 SPs of any size distributed throughout the colon.¹

Results: A total of 3089 individuals were analyzed. 47.5% were male, median age was 62 years (interquartile range 56, 70). Overall adenoma detection rate was 33.9%. Detection rates for SPs, HPs, SSAs and TSAs were 21%, 18%, 4%, and 0.2%. Of all individuals with detected SPs none fulfilled the diagnostic criteria for SPS. Hence, we determined a prevalence of SPS of 0% in our cohort.

Conclusion: In our study, the prevalence of SPS in average-risk individuals undergoing screening colonoscopy was 0%. Because overall ADR was above the recommended values for screening colonoscopies, we conclude that this low prevalence might be attributed to a lack of awareness for SPS rather than to low-quality procedures. However, we were not able to obtain information about first-degree relatives with SPS from medical records of individuals with SPs to check the second diagnostic criterion for SPS. We also included only one colonoscopy per individual. It has been shown that prevalence increases when follow-up colonoscopies are included as well.³ Both facts might have caused an underestimation of the true prevalence of SPS in our cohort.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Early onset gastroenterological cancers lacking a positive family history are an increasingly worrisome entity. On one hand, early onset is the cornerstone of genetically determined oncological problems, but on the other negative family history does not support the suspect of familial syndromes.

Aims & Methods: We addressed the contribution of germline mutations to non familial early onset cancers. Patients with pancreatic, gastric, esophageal, duodenal and colorectal cancers were enrolled from 2015 to 2017 at the Gastrointestinal Personalized Medicine Unit. Eligibility criteria were the juvenile onset and the negativity for clinical criteria of hereditary cancer syndromes. Early onset colorectal cancer was defined as <45 yrs. For the other cancers, the threshold was defined at 50. Eligible patients provided informed consent. Genes were sequenced by means of a validated Next Generation Sequencing panel of oncological susceptibility genes and confirmed by means of Sanger sequencing.

Results: Among 12 colorectal cancer patients (7F, 5M), NGS analysis showed: 2 mutations of MSH2 and MSH6 occurring de novo, given the absence of family history; 3 variants of unknown significance (VUS) (2 MSH2 and 1 MLH1); and 7 were negative. Age-stratification revealed that, among those ≤35 years (n=4), 1 had MSH2 gene mutation and 3 were negative. In the 36–40 age group (n=3), 1 had a VUS in MLH1 and 2 were negative. In the age group 41–45 (n=5), 1 MSH6 mutation and 2 VUS were found, alongside 2 negative results.

Among the colorectal cancers, 17% of patients had a de novo mutation of Lynch Syndrome, 25% had a VUS, and 58% were negative.

2 gastric diffuse cancer underwent NGS analysis (40 and 45 yrs, 1M and 1F), both negative.

Among 2 pancreatic cancer patients (<50 yrs, 2 F), one tested negative and the other had a VUS on PMS2.

NGS analysis performed on 1 esophageal cancer (46 yrs, M) was negative.

1 duodenal cancer (46 yrs, F) has a MSH2 mutation and 2 VUS (MSH6 and PMS2).

Conclusion: A significant percentage (17%) of early onset colorectal cancers resulted in Lynch Syndrome even when family history is not suggestive of hereditary cancer. We reliably infer the determinant role of genetics, even when the family history does not support the hypothesis. Elsewhere, our results suggest that the already known susceptibility genes seldom contribute to sporadic early onset cancers. Other genes and mechanisms may explain the early onset phenotype. Our data show that NGS is often non conclusive in early onset GI cancers, and further development is needed to better classify VUS (25%).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1748 IMPACT OF COLIBACTIN-PRODUCING ESCHERICHIA COLI ON IMMUNE MICROENVIRONMENT IN PRECLINICAL COLORECTAL CANCER MODELS

Introduction: Increasing evidence links the immune microenvironment, microbiota and colorectal cancer (CRC). Colibactin-producing *E. coli* are more frequently detected on mucosa CRC patients and exhibit procarcinogenic properties on CRC murine models. Aim of this work was to evaluate the impact of chronic infection by colibactin-producing *E. coli* on immune cells in APC^{min/+} mice models.

Aims & Methods: Min mice were per os inoculated with a CRC-colibactin-producing *E. coli* strain (11G5), non pathogenic *E. coli* (K-12 MG1655) or PBS. Using optical in vivo imaging (IVIS spectrum), we evaluated oxidative stress induction with a bioluminescent inflammation probe in Min mice chronically infected. After 7 weeks, number and volume of polyps were evaluated and colonic samples were histologically analysed. Detection of immune cells was quantified by immunofluorescent labelling using a specific and innovative algorithm created with Tissue Studio software. Then, the density and localization of immune cells were performed in the three colon regions of interest: lymphoid follicle, mucosa and tumor.

Results: Using optical imaging, we detected a significant increase of luminescent signal in the gut of the infected group suggesting an increase of oxidative stress and inflammation. Histological analyses showed no difference about intra-tumoral immune infiltrate density on 11G5 and K12-infected mice. However, using our specific algorithm, we observed a significant increase of lymphoid follicle size in the gut of mice infected with the 11G5 strain compared to mice feeding with non-pathogenic K12 strain. Interestingly, follicle size was positively correlated with tumor volume, on the 11G5 infected group suggesting an association between pro-carcinogenic properties of this strain and gut immune response. In addition, we observed an increase of neutrophils (Ly6G⁺ cells) on mucosa and lymphoid follicle of mice infected with 11G5 compared to K12 and non-infected mice. These results can be linked with our *in vivo* optical imaging observations and our results about the increase of lymphoid follicle associated with CXCL1 and CCL20 measured by qRT-PCR after infection. Analyses of T cells, macrophages, B cells and myeloid suppressive cells are in progress.

Conclusion: Here we can observe an increase of lymphoid follicle associated with tumor volume after colibactin-producing *E. coli* infection. Our first results suggest that neutrophils can be one of the immune cells implicated in this process. This work shows a link between immune microenvironment, pathogenic *E. coli* and tumor development.

P1749 INVESTIGATING THE DIRECT INTERACTION BETWEEN CD24 AND B-CATENIN IN INTESTINAL TUMORIGENESIS

N. Arber¹, A. Fokra¹, S. Shapira¹, D. Kazanov¹, F. Bedny², B. Eli², C. Varol³
¹Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel
²Tel Aviv Medical Center, Tel Aviv/Israel
³Gastroenterology, Tel-Aviv Sourasky Medical Center, Tel-Aviv/Israel

Contact E-mail Address: nadira@tlvmc.gov.il

Introduction: CD24 is a glycosylphosphatidylinositol-linked protein that functions as an adhesion molecule and is overexpressed at an early stage of CRC (Sagiv et al., 2006). The Wnt/b-catenin signaling pathway plays an important role in the CRC carcinogenesis process. C57BL6/J mice carrying the ApcMin mutation develop ~24.3 ± 3.7 adenomas and several carcinomas in the small intestine by the age of 16 weeks compared to the ~7 ± 1.7 polyps that ApcMin/CD24^{-/-} ("double KO") mice developed. Mice colonoscopy showed a significant reduction in the number and size of polyps upon depletion of CD24 alleles. The ApcMin mice displayed severe splenomegaly (355 ± 68 mg) compared (141 ± 49 mg) in double KO mice similar to WT mice. Hb level in the ApcMin was 3.8 ± 2.5, significantly lower than in the double KO mice (8.2 ± 0.9) and their WT littermate.

Aims & Methods: We aimed to study the cellular interactions between CD24 and β-catenin, and effects of their interaction on intestinal tumorigenesis. CD24-inducible 293T-Rex cells previously developed in our lab (Shapira et al., 2011) and SW480 CRC cells stably transfected with CD24 (Naumov et al., 2014) were used to study this interaction in vitro. Coimmunoprecipitation and immunofluorescent staining were used to investigate the interaction between the two proteins. Far western blotting (WB) analysis was used to confirm this direct interaction by probing the standard WB membrane with the purified CD24 protein.

Results: In vitro: Western blotting analyses showed that expression of CD24 in 293T-Rex cells induced the activation of β-catenin, while down-regulation of CD24 in SW480 cells caused a decrease in the level of active β-catenin. Cytoplasmic/nuclear fractionation showed that more active β-catenin entered the nucleus in cells that expressed CD24 (clone1) as compared to control cells (clone 4). In addition, in both cell lines, TOP/FOP luciferase reporter assay showed a significant increase in Luciferase activity upon CD24 expression induction. Co-immunoprecipitation studies of CD24 and β-catenin indicated that these two proteins might be interacting. In addition, In HEK-293T cells and SW480 cells, immunofluorescent staining of CD24 and β-catenin showed that these two proteins co-localize on the cellular membrane. Furthermore, far western blotting analysis suggests that a direct interaction between the proteins exist.

Conclusion: 1. CD24 plays a major role in intestinal tumorigenesis. 2. CD24 interacts with the Wnt pathway by activating β-catenin. 3. CD24 interacts directly with β-catenin 4. Down-regulation of CD24 may be an important aim in the therapy of CRC.

Introduction: Cancer stem cells survive as the leading reason to tumor recurrence after tumor repressive treatments. Therefore, it is worth discovering specific and efficient inhibitors against cancer stemness for applications in reducing tumor recurrence. Previously, literature has indicated that YM155 can significantly reduce the stemness-derived tumorsphere formation of gastric cancer and suppress EGFR activity. However, the pharmaceutical mechanism of YM155 is not completely clear.

Aims & Methods: The aim of this study attempted to investigate the potential mechanism of YM155 against cancer stemness in EGFR-positive cancers. The tumorspheres derived from EGFR-mutant HCC827 and EGFR-wild-type HCT116 and A549 cells expressing higher cancer stemness markers, *CD133*, were used as cancer stemness models.

Results: We found that higher EGFR autophosphorylation (Y1068) in HCC827-, A549-, and HCT116- derived tumorspheres compared to the parental cells, which induced tumorsphere formation through activating G9a-mediated stemness property. YM155 was demonstrated to inhibit the tumorsphere formation by unexpectedly blocking the autophosphorylation of EGFR and EGFR/G9a-mediated stemness pathway. The chemical and genetic inhibitions of EGFR and G9a revealed the significant role of EGFR-G9a pathway in maintaining the cancer stemness property.

Conclusion: In conclusion, this study not only revealed that EGFR triggered the formation of tumorspheres through elevating the G9a-mediated stemness, but also demonstrated that YM155 inhibited the formation of tumorspheres by simultaneously blocking autophosphorylation of EGFR and activity of G9a as a potent anti-stemness agent against EGFR-positive cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1753 COLORECTAL CANCER CELLS INDUCE NEUROGENESIS IN THE ENTERIC NERVOUS SYSTEM OF THE TUMOR MICROENVIRONMENT VIA A NGF-DEPENDENT PATHWAY

F. Drissi, A. Bessard, M. Touvron, H. Boudin, F. Cossais, L. Van Landeghem, M. Neunlist, E. Duchalais

Contact E-mail Address: farouk.drissi@gmail.com

Introduction: Several studies have demonstrated that the colorectal cancer (CRC) microenvironment harbors an increased neurite density as compared to healthy areas. Moreover recent findings indicate that specific stimuli activate neurogenesis in the enteric nervous system (ENS), in adult mice. However whether tumor epithelial cells (TEC) induce neuritogenesis and/or neurogenesis in the ENS during CRC remains unknown.

Aims & Methods: Human colon specimens from patients with CRC and from AOM/DSS treated mice were whole-mount dissected in order to isolate the myenteric and submucosal plexus from healthy area and tumor margin. The number of enteric neurons per ganglia was compared between healthy area and tumor margin after anti-Hu immunostaining in both plexus. Human CRC supernatants, TEC (Caco-2 cells)-conditioned medium or NGF were added to primary culture of rat enteric nervous system and primary culture of rat enteric neurons. In fixed primary cultures, the number of enteric neurons per ganglia and the length of neurites were calculated after anti-Hu and anti-tubulin-III immunostaining respectively. In order to determine the role of NGF in CRC supernatants and TEC-conditioned medium effects, anti-NGF blocking antibodies were added to primary cultures.

Results: Immunofluorescence studies on whole-mount dissected ENS plexus demonstrate that the densities of neuronal bodies were significantly increased in the margins of both human CRC and murine AOM/DSS-induced dysplasia compared to healthy areas (n=7 and n=5 respectively; p<0.05). The increase in neuronal density was similar in low-grade and high-grade dysplasia as well as carcinoma (n=5). In vitro human CRC supernatants and TEC-conditioned medium enhanced the densities of neurites and neuronal cell bodies in primary cultures of ENS (pcENS) as compared to healthy mucosa supernatants and control medium, respectively (n=6; p<0.05). Finally, nerve growth factor (NGF) induced an increase in the density of neuronal bodies in pcENS (n=4; p<0.05), and our preliminary data show that the addition of an anti-NGF blocking antibody to human CRC supernatant and TEC-conditioned medium inhibits their impact on neurogenesis and neuritogenesis (n=6; p<0.05).

Conclusion: Altogether these results indicate that the increased neuronal density in CRC margin may result from the activation of neurogenesis in the ENS induced by TEC via a NGF-dependent pathway.

Introduction: Promoter hypermethylation-induced epigenetic silencing of tumor related genes played a key role in the initiation and development of colorectal cancer (CRC). Using Methylated DNA Immunoprecipitation (MeDIP), we identified that Fibroblast Growth Factor 14 (FGF14) was preferentially methylated in CRC.

Aims & Methods: We aimed to investigate the epigenetic regulation and biological function of FGF14 in CRC. The expression of FGF14 in 10 CRC cell lines and 24 pairs of CRC tissues and paired adjacent normal tissues by real-time PCR. CRC cells were treated with DNA demethylating agent 5-aza-2'-deoxycytidine (5-Aza). The methylation status of FGF14 in CRC cell lines and CRC were determined by real-time MSP. The biological function of FGF14 in CRC was interrogated by cell viability assay, colony formation, immunofluorescence and flow cytometry, as well as in vivo study.

Results: FGF14 was downregulated or silence in all (10/10) CRC cell lines, while it was readily expressed in normal colonic tissues. The expression of FGF14 was significantly lower in primary CRCs as compared to their adjacent normal tissues (P<0.01). The loss of FGF14 gene expression was restored by treatment with DNA demethylating agent 5-Aza. Re-expression of FGF14 in CRC cell lines inhibited colony formation, suppressed cell viability, and induced cell apoptosis via AMPK/mTOR pathway, accompanied with enhanced protein expression of cleaved caspase-3, cleaved caspase-7, cleaved caspase-9 and PARP. In xenograft mouse model, overexpression of FGF14 significantly reduced tumor growth (P<0.001).

Conclusion: FGF14, which induces cell apoptosis via AMPK/mTOR pathway, is a novel tumor suppressor down-regulated by epigenetic inactivation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A cancer with a number of somatic mutations is defined as “hypermutator”, and shows therapeutic features, such as high sensitivity to immune checkpoint inhibitor. However, to date, analyses of hypermutator have not been done with a large number of cases.

Aims & Methods: The aim of this study is to analyze the incidences and characteristics of hypermutator in digestive system cancers. We analyzed somatic mutation of digestive system cancers in 1145 cases (age: 67.4 ± 11.3 yrs., M:F = 755: 390), those underwent surgery after full informed consent during 2014 to 2015. Genomewide sequencing was performed on 47 inherited cancer-associated genes and 411 cancer-associated genes using next generation sequencer (Ion Torrent Proton sequencer and Ion AmpliSeq Exome RDY kit, Thermo Fisher Scientific). Hypermutator was defined when a tumor having > 500 mutations in the somatic DNA.

Results: The 1145 subjects included 583 colorectal cancers (CRC), 229 gastric cancers (GC), 103 metastatic liver tumors, 100 hepatocellular carcinomas (HCC), 45 pancreatic cancer, 23 GISTs, 15 esophageal cancers and 14 neuroendocrine tumors, etc. Hypermutator was recognized in 66 cases (5.8%). Age and gender were not different by the hypermutation. Hypermutator was recognized in 6.2% (36 cases) of CRCs, 11.8% (27 cases) of gastric cancers, 2% (2 cases) of HCCs, and one case of small intestinal cancer. Within the hypermutator group, multiple cancers developed in 13.9% of CRC patients and 25.9% of GC patients. Mutation of *BRAF* was detected in 33.3% (22 cases), that of mismatch repair genes (either of *MLH1*, *MSH2*, *MSH6*, *PMS2*) in 13.6%, *POLE* in 9.1%, and *POLD1* in 4.5%, respectively, in the hypermutator group.

Conclusion: Hypermutator was recognized in 5–10% of digestive system cancers, predominantly seen in CRCs and GCs. Cases of hypermutator sometimes develop multiple cancers, associated with a somatic mutation of mismatch repair genes. Further research must be needed to clarify the characteristic of hypermutator of the digestive organs in the therapeutic aspects.

P1756 UNBIASED ANALYSIS OF REGULATION OF TRANSCRIPTION FACTORS UPON ER STRESS IN THE LS174T COLORECTAL CANCER CELL LINE EXPOSES CTBP2 AS A POTENTIAL REGULATOR OF STEMNESS

B. J. Meijer¹, B. F. Westendorp¹, J. H. m. Van Der Meer¹, W. L. Smit¹, J. Heijmans¹, V. Muncan¹, G. R. Van Den Brink¹

Introduction: In the intestinal epithelium, stem cells are located at the bottom of the crypt and their maintenance and differentiation is essential for sufficient organ function. Accumulation of mis- or unfolded proteins in the endoplasmic reticulum, so-called ER-stress, leads to an unfolded protein response (UPR) which can force an intestinal epithelial stem cell (iESC) into differentiation. However, the molecular mechanism of this differentiation process upon ER stress is largely unknown. A prominent feature of the UPR is translation inhibition via PERK-eIF2α phosphorylation and we have previously shown that the differentiation upon ER-stress is dependent on PERK-eIF2α phosphorylation¹. Therefore we hypothesize that ER stress influences stem cell differentiation on a translational level by downregulating key transcription factors (TFs) that serve an important role in maintaining stem cell fate.

Aims & Methods: Our aim is to identify transcription factors important for stem cell maintenance using a transcriptomics approach. On thapsigargin treated LS174T-cells, a cell line with a transcriptional profile resembling intestinal stem cells, we performed a TF DNA-binding assay (catTFRE) in which TFs present in cellular lysate are bound to plasmid DNA, co-extracted and quantified using mass-spectrometry². We confirmed downregulation using immunoblots in colorectal cancer cell lines. Additionally, we examined CtBP2 expression in mouse intestine using *in situ* hybridization, epithelial FACS sorting and immunohistochemistry. To study CtBP2 function, we transfected a LS174T cell line with shRNA CtBP2 and analyzed stemcell and differentiation markers.

Results: By using the CatTFRE assay we quantified the binding activity for > 1000 transcription factors. Forty-three TFs showed significant downregulated binding to template DNA upon thapsigargin treatment compared to control. We confirmed downregulation of eight of these TFs on protein level, suggesting a loss of binding due to translation inhibition upon ER stress. We identified transcriptional corepressor CtBP2 as the most significantly downregulated protein. Interestingly, in mouse small intestine, CtBP2 is expressed in the proliferative compartment where stem cells reside. Additionally, mRNA expression analysis showed abundance of CtBP2 in iESCs. We next investigated the effect of CtBP2 knockdown on stemness in the LS174T cell line. Three days upon shCtBP2 transfection we showed a significant decrease in mRNA levels of stem cell markers *Lgr5* and *Olfm4* compared to control and an increase in differentiation markers *Villin* and *P21*, suggesting induced iESC differentiation.

Conclusion: Using an unbiased transcriptomics approach we identified transcription factors that are lost on protein level upon ER stress. Furthermore, our data suggests that the significant loss of the transcriptional regulator CtBP2 contributes to intestinal epithelial stem cell differentiation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Location and somatic gene signature of CRCs may impact prognosis and therapy response. A relative specific CRC-related dysbiosis has been characterized.

Aims & Methods: The aim was to characterize colon microbiota in CRC patients regarding location, gene markers and outcome. Patients (N = 173) signed consent for whole metagenome (shotgun sequencing on Illumina HiSeq2500) analysis of stool DNA: 72 CRC (53 sporadic-S, 19 Lynch-L), 87 asymptomatic subjects (normal colonoscopy), 14 first degree healthy relatives from Lynch families. "MOCAT" pipeline was used, library sorted (Phred quality score 20 Alentrimmer v0.4.0) after exclusion of < 35 nt, human genes or phage sequences. Quality sequences were aligned (REFMG.V13) and most abundant genes constructed (MBMA program v0.1). The Shaman program (shaman.c3bi.pasteur.fr) was used. The number of bacteria was estimated (REFMG program). The linear model (GLM) was implemented in the DESeq2 R kit. Differences between Control (N = 87) and CRCs (N = 69), between L (N = 19) and S CRCs (N = 50), and between LCRC (N = 19) and Healthy Lynch relatives were obtained after interaction of age, BMI and gender was considered (GLM model). The P < 0.1 value was retained after correction (Benjamini and Hochberg). The specific taxonomic composition of the control and CRC groups was subjected to random analysis (Caret's R package) with two optimization parameters (precision and kappa) in the model.

Results: There was no difference for gender, age (p = 0.08) and BMI (p = 0.187) in the L and S CRCs. Significant differences were observed between Normal and CRCs, C-CRC and L-CRC, L-CRC and first degree relatives based on the common component (similarity of sequences): 13 species differentiated Normal and CCRs, two were more prevalent in L-CRCs. The panels of bacteria linked with location, MSI, Ras mutations, methylation phenotypes and survival were identified. No significant link was observed with TNM Staging: I (N = 17, 2L and 15S), II (N = 12, 5L and 7S), III (N = 20, 10L, 10S), IV (N = 22, 1L, 21S). DFS might be dysbiosis dependent.

Conclusion: CRC dysbiosis is location-dependent. Several bacteria are associated with Ras mutation, MSI, and methylation status. They may directly or through therapies impact the prognosis. Microbiota signature should be taken in consideration in trials.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal serrated lesions (SLs) include hyperplastic polyp (HP), traditional serrated adenoma (TSA) and sessile serrated adenoma/polyp (SSA/P). SSA/Ps are well-known precursors of colorectal cancer (CRC) characterized by BRAF mutation and microsatellite instability (MSI), whereas the molecular characteristics of TSAs are not fully understood.

Aims & Methods: We aimed to identify epigenetic alterations associated with the development of TSAs and to clarify the associations between clinical, pathological and molecular characteristics in colorectal lesions. The genome-wide DNA methylation status in TSAs consisting of protruding and flat components was analyzed using an Infinium HumanMethylation450 BeadChip, and changes in DNA methylation during the development of TSAs were identified. Methylation of identified genes and CIMP markers (MINT1, -2, -12, -31, p16 and MLH1) and BRAF/KRAS mutations were analyzed in 847 colorectal lesions and 61 samples of normal colonic tissue. Effects of ectopic expression on CRC cell growth in a prevalently methylated gene in TSAs were assessed in vitro and in vivo.

Results: BeadChip analysis revealed 11 genes in which methylation levels were progressively increased during development of TSAs. Among them, SMOC1 was prevalently methylated in TSAs, but was rarely methylated in SSA/Ps ($p < 0.001$). RT-PCR revealed that SMOC1 is abundantly expressed in normal colon and SSA/Ps, but is significantly downregulated in TSAs. Immunohistochemical analysis showed that SMOC1 was expressed in the epithelium of normal colonic tissues and SSA/Ps, but that expression is significantly reduced in TSAs. Ectopic expression of SMOC1 suppressed proliferation, colony formation and in vivo tumor formation by CRC cells. Analysis of colorectal lesions revealed that SMOC1 is frequently methylated in TSAs and CRCs, and that SMOC1 methylation is strongly associated with KRAS mutation and CIMP-low.

Conclusion: Methylation of SMOC1 is associated with TSA development but is rarely observed in SSA/Ps. Immunohistochemical analysis of SMOC1 may be a useful marker to discriminate between SSA/Ps and TSAs. Our data suggests SMOC1 methylation may play a role in the neoplastic pathways arising in TSAs.

Introduction: The number of individuals partaking in colorectal cancer (CRC) screening still remains to be low even after the implementation of the Korean Government's National Cancer Screening Program for CRC. The aim of this study is to identify factors associated with partaking in CRC.

Aims & Methods: The Korean National Health and Nutrition Examination Survey (KNHANES) 2007~2010 datasets were used to develop a CRC screening participation screening score. 10,527 individuals aged ≥ 50 who completed the survey and not previously diagnosed with CRC were selected. Both logistic regression (LR) analysis and artificial neural network (ANN) were used to develop predictive models. Multilayer perception ANN was constructed based on 16 clinical variables. We then validated the models using the KNHANES 2011 and 2012 ($n = 5986$) datasets and compared them with each other.

Results: Out of 10,527 individuals selected, 57.0% ($n = 6005$) responded unscreened for CRC. Among various demographic and socioeconomic factors, following 8 parameters including age, household income, marital status, education level, private health insurance, self-reported depression, self-reported health status, and residence were found to be independently associated with CRC screening participation. LR analysis produced screening score (range 0–10.3), and a cutoff point of ≥ 5.5 defined 49% as unscreened for CRC and yielded area under the curve (AUC) of 0.626. When validated with KNHANES 2011 and 2012 datasets, the AUC of the defined LR model was 0.663, meanwhile the AUC of ANN based predictive model was 0.743.

Conclusion: The ANN produced better performing model than LR analysis based model in identifying population with low CRC screening participation. Sensible approaches should be implemented to encourage partaking in CRC screening in the identified individuals.

Introduction: Background: CD24, a mucin-like cell surface molecule, highly expressed in large variety of solid tumors and hematological malignancies (HM) (*Gastro* 2006, *Clin Can Res* 2007, *Can Res* 2008). mAb to CD24 were found to inhibit the growth CD24 cancer cells (*Gastro* 2009). We have shown that a simple non-invasive blood test evaluating CD24 levels on PBL had good sensitivity and specificity for detecting colorectal neoplasia in subjects undergoing screening colonoscopy (Kraus et al., 2009).

Aims & Methods: We aimed to improve a simple, noninvasive blood test that could reliably identify individuals with different types of cancer.

Blood was taken from patients with various malignancies (CRC, Pancreatic Cancer (PC), gastric cancer (GC), sarcoma and HM), that was confirmed by histology. Age, gender and ethnic matched healthy individuals served as controls. Healthy subjects were indeed very healthy. They underwent a thorough and extensive workout at the Integrated cancer prevention center at Tel Aviv Medical Center (*Eur J Intern Med*. 2013) All samples were collected and processed identically. For each sample, 20,000 leukocytes were analyzed by flow cytometry for the expression of CD24. An initial template file has been generated using gates within the software to create a hierarchical population tree at the beginning of the screen. All additional analyses were accomplished after data acquisition have been completed. The template file include compensation adjustment, which is uniformly applied to all the data collected in order to minimize fluorescence overlap between detection channels

Results: The novel assay was improved significantly. distinguished healthy from CRC (Fig.1a) ($P < 0.013$), PC (Fig.1b) ($P < 0.018$), biliary tract ($P < 6.45E-12$), sarcoma ($P < 0.036$), multiple myeloma (Fig 2a) ($P < 0.4E-08$), MDS ($P < 0.1$) and Lymphoma ($P < 2.1E-07$) patients. CD24 expression levels were higher by up to 25% in cancer cases as compared to normal subjects. The sensitivity and specificity for CRC were 79.2% and 74.7%, and for PC 70.0% and 75.9%, respectively.

The positive (PPV) and negative predictive (NPV) values of CD24 for the detection of CRC was 38% and 94.8%, and for PC 17.1% and 97.3%, respectively. Specificity and sensitivity for HM were also statistically significant (data not shown). The CD24 test could not discriminate between patients with cervical, stomach and lung cancers and healthy subjects.

Conclusion: Conclusions: CD24 expression in PBLs is a promising blood test for the early detection of CRC, PC and HM.

Introduction: Colonoscopy is considered the gold standard for prevention and early detection of colorectal cancer (CRC), however its effectiveness is directly related to quality of bowel preparation. Two of the quality measures of colonoscopy, cecal intubation rate and adenoma detection rate, are both associated with adequate bowel preparation. Data on factors associated with quality of preparation using Picolax® are limited.

Aims & Methods: We aimed to evaluate factors associated with a good bowel preparation using Picolax® (Sodium picosulfate/magnesium citrate) in the Israeli heterogeneous population. Consecutive outpatients referred for colonoscopy were prospectively assessed by a nurse practitioner filling out a questionnaire. Bowel preparation consisted of Bisacodyl 10mg/d 3 days before colonoscopy and split dose picolax. Demographics, medical history, Bisacodyl and water consumption, time of total preparation and time between end of prep to colonoscopy were evaluated. Quality was assessed using the Boston Bowel Preparation Score (BBPS). Bowel prep was considered "good" if BBPS was ≥ 6 and ≥ 2 in each 1 segment or "low" if BBPS was < 6 or < 2 in any colonic segment.

Results: A total of 452 patients were included in the study ($M = 54\%$, mean age 56.5 ± 16.3 yrs), 366452 (81%) achieved a "good" bowel preparation, and 86 (19%) were classified as "not good." No significant difference was observed between ethnicities and gender in terms of achieving a good bowel preparation ($p = 0.77$, $p = 0.054$). There was a significant difference among diabetics ($n = 93$, 20.6%) and non-diabetics ($n = 359$, 79.4%) in quality of the bowel prep. While 69.9% of diabetics achieved a good bowel preparation only 83.8% of non diabetics achieved a good bowel preparation ($p = 0.004$). In the univariate analysis, Bisacodyl had no effect on bowel preparation ($p = 0.83$) except in the diabetics, where those who took an average of 5.3 ± 1.9 (median = 6) vs. 4.31 ± 1.5 (median = 4) tablets fared better ($p = 0.018$). Other chronic diseases had no effect on bowel preparation. Drinking 3–7 vs 8–15 glasses of water achieved good preparation in 72.7% vs 83.8% of cases, respectively ($p = 0.01$). Time from end of preparation to colonoscopy < 8 hrs achieved significantly better prep vs > 8 hrs ($p = 0.002$). In the multivariate model for prediction of quality of bowel preparation that included the time between sachets of picolax, number of water cups consumed, diabetes, gender, and age we found that all, excluding age, were good predictors of bowel preparation. Women had a better chance of achieving an adequate bowel preparation (OR 1.68, $p = 0.045$, 95%CI = 1.01–2.79). Patients without diabetes had a better chance of achieving an adequate bowel preparation (OR = 2.05, $p = 0.014$, 95%CI = 1.16–3.63). Patients who had 5–9 hours between the 2 sachets of picolax had a lower chance of achieving an adequate bowel preparation as compared to those who had 9 to 24 hours between the 2 sachets (OR = 0.375, $p = 0.009$, 95%CI = 0.180–0.785). Lastly, drinking fewer than 8 cups lowers the chance of achieving an adequate bowel preparation (OR = 0.461, $p = 0.003$, 95%CI = 0.275–0.775).

Conclusion: Diabetics require a more intense bowel preparation aided by Bisacodyl, which does not help others. Time between both doses should exceed 8 hours and preparation should end no later than 8 hours prior to colonoscopy. Patients should be instructed to drink a minimum of 8 glasses of water with each dose of picolax.

Introduction: Colonoscopy is the gold standard method of colorectal cancer and polyp screening, but polyps are missed during a colonoscopic examination at a rate that varies from 6% to 27%. Improved adenoma detection rates can be achieved with optimized endoscopic visualization methods. A recently developed new Fujinon endoscope system, Eluxeo carries a new function of electronic chromoendoscopy, Linked Color Imaging (LCI), that enhances the coloring and contrast of mucous membranes and blood vessels which are difficult to see with the conventional endoscopes. In our prospective randomized study, we evaluated the effectiveness of LCI, a new endoscopic visualization technique that may enhance image quality to improve colonic adenoma detection.

Aims & Methods: Up till now 247 eligible patients, elder than 45 years, admitted for screening outpatient colonoscopy were randomly enrolled to undergo high-definition white-light colonoscopy (WLC) or LCI colonoscopy during instrument withdrawal. The colonoscopic procedures were performed by three experienced endoscopists with Fujinon 7000 processor and with either the conventional high-definition Fujinon EC 590Z or a new EC 760Z VS Eluxeo colonoscope. All of the colonoscopic procedures were made under Propofol deep sedation guided by an anesthesiologist team. The minimum withdrawal time was defined as more than 6 minutes. All colonoscopies were routinely assisted with pure CO₂ insufflation. The primary outcome parameter of our study was to assess and compare the polyp and adenoma detection rate with the two endoscopic technology.

Results: A total of 247 patients were randomized (mean age 58.7 years), 101 patients enrolled in the WLC group and 146 patients in the LCI group. No significant differences have been observed in the patient demographics and colonoscopy withdrawal time between the two groups. Patients having both colorectal polyps and adenomas were detected more frequently in the LCI group than in the control group: 60.9% and 43.8% versus 55.4% and 33.6% respectively, however, this was not statistically significant ($p=0.32$ and 0.16). In contrast, the total number of adenomas relative to the total number of polyps detected with LCI withdrawal were significantly higher than with conventional WLC: 105 vs. 159 and 55 vs. 102, respectively ($p < 0.0498$).

Conclusion: The LCI enhancement of the Fujinon Eluxeo colonoscopy system was superior to the conventional HD-WLC in detecting patients with colorectal adenomas, which was mainly due to the ability of the more sensitive detection of minute (less than 5 mm) adenomas. (Study was supported by ECT grant GINOP 2.1.1.-15- 2015-00128.)

Contact E-mail Address: alexandra.kalmar@gmail.com

Introduction: Long non-coding RNAs (lncRNAs) play role in colorectal cancer (CRC) development, however, lncRNA expression profile in CRC and its relation to the epigenetic regulatory system still remain incomplete.

Aims & Methods: We aimed to perform whole genomic lncRNA expression profiling and the analysis of underlying functional interactions of aberrantly expressed lncRNAs. lncRNA expression levels were analyzed on 60 colonic biopsy samples (20 CRCs, 20 adenomas, 20 normals) by Human Transcriptome Array (HTA) 2.0. Expression alteration of certain candidates was verified by qPCR. Furthermore, in silico validation was performed on HGU133 Plus 2.0 array data and also on TCGA COAD dataset. miRNA targets of lncRNAs were predicted with the miRcode algorithm and miRNA expression was analyzed using miRNA 3.0 Array. Comprehensive lncRNA-mRNA coexpression pattern analysis was also performed.

Results: According to HTA results in adenomas 12 lncRNAs (e.g. LINC00278) were upregulated and 6 lncRNAs (e.g. RP11.747D18.1) were downregulated compared to normals, while in CRCs 1 lncRNA (UCA1) was overexpressed and 8 lncRNAs (e.g. LINC00350) were underexpressed compared to adenomas ($p < 0.05$; $-2 \geq Fc \geq 2$). In CRC samples 8 lncRNAs (e.g. AC123023.1) were overexpressed and 9 lncRNAs (e.g. RP13-497K6.1) were downregulated

compared to normals. 42% of lncRNAs upregulated in CRC samples showed elevated expression ($p < 0.05$) already in adenomas (e.g. overexpressed CCAT1, downregulated LINC01133). In line with aberrant expression of certain lncRNAs in tumors, miRNA and mRNA targets' expression showed systematic alterations, e.g. UCA1 upregulation in CRC samples in parallel with miR-1 down-regulation accompanied by CMET target mRNA overexpression ($p < 0.05$).

Conclusion: The defined lncRNA sets (e.g. CCAT1, UCA1) may have a regulatory role in adenoma and CRC development and in tumor cell growth pathways. A subset of CRC-associated lncRNAs showed significant differential expression in precancerous samples, that raise the possibility to develop potential adenoma-specific markers and achieve early detection of colon lesions.

Introduction: Serine protease inhibitors (Serpins) play an important role in the regulation of enzymes involved in proteolytic cascades. Members of the family are: alpha1-antitrypsin, alpha1-antichymotrypsin, C1 inhibitor, antithrombin and neuroserpin. Kallikrein-related peptidases (KLKs) are involved in proteolytic cascades of different tissues. KLK14, acting via PAR-2, represents an auto-crine/paracrine regulator of colon tumorigenesis and alpha1-antitrypsin is a natural inhibitor of KLK14. Therefore its role in regulating the proteolytic cascade in colorectal tumorigenesis is of great importance.

Aims & Methods: The aim of this study was to analyze A1-antitrypsin (AAT) expression in tissue samples at different stages in the process of colon cancer development. We examined a total of 245 colon samples. Of those, there were 101 colorectal carcinoma tissues, for 70 of which paired normal mucosa was also examined. A total of 74 colorectal adenomas were examined. Quantitative real time PCR was used to measure AAT expression. Clinical evaluation of AAT levels was demonstrated in terms of disease-free survival (DFS) and overall survival (OS).

Results: Alpha1-antitrypsin expression was found to be significantly associated with TNM stage ($p=0.028$). Cox proportional hazard regression model using univariate analysis revealed that high status alpha1-antitrypsin expression is a significant factor for disease-free survival (DFS) ($p=0.002$) and overall survival (OS) ($p=0.026$) in patients with colorectal cancer. Kaplan-Meier survival curves demonstrated that low alpha1-antitrypsin expression is significantly associated with longer DFS ($p=0.001$) as well as OS ($p=0.021$).

Conclusion: Our data suggests that alpha1-antitrypsin expression could be considered as a potential biomarker of unfavorable prognosis for colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Real-time differentiation between neoplastic and non-neoplastic colorectal lesions may be crucial during colonoscopy. While adenomas are

neoplastic, and therefore should be resected, hyperplastic polyps never turn malignant and do not require specific endoscopic therapy. The aim of our prospective, randomized study was to distinguish subcentimetric hyperplastic and adenomatous polyps based on Fujinon FICE versus Eluxeo BLI electronic chromoendoscopic technology with high-definition colonoscopy with and without optical magnification.

Aims & Methods: In order to create a video and digital picture library of polyps, patients undergoing screening or diagnostic colonoscopy were considered for inclusion. Patients with at least one histologically verified <10 mm polyp were included. A short (20sec) video-clip and at least one still picture of each polyp without and with 50x optical zoom at standard white-light (WLI), and with FICE-light or BLI-light were recorded with Fujinon EC 590Z and EC760Z endoscopes and stored in an anonymized database. Once the video-library was completed, each of our 5 colonoscopic experts (ML, SZM, OL, DZS, and SZA) independently and randomly reviewed all of the cases with a standardized electronic questionnaire. In each case, all of the observers had to assess the color, the vascularization and the surface of the polyps, and the pit pattern was also analyzed according to the Kudo classification. Finally, with the degree of confidence (low/medium/high on VAS), the histological prediction and the final decision has been clarified on each lesion as neoplastic or non-neoplastic (hyperplastic).

Results: Up till now 115 polyps were enrolled and recorded into our digital web-based library, 59 were assigned into the FICE and 56 into the BLI group. All of the detected 115 polyps were endoscopically removed and histologically analyzed and this was regarded as gold standard. The overall accuracy with WLI versus FICE versus BLI technology of the 5 experts without zoom and with 50x times magnification to differentiate between hyperplastic and adenomatous lesions were 77.62% and 84.51%, vs. 74.58% and 83.90% vs. 83.93%, and 88.84%, respectively. There was an excellent correlation between the histopathological results and our KUDO classification with both FICE and BLI technology. Both 50x times optical zoom and BLI technology were independently and significantly improved our confidence rate that was associated with a more precise histological prediction as compared to non-zoom, WLI or FICE endoscopic polyp assessment.

Conclusion: The new electronic chromoendoscopic technology with Eluxeo BLI significantly improved the reliability of the histology prediction as compared to FICE technology of Fujinon. High-confidence predictions for the differentiation of neoplastic and non-neoplastic polyps with Eluxeo BLI electronic chromoendoscopy provide a potential for real-time endoscopic diagnosis of hyperplastic polyps to support resect and discharge strategy. (Study was supported by ECT grant GINOP 2.1.1.-15- 2015-00128)

Introduction: Colorectal cancer (CRC) is the 4th commonest cancer in the UK but has an excellent prognosis upon early diagnosis accounting for the development of bowel cancer screening. However not all patients are eligible for this. Furthermore, colorectal investigations have the potential to miss the diagnosis and lack of appropriate investigation of alarm symptoms may also delayed diagnosis.

Aims & Methods: We aimed to determine the miss rate of previous investigations and reviews for colorectal symptoms and iron deficiency anaemia (IDA) over the preceding 3 years prior to CRC diagnosis at our institution. 215 patients were identified from the local CRC registry between 1/10/15–30/9/16 and electronic records reviewed to determine if any review for lower GI symptoms or IDA had occurred in the preceding 3 years. Missed diagnoses were defined as patients having prior endoscopic or cross sectional imaging viewing the affected area or having prior clinic/inpatient review failing to adequately investigate colorectal alarm symptoms.

Results: Of the 215 patients 37 (17%) were deemed to have undergone possible delay in their diagnosis causing an average 9.6 and median 5 months delay (1.5–33 months). Cancers were right sided in 18 patients (49%), Dukes C or above in 76%, with 57% only suitable for palliative therapy. Of the 37 patients with a delayed diagnosis 22 (59%) were deemed possible missed diagnoses. The remaining 15 delays (41%) were due to patient choice (11%) or delayed clinic review/investigation (30%); in this latter group the delay was a mean 3.9 months (1.5–7 months). Missed diagnosis occurred at: 1) Endoscopy in 10 (48%); 8 colonoscopies (median 18 (4.5–27) months earlier), 2 sigmoidoscopies (1 and 3 months earlier), 2) Radiology: CTvc missed 2 CRC (15 and 2 months earlier but laparoscopy for a presumed benign lesion was planned for the latter); CTAP/CTKUB missed 8 cases (median 5(2–26) months previously), 3) Clinical assessment: missed appropriate inpatient/outpatient investigation based on presenting with colorectal alarm symptoms or IDA occurred in 7 cases (median 3(2–16) months delay). 2 patients were a miss on both CT and endoscopy and 3 on CT and clinic review. Delayed follow-up upon re-referral compounded delayed diagnosis in 11 (50%) of the 22 missed cases.

Conclusion: Our data suggest a delay in CRC diagnosis occurred in almost a fifth of cancer diagnoses. Delayed cancer diagnosis tended to occur in right-sided lesions and resulted in a median 5-month delay with lesions generally advanced at diagnosis. In 59% the diagnosis could have been expedited by earlier follow-up

and/or investigation. While miss rates for endoscopic and imaging modalities were low, 19% of missed cancer diagnosis were due to lack of appropriate investigations following outpatient or inpatient review for colorectal alarm symptoms or IDA; this might be improved by increasing specialist inpatient in-reach services and senior review of outpatient cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Till now, narrow-band imaging (NBI) could make it possible to analyze the surface microvessels of colorectal lesions for differentiating neoplasms from non-neoplasms and for predicting the histopathological diagnosis. Endocytoscopy (EC) is the next generation of ultramagnification endoscopy that allow visualization of the glandular structure and cellular atypia. EC has visualized living tumor cells in vivo and obtained an ultra-magnification pathological image simply by applying the scope to the target mucosa during an endoscopic examination. However, in order to visualize cell nuclei, dye staining (i.e. methyleneblue) is always required. Since dye staining complicates the procedure, new observation method without use of dye has been strongly desired. On the other hand, EC with NBI (EC-NBI) allows ultra-magnified microvessel observation without using any dye solution.

Aims & Methods: The aim of this study was to validate the evidence whether the observation of surface microvessels using EC-NBI was useful in predicting the histopathology of colorectal lesions. The study included 438 patients who underwent complete colonoscopy and endoscopic or surgical treatment between April 2006 and June 2015. A total of 576 lesions (45 Non-neoplastic polyps, 304 adenomas, 71 intramucosal cancer, 21 slightly invasive submucosal cancer (SMs) and 135 massively invasive submucosal cancer) were retrospectively evaluated. We used the Kudo classification for the degree of submucosal invasion and classified cancers accordingly. SMs cancer without vessel permeation does not metastasize. In contrast, SMm lesions show a substantial proportion (~10%) of lymph node metastasis. We named the ultra-magnified microvessel findings as endocytoscopic vascular (ECV) pattern and classified into the following 3 groups: EC-V1, the surface microvessels were very fine obscure; EC-V2, the surface microvessels were more clearly seen and showed a regular vessel network, and their caliber and arrangement were uniform; and EC-V3, the surface microvessels were thick, and their caliber and arrangement were non-homogeneous.

Results: The sensitivity, specificity and accuracy of EC-V1 for diagnosis of hyperplastic polyp were 88.9%, 98.5% and 97.7%, respectively. As regards the sensitivity, specificity and accuracy of EC-V3 for diagnosis of SMm were 82.2%, 98.0% and 94.3%, respectively.

Conclusion: Endocytoscopic vascular pattern was helpful in predicting the histopathology of colorectal lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1768 CONSIDERATION OF RECTAL NEUROENDOCRINE TUMOR IN OUR HOSPITAL

M. Akita

Internal Medicine, Mitoyo General Hospital, Kanonji City/Japan

Contact E-mail Address: m_akita1976@yahoo.co.jp

Introduction: Although patients with endoscopic treatment indications for rectal neuroendocrine tumours (NETs) are recommended to undergo endoscopic therapy, those with a tumour diameter of ≤10 mm and up to the deep submucosal layer. However, no clear guideline has been established on the radical criteria and additional resection. Prognosis of the disease is also unclear. The validity of the diagnosis and treatment recommended in the guideline for rectal NETs will be examined in the cases treated at our hospital.

Aims & Methods: We examined the macroscopic features, pathological features, treatment methods, and prognosis of 22 patients diagnosed as having a rectal NET and treated at our hospital between 2007 and May 2016.

Results: The mean age of the patients was 65.2 years (range, 49–88 years); male-to-female ratio, 15:7; diagnosis opportunity, 21 asymptomatic cases and 1

symptomatic condition (lumbago); lesion site (Rs/Ra/Rb), 1/2/19 cases; mean tumour diameter, 8.2 mm; presence of biopsy, 14/8 cases; biopsy diagnosis rate, 11/14 (78.5%); presence/absence of endoscopic ultrasonography, 11/11 cases; and M/SM/MP, 1/19/1 cases. The TNM classification of the cases was as follows: T1a, 16 cases; T1b, 5 cases; T2, 1 case; N1, 1 case; and M1, 1 case. The treatment was endoscopic mucosal resection/endoscopic mucosal resection with ligation/endoscopic mucosal resection/endoscopic submucosal dissection/surgery/drug therapy in 5/5/7/2/1/1 case. Of 19 endoscopic treatment cases, 15 corresponded to a tumor diameter of ≤ 10 mm, with negative resection margin and vascular invasion as criteria for curative resection, and 3 cases of unknown stump were recognised. In the EMRL group, all cases were negative. In all the cases except the case of other-disease death, it elapsed without recurrence. Both surgical cases showed a positive vascular invasion, and one case was a confirmed N1, but neither of the patients survived without a relapse. In the case with hepatic and bone metastases, medication was administered, and the effect was temporarily effective, but the patient died a year and a half later.

Conclusion: Endoscopic treatments are considered appropriate for rectal NETs with no evidence of ulcer or depression, no apparent metastasis, and not > 10 mm in diameter. Among the treatment options, EMRL is considered useful and well tolerated. However, follow-up observation and case accumulation seem necessary to determine the long-term prognosis in NET, which may recur after years of surgery.

Introduction: Inactivation of TP53 is the most frequent genetic damage in human cancer. In addition, hyperactivation of the RAS pathway is common in many human malignancies (Lung (LC)~40%, pancreatic (PC)>95% and colorectal cancer (CRC)~50%). Despite multiple attempts, targeting these pathways for the treatment of cancer, for example through the development of RAS pathway inhibitors has not proven to be effective thus far. Herein, we propose to exploit the hyperactive RAS pathway and TP53 mutation status of human cancer to deliver targeted antitumor therapy. We had previously reported that a recombinant adenovirus, carrying a pro-apoptotic gene (PUMA) under the regulation of RAS-responsive elements (PY4) effectively suppressed the growth of human cancer cells harboring hyperactive RAS (Giladi et al, 2007). Furthermore, we had shown, both in vitro and in vivo, that replacing the pro-apoptotic gene with a bacterial toxin can improve the efficacy of this system (Shapira et al, 2015).

Aims & Methods: We aimed to establish a tight regulated dual system by expressing a toxin under PY4 elements in cancer cells, while sparing normal cells by expressing the anti-toxin under p53 responsive elements (RGC) specifically in non-malignant cells. Adenoviral vectors carrying the toxin (PY4-MazF-mcherry) and the antitoxin (RGC-MazE-GFP) were designed under the regulation of RAS and p53 responsive elements, respectively. A virus carrying the toxin but lacking the PY4 serves as a control virus. Those three constructs were cloned into a "first generation" $\Delta E1/\Delta E3$ human type5 adenoviral vector. Virus particles were produced, their titer was calculated by the End-Point Dilution Assay and their potency was tested in vitro. Cell death was measured qualitatively by using the fluorescent microscopy and was quantified by the enzymatic MTT assay. HCT116+/+;Rasmut/p53wt and HCT116-/-;Rasmut/p53 mut CRC cell lines, as well as, A549;Rasmut/p53wt and H2030 Rasmut/p53wt LC cells were used for testing the potency and safety of the system

Results: Massive cell death was induced in a dose-dependent manner (~60%; 7.5 MOI) in CRC cells harboring mutated Ras after co-infection with the toxin and the antitoxin viruses. The antitoxin was able to protect ~70% of the cells that were affected by background low level expression of the toxin construct, due to promoter leakage [Fig1]. Similar results were obtained in a colony formation assay and FACS analysis of co-infected LC cells. A549 harboring mutated Ras showed greater sensitivity (~82% early apoptotic cells) compared to H1650 cells harboring WT Ras (~27% early apoptotic cells) [Fig2]. These results indicate that the antitoxin indeed actively protects cells with WT p53.

Conclusion: Exploiting the activated RAS pathway and mutation in p53 holds promise for effective and safe therapy that could specifically target tumor cells while sparing normal tissues.

P1770 USE OF A COMBINATION OF LENTIVIRUS PARTICLES AND A SPECIFIC PEPTIDE FOR ERADICATION OF CD24-EXPRESSING

N. Arber¹, F. Eynat², L. Abraham², S. Shapira¹

¹Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel

²Kaplan Medical Center, Hadassah-Hebrew University, Rehovot/Israel

Contact E-mail Address: nadira@tlvmc.gov.il

Introduction: Lentiviral replication is driven by a molecular motor consisting of the three viral enzymes: the reverse transcriptase, protease and integrase (IN). The genomic RNA of the virus is used to produce a copy of viral DNA by reverse transcription, and the integrase catalyses the covalent insertion of this DNA into the chromosomes of the infected cells. Integration of the viral DNA –which is flanked by LTR sequences- proceeds through a combination of cleavage and ligation resulting in the appearance of double-stranded breaks in the host genome that eventually leads to apoptosis. CD24 is a heavily glycosylated cell-surface GPI-anchored protein. We have previously shown that CD24 is an important player in the multistep process of GI carcinogenesis (Gastro 2006, Clin Can Res 2007, Can Res 2008) as well as in many other human malignancies (Cervical, Bladder, Esophageal squamous cell carcinoma, Glioma, Breast etc.).

Aims & Methods: We aimed to develop and specifically direct lentiviruses towards target cells for effective and selective eradication by stimulation of the viral integrase. Integrase derived peptides (designated as INS) were synthesized as well as control peptide. Humanized Anti-CD24 antibody fragment (scFv) was engineered and fused to the lentivirus envelope. Cell death was measured qualitatively by using fluorescent microscopy and was quantified by the enzymatic MTT assay. Human colorectal, pancreatic, lung and triple negative breast cancer cells were used for testing the potency of the lentiviral-based system.

Results: INS was able to stimulate the viral Integrase enzyme in test tubes and in viral infected cells. The anti-CD24 antibody fragment has a high affinity and specificity toward CD24, allowing targeted precision of viral transduction (Figure 1). These Lentivirus particles contain DNA molecules with flanked LTRs allowing their integration into the CD24-expressing target cells DNA and formation of double-strand breaks due to the action of the particles integrase whose activity was stimulated by the IN derived peptides. Massive cell death was induced upon exposure of the infected cells to the INS peptide compared to the control peptide.

Conclusion: The use of IN derived peptides together with the CD24-targeted lenti-therapy approach suggest a novel strategy to specifically promote death of CD24-expressing cancer cells.

P1771 ILF3 STABILIZES AND ACTIVATES EGFR-MEDIATED G9A PATHWAY FOR MAINTAINING CANCER STEMNESS PROPERTY IN EGFR-POSITIVE CANCERS

C. Cheng¹, A. Ho²

¹Hematology And Oncology, Mackay Memorial Hospital, Taipei/Taiwan

²Division Of Gastroenterology, Cheng Hsin General Hospital, Taipei/Taiwan

Contact E-mail Address: aisheng49@gmail.com

Introduction: A specific inhibitor of interleukin enhancer binding factor 3 (ILF3), YM155, suppresses EGFR phosphorylation and significantly inhibits the formation of cancer stemness tumorspheres in vitro, suggesting that ILF3 as an oncogene participates in the maintaining of cancer stem cell property through stabilizes EGFR-mediated stemness pathway. Since cancer stemness cell is the leading reason for tumor recurrence in the tumor repressive treatments, and EGFR enhances the formation of cancer stemness, it is worthy of investigating the function of ILF3 for maintaining the cancer stemness property in the EGFR-positive cancers.

Aims & Methods: The tumorspheres derived from EGFR-wild-type and KRAS-mutant colorectal HCT116 and lung A549 cells expressing higher cancer stemness markers, *CD133*, were used as cancer stemness models in this study. RNAseq was utilized to search for the putative genes involving in the formation of tumorspheres as the cancer stemness markers. Meanwhile, the differentiating stemness markers were also compared between ILF3-knockdown and the control shLuc cells. Then, the protein level and phosphorylation of EGFR were investigated in the YM155-treated and ILF3-knockdown cells for validating that EGFR was regulated and stabilized by ILF3. The ILF3-knockdown cells were also transplanted into SCID mice for evaluating the function of ILF3 in vivo.

Results: We found that higher EGFR autophosphorylation (Y1068) in HCC116- and A549-derived tumorspheres compared to the parental cells. The results of RNAseq evaluated that *CD133* was a positive stemness marker, whereas *MARCH4* as a negative marker. Knockdown of ILF3 reduced the cell proliferation in A549 cells in vitro and in vivo, demonstrating that ILF3 was an oncogene involving in cancer cell survival. Moreover, inhibition of ILF3 by YM155 blocked the autophosphorylation of EGFR and inhibited the EGFR-downstream G9a activation, leading to a reduction of stemness property. Moreover, Knockdown of G9a reduced the *CD133* expression and increased *MARCH4* expression, revealing that G9a was essential for maintaining for cancer stemness property in the EGFR-positive cancers.

Conclusion: In conclusion, this study demonstrated that ILF3 played an important role maintaining the EGFR-mediated cancer stemness property in HCC116 and A549 EGFR-positive cancer cells. We demonstrated that ILF3 stabilized and phosphorylated EGFR to enhance the activation of G9a, leading to increasing *CD133* and decrease *MARCH4* expressions. Therefore, we suggested that the ILF3 inhibitor, YM155, was potential for utilization in cancer therapy against the EGFR-positive cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1772 EFFICACY AND SAFETY OF TWELVE CHEMOPREVENTIVE REGIMENS FOR THE RECURRENCE OF COLORECTAL ADENOMAS: A NETWORK META-ANALYSIS

H. Chen

Jiangsu Province Hospital, Nanjing/China

Contact E-mail Address: chenhan068@hotmail.com

Introduction: Although various pharmacological agents have been trialed for recurrent colorectal adenomas, their comparative effectiveness remains unknown. We conducted both direct and indirect comparisons of twelve chemopreventive agents for recurrent colorectal adenomas.

Aims & Methods: MEDLINE, EMBASE, Scopus, Web of Science, and Cochrane Central Register of Controlled Trials, and ClinicalTrials.gov were searched up to May 1, 2016. RCTs were assessed by a random-effects model within a Bayesian framework. Agents for each outcome were ranked by surface under the cumulative ranking area (SUCRA). This study is registered with PROSPERO, number CRD42016041923.

Results: 33 RCTs were eligible, enrolling 44,647 participants treated by twelve regimens: 9 aspirin and other NSAIDs, 11 antioxidants, 4 dietary supplements, 3 calcium, 4 folic acid, 2 calcium plus antioxidants, 2 aspirin plus folic acid and 1 each metformin, ursodeoxycholic acid (UDCA), aspirin plus calcium with vitamin D, and difluoromethylornithine (DMFO) plus sulindac. For recurrent colorectal adenomas, findings were significantly better for sulindac plus difluoromethylornithine than other tested agents. Aspirin/NSAIDs was more effective than placebo in both pairwise (OR, 0.73 [95%CI, 0.59 to 0.90]) and NMA (OR, 0.75 [95%CrI, 0.57 to 0.98]). Subgroup analysis showed the highest probability of aspirin (≤ 160 mg/L) to be the most efficacious agent among all NSAIDs (SUCRA = 71.7%). For safety profiles, the top three ranked agents were metformin (86.7%), antioxidants (82.0%) and dietary supplements (65.9%), but none reached statistical significance when compared with placebo. Aspirin/NSAIDs performed the worst (16.4%) with significantly more serious adverse events than placebo (pairwise: OR, 1.25 [95%CI 1.14 to 1.38]); NMA (OR, 1.26 [95%CrI 1.12 to 1.44]). Other regimens were not significantly different to each other in both pairwise and network comparisons, these agents include antioxidants, dietary supplements, calcium as well as folic acid.

Conclusion: For individuals with presumed increased risk of CRC, moderate-to-low dose aspirin and sulindac-associated combination therapy are both effective for recurrent colorectal adenomas. Future studies are required to provide more precise estimates of the optimal NSAIDs with an effective dose and low adverse events. We also suggest the further evaluation of NSAIDs-associated combination regimens and other novel agents (e.g. metformin) in the chemoprevention of CRC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1773 COX-2 MEDIATES RESISTANCE TO EICOSAPENTAENOIC ACID IN COLORECTAL CANCER CELLS

M. Volpato, L. Coletta, M.A. Hull

Leeds Institute Of Biomedical And Clinical Sciences, University of Leeds, Leeds/United Kingdom

Contact E-mail Address: m.volpato@leeds.ac.uk

Introduction: The omega-3 polyunsaturated fatty acid eicosapentaenoic acid (EPA) has anti-colorectal cancer (CRC) activity. Several mechanisms of action have been described, including lipid mediators metabolism and surface receptor signalling. Aspirin is a known cyclo-oxygenase (COX) inhibitor with cancer preventive properties.

Aims & Methods: The aim of this study was to identify possible mediators of resistance to EPA in CRC cells. Human and mouse CRC cell lines were screened

for their sensitivity to EPA by MTT assay *in vitro* (n = 3). The MC38/MC38r and CT26 wt/COX2 CRISPR/Cas9 knocked out (COX2ko, gifted by Dr Zelenay, Manchester, UK) isogenic mouse CRC line pairs were used to further investigate the molecular basis of resistance to EPA. COX-1/2 protein expression was measured by western blot *in vitro* and by immunohistochemistry *in vivo*. Aspirin was used at a non-cytotoxic dose of 500µM to provide COX inhibition in combination studies (n = 3). *In vivo* studies were performed using female CD1-nude mice, fed diets supplemented with 7%(v/w) control corn oil, 6.1%(v/w) EPA-triglyceride oil + 0.9%(v/w) control oil, 600 ppm aspirin or a combination of both EPA and aspirin (n = 14) for 4 weeks. After the first 2 weeks, 5x10⁶ MC38 and MC38r cells were injected as subcutaneous tumours on the right flank, before sacrifice 2 weeks later. Tumour volumes were measured by calipers.

Results: The human and mouse CRC cell lines tested displayed varying levels of sensitivity to EPA (IC₅₀ range: 36 ± 1 µM to 242 ± 2 µM). HT29 cells were sensitive human CRC cells (IC₅₀ = 89 ± 1 µM) and CaCo2 cells were the least sensitive (IC₅₀ = 228 ± 1 µM). In particular, MC38 mouse CRC cells were the most sensitive to EPA (IC₅₀ = 36 ± 1 µM) of all cell lines tested, whilst isogenic MC38r cells were 3.9-fold more resistant (IC₅₀ = 163 ± 1 µM). We found a strong increase in COX1 and COX2 protein expression in EPA-resistant MC38r compared to MC38 cells. Genetically modified CT26 COX2ko cells were used to assess whether COX2 specifically played a role in EPA resistance. Indeed, CT26 COX2ko cells were 3 times more sensitive to EPA (IC₅₀ = 78 ± 1 µM) than parental CT26 cells (IC₅₀ = 242 ± 2 µM, high COX2 expression). Aspirin was then evaluated as a potential combination treatment with EPA. A decrease in IC₅₀ values for EPA was observed in 8 out of 10 CRC cell lines tested (1.1-fold to 4-fold increase in sensitivity to EPA). Whilst the response of MC38 cells to EPA was increased 2-fold [IC₅₀ (EPA + aspirin) = 19 ± 1 µM], MC38r cell response was increased 3.8-fold [IC₅₀ (EPA + aspirin) = 42 ± 1 µM]. Aspirin increased CT26 wt response to EPA [IC₅₀ (EPA) = 242 ± 1 µM compared with IC₅₀ (EPA + aspirin) = 99 ± 1 µM] but did not affect the EPA response of CT26 COX2ko cells [IC₅₀ (EPA) = 78 ± 1 µM and IC₅₀ (EPA + aspirin) = 84 ± 1 µM]. We measured EPA incorporation in these cells and observed an increased accumulation of EPA in CT26wt cells treated with both EPA and aspirin compared to EPA alone. A similar pattern of response was measured *in vivo*. EPA administration exerted anti-tumour activity in MC38 subcutaneous tumour-bearing CD1-nude mice (n = 14, 37% decrease in mean tumour volumes, p = 0.02), which was not augmented by combination with aspirin. However, EPA alone did not significantly impact on tumour volumes in EPA-resistant MC38r tumour bearing mice whilst the EPA-aspirin combination was associated with a 42% reduction in tumour volume compared with control (n = 14, p = 0.003). Administration of aspirin, alone or in combination with EPA, did not alter COX1/2 protein expression in tumour tissues.

Conclusion: Human and mouse CRC cells display differential sensitivity to EPA *in vitro*. Our data indicate that COX2 mediates resistance to EPA in CRC cells by a mechanism that likely involves EPA substrate utilisation, thereby reducing EPA levels. Aspirin combination sensitises CRC cells to EPA *in vitro* and *in vivo* and may be a clinically relevant candidate for prevention and treatment of CRC in combination therapy.

Introduction: Colorectal cancer (CRC) is the third most common cancer worldwide and accounts for 10% of all newly diagnosed cancers. Although the therapies have dramatically developed, the long-term survival rate of patients with CRC remains low. In recent years, great efforts have been made to identify inflammation-related factors for precise prediction of disease prognosis. Glasgow Prognostic Score (GPS) is such an inflammation-based factor, defined by the combination of the level of serum C-reactive protein (CRP) and albumin, which are indicators of systematic inflammatory response and nutritional status respectively. Growing evidence suggested that GPS was served as an independent prognostic index in a variety of malignant cancers. For patients with CRC, the GPS system was also widely studied, but the results were controversial.

Aims & Methods: To investigate the correlation between GPS and prognosis of patients with CRC to further clarify its clinical significance. A comprehensive search of Pubmed, Embase, Cochrane library, Web of Science, ChinaInfo and Chinese National Knowledge Infrastructure was performed to identify eligible studies, from which the risk of overall survival (OS) and cancer-specific survival (CSS) were extracted. A random-effect model was adopted to combine hazard ratio (HR) and 95% confidence interval (CI). Heterogeneity and publication bias among studies were assessed.

Results: 25 articles with a total of 5660 participants were included. The pooled results indicated that elevated GPS was associated with poor OS (HR = 2.83, 95%CI: 2.00–4.00, P < 0.01) and CSS (HR = 1.94, 95%CI: 1.51–2.49, P < 0.01). This correlation was confirmed both in primary operable and advanced inoperable patients. Increased GPS was also closely related to advanced tumour-node-metastasis (TNM) stage (odds ratio [OR] = 1.44, 95%

CI: 1.010–2.065, $P < 0.05$) and elevated level of serum carcinoembryonic antigen (OR = 2.252, 95% CI: 1.508–3.362, $P < 0.01$). Subgroup analysis revealed a significant association between high GPS and poor survival outcome according to the factors of sample size, study of region and cut-off value of GPS level.

Conclusion: GPS could serve as a reliable predictive index for patients with CRC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1775 COST EFFECTIVENESS OF THE FIRST SURVEILLANCE COLONOSCOPY IN POPULATION WITH ADVANCED COLORECTAL POLYPS OR MULTIPLE POLYPS FROM COLORECTAL CANCER SCREENING PROGRAM

L. Carot¹, M. González¹, M. Batlle¹, A. Buron², X. Bessa Casserras², M. Andreu García², A. Álvarez-Urturi¹

Introduction: The implementation of the CRC screening program has generated an increase in surveillance colonoscopies. However, the intermediate-high risk group that included advanced lesions (size ≥ 10 mm, villous component or high grade dysplasia) or the presence of 3 or more polyps, has a low incidence of metachronous risk lesions when performing colonoscopy at 3 years according to the current recommendations. Identifying predictors of metachronous lesions would provide a better risk stratification and improve the efficiency of surveillance programs.

Aims & Methods: We aimed to identify the cost effectiveness of the first surveillance colonoscopy and the predictive factors of metachronous lesions at 3 years in individuals with advanced lesions or ≥ 3 polyps detected at baseline screening colonoscopy. This was an analysis of all cases with advanced polyps and/or multiplicity from CRC screening program population of Barcelona detected at baseline colonoscopy during the years 2010–2011 and with a performed colonoscopy after 3 years. Epidemiological and clinical data of all individuals were collected as well as the morphological data of all polyps. For the statistical study, a bivariate analysis and logistic regression were performed.

Results: 638 cases were identified, with mean age of 64 years. 342 were men (66.2%). 23.8% required more than one colonoscopy for the complete removal of all the polyps. A complete surveillance colonoscopy at 3 years was performed in 518 cases (82%) with an average surveillance time of 38 months [15–75]. Mean fecal hemoglobin was 440 ng/ml. 51.8% suffered from hypertension, 15% from diabetes mellitus, 46.5% from dyslipidemia and 12.3% from chronic obstructive pulmonary disease. 45.8% of individuals were overweight (BMI ≥ 25) and 34.7% were obese (BMI ≥ 30). Surveillance colonoscopy was normal or with low-risk polyps in 420 cases (80.1%); and advanced polyps or multiplicity were identified in 98 cases (18.9%) 73 advanced adenoma in 59 cases (11.4%), ≥ 3 adenomas in 62 cases (11.9%), ≥ 3 adenomas and/or serrated in 71 cases (13.7%). The presence of ≥ 3 adenomas and/or serrated polyps was the only variable that was associated with increased risk of the diagnosis of advanced adenomatous or serrated lesions in surveillance colonoscopy ($p < 0.001$).

Conclusion: In individuals with advanced polyps and/or multiplicity the incidence of metachronous risk lesions at 3 years is low. Assessment a quality baseline colonoscopy with complete removal of all the polyps could allow to increase the interval of surveillance, maintaining and ensuring the compliance of the surveillance at 3 years in the cases with multiplicity in the basal colonoscopy

²Humanitas Research Hospital, Rozzano/Italy

Contact E-mail Address: roberta.maselli@humanitas.it

Introduction: Colorectal Endoscopic Submucosal Dissection (ESD) is recommended for superficial neoplastic lesions at high risk of submucosal invasion. ESD allows an en-bloc resection but ESD experience is still limited in Western countries.

Aims & Methods: The aim of this retrospective study was to evaluate technical and clinical outcomes of colorectal ESD, in a single tertiary European center. We retrospectively analyzed all consecutive patients treated by ESD for colorectal lesion at Humanitas Research Hospital (Milan, Italy) from January 2011 to September 2016. The primary outcomes were technical success, defined as en-bloc resection and clinical success, defined as curative resection (R0) without need for surgery. Secondary study outcomes were complication rate and adenoma/carcinoma recurrence. Complications were divided in early (≤ 24 hours) and delayed (> 24 hours) and included bleeding and perforation. Recurrences were identified as the presence of adenoma or carcinoma at the endoscopic follow-up performed at 6 months, 1, 3 and 5 years. Data were analyzed by STATA 14 statistical software.

Results: A total of 185 lesions in 185 patients (M/F 97/59, mean age 67.6 ± 11.5). Lesions were located in the rectum (64.3%), left colon (9.7%), transverse (11.9%) and right colon (14%). Mean lesion size was 39.3 ± 16.7 mm. Histology revealed low-grade dysplasia (LGD) in 64 (34.6%), high-grade dysplasia (HGD) in 78 (42.2%) and adenocarcinoma in 42 (22.7%) cases. Only 1 NET (0.5%) was found. En bloc resection was achieved in 88% of lesions. Clinical success (R0) was obtained in 84.8% of patients. The remaining 28 patients (15.2%) needed surgery for unfavorable histology. A total of 12 complications were reported: 10 early complications (8 perforations and 2 bleeding) and 2 delayed complications (1 bleeding and 1 perforation). All but one adverse events were managed endoscopically. Surgery was required in the only case of delayed perforation. All patients untreated with surgery ($n = 156$) underwent follow-up evaluation. In particular, all patients had 6 months follow up, 97 patients had 1 y follow-up, 26 patients had 3 y follow-up, 9 patients had 5 y follow-up. Adenoma recurrences were found in 3.8% at 6 months and 2% at 1 year. We did not find any adenoma recurrence at 3 and 5 years. No cancer recurrence occurred in the follow-up period.

Conclusion: ESD is a feasible strategy to manage superficial colorectal tumors. This study demonstrates favorable technical and short-term clinical outcome of colorectal ESD, but further studies are needed to confirm the long-term efficacy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1777 POPULATION-BASED COLORECTAL CANCER SCREENING IN THE CZECH REPUBLIC—FIRST RESULTS OF THE NEW PROGRAM SETTINGS

Introduction: The organized non-population based National Colorectal Cancer (CRC) Screening Program in the Czech Republic has been running since year 2000. In January 2014, the transition to population based setting has been implemented. Currently, the annual immunochemical FOBT (FIT) is offered at the age 50–54, followed by FIT+ colonoscopy, if positive. In age of 55, there is a choice of either FIT biannually or screening colonoscopy in 10 years' interval.

Aims & Methods: Main aim was to assess the impact of the first 30 months of the population-based CRC screening program on the target population participation and colorectal neoplasia detection. The data from National Reference Center (health insurance companies database) and Preventive Colonoscopies Registry in years 2013 (non-population based settings) and 2014–2015 (population-based settings) were evaluated and compared.

Results: In year 2014, there were 1,500,897 individuals (53% of all CRC screening target population) invited to FIT or colonoscopy, with 17.3% response. It resulted in the coverage increase by 4.3 percent points in comparison with year 2013 (31.5% in year 2014). This trend continued in year 2015 with the target population participation at 33.1%. This has influenced the increase of number of detected adenomas (by 42%) and cancers (by 20%) detection in year 2014. In year 2015, all the results remained stable (detailed results in the table).

Year	Colonoscopy (numbers)	Adenomas (numbers)	Ratio	Cancers (numbers)	Ratio
2013	26 940	10 126	37.6%	867	3.2%
2014	38 128	14 416	37.8%	1 042	2.7%
2015	37 330	14 081	37.7%	969	2.6%

Conclusion: The transition to population-based program resulted in the improvement of target population participation followed by increase in colorectal neoplasia detection.

Disclosure of Interest: All authors have declared no conflicts of interest. Supported by the projects MO1012 and PRVOK-P27/LF1/1

P1778 LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY CANCER AND HIGH GRADE DYSPLASIA IN COLORECTUM

P. Zhou¹, T. Chen¹

¹Endoscopy Center, Zhongshan Hospital, Fudan University, Shanghai/China

Contact E-mail Address: chentao66@yahoo.com

Introduction: Although endoscopic submucosal dissection (ESD) is a widely accepted treatment for colorectal neoplasia, little is known about large consecutive studies evaluating long-term outcomes of early cancer and high grade dysplasia. We investigated the efficacy and safety of ESD for early cancer and high grade dysplasia in colorectum and evaluated the long-term outcomes, including local recurrence and metastasis.

Aims & Methods: We performed a retrospective analysis of data collected from 514 consecutive patients with 520 colorectal early cancer and high-grade dysplasia treated with ESD between January 2007 and December 2013. Histology and patient data were collected during an average follow-up time of more than 5 years to determine tumor stage and type, resection status, complications, tumor recurrence, and distant metastasis.

Results: The overall rates of *en bloc* resection, complete resection, R0 resection, major complications were 94.4%, 91.3%, 89.2% and 2.1%, respectively. Large tumors and snare-assisted ESD were independent factors of piecemeal resection. ESD of colon tumors increased the risk for complications. During the follow-up period, all patients remained free from metastasis. However, local recurrence occurred in 4 patients (0.8%); large tumors and piecemeal resection were risk factors.

Conclusion: ESD is effective and safe for resection of early cancer and high grade dysplasia in colorectum and long-term outcomes are favorable. ESD is indicated for the treatment of colorectal early cancer and high grade dysplasia to obtain curative resection and prevent the local recurrence.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1779 LOW UPTAKE OF PSYCHOLOGICAL THERAPIES AMONG PATIENTS WITH IRRITABLE BOWEL SYNDROME IN SECONDARY CARE

O. Craig¹, C. Black¹, L. Houghton², A.C. Ford¹

¹Leeds Gastroenterology Institute, St. James's University Hospital, Leeds/United Kingdom

²Leeds Institute Of Biomedical & Clinical Sciences, St.James's University Hospital, Leeds/United Kingdom

Contact E-mail Address: ofcraig@gmail.com

Introduction: Patients with irritable bowel syndrome (IBS) often have co-existent mood disorder and psychological illness. Meta-analyses of randomised controlled trials consistently demonstrate that psychological therapies, such as cognitive behavioural therapy (CBT) and hypnotherapy, are effective treatments for IBS. In the UK the National Institute for Health and Care Excellence (NICE) recommends considering the use of these in patients with no response to pharmacological therapies, and for refractory symptoms.

Aims & Methods: We performed a cross-sectional survey to examine willingness of patients with IBS to engage with psychological therapies. We collected complete symptom data from consecutive, unselected referrals to secondary care seen in a specialist IBS clinic. All participants completed the validated Rome IV questionnaire for IBS, the IBS severity scoring system (IBS-SSS), the hospital anxiety and depression scale (HADS) to assess mood, and the patient health questionnaire-12 (PHQ-12) to examine somatoform-type behaviour. They also provided their opinion on possible treatment options, and were asked to rank medical therapies, dietitian input, psychological therapies, including CBT and hypnotherapy, and explanation of the condition and/or reassurance in order of preference.

Results: Among 93 adults with confirmed IBS (74 (79.6%) female, mean age 36.0 years (range 16 to 77 years)), 35 (37.6%) had high levels of anxiety, 22 (23.7%) had high levels of depression, and 23 (24.7%) had severe levels of somatoform-type behaviour. Despite this, only 10 (10.8%) of 93 patients ranked psychological therapies as their first-choice treatment option. In total, 8.8% of patients with high levels of anxiety ranked psychological therapies as their first-choice treatment option, versus 13.2% without ($P=0.64$), 9.5% of those with high levels of depression, versus 12.1% of those without ($P=0.91$), and 17.4% of patients with severe somatoform behaviour, versus 9.2% of those without ($P=0.26$). Those with severe symptoms according to the IBS-SSS were no more likely to select

psychological therapies as their first-choice treatment option than those with mild or moderate symptoms (7.7% versus 21.7%, $P=0.10$).

Conclusion: Despite high levels of psychological comorbidity and NICE recommendations, patients with IBS in a specialist clinic were generally reluctant to consider psychological therapies such as CBT or hypnotherapy. Those with anxiety, depression, somatoform-type behaviour, or severe symptoms were no more willing to consider these therapies than those without.

P1780 GUT SYMPTOMS AND TRANSIT DISTURBANCE IN PARKINSON'S DISEASE ARE PAN-ENTERIC BUT NOT UBIQUITOUS: A WIRELESS MOTILITY CAPSULE STUDY

V. Passananti, N. Zarate Lopez, R. Sweis, A. V. Emmanuel

GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassananti@gmail.com

Introduction: Symptoms of gastrointestinal dysfunction are among the most common non-motor complaints in Parkinson's patients. These may involve muscles from the oropharynx to the anorectum, and the autonomic and enteric nervous system are often involved, resulting in secondary bowel dysmotility.

Aims & Methods: The objectives of this study were to evaluate a technology measuring the spectrum of gut dysfunction, the Wireless Motility Capsule (WMC), in Parkinson's disease. We also wanted to correlate transit measures with gastrointestinal symptoms. Fifteen PD patients and 7 controls (table1) were included. PD severity were scored with the modified Hoehn and Yahr (H&Y) staging scale. GI symptom burden was identified by Wexner constipation score and Gastroparesis Cardinal Symptom Index (GCSI). Acidity, motility and transit data were obtained, as standard, by WMC. All medications affecting pH and motility, including L-dopa, were discontinued for 5 days before and for the duration of the WMC study. We analyzed data about gastric emptying time (GET), small bowel transit time (SBTT), colonic transit time (CTT) and whole gut transit time(WGTT).

Results: One patient could not swallow the capsule, and of the 14 patients completing the study, 8 reported GI symptoms. Compared to non-symptomatic patients, those with GI symptoms showed significant delayed transit in the stomach, colon and whole gut (table 1). However, small bowel transit did not significantly differ. GI dysfunction was not correlated with H&Y score in this small study. GCSI and Wexner constipation scores were correlated, suggesting a pan-enteric problem in symptomatic individuals. There was a significant correlation between the Wexner constipation score and CTT in all patients ($p < 0.01$) but not GCSI and GET ($p > 0.10$). The results of Wireless Motility Capsule did not differ between non-symptomatic PD and controls.

	Non symptomatic PD (n = 6)	Symptomatic PD (n = 8) [p value vs Non symptomatic PD]	Controls (n = 7) [p value vs Non symptomatic PD]
Sex (M:F)	5:1	6:2	5:2
Age	61.2 ± 10.9	69.6 ± 13.4 [0.2744]	56.8 ± 13.1 [0.0924]
GCSI	3.3 ± 1.5	22.6 ± 9.6 [0.0017]	2.4 ± 1.4 [0.5704]
Wexner	2.2 ± 2.0	14.3 ± 3.2 [0.0003]	2.1 ± 3.0 [0.6428]
GET	2.74 ± 1.05	5.18 ± 0.58 [0.0007]	2.58 ± 1.14 [0.4713]
SBTT	4.08 ± 0.71	4.17 ± 0.34 [0.7193]	4.10 ± 0.40 [0.7294]
CTT	27.44 ± 7.89	57.82 ± 30.61 [0.0426]	28.3 ± 6.90 [0.5156]

Conclusion: We have shown that Parkinson's patients with gut symptoms have both upper and lower complaints. Symptomatic PD patients also have markedly delayed transit times throughout the whole gut compared to asymptomatic PD patients and controls. Whilst severity of constipation is related to delayed colonic transit no such relationship is present between gastroparesis symptoms and gastric emptying. The implication is that treating symptomatic Parkinson's patients should address the whole gut, whether with prokinetics or dual therapy.

Introduction: Bloating and abdominal distension are common and bothersome symptoms and a frequent complaint of patients affected by functional gastrointestinal disorders (FGID). Recent studies demonstrated that an impairment in

the handling of gas is a relevant underlining mechanism in FGID patients with bloating. However, solid data on defecation pattern in these patients are lacking.

Aims & Methods: Our aim is to study the relationship between the defecation pattern, the severity of bloating and the abdominal girth measurements in FGID patients consulting for bloating as primary complain with/without visible abdominal distension unresponsive to diet advice. We performed a prospective, multi-center study of patients with severe abdominal bloating (VAS score ≥ 24 on a 100-mm scale) as primary complain with/without visible abdominal distension. Patients were recruited at 4 gastroenterology outpatient clinics in Italy. Comorbid FGID were grouped according to Rome III criteria. All patients were prescribed a lactose-free diet supplemented by dietary advice according to the NICE guidelines for two weeks. A belt around the abdomen at standardized sites provided assessment of abdominal girth measurements. During the 2-week run-in period patients completed a daily diary log including abdominal bloating and pain/discomfort scores (100-mm VAS), Bristol Stool Form and stool frequency. At randomization visit, all patients filled in a questionnaire on adequate relief of bloating on a Likert scale and a further abdominal bloating 100-mm VAS. A belt around the abdomen at standardized sites provided assessment of abdominal girth two hours after a meal. All patients reporting insufficient adequate relief of abdominal bloating at the end of the run-in period underwent a standardized balloon expulsion test (BET) scored as either successful or failed. A straining questionnaire was also administered.

Results: 76 patients (66 female, 39.8 \pm 12.2 mean age, 6 IBS-D, 6 IBS-M, 30 IBS-C, 9 IBS-U, 6 FC, 16 FB, 3 FD) completed the 2-week run-in period. A significant negative correlation was found between adequate relief and both bloating and abdominal girth changes ($r = -.53$ and $-.52$, $p < 0.001$, respectively). 53/76 (70%) patients reported inadequate relief (worse or no improvement). Among the non-responders the vast majority (68%) failed the BET. Multiple regression analysis showed that BET (successful or failed), as dependent variable, was significantly related to bloating severity. No relationship was demonstrated for abdominal girth changes, FGID diagnosis and straining questionnaire.

Conclusion: In this prospective, multicenter trial simple diet advice was of benefit in approximately 30% of FGID patients consulting for severe bloating. In the non-responders outlet dysfunction was prevalent and correlated with subjective bloating perception. The study is ongoing, but our data may support bowel retraining as potential treatment option for functional bloating.

Introduction: Faecal Incontinence (FI) is a common and socially disabling condition, more prevalent among females over 50 years old. Detailed anatomical and physiological assessment of each patient is important to determine the correct cause of FI and selection the most appropriate therapy. Conventional and High Resolution (HR) Anorectal Manometry (ARM) is a useful tool to categorize anal and/or rectal dysfunction in addition to provide physiological assessment of both anal sphincters and rectum.

Aims & Methods: To evaluate symptoms and anorectal function of patients affected by FI, we included 358 patients with FI (77% female (F) and 23% men (M), mean age 63 (range 22–92 year) referring to the outpatient unit of Digestive Pathophysiology of S. Giovanni-Addolorata Hospital, Rome from January 2006 to December 2016. Clinical presentation (history, symptom profile and severity) and anorectal physiological evaluation (digital examination, manometry, rectal sensory testing, balloon evacuation test) were analyzed. The manometric parameters obtained with conventional and HR-ARM were: resting pressure, squeeze pressure, rectal compliance, rectal sensibility and the anorectal pattern during the defecatory maneuvers.

Results: 114 out of 358 patients (32%) reported both FI and difficulty evacuating stools. 168 with FI had also urinary incontinence UI (47%). Proctological surgery (n 122, 34%), pelvic surgery (n 77, 21%) and traumatic anal or vaginal history (n 144, 40%) were statistically associated with FI ($p \leq 0.05$). Normal manometric parameters were found in 16 patients (4%). Manometric alterations observed were: internal anal sphincter (IAS) dysfunction: 228 (64%); isolated external anal sphincter (EAS) dysfunction: 274 (76%); combined sphincter dysfunction IAS and EAS: 198 (55%); isolated dyssynergic defecation: 100 (28%); rectal hypersensitivity: 130 (36%).

Conclusion: In our study, in accordance with the literature, we observed a female prevalence in FI. FI is significantly associated with UI. This may be expired by risk factors in common with these clinical conditions. In effect FI is significantly associated with previous proctological/pelvic surgery and traumatic anal/vaginal delivery. Furthermore, patients with FI referred difficulty evacuating stools, too. In fact in patients with dyssynergic-type constipation, the FI may be confused with an encopresis. Finally we observed these prevalent manometric alterations: combined dysfunction IAS and EAS, and rectal hypersensitivity. Manometric findings could help physicians to identify appropriated patients for a biofeedback therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Bile acid malabsorption (MAB) is a common and frequently under-investigated cause of chronic diarrhoea. Most of the cases of chronic diarrhoea after excluding organic disorders are labelled as functional diarrhoea or irritable bowel syndrome (IBS). The most commonly used diagnostic test is Selenium homocholic acid taurine (SeHCAT) scan due to its sensitivity, specificity, safety and low cost. However this test is not frequently used in the algorithm for the diagnosis of chronic diarrhoea.

Aims & Methods: We aimed to evaluate the usefulness of SeHCAT scan in evaluating patients with chronic diarrhoea and identify potential risk factors associated to MAB. We retrospectively reviewed all patients who had SeHCAT scan between June 2014 and October 2016 in a University Hospital. BAM was defined as SeHCAT retraction of less than 15%. We collected the following variables: demographic characteristics, IBS-D Rome III criteria, duration of diarrhoea (months), stool culture, parasitic investigation of stool specimens, background of comorbid gastrointestinal and other comorbid conditions, positive HLA-DQ2 and DQ8 haplotype.

Results: 137 patients referred to clinic for chronic diarrhoea underwent SeHCAT testing over the reviewed period. 42M; 95F, median age 46 y (95% C.I. 44.0–50.1), median BMI 25.34 kg/m² (95% C.I. 24.88–27.00), 70.4% of patients met IBS-D Rome III criteria, median duration of diarrhoea 48 months (95% C.I. 43.10–59.24). Background of co-morbid gastrointestinal conditions 45.3% (62/136), other co morbid conditions 55.3% (73/136). History of previous positive stool culture 1.5% and parasitic investigation of stool specimens 13% (17/131). Percentage of positive HLA-DQ2 and DQ8 haplotypes were 27.8% (35/126) and 10.2% (13/127), respectively. SeHCAT test was positive for BAM in 48.9% (67/137); 25.4% (mild 10–15%); 31.3% (moderate 5–10%), and 43.3% (severe < 5%). Patient characteristics between positive and negative SeHCAT test were similar (Table 1). Interestingly, patients with SeHCAT test exhibited longer periods of diarrhoea.

Table 1

	Positive SeHCAT test	Negative SeHCAT test
Sex (M/F)	30/37	12/58
Age y (median; 95% C.I)	48.00 (44.52–53.4)	40.50 (40.69–49.4)
BMI (median; 95% C.I)	26.84(25.56–28.78)	23.64(23.31–25.98)
Duration of diarrhoea (months; median; 95% C.I)	60.00 (43.51–66.95)	24.00 (35.53–58.34)
IBS-D Rome III criteria (%)	67.2%(45/67)	71.4%(50/70)
Abdominal surgery (%)	34.3%(23/67)	14.3%(10/70)
Cholecystectomy (%)	14.9% (10/67)	0
Gastrointestinal conditions (%)	41.8%(28/67)	48.6%(34/70)
Other co morbid conditions (%)	57.1%(36/63)	53.6%(37/69)

(continued)

Table 1 Continued

	Positive SeHCAT test	Negative SeHCAT test
HLA-DQ2 Haplotype (%)	23.8%(15/63)	31.7%(20/63),
HLA-DQ8 Haplotype (%)	14.1%(9/64)	6.3%(4/63)

Patients who exhibited MAB (confirmed by SeHCAT test) were treated with colestyramine, 37.1% (23/67) exhibited partial response, 33.9% (21/67) exhibited total response, 3.2% (2/67) exhibited no good tolerance, we had no information in 21%(13/67).

Conclusion: SeHCAT scanning must be considered as a diagnostic tool for the for the diagnosis of chronic diarrhoea, specially in those patients with long-standing diarrhoea.

Introduction: The cause of IBS is uncertain; however, food intolerance shares many features with this condition. Consumption of FODMAPs has been shown to induce IBS-type symptoms (Shepherd 2008) and clinical trials have shown that a low FODMAP diet can improve symptoms in this patient group (Halmos 2014). However, FODMAP intake is not higher in IBS than in health (Bohn 2013) and it is not proven that the outcome of low FODMAP diet is better than standard dietary advice in this condition (Bohn 2015). Recent, experimental research has shown that psychological factors are associated with increased postprandial symptoms in IBS patients (Zhu 2013, Van Oudenhove 2016). This study was designed to assess the relative importance of, and interaction between, psychiatric disease, social stress and diet in the aetiology of IBS in the general community.

Aims & Methods: This population based study tested the hypothesis that high FODMAP intake increases the risk of IBS more in individuals with psychiatric disease and/or life event stress than other members of the community.

Subjects aged 16–74 were randomly selected from five South-Chinese communities. All subjects completed questionnaires by face-to-face inquiry with investigators including demographic information, gastrointestinal symptoms (Rome III), dietary intake (food frequency chart validated in Chinese community), psychiatric disease (HADS), life event stress (LES) and quality of life (SF-8).

Results: From 1999/2115 (94.7%) members of the community that completed study questionnaires, 117 (5.9%) had IBS by Rome III criteria. The IBS group ingested less lactose than the "No-IBS" group ($P=0.024$). Intake of other FODMAPs was similar in both groups ($P=0.346$). Compared to the "No-IBS" group, individuals with IBS had a greater likelihood of depression (OR 1.5 (0.97–2.32); $p=.05$), anxiety (2.84(1.84–4.39), $p<0.001$), recent life event stress (1.5(1.03–2.20); $P=0.03$) or medical and/or surgical co-morbidity (OR 2.90(1.30–5.45), $P<0.001$). The IBS group also had lower quality of life ($P<0.001$). Joint risk analysis identified high intake of total FODMAP intake as a risk factors for IBS *only* in subjects with psychiatric disease and/or life event stress (table). Similar effects were seen for individual symptoms, in particular bloating (OR 2.4(1.25–4.60), $p<0.008$). Increased risk of IBS was identified with ingestion of high intake of individual FODMAPs (e.g. fructose, fructans, lactose) in combination with psychosocial factors, but not with sucrose (control) in any group.

Table: Joint effects of psychiatric disease, life stress & total FODMAP intake on relative risk of IBS in community

Psych Disease	FODMAP	Life Stress	IBS	No IBS	Adjusted* OR	p-value
No	Low	Low	19 (5.1)	356 (94.9)	1.0	–
"	"	High	23 (6.8)	315 (93.2)	1.2 (0.6–2.4)	0.530
"	High	Low	14 (3.5)	383 (96.5)	0.6 (0.3–1.3)	0.213
"	"	High	16 (4.5)	342 (95.5)	0.9 (0.5–1.9)	0.886
Yes	Low	Low	9 (7.6)	109 (92.4)	1.6 (0.7–3.8)	0.274
"	"	High	16 (9.5)	152 (90.5)	1.9 (0.9–3.9)	0.094
"	High	Low	5 (4.9)	97 (95.1)	1.0 (0.4–2.9)	0.932
"	"	High	15 (10.5)	128 (89.5)	2.3 (1.1–4.8)	0.029

*Adjusted variables: age, sex, marital status, education, job, income, smoking, drinking, and medical history.

Conclusion: FODMAP intake was similar in IBS and No-IBS groups in the community (lactose intake was lower in IBS subjects, likely due to avoidance of dairy products (Long 2017)). However, as expected, IBS patients in the community had a greater likelihood of psychiatric disease, life event stress and clinical co-morbidity. Joint effects analysis demonstrated that high FODMAP intake alone was not associated with abdominal symptoms; however, IBS was more common in those with a high FODMAP intake and concomitant psychosocial factors known to increase visceral sensitivity to digestive dysfunction (Zhu 2013). (ClinicalTrials: NCT01286597)

P1785 CHARACTERIZING IBS PATIENTS WITH ANXIETY OR DEPRESSION

I. Pontén¹, M. Simrén¹, H. Törnblom¹

¹Department Of Internal Medicine And Clinical Nutrition, Sahlgrenska Academy, University of Gothenburg, Gothenburg/Sweden

Contact E-mail Address: irina.ponten@gu.se

Introduction: A large proportion of patients with irritable bowel syndrome (IBS) suffer from anxiety or depression, but the associations with pathophysiological findings and overall symptom reporting are not clear.

Aims & Methods: We included 772 patients with IBS (Rome III criteria) who attended a university hospital-based outpatient clinic specialized in functional GI disorders between 2005 and 2015. The patients underwent examinations to investigate oro-anal transit time (OATT) and visceral sensitivity (rectal balloon distension and a lactulose challenge test), and they also completed questionnaires to assess anxiety and depression (HAD), overall IBS symptoms (IBS-SSS), bowel habits (BSF), quality of life (IBSQOL), extraintestinal somatic symptoms (PHQ-12), sense of coherence (SOC), fatigue (MFI), GI-specific anxiety (VSI) and physical and sexual abuse.

Results: Based on validated HAD cut-off levels (≥ 8), anxiety and depression were present in 55% and 26% of the IBS patients, respectively. More women were anxious ($p<0.001$), but for depression no gender differences were detected ($p=0.76$). IBS patients with anxiety or depression were younger ($p<0.001$, $p=0.01$), and more commonly reported sexual and/or physical abuse ($p<0.001$) than IBS patients without anxiety or depression. The presence of anxiety or depression did not differ between IBS subgroups based on the predominant bowel habit ($p=0.41$, $p=0.18$). For an overview of comparisons of data from questionnaires and pathophysiological examinations, see table 1. Both the presence of anxiety and of depression were associated with reports of more severe GI and extraintestinal symptoms, GI-specific anxiety, fatigue, and lower sense of coherence. Regarding pathophysiological examinations, the findings were more inconsistent. OATT was similar between groups, as was stool form and frequency. Visceral sensitivity tended to be higher in patients with anxiety, and depressed patients reported more severe pain during the lactulose challenge

test. Quality of life (IBSQOL) was reduced for all domains in patients with anxiety and depression ($p < 0.001$ for all comparisons).

Table 1: Characterization of IBS patients with anxiety or depression

Variable	Anxiety	Median	P-value	Depression	Median	P-value
IBS-SSS	No Yes	283 331	<0.001	No Yes	298 330	<0.001
VSI	No Yes	33 52	<0.001	No Yes	39 56	<0.001
SOC	No Yes	153 124	<0.001	No Yes	146 111	<0.001
PHQ-12	No Yes	6 9	<0.001	No Yes	7 10	<0.001
MFI	No Yes	14 14	<0.001	No Yes	15 19	<0.001
OATT (days)	No Yes	1.3 1.4	0.67	No Yes	1.3 1.4	0.52
Stool form (BSF)	No Yes	4 4	0.93	No Yes	4.0 4.0	0.49
Stool frequency (stools/day)	No Yes	1.7 1.7	0.53	No Yes	1.7 1.8	0.36
Lactulose challenge test, perceived pain (AUC)	No Yes	776 833	0.06	No Yes	705 1710	0.01
Balloon distension, pain threshold (mmHg)	No Yes	28 24	0.01	No Yes	24 28	0.53

Conclusion: The presence of anxiety and depression seems to clearly potentiate the already substantial disease burden in IBS patients. However, the association with other pathophysiological findings is less distinct. This group of patients with complex and severe symptoms will benefit from a holistic management approach.

P1786 THE ASSOCIATION BETWEEN IRRITABLE BOWEL SYNDROME AND LACTOSE INTOLERANCE

R. Dabak¹, T. Arslan Kucuk¹, S. Tuzun¹, H. Cetin¹, E. Ahishah², C. Dolapcioglu²

¹Family Medicine, Dr. Lutfi Kırdar Kartal Research And Training Hospital, Istanbul/Turkey

²Gastroenterology, Dr.Lutfi Kırdar Kartal Training and Research Hospital, Istanbul/Turkey

Contact E-mail Address: resat_dabak@hotmail.com

Introduction: Irritable bowel syndrome (IBS) and lactose intolerance may co-exist and readily cause diagnostic confusion due to similar symptomatology (1,2).

Aims & Methods: This study aim to examine the incidence of lactose intolerance in healthy controls and in subjects diagnosed with IBS based on Roma III criteria, as an effort to investigate the association between IBS and lactose intolerance. The patient population consisted of individuals between 18 and 80 years of age who attended between June-December 2013. Patients diagnosed with IBS based on Roma III criteria comprised the IBS group, and subtypes of IBS. Control subjects were healthy volunteers over 18 years of age with no IBS-like symptoms. All participants ingested 25 g of lactose dissolved in 250 ml of water within 5 minutes after 8 hours of fasting, in order to evaluate the lactose intolerance via hydrogen breath test (0, 15, 30, 60, 90, and 120 minutes). Additionally, symptoms arising during the test were assessed.

Results: Of the total 200 participants, 100 (50%) were in IBS and 100 (50.0%) were in control group. There were 133 females (66.5%), and the mean age was 40.5 ± 12.3 years. Of the total 70 patients (35.0%) with lactose intolerance, 47 (47.0%) were in IBS and 23 (23.0%) were in control groups ($p=0.001$). Symptoms related to IBS were more common in participants with lactose intolerance in both groups ($p=0.001$, $p=0.001$ respectively). A comparison of the two groups with regard to symptomatology after the test showed the presence of complaints in 35 (35.0%) patients in IBS group as compared to 24 (24.0%) subjects among controls ($p=0.092$). The incidence of lactose intolerance in patients with IBS subtypes of diarrhea-predominant IBS, constipation-predominant IBS, mixed IBS, and unspecified IBS were 27 (57.4%), 7 (4.9%), 10 (21.3%), and 3 (6.4%), respectively, with no significant differences ($p=0.161$, $p=0.124$, $p=1.000$, and $p=0.661$ respectively).

Conclusion: A significantly increased frequency of lactose intolerance was found among IBS patients than in controls. In additional, symptoms associated with lactose intake occurred at a higher frequency in IBS patient, although the difference was insignificant.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The population prevalence of Rome IV functional gastrointestinal disorders (FGIDs) and their cumulative effect on health impairment is unknown. We sought to address this issue.

Aims & Methods: An Internet-based health survey was completed by 5931 of 6300 general population adults from three English-speaking countries (2100 each from US, Canada, and UK). The survey included questions on demographics, medication, surgical history, somatisation, quality of life, doctor-diagnosed organic GI disease, and criteria for the Rome IV FGIDs. Comparisons were made between those with Rome IV FGIDs against non-GI and organic GI disease controls.

Results: The number of subjects having symptoms compatible with a FGID was 2083 (35%) compared to 3421 (57.7%) non-GI and 427 (7.2%) organic GI disease controls. The most frequently met diagnostic criteria for FGIDs was bowel disorders ($n=1665$, 28.1%), followed by gastroduodenal ($n=627$, 10.6%), anorectal ($n=440$, 7.4%), oesophageal ($n=414$, 7%), and gallbladder disorders ($n=10$, 0.2%). On average, the 2083 individuals who met FGID criteria qualified for 1.5 FGID diagnoses, and 742 of them (36%) qualified for FGID diagnoses in more than one anatomic region. The presence of FGIDs in multiple regions was associated with increasing somatisation, worse mental and physical quality of life, greater use of medical therapies, and a higher prevalence of abdominal surgeries; all $p < 0.001$, see table. Notably, individuals with FGIDs in multiple regions had worse somatisation and quality of life scores than organic GI disease controls.

	No FGID (healthy)	One FGID region	Two FGID regions	Three FGID regions	Four FGID regions	Organic GI-disease
Number of subjects	3421	1341	493	166	83	427
Mean number of somatic symptoms	2.8	4.6	5.6	6.3	7.3	4.7
Mean PHQ-12 score	3.3	6	7.5	9.1	10.9	6.3
Mean SF8-MCS QOL	52.1	45.7	42.8	38.6	37.2	47.9
Mean SF8 PCS-QOL	51.9	47.4	44.1	40.2	38.6	43.8
GI-related medication (%)	35%	59%	74%	84%	93%	71%
Abdominal surgery (%)	19%	26%	31%	37%	54%	53%

Conclusion: Roughly a third of the general adult population fulfils diagnostic criteria for a Rome IV FGID. In a third of this subset multiple GI regions are involved and this overlap is associated with increased health impairment. Study Support: The Rome Foundation

Introduction: Although correlations between features of irritable bowel syndrome (IBS) have been reported, these were based on between-person rather than within-person variation. We investigated the longitudinal within-person correlations between features of IBS.

Aims & Methods: We used a longitudinal cohort of 276 IBS patients, who filled out questionnaires once annually over five years on the following features: gastrointestinal (GI) symptom severity (GSS), quality of life (QOL), GI specific anxiety (VSI), general anxiety and depression (HADS), coping resources (CRI), and sense of coherence (KASAM). For each participant, scores were centered on their own mean, and within-person correlations were computed for all pairs of features.

Results: Aggregate within-person correlations are shown in figure 1. Within-person correlations were strong for the triad GI symptom severity, GI specific anxiety, and QOL ($|r|$: 0.47 to 0.64). Another set of features was comprised of general anxiety, depression, coping resources, and sense of coherence ($|r|$: 0.39 to 0.57). Within-person correlations between the two sets were weak ($|r|$: 0.00 to 0.37). However, within-person correlations tended towards bimodal distributions across the population, especially for GI symptom severity and depression ($r \sim 0.6$ for half of participants, and $r \sim -0.4$ for the other half).

Conclusion: Here we show that, within individual IBS patients, GI symptom severity is strongly correlated with GI specific anxiety and QOL, but not with four other psychological features. The presence of negative within-person correlations in some individuals may imply a lack of relation, but could also signal long-term causative processes.

Introduction: Irritable bowel syndrome with constipation (IBS-C) is a chronic gastrointestinal disorder associated with significant impairment in health-related quality of life (HRQoL). However, information on the impact of IBS-C symptom severity on patients' HRQoL is lacking.

Aims & Methods: This *post hoc* analysis assessed the burden of IBS-C on HRQoL according to symptom severity among adult patients meeting the modified Rome II criteria for IBS based on baseline data from two Phase 3 clinical trials of linacotide. HRQoL was evaluated based on the disease-specific Irritable Bowel Syndrome Quality of Life questionnaire (IBS-QOL) and the EuroQol-5-Dimension (EQ-5D). The IBS-QOL includes eight subscales (dysphoria, activity interference, body image, health worry, food avoidance, social reaction, sexual, relationships), with total and subscale scores calculated on a 0–100 scale and higher scores indicating better IBS-specific HRQoL. A within-person change of ≥ 10 points is considered clinically meaningful. The EQ-5D assesses five dimensions of general health (mobility, self-care, usual activities, pain/discomfort, anxiety/depression), generating an overall index score of between 0 (worst possible health state) and 1 (best possible health state); a within-person change of 0.05 is considered meaningful. Symptom severity was assessed during the pre-treatment period based on the global symptom score (GSS) on a scale of 0–4, where 0 = no symptoms and 4 = very severe symptoms. Data from both trials were pooled and scores for both instruments were assessed for all patients based on GSS (<3 or ≥ 3), as well as age (<65 or ≥ 65 years) and sex.

Results: A total of 1602 IBS-C patients were included for analysis. Compared to patients with GSS <3 , those with GSS ≥ 3 had lower HRQoL as indicated by lower mean IBS-QOL overall and subscale scores, with the greatest differences seen for body image (15-point difference), dysphoria and health worry (both 13-

point difference) subscales (Table). Patients with GSS ≥ 3 also had a lower EQ-5D index score compared to those with GSS <3 (0.67 vs 0.72) (Table). Women reported a slightly lower mean total IBS-QOL score compared to men, but had a notably lower score (14-point difference) on the body image subscale (Table). No difference in mean EQ-5D score was observed between sexes. IBS-QOL total and EQ-5D index scores were similar between patients aged <65 and ≥ 65 years, though the younger subgroup generally had lower scores on the IBS-QOL, including on the food avoidance and sexual subscales (Table).

Table

Instrument	Pooled Phase 3 trials baseline data						
	Total	Sex		Age		GSS	
		F	M	<65	≥ 65	<3	≥ 3
IBS-QOL							
n	1595	1437	158	1511	84	92	1503
Total score, mean	61.1	60.8	63.8	60.9	65.0	71.5	60.4
Dysphoria	62.3	62.2	62.8	62.2	64.2	74.6	61.5
Activity interference	68.0	68.2	66.4	68.1	67.1	76.4	67.5
Body image	48.2	46.8	61.0	47.8	55.5	62.0	47.4
Health worry	44.9	44.4	49.3	44.7	49.5	57.3	44.2
Food avoidance	50.1	49.7	54.1	49.6	59.5	59.0	49.6
Social reaction	67.1	66.7	70.0	66.8	71.5	75.5	66.5
Sexual	67.9	67.0	75.5	67.2	80.4	77.8	67.2
Relationships	73.4	73.6	71.6	73.3	75.3	80.6	72.9
EQ-5D							
n	1598	1440	158	1513	85	93	1505
Index score, mean	0.68	0.68	0.67	0.68	0.70	0.72	0.67

Conclusion: Among this patient population, IBS-C patients with higher symptom severity reported greater impairments in HRQoL. These results indicate that symptom severity may be an important consideration for disease management and emphasise the need for IBS-C treatments that improve both symptom burden and HRQoL.

Introduction: No population-based studies have investigated the symptom burden and healthcare utilization associated with Rome IV defined irritable bowel syndrome (IBS).

Aims & Methods: The aim of the current study was to assess these variables in IBS subjects in the general population. An Internet survey was completed by 6300 individuals distributed equally between United States, United Kingdom and Canada. Equal sex, age and education distribution across the countries was ensured by use of quota-based sampling. The survey included questions on demographics, the Rome IV diagnostic questionnaire, the patient health questionnaire (PHQ-12), the 8-item Short Form (SF-8) quality of life (QOL) questionnaire, health care utilization and past gastrointestinal (GI) disease diagnoses by doctors. Respondents with an organic GI disease were excluded from the IBS population.

Results: From the 6300 individuals who completed the survey, 369 were excluded due to inconsistent responses, leaving 5931 (49.2% female; mean age 47.4 ± 17.1 years) to be included for analysis (1949 US, 1994 UK, 1988 Canada). 305 (5.1%) of these fulfilled Rome IV diagnostic criteria for IBS, after 36 individuals were excluded due to organic disease. Compared to the non-IBS population, the IBS population was younger (mean-age 44.7 ± 14.5 years; $p=0.004$) and predominantly female (66%; $p<0.001$). Apart from reporting more frequent GI

symptoms, IBS subjects also reported more somatic symptoms; 103 (34%) had abdominal pain at least 3 times/week, 232 (76%) subjects reported sensation of bloating at least 3 times/month, and 232 (76%) scored ≥ 7 on PHQ-12, indicating high somatic symptom burden ($p < 0.001$ for all). They also had poorer self-rated overall health, more general body pain, and more health-related impairment of social activities ($p < 0.001$ for all). See table 1 for details. IBS subjects also reported more frequent visits to the doctor compared to the non-IBS population, both for non-GI and GI related problems; 241 (79%) vs. 3133 (56%) reported visiting a doctor at least once/year for any health issue and 195 (63%) vs. 1144 (20.5%) had seen a doctor for GI problems ($p < 0.001$ for all). IBS subjects also reported higher frequency of visits to gastroenterologists, gynaecologists and surgeons in secondary care; $p < 0.001$ for all. The use of medication for pain (both subscribed and over the counter), GI related symptoms, depression and anxiety was increased amongst subjects with IBS, as was the rate of abdominal surgery ($p < 0.001$ for all), appendectomy excluded. See table 1 for details.

	IBS, n = 305 n(%)	Not IBS n = 5590 n(%)	p-value
GI symptoms			
Abdominal pain > 3times/week	103 (33.8)	88 (1.6)	<0.001
Bloating > 3 times a month	232 (76.1)	849 (15.2)	<0.001
Somatization PHQ-score 7 or above	323 (76.1)	1381 (24.7)	<0.001
Quality Of Life			
Overall estimation of health past 4 weeks (SF-8). Very poor/poor	90 (29.5)	273 (4.9)	<0.001
Fair/good Very good/excellent	182 (59.7)	3026 (54.1)	
Bodily pain past 4 weeks (SF-8)/None/very mild/Mild/moderate Severe/very severe	33 (10.8)	2291 (41.0)	
Limitation in social activities due to physical health or emotional problems past 4 weeks (SF-8)	41 (13.4)	3567 (63.8)	<0.001
Not at all Very little/somewhat Quite a lot/could do no social activity	168 (55.1)	1707 (30.5)	
Frequency of doctor visits At least once/year	96 (31.5)	316 (5.6)	<0.001
Medication use	53 (17.4)	3084 (55.2)	<0.001
For constipation For diarrhea	144 (47.2)	2021 (36.2)	
Pain, prescribed Pain, over the counter Gas/bloating	108 (35.4)	485 (8.7)	
Anti-depressive Anti-anxiety	241 (79)	3133 (56)	<0.001
Surgery			
Cholecystectomy	76 (24.9)	274 (4.9)	<0.001
Appendectomy	62 (20.3)	163 (2.9)	<0.001
Hysterectomy Other abdominal surgery	122 (40)	775 (13.9)	<0.001
	114 (37.4)	972 (17.4)	<0.001
	67 (22.0)	249 (4.5)	<0.001
	107 (35.1)	669 (12.0)	<0.001
	92 (30.2)	557 (10.0)	<0.001

Conclusion: Individuals fulfilling the Rome IV criteria for IBS in the general population have increased GI and non-GI healthcare utilization in primary and secondary care, excess non-GI symptom burden and impaired QOL. [Support: Rome Foundation]

P1792 ISCHAEMIC COLITIS AND VITAMIN K DEFICIENCY: A HYPOTHESIS

A. G. Tsimperidis, I. A. Linardou, A. N. Kapsoritakis, A. K. Psychos, S. P. Potamianos

Department Of Gastroenterology, Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa/Greece

Contact E-mail Address: atsimperidis@yahoo.com

Introduction: Ischaemic colitis (IC) is the most common vascular disease of the colon, although its exact pathophysiological mechanisms remain unclarified.¹

Aims & Methods: The aim of this study was to evaluate routine coagulation parameters associated with vitamin K in patients with IC and to compare them with a group of controls (individuals with known predisposing factors for IC but without evidence of the disease). This study was carried out in the context of a study evaluating thrombophilia among IC patients. The present study used the same study groups as the latter.² History of malignancy, systemic inflammation, liver disease-cirrhosis or use of anticoagulants were exclusion criteria for both patients and controls. The control group was using more antihypertensive drugs compared to the patients' group, while no difference was observed in any other drug category. Fifty-six cases of IC (admitted from September 2007 until June 2011 at the tertiary Department of Gastroenterology in central Greece) and 44 controls (subjects admitted for

upper gastrointestinal bleeding, cholelithiasis, and colon polyps) with known predisposing factors but no evidence of IC were evaluated. Coagulation indices measured were: prothrombin time (PT), activated partial thromboplastin time (aPTT) and lupus anticoagulant (LA). Venous blood collected from all IC patients and controls at the second or third day of hospitalization (1–3 days from the onset of symptoms).

Table 1: Coagulation tests in IC and control groups.

Parameter	IC group	Controls	Normal range	Units	p value
PT	14.5 [13.7–15.7]	13.1 [12.3–13.9]	9.0–14.0	sec	.0005
INR	1.15 [1.09–1.22]	1.02 [0.96–1.07]	0.85–1.15		.0005
aPTT	28.7 [26.7–31.7]	26.4 [24.9–28.6]	25.0–35.0	sec	.0005
LA	1.05 [0.97–1.13]	1.04 [1.03–1.10]	0.8–1.22		.948

Results: Significant differences were recorded in the levels of PT (median: 14.5 vs 13.1 sec, $p = .0005$) and aPTT (median: 28.7 vs 26.4 sec, $p = .0005$) between patients and controls, respectively. Prolongation over the upper limit of normal of PT (> 14 sec) was most common in IC patients, 67.9% vs 18.2% ($p = .0005$) as well as the prolongation of aPTT (> 35 sec), 12.2% vs 6.2% ($p = .469$). The presence of LA was characterized as weakly present in 5 of 6 patients with the aPTT prolongation (9.6%, normalized LAC ratio: 1.2–1.5) and moderately present in 1 patient (1.9%, normalized LAC ratio: 1.5–2.0).

Conclusion: Prolongation of PT and aPTT, possibly indicating a chronic Vitamin K deficiency state, may be implicated in the pathophysiological mechanisms of IC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: magnovitorp@gmail.com

Introduction: Ischaemic colitis (IC) encompasses a number of clinical entities resulting in insufficient blood supply to the colon. The incidence of adverse outcome in patients with IC remains high.

Aims & Methods: We conducted a multicenter retrospective cohort study including consecutive patients with IC diagnosed between January 2013 and December 2016, according to the Modified Brandt and Boley criteria (clinical, colonoscopy, pathology consistent with IC and negative culture). The following data were collected: age, sex, clinical symptoms, comorbidities, organ failure, laboratory (hemoglobin, platelet number, leucocytes, C-reactive protein, creatinine, sodium, potassium, arterial pH and arterial lactate and LDH), endoscopic and CT findings, surgery and death. Logistic regression was used to study association with poor outcomes - surgery and overall mortality.

Results: In this study, 349 patients were registered and 193 fulfilled the pre-determined criteria: 121 (62.7%) were females and mean age was 72-years-old (IQR: 23–94). At admission a total of 165 (85.5%) patients presented with hematochezia, 112 (58%) with abdominal pain, 82 (42.5%) with diarrhea, 27 (11.9%) with shock and 7 (3.6%) with occlusion. Twenty three (11%) required surgery. In-hospital, 30-day and overall follow-up mortality rates (up to 205 weeks) were 7.3%, 6.7% and 14%, respectively. On multivariate analysis, surgery was independently associated with shock (OR: 4.8; $p = 0.011$) intestinal occlusion (OR: 3.5; $p = 0.046$), and arterial lactate (OR: 1.3; $p = 0.012$). On univariate analysis, hemoglobin, hematocrit, C-reactive protein, LDH, the number of risk factors, arterial pH, and the need of red blood support IQ were significantly ($p < 0.05$) associated with in-hospital and 30-day mortality. Creatinine was also associated with intra-hospital mortality. The variables that correlated independently in the multivariate analysis with in-hospital mortality were male gender (OR: 4.5; $p = 0.03$), and arterial pH (OR: 0.001; $p = 0.036$) and with 30-day mortality was the need of red blood cells support (OR: 2.1; $p = 0.0086$).

Conclusion: In our cohort of predominant elderly patients, arterial pH, shock and lactate were significantly associated with need of surgery. Arterial pH on admission was also independently associated with in-hospital mortality. Early identification of these factors can anticipate decision management in this context and select the best care level for each patient.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1795 THE RISK PREDICTIVE VALUES OF ACG CLASSIFICATION IN A COHORT OF ISCHEMIC COLITIS—REFINING THE DEFINITION OF MILD DISEASE

V. Magno Pereira¹, C. Simões², M. Silva³, J. Carvão¹, A. Oliveira¹, C. Baldaia², G. Serrão¹, L. Jasmins¹, J. Velosa³

¹Gastroenterology, Hospital Central do Funchal, Funchal/Portugal

²Department Of Gastroenterology And Hepatology, North Lisbon Hospital Center, University of Lisbon, Lisbon/Portugal

³Gastroenterology, Hospital São João, Oporto/Portugal

Contact E-mail Address: carolinabaptistasimoes@gmail.com

Introduction: Although most cases of colon ischemia (IC) are mild and self-limiting, when severe it implies high mortality rates. We aimed to evaluate the risk predictive value of the classification of disease severity proposed by American College of Gastroenterology (ACG) guidelines (2015), created to provide a management algorithm for these patients and select the level of care.

Aims & Methods: A retrospective multicenter study was conducted on adult patients with definite CI (clinical, colonoscopic, pathologic and culture criteria), between 2013 and 2016. Data was collected on clinical presentation, comorbidities, organ failure, management and outcome. Each case was classified according to ACG guidelines after assessment of the number of risk factors (gender, systolic blood pressure <90 mm Hg, heart rate >100 beats per min, abdominal pain without rectal bleeding, BUN >20 mg/dl, Hgb <12 g/dl, LDH >350 U/l, serum sodium <136 mEq/l (mmol/l), WBC >15 × 10⁹/cmm). Patients were then classified as mild (0 risk factors (RF)), moderate (1–3 risk factors), and severe (more than 3 risk factors or any of the following: peritoneal signs, pneumatosis or portal venous gas, gangrene on colonoscopic examination and pan-colonic or isolated right-colon ischemia involvement on imaging by colonoscopy or computed tomography).

Results: 349 cases with the clinical diagnosis of IC were analyzed. 193 patients met the inclusion criteria of definitive diagnosis of CI (62.7% females; mean age 72 years (±13)). ACG classification of mild, moderate and severe disease was attributed respectively to 21% of patients (0 intra-hospital deaths), 45% (2 deaths) and 34% (12 deaths). The number of ACG RF was: 40% with 0 RF, 8% with 1, 9% with 2, 15% with 3, 16% with 4, 8% with 5, 4% with 6 and 1% with 7. No patient with 0 or 1 RF died. Only 1 patient with 2 RF died. The remaining 13 deaths were verified with at least 3 RF. The univariate analysis revealed a statistical correlation between RF and intra-hospital or 30-day mortality as well as the need for surgery (mean = 4.06, sd = 1.85). ACG classification presented high predictive accuracy for in-hospital and 1-month mortality with an AUROC of 0.78 and 0.79 (p < 0.001), respectively. For a cutoff of 2 ACG RF, the sensitivity (SE) for death was 100%, specificity (SP) 52%, with a positive predictive value (PPV) of 14% and negative predictive value (NPV) of 100%. For 3 ACG RF the results were: SE 93%, SP 61%, PPV 16% and NPV 99%. 3 or more risk factors had an odds ratio of 20.2 (confidence interval (CI) 2.59–158) for intra-hospital mortality and 18.42 for 1-month mortality (CI 2.34–144).

Conclusion: No patient in this cohort with less than 2 ACG RF died, suggesting that the ACG classification as mild disease may include 0 and 1 risk factor without changing the prognosis. Short-term mortality risk increases significantly in patients with at least 3 ACG RF.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1796 HOW COST AFFECTS THE TREATMENT CHOICE FOR IRRITABLE BOWEL SYNDROME WITH DIARRHEA PATIENTS: A COST-EFFECTIVENESS ANALYSIS OF TRICYCLIC AGENTS AND RIFAXIMIN

E. D. Shah, E. Andraska, J. Li, S. Zhang, W.D. Chey

Division Of Gastroenterology, University of Michigan, Ann Arbor/United States of America

Contact E-mail Address: ershah@med.umich.edu

Introduction: Drug pricing and third party payer coverage exert a profound effect on access to prescription therapies in patients with irritable bowel syndrome with diarrhea (IBS-D). We performed a cost-effectiveness analysis to assess the trade-offs associated with treating IBS-D patients with a tricyclic agent (TCA) or rifaximin.

Aims & Methods: We constructed a decision analytic model evaluating three treatment strategies for IBS-D in the United States healthcare system: first-line therapy with TCA-only, first-line rifaximin followed by second-line TCA for nonresponders, and first-line TCA followed by second-line rifaximin for nonresponders. This model accounted for direct and indirect costs of therapy (Medicaid NADAC database and Healthcare Blue Book) and work-productivity loss (published literature and US Bureau of Labor) with a 3% per annum discount rate. Rifaximin was administered in 4-month treatment cycles based on published clinical experience. Responder and discontinuation rates were derived from clinical trial data, and validated health utility values were assigned to

terminal health states. Base-case analysis was performed to determine incremental cost-effectiveness ratios (ICER) for both rifaximin strategies. Threshold analysis assessed rifaximin pricing at contemporary willingness-to-pay (WTP) levels per quality adjusted life year (QALY). Appropriate sensitivity analyses were conducted. Analysis was performed with a 1-year time horizon from societal and payer perspectives.

Results: Based on the average acquisition cost of rifaximin (USD \$29.78/pill), second-line rifaximin could be cost-effective from a societal perspective (Table 1). However, at contemporary WTP thresholds neither rifaximin strategy was cost-effective from a payer perspective despite greater effectiveness than TCA alone. Dependent on WTP, a 12–62% price reduction (USD \$18.46–\$26.34/pill) would enable the first-line TCA followed by second-line rifaximin to be more cost-effective than a TCA-only strategy (Table 1). An 84–88% price reduction (USD \$3.53–\$4.71/pill) would enable first-line rifaximin followed by second-line TCA to be more cost-effective than TCA-only, though first-line TCA followed by second-line rifaximin would remain the more cost-effective strategy. Our model was robust in tornado analysis and most influenced by rifaximin treatment interval. Sensitivity analysis on rifaximin retreatment interval suggests that current pricing may be based on longer retreatment intervals than those found in clinical literature (Fig 1a). Sensitivity analysis with a lower TCA responder rate could enable first-line rifaximin to be the preferred strategy, albeit at a reduced price (Fig 1b).

Conclusion: Rifaximin is an effective therapy for IBS but is less cost-effective than TCA as currently priced. We propose an evidence-based pricing strategy which would maximize the cost-effectiveness of rifaximin in IBS-D patients.

P1797 PREDICTIVE FACTORS FOR BETTER OUTCOMES IN COLONOSCOPY-ASSOCIATED PERFORATION

B. Kim, S. Park, M.A. Yang, S.H. Yun, Y. Lee, J.W. Kim, J. Cho

Gastroenterology Division, Internal Medicine Department, Presbyterian Medical Center, Jeonju-si/Korea, Republic of

Contact E-mail Address: cccagape@hanmail.net

Introduction: Colonoscopy has been widely used for diagnostic and therapeutic purposes. Although the incidence is very low, perforation is one of the most serious complications. It is important to decide whether to try endoscopic clipping or to perform prompt surgical management.

Aims & Methods: We retrospectively reviewed charts of all patients who experienced colonoscopy-associated perforation in a single center between May 2009 and July 2015, and totally 45 patients were enrolled.

Table: The risk factors surgical treatment in colonoscopy-associated perforation

variable	Surgery group (N = 18)	Conservative group (N = 27)	P value
Age(year)	66	67	.688
Sex(M/F)	10/8	14/13	.807
Purpose of colonoscopy			.000
Therapeutic	9	27	
Diagnostic	9	0	
Location of perforation			.002
Rectum	2	6	
Sigmoid	14	7	
Descending	0	1	
Transverse	2	3	
Ascending	0	10	
Endoscopic clipping			.007
Yes	8	23	
No	10	4	

Results: Diagnostic cases in purpose, sigmoid colon in location and non-clipping status were significantly more common in surgery group than conservative group (Table). Endoscopic clipping was performed in 31 cases (immediate; 23, delayed; 8), and immediate clipping group had significantly lower rate of operation (p = 0.013) and better clinical outcome (duration of antibiotics: p = 0.006, hospital stay: p = 0.001). Among 18 surgical cases, 13 patients had primary closure and 5 patients had complex surgery (2; segmental resection, 3; Hartmann's procedure). The early (<24hr) surgical management significantly decreased the possibility of complex surgery (p = 0.002), as well as had better clinical outcomes such as duration of antibiotic use, fasting time and length of hospital stay (p = 0.003, p = 0.001, p = 0.005, respectively). In therapeutic cases, all five perforated patients who had surgery within 1 day could be managed by simple primary closure, but all four patients who had surgery after 1 day required complex surgery.

Abstract No: P1796**Table 1:** Comparative cost-effectiveness of treatment approaches with and without rifaximin in irritable bowel syndrome with diarrhea (IBS-D)

Strategy	Total cost (USD/yr)	Total effectiveness (QALY gained)	Incremental cost (USD)	Incremental effectiveness (QALY)	ICER (USD/QALY gain)
<i>Societal perspective</i>					
TCA only	\$4,355	0.017			
Rifaximin as first-line for IBS-D	\$7,608	0.020	\$428	+0.0029	\$1,138,254 (dominated*)
Rifaximin as second-line for IBS-D	\$4,783	0.022	\$3,252	+0.0052	\$82,375
<i>Payer perspective</i>					
TCA only	\$728	0.017			
Rifaximin as first-line for IBS-D	\$4,177	0.020	\$894	+0.0029	\$1,207,136 (dominated*)
Rifaximin as second-line for IBS-D	\$1,622	0.022	\$3,449	+0.0052	\$171,850

*first-line rifaximin strategy was dominated (less effective and more expensive) than a second-line rifaximin strategy at all price points. ICER = incremental cost effectiveness ratio; QALY = quality adjusted life year; TCA = tricyclic antidepressant; IBS-D = irritable bowel syndrome with diarrhea; USD = US dollar.

Conclusion: In colonoscopy-associated perforation, immediate endoscopic clipping decreases the possibility of operation and shows better clinical outcomes, and early surgical approach decreases complex operation rate. Especially, early operation need be considered in diagnostic perforation regardless of endoscopic clipping.

Introduction: Despite diagnostic criteria and effective management options for functional gastrointestinal disorders (FGID), confidence in managing these disorders in primary care is low, and long waiting lists for specialist care are common. New models which efficiently transfer specialist-held expertise to primary care practitioners is needed.

Aims & Methods: We aimed to explore and describe the patient and primary healthcare provider (PHCP) experience of a novel non-specialist-dependent algorithm-based approach to the diagnosis and management of FGID (ADAM-FGID). Consecutive patients triaged to the 'routine waitlist' of an Australian public hospital Gastroenterology Department over 2 years, with non-specific gastrointestinal symptoms (no alarms) were randomised to waitlist control or the algorithm (2:1). Algorithm patients were screened for organic disease with an alarms-based questionnaire and panel of routine blood/stool tests. When patients had clinical alarms or abnormal tests, data were reviewed by a gastroenterologist and, if appropriate, prompt gastroenterologist appointment offered. All others were classified using Rome III criteria, and received a letter explaining their FGID diagnosis and dietary/psychological management options. Waitlist control patients were not screened. All participants completed follow-up surveys at 6, 26 and 52 weeks. Referring doctors of the algorithm group were sent a feedback survey at study completion.

Results: 89 participants were screened (42 years [SD 14], 62% female). 35 had clinical alarms warranting gastroenterologist review and 45 were diagnosed with FGID (9 excluded). At 6 week follow up: 35/36 FGID respondents had read the diagnostic/management letter, and most (n=25) found it useful (17 useful, 8 partially useful). Few discussed it with their PHCP (n=13), yet most (n=28) commenced management (n=33 by 12 months). Dietary management options were preferred over psychological therapies (n=30 vs n=16) (p=.001), as were do-it-yourself options above therapist consultation. 61% (n=22) of patients saw symptom improvement at 6 weeks, (18/21 at 12 months). 2 did not accept the diagnosis, and 3 consulted a specialist privately. 19/36 participants had no concerns at 6-week follow-up (19/21 at 12 months). Common concerns included symptom persistence (6-wk n=10, 12-mth n=10) and fear of missed pathology (6-wk n=4, 12-mth n=4). Most respondents (74%, 46/62) found the approach acceptable (FGID group: acceptable 12/36, moderately acceptable 10/36; Screen Fail Group: acceptable 20/26, moderately acceptable 4/26). Others expressed dissatisfaction with the healthcare system (n=4), diagnosis (n=3), screening questionnaire (n=1) and lack of improvement in symptoms (n=1). All responding PHCPs (23/80; 14 FGID group, 9 screen-fail group) found the approach acceptable (13 acceptable, 12 moderately acceptable).

Conclusion: An algorithm-based approach to the diagnosis and management of FGIDS, which does not rely on specialist input is feasible, acceptable and effective. A larger scale randomised controlled trial of this new clinical pathway for the diagnosis and management of FGIDs, in primary care is warranted.

Introduction: Colonoscopy every 5 years, starting at the age of 40 years, is considered the first-choice screening strategy in first degree relatives (FDR) of patients with colorectal cancer CRC, as these individuals are considered at higher risk of developing CRC than average-risk individuals. However, this practice has a low adherence and remains opportunistic. Recently, it has been suggested that annual fecal immunochemical testing (FIT) might be a valid alternative to colonoscopy in this setting. However, there are scarce data regarding cost-effectiveness of these strategies from the perspective of healthcare services.

Aims & Methods: This study was aimed to compare the cost-effectiveness of annual FIT and colonoscopy every 5 years, to reduce CRC mortality, in FDR of patients with CRC. A Markov model was constructed to simulate the efficacy and cost of annual FIT (cut-off 10 µg Hb/g feces) or colonoscopy every 5 years of

previously unscreened FDR, starting at age 40 years and ending at age 75. A 50% adherence for each strategy was assumed. The model was adjusted to the incidence of CRC in Spain and real prevalence of advanced adenoma and CRC in the familial-risk population (<http://dx.doi.org/10.1371/journal.pmed.1002008.g001>). The main outcomes were quality-life-year (QALY) gained compared with no screening, lifetime burden of colonoscopy, lifetime number of colonoscopy complications, and the incremental cost-effectiveness ratio (ICER). We applied a willingness-to-pay threshold of €25,000 per QALY gained. Data from a prospective EuroQoL survey carried out on 920 Spanish patients at different disease stages were used for QALY measurement. Sensitivity analysis was performed to evaluate the robustness of the model.

Results: In a hypothetical cohort of 10,000 asymptomatic FDR, annual FIT and colonoscopy every 5 years were cost-effective over no screening. Taking no screening as comparator, ICER for annual FIT and colonoscopy every 5 years was 1989 and 4472 euros/QALY, respectively. Compared to no screening, annual FIT and colonoscopy every 5 years reduced CRC mortality by 59% and 81%, respectively. The annual FIT strategy saved 33% of colonoscopies and was associated with a lower number of complications compared to colonoscopy every 5 years. The results were robust in sensitivity analyses.

Conclusion: Assuming a 50% adherence, annual FIT is less costly than colonoscopy every 5 years for CRC screening and reduces mortality in the familial-risk population. These data suggest that FDR of patients with CRC could be included in organized nationwide FIT-based screening programs.

Introduction: Faecal occult blood test (FOBT) is a non-invasive and easily performed test which has demonstrated to reduce CRC incidence and mortality in the populations. Faecal calprotectin (FCP) has good evidence for detecting inflammatory bowel disease but its value in CRC and adenoma detection in the symptomatic population is less well studied. Most patients with symptoms have benign pathology but in an effort to detect most cancer or pre-cancerous lesions, almost all patients undergo colonoscopy.

Aims & Methods: To evaluate and compare the diagnostic accuracy of the combination of FOBT plus FCP versus each test alone in symptomatic patients referred for diagnostic colonoscopy. A total of 171 patients who completed colonic investigations and returned stool samples, were prospectively recruited and included in the final analysis. FOBT was performed by SENTI FIT 270 test (Sentinel Diagnostics, Milan, Italy) and FCP by the EliA Calprotectin immunoassay (Thermo Fisher Scientific, Waltham, United States). Reference cut-off levels for abnormal test were 117 ng/ml for FOBT and 50 µg/g for FCP respectively. The diagnostic accuracy of FOBT and FCP were evaluated by a logistic regression model. CRC, advanced adenoma, IBD and angiodysplasia were considered as relevant pathology. Positive and negative predictive values, sensitivity and specificity were calculated. MedCalc was used for the ROC curve analysis.

Results: 171 patients (42.7% female; median age 62 years, IQR: 51–68) were included. 37 (21.6%) had relevant colonic pathology. The most frequent indications for colonoscopy were previous episode of rectal bleeding in 71 (42%) patients, change of bowel habits in 28 (16%) and anaemia in 22 (13%). Diagnostic accuracy of FOBT, FCP and combination of both are summarized in table 1.

PPV: predictive positive value; NPV: predictive negative value

Test	Normal test	Abnormal test	PPV	NPV	Sensitivity	Specificity
FOBT	131	40	55%	89%	59%	89%
FCP	81	90	30%	88%	73%	53%
Combination	114	57	56%	96%	86%	81%

AuROC curves for relevant colonic pathology were 0.777 (95% CI: 0.708–0.837; $P < 0.0001$) for FOBT, 0.692 (95% CI: 0.617–0.760; $P = 0.0005$) for FCP and 0.848 (95% CI: 0.785–0.898; $P < 0.0001$) for combination of both tests respectively. Combination of both test have a significant better diagnostic accuracy compared to either test alone ($P = 0.043$ vs FOBT and $P = 0.002$ vs FCP) with a higher NPV. No significant difference was observed between FOBT and FCP ($P = 0.221$).

Conclusion: Our model based on combination of FOBT and FCP has a better diagnostic accuracy performance compared to each test alone for the detection of relevant colonic pathology. Because of high NPV, performing FOBT and FCP in symptomatic patients before colonoscopy could be a feasible strategy in order to avoid unnecessary procedures

P1801 CLINICAL PRACTICE, MONITORING, AND PATIENT SAFETY DURING PROCEDURAL SEDATION IN FIVE COUNTRIES

R. Saunders¹, J. Davis¹, R. Weissbrod², P. Kranke³, J. R. Lightdale⁴, D. Whitaker⁵

¹Health Economics, Coreva Scientific, Freiburg/Germany

²Medtronic, Jerusalem/Israel

³University of Würzburg, Würzburg/Germany

⁴University of Massachusetts, Worcester/United States of America

⁵Manchester Royal Infirmary, Manchester/United Kingdom

Contact E-mail Address: jason@coreva-scientific.com

Introduction: Procedural sedation is considered an integral part of gastrointestinal endoscopy in many countries. The use of sedation does, however, vary internationally and can present patient safety concerns. It has been questioned whether trials assessing patient safety in endoscopy can be generalized worldwide given variations in sedation practice and adverse events rates.

Aims & Methods: We conducted an international survey to examine procedural sedation practices and the incidence of adverse events (AEs) during procedural sedation in France, Germany, Italy, UK, and USA. Data collection from providers (nurses, physicians, and anaesthesiologists) was via online surveys. Respondents were screened to assure that they had the expertise and experience to complete the survey. The survey covered topics such as guidelines, sedation agents, monitoring, patient throughput, and AE incidence, treatment, and outcomes as defined by World SIVA¹. Data analysis took a global approach with subgroup analysis by location.

Results: 101 providers completed the survey, with 20 responses per country, excepting the USA with 21. More than 62% of respondents were gastroenterologists and anaesthesiology nurses. The main sedation agents reported employed were midazolam (93 respondents), propofol (90), fentanyl (75), ketamine (57), and meperidine (15). Respondents from France reported higher ketamine and lower fentanyl use than other countries ($p = 0.03$). Standard of care monitoring was generally reported to be comprised of pulse oximetry plus blood pressure and/or heart rate. Capnography use varied by country, and was standard of care for 46% of respondents (ranging from 15% in Italy to 67% in the US). The most desired property of a monitoring modality across all countries was one that “provides an early warning of patient compromise”. “Data displays and alarms relating to clinical events” was ranked second globally and in all countries apart from Italy. All respondents reported experience with patient safety issues in the last year, with hypotension the most common (67%), followed by mild desaturation (63), bradycardia (63) and prolonged desaturation (52). AE incidence was influenced by monitoring modalities used. Among German respondents, for example, 7 of 11 who did not use capnography as standard of care reported severe oxygen desaturation events, compared with versus 0 of 9 who routinely use it ($p = 0.005$). Providers also differed in their reported adverse event incidence. Gastroenterologists most commonly reported mild oxygen desaturation to occur, while anaesthesiologists and nurses reported hypotension to be the most common AE experienced during procedural sedation (Table).

Conclusion: Clinical sedation practices are relatively consistent across countries, as are the occurrence of adverse events. Pulse oximetry monitoring is almost universally used during sedation, while capnography use is more variable. Sedation monitoring that provides an actionable early warning of patient compromise remains a priority.

Introduction: The success of colonoscopy depends on the quality of the bowel preparation, which is estimated to occur in as many as 25% of colonoscopy procedures. The MOTUS GI Pure-Vu™ System (Tirat Carmel, Israel) is an FDA cleared device designed to improve visualization in an inadequately prepared colon by facilitating intra-procedural cleaning.

Aims & Methods: This study aims to evaluate the performance of the Pure-Vu System in cleansing a poorly prepared colon, assess the system's usability, patient satisfaction and safety. Forty-seven cases were planned to be enrolled at three clinical sites, of which 32 had completed the study so far. Pure-Vu was used in subjects with a partially prepped colon after 2x10 mg Bisacodyl, diet restrictions (no dried fruit, seeds or nuts) starting 2 days before the procedure and a 24-hour clear liquid diet prior to the colonoscopy. Study endpoints were: (1) Safety, (2) Improvement of colon cleansing level as per the Boston Bowel Preparation Scoring (BBPS) when comparing before and after Pure-Vu use, (3) Pure-Vu usability via questionnaire and (4) Patients' satisfaction via questionnaire.

Results: Thirty-two subjects (41% males), aged 31–74 years and with a mean BMI of 26±3.9, were included in the analysis. Indications for colonoscopy included family history of CRC (56%) and polyp surveillance (44%). No serious adverse events were reported. The Pure-Vu significantly increased the number of subjects with an adequate cleansing level (BBPS ≥ 2 for all 3 colon segments) from 25%; CI 95% [11%, 43%] at baseline to 100%; CI 95% [89%, 100%] after Pure-Vu and the cecum was reached and visualized in all study cases (i.e., 100%; CI 95% [89%, 100%]). Mean post-treatment BBPS score was 8.5±0.8 vs. 3.38±2.3 prior to Pure-Vu use. Physicians were satisfied with the device's general use of ease and found it in most cases acceptable to good or excellent to insert and to angulate the colonoscope. No major difficulties were experienced when performing polypectomy. Thirty of 32 (94%) patients reported that they would recommend Pure-Vu to their friends and family members who need a colonoscopy. Thirty (94%) of the patients found the overall bowel preparation as very tolerable (55%) or acceptable (39%). Seventy-nine percent of patients who had a previous colonoscopy procedure reported that the Pure-Vu bowel preparation was more tolerable as compared to their previous colonoscopy preparation and 14% of the patients reported it to be about the same.

Conclusion: The Pure-Vu System was found to be safe and effective in cleaning inadequately prepared colons to an adequate level for a thorough exam. Based upon these early results it is expected that the device may play a role in patients

P1803 THE EUROPEAN SOCIETY OF GASTROINTESTINAL ENDOSCOPY KEY PERFORMANCE MEASURES FOR COLONOSCOPY IN THE POLISH COLORECTAL CANCER SCREENING PROGRAM

M. Bugajski¹, P. Wieszczy², M. Rupinski¹, J. Regula², M.F. Kaminski¹

¹Department Of Gastroenterological Oncology, The Maria Skłodowska-Curie Memorial Cancer Centre and Institute of Oncology, Warsaw, Poland, Warsaw/Poland

²Department Of Gastroenterology, Hepatology And Oncology, Medical Center for Postgraduate Education, Warsaw, Poland, Warsaw/Poland

Contact E-mail Address: marek.bugajski@gmail.com

Introduction: Recently, the European Society of Gastrointestinal Endoscopy (ESGE) published guidelines on key performance measures for colonoscopy (1). We analyzed feasibility of monitoring these measures and whether the proposed standards were met in the Polish Colonoscopy Screening Program (PCSP). **Aims & Methods:** We analyzed database records for 40,644 participants aged 55 to 64 years, who between 2014 and 2015, underwent screening colonoscopy in 24 centers of population-based PCSP. We used the ESGE guideline definitions to calculate values of all seven key performance measures. We compared key performance measures within the PCSP against proposed standards on the program and center level. Data on adequacy of bowel preparation was routinely assessed with the Boston Bowel Preparation Scale, whereas data on patient experience with the validated Gastronet questionnaire (2). Data on complication rates were collected from the National Health Fund database and Personal Identification Number Registry.

Results: Overall, on the program level, all minimum standards for colonoscopy key performance measures were met. Rate of adequate bowel preparation was 92.1% for the whole program, ranging 80.9–99.2% per individual center, with 7 centers (29.2%) not reaching minimum standard of 90% and 9 centers (37.5%) reaching the target standard of 95%. Cecal intubation rate was 97.4% (range 93.4–99.4%), with all centers reaching minimum standard of 90% and only one center not reaching target standard of 95%. Adenoma detection rate was 29.9% (range 19.1–39.1%), with 7 centers (29.2%) not reaching minimum standard of 25%. Appropriate polypectomy technique was applied in case of 90.9% 6 to 9 mm polyps (range 64.3–100%) with only 2 centers not reaching minimum standard of 80% and 48.2% of 4 to 5 mm polyps (range 0–100%) with only 6 centers reaching minimum standard of 80%. Target standard of 90% was reached in 15 centers for polyps 6 to 9 mm in diameter and only 2 centers for polyps 4 to 5 mm in diameter. For the whole program, 7-day hospitalization rate after screening colonoscopy was 0.3% (122 cases) and 30-day all-cause mortality was 0.02% (9 cases). Gastronet questionnaire coverage is assumed to be 100%, however the response rate was 65.3% (range 7.6%–81.8%), with painful colonoscopy rate of 19.2%. No minimum standard is set, however target standard of 90% of procedures with measured patient's experience was not met. Appropriate post-polypectomy surveillance, based on the European guidelines, was proposed in 95.4% of cases (range 84.9–99.7%). Target standard of 95% was met in 15 centers, the minimum standard is not set.

Conclusion: Monitoring ESGE performance measures for colonoscopy is feasible in colonoscopy programmatic screening setting. 6 of 7 performance measures were easy to monitor with PCSP database, however monitoring complications needs further development to avoid extracting data from external registries. PCSP meets proposed minimum standards on program level, however some centers need additional interventions to meet the quality standards. Applying appropriate polypectomy technique for polyps ranging 4 to 5 mm in diameter

is currently the biggest issue in PCSP and further training is needed to reach minimum standard for this performance measure.

P1805 VALIDATION OF THE “FAILURE TO PROVIDE ADEQUATE RELIEF” (F-PAR) SCALE IN A SPECIALIST CLINIC SETTING

V. Passananti, N. Zarate Lopez, A. V. Emmanuel

GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassananti@gmail.com

Introduction: Treatment of chronic idiopathic constipation is somewhat empiric, but based on step-wise approach[1]. If first-line conservative treatment (lifestyle advice and laxatives) do not relieve symptoms sufficiently, secondary approaches with prokinetic or secretagogue drugs are used before considering hospital-based care (biofeedback, psychosocial support, transanal irrigation (TAI), surgery). Nevertheless, patients are often dissatisfied with care[2] and fail to progress to adequate levels of therapy. The 5-point Failure to Provide Adequate Relief (F-PAR) scale[3] was developed to facilitate the recognition of when to move from one step to the next.

Aims & Methods: The aim of this study was to validate F-PAR in a tertiary clinic setting. We studied 403 consecutive consultations of 331 patients (262 women, mean age 41) in our specialist clinic. All fulfilled Rome III/IV diagnostic criteria for chronic constipation. Immediately prior to each face-to-face clinical assessment by one of 2 experienced physicians, participants completed the F-PAR scale; patients were seen blind to the F-PAR result. Standard clinic assessment was undertaken to identify efficacy of the current management as the gold standard.

Results: Of the 403 consultations, clinical assessment identified inadequate relief with current therapy was identified in 200. Neither duration nor type of treatment were correlated with relief. The table stratifies, by clinical gold standard, each item of the F-PAR and in the lower panel the total number of F-PAR items replied to positively.

Table: Positive F-PAR items correlated to clinical assessment of relief

	Adequate relief (Clinical) n = 203	Inadequate relief (Clinical) n = 200
Bowel frequency inadequate	5	71
Strain most occasions	6	89
Stool hardness	3	21
Onset other symptom	2	57
Current therapy poor tolerable	8	80
0 FPAR replies	187	1
1 FPAR replies	10	41
2 FPAR replies	4	67
3 FPAR replies	2	22
4 FPAR replies	0	8
5 FPAR replies	0	9

Conclusion: Our findings showed that the F-PAR with only five questions can be considered sufficient to provide clinical evidence of treatment failure. The use of standardized process to investigate the efficacy of treatment may reduce the time and improve the quality of managing for the chronic constipation patients.

P1806 ADHERENCE WITH TRANSANAL IRRIGATION USING THE NAVINA™ SYSTEM IS ASSOCIATED WITH PERSONALITY TRAITS EVEN WHEN THERE IS IMPAIRED HAND FUNCTION

V. Passananti, J. Storrie, N. Zarate Lopez, A. V. Emmanuel

GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassananti@gmail.com

Introduction: Transanal irrigation has become a key therapeutic modality in managing patients with neurological diseases who experience constipation and/or faecal incontinence. Such neurogenic bowel dysfunction (NBD) complicates over three quarters of patients with spinal cord injury (SCI) and multiple sclerosis (MS). Approximately 60% of patients who start TAI continue with long-term treatment. A common cause of treatment cessation is impaired hand⁽¹⁾. Training of the patient is a key aspect of TAI therapy and requires patients to be willing to manage their health themselves: self-efficacy.

Aims & Methods: We wished to study whether use of a novel TAI system, Navina™ Smart, which has an electronic pump component allows patients with impaired levels of hand function to adhere to TAI therapy. We also wished to identify if there were physiological or psychological correlates of adherence. Twenty-eight consecutive patients (19 SCI and 9 MS; 17 male, mean age 42) were studied. All patients scored greater than 18 on the Cochin Hand Function questionnaires were completed to assess anxiety/depression and locus of control respectively. Anorectal physiology (manometry, sensation and rectal compliance) was undertaken at baseline. Training in TAI was undertaken by the same experienced nurse, with weekly follow up until a stable regime was established. Adherence with therapy at 12 weeks was identified.

Results: At 12 weeks, 16/28 (57%) of patients were still using Navina TAI, similar proportions with SCI (11/19) and MS (5/9). There was no difference in baseline scores for HAD-anxiety (6.4 ± 2.3 vs 5.9 ± 2.9 ; $p = 0.37$) and HAD-depression (8.6 ± 3.9 vs 8.8 ± 4.2 ; $p = 0.46$) and were similar in both those who were and were not still using TAI (mean \pm SD respectively). The Rotter score for non-adherers was significantly greater than adherers (14.2 ± 6.7 vs 10.6 ± 5.9 respectively; $p = 0.008$). There was no difference in any of the anorectal parameters between those who did or did not adhere with TAI.

Conclusion: Navina Smart TAI is an effective therapy in 57% of NBD patients with significant hand dysfunction. Anorectal physiology, anxiety and depression did not predict likelihood of treatment adherence. An external locus of control, reflecting a belief that health events occur because of outside forces (such as fate, chance, or powerful others), is associated with reduced treatment success. The results suggest that future studies of TAI should consider locus of control as an important potential predictor of outcome.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The microbiota inhabiting the gastrointestinal (GI) tract plays an essential role in gut health. Although mucosal biopsies are increasingly used for microbiota studies, these are subject to variations introduced through sampling technique and patient preparation. The impact of bowel preparation on the mucosa-associated microbiota (MAM) is of particular interest given it results in complete emptying of bowel contents via laxative ingestion. Although bowel preparation does not appear to induce long term changes to stool microbiota [1], it can induce short-term changes to the colonic MAM [2]. While improvements in clearance of the small intestine after bowel preparation have been reported [3], the impact on the upper GI microbiota is currently unknown. Given patients may undergo both upper GI endoscopy and colonoscopy consecutively, a subset of endoscopy patients will have consumed bowel preparation prior to their procedure, representing a potential bias in MAM analyses. Therefore, this study aimed to assess the impact of bowel preparation on the duodenal MAM.

Aims & Methods: Individuals undergoing upper GI endoscopy, with or without concurrent colonoscopy, were recruited consecutively with ethical approval. Individuals underwent upper GI endoscopy following overnight fast (n = 58), or both upper endoscopy and colonoscopy following polyethylene glycol bowel preparation (n = 48). Participants were undergoing screening for iron deficiency anaemia or GI symptoms with no evidence of mucosal disease/inflammation (n = 88), or with diagnosed Crohn's disease (n = 18). Duodenal biopsies were obtained and gDNA extracted. Amplicon libraries of the 16S rRNA gene were sequenced (Illumina MiSeq). Sequencing of reagent controls enabled exclusion of

non-duodenal sequences. Bioinformatics and statistics were performed in QIIME and Calypso.

Results: A diverse microbiota was observed in duodenal mucosal samples from all subjects, following overnight fasting or bowel preparation. Overall the duodenal microbiota was dominated by the genus *Streptococcus*, followed by *Prevotella*, *Veillonella* and *Neisseria*. Microbial diversity within samples was not significantly different with and without bowel preparation (Chao1 metric). Principal coordinates analysis (weighted UniFrac) revealed substantial overlap between the two groups, and no significant clustering was observed (ADONIS) based on whether patients had undergone overnight fasting or bowel preparation. Similar findings were obtained when these analyses were repeated with exclusion of the Crohn's disease population.

Conclusion: This study reveals a diverse duodenal MAM is retained following bowel preparation. The comparison of overnight fasting and bowel preparation indicates these differences in patient preparation do not substantially alter the duodenal MAM. Thus patients undergoing concurrent upper GI endoscopy and colonoscopy can be included in study cohorts investigating the upper GI MAM without risk of a substantial confounding effect.

P1808 PERFORMANCE OF GLASGOW-BLATCHFORD, ROCKALL AND AIMS65 SCORES TO PREDICT OUTCOMES AND TO IDENTIFY THE LOW-RISK GROUP AFTER UPPER GI BLEEDING IN PATIENTS WITH CANCER

M. C. Franco¹, S. Jang², B. D.C. Martins¹, T. Stevens², V. Jairath³, R. Lopez², J. J. Vargo², A. Barkun⁴, F. Maluf-Filho¹

Introduction: Upper gastrointestinal bleeding (UGIB) in patients with cancer presents a unique and difficult challenge as these patients are at higher risk for rebleeding and mortality.¹ Currently available prognostic scoring systems for UGIB for the general population have produced variable accuracy in their validation studies.² An effective method of stratification for cancer patients to identify the high-risk group for early hospital-based intervention and death could enhance the outcomes of this specific population.

Aims & Methods: The primary aim of this study was to compare the Glasgow-Blatchford score (GBS), Rockall score (RS) and AIMS65 score for predicting ICU admission, blood transfusion, hemostatic therapy, rebleeding, and in-hospital mortality in cancer patients with UGIB. The secondary aim was to assess the above cited scores in correctly identifying low-risk patients that can be effectively managed as an outpatient. An IRB-approved, prospective study was conducted at the Cancer Institute of Sao Paulo, Brazil. Consecutive patients with known cancer admitted with UGIB were enrolled. Pre-endoscopic clinical parameters, endoscopic findings pertinent to the scoring systems, hemostasis techniques, and outcomes were collected into a prospective registry. Patients were followed for at least 30 days or until the day of discharge, whichever was longer. The low-risk group was defined as those without blood transfusion, hemostatic therapy (by endoscopy, radiotherapy, angiographic or surgical intervention), rebleeding or mortality in 30 days. Multiple logistic regression with receiver operating characteristics analysis was done to assess the predictive ability of each scoring system for the above outcomes.

Results: From April 2015 to May 2016, 394 consecutive patients were screened, while 259 patients met the inclusion criteria. A total of 243 patients were considered for the final analysis, after excluding 16 patients due to missing data or lost to follow up (Table 1). Predicting outcomes: The AIMS65 score (area under curve [AUC] 0.85) was significantly better for predicting ICU admission than GBS (AUC 0.79; $p=0.04$), both the total and clinical RS (AUC 0.71 and 0.66; $p<0.001$ for both). The GBS best predicted the need for blood transfusion (AUC 0.82, sensitivity 71% and specificity 80% for GBS ≥ 12) compared with the other prognostic scores. All scores performed poorly in predicting the need for hemostatic therapy and risk of rebleeding. The AIMS65 score best predicted in-hospital mortality (AUC 0.84) compared to the GBS (AUC 0.75; $p=0.004$), both the total and clinical RS (AUC 0.70 and 0.69; $p<0.001$ for both). Among patients with confirmed bleeding at EGD, there was no difference in 30-day mortality if the etiology of bleeding was tumoral or non-tumoral disease (38.1% vs 31.9%; $p=0.46$). Identifying low-risk group: With GBS score of 0 as the cut-off value, its specificity was 100% with sensitivity of 5.8%. When GBS ≤ 2 was used as cut-off, its specificity was maintained at 100%, while sensitivity was increased to 23.5%. This change increased the proportion of the patients from 1% to 5% without erroneously discharging high-risk patients. In comparison, when an AIMS65 value of 0 was chosen as definition for low-risk, this tool misclassified 20 patients who needed hospital interventions (specificity of 53% and sensitivity of 89.5%). Finally, head-to-head comparison between GBS vs. RS, and GBS vs. AIMS65 scoring system revealed GBS to be superior

to both the clinical RS ($p<0.001$) and AIMS65 ($p=0.001$) in correctly identifying low-risk patients.

Table 1: Demographic and Clinical Characteristics

Factor	Total (n=243)
Age (years)	60.6 \pm 13.6
Female/Male	71 (29.2%)/172 (70.8%)
Outpatient/Inpatient	178 (73.3%)/65 (26.7%)
Cancer in the Upper GI Tract	74 (30.5%)
Cancer Stage:	
I or II	17 (7.0%)
III	48 (19.8%)
IV	177 (73.1%)
Hemoglobin	8.1 \pm 2.9
Albumin	2.8 \pm 0.75
Rebleeding	24 (9.9%)
RBC Transfusion	147 (60.5%)
ICU	107 (44.0%)
Hemostatic Therapy	104 (42.8%)
30-day Mortality	66 (27.2%)
Follow-up time (days)	30.0 [22.0,30.0]
Clinical Rockall	4.6 \pm 1.2
Total Rockall	7.0 \pm 2.0
AIMS65	1.7 \pm 1.2
Glasgow-Blatchford	10.8 \pm 4.2

Conclusion: The AIMS65 score was superior to other scoring systems in predicting in-hospital mortality and ICU admission in patients with cancer and UGIB, whereas the GBS was superior for predicting the need for blood transfusion. All scores performed poorly in prediction of hemostatic therapy and rebleeding. The GBS was superior in accurately identifying low-risk patients. Furthermore, the cut-off ≤ 2 in GBS score displays increased sensitivity without compromising specificity, effectively increasing the number of patients who can be safely managed as an outpatient.

Introduction: Endoscopists are more frequently performing endoscopic resection (ER) in patients on antiplatelet or anticoagulant therapy and nowadays patients have increasingly started taking direct oral anticoagulant (DOAC) therapies, including direct anti-Xa and thrombin inhibitors. Major guidelines recommend the cessation of anticoagulants before ER and heparin bridging therapy (HBT) for high thrombotic risk cases, although these are still controversial. A recent study has suggested that HBT may be associated with a higher post-endoscopic resection bleeding (PEB) rate in patients on anticoagulants.

Aims & Methods: This study aimed to evaluate the effect of anticoagulants on PEB rate. This was a retrospective study based on medical records from three centers. PEB was defined as bleeding that occurred 6 h to 10 days after ER, which required endoscopic hemostasis. We reviewed 108 gastric tumors including adenoma and early cancer in 97 patients on anticoagulant therapy who underwent endoscopic submucosal dissection (ESD) in our hospitals between June 2008 and February 2016. Further, we reviewed 69 colorectal polyps including adenoma and early cancer in 69 patients on anticoagulant therapy who underwent ER in our hospitals between October 2013 and September 2016. ER included polypectomy, endoscopic mucosal resection (EMR), and ESD. Patients were divided into two groups: those prescribed warfarin and patients prescribed DOAC. The management of antithrombotics was based on the Japanese Gastroenterological Endoscopy Society guidelines published in 2005 and 2012. The anticoagulants used during the study period were warfarin, dabigatran, rivaroxaban, apixaban, and edoxaban. Warfarin was discontinued 4–5 days before ER, whereas the others were stopped 24–48 h prior to the procedure. For patients at a high thrombotic risk, intravenous unfractionated heparin was administered after ceasing anticoagulants.

Results: Warfarin and DOAC were prescribed to 73 (75%) and 24 (25%) patients, respectively. Apixaban was administered to 1 (1%), dabigatran to 12 (12%), rivaroxaban to 11 (11%) patients. There were no significant differences between the DOAC and warfarin groups in terms of clinical characteristics or

PEB rate. Overall, 57 patients (78%) in the warfarin group underwent HBT, and were significantly associated with PEB rate compared to the patients who did not undergo HBT in the warfarin group (36% vs. 0%, $p < 0.05$). Although there was no significant difference in the PEB rate between the group that did and did not undergo HBT in the DOAC group, the PEB rate was higher among rivaroxaban recipients than dabigatran recipients (45% vs. 0%; $p < 0.05$). Multivariate analysis revealed that HBT, rivaroxaban, and anticoagulants plus antiplatelet therapy were associated with PEB ($P < 0.05$). Warfarin and DOAC were prescribed to 72 (57%) and 54 (43%) patients, respectively. Dabigatran was administered to 16 (13%), rivaroxaban to 18 (14%), apixaban to 18 (14%), edoxaban to 2 (1.6%) patients. Patients underwent polypectomy ($n = 50$), EMR ($n = 62$), or ESD ($n = 10$). PEB occurred in 5 (4.0%) patients (one polypectomy and four EMRs). Among them, warfarin was prescribed to one patient (1.4%) who also underwent HBT. Rivaroxaban and apixaban were prescribed to two patients (11%) each. PEB rate was higher in the DOAC group than in the warfarin group (7.4% vs. 1.4%).

Conclusion: Patients on HBT, rivaroxaban, and anticoagulants plus antiplatelet therapy are at an increased PEB risk after ESD for gastric tumors. In patients who underwent ER for colorectal polyps, PEB was more common in DOAC than that in warfarin recipients. That was the difference between ER for colorectal polyps and ESD for gastric tumors. We suggested that the PEB rate differs among DOACs because each drug has its own blood concentration and metabolism. Most clinicians have a limited knowledge on PEB during DOAC therapy because these are relatively new drugs, and because PEB has a low prevalence. Therefore, comparative data on larger patient series are needed to address this issue.

Introduction: Although endoscopic hemostasis is usually effective in controlling gastrointestinal (GI) hemorrhage, some have difficulty in achieving successful hemostasis depending on the location and severity of hemorrhage. NEXPOWDER® (Next Biomedical, Incheon, South Korea) is a biocompatible and biodegradable powder and the hemostatic effects are accomplished by physical barrier when this powder immediately forms mucoadhesive hydrogel after contacting blood or water. It shows high adhesiveness and persistency of gel on ulcer base. In addition, new powder delivering device was developed to reduce catheter clogging during endoscopic application.

Aims & Methods: The aims of this study were to confirm 1) success rate of hemostasis using NEXPOWDER® in acute GI bleeding from post-endoscopic procedure or various causes, 2) re-bleeding rate on second-look endoscopy at 1 or 3 days after the procedure, 3) persistent rate of hydrogel on ulcer base at follow-up endoscopy, and 4) clogging rate of catheter during spraying powder. The NEXPOWDER® was delivered by newly developed spraying device through an 8 Fr catheter. We defined the initial hemostatic success as when the bleeding disappeared within 10 minutes. A second-look endoscopy was performed in one and three days after the procedure.

Results: A total of 57 patients were enrolled. The bleeding developed in 46 patients with post-endoscopic resection ulcers (41 ESD induced ulcers and 5 EMR induced ulcers), 8 patients with peptic ulcers and 3 patients with other causes. 1) Success rates of hemostasis in acute bleeding were 96.5% (55/57) of NEXPOWDER® group. 2) Re-bleeding rates were 5.3% (3/57) of NEXPOWDER® group. 3) Persistent rate of NEXPOWDER® on ulcer base was 70.3% (26/37) 1 day after the procedure, and 38.5% (15/38) 3 days after the procedure. 4) Clogging rate of spraying catheter was 3.5% (2/57).

Conclusion: The endoscopic application of NEXPOWDER® is effective for the several types of acute GI bleeding. This effective hemostatic action of NEXPOWDER® might be achieved by physical barrier of mucoadhesive and persistent hydrogel on ulcer base. And new powder delivering device shows low rate of catheter clogging. In addition, a newly developed powder delivering device shows low scattering and targeted spraying properties onto bleeding site.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1811 CLINICAL FEATURES OF DELAYED BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC NEOPLASMS IN HIGH-RISK AND LOW-RISK PATIENTS

T. Inoue, Y. Maegawa, S. Ito, T. Shimizu, Y. Yokoyama, S. Tawara, S. Ishii, Y. Haruna, T. Yakushijin, A. Inoue

Gastroenterology, Osaka General Medical Center, Osaka/Japan

Contact E-mail Address: taktaktakkun@gmail.com

Introduction: Antithrombotic drugs are administered to patients undergoing endoscopic treatment at high risk for thromboembolism. However, antithrombotic drugs have been also known as a cause of delayed bleeding associated with endoscopic treatment, including endoscopic submucosal dissection (ESD). We previously reported the clinical features of postpolypectomy bleeding associated with heparin bridge therapy (1), and then various risk factors of delayed bleeding after endoscopic treatment have been reported.

Aims & Methods: The aims of the present study are to investigate the risk factors of delayed bleeding after gastric ESD and to clarify the clinical features of delayed bleeding in high-risk and low-risk patients. Data of consecutive inpatients who underwent ESD for gastric neoplasms in Osaka General Medical Center between January 2009 and December 2016 were retrospectively investigated. Independent risk factors of delayed bleeding were analyzed by using a multivariate analysis by logistic regression model, and three predictors of delayed bleeding were selected. Patients were categorized into a high-risk group or low-risk group for bleeding, and the clinical features of post-procedural bleeding in each group were investigated.

Results: A total of 717 patients with 781 gastric neoplasms were identified. Mean age was 74.6, and 71.6% was male. With regard to comorbidity, the proportion of hypertension, diabetes, chronic liver disease, and hemodialysis was 50.2%, 19.2%, 2.7%, and 6.1%, respectively. Total 188 patients have taken oral antithrombotic drugs, and of them, 50 patients treated by gastric ESD under heparin bridge therapy. Two-thirds lesions were located in gastric body and median tumor size (range) was 15 (3–80) mm. En-bloc resection was achieved in 751 lesions (96.2%), and no uncontrollable bleeding occurred. Forty-nine patients (6.8%) experienced delayed bleeding after gastric ESD. Hospital stay was significantly longer in bleeding cases than in non-bleeding cases [median hospital stay (range) 11 (3–20) vs. 9 (9–25), $p = 0.007$]. A univariate and multivariate analysis showed heparin bridge therapy, antiplatelet therapy, and hemodialysis, and age ($75 <$) were the independent risk factors for delayed bleeding. We defined patients with heparin bridge therapy, antiplatelet therapy, and hemodialysis as a high-risk group for bleeding, and the remainder as a low-risk group. The incidence of delayed bleeding was significantly higher in the high-risk group than in the low-risk group (14.3% vs. 3.6%, $p < 0.001$). Severe bleeding requiring transfusion and recurrent bleeding were more often in the high-risk group than in the low-risk group. Median onset (range) of delayed bleeding was POD1 (0–16) in low-risk group and POD6 (0–15) in high-risk group. No thromboembolism occurred in each group.

Conclusion: Bleeding high-risk patients with heparin bridge therapy, antiplatelet therapy, and hemodialysis should be carefully observed after gastric ESD while early hospital discharge is acceptable for bleeding low-risk patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There are few studies of the efficacy of parenteral ferric carboxymaltose (FCM) treatment in acute gastrointestinal bleeding (GIB) of different origins. Few data are available on its use to treat anaemia post-acute haemorrhage.

Aims & Methods: To determine the efficacy and safety of FCM treatment in patients with acute GIB not associated with portal hypertension. A retrospective descriptive 3-year study of patients with acute GIB (anemia with evident bleeding and/or hemodynamic instability) treated with FCM as part of our hospital's habitual clinical practice.

Results: Analysis of 84 patients admitted with acute GIB (69.0% male, mean age 68.0 years [SD 6.9]), with a Charlson index ≥ 3 in 67.1% of cases (≥ 5 in 31.6%). 15.5% had previously suffered acute GIB due to peptic ulcer. There were 86 hospital admissions for acute GIB; 93.8% were upper GIB (above the angle of Treitz). The most frequent clinical presentation was melena, in 76.7% of cases. 25.6% presented hemodynamic instability at admission. The mean Glasgow-Blatchford index score was 10.1 (SD 2.7) and the mean Rockall score post-endoscopy was 4.2 (SD 1.7). The most common causes of bleeding were: 36.0% duodenal ulcer, 29% gastric ulcer, 9.3% gastritis/erosions, and 7.3% angiodysplasia of the colon. The mean Hb at admission was 9.0 g/dL (SD 2.2)

and the mean of the lowest Hb during admission was 7.6 g/dL (SD 1.3). The most common total dose of FCM administered was 1000 mg. During admission, a mean Hb increase of 0.8 g/dL (SD 2.3) was observed in a mean period of 5.7 days (median: 4.0) after treatment with FCM, with an increase of 4.2 g/dL (SD 2.6) 30 days after acute GIB. After FCM administration, the mean Hb increased significantly ($p < 0.0001$) in patients ≥ 75 years (2.1 g/dL [SD 1.7]), in patients with Charlson index ≥ 3 (1.9 g/dL [SD 1.6]), and when Hb level during admission was < 10 g/dL (2.0 g/dL [SD 1.7]). No adverse reactions were observed.

Conclusion: In patients with acute GI bleeding the administration of ferric carboxymaltose improves Hb levels promptly and safely, especially in patients of advanced age and with associated comorbidities.

Introduction: Endoscopic Injection of adhesive agents such as N-Butyl-2-Cyanoacrylate (NBC) is an accepted option for the management of gastric varices. Recently the combination of NBC and coils has been used with endoscopic ultrasound (EUS) assistance. Nevertheless adhesive properties of the polymer can cause blockage of instrumentation material and damage to endoscopes. Some adverse events include ulcers, vascular wall necrosis, rebleeding and distal embolism. Ethylene-vinyl alcohol (EVOH) has been extensively used in interventional radiology to treat cerebral arteriovenous malformations and has the advantage of being radiopaque.

Aims & Methods: We aimed to demonstrate a novel gastric varices embolization therapy with EUS-guided injection of a composite non-adhesive endovascular liquid agent EVOH combined with Dimethylsulfoxide (DMSO) as a primer. Five cases of EUS-guided Injection under fluoroscopic vision with EVOH is described in 3 men and 2 women, aged 50–65 years with gastric fundus varices, portal hypertension, Child-B hepatic cirrhosis and previous episodes of bleeding. The ecoendoscope was advanced to the gastroesophageal junction. The selected gastric varix was punctured using a 22 Gauge needle. EVOH injected volume ranged between 1.5 and 3cc. Vascular flow progressive obliteration was real time monitored by EUS. Ceftriaxone was intravenously administered during the procedure. Patients were discharged on the same day. The mean follow-up was 6 months. Endoscopic and radiological control was performed at 1 and 3 months. The average procedure time was 20 min.

Results: All patients presented mild epigastric pain during the first 12 hours effectively managed with oral analgesics. The obliteration of variceal flow was achieved in all patients in a single session. There were no new episodes of bleeding or complications related to the technique.

Conclusion: EUS-guided embolization of gastric varices with EVOH can be considered as an efficient alternative. The procedure promises effective advantages in terms of number of sessions required, local or systemic adverse events and endoscopes damage. Prospective multicenter study with greater number of cases and cost evaluation against coils alone or combined with NBC are required.

Introduction: The increase in life expectancy and the increased use of antiplatelets, oral anticoagulants and nonsteroidal anti-inflammatory drugs (NSAIDs) may account for the increasing frequency of older patients with upper gastrointestinal bleeding.

Aims & Methods: The aim of this study was to assess the clinical and endoscopic aspects, hospital course and mortality rate in the elderly population with peptic ulcer bleeding. In this prospective study we enrolled all patients diagnosed with peptic ulcer bleeding, who were hospitalized in a tertiary medical center over a period of 24 months (January 2015- December 2016). Patients were divided into two groups, according to their age: patients with age below and over 75 years old. The following characteristics were analyzed in both groups: antiplatelets, oral anticoagulants and NSAID's uses, smoking, alcohol consumption, presence of comorbidities, (quantified by Charlson score), endoscopic aspect of ulcer (Forrest IA, IB, IIA, IIB were quantified as high risk endoscopic stigmata), while Forrest IIC and III were considered as low risk endoscopic stigmata) and the number of ulcers. We also analyzed comparatively the need of transfusion, hospitalization duration, rebleeding, need for surgery and in-hospital mortality.

Results: 431 patients have been included in this study. 24.8% of patients were over 75 years old. The following differences have been observed by comparing the two groups of patients (over and below 75 years old): female 47.7% vs 25.3% ($p < 0.001$); antiplatelets use 40.2% vs 20.1% ($p < 0.001$); oral anticoagulants use 20.6% vs 7.7% ($p < 0.001$); NSAIDs use 25.2% vs 33.6% ($p = 0.133$); smoking 5.6% vs 35.2% ($p < 0.001$); alcohol consumption 17.8% vs 45.4% ($p < 0.001$); one or more comorbidities 77.6% vs 62% ($p = 0.005$); high risk endoscopic stigmata 61.7% vs 64.4% ($p = 0.724$); multiple ulcers 41.1% vs 31.8% ($p = 0.099$); need for blood transfused 59.8% vs 58% ($p = 0.832$); hospitalization duration 8.4 ± 6.1 vs 7.8 ± 6.0 days ($p = 0.382$); rebleeding 10.3% vs 11.4% ($p = 0.745$); need for surgery 2.8% vs 4.6% ($p = 0.589$) and in-hospital mortality 13.1% vs 6.2% ($p = 0.021$). In most of the cases (88.2%), the cause of death was other than hemorrhagic shock (92.9% vs 85.0%, $p = 0.484$). Using multivariate analysis, three out of these factors were identified as representing independent factors significantly associated with the age over 75 years old: oral anticoagulants use (OR = 2.40, 95%CI:1.24-4.62, $p = 0.009$), antiplatelet use (OR = 2.33, 95%CI:1.43-3.81, $p = 0.001$) and in-hospital mortality (OR = 2.09, 95%CI:1.27-4.47, $p = 0.048$).

Conclusion: The use of oral anticoagulants and antiplatelet was significantly higher in older patients, compared to the younger group. Elderly patients with peptic ulcer bleeding do not have a different rebleeding, need for surgery, need of transfusion or hospitalization duration than younger patients. In-hospital mortality was higher in elderly patients due to more frequent association of comorbidities.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Peptic ulcers are the most frequent cause of upper gastrointestinal bleeding. In different population based surveys regarding all-cause UGIB, mortality ranges between 3% and 14%.

Aims & Methods: The aim of this study was to assess in-hospital mortality in patients with peptic ulcer bleeding and to evaluate the risk factors associated with mortality. In this prospective study we enrolled all patients diagnosed with peptic ulcer bleeding, who were hospitalized in a tertiary medical center over a period of 24 months (January 2015- December 2016). Patients were divided into two groups - those who died and those who survived - and the following parameters were compared: age, signs of hemodynamic instability (hypotension, tachycardia), presence of comorbidities (quantified by Charlson score), endoscopic aspect of ulcer (Forrest IA, IB, IIA, IIB were quantified as high risk endoscopic stigmata), while Forrest IIC and III were considered as low risk endoscopic stigmata), number of ulcers, Rockall score, Blatchford score, degree of anemia, coagulation disorders, renal function. We also analyzed comparatively rebleeding, the need of transfusion and need for surgery.

Results: The study included 431 patients. In-hospital mortality rate was 7.9%. The following differences have been observed by comparing patients who died and those who survived: age > 75 years 41.2% vs 23.4% ($p = 0.036$); hypotension 17.6% vs 2.3% ($p < 0.001$); tachycardia 47.1% vs 21.4% ($p = 0.001$); one or more comorbidities 94.1% vs 63.5% ($p = 0.001$); high risk endoscopic stigmata 79.4% vs 62.2% ($p = 0.070$); multiple ulcers 41.2% vs 33.5% ($p = 0.473$); Rockall score ≥ 5 points 94.1% vs 46.9% ($p < 0.001$); Blatchford score ≥ 10 points 91.2% vs 66.2% ($p = 0.005$); hemoglobin < 9.5 g/dl 70.6% vs 41.1% ($p = 0.002$); INR ≥ 2.5 17.6% vs 5.8% ($p = 0.022$); creatinine ≥ 1.5 mg/dl 38.2% vs 10.8% ($p < 0.001$); rebleeding 20.6% vs 10.3% ($p = 0.123$); need for blood transfusion 82.4% vs 56.4% ($p = 0.006$); need for surgery 11.8% vs 3.5% ($p = 0.063$). In most cases (88.2%), the cause of death was other than hemorrhagic shock. Using multivariate analysis, three out of these factors were identified as representing independent factors significantly associated with in-hospital mortality: tachycardia (OR = 2.83, 95%CI:1.21-6.58, $p = 0.016$), Rockall score ≥ 5 (OR = 6.65, 95%CI:1.46-30.16, $p = 0.014$) and creatinine ≥ 1.5 mg/dl (OR = 1.25, 95%CI:1.25-7.73, $p = 0.014$).

Conclusion: In-hospital mortality rates in patients with peptic ulcer bleeding was 7.9%. Tachycardia, Rockall score ≥ 5 and creatinine ≥ 1.5 mg/dl were the independent risk factors significantly associated with in-hospital mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1816 ANAEMIA AND UPPER GI BLEEDING: A LOCAL EXPERIENCE

M. Ding, R. Prawiradiradja, Z. Arastu, H. Sabri, M. Smith
Gastroenterology, Royal shrewsbury hospital, Shrewsbury/United Kingdom

Contact E-mail Address: Michaeljdjw@gmail.com

Introduction: There has been significant research recently on the use of blood transfusions in upper GI bleeding (UGIB) [1] with recent evidence advocating a restrictive approach to blood transfusions as well as the use of iron therapy [2] for anaemia post UGIB. Our team conducted a local retrospective analysis on patients admitted with UGIB over a six month period and analysed the use of blood transfusions at our trust which consists of two District General Hospitals. Patient data over a period of up to 12 months post discharge was collected to monitor their anaemia.

Aims & Methods: Our aim was to monitor the appropriateness of transfusions in Upper GI Bleeding as well as monitoring the response to iron therapy following discharge. All inpatients that had an Upper GI endoscopy for UGIB were analysed. Electronic patient records were obtained from our endoscopy software and hospital database. Patients were selected over a time period of six months from 1/6/2015 to 31/12/2015. A Student's T-Test was used to compare the average increase in haemoglobin (Hb) for patients discharged with iron therapy against those who were not.

Results: There were 148 patients, 81 male and 67 female. The mean age was 69.3, minimum 20 and maximum of 98. The average Hb on admission was 103 g/L (min = 32 g/L, max = 178 g/L). 78 out of 148 (52.7%) patients presenting with UGIB received a blood transfusion. The mean amount of blood received for those transfused was 3.7 units. 48 out of 78 (61.5%) of blood transfusions were given when Hb was below 70 g/L. 30 of 78 (38.5%) were transfused above a Hb of 70 g/L. (36.7%, n = 11) of those who were transfused with Hb above 70 had cardiac risk factors. The mortality rate in those transfused above Hb of 70 was 13.3% (n = 4) vs 10.4% (n = 5) 41.5% (n = 44) patients who were anaemic post-UGIB were discharged with iron therapy. The average rise in Hb was 26.5% for those discharged on iron vs 12.1% for those who did not. There was a statistically significant rise in Hb for those discharged with iron therapy (p < 0.005) on follow-up versus those who did not receive it (n = 62). The anaemia related readmission rates were similar for patients discharged on iron or not (9.1% n = 4 vs 9.7% n = 6).

Conclusion: The data obtained supports a restrictive transfusion policy (mortality rate of 13.3% vs 10.4%). 58.5% of patients who were anaemic on discharge did not receive any iron therapy. On follow up, there was a statistically significant rise in Hb level in the group discharged on iron. Our data affirms recent evidence favouring iron therapy post UGIB. Further education is needed to improve outcome in patients presented with GI bleed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1817 THE RELATIONS AMONG SERUM GHRELIN, MOTILIN, CIRCULATING ANTIMYENTERIC ANTIBODIES AND GASTRIC EMPTYING AND AUTONOMIC NERVOUS SYSTEM FUNCTION IN PATIENTS WITH AUTOIMMUNE GASTRITIS

Ç. Kalkan, F. Karakaya, I. Soykan
Gastroenterology, Ankara University, Ankara/Turkey

Contact E-mail Address: mfkarakaya@yahoo.com

Introduction: Autoimmune gastritis (AIG) is an organ-specific autoimmune disease of the stomach marked by autoantibodies directed to hydrogen/potassium-ATPase and intrinsic factor. Gastric emptying of solids is delayed and autonomic nerve dysfunction is detected in patients with autoimmune gastritis. This may be a cause of symptoms and also there is a close relation between autonomic nerve dysfunction and delayed gastric emptying. As ghrelin and motilin are putative regulators of gastric emptying and, some autoimmune gastritis patients may have delayed gastric emptying leading upper gastrointestinal symptoms.

Aims & Methods: The aims of this study were to: (i) compare serum levels of ghrelin and motilin in patients with delayed to normal gastric emptying and (ii) investigate whether circulating antimyenteric antibodies, serum levels of ghrelin and motilin have any effect on autonomic nerve function and gastric emptying. Forty-one patients with AIG were included into this study. Autoimmune gastritis was diagnosed depending upon histopathological findings in gastric biopsy specimens. Non-invasive cardiovascular reflex tests were used in order to evaluate autonomic nervous system function. Sympathetic nerve function was evaluated with two tests: blood pressure response to standing and handgrip test. Parasympathetic nerve function was evaluated with three tests: valsalva manoeuvre, heart rate response to deep breathing (E/I ratio) and orthostatic blood

pressure testing. Dysfunction was considered to exist if at least two tests were positive. Gastric emptying time was evaluated by a standard 2-hour scintigraphic test using a solid meal. A half-time of longer than 110 minutes was chosen in the present study to further investigate patients with delayed gastric emptying. Serum ghrelin and motilin levels were tested by ELISA and circulating antimyenteric antibodies were tested by IFA.

Results: Forty-one patients (27 women), mean age 56.61 ± 11.79 years with AIG were included into the study. Overall, 22 (53.6%) patients showed delayed GE and 19 patients showed normal GE (GET ½: 241.19 ± 199 vs 90 ± 19 mins, p < 0.001). Serum ghrelin and motilin levels of patients with delayed GE were significantly decreased compared to patients with normal GE, respectively (67.55 ± 8.81 vs 126.79 ± 25.81 pg/mL, p < 0.001 and 279.59 ± 111.12 vs 500.42 ± 155.95 pg/mL, p < 0.001). In all, 26 (63.4%) patients showed autonomic nervous system dysfunction and, 15 (36.5%) patients had normal autonomic nervous system test findings (total autonomic test score: 0.8 ± 0.25 vs 5.65 ± 1.74, p < 0.001). Serum ghrelin and motilin levels of patients with deranged autonomic nervous system function were significantly decreased compared to patients with normal autonomic nervous system function, respectively (80.73 ± 28.46 vs 127.79 ± 28.06 pg/mL, p < 0.001 and 316.92 ± 160.47 vs 490.20 ± 141.02 pg/mL, p < 0.001). In multivariate analysis, plasma motilin level was found as an independent factor that affected serum ghrelin level (r = 0.623, p = 0.019). However, serum ghrelin (r = 0.623, p = 0.019) and gastrin (r = -0.70, p < 0.001) levels were found as independent factors that affected plasma motilin level. We also investigated the presence of antimyenteric antibodies, however all the patients were negative by means of antimyenteric antibodies therefore, no further relationship was sought.

Conclusion: Mean fasting serum ghrelin and plasma motilin levels in autoimmune gastritis patients with delayed GE and deranged autonomic nerve function were significantly decreased. None of the patients in our study were positive for circulating antimyenteric antibodies. These decreased serum ghrelin and plasma motilin levels in patients with autoimmune gastritis suggest a potential role for ghrelin and motilin in explaining the finding of the delayed gastric emptying observed in an important part of autoimmune gastritis patients. We believe that these new observations supply more insight into the pathophysiology of autoimmune gastritis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The interaction between gut microbiota and enteroendocrine cells alterations is believed to play an important role in the pathophysiology of irritable bowel syndrome (IBS). The densities of the duodenal enteroendocrine cells are abnormal in IBS patients, which appears to be caused by a reduced stem cells density and their differentiation into endocrine cells (1).

Aims & Methods: The aim is to investigate the effects of faecal microbiota transplantation (FMT) on the differentiation of the stem cells into enteroendocrine cells as detected by neurogenin 3, the stem cells as detected by Musashi 1 and the enteroendocrine cells in the duodenum of patients with IBS. The study included 16 IBS patients according to Rome III criteria and four patients were excluded. The remaining patients (n = 12, 4 females and 8 males, age range 20–44 years) were divided according to the cause of IBS into PI-IBS patients (n = 6) and idiopathic IBS (n = 6) and received FMT donated from their relatives. The patients completed the IBS-symptom severity scoring system (IBS-SSS) before and 3 weeks after FMT. The patients underwent gastroscopies with biopsies taken from the descending part of the duodenum at baseline and 3 weeks after FMT. The biopsies were immunostained for neurogenin 3, Musashi 1 and all types of duodenal enteroendocrine cells, and quantified by computerized image analysis.

Results: The score of IBS symptoms as assessed by IBS-SSS was significantly reduced 3 weeks after (240.2 ± 33.6) compared to before (326.6 ± 22.3) receiving FMT, P = 0.0009. The scores of IBS-SSS before and 3 weeks after FMT for PI-IBS are 300.8 ± 27.8 and 210 ± 41, respectively (P = 0.025), and for idiopathic IBS are 352 ± 34 and 270.3 ± 54, respectively, (P = 0.034). The densities of neurogenin 3, Musashi 1 and enteroendocrine cells in the duodenum of IBS patients before and 3 weeks after receiving FMT are presented in Table 1.

Conclusion: Faecal microbiota transplantation improved the symptoms in IBS patients, both PI and idiopathic. This improvement was associated with a change in the enteroendocrine cell density. The changes in the enteroendocrine cell density does not appear to be caused by changes in the stem cells or their early progenitors, but rather by changes in the differentiation progeny as detected by changes in neurogenin 3.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Neuronal plasticity has been reported to develop following nociceptive emotional experience in prefrontal cortex (PFC) and hippocampus. The N-methyl-D-aspartate receptor (NMDAR) and D-serine, the endogenous coagonist of NMDAR1, may mediate the neural plasticity. However, whether the neural plasticity participates in the mechanism of esophageal visceral hypersensitivity is little known.

Aims & Methods: This study aims to investigate the expression of NMDAR and the alteration of D-serine after neonatal and adult esophageal acid exposure. All rats were exposed to esophageal acid or saline at postnatal days 7–15 (P7-P15), and most rats underwent acute acid or saline exposure again at adult time (P60). All rats were randomly distributed to 5 groups, including P7S, P7H, P7H + P60H, P7H + P60S, P7S + P60H (P7: postnatal 7–15 days; P60: adult at postnatal 60 days; H: 0.1N HCL infusion; S: saline control). The tissue harvest was conducted at P60. We examined the expression of subunits of NMDAR (including NR1, NR2A, and NR2B), c-fos, and serine racemase in PFC, dorsal hippocampus (DH) and ventral hippocampus (VH). We also determined the D-serine and L-serine in PFC and hippocampus by LC-MS analysis. Statistic comparisons were performed by General Linear Model and one way ANOVA in SPSS.

Results: In PFC, compared with adult saline treatment (AS, including P7H + P60H and P7S + P60H group) and without adult treatment (A-, including P7S and P7H group), adult acid exposure (AH) increased the expression of NR1 ($P=0.052$, $P=0.298$), NR2B ($P=0.035$, $P=0.045$), and serine racemase ($P=0.022$, $P=0.017$) significantly. In ventral hippocampus, compared with adult treatment absence, adult acid exposure caused increasing expression of NR2B ($P=0.012$) and NR1 ($P=0.024$) significantly. In PFC, the expression of serine racemase in the P7S + P60H group was obviously higher than that of other groups ($P=0.008$). See Table1. In dorsal hippocampus, there was statistical significance on the level of c-fos between the P7S + P60H group and other groups ($P=0.008$). Table1. In PFC, the LC-MS analysis results that D-serine (AH vs A-: $P=0.000$, AS vs A-: $P=0.042$, AH vs AS: $P=0.081$) and L-serine (AH vs A-: $P=0.000$, AS vs A-: $P=0.015$, AH vs AS: $P=0.082$) decreased in the AH and AS group, comparing with A- group.

The expression of serine racemase in PFC and c-fos in VH

Group (n = 8/group)	PFC Serine Racemase		VH c-fos	
	(mean ± SD)	P value (vs P7S + P60H)	(mean ± SD)	P value (vs P7S + P60H)
P7S	0.139 ± 0.131	0.03	0.035 ± 0.008	0.021

(continued)

Continued

The expression of serine racemase in PFC and c-fos in VH

Group (n = 8/group)	PFC Serine Racemase		VH c-fos	
	(mean ± SD)	P value (vs P7S + P60H)	(mean ± SD)	P value (vs P7S + P60H)
P7H	0.141 ± 0.083	0.034	0.036 ± 0.015	0.026
P7H + P60H	0.166 ± 0.066	0.119	0.035 ± 0.011	0.023
P7H + P60S	0.124 ± 0.031	0.014	0.040 ± 0.015	0.057
P7S + P60H	0.300 ± 0.149	–	0.083 ± 0.060	–

Conclusion: Acute esophageal acid exposure may increase the expression of NMDAR in PFC and ventral hippocampus. We also found the first acid exposure at adult stage may enhance the expression of serine racemase in PFC and c-fos in ventral hippocampus, but this phenomenon may be absent in those rats having the experience of acid exposure in early life. Those long-term and transitional molecular alterations may mediate the development of acid exposure related esophageal visceral hypersensitivity.

Introduction: Globus pharyngeus, a sensation of a lump or tightness in the throat, is a well-defined clinical symptom that is usually long-lasting, difficult to treat, and has a tendency to recur. More than half of globus patients suffered from probable psychological disorders, such as anxiety and depression¹. Antidepressants are used in the treatment of functional gastrointestinal disorders (FGIDs) and showed a promising efficacy. Our study manifested that low-dose amitriptyline is well tolerated and effective for general globus pharyngeus patients². Our anterior study had ever speculated that AMT could modify brain-gut axis function, up-regulating brain-gut peptides, reducing the visceral sensitivity and regulating the secretory and motor functions of the gastrointestinal tract³, so that gastrointestinal symptoms as well as emotional well-being could be significantly improved. As we known, serotonin (5-hydroxytryptamine, 5-HT) is an important factor in gut function, playing key role in intestinal peristalsis, secretion, and sensory signaling in the brain-gut axis⁴⁻⁵. Several studies have investigated the association between SLC6A4 and functional gastrointestinal disorders, including IBS and FD. Besides, the association between various complex behavioral traits and disorders were also studied, including anxiety, major depression, suicide, smoking behavior, alcohol dependence. A single gene (SLC6A4), located on the human chromosome 17q11.2. 17q12, is coded by serotonin transporter (5-HTT). The polymorphism of this gene is characterized by the insertion or deletion of the 44-bp sequence and this is related to the different transcriptional activity of the gene. Allele with 44-bp deletion (short allele) is characterized by a three times lower transcriptional activity than allele with 44-bp insertion (long allele). Compared to other FGIDs, the researches about globus are rare. The pathogenesis of globus pharyngeus is still unknown.

Abstract No: P1818

To the best of our knowledge, our findings are the first to establish an association between SLC6A4 gene polymorphism and globus.

Aims & Methods: 84 patients diagnosed with globus according to Rome III and 160 healthy controls were genotyped for 5-HTTLPR polymorphism by PCR amplification and agarose gel electrophoresis. All globus patients were studied with high-resolution manometry pre-therapy. Globus patients were randomized into paroxetine group; amitriptyline group for 6-week treatment, and were asked to complete the following questionnaires pre- and post-therapy: Glasgow Edinburgh Throat Scale (GETS), Pittsburgh Sleep Quality Index, Hamilton Rating Scale Anxiety/Depression. Treatment response was defined as a >50% reduction in GETS scores.

Results: The significant difference was shown in globus performed S/S genotype with anxiety when compared to without ($X^2 = 14.579$, $P = 0.006$). The L/S genotype was significant difference between high upper esophageal sphincter pressure (>104 mmHg) and non-high upper esophageal sphincter pressure patients ($X^2 = 14.433$, $P = 0.006$). There was significant association between the S/S genotype and the response to antidepressants treatment, while patients with sleep disorders or depression not.

Conclusion: A significant association was observed between S/S genotype of SLC6A4 polymorphism and globus pharyngeus, suggesting that SLC6A4 is a potential candidate gene involved in the pathogenesis of globus pharyngeus.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Multiple rapid swallows (MRS) and rapid drink challenge (RDC) are provocative tests that can enhance the diagnostic value of esophageal HRM. The discriminatory characteristics of these provocative tests were evaluated in symptomatic patients referred for esophageal HRM.

Aims & Methods: Consecutive patients presenting for esophageal HRM over a 2-month period underwent provocative testing with MRS and RDC in addition to the standard manometric protocol. Integrated relaxation pressure >15 mmHg identified outflow obstruction; those without outflow obstruction were further analyzed using software tools (IRP, distal contractile integral, DCI; intrabolus pressure, IBP) for peristaltic reserve (MRS or RDC DCI > mean DCI from wet swallows), and obstruction (IBP >30 mmHg during MRS or RDC). All patients completed symptom questionnaires addressing reflux symptoms (GERD-Q), dysphagia (Mayo Dysphagia Questionnaire, MDQ) and global symptom severity (GSS) on a 100 mm visual analog scale (VAS). Univariate and multivariate analyses were performed to evaluate overall yield (proportions with MRS/RDC findings not seen with the standard HRM protocol) and to assess association of presenting symptoms with results of MRS and RDC in patients without outflow obstruction.

Results: 149 patients (55.4 ± 1.2yr, 68% F) fulfilled inclusion criteria and had no outflow obstruction on HRM. Of these, 91 (61%) had peristaltic reserve on MRS, 19 (12.6%) on RDC ($p < 0.001$), only 10 were concordant. Obstruction was noted in 16 (9.8%) on MRS, 8 (4.9%) on RDC ($p = 0.09$), and 5 were concordant; of these, only 2 patients had panesophageal compartmentalization of pressure, and only 1 had elevated IRP during provocative measures. Within ineffective esophageal motility, peristaltic reserve was noted in 59.3%. Within dysphagia presentations, obstruction was noted in 7.7%, and absent peristaltic reserve in 50%. Thus, the overall yield of MRS was 80.5%, and RDC 19.8% ($p < 0.001$). 131 patients had adequate questionnaire data. Findings on provocative tests did not predict presenting symptoms (GERD-Q or MDQ). Obstruction on RDC predicted higher GSS (odds ratio 5.56, 95% CI 1.04–29.72).

Conclusion: MRS identifies peristaltic reserve better than RDC and has higher overall clinical value. While both MRS and RDC identify outflow obstruction, only RDC obstruction predicts higher symptom burden. Neither MRS nor RDC findings correlate with presenting symptoms.

Introduction: Achalasia is an uncommon condition of failed lower oesophageal sphincter relaxation. Data regarding the incidence and prevalence are limited. The aim of this study was to provide accurate, contemporary epidemiological data utilising two national databases.

Aims & Methods: Hospital Episode Statistics (HES) includes demographic and diagnostic data for all English hospital admissions. The Health Improvement Network (THIN) database includes primary care records of 7% of the UK population, representative of national demographics. Both were searched for incident cases and THIN for prevalent cases of achalasia.

Results: There were 10,509 and 711 new achalasia subjects in HES and THIN respectively. The incidence per 100,000 population in HES was 1.99 (95% CI 1.87–2.11) and 1.53 (1.42–1.64) per 100,000 person years in THIN. The prevalence measured in THIN was 27.1 (25.4–28.9) per 100,000 population.

Table 1: Annual incidence and prevalence of achalasia

Year	Incidence rate HES (per 100,000 population)	95% CI	Incidence rate THIN (per 100,000 person years)	95% CI	Prevalence THIN (per 100,000 population)
2006	1.733	1.62–1.85	1.409	1.08–1.81	21.14
2007	1.798	1.69–1.92	1.656	1.39–2.08	21.72
2008	1.789	1.68–1.91	1.550	1.21–1.96	22.49
2009	1.853	1.74–1.97	1.696	1.34–2.12	23.16
2010	2.015	1.90–2.14	1.663	1.31–2.09	23.66
2011	1.781	1.67–1.90	1.424	1.09–1.82	24.62
2012	2.032	1.91–2.16	1.549	1.20–1.96	25.23
2013	2.179	2.06–2.31	1.618	1.26–2.05	26.06
2014	2.421	2.29–2.56	1.476	1.12–1.91	26.34
2015	2.236	2.11–2.36	1.342	0.96–1.80	27.10

Conclusion: The incidence of oesophageal achalasia was approximately 15 to 20 per 1 million population. There were approximately 17,500 patients with achalasia in UK. In 2015 the above data represents the largest published epidemiological investigation of achalasia. The variation of findings between the databases likely results from differences in coding practice and marginally different population structures.

Introduction: Resistance to bolus flow across the lower esophageal sphincter (LES) is a hallmark of achalasia. Presently the gold standard of diagnosis is by high-resolution manometry (HRM) demonstration of raised integrated relaxation pressure (IRP) following ten 5 mL water swallows; however, this does not replicate normal swallowing behavior. It has been demonstrated that the addition of adjunctive tests improves sensitivity of identifying relevant dysmotility. Such tests include multiple water swallows (MWS; 200 mL water drunk freely) and solid swallows. In addition, the timed barium esophagram (TBE) measures esophageal emptying. This study describes a cohort of patients who have been treated as having achalasia based on resistance to flow not exhibited with single water swallows.

Aims & Methods: Inclusion criteria were all patients between October 2014–2016 with normal mean and median IRP with 5 mL water swallows but considered to have achalasia due to resistance to flow demonstrated by pan-esophageal pressurization (PEP) during MWS or solid swallows and/or a persistent column at 5 minutes during TBE. Outcome following treatment was based on the Eckardt symptom score (ES).

Results: 14 patients (9 male) fulfilled inclusion criteria. 7 were treatment-naïve and 7 treatment-experienced (3 myotomy, 4 dilatation). Mean resting LES pressure was 14.6 ± 7.4 mmHg. In all patients, mean and median IRP values for ten 5 mL water swallows were non-raised (mean 9.1 ± 4.3 and 8.7 ± 4.5 mmHg respectively). Of the 7 treatment-naïve patients, 5 demonstrated PEP on MWS, 3 on solid swallows and 6 had a positive TBE at 5 minutes. In treatment-experienced patients, 5 had PEP on MWS, 1 on solid swallows and all had a positive TBE. Of the 13 who had resistance to flow on TBE, 10 (77%) also had resistance demonstrated during MWS and/or solid swallows. Mean height of the 5-minute column of barium at baseline was 16.5 ± 8.9 cm. 8 patients have (so far) undergone therapy based on these findings; one per-oral endoscopic myotomy and 7 pneumatic dilatations. The median baseline ES was 7.5 (IQR 5–8). The median ES at minimum 3 months (range 3–15 months) following treatment was 1 (IQR 0–2.5; $P < 0.01$ cf. baseline). Similarly, there was significant improvement in TBE findings post-therapy (mean 5-minute column height 3.5 ± 4.1 cm; $P = 0.04$ cf. baseline).

Conclusion: A normal IRP for water swallows does not preclude a diagnosis of achalasia. The addition of free drinking/solids during HRM or the TBE can identify pathology that might have been missed with standard 5 mL water swallows alone as normal, clinically relevant swallowing behavior is reproduced. Patients treated based on this algorithm exhibit excellent treatment outcomes, validating this approach. Further, the close correlation of HRM adjunctive testing with TBE supports its routine inclusion in clinical practice.

P1824 200ML RAPID DRINK CHALLENGE DURING HIGH RESOLUTION MANOMETRY PREDICTS OESOPHAGOGASTRIC JUNCTION OBSTRUCTION IN DYSPHAGIA, AND IS CORRELATED WITH SYMPTOM SEVERITY IN ACHALASIA

Introduction: In patients with dysphagia, the identification of obstruction at the OGJ level determines the need for further endoscopic or surgical therapy. Timed barium oesophagogram (TBO) is regularly used to detect impaired oesophageal emptying in due to OGJ obstruction in patients with dysphagia and achalasia. “Volume loading” the oesophagus with a 200 ml rapid drink challenge (RDC) has recently been shown to help with the diagnosis of oesophageal motility disorders. We predict that this test can evaluate OGJ emptying at HRM without need for further TBO study. As such we hypothesised that RDC can predict pathological barium column at TBO, and associates with symptom severity in achalasia.

Aims & Methods: 39 patients with untreated dysphagia (mean age 55yr) were evaluated. All patients underwent HRM with standard protocol plus RDC, followed by TBO. In patients with achalasia, symptoms were recorded by Eckhardt score. Analysis of HRM followed the Chicago Classification v3 algorithm. During TBO, oesophageal emptying was assessed at min 1, 3 and 5. OGJ obstruction was diagnosed by persistent barium column at 5 minutes. During RDC, the mean IRP was measured during the rapid drinking period.

Results: HRM diagnosis was normal or minor peristaltic abnormality ($n=5$), achalasia type I ($n=3$), achalasia type II ($n=22$), achalasia type III ($n=2$), oesophagogastric junction outflow obstruction ($n=3$), absent contractility ($n=2$) and Jackhammer ($n=2$). ROC curve analysis showed that a mean IRP during RDC > 17 mmHg had a sensitivity of 100% and specificity of 87% for an abnormal TBO. In patients with achalasia, only mean IRP during RDC correlated with Eckhardt score ($r=0.42$, $p=0.03$). No standard HRM parameters or TBO findings correlated with Eckhardt score.

Conclusion: 200 ml rapid drink challenge during HRM is a useful adjuvant in assessment of oesophageal motility disorders. It can predict an abnormal TBO with excellent sensitivity and specificity in patients with dysphagia. In patients with achalasia, a higher mean IRP during 200 ml rapid drink challenge is the only HRM metric that correlates with worse symptom burden. These findings suggest that the rapid drink challenge is a clinically relevant parameter.

P1825 THE TIMED BARIUM ESOPHAGRAM SURFACE AREA CORRELATES WITH SYMPTOM IMPROVEMENT BETTER THAN COLUMN HEIGHT FOLLOWING TREATMENT IN ACHALASIA

S. Sanagapalli¹, J. Maynard¹, A. Plumb², A. V. Emmanuel³, A. Raeburn¹, M. Banks⁴, R. Haidry⁴, L. Lovat⁴, R. Sweis¹

Introduction: The timed barium esophagram (TBE) is an objective measurement of esophageal emptying used in the assessment of achalasia. Post-therapy reduction of the maximum height of the residual barium column has been found to correlate imperfectly with short-term symptomatic outcomes, but carries long-term prognostic implications. We hypothesize that the surface area (SA) of the barium column may be more accurate than height; firstly, by incorporating improvement in esophageal width that often occurs post-therapy, but also by correcting for artificially higher height values due to esophageal (longitudinal) contraction occurring during a single image. We aimed to compare the correlation of TBE outcome measures of height and SA with symptom improvement post-therapy.

Aims & Methods: Inclusion criteria were achalasia patients who underwent therapy between August 2015–6 and had TBE and Eckardt score (ES) performed at baseline as well as within 6 months post-therapy. With TBE upright single images were acquired at 1,2 and 5 minutes following ingestion of 100–200 mL of low-density barium sulfate. Barium height was measured between the gastro-esophageal junction and the superior extent of any residual barium column. After manually defining the column boundaries, software was used to calculate SA (AGFA IMPAX surface area tool (Figure)). Adequate symptom relief was defined as reduction in ES to ≤ 3 . On TBE, metrics of adequate emptying evaluated were i) post-therapy column height < 5 cm, ii) $> 50\%$ reduction in column height from pre to post-therapy and iii) $> 50\%$ reduction in column SA from pre to post-therapy. Associations between symptom improvement and TBE measures of emptying were assessed using Pearson's correlation (R). Paired *t*-tests compared TBE measures before and after therapy.

TBE parameter	Cut-off value for adequate emptying	Concordance between adequate TBE & symptom relief (based on ES) n/total (%)	Pearson's correlation between TBE & post-therapy ES R
Post-therapy 5-min barium column	< 5 cm	7/18 (39%)	−0.05
% Reduction in 5-minute barium height post-therapy from baseline	$> 50\%$	8/18 (44%)	0.20
% Reduction in SA of 5-min barium post-therapy from baseline	$> 50\%$	12/18 (67%)	0.36

Results: 18 patients (9 male; 6 Type I, 11 Type II, 1 Type III) were included. 11 had dilatation and 7 endoscopic myotomy. Reductions with therapy of both mean 5-minute barium column height (14.7 ± 8.7 to 7.9 ± 6.0 cm; $P=0.01$) and SA (52.7 ± 43.5 to 24.5 ± 26.0 cm²; $P=0.02$) were noted. Symptoms also improved with treatment; median baseline ES of 7 (IQR 5.25–8) improved to 0 (IQR 0–1) post-therapy. Only 2 patients had inadequate symptom relief and are awaiting further treatment. However there was poor concordance between post-therapy barium column height and symptomatic relief (i.e. post-therapy column > 5 cm despite ES ≤ 3 or vice versa), and the correlation (R) between these two variables was poor (Table). Similar poor concordance was seen when adequate emptying was defined by $> 50\%$ reduction in column height, but $> 50\%$ reduction in SA paralleled symptom relief most closely.

Conclusion: In TBE performed on achalasia patients post-therapy, reduction in SA of the residual barium column compared with baseline values parallels symptomatic relief more closely than reduction of column height.

P1826 NUTRIENTS ENHANCE BELCHING AND REDUCE INTESTINAL PROPULSION OF GASTRIC GAS IN HEALTHY HUMANS

E.N. Caballero De Garcia, B. Benslaiman Seyid-Jebari, J. Serra Pueyo
Gut Motility Unit, Hospital Unversitary Germans Trias i Pujol, Badalona/Spain

Contact E-mail Address: noecaballerosuarez@gmail.com

Introduction: During meal intake, large volumes of gas can be ingested together with nutrients, and patients with gas-related abdominal symptoms often refer symptom exacerbation by meals. Previous studies have shown that under fasting conditions gastric gas is rapidly eliminated from the stomach, either via gas emptying to the small bowel and colon, or via belching. Nutrients have several effects on gastric and intestinal motor function that could modulate gas transport and symptoms.

Aims & Methods: We aimed to determine the effect of gastric nutrients on transport of gastric gas, and its relationship with abdominal symptoms. In 7 healthy volunteers without gastrointestinal symptoms (4 women and 3 men, age-range 21–25 yrs), a mixture of non-absorbable gases was infused into the stomach, 5-cm caudal to the lower margin of the LES, at 25 mL/min during 60 min (Total gas infused: 1500 ml). In each subject two gas infusion tests were performed on separate days, with simultaneous infusion of nutrients (Nutridrink 1.5 Kcal/ml, total 315 Kcal) or saline. Belching, by an esophageal multilumen impedance manometry catheter, rectal gas evacuation, via a rectal tube connected to a barostat, and epigastric and abdominal symptoms, by specific questionnaires (from 0–6), were continuously recorded from the start of gas infusion until 30 min after gas infusion stopped. (Total recording time: 90 min).

Results: During saline infusion, participants evacuated via the rectum virtually all the infused gas (1613 ± 87 ml), with exceptional belching (1.1 ± 0.8 belches) and mild epigastric perception (score 1.7 ± 0.6 at the end of infusion), that decreased during the 30 min following infusion stop (score 1.1 ± 0.4 ; $p=0.051$ vs infusion

stop). Gastric nutrients reduced significantly rectal gas evacuation (1220 ± 187 ml; $p=0.016$ vs saline), increased the number of recorded belches (3.3 ± 1.3 belches; $p=0.018$ vs saline), and produced greater epigastric perception (score 2.7 ± 0.6 ; $p=0.030$) that decreased during the 30 min following infusion stop (score 1.6 ± 0.7 ; $p=0.042$ vs infusion stop). By contrast to epigastric perception, abdominal perception was only somewhat higher during gas infusion with nutrients (score 2.6 ± 0.5) than during saline (score 2.1 ± 0.5 ; $p=0.100$ vs nutrients).

Conclusion: Gastric nutrients modulate transit of gastric gas, by reducing gas propulsion to the distal gut, and enhancing retrograde gas evacuation via belching.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1827 MODIFICATIONS OF THE ECKARDT SCORE PARAMETERS AFTER PERORAL ENDOSCOPIC MYOTOMY

Introduction: Peroral endoscopic myotomy (POEM) is a recently developed technique for the treatment of lower esophageal sphincter achalasia. POEM could be as efficient as surgical Heller myotomy, while associated with lower morbidity. Currently, the Eckardt score is the clinical score that is the most widely used to assess the outcomes after the treatment of achalasia, clinical success being defined by a score below 4. However, POEM might not equally improve all four parameters of the Eckardt score.

Aims & Methods: All consecutive patients undergoing POEM for achalasia at our institution performed by 3 operators with at least 6 months follow-up were prospectively included. Demographic, clinical, procedural, manometric and radiological data were collected.

Results: Between March 2013 and July 2016, 62 POEM procedures were performed in 59 patients (Male/female 33/26; Median age \pm SD = 47 ± 17 , range 15–77). Median (IQR) follow-up time was 8 (3–13) months. Achalasia was diagnosed for a median (IQR) of 24 (13–62) months, and 42% of the patients had received a previous treatment, by botulinum toxin injection (8%), pneumodilation (32%), or Heller myotomy (7%). Achalasia subtypes were type I/II/III in 37%/47%/15% of cases. Median Eckardt score and integrated resting pressure were 7 (6–8) and 24 (19–33) mmHg, respectively. An anterior myotomy was done in 60% of cases, and a posterior myotomy in 40% of cases. Median myotomy length was 14 (12–16) cm, and hospital stay was 3 (2–4) days. Severe complications occurred in 5% of cases (1 pleural effusion requiring drainage, 2 pneumonias with more than 10 days of hospital stay). Success rates were similar between patients treated by anterior or posterior myotomy (92% vs 92%, $p=1$), or between treatment naïve or pretreated patients (88% vs 96%, $p=0.32$). Six treatment failures were treated by redo POEM in 3 cases, pneumodilation in 2 cases, and esophagectomy in one case. Median Eckardt score varied from 7 (6–8) to 1 (0–2) at 3 months and 2 (0–3) at 12 months ($p < 0.0001$). Dysphagia score varied from 3 (3–3) to 0 (0–1) and 1 (0–3) ($p < 0.0001$), while regurgitations varied from 2 (1–3) to 0 (0–1) and 1 (0–1) ($p < 0.0001$), chest pain varied from 1 (0–2) to 0 (0–1) and 0 (0–1) ($p=0.006$), and weight loss from 2 (1–3) to 0 (0–0) and 0 (0–0) ($p < 0.0001$). At three months, median (range) drop of the integrated resting pressure was 16 (12; 22) mmHg. At last follow-up visit, 86% of patients still had clinical success, and 31% reported gastro-esophageal reflux symptoms.

Conclusion: Our results confirm the efficacy of the POEM as a first line or rescue treatment for achalasia, with a low complication rate. POEM is most effective on dysphagia and weight loss, while chest pain and regurgitations tend to persist after treatment.

Introduction: Well-proven therapeutic options for the therapy of functional gastrointestinal diseases are rare and therefore gain high attention. One of these is STW 5 (Iberogast), for which more than five decades of therapeutic experience in more than 73 Mio patients are available. For determining whether its efficacy in functional dyspepsia proven by meta-analyses is comparable in male and female as well as patients of different age groups, sub-group analyses were conducted.

Aims & Methods: After meta-analyses of randomized placebo-controlled double blind trials with STW 5 have proven compliance to modern standards for a proof of efficacy, now sub-group analyses were conducted. The analyses (ANCOVA) were based on the original single patient data from the trials, including demographic data and primary endpoints.

Results: As the primary outcome variable, the validated gastrointestinal symptom score (GIS) [1], as well as the therapeutic dose (3×20 drops/day) were identical in all trials, a uniform evaluation was possible. The full analysis set (FAS)

included 557 patients (272 resp. 285 for placebo resp. verum). The mean age (48 resp. 49 years), the mean body size (in both groups 168.7 cm), the mean body weight (72.0 resp. 72.2 kg), the BMI (25.35 resp. 25.54), the gender distribution (67.3 resp. 69.5% females), the duration of the disease at the time of inclusion and the baseline of the GIS (11.6 resp. 11.5 points) were very well comparable between both groups. For the primary variable GIS the difference between placebo and verum after 28 days of treatment showed a highly significant ($p < 0.0001$) difference between placebo and verum (6.7 resp. 4.7 points). The analyses in different age groups (up to 30, 30–40, 40–50, 50–60, above 60) and in male and female patients did show a comparable efficacy in all these groups.

Conclusion: These meta-analyses therefore clearly show the efficacy of STW 5 (Iberogast) and its therapeutic usefulness irrespective of age and gender. Given also the very good tolerability shown by the study data and the pharmacovigilance data, STW 5 is well suitable also in self-medication. Additional insights can be expected from additional sub group analyses, as e.g. the evaluation of subgroups with specific predominant symptoms.

Introduction: Achalasia is a chronic condition presenting with dysphagia, regurgitation, chest pain and/or weight loss. Management options include Heller's myotomy, Botox, pneumatic dilatation and Per-Oral Endoscopic Myotomy (POEM). Treatments carry risks of bleeding and perforation. Concomitant portal hypertension with varices is very rare and achalasia treatment in this context has only been described in single case reports.

Aims & Methods: Experience from physicians/surgeons treating these disorders was sought through the International Manometry Working Group.

Results: 13 patients with portal hypertension from 6 international centres have been collected; mean age 61 ± 9 years. The median pre-therapy Eckardt score was 7 (IQR 6–9). 9/13 (69%) patients had a barium swallow and 12/13 (92%) had oesophageal physiology studies performed. There were 3 Type I, 6 Type II, 2 Type III achalasia and 2 with oesophago-gastric outflow obstruction. Varices were identified endoscopically in 7 patients, radiologically in 5 and in 1 patient varices were first noted during surgical myotomy. 2 patients had grade 3 varices, 3 had grade 2 and 3 had grade 1 varices (grading not provided for the rest). Cirrhosis was due to alcohol in 7 patients, non-alcoholic steatohepatitis in 3, cryptogenic in 2 and 1 had hepatitis C cirrhosis. 75% were Child-Pugh A and 25% were Child-Pugh B. Patients had diverse treatments for their achalasia. 4 were treated with Botox injections (1 with EUS), 4 had dilation alone, 3 received a POEM, another had POEM then dilation and 1 patient had Botox followed by Heller's myotomy. 3 patients underwent variceal eradication in advance; all had banding first but in 2 patients superficial eradication was followed by a transjugular intrahepatic portosystemic shunt (TIPSS) before endoscopic dilation. All patients had symptomatic improvement with median Eckardt score post intervention = 1 (IQR 0–2) $p < 0.0001$ compared to baseline. A matched group of 20 patients who underwent treatment for achalasia (all subtypes) but without varices had similar outcomes ($p=NS$). No patients had recorded complications of bleeding or perforation; however both patients who had TIPSS had temporary hepatic decompensation.

Conclusion: This reports 13 patients from international centres who have had interventions for achalasia on the background of oesophageal varices. None had bleeding complications despite only 3 having had variceal eradication. Symptom response mirrored those who undergo standard achalasia therapy,

regardless of the severity of varices, treatment modality provided or achalasia subtype.

Introduction: Esophageal achalasia is classified into three clinically relevant patterns at High Resolution Manometry (HRM) and according to Chicago Classification. Currently, it is unclear whether they represent distinct entities or are part of a disease continuum.

Aims & Methods: The aims of this study were: a) to test the hypothesis that the three manometric patterns represent different stages in the evolution of esophageal achalasia and b) to investigate whether manometric patterns change after Laparoscopic Heller-Dor (LHD). We evaluated the patients who had a diagnosis of achalasia and underwent LHD as first treatment from 1992 to May 2016. Symptoms were scored using a detailed questionnaire for dysphagia, food-regurgitation, and chest pain; barium swallow, endoscopy, and esophageal manometry (conventional or High Resolution technique) were performed, before and 6 months after surgical treatment. All conventional manometric tracings, before 2010, were reviewed and re-classified according to the manometric-pattern classification, whereas after 2010 the HRM data were prospectively collected.

Results: Five-hundred and eleven consecutive achalasia patients (M:F=283:228) represented the study population. Based on their manometric findings, 231 patients (45.2%) were classified as having pattern I, 241 (47.2%) had pattern II, and 39 (7.6%) had pattern III. Demographic and clinical data showed that pattern III cases had a shorter duration of symptoms, a more incidence of chest pain, and a less dilated gullet ($p < 0.001$). Further, all patients with a sigmoid-shaped mega-esophagus (radiological grade IV) had pattern I achalasia. One patient with diagnosis of pattern III achalasia, who refused any treatment evolved to pattern II at a follow-up manometry performed for a progressive worsening dysphagia after 36 months. At a median follow-up of 30 months (IQR 12–56), the outcome of surgery was positive in 479 patients (91.7%). The only predictor of final outcome was the preoperative manometric pattern ($p < 0.001$). All patients (42) whose surgical treatment failed underwent one or more endoscopic pneumatic dilations using Rigidflex balloons (30, 35 or 40 mm). The overall success rate of the combined treatment (LHD plus endoscopic dilations where necessary) was 98%. All patients with pattern I preoperatively had the same pattern after LHD, whereas more than 50% of patients with pre-treatment pattern III had patterns I or II after surgery. There were no cases showing the opposite trend (Table 1). Five patients showed signs of a partial recovery of peristalsis (all patients had a pattern II before LHD).

Table 1: Changing manometric patterns after LHD. *5 patients had a recovery of peristalsis

	Pattern 1 post	Pattern 2 post	Pattern 3 post
Pattern 1 pre	159(100%)	0	0
Pattern 2 pre*	65 (29.5%)	149 (67.7%)	0
Pattern 3 pre	7 (24.1%)	8 (27.6%)	8 (48.3%)

Conclusion: The data of this study strongly support the hypothesis/theory that the different manometric patterns of achalasia could represent different evolutive stages of the disease - where pattern III is the earlier stage, pattern II an intermediate stage, and pattern I the end stage.

Introduction: The development of non-invasive methods to detect the presence of *H. pylori*, and to estimate the extent and severity of gastritis, have reduced the need for diagnostic endoscopy in asymptomatic individuals. However, it is not known whether the use of non-invasive diagnostic methods is effective in dyspeptic patients.

Aims & Methods: To use a non-invasive blood test with four stomach-specific biomarkers to assess the prevalence of different stomach conditions: gastroesophageal reflux disease (GERD), *H. pylori* (HP) infection, chronic atrophic gastritis (CAG), and the efficacy of proton pump inhibitor (PPI) therapy in a primary care population. A cohort of 2583 dyspeptic patients (male 36%, mean age 44.0 yrs, range 6–95) was selected in a primary care population and examined with a panel of biomarkers [Pepsinogen-I (PG-I) and -II (PG-II), amidated gastrin-17 (G-17), and HP IgG (Biohit, Finland)]. A standard questionnaire, including upper gastrointestinal symptoms and PPI use, was administered. Exclusion criteria were dysphagia, anemia, weight loss and vomiting. CAG patients underwent to endoscopy and histological examination.

Results: Healthy stomach was found in 21.2% patients. Prevalence of CAG increased with patient's age in both sexes as well as the use of PPIs ($p = 0.0001$). Table 1 shows the serum biomarkers values divided according to five categories: healthy stomach (H), GER, HP, CAG, and PPIs therapy.

Conclusion: The combination of data on the levels of PG-I, PG-II, G-17 and HP IgG allow to diagnose different pathological conditions such as HP- and non HP-related gastritis, the appropriateness of PPI administration, GERD and CAG, a precancerous condition.

Introduction: Functional dyspepsia (FD) is one of the most common functional gastrointestinal disorders characterised by chronic or relapsing symptoms without structural or biochemical abnormalities that can be identified in the routine clinical setting. Thus, treatment targets symptoms. Very little is known about prolonged treatment for more than 4 weeks.

Aims & Methods: The aim of the additional data analysis of a previous randomized placebo-controlled trial was to explore post-treatment effects that occurred after continuation of therapy after a 4-week randomized placebo controlled treatment with Menthacarin¹ with regard to disease-specific symptoms and QoL in FD patients. After the 4-week randomised placebo-controlled treatment period, patients were allowed to continue the treatment. The treatment was given in a double-blind fashion and allocation of treatment followed the initial randomisation. 114 adult FD outpatients were initially treated and received twice a day one enteric-coated Menthacarin capsule or a matched placebo capsule for 4 weeks. Fifty-four of them participated in the optional follow-up phase and received Menthacarin (34) or placebo (20) for further 8 weeks according to their original randomization. The results of these 54 patients are reported here. Outcomes were assessed utilising the validated self-rating Nepean Dyspepsia Index (NDI). Intra-individual differences between baseline and week 4/week 12 for NDI sub-scores for pain (sum of the NDI items 'pain or ache in upper

		H vs GER ^a $p = 0.0001$	H vs P ^b $p = 0.0001$,	H vs CAG ^c $p = 0.0001$,	H vs PPI ^d $p = 0.0001$

abdomen', 'discomfort in upper abdomen', 'cramps in upper abdomen' and 'bloating in upper abdomen') and discomfort (sum of the NDI items 'pressure in upper abdomen' and 'fullness after eating or slow digestion') and for QoL by NDI total score were compared and descriptively tested by means of Wilcoxon-Mann-Whitney U-tests.

Results: After the initial 4 weeks, 54/114 patients opted for an extension of therapy. Interestingly, 34 out of 52 patients had been on active therapy while only 20 had received placebo. Until week 4, the NDI sub-score for pain had decreased by 7.5 ± 3.9 points during Menthacarin treatment as compared to 5.0 ± 4.1 points during placebo treatment ($p = 0.0371$). After the follow-up, overall reduction for Menthacarin (8.7 ± 4.9 points) was also significantly better as compared to placebo (5.1 ± 4.9 points, $p = 0.005$). The NDI sub-score for discomfort had decreased until week 4 by 3.5 ± 2.1 points during active therapy as compared to 1.2 ± 2.1 points during placebo treatment ($p = 0.0003$). For the 12-week therapy, the score had declined by 3.7 ± 2.5 points and 1.3 ± 2.6 for Menthacarin and placebo, respectively ($p = 0.0014$). Overall QoL improvement was better for active medication for 4 and 12 weeks as compared to placebo.

Conclusion: After 4 weeks of randomised double-blind, placebo-controlled treatment with either Menthacarin or placebo, patients who received active medication are more likely to opt for a continuation of therapy as compared to patients on placebo. The gain over placebo remained significant even after 12 weeks of treatment. ¹ Menthacarin® is a proprietary combination of essential oils of a specified quality from *Mentha × piperita* L. (90 mg Peppermint oil WS® 1340) and *Carum carvi* (50 mg Caraway oil WS® 1520)

Introduction: The introduction of proton pump inhibitors (PPIs) into clinical practice has revolutionized the management of acid-related diseases. Studies in primary care and emergency settings suggest that PPIs are frequently inappropriately prescribed or used in clinical conditions with little benefit.

Aims & Methods: To evaluate the role of Gastropanel in relation to the appropriateness of PPI-therapy prescription. 2583 dyspeptic patients (male 36%, mean age of 44.0 yrs, range 6–95) with no alarm symptom (i.e., dysphagia, anemia, weight loss and vomiting) from a primary care population were included in the study. For each patient a blood sample was collected for serum Pepsinogen I (PG-I) and II (PG-II), Gastrin 17 (G-17) and IgG HP (Biohit, Oyj, Finland); moreover, a clinical questionnaire searching for symptoms and presence of HP, and PPI therapy was filled out. We have evaluated the following serological profiles: HP infection, chronic atrophic gastritis (CAG), response to PPI therapy. The results obtained were used to evaluate the appropriateness of PPI-therapy prescription.

Results: 1015/2583 (39.3%) received PPI therapy up to three months before serum sampling and were included in the study. Among 1015 patients under PPI therapy, 294 (29.0%) received half-dose PPIs, 709 (69.8%) full-dose PPIs and 12 (1.2%) an exceeding-dose PPIs. 38 patients under PPIs therapy (3.7%) showed a serological status compatible with body CAG (the definitive diagnosis was confirmed histologically). 68 (6.7%) presented HP infection. Table 1 shows the values of PG-I and G-17 values according to the response to PPI therapy.

Conclusion: An appropriate prescription of PPI should be preceded by the assessment of gastric functional status. In particular, patients with HP infection should be eradicated before PPI therapy, while CAG patients should not receive PPI therapy because they are no responder. Patients who do not respond to PPI therapy should be further investigated (compliance, diagnosis).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1834 DUODENAL ACID PERFUSION INCREASES DUODENAL PERMEABILITY AND ACTIVATES THE DUODENOGASTRIC REFLEX, INDEPENDENTLY FROM MAST CELL ACTIVATION

H. Vanheel¹, R. Farré¹, D. Beekmans¹, M. Vicario², J. Tack¹, T. Vanuytsel¹

¹Targid, KU Leuven, Leuven/Belgium

²Vall d'Hebron Institut Recerca Gastroenterology, Barcelona/Spain

Contact E-mail Address: hanne.vanheel@med.kuleuven.be

Introduction: We recently reported that functional dyspepsia patients show impaired duodenal integrity, associated with low-grade inflammation (Vanheel, Gut 2014). A potential cause underlying this phenomenon may be the increased duodenal acid exposure that has been demonstrated in some of these patients.

Aims & Methods: Our aim was to evaluate the effect of duodenal acid perfusion on duodenal permeability in healthy volunteers and to investigate whether mast cell activation is required for acid-induced impairment of mucosal integrity. As it has already been shown that duodenal acid activates duodenogastric reflex pathways, we also assessed intragastric pressure (IGP). This study consisted of 2 parts, each including 10 healthy volunteers. 1) An infusion tube was positioned in the second part of the duodenum and a high resolution manometry probe was positioned in the stomach to measure IGP. HCl 0.1N or saline was infused in the duodenum during 30 min (5 mL/min) in a randomized, double-blind manner. Duodenal biopsy specimens were obtained after infusion to measure transepithelial electrical resistance (TEER) and paracellular passage (fluorescein-labeled dextran, 4 kDa) in Ussing chambers. Expression of cell-to-cell adhesion proteins (claudin 1–4, occludin, zonula occludens 1–3, β-catenin, E-cadherin, desmocollin-2, desmoglein-2) in biopsies was evaluated by PCR, western blot and/or immunofluorescence. The number of mast cells and eosinophils was counted using immunohistochemistry for tryptase and eosinophilic major basic protein respectively, and by evaluating the expression of these proteins using PCR and western blot. 2) The participants were orally treated with placebo or with the mast cell stabilizer disodiumcromoglycate (DSCG) 200mg qid for 2 weeks. After treatment, the study design was as described above (although only acid perfusion was performed).

Results: IGP was significantly lower during acid perfusion compared with saline perfusion ($p = 0.003$). Acidification also resulted in decreased TEER ($p = 0.005$), increased passage ($p = 0.007$) and lower protein expression of claudin 3 ($p = 0.0006$). No difference in mast cell ($p = 0.34$) and eosinophil ($p = 0.34$) counts were detected, but an increased protein expression of tryptase ($p = 0.0008$) was found after acid perfusion. In the placebo and the DSCG group, acidification induced a similar drop in IGP ($p = 0.68$). There was also no difference in TEER ($p = 0.70$) and passage ($p = 0.21$) after acid perfusion between both pretreatments.

Conclusion: Duodenal acid perfusion in healthy volunteers disrupts epithelial integrity and activates an inhibitory duodenogastric reflex. Although this effect seems to be independent from mast cell activation, increased duodenal acid exposure in functional dyspepsia is a potential pathophysiological mechanism contributing to abnormalities in duodenal and gastric structure and function observed in patients with functional dyspepsia.

Disclosure of Interest: All authors have declared no conflicts of interest.

increasing. Pepsinogen I (PGI) $<30\mu\text{g/L}$, PGI/PGII <3 and gastrin-17 (G17) $>10\text{pmol/L}$ are non-invasive serological markers surrogate to explore gastric function, with a negative predictive value for chronic atrophic gastritis (CAG) of 96%.

Aims & Methods: Aim of the study was to evaluate gastric function by means of serology (PGI, PGII, G-17 and IgG-antibodies against *Helicobacter pylori*) in very elderly patients, including centenarians. A total of 379 patients were prospectively enrolled (M=126, F=253, mean age=83.6 \pm 8.7, range 70–106). They were divided in four groups: 132 subjects with an age between 70 and 79 years old (first group), 146 subjects between 80 and 89 (second group), 76 subjects between 90 and 99 (third group) and 25 subjects between 100 and 106 (fourth group). Demographics and drug intake, particularly the PPI intake, were collected. For all patients, serological markers were determined in fasting blood by using Gastropanel® (Biohit Oyj, Finland; normal values: PGI: 30–120 $\mu\text{g/L}$; PGII: 2–15 $\mu\text{g/L}$; PGI/PGII ratio: >3 ; G17: 1–9 pmol/L ; H.p.-IgG: $<30\text{EIU}$).

Results: In the first group (age 70–79), 18.2% of the subjects showed *H. pylori* infection (PGII $>10\mu\text{g/L}$, IgG against H.p. $>30\text{EIU}$), 22.7% had CAG (PGI $<30\mu\text{g/L}$ and PGI/PGII <3) and 53.8% were under PPI therapy. 16.9% of the patients on PPI therapy had CAG. In the second group (age 80–89), 32.9% of the subjects showed *H. pylori* infection, 8.9% had CAG and 48.6% were under PPI therapy. 8.5% of the patients on PPI therapy had CAG. In the third group (age 90–99), 22.4% of the subjects showed *H. pylori* infection, 10.5% had CAG and 48.7% were under PPI therapy. 8.1% of the patients on PPI therapy had CAG. In the fourth group (age 100–106), 44.0% of the subjects showed *H. pylori* infection, 16.0% had CAG and 72.0% were under PPI therapy. 16.7% of the patients on PPI therapy had CAG.

Conclusion: Acid secretion is preserved in most of the elderly and very elderly subjects, even in centenarians. Serological markers may be helpful to identify patients affected by CAG in which the administration of PPI is inappropriate, especially in the elderly.

PI836 THE PSYCHOLOGICAL CHARACTERISTICS OF REFLUX HYPERSENSITIVITY-A PILOT STUDY BASED ON SCL-90 QUESTIONNAIRE AND 24 HOUR PH-IMPEDANCE MONITORING

K. Wang, Z. Xu, Z. Xia, Y. Ge, L. Duan

Department Of Gastroenterology, Peking University Third Hospital, Beijing/China

Contact E-mail Address: duanlp@bjmu.edu.cn

Introduction: Reflux hypersensitivity (RHV) was lately defined as a functional esophageal disorder by Rome IV workshop. The clinical and psychological characteristics are still unknown.

Aims & Methods: The aim of this study was to assess the reflux and psychological characteristics of RHV. Patients who underwent 24h pH-impedance monitoring were screened from Jan 1st 2011 to Nov 31st 2015. The patients with heartburn or chest pain ≥ 2 days/week for more than 6 months were enrolled. Healthy volunteers (HV) were enrolled too. All subjects fulfilled the SCL-90 questionnaire, underwent gastroscopy to exclude upper gut organic diseases and underwent HRM test to exclude main motility disorders. The patients with normal esophageal mucosal but overload acid, weakly acid or non-acid reflux were diagnosed as non-erosive reflux disease (NERD). The patients with normal esophageal mucosal and normal reflux but positive symptom index (SI) or symptom association possibility (SAP) were diagnosed as RHV. And the patients with normal mucosal, normal reflux, normal SI or SAP and negative PPI test results were enrolled in functional heartburn (FH) group. The reflux and psychological characteristics were compared among NERD, RHV and FH.

Results: Total 231 patients were enrolled. 107 were NERD (48.25 \pm 1.18 yrs, M:F=55:52), 92 were FH (48.30 \pm 1.27yrs, M:F=9:83), 32 were RHV (48.41 \pm 2.36yrs, M:F=4:28). 28 HVs (47.21 \pm 2.27, M:F=8:20) were enrolled as controls. NERD presented significantly higher acid exposure time (pH > 4.2) than those of FH, RHV and HV (6.55 \pm 0.71, 1.25 \pm 0.12, 1.90 \pm 0.33, 2.95 \pm 0.53, respectively, $p < 0.005$). The acid reflux and weakly acid reflux were both higher in NERD than that in FH, RHV and HV ($p < 0.001$). The total scores of SCL-90 of each group of patients were significantly higher than HV (NERD:HV, 133.15 \pm 3.68 vs. 108.61 \pm 4.51, $p=0.004$; FH:HV, 133.15 \pm 3.68 vs.

108.61 \pm 4.51, $p=0.003$; RHV:HV, 142.67 \pm 8.91 vs. 108.61 \pm 4.51, $p=0.002$). RHV patients presented higher compulsive factor score than FH (1.85 \pm 0.16 vs. 1.58 \pm 0.06, $p=0.047$) and HV (1.85 \pm 0.16 vs. 1.37 \pm 0.09, $p=0.004$). The patients of NERD, FH and RHV presented significantly higher depression, anxiety, hostile factor scores than those of HV ($p < 0.05$).

Conclusion: NERD, RHV and FH patients showed higher scores than HVs in total and most factors of SCL-90. Furthermore, RHV patients presented higher compulsive score than FH, NERD and HVs. The role of senseless thought, impulse, and act of compulsive behavior in the pathogenesis of RHV needs to be studied furtherly.

Introduction: High-Resolution Manometry (HRM) has recently become the gold standard for the evaluation of esophageal motility. A new classification of esophageal motility disorders (Chicago Classification, v. 3.0) has been developed, based on the findings from a given hardware and software. Different systems for HRM and new features of the existing ones have recently been developed.

Aims & Methods: In this study we aimed to evaluate a new solid-state HRM system and a new 3-D catheter and system for the study of lower esophageal sphincter (LES). Fifteen healthy volunteers (7m, 8f, median age 27) underwent two consecutive Esophageal HRM studies by using two different solid state systems (ManoScan, Medtronic, Minneapolis, USA and Medica SpA, Italy with Unisensor AG, Attikon, Switzerland catheter). The studies were performed in a random order using the standard protocol. Furthermore, a new 3-D catheter for the study of sphincters was evaluated in 12/15 volunteers.

Results: Table 1 reports the findings obtained with the Medica system compared to the consolidated Medtronic system. The data of the 3-D evaluation are also reported. The data are expressed as medians (and 5th-95th percentiles).

Conclusion: Significant differences were recorded in most of the considered parameters obtained by the two HRM systems. This is particularly relevant in the evaluation of the LES relaxation, the cardinal point in the hierarchical approach of the Chicago Classification, probably due to different analysis used by the two systems (the lowest residual pressure vs IRP). Furthermore, the differences found in the measurement of the LES resting pressure and abdominal length may rely either on the different technology (3-D vs linear transducers) or on the different algorithms and thresholds used. The latter may probably also apply to the differences found with the two systems in the duration of the esophageal contractions and in the new contractile parameters (i.e.: DCI and DL) introduced by the Chicago Classification. This study emphasizes the need for a careful validation of any new system for esophageal manometry. The acquisition of new sets of normal values, to be used to compare the data measured in patients, is therefore mandatory. The results of our study may represent the reference normal values for other esophageal laboratories that are using the HRM systems and devices we tested here.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Proton Pump Inhibitor-response esophageal eosinophilia (PPI-REE) is a condition characterised by symptoms of esophageal dysfunction in the setting of eosinophilic inflammation on esophageal biopsies responding to a course of 8 weeks of PPI therapy. Recent data collected by using esophageal high resolution manometry (HRM) documented that patients with PPI-REE present frequently motility abnormalities, mostly weak peristalsis and hypotensive esophagogastric junction (EGJ). Data on the effect of PPIs in improving these motor abnormalities are lacking.

Aims & Methods: We aimed to prospectively compare HRM features of patients with PPI-REE before and after a course of PPI therapy. Consecutive patients with symptoms suggestive of EoE underwent upper endoscopy to assess the presence of at least 15 eos/hpf on oesophageal biopsies at mid/proximal esophagus and, then, were treated with twice-daily PPIs for at least 8 weeks. Thereafter, patients repeated upper endoscopy and PPI-REE was identified in case of less than 15 eos/hpf and a 50% decrease from baseline. Patients with PPI-REE underwent HRM at the time of the diagnosis (off-PPI) and after the course of PPIs (on-PPI). Patients with achalasia and absent peristalsis were excluded (Chicago Classification v.3).

Results: Twenty-eight patients [23M/5F; mean age 35] reporting dysphagia (93%), bolus impaction (68%) and chest pain (25%) were diagnosed with PPI-REE. After anti-secretory therapy, most of the patients reported complete resolution of esophageal symptoms directly linked to esophageal infiltration ($p < 0.001$), namely dysphagia, bolus impaction and chest pain. Compared to HRM features at baseline, HRM after PPI therapy showed that patients with PPI-REE had higher median EGJ resting pressure [baseline 11 (1–34) vs. post-PPI 17 (1–34); $p < 0.05$], greater mean distal contraction integral [1094 (483–5281) vs. 2634 (495–6450); $p < 0.01$], and less frequent panesophageal pressurization [6 (21%) vs. 0 (0%); $p = 0.02$]. No differences were observed in terms of distal latency and rate of different EGJ subtypes ($p = ns$). As to the manometric diagnoses, after PPI therapy patients with PPI-REE showed a reduced rate of ineffective motility or fragmented peristalsis [16 (57%) vs. 7 (25%), $p = 0.02$] and increased frequency of normal peristalsis [9 (32%) vs. 18 (64%), $p = 0.03$]. No differences were observed in terms of frequency of distal esophageal spasm and outflow obstruction diagnoses ($p = ns$).

Conclusion: In most PPI-REE patients, PPI therapy restores the impairment of esophageal motility as expressed by ineffective or fragmented peristalsis, thus favouring the return to a normal motility pattern. This finding, paralleled with symptoms improvement in the same subjects, seems to emphasize the important role of inflammation linked to the eosinophilic infiltration of the esophageal wall in inducing motor dysfunction and related symptoms.

PI839 EOSINOPHILIC ESOPHAGITIS: MANAGEMENT IN THE DAILY CLINICAL DUTCH PRACTICE

B. Vermeulen¹, A. Bogte², P.D. Siersema¹

¹Gastroenterology And Hepatology, Radboudumc, Nijmegen/Netherlands

²University Medical Centre Utrecht, Utrecht/Netherlands

Contact E-mail Address: bram.vermeulen@radboudumc.nl

Introduction: In recent years, new guidelines and recommendations have been published regarding the diagnostic criteria and therapeutic management of eosinophilic esophagitis (EoE).

Aims & Methods: The aim of this study was to assess the diagnostic and therapeutic management of patients diagnosed with EoE in daily clinical Dutch practice and whether this was according to guidelines and recommendations.

A population-based, retrospective cohort study was conducted using data from the Dutch national pathology registry (PALGA), medical records, and telephone interviews of patients diagnosed with EoE in two academic and two non-academic hospitals in the period 2004–2014. Data regarding demographics, clinical manifestations, endoscopic results, histologic samples and therapeutic strategies

were collected. Standard statistical analyses were performed to summarize the patient characteristics.

Initial treatment after diagnosis EoE

Treatment, n (%)	Total, n (%) (n = 119)	AC 1, n (%) (n = 49)	AC 2, n (%) (n = 27)	Non AC 1, n (%) (n = 25)	Non AC 2, n (%) (n = 18)
TCS	36 (30.3)	17 (34.7)	5 (18.5)	11 (44.0)	3 (16.7)
PPI	35 (29.4)	16 (32.7)	8 (29.6)	4 (16.0)	7 (38.9)
PPI + TCS	12 (10.1)	5 (10.2)	1 (3.7)	4 (16.0)	2 (11.1)
Dilation	3 (2.5)	0	2 (7.4)	0	1 (5.6)
Prednisone	2 (1.7)	0	1 (3.7)	1 (4.0)	0
TCS + dilation	1 (0.8)	1 (2.0)	0	0	0
Diet	0	0	0	0	0
None	24 (20.2)	9 (18.4)	8 (29.6)	4 (16.0)	3 (16.7)
Missing	6 (5.0)	1 (2.0)	2 (7.4)	1 (4.0)	2 (11.1)

Results: In total, 119 patients were diagnosed with EoE and included in this study. The median age at onset of symptoms was 29 years (IQR, 15–42) and the median age at diagnosis was 38 years (IQR, 23–51 years), leading to a median diagnostic delay of 6.5 years (IQR, 2–14 years). The median delay in diagnosis between first contact in the hospital and diagnosis was 1.0 year (IQR, 2–14 years). The incidence of patients newly diagnosed with EoE increased steadily over a period of 11 years. Criteria for the microscopic diagnosis of EoE varied between pathologists in each hospital. Initial treatment included topical corticosteroids (30.3%), proton pump inhibitors (PPIs) (29.4%) or a combination of both (10.1%). A follow-up endoscopy was performed in 40.3% of patients. During follow-up, treatment included PPIs (76.0%), topical corticosteroids (59.6%) or a combination of both (45.4%).

Conclusion: Diagnostic and therapeutic discrepancies between daily clinical practice and recommendations from current and past guidelines were observed. Remarkably, the diagnostic entity PPI-responsive EoE was only used in one center, follow-up endoscopy was performed in less than half of patients and all pathologists used different criteria for the microscopic diagnosis of EoE. Moreover, varying therapeutic strategies were utilized in the participating centers. Our results show that apart from developing guidelines, efforts should be undertaken to implement them in daily clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Eosinophilic Esophagitis (EoE) is a chronic immune disease of the esophagus, which is presented by esophageal dysfunction and histologically characterized by a predominant eosinophilic inflammation. EoE is mainly found in patients with atopic conditions. However, recently an association with IgG4 but not with IgE has been reported. Gastroesophageal reflux disease (GERD) is the most important differential diagnosis of EoE. In this study we measured systemic serum IgG4 and IgE levels of EoE patients before and after a topic steroid therapy, correlated them to esophageal IgG4-positive plasma cells and compared them to GERD patients.

Aims & Methods: Serum levels of IgG4 and IgE of 19 EoE patients were measured before and after eight weeks of therapy with budesonide (1 mg twice a day). Biopsies were taken from the esophagus before and after therapy for histological and immunohistochemical evaluation. 14 patients with GERD without histological proof of eosinophilic granulocyte infiltration were taken as a control group. Serum levels of IgG4 and IgE of 19 EoE patients were measured before and after eight weeks of therapy with budesonide (1 mg twice a day). Biopsies were taken from the esophagus before and after therapy for histological and immunohistochemical evaluation. 14 patients with GERD without histological proof of eosinophilic granulocyte infiltration were taken as a control group.

Results: Serum IgG4 levels of EoE patients were significantly higher than in GERD patients (mean: 121.0 mg/dL vs. 71.2 mg/dL, $p=0.034$). In contrast, no significant difference of IgE levels in EoE and GERD patients was observed. In EoE patients, the number of eosinophilic granulocytes in histology was decreased at a significant level after topic steroid therapy (mean: 51.9 eosinophiles/high power field (hpf) vs. 6.4 eosinophiles/hpf $p < 0.001$). After therapy lower levels of IgG4-serum-levels could be measured (mean: 121.0 mg/dL vs. 104.2 mg/dL $p=0.019$), whereas IgE levels did not show a significant difference. The esophageal biopsies of EoE patients showed a high number of IgG4-positive plasma cells (mean expression of 27.4 IgG4-positive plasma cells of 46.4 stromal plasma cells/hpf).

Conclusion: EoE patients show higher systemic IgG4- but not IgE-serum levels compared to GERD-patients. These elevated levels normalize under effective topic steroid therapy. Additionally high local expression of IgG4- positive plasma cells can be seen in EoE patients. These findings might be further evidence for a possible IgG4-association of EoE.

P1841 SYSTEMATIC REVIEW: HEALTH-RELATED QUALITY OF LIFE IN CHILDREN AND ADULTS WITH EOSINOPHILIC ESOPHAGITIS: MEASURE INSTRUMENTS AND DETERMINANT FACTORS

A. J. Lucendo Villarin, L. Arias-González, J. Molina-Infante, Á. Arias
Dept. De Gastroenterología, Hospital General de Tomelloso Dept. of Digestive Health Dept. of Gastroenterology, Tomelloso/Spain

Contact E-mail Address: alucendo@vodafone.es

Introduction: Measurement of Health-related quality of life (HRQoL) with generic or specific instruments has been increasingly used in patients suffering from EoE to support both research and clinical care. Generic instruments aim at measuring the overall HRQoL of patients across several conditions, being useful to compare HRQoL across different disease states and for evaluating health economics outcomes. Disease-specific instruments assess domains specific to a given disease and are considered more sensitive to changes in the patient's health state. An up-to-date systematic review will provide a useful resource for researchers and EoE specialists to ensure they can select an appropriate HRQoL measure for patients in their practice in order to identify correctable factors determining an impaired perception and to improve treatment outcomes.

Aims & Methods: We aim to systematically review the current HRQoL measures for patients with EoE and to appraise their measurement properties using a robust evaluation methodology checklist. We also sought to identify disease-specific determinant factors for HRQoL in children and adults with EoE, and the effect of investigations and interventions for EoE on HRQoL. A search strategy was designed to identify and retrieve all documents dealing with the relationship between HRQoL and EoE in children and adults. This systematic literature search was performed in 5 major databases (PubMed, EMBASE, Scopus, PsycInfo and Web of Science) for the period up to March 2017. The measure properties of each specific EoE instrument identified and their performance properties were assessed using the quality properties checklist proposed by Terwee et al. Levels of the HRQoL measure establishment or use in literature: we used Cohen's criteria. Cohort studies, case series and case reports were evaluated for the risk of bias with the aid of the Joanna Briggs Institute critical appraisal checklist. A descriptive summary with data tables was produced to summarize the literature. Quantitative pooling of data was not meaningful so a narrative synthesis of the data was undertaken.

Results: Of the 596 references identified, data was collected from 34 studies including a total of 1,842 individual patients. Three disease-specific HRQoL measures in EoE covering different aspects of patients' lives and developed in English were scored positive regarding measurement properties. Respectively, the PedsQL inventory (including parent and child report forms) and the Peds-QoL EoE module were the generic and specific instruments respectively used in children, while the SF-36 and EoE-QoL-A were the most used questionnaires in adults. EoE significantly impairs HRQoL of affected children and adolescents, which manifests in the normal development of their daily activities, their physical health and their mental status, with parents generally underestimating the impact of the disease regarding children declared HRQoL. Regarding determinant factors, age was not associated with HRQoL. Number and severity of symptoms negatively correlated with child-reported and Parent proxy-reported PedsQL score and family impact score. Disease duration was identified as a risk factor for a low SF-36 score. EoE impacts on a number of domains including frustration, embarrassment or fear about the disease outcomes. No significant differences in the overall QoL score were found in adult patients managed with dietary or pharmacological therapy, with specific treatment modalities having a negligible influence on overall EoE-specific QoL. Symptoms scores determined exerted an increased impact on swallowing anxiety and emotional impact subscales. Female gender negatively influenced QoL scores. Disease activity, as expressed by endoscopic findings, were also significant determinants of QoL. A higher educational level was also found to be a strong determinant for a worse QoL.

Emotional impact was the only dimension with a significantly worse score in patients under dietary restrictions.

Conclusion: HRQoL is a relevant outcome that should be considered in clinical practice and research of EoE. Further validation studies in several languages and populations are required to support the use of disease-specific HRQoL measures.

Introduction: Available treatment options for adult EoE patients include drugs (proton-pump inhibitors [PPI], swallowed topical corticosteroids [STC]), food elimination diets, and esophageal dilation. Knowledge about patients' view regarding the different therapeutic options is very limited.

Aims & Methods: We aimed to systematically assess adult EoE patients' satisfaction with different EoE-specific treatment modalities. We first created a questionnaire that included items that queried general demographic characteristics (7 items), EoE-specific patient history and presence of atopic disease (8 items), past and present EoE-specific therapy (9 items), concomitant medication use (7 items), important considerations for choice of therapy (2 items), as well as treatment satisfaction with various therapies recalled over a period of 12 months (assessed using the validated "Treatment Satisfaction Questionnaire for Medication" [TSQM], 52 items). The TSQM consists of 14 items falling into 4 scales: effectiveness (3 items), side effects (5 items), convenience (3 items), and overall satisfaction (3 items). The score for each TSQM scale ranges from 0 (dissatisfied) to 100 (satisfied). In analogy with other conditions, a score above 66.6 and 83.3 identifies patients that are 'satisfied' and 'very satisfied' with therapy, respectively. The psychologist-guided focus groups with adult EoE patients were conducted to inform the content and the structure of the questionnaire and ensure that patient understand the items, instructions, and response options. The questionnaire was sent to 148 patients in Switzerland. Data were double-entered by two researchers into an EpiData database (version 3.1, the EpiData Association, Odense, Denmark). Dataset was then imported into Stata (version 13, College Station, Texas, USA) for analysis.

Results: Patient response rate was 73.5% (108/147). Mean patient age at inclusion was 46.3 ± 15.9 years, 85/108 (78.8%) of patients were male, and mean disease duration (from the time of diagnosis to the time of enrollment) was 6.8 ± 5.1 years. In the last 12 months, 11.1%, 48.1%, 10.2%, and 28.7% of patients reported to have suffered from symptoms of asthma, rhinoconjunctivitis, eczema, and food allergy, respectively. In the last 12 months, 25.0%, 3.7%, 77.8%, 1.9%, 19.4%, and 13.0% were treated with PPI, STC in the form of a spray, STC in the form of a powder, STC in a form of a spray, diet, and esophageal dilation, respectively (37.0% patients received more than one treatment; 7.4% of patients did not receive any treatment). Patients identified the following considerations as important for the choice of therapy: the effect of the treatment on the symptoms (88.9%), the effect of treatment on esophageal inflammation (75.9%), possible side effects (69.4%), ease of therapy use (58.3%), recommendation of the physician (50.0%), and compatibility of therapy with lifestyle (46.3%). When asked about single most important criterion for the choice of therapy, 48.5%, 33.7%, 11.9%, 3.0% and 2.0% of patients chose the effect of treatment on symptoms AND esophageal inflammation, the effect of the treatment on the symptoms, the effect of treatment on esophageal inflammation, compatibility of therapy with lifestyle, possible side effect, and recommendation of the physician, respectively, as deciding factor. The TSQM scales scores as well as average TSQM values for patients on PPI, STC, and diet are shown in Table 1.

Conclusion: Adult EoE patients consider both effect of medication on symptoms as well as inflammation as most important criteria, when choosing EoE therapy. EoE patients appear to be 'satisfied' with PPI, STC, and dietary therapy and 'very satisfied' with STC, if the therapy is taken twice daily.

Introduction: For technical reasons, the histologic characterization of eosinophilic esophagitis (EoE)-specific alterations is almost exclusively based on those found in the esophageal epithelium, whereas little is known about subepithelial abnormalities.

Aims & Methods: In this study, we aimed to systematically assess the nature of subepithelial histologic alterations, analyze their relationship with epithelial histologic findings, endoscopic features, and symptoms, and evaluate the diagnostic impact of subepithelial eosinophil counts in patients with an epithelial peak eosinophil count of <15/hpf. We prospectively included in this cohort study adult EoE patients who underwent assessment of clinical, endoscopic, and histologic disease activity using scores.

Results: We included 200 EoE patients (mean age 43.5 ± 15.7 years, 74% males) with a median peak count of 36 intraepithelial eosinophils/hpf [IQR 14–84]. The following histologic features were identified in the subepithelial layer: eosinophilic infiltration (median peak count of 20 eosinophils/hpf [IQR 10–51]), eosinophil degranulation (43%), fibrosis (82%), and lymphoid follicles (56%). Peak intraepithelial eosinophil counts were higher, identical, and lower when compared to the subepithelial layer in 62.5%, 7%, and 30.5% of patients, respectively. Subepithelial histologic activity correlated with epithelial histologic activity (ρ 0.331, $p < 0.001$), endoscopic severity (ρ 0.208, $p = 0.003$), and symptom severity (ρ 0.179, $p = 0.011$). Forty percent (21/52) of patients with <15 intraepithelial eosinophils/hpf had subepithelial peak counts of ≥ 15 /hpf.

Conclusion: In one third of patients subepithelial peak eosinophil counts are higher than epithelial eosinophil counts. Systematic assessment of subepithelial eosinophil counts can aid in diagnosing EoE in additional 40% of all patients with epithelial eosinophils <15/hpf.

Introduction: The modern understanding of gastroesophageal reflux disease (GERD) pathogenesis includes cell and molecular mechanisms of associated esophagus mucosal inflammation and Th1/Th2 immune response imbalance due to the recurrent exposure to acidic and nonacidic refluxate of gastric contents. Th1 or Th2 immune response is mainly predetermined by innate and adaptive immune response cells - macrophages. Considering the concept of M1/M2 macrophage phenotype programming and paradigm of Th1/Th2 immune response M1/M2 macrophage phenotype imbalance is one of the main cell components of GERD mucosal inflammation.

Aims & Methods: We aimed to assess the influence of refluxate type on macrophage phenotype and compare the data with predominated macrophage phenotype in systemic circulation in GERD patients. 68 patients with different forms of GERD and Barrett's esophagus were included in the study. Macrophage phenotype was assessed in vitro by adding acidic and nonacidic refluxates of patients ($n=68$) with different pH (4.6–6.6, $n=31$ (group I); 6.7–7.2, $n=28$ (group II); 7.3–8.1, $n=6$ (group III)) to peritoneal macrophages of C57/BL6 mice ($n=68$) with the following macrophage culturing in standard conditions (10% FBS, RPMI1640) for 36 hours. Monocytes were isolated from the patients' blood samples and cultured to macrophages (monocyte derived macrophages, MDM) in standard conditions -RPMI1640 medium, 10% FBS, 37°C, 5% CO₂. Pooled analysis of macrophage and MDM phenotype included assessment of secretory activity (Th1/Th2 cytokine production in culture medium, Antigenix, USA),

typical M1/M2 surface macrophage CD markers (CD25, CD80 and CD163, CD206, respectively) performed by flow cytometry (Beckman Coulter FC500).

Results: Analysis of cytokine macrophage production revealed the prevalence of Th1 and Th1/Th2 bivalent (IL-2, IL-6) cytokines as compared to Th2. The most significant changes due to the influence of refluxate pH were observed in Th1 cytokine IL-8, TNF α and TNF β . Increasing of pH resulted in 2 times-fold, 1.8 times-fold and 3.5 times-fold fall of these cytokines production respectively ($p < 0.05$). Th2 cytokine macrophage production increased with increasing pH, and most significantly changed in IL10: 8.43 ± 3.13 pg/ml in group I vs. 27.7 ± 8.65 pg/ml in group III ($p < 0.05$). The expression of surface M1/M2 macrophage CD markers significantly varied depending on the acidity of refluxate. Mild-alkaline pH (III group) resulted in increasing expression of M2 markers CD163/CD206 as compared to M1–CD80/CD25, but changing M1/M2 index of CD expression still showed the prevalence of M1 phenotype in groups: 2.49 ± 0.15 (II) vs. 1.29 ± 0.12 (III) ($p < 0.05$). Analysis of MDM phenotype showed the prevalence of M1 phenotype in all groups.

Conclusion: Pooled analysis of GERD patients refluxate type influence on macrophage phenotype showed the prevalence of M1 proinflammatory activated macrophages (Th1) with increased expression of M1 surface markers and predominantly increased production of Th1 cytokines (IL-8, TNF α , TNF β). The changes were more expressed in macrophages exposed to acid refluxate. The effect of mild-alkalotic refluxate resulted in definite trend of increasing expression of CD M2 markers and increased production of Th2 cytokines as compared to the other refluxate types. Analysis of MDM phenotype showed the prevalence of M1 phenotype regardless of refluxate pH.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1845 THE LOCATION OF OESOPHAGEAL MUCOSAL AFFERENT NERVES ARE MORE SUPERFICIAL IN PATIENTS WITH NERD THAN IN HEALTHY VOLUNTEERS AND PATIENTS WITH BARRETT'S OESOPHAGUS

Introduction: The pathophysiology of heartburn perception in gastro-esophageal reflux disease (GERD) remains unclear. The degree of reflux-induced epithelial change seldom predicts symptom severity, as evidenced by the greater symptom burden seen in non-erosive reflux disease (NERD) compared to patients with Barrett's esophagus (BE). Existing models of acid hypersensitivity are inadequate to explain this discordance.

Aims & Methods: To test the hypothesis that differences in peripheral esophageal mucosal innervation may be relevant, we studied the distribution of mucosal nerve fibers in patients with NERD and BE and compared the results with that of healthy subjects. 13 patients with NERD undergoing reflux testing and 16 patients with BE undergoing endoscopic surveillance were prospectively recruited. Biopsies were obtained from the proximal and distal esophageal mucosa in NERD patients and the distalmost squamous epithelium in BE patients, then examined immunohistochemically for presence and location for calcitonin gene-related peptide (CGRP)-immunoreactive nerve fiber. The results were compared with those from 10 healthy volunteers (HV) previously studied by our group.

Results: The distribution of mucosal CGRP-immunoreactive nerves is equidistant from the distal esophageal lumen in HV and BE (median 25.5 cell layers to surface [IQR 21.4–28.8] vs 21.5 [16.1–27.5] respectively, $p = 0.155$). Mucosal innervation is significantly more superficial in NERD both distally (9.5 cell layers [1.5–13.3], $p < 0.0001$ vs both BE and HV) and proximally (5.0 [2.5–9.3], $p = 0.0098$ vs HV).

Conclusion: The acid hypersensitivity seen in NERD may be partially explained by the increased proximity of mucosal afferents to the esophageal lumen, and therefore greater exposure to noxious substances in refluxate. Conversely, the relative acid hyposensitivity in BE may be attributed to the deeper location of mucosal nerves.

P1846 BELCHING PATTERNS IN PATIENTS WITH ISOLATED PATHOLOGICAL UPRIGHT REFLUX AND PATHOLOGICAL BIPOSITIONAL REFLUX

J.M. Conchillo, J. T.w. Snijders, J. Santos Fernandez, A. A.m. Masclee
Gastroenterology, Maastricht UMC, Maastricht/Netherlands

Contact E-mail Address: j.conchillo@mumc.nl

Introduction: Belching is a commonly occurring symptom in patients with gastroesophageal reflux disease (GERD). Belching may elicit reflux. It is unknown whether GERD patients with isolated pathological upright reflux (UP) have belching patterns that are different from GERD patients with pathological bipositional reflux (BIP).

Aims & Methods: Aim of this study was therefore to examine the belching patterns of UP reflux patients as compared with BIP reflux patients. We included 50 consecutive patients with pathological reflux and typical symptoms who underwent 24-h pH-impedance monitoring at the Maastricht University Medical Centre from 2015 to 2017. Patients referred for excessive belching were excluded. A group of 25 UP reflux patients (10 male, mean age 52.9 years (range 22–77)) and 25 BIP reflux patients (11 male, mean age 47.9 years (range 18–77)) were enrolled. All 24-h pH-impedance tracings were analysed manually. We classified belches according to: a) physiological mechanism: supragastric vs. gastric; and b) their temporal relationship with a liquid reflux episode: isolated belch, preceding or during a liquid reflux episode. Symptom-association analysis was performed to assess a relationship between reported symptoms and reflux episodes.

Results: BIP patients showed higher acid reflux time ($17.8 \pm 2.4\%$ vs. $7.3 \pm 0.6\%$, $p < 0.001$) and higher number of total reflux episodes (121 ± 9 vs. 97 ± 8 , $p = 0.001$) than UP patients. Notably, both the proportion of reflux episodes with belches of any type and the proportion of belches preceding liquid reflux were higher in UP patients than in BIP patients ($51.7 \pm 3.6\%$ vs. $32.1 \pm 3.7\%$, $p < 0.001$ and $27.3 \pm 3.1\%$ vs. $17.8 \pm 2.9\%$, $p = 0.03$, respectively). No difference was found in the proportion of both supragastric and gastric belches between groups. During 24-h pH-impedance monitoring UP patients reported more symptoms (21 ± 6 vs. 12 ± 3 , $p = 0.16$) and had more positive symptoms with belches ($60.2 \pm 7.1\%$ vs. $39.0 \pm 6.6\%$, $p = 0.03$) than BIP patients. Of the total number of belches that were detected using 24-h pH-impedance, more belches were symptomatic in UP patients than in BIP patients ($24.4 \pm 6.4\%$ vs. $11.1 \pm 2.5\%$, $p = 0.06$).

Conclusion: In our study, GERD patients with isolated pathological upright reflux had more often (symptomatic) belches than GERD patients with pathological bipositional reflux. Therefore, examination of belching patterns can assist diagnostic and therapeutic strategic planning in GERD patients who are refractory to medical therapy.

P1847 IS REFLUX DURING NAPS WORSE THAN DURING NIGHT-TIME SLEEP?

C. Teruel Sánchez-Vegazo, M. J. De Higes Ruiz, A. Albillos
Gastroenterology, Hospital Ramón y Cajal, Madrid, Madrid/Spain

Contact E-mail Address: cteruelvegazo@yahoo.es

Introduction: Gastroesophageal reflux in the recumbent period is related to a higher risk of developing oesophageal lesions (severe esophagitis or Barrett oesophagus). The only study to date that analysed reflux during daytime naps suggests that it is worse than that which occurs during the night-time sleep. Our objective was to determine if reflux during naps is more severe than during night-time sleep.

Aims & Methods: Between February 2015 and November 2016 patients that underwent ambulatory 24-hour oesophageal pH monitoring at our motility unit were screened. Those who slept an afternoon nap in the recumbent position in addition to the regular night-time sleep, and had a pathological acid exposure (deMeester score > 14.72) were included. We excluded those patients with previous foregut surgery or sleep apnea, those taking sleeping medication and those who were in recumbent position more than twice during the study. All studies were done off-therapy. Number of refluxes, number of refluxes per hour, reflux duration and oesophageal acid exposure (AET) time were compared between the two recumbent periods. Correlation between AET and meal-to-bed time was analysed, both for naps and night-time sleep.

Results: A total of 32 patients were selected (59.4% women, mean age 51.31 ± 14.59 , median BMI 26.48 (range 21.63–38.71)). Indication was typical GERD symptoms in 68.8% and atypical symptoms in 32.3%. Oesophageal manometry revealed normal oesophageal body motility in 65.6%, inefficient peristalsis in 28.1%, and a median lower oesophageal sphincter pressure of 8 mmHg (range 1–24). Median nap duration was shorter than that of the night-time sleep: 108 mins (range 30–375) vs 454 mins (range 240–593) ($p = 0.00$). Median meal-to-bed time was also shorter for naps: 30.5 mins (range 4–185) vs 110.5 mins (range 9–247) ($p = 0.00$). Median number of refluxes per hour and median recumbent AET were similar in both periods: 1.71 (range 0–26.5) vs 1.85 (range 0–12.8) ($p = 0.45$) and 1.55 (range 0–61) vs 5.9 (range 0–36.1) ($p = 0.57$), respectively. 87% of total recumbent reflux took place during the

night. Correlation between AET and meal-to-bed time trended to be significant for naps (Spearman $\rho = 0.33$, $p = 0.065$), and was not significant for night-time sleep (Spearman $\rho = 0.02$, $p = 0.94$). All 5 patients who waited more than an hour after lunch to lay down had an AET during the nap of less than 1%.

Conclusion: Naps are not associated with a more severe acid reflux than night-time sleep, what does not support a specific recommendation against taking daytime naps for GERD patients. Avoiding short meal-to-bed time specifically for naps could be advisable.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1848 TREATMENT WITH PROTON PUMP INHIBITORS (PPI) DOES NOT REDUCE ACIDIC LARYNGOPHARYNGEAL REFLUX (LPR) DESPITE REDUCING DISTAL ACIDIC GASTROESOPHAGEAL REFLUX AND IMPROVING SYMPTOMS IN PATIENTS WITH LPR

Contact E-mail Address: pbanovcin@gmail.com

Introduction: PPI improve LPR symptoms in many patients. It is implicitly assumed that this effect is due to reduction of acidic LPR by PPI. Here we tested this assumption. We evaluated LPR and distal gastroesophageal reflux by using simultaneous pH/impedance monitoring in laryngopharyngeal segment and in distal esophagus before and after PPI treatment.

Aims & Methods: Patients referred for suspected LPR were screened and those with positive reflux finding score (RFS > 7 , determined by ENT physician) and/or positive reflux symptom index (RSI > 13) and at least one acidic LPR episode during 24 h pH-impedance study were enrolled. The RSI, RFS and dual pH/impedance study of LPR and distal reflux were completed before and after 3 months therapy with PPI twice a day. Appropriate distance between pH sensors was chosen based on manometrically determined LES and UES so that the proximal pH sensor was positioned 1 cm above UES and distal sensor was positioned 4–6 cm above LES. By definition each LPR event was preceded by reflux detection in the distal esophagus.

Results: 18 patients (11M/7F, 51 ± 10 yrs) completed the study. In this group the PPI treatment substantially improved the symptoms of LPR. Reflux finding score (RFS) was decreased by 40% from 9 ± 1 to 5 ± 1 ($P < 0.01$). Reflux symptom index (RSI) was decreased by 40% from 23 ± 3 to 14 ± 3 ($P < 0.01$). As expected distal acidic reflux was dramatically (by 75%) decreased by PPI treatment ($P < 0.01$). The number of distal acidic reflux episodes was reduced from 17 ± 2 to 3 ± 1 ($P < 0.01$). Surprisingly, acidic LPR was not decreased by PPI treatment. The number of LPR with $\text{pH} < 5.0$ was 2 ± 0.5 vs. 3 ± 1 , $P = \text{NS}$, and the number of LPR episodes with $\text{pH} < 4.0$ was 0.7 ± 0.1 vs. 0.6 ± 0.2 , $P = \text{NS}$. Surprisingly, the number of acidic LPR episodes with $\text{pH} = 5.0–6.0$ was even increased (14 ± 2 vs. 21 ± 3 , $P < 0.05$) leading to an increase in the overall number of LPR episodes by approximately 50% from 16 ± 2 to 24 ± 3 ($p < 0.05$). PPI treatment did not decrease laryngopharyngeal time the pH was < 6.0 (258 ± 48 s vs. 301 ± 64 s, $P = \text{NS}$) and did not alter the composition of laryngopharyngeal reflux ($P = \text{NS}$).

Conclusion: Proton pump inhibitor treatment does not reduce acidic laryngopharyngeal reflux despite substantially improving symptoms in patients with objectively established LPR. This suggests that PPI treatment influences some aspects of pathogenesis of LPR symptoms that are not readily detected by laryngopharyngeal pH/impedance monitoring.

Introduction: Menthol is widely used as a food flavourant. In general, it is considered a trigger of gastroesophageal reflux symptoms. It has been assumed that menthol reduces the tone of the lower esophageal sphincter (LES) as a consequence of direct effect on the smooth muscle of the LES. Evidence has been provided that menthol sprayed on the gastric mucosa significantly suppresses gastric peristalsis (1). However, there is no clear evidence of the impact of menthol on the esophageal peristalsis and LES tone.

Aims & Methods: The aim of the study was to evaluate the effect of the menthol infusion into the esophagus on the esophageal peristalsis and lower esophageal sphincter pressure in healthy volunteers. High-resolution manometry and the parameters of esophageal pressure topography were used to quantitatively evaluate the certain components of esophageal motility. 13 healthy volunteers without esophageal symptoms were enrolled. High-resolution manometry catheter with a thin silicon tube attached were placed transnasally so that the distal end of the tube was 5 cm above the LES. After a 5 min. adaptation period the measurement was performed in the supine position according to the protocol as follows: after the baseline recording 10 water swallows of 5 ml and 3+3 water swallows of 10 and 15 ml 15 ml. After that a 20 min. infusion challenge with 3 mM menthol 8 ml/min. was carried out and subsequently the water swallows in order described above were repeated. HRM tracings were manually analyzed using ManoScan software and parameters used in the Chicago classification (v3.0) were evaluated. Integrated relaxation pressure (IRP), nadir LES pressure and distal contractile integral (DCI) values from 5 ml, 10 ml and 15 ml swallows were obtained. These were compared before and after the menthol infusion. Paired parametric tests were used for statistical analysis.

Results: None of the subjects had any motility disorder defined by the Chicago Classification v3.0. Few volunteers reported only mild cold sensation during infusion presumed to be of the esophageal origin. The nadir LES pressure before and after menthol infusion was 7.5 ± 0.8 mmHg vs. 7.3 ± 0.7 mmHg, respectively ($p > 0.7$). IRP of 5 ml swallows was 2.8 ± 0.6 mmHg vs. 2.1 ± 0.5 mmHg showed significance ($p = 0.01$). However, difference of IRP of 10 ml and 15 ml swallows was not significant ($p > 0.1$, $p > 0.5$, respectively). Average DCI pressure (5 ml swallows) was 737.8 ± 126.2 mmHg and 814.2 ± 116.2 mmHg before and after menthol infusion, respectively ($p > 0.5$). We found no difference in DCI in 10 ml and 15 ml swallows before and after menthol infusion. Menthol seemed to have had only a marginal insignificant effect on IRP and DCI in rapid swallow test.

Conclusion: We quantified the effect of menthol on the esophageal function and LES pressure in healthy volunteers using high resolution manometry. The analysis of HRM tracings revealed that menthol has no effect on particular parameters of the LES pressure and esophageal peristalsis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: lenka.bubernakova@gmail.com

Introduction: Globus is considered to be related to the gastroesophageal reflux disease/laryngopharyngeal reflux (LPR). However, a substantial part of subjectiveness and self-perception of globus sensation which is impossible to measure objectively makes this symptom difficult to study. Visceral hypersensitivity and/or altered functional state of the afferent nerve endings in the hypopharynx resulting from reflux have been suggested responsible for the development of globus. We hypothesized differences in the reflux burden and esophageal/pharyngeal acid exposure between the patients with LPR symptoms with globus compared to the patients with LPR symptoms without globus.

Aims & Methods: Patients referred for suspected LPR were screened and those with positive reflux symptom index (RSI > 13) and at least one acidic LPR episode during 24 h pH/impedance study were enrolled. We recruited patients that were at least 30 days without PPI treatment. Appropriate distance between pH sensors was chosen based on manometrically determined LES and UES so that the proximal pH sensor was positioned 1 cm above UES and distal sensor

was positioned 4–6 cm above LES. For each LPR event we determined the maximum drop of pH on the pH levels <5.5 and <5.0. For these pH levels we determined pharyngeal acid exposure time calculated as cumulative time of pharyngeal reflux below that pH level during 24 h. According to the question 8 (sensations of sticking/lump in the throat) of self-evaluated RSI questionnaire the patients were divided into globus positive group (tick 4–5 in the RSI) or globus negative (tick 0–1 in the RSI).

Results: 19 (13M/6F) completed the study. The number of globus positive and negative patients was 11 and 8, respectively. There were no major differences between groups. Disregarding the question about globus in the RSI, there was no significant difference of the RSI between the globus positive and negative group (25 ± 2 vs. 21 ± 2 , respectively, $p = \text{NS}$). As for the reflux in distal esophagus, we observed no difference in the acid exposure time between the globus positive and negative patients ($2.2 \pm 0.5\%$ vs. $3.9 \pm 1.1\%$, respectively, $p = \text{NS}$). We therefore assumed differences in the results from the hypopharyngeal pH sensor. However, the number of LPR events with pH drop to <5.5 showed no significant difference between the globus positive and negative patients, either for the number of LPR events [$5[2.5-6.5]$ vs. $3.5[1.8-6.3]$, respectively, $p = \text{NS}$], or for the pharyngeal acid exposure time (45 ± 14 s vs. 88 ± 42 s, respectively, $p = \text{NS}$). We speculated that more acidic LPR events (pH drop to <5) might be of greater relevance. However, no significant difference was found between the globus positive and negative patients either in terms of the number of these LPR events [$1[0-2]$ vs. $1[1-1]$, respectively, $p = \text{NS}$], or the pharyngeal acid exposure time (16 ± 6 s vs. 42 ± 36 s, respectively, $p = \text{NS}$).

Conclusion: We found no significant difference in the reflux burden in the distal esophagus/hypopharynx between the groups of symptomatic LPR patients with and without globus using 24 h dual channel pH/impedance. Other factors, e.g. visceral hypersensitivity might play a role in the development of globus symptoms, even in patients with objectively established LPR.

Introduction: Due to a negative feed-back mechanism, gastrin-17 (G17) can be considered a mirror of acid secretion: the lower G17 values, the higher gastric acid secretion. Some studies suggest serum G17 low levels as a marker of acid-related conditions, like Gastroesophageal Reflux Disease (GERD). Aim of the study was to evaluate the property of low levels of G17 in GERD diagnosis, in comparison with clinical and instrumental GERD gold-standards (typical symptoms, esophagitis at endoscopy, a positive Demeester score at pH-metry).

Aims & Methods: We enrolled 777 consecutive patients ($M = 369$; mean age = 55.3 ys; range = 33–76y ys) affected by upper gastrointestinal (GI) troubles, showing low levels of serum G17 (BioHit Oyj, Finland; mean values: 1–9 pmol/l). Exclusion criteria included: current Proton Pump Inhibitors, previous history of surgery, neoplasms, current *Helicobacter Pylori* infection. Both typical, atypical and extra esophageal GERD symptoms, according with Montreal Classification were collected. All patients underwent upper GI endoscopy and esophagitis was classified according with Los Angeles criteria. In a subgroup of 221 patients ($M = 103$; mean age = 52.5 ys; range = 35–69 ys) with Non Erosive Reflux Disease (NERD) a 24 hours pH-metry was performed using the Demeester score of 14 to establish a condition of acid reflux.

Results: Typical symptoms (heartburn and/or regurgitation) have been detected in 547 patients, being in 479 ones heartburn the prevalent symptom and in 68 ones regurgitation. Extra-esophageal symptoms (mainly chronic cough) were present in 303 patients. At the endoscopic evaluation, 349 subjects showed a picture of esophagitis with different degrees of severity of Los Angeles score. One hundred and seventy out 221 patients which underwent 24 h pH-metry showed a positive Demeester score for acid gastroesophageal reflux. Summarizing, 700 out of the 777 subjects included in the study showed at least one of the criteria (clinical, endoscopic or functional) accepted to support the diagnosis of GERD.

Conclusion: By using low levels of G17 as a non-invasive marker of GERD, in more than 90% (700 out of 777 pts) the diagnosis of reflux disease was confirmed, according with the current clinical or instrumental gold standard criteria, suggesting the use of this simple method to identify subjects with suspected GERD almost when typical symptoms are lacking or a NERD picture is found.

Introduction: Sliding hiatal hernia (HH) is a frequent diagnosis during upper endoscopy (UE) in patients with GERD-related symptoms. Recently, high resolution manometry (HRM) allowed an accurate evaluation of the esophago-gastric junction (EGJ) and its sub-types (Chicago Classification V3.0; CCv3). Few data are available comparing the diagnostic accuracy of HRM and UE to detect HH.

Aims & Methods: The aim of this study was to compare the prevalence of HH obtained with UE and HRM and to determine the role of this finding by diagnosing gastroesophageal reflux disease (GERD) on the basis of impedance and pH (MII-pH) monitoring. We enrolled consecutive patients with heartburn and HH diagnosed with UE. After UE, all patients underwent HRM and MII-pH to investigate GERD. All tests were performed previous a 20-day wash-out from proton pump inhibitors. Erosive esophagitis (ERD) was diagnosed according to the Los Angeles Classification, and HH was diagnosed when the separation between the squamo-columnar junction and the diaphragmatic impression was greater than 2 cm. Patients with achalasia or major disorders of peristalsis or previous surgery were excluded. MII-pH monitoring allowed to sub-classify patients with non-erosive GERD in: NERD (abnormal AET), hypersensitive esophagus (normal AET, reflux events but positive symptom-reflux association, HE) and functional heartburn (normal AET, reflux events and negative symptom-reflux association, FH). All patients underwent barium X-ray to measure HH. Recognition of two rings larger than 2 cm (recumbent position) between EGJ and diaphragmatic hiatus was necessary to detect HH.

Results: We evaluated 151 patients (94 females) with mean age of 56.2 ± 15.4 yrs. ERD was diagnosed in 34 patients (22.5%). MII-pH allowed to subgroup patients in: 48 (31.8%) NERD, 43 (28.5%) HE, and 26 (17.2%) FH. As expected, MII-pH showed a higher AET in ERD and NERD group ($p < 0.001$). HRM was normal in 131/151 (86.8%) and 20/151 (13.2%) had ineffective motility. HH was confirmed in 83/151 patients (HRM 55% vs UE 100%; $p < 0.05$) with HRM and in 88/151 patients (barium 58.3% vs UE 100%; $p < 0.05$) with barium X-ray. The mean length of HH during endoscopy (5.4 ± 2.6) was reported greater than that during HRM (3.9 ± 2.2) and Barium X-ray (4 ± 2.5) ($p < 0.05$). All details are reported in Table 1.

Table 1: Characteristic of the enrolled population stratified for GERD diagnosis

	ERD (34)	NERD (48)	HE (43)	FH (26)	p
EGJ pressure (mean)	25.86 ± 11.8	30.3 ± 13.2	31.4 ± 12.6	33.1 ± 13.7	0.635
DCI	1001 ± 683	1431 ± 1632	1577 ± 1365	1799 ± 1453	0.042
IRP	11.8 ± 5.1	12.6 ± 7.2	13.1 ± 7.8	11.4 ± 7.1	0.57
DL	6.8 ± 1.6	6.8 ± 1.1	6.6 ± 1.4	6.9 ± 1.5	0.836
AET (%)	7.7 ± 2.9	5.1 ± 2.3	2.7 ± 1.4	1.1 ± 0.9	<0.001
Reflux number	77.8 ± 23.7	66.9 ± 31.4	24.6 ± 9.1	17.9 ± 7.5	<0.001
Hiatal hernia (HRM)	33 (97.1%)	34 (70.8%)	16 (37.2%)	0	<0.001
Hiatal hernia (X-ray)	34 (100%)	36 (75%)	17 (39.5%)	1 (3.8%)	<0.001

Conclusion: HRM and barium X-ray showed similar diagnostic accuracy to detect HH. Thus, HRM might be considered the test of choice during pre-surgical evaluation for laparoscopic antireflux surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI853 HIGH RESOLUTION MANOMETRY CAN BE PREDICTIVE OF GERD AS CONFIRMED BY IMPEDANCE-PH MONITORING: DEVELOPMENT AND INTERNAL VALIDATION OF A PREDICTIVE MODEL

Introduction: In patients with symptoms suggestive of gastroesophageal reflux disease (GERD) candidate to anti-reflux surgery or in those refractory to antacid therapy, it is recommended to perform function tests in order to objectively diagnose GERD. Esophageal manometry is currently considered the gold standard method to assess esophageal motility. However, it has been shown limited capability to diagnose GERD. With the advent of high-resolution manometry (HRM), new metrics have been developed to investigate esophageal motor function, esophagogastric junction (EGJ) morphology and their function. In particular, the antireflux barrier function of EGJ can now be assessed evaluating the contraction integral of the EGJ.

Aims & Methods: Our aim was to assess the differences in terms of HRM characteristics between patients with typical reflux symptoms with GERD and those with functional heartburn (FH), classified by means of upper GI endoscopy and impedance-pH (MII-pH) monitoring off-medication. We also aimed to develop a predictive model for distinguishing FH from GERD by using the prevalence of these HRM features. Consecutive patients with heartburn and/or regurgitation and a recent endoscopic assessment were enrolled. All patients underwent HRM to assess the EGJ and 10 single water swallows to evaluate esophageal peristalsis and EGJ function and one multirapid swallow (MRS). The tracings were analyzed according to the Chicago Classification 3.0. EGJ pressure, EGJ contractile integral (EGJ-CI), EGJ morphology, mean and peak distal contractile integral (DCI), MRS DCI/mean DCI ratio and motility pattern were measured. Moreover, all patients underwent MII-pH off-therapy. We measured the esophageal acid exposure time (AET), number of total impedance reflux episodes and symptom association analysis using both symptom association probability (SAP+ if $\geq 95\%$) and symptom index (SI+ if $\geq 50\%$). GERD was diagnosed in case of one or more abnormal parameters at MII-pH. To analyze the differences between patients with MII-pH positive and negative for GERD, Mann-Whitney's U test for continuous variables was used and significance was set at $P < 0.05$. A multivariate logistic regression analysis was then carried out to identify factors independently associated with MII-pH positivity for GERD, significance settled at $P < 0.05$. According to Hosmer's purposeful selection of covariates, a predictive model based on HRM variables was built by logistic regression analysis. The model was tested for discriminative performance by computing the area under ROC curve (AUROC), and calibration was assessed by Hosmer-Lemeshow goodness-of-fit test. The bootstrap re-sampling method was used to evaluate the internal validity of the model and to correct for overfitting.

Results: Overall, 68 patients (39 F/29 M, median age 42.3) underwent HRM and MII-pH. HRM findings stratified according to MII-pH positivity for GERD are provided in Table 1. At univariate analysis, statistically significant differences were found in EGJ pressure, EGJ-CI, mean DCI and MRS DCI/mean DCI ratio between GERD and FH. Based on logistic regression analysis and according to Hosmer's purposeful selection of covariates, we developed a predictive model which ultimately encompassed two HRM variables, i.e. DCI MRS/mean DCI ratio (OR 1.614, 95%CI 0.993–2.895) and EGJ-CI (OR 0.952, 95%CI 0.913–0.985). The model had a fair discriminative performance (AUROC: 0.798, 95%CI: 0.650–0.894) between MII-pH positivity and negativity for GERD and was well calibrated according to Hosmer-Lemeshow goodness-of-fit test ($p = 0.769$). The internal validation of the model by bootstrap method showed AUROC = 0.779. Considering as cut-off the predicted probability of MII-pH for GERD which maximized sensitivity and specificity (i.e. 67.4%), sensitivity and specificity of the predictive model in predicting GERD against FH were 80.8% and 76.2%, respectively.

Table 1

HRM variable	GERD group (n = 47)	No GERD group (n = 21)	P value
EGJ resting pressure, mmHg (median, IQR)	17.6 (16.9)	22.7 (19.1)	0.028°
Peak DCI, mmHg * cm * sec (median, IQR)	991 (1887)	1632 (2160)	0.018°
Mean DCI, mmHg * cm * sec (median, IQR)	590 (1299.5)	1191 (1166)	0.004°
DCI MRS, mmHg * cm * sec (median, IQR)	1039 (1983)	842 (1764)	0.465°
DCI MRS/mean DCI, mmHg * cm * sec (median, IQR)	1.723 (2.299)	1.113 (1.212)	0.012°
EGJ CI, mmHg * cm * sec (median, IQR)	7 (18)	22 (17.6)	0.004°
EGJ morphology (type II and III vs. type I), n (%)	14 (29.8)	3 (14.3)	0.232°

Conclusion: Our data indicate that HRM can be useful in detecting GERD, with our predictive model allowing a high level of suspicion for reflux disease. In particular the role of the EGJ-CI in GERD pathophysiology has been

emphasized highlighted. Further larger studies considering different GERD phenotypes are needed.

Contact E-mail Address: j.labenz@t-online.de

Introduction: Randomized controlled trials report about 30% of GORD patients complain of bothersome remaining symptoms (heartburn, regurgitation) despite PPI. The LOPA (Lost Patients) I Study of 333 GORD patients seen in general practice revealed 46% of patients experienced heartburn or regurgitation symptoms at least twice per week despite PPI. A total of 20% were dissatisfied with their treatment. Few patients had received specific GORD diagnostics or recommended other options (<10%).

Aims & Methods: The LOPA II study is a prospective, multicenter, observational study conducted in 17 general practice clinics. Patients with chronic GORD, taking PPI therapy for at least 1 year, and not satisfied with their treatment were asked to complete a questionnaire. Patients were asked the duration of their PPI therapy, satisfaction with their current condition, frequency of symptoms in the last week, whether they had previously received diagnostic evaluation or surgical consult related to GORD, whether they plan to consult a reflux specialist for further diagnostics, and reasons for dissatisfaction with their current medication treatment. "Lost Patients" were defined as those with a satisfaction score of 1 or 2 on a 5-point Likert scale (1: very dissatisfied; 2: dissatisfied), GerdQ score at least 8, and have not previously received specialized GORD diagnostics.

Results: 510 consecutive patient responses were collected within one year. Patients suffered from GORD an average of 9.6 years and prescribed PPI therapy for an average duration of 7.9 years. 70% were dissatisfied or very dissatisfied on their current PPI therapy (score of 1 or 2). 83% reported heartburn or regurgitation at least 2 days in the prior week (53% 4-7 days). 49% reported using additional medication other than their prescribed PPI at least 2 days per week (34% 4-7 days). In patients dissatisfied on PPI, most cited insufficient symptom control (87%) as a reason for dissatisfaction. In addition, 31% cited concern with long-term use of drugs and 27% the need for daily medication. 92% of patients had received an upper endoscopy, 12% had a prior pH-metry, 7% manometry, and 9% received prior surgical consult for GORD. Of patients who never received surgical consult, 48% were not aware of any surgical anti-reflux methods, 25% were concerned about possible complications, 18% felt their condition is not serious enough, 6% were recommended against anti-reflux procedure by their doctor.

Conclusion: Chronic GORD patients who are dissatisfied with their PPI therapy are rarely offered specialized GORD diagnostic procedures or treatment alternatives. Half of the patients took medication in addition to PPI to control their reflux. In addition to persistent symptoms, concerns of long-term PPI use and burden of daily medication play a role in patient dissatisfaction with PPI therapy.

Introduction: Autoimmune gastritis (AIG) is characterized by corpus-predominant atrophy with consequent hypo-achlorhydria. In AIG patients dyspepsia is frequent but acid reflux symptoms not uncommon, with few data available regarding gastroesophageal reflux disease (GERD) in AIG.

Aims & Methods: Our study was aimed to define the prevalence of reflux symptoms in AIG patients, to evaluate the serological, histological and clinical differences in AIG patients with or without reflux symptoms and to investigate the physiopathology behind these symptoms. One hundred and fifty AIG outpatients were evaluated and 87 were included in the study: 29 AIG patients with reflux symptoms (AIG-R) and 58 without (controls), selected with similar age and gender distribution. AIG-R underwent a pH-impedance (pH/I) and high resolution manometry (HRM). Serum biomarkers, EGDS, histology and anamnestic data were evaluated in both groups. Statistics was performed as indicated.

Results: AIG-R were 19% overall and 28% of them showed endoscopic esophageal lesions, with more frequent hiatal hernia than in controls ($p < 0.02$). pH/I diagnosed acid reflux, esophageal hypersensitivity and a normal pattern in 7%, 28% and 66% patients, respectively. The number of non-acid reflux (NAR) was higher when compared with acid ones ($p < 0.0001$), moreover NAR and NAR proximal extension were associated with endoscopic lesions ($p < 0.03$ and

$p < 0.05$, respectively). HRM revealed normal pattern in 62% of patients, minor peristalsis disorders in 24%, and outflow obstruction in 14%. According to the new Rome IV criteria, 55% of patients presented "functional esophageal disorders" (Rome IV-IN). No differences were detected in serological marker and clinical presentation. AIG-R presented lower antrum gastritis ($p < 0.006$) and a trend toward lower atrophy stage ($p = 0.07$) when compared with controls. The two patients with acid GERD were an OLGA 0 with mild gastrin increase and an OLGA I with short segment Barrett's esophagus. Lower OLGA stages, lower corpus atrophy ($p < 0.02$) and more frequent response to PPI ($p < 0.05$) were associated with Roma IV-OUT status.

Conclusion: AIG-R patients are not uncommon despite the hypo-achlorhydria. Acid reflux is rare in AIG, while motility and "functional" disorders are frequent. Lower corpus atrophy and OLGA stage in Rome IV-OUT patients, with an at least partly preserved secretion, is likely relevant in the pathogenesis of symptoms. Treatment should consider use of proton pump inhibitor drugs only in specific patients.

Introduction: Gastroesophageal reflux disease (GERD) is a common disorder commonly overlapping with several functional or allergic/immunological disorders, whose symptoms are related to food intake. Awareness of health care costs and potential side effects of long-term acid suppression has increased the attention in non-pharmacologic treatment for alleviating reflux symptoms.

Aims & Methods: The aim of our prospective study was to evaluate the non-inferiority of a controlled diet compared to antacid compounds in relieving reflux symptoms in patients suffering from mild GERD. We considered 500 consecutive patients referred to the Division of Allergy and Clinical Immunology of Azienda-IST IRCCS San Martino of Genoa for gastrointestinal symptoms associated to food intake. Patients with a clinical and instrumental diagnosis of food allergy, food intolerance, Irritable Bowel Syndrome (IBS) and Small intestinal Bacterial Overgrowth (SIBO) were excluded. Patients with a diagnosis of GERD based on clinical history represented our study population. Basal metabolic rate and calories need of patients was assessed by means of Harry-Benedict equation corrected for their physical activity. Patients were asked to take antacids for one month. Subsequently patients discontinued medication consumption and followed an elimination diet of food commonly associated to eliciting reflux symptoms, based on their calories need. Efficacy of the two treatments was evaluated by means of a validated symptomatic questionnaire (RDQ administered at baseline, after antacids course (1 month) and after diet (1 month). A treatment was considered effective if a 50% improvement in the symptomatic score was recorded.

Results: After investigations 261 patients out of 500 (52.2%) were excluded because of IBS (140), celiac disease (6), nickel allergy (25), lactose intolerance (60), SIBO (10), and allergy to other foods (20). The remaining 239 patients were diagnosed as affected by mild GERD (median age 47; BMI 24; 132F/107M; no erosive reflux disease) and were included in our interventional prospective study. Among them, antacids treatment was effective in 180 cases (75.3%). Symptoms relief was reported by 220 patients (92.1%) after diet based on calories need. No differences were noted between responders and not responders in terms of BMI, age and gender. Diet was more effective than antacids treatment in relieving reflux symptoms in mild GERD ($p < 0.01$).

Conclusion: A structured diet regimen, tailored on the metabolic need of the patients, appears more effective than antacids alone in relieving reflux symptoms in patients with mild GERD. Further controlled studies are mandatory to confirm these preliminary data.

Introduction: Safety and efficacy of electrical stimulation of the lower oesophageal sphincter (ES-LOS) using the EndoStim® LOS Stimulation System (Nijmegen, The Netherlands) has been demonstrated in clinical trials up to >5 years. Data on outcomes in routine clinical practice is growing.

Aims & Methods: An ongoing, prospective international multicenter web-based registry is collecting data in patients with disruptive GORD symptoms, treated with ES-LOS in clinical practice. Data is collected at baseline and at routine follow-ups for 5 years. Demographics, adverse events, GORD symptoms, GORD health related quality of life (GORD-HRQL) scores, use of proton pump inhibitors (PPIs) and physiological data (oesophageal pH/manometry) are collected when available.

Results: 180 patients at 13 sites in Europe and Latin America have been enrolled. Follow-up data up to 2 years is available. Median (IQR) age at the time of implant was 51 (41–60), 57% were male. All patients were taking prescription PPI at baseline. At their last follow-up between 6 and 24 months post op, 70% (84/121) were completely off PPI ($p < 0.001$). Median (IQR) composite GORD-HRQL score improved from 23 (17–29) preoperatively to 8 (4–15) at 6 months, 7 (2–12) at 12 months, and 8 (4–15) at 24 months ($p < 0.001$ at all time points, $n = 154, 121, 66, 33$ at baseline, M6, M12, M24, respectively). Oesophageal pH testing post-op was performed by a few sites either as standard of care or in patients with residual symptoms. Median (IQR)% 24-hour oesophageal acid exposure improved from 8.2% (4.6–18.4) at baseline to 4.7% (1.4–14.5) at 6 months ($p = 0.26$) and 3.6% (1.0–5.8) at 12 months ($p = 0.04$) ($n = 120, 39, 10$ at baseline, M6, M12, respectively). The proportion of patients with moderate to severe regurgitation decreased from 64% at baseline to 22.5% after 6 and 13.4% after 12 months. Extra-oesophageal symptoms (recurrent cough, pneumonitis, shortness of breath) and sleep disturbances also decreased substantially. Overall, dysphagia and gas were less common at 12 months than preoperatively. Four serious adverse events were reported in 3 patients. One myocardial infarction related sudden death at 11-month post-op, not related to the device or procedure; 1 event of asymptomatic electrode erosion into the oesophagus detected during routine endoscopy and the device safely removed during laparoscopic fundoplication; and 2 events of gastroparesis in 1 patient requiring hospitalization, possibly related to the device, were reported.

Conclusion: ES-LOS is safe and effective in treating patients with disruptive GORD symptoms despite PPI in routine clinical practice. ES-LOS should be considered a viable treatment option for treating these patients.

Contact E-mail Address: amolbapaye@gmail.com

Introduction: PPI therapy remains the mainstay for treatment of gastroesophageal reflux disease (GERD), however laparoscopic fundoplication is recommended in refractory patients. Various endoscopic methods have been attempted with variable success. Anti-reflux mucosectomy (ARMS) is a recently introduced endoscopic therapy for refractory GERD.

Aims & Methods: The current study describes initial clinical experience of ARMS. Data from a prospectively maintained database of consecutive patients undergoing ARMS for refractory GERD was abstracted. Inclusion criteria—GERD symptoms >1 year, daily PPI usage >=6 months; absence of hiatus hernia >3 cm on EGD and normal esophageal body motility on high-resolution manometry (HRM). Exclusions—hiatus hernia >3 cm, poor or absent esophageal body motility, poor-risk candidates for anesthesia or invasive procedure. Pre-ARMS evaluation—EGD to assess Hill's grade of flap valve, esophageal manometry, 24-hour ambulatory esophageal pH studies, PPI requirement and GERD-HRQL questionnaire. ARMS performed using cap EMR technique. Follow up protocol—EGD at 2–4 weeks, GERD-HRQL questionnaire, pH studies and PPI requirement at 4–6 weeks. Parameters for data analysis - pre-and post-ARMS GERD-HRQL questionnaire and Deemester scores, Hill's grading of gastroesophageal valve on EGD, PPI requirement and procedure-related adverse events (AE).

Results: $N = 15$, duration—12-months. Mean age—40.8 years (Range 22–69); M: F—11: 4. HRM—normal esophageal body motility in all. Mean GERD-HRQL score improved significantly from pre-ARMS—40.4 to post-ARMS—7.6 ($p < 0.05$). Mean Deemester score decreased from 85.8 pre-ARMS to 5.9 post-ARMS ($p < 0.05$). Mean Hill's valve grade decreased pre-ARMS=2.8; post-ARMS=1.6 ($p < 0.05$). Three AE's—muscle injury—2 (treated by endoclips), grade I dysphagia—1. At 4 weeks follow up, 11/15 patients (73.3%) had discontinued PPI, 4/11 (36.3%) had >50% reduction in PPI dosage.

Conclusion: Current study shows impressive short-term results for ARMS. Significant symptom resolution and acid exposure reduction occurred in all patients. 100% patients could discontinue or reduce PPI usage. AE's were minor. Larger randomized studies with longer term follow up are recommended.

P1859 EFFECTIVENESS OF SELECTIVE SEROTONIN REUPTAKE INHIBITORS IN PATIENTS WITH NON-EROSIVE REFLUX DISEASE: A RANDOMIZED TRIAL

I. Biriuchenko, N. Bondarenko, A. Svintsitsky

National Medical University, Kyiv/Ukraine

Contact E-mail Address: doctor.gastro@yahoo.com

Introduction: To date a large quantity of 5-HT₄ receptors were found in esophageal mucosa that indicates on an important role of this neuromediator in pathogenesis of non-erosive reflux disease (NERD) and gastroesophageal reflux disease (GERD). Antidepressants seems to be effective, as they have central analgesic effect, reduce chemical and mechanical sensitivity and have local effect on gastrointestinal tract.

Aims & Methods: Our aim was to assess the superiority of combined treatment using proton pump inhibitor (PPI) plus antidepressant by comparison with PPI for patients with NERD. Methods: In this randomized superiority study adult patients (18–65 years) with confirmed diagnosis of NERD were eligible to participate. Exclusion criteria: the presence of “red flag” signs and other comorbidities that could explain the symptoms. Patients were assessed in clinically and psychologically. Psychological testing was done using validated short-form version of the depression anxiety stress scales (DASS-21) and Toronto alexithymia scale (TAS). All the patients were randomly divided into two arms: patients of the first arm received PPI (pantoprasole) 40 mg once a day plus escitalopram as follows: initial dose - 5 mg/day for the first two weeks of treatment; depending on individual response the dose was increased to 10 mg/day. The second arm received only PPI 40 mg once a day. Patients were assessed on the 4th and 8th week of treatment. The superiority was shown if there was more lasting decrease in heartburn severity, reduced anxiety (A), depression (D) and alexithymia levels.

Results: Of 75 randomized patients 39 were allocated to the first arm and 36 to the second one. The groups were statistically comparable in age and sex. Treatment results showed reduction of heartburn severity in both groups on the 8th week, however more significant in the first group (1group-89.7%, 2group-61.1%, $P < 0.001$). Also both A and D levels were much lower in the first group compared to the second one ($P < 0.001$). Comparing the levels alexithymia between two arms on the 8th week after the initiation of treatment we found that alexithymic type of personality prevailed in patients that received PPI only ($P < 0.001$).

Conclusion: The combination of PPI plus antidepressant demonstrates superiority to PPI therapy alone, showing more lasting symptoms regression and improved psychological and emotional condition of patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1860 QUALITY OF ESOPHAGEAL MUCOSAL HEALING IN EROSIIVE REFLUX DISEASE: A RANDOMIZED COMPARATIVE TRIAL WITH LANSOPRAZOLE ALONE OR COMBINED WITH REBAMIPIDE

K. Song¹, Y.C. Lee², S.J. Hong³, S.W. Jeon⁴

Contact E-mail Address: postit2@daum.net

Introduction: The quality of histologic healing or inflammatory cytokine-related change in erosive reflux disease (ERD) had been verified in few studies. Rebamipide is an anti-inflammatory drug promoting gut mucosal healing.

Aims & Methods: We conducted double-blinded comparative study to assess endoscopic, histologic quality of mucosal healing in ERD, following 4-week medical treatment with lansoprazole combined with rebamipide or not. The patients with ERD in modified LA classification grade A-D were enrolled via four referral institutes, regardless of GERD related symptoms. The enrolled subjects were randomly allocated to ingest 30 mg lansoprazole alone or ingest lansoprazole 30 mg with rebamipide 100 mg three times in a day for 4 weeks. Baseline and follow up endoscopies were performed to assess endoscopic healing (regressed into minimal change or normal), and to obtain esophageal biopsy specimens (at 3 o'clock direction, 3 cm proximal area from squamocolumnar junction). Additional tissue samples were obtained to measure tissue inflammatory cytokines (IL-8, PAF, at 9 o'clock direction, 3 cm proximal area from squamocolumnar junction).

Results: Overall 109 patients were enrolled and randomly allocated to lansoprazole group ($N = 54$) or combination group ($N = 55$). Demographic data, smoking or drinking habits were not significantly different between both groups. The endoscopic healing rate at 4-week was not different significantly (75.0% vs 78.9%; $P = 0.686$, Difference 3.95%, 95%CI [-15.24, 23.13]). The histologic changes of basal layer thickness, intraepithelial infiltration of inflammatory cells (eosinophils, neutrophils) were normalized in subsets of patients regardless of the fate of endoscopic healing, and were not different in both groups. In contrast, papillary length, intraepithelial infiltration of T lymphocyte and the dilated intercellular space (DIS) was normalized significantly in endoscopically

healed combination group. When both group were pooled in a group (proton pump inhibitor administration), the papillary length and DIS was significantly improved in endoscopically healed patients. Tissue level of IL-8, but not Lyso-PAF, was significantly decreased in lansoprazole alone group.

Conclusion: Adjuvant therapy of rebamipide to lansoprazole failed to reveal additional esophageal healing effect by endoscopic or histologic evaluation. Papillary length and DIS was more evident parameter of quality of mucosal healing in patient of erosive reflux disease treated with proton pump inhibitor. Long term follow-up data are needed on whether these histologic parameters of mucosal healing can help predict the prognosis of gastroesophageal reflux disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1861 LONG-TERM RESULTS OF RADIOFREQUENCY ABLATION (RFA) IN PATIENTS WITH BARRETT'S ESOPHAGUS RELATED NEOPLASIA

J. Krajciová¹, J. Malusková², M. Kollar², Z. Vacková¹, J. Spicak¹, J. Martinek¹

²Clinical And Transplant Pathology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: kraj@ikem.cz

Introduction: Radiofrequency ablation (RFA) with or without endoscopic resection (ER) is an established endoscopic treatment of early Barrett's esophagus (BE) related neoplasia (BORN). After successful treatment, follow-up is still required as recurrences may occur. The aim of this prospective single-center case series was to assess the long-term efficacy of endoscopic treatment (RFA with or without ER) for BORN. Main outcomes were complete remission of neoplasia (CR-N) and intestinal metaplasia (CR-IM) and recurrence of IM (R-IM) and neoplasia (R-N).

Aims & Methods: A total of 99 consecutive patients with BORN have been treated since 2009. Of those, 87 patients (75 men, mean age 64, range 22-91) completed the treatment and were included into this analysis. The patients had been followed up during 296 patient-years (mean 3.4 years, range 0.5-6). Thirty-three patients were diagnosed with adenocarcinoma (38%), 24 patients with high-grade dysplasia (28%) and 30 patients with low-grade dysplasia (34%). Prior to RFA, ER for visible lesions was performed in 57 patients (66%). Mean length of the Barrett's esophagus (BE) was 4.6 cm (range 1-13 cm). After treatment, the patients have undergone regular endoscopic surveillance with multiple biopsies.

Results: Complete remission of IM (CR-IM) and complete remission of neoplasia (CR-N) were achieved in 54 patients (54/83 pts, 65.1%; 95% CI 54.3-74.5) and 82 patients (98.8%; 95% CI 92.8-99.9), respectively. All patients who did not achieve CR-IM had macroscopically normal neo-Z-line without visible abnormalities except one patient where macroscopic eradication of BE was not achieved due to giant hiatal hernia and who was referred for anti-reflux surgery. During the follow-up, 18 patients (33.3%, 18/54 pts) experienced a recurrence of IM and 3 patients (3.7%, 3/82 pts) had a recurrence of neoplasia (LGD 2x, HGD 1x). We did not encounter any patient with a subsquamous neoplasia. All recurrences occurred at the level of neo-Z-line and 6 patients with recurrent IM had also macroscopic recurrence of BE. A total of 13 patients underwent endoscopic retreatment: 7x probe-based re-RFA, 5x escape argon plasma coagulation (APC) and 1x ER. After retreatment, we achieved 100% CR-N and 54% (7/13 pts) CR-IM. Treatment-related adverse events occurred in 22 patients (25%): 12x chest pain and 10x stricture. Two patients with a stricture had to undergo surgical resection - first patient due to perforation during balloon dilatation of a post-RFA stricture, the second because of refractory post-RFA stricture after 20 sessions of dilatation.

Conclusion: RFA combined with ER for patients with BORN achieves a high success rate of CR-N with durable results. Recurrence of IM occurs in approximately one-third of patients and supports continuous endoscopic surveillance even after complete eradication. Nonetheless, the majority of recurrent IM occurs within a normally appearing neo-Z-line with questionable clinical relevance.

Disclosure of Interest: All authors have declared no conflicts of interest.

Abstract No: P1862

Table 1: The measurements of Barrett's thickness in one patient, using the two different measurement protocols.

Pt.	Age (years)	SEX	BMI	Highest grade prior biopsy	Prior Treatment	Prague Length, circumferential and maximum extend in cm	Thickness subjective measured, pixels [SEM, number of measurements]	Thickness objective measured, pixels [SEM, number of measurements]
1	85	Male	25.8	High grade dysplasia	None	C16M16	317.38 [9.96, 65]	286.85 [8.96, 65]

P1862 METHODS OF MEASURING BARRETT'S MUCOSAL THICKNESS WITH VOLUMETRIC LASER ENDOMICROSCOPY (VLE), AS A BIOMARKER TO GUIDE TO TREATMENT CHOICE

Introduction: Barrett's Esophagus (BE) is a premalignant condition, in which prolonged gastroesophageal reflux results in intestinal metaplasia, leading to an annual risk of adenocarcinoma 0.12%/year¹. The current standard of treatment is Endoscopic Resection (ER) of visible nodular lesions and Radiofrequency Ablation (RFA) of flat Barrett's, which has a success rate of 92%². For refractory cases, wide field ER, cryotherapy and other methods are used, but may have higher adverse events. We hypothesize that thicker Barrett's tissue is less likely to respond to RFA and have developed methods to precisely measure tissue thickness with Volumetric Laser Endomicroscopy (VLE). These methods may facilitate future studies, correlating tissue thickness with response to therapy and prediction of optimal treatment.

Aims & Methods: We performed a nested cohort study from the U.S. VLE Registry (which comprises 1000 patients) of patients with BE, who had a baseline VLE scan, followed by RFA ablation and had at least one follow up exam. We excluded patients who had any ablative therapy prior to baseline VLE. The primary outcome was the percentage reduction of Prague length after the first treatment. Secondary outcomes were: 1. complete remission of intestinal metaplasia (CRIM) during 12 months after baseline procedure, 2. complete remission of dysplasia (CRD) during 12 months after baseline procedure, and 3. number of RFA treatments necessary for complete response of intestinal metaplasia. We estimated the thickness of BE mucosal layers, by measuring the distance between the esophageal surface to the deepest edge of the lamina propria. In order to do so, we developed an algorithm (ImageJ software; imagej.nih.gov/ij/) that automatically adjusts every clockwise image into a high-resolution vertical scan with enhanced contrast. We used two measurement protocols: subjective, by drawing a line from the surface to the edge of the lamina propria (LP) and by plotting a grayscale density plot at the same location, using the sharp drop off in density to indicate the lamina propria.

Results: We included 92 patients with BE (at least C0M1), who had a baseline VLE scan, followed by RFA, and had no prior ablative therapy. These patients were divided in three patient groups: without prior EMR and treated with only RFA (n = 70, mean Prague length(M) = 5.399, SEM = 0.520), without prior EMR treated with combined EMR and RFA at baseline (n = 3, mean Prague length(M) = 6.67, SEM = 1.67), with prior EMR and RFA at baseline (n = 19, mean Prague length (M) = 3.816, SEM = 0.616). After determination of gastro-esophageal junction (GEJ) location on VLE, we measured mucosal thickness in 8 segments at 0.5 cm intervals from GEJ to the top of the Barrett's tissue. The mean amount of selected cross sections per scan in the first 40 patients was 6.33 (SEM = 0.50; n = 40). The measurements of thickness, using the subjective and objective protocol in one patient is shown in Table 1.

Conclusion: We developed an algorithm, that automatically adjusts raw VLE images in order to recognize superficial layers of the esophageal wall and measure the thickness of these different layers in Barrett's tissue. We performed both subjective and objective methods for thickness calculation. This is the first step to the production of a biomarker for the prediction of treatment response in patients with Barrett's Esophagus. Further research is needed to demonstrate which of these two measurement protocols can predict the response to RFA and ER.

Disclosure of Interest: G. Tearney: Tearney G is the co-inventor of the VLE scan; he contributed VLE expertise to be able to do the measurements. The measurements itself were done by Iris Levink.

S. Schlachter: Schlachter, S is an employee at Ninepoint Medical and manages the data of the Ninepoint registry. Schlachter, S had no influence on the outcomes of the measurements. The measurements were done by Levink, I. All other authors have declared no conflicts of interest.

²Pathology, Academic Medical Center, Amsterdam/Netherlands

Contact E-mail Address: k.belghazi@amc.uva.nl

Introduction: Radiofrequency ablation (RFA) of Barrett's esophagus (BE), with or without prior endoscopic resection (ER) of focal lesions, results in complete eradication of intestinal metaplasia (CE-IM) and complete eradication of neoplasia (CE-neo) in 93–100% and 96–100%, respectively.

Aims & Methods: The aim of this study was to assess if the excellent results after successful RFA for BE with high-grade dysplasia (HGD) or early cancer (EC) are sustained on the long term. We screened all patients treated with RFA, and ER in case of visible lesions, for BE with histologically proven HGD/EC, who were previously enrolled in 5 consecutive cohort studies in a tertiary referral center in the Netherlands. All patients who had reached endoscopic and histologically confirmed CE-neo and CE-IM after RFA were included for evaluation of long-term follow-up (FU). Primary outcome: recurrence of HGD/EC; recurrence of endoscopically visible Barrett's mucosa. Secondary outcomes: Buried Barrett's glands; IM in biopsies obtained distal to a normal appearing neo squamocolumnar junction (neo-SCJ); need for retreatment; sustained CE-IM and CE-neo at last FU.

Results: 68 patients were included (55 men, median 64 yrs, median BE C5M6). In 53/68 patients ER was performed (worst pathology: low-grade dysplasia (LGD) (n=3), HGD (n=23), EC (n=27)). Worst pathology pre-RFA (after any ER) was: non-dysplastic IM (n=9), LGD (n=27), HGD (n=32). Median FU was 85 months (IQR 58–96) with a median of 7 FU endoscopies per patient. Recurrence of HGD/EC was found in 2 patients (3%): one patient with a T1m2 EAC 3 cm above the neo-SCJ after 44 months and one patient had a visible lesion at the neo-SCJ with HGD after 22 months, both were treated successfully with ER. Recurrence of endoscopically visible Barrett's mucosa was seen in 22 patients (32%) after a median of 20 months: small Barrett island (n=10), BE tongue (≤ 1 cm n=9, ≤ 2 cm n=1), circumferential BE ≤ 2 cm (n=2). In 3 patients Buried Barrett's glands were detected (overall 3/448 FU endoscopies, 0.7%). IM in a normal appearing neo-SCJ was found in 19 patients (28%), and this was not reproduced in 84%. In 2 patients LGD without IM was found in the neo-SCJ. Eleven patients required retreatment: APC for small areas of visible Barrett's mucosa (n=5), six patients had additional ER (1x T1m2, 1x HGD, 2x LGD, 2x visible Barrett's islands), RFA for LGD without IM in the neo-SCJ (n=1). CE-neo and CE-IM (excluding IM in the neo-z-line) at the last FU endoscopy was seen in 100% and 96% respectively.

Conclusion: With 7-years of follow-up, this study presents the longest published follow-up data on RFA for BE with HGD/EC to date. Our long-term outcomes show that after successful RFA recurrence of HGD/EC is rare (3%). Recurrence of endoscopically visible BE was found in 32% of patients, however it was confined to small islands or tongues ≤ 1 cm in the vast majority of patients.

P1864 ACTION IS REQUIRED TO IMPROVE UNDERSTANDING AND REDUCE ANXIETY LEVELS AMONGST PATIENTS IN THE BARRETT'S SURVEILLANCE PROGRAMME

V. Sehgal, A. Kumar, D. S. Kalsi, P. Jegatheesvaran, J. Walton, J. Sadeghian, S. Murray

Gastroenterology, Homerton University Hospital NHS Foundation Trust, London/United Kingdom

Contact E-mail Address: vsehgal@doctors.org.uk

Introduction: Barrett's oesophagus (BE) is the only identifiable pre-cursor condition for oesophageal adenocarcinoma. Endoscopic surveillance is performed in BE to detect dysplasia as it likely to be amenable to curative therapy. There is data to suggest that a diagnosis of BE has a negative impact on the quality of life of patients. To our knowledge, no guidance exists on the counselling of patients entered into endoscopic surveillance for BE. The aim of this study was to check patient understanding of their diagnosis of BE and associated anxiety levels at a district general hospital.

Aims & Methods: An in-house database was used to identify patients with BE over a 10-year period (2006–17). A simple, 14-point based questionnaire was devised and answers obtained via a telephone consultation (Table 1).

Results: 163 patients with BE were identified. In total, 104 patients (70 male, 34 female) were recruited (13 deceased, 38 did not answer, 8 declined). 2 patients had previously undergone therapy for BE (1 RFA, 1 fundoplication). Results are displayed in Table 1. Less than a third of patients remembered meeting a clinician to discuss their diagnosis and the rationale for follow-up. Consequently, only 41% of patients understood their diagnosis and 44% the rationale for surveillance. Although almost all patients (92%) were on a regular proton pump inhibitor, less than half (48%) understood why. Only 11% of patients were aware of the overall cancer progression risk and even fewer (7%) of the treatment options that are currently available. Interestingly, half of all patients admitted feeling anxious about their diagnosis with the majority (82%) admitting that further counselling would benefit in this regard.

Table 1: A 14-point based questionnaire which was used to check the understanding amongst patients with Barrett's Oesophagus (BE–Barrett's Oesophagus, OAC–Oesophageal adenocarcinoma PPI–Proton pump inhibitor).

	Yes (%)	No (%)
1. Did you receive a letter or see someone in clinic to discuss your diagnosis and plans for future follow-up?	32 (31)	72 (69)
2. If yes, did you understand this?	15 (47)	17 (53)
3. Broadly speaking, do you understand what BE is?	43 (41)	61 (59)
4. Do you understand that chronic acid reflux into the lower oesophagus is the most likely cause of BE?	50 (48)	54 (52)
5. Are you on a regular PPI?	96 (92)	8 (8)
6. Do you know what the overall risk of progression to cancer is?	11 (11)	93 (89)
7. Are you aware of the term 'dysplasia' and how this helps to risk stratify your condition and interval length for surveillance endoscopy?	6 (6)	98 (94)
8. Do you understand what the rationale for endoscopic surveillance in BE is?	46 (44)	58 (56)
9. Have you ever been told if you have a short or long segment of BE and the importance of this?	6 (6)	98 (94)
10. Are you aware of any treatment options for BE?	7 (7)	97 (93)
11. If yes, do you know when this indicated?	4 (57)	3 (43)
12. Does or has anyone in your family suffered with BE or OAC?	36 (35)	68 (65)
13. Do you feel or have you ever felt anxious about your diagnosis of BE?	53 (51)	51 (49)
14. Do you think it would be useful for your understanding or reduce your anxiety if you either sat down with someone in clinic or spoke to someone over the phone regarding your BE?	82 (79)	22 (21)

Conclusion: We have demonstrated that patients with BE have a relatively poor understanding of their diagnosis and the treatment options that are available to them. Further efforts need to be made to address this and help empower a group of patients who are understandably anxious about their diagnosis.

Contact E-mail Address: manol.jovani@mail.harvard.edu

Introduction: Data on the association between inflammatory and metabolic biomarkers and Barrett's esophagus (BE) are scant and conflicting.

Aims & Methods: We aimed to study the association between circulating inflammatory biomarkers (interleukin-6 [IL-6], high-resolution C-reactive protein [hrCRP], intra-cellular adhesion molecule [ICAM], tumor necrosis factor receptor-2 [TNF-R2]) and metabolic biomarkers (leptin, adiponectin, C-peptide, insulin-like growth factor 1 [IGF-1], and insulin-like growth factor binding proteins -1, -2 and -3 [IGFBP-1, -2 and -3]) with BE. This was a case-control study, nested within two female-only prospective cohort studies (Nurses' Health Study 1 and 2) and one male-only prospective cohort (Health Professional Follow-up Study). Participants of provided biennial detailed information on demographic, lifestyle, dietary and medical factors, including endoscopy use. Overall, 80,437 participants enrolled in these cohorts provided a prediagnostic blood specimen between 1989 and 1995. Among these participants, through 2012, we identified 283 cases of BE (163 females and 120 males). Two study physicians, blinded to biomarkers results, reviewed the medical records of patients reporting BE. We matched BE participants with 626 controls who underwent upper endoscopy during the same time period and did not have BE (361 females and 265 males) on year of birth, year of blood collection, month of blood collection, fasting status and "am or pm" blood draw. We used multivariable conditional logistic regression models, adjusting for known and putative risk factors for BE, to assess the association between each biomarker and the risk of BE. We used the lowest quintile as reference, and assessed linear trend across exposure categories using the median of each quintile as a continuous variable.

Results: In women, plasma adiponectin was significantly associated with BE ($p_{\text{trend}} = 0.01$). When compared to the lowest quintile (Q_1), the multivariate odds ratio (OR) for the highest quintile (Q_5) of adiponectin was 0.39 (95%CI 0.17, 0.88). This association was not materially altered after further adjustment

for leptin. The association did not differ according to subgroups defined by BMI ($p_{\text{interaction}} = 0.33$) or regular aspirin use ($p_{\text{interaction}} = 0.82$). Among men, we observed that adiponectin was not associated with BE. However, we observed an OR of 0.41; 95%CI 0.17, 0.99 comparing extreme quintiles of IGFBP-3 ($p_{\text{trend}} = 0.11$). Among both women and men, we did not observe any other significant associations between inflammatory or metabolic biomarkers and BE.

Conclusion: There was little evidence that pre-diagnostic inflammatory or metabolic biomarkers are associated with risk of BE. Only adiponectin was associated with a decreased risk of BE in women but not in men. These findings may serve to provide input for clinical risk assessment for BE and shed light on potential mechanisms of its pathogenesis.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI866 OUTCOMES OF TREATMENT OF PATIENTS WITH EARLY-STAGE ADENOCARCINOMA OF THE ESOPHAGUS WITH INCIPIENT SUBMUCOSAL INVASION, RETROSPECTIVE ANALYSIS OF 19 CASES FROM A TERTIARY REFERRAL CENTER IN THE UK

Introduction: Endoscopic mucosal resection (EMR) is an established diagnostic and treatment tool in the management of Barrett's oesophagus (BO) with early neoplasia. However there is not enough clinical evidence on the management of the patients, in whom the EMR's histologic assessment identifies early-stage adenocarcinoma of the oesophagus with incipient submucosal invasion (pT1b sm1).

Aims & Methods: We have conducted a retrospective analysis using our electronic database for endoscopic procedures for patients with BO, who underwent EMR from October 2010 to December 2016. We investigated the size of the EMRs, the complication rates of the EMRs, the histological features and the resection margins of the EMR specimens and also the outcomes with the mortality.

Results: A total of 99 patients underwent 134 EMR procedures, and the histology identified early adenocarcinoma with incipient invasion of the submucosa in 25 patients. 23 (92%) were male, the mean age at the EMR was 71 years (SD: 8.1). In all 25 EMRs 7 (28%) patients had a single piece, 7 (28%) patients a 2 piece, 7 (28%) patients 3 piece and 4 (16%) patients 4 piece EMR. The median length of the circumferential and maximum extent of the BO segments were 2 and 5 cm respectively (interquartile range (IQR) 2-4). We observed 6 (24%) intra-procedural bleedings and 2 (8%) patient needed admissions with post procedural bleeding and 1 (4%) of them required transfusion. Stricture was endoscopically detectable but not causing any symptoms in 1 (4%) patient and another patient (4%) had slight dysphagia post EMR, but did not need dilation. Histology showed lymphovascular invasion in 6 (24%) patients and vascular invasion in 1 (4%) patient. Of all 25 early adenocarcinomas 7 (28%) were reported as poorly differentiated, 11 (44%) as moderately differentiated and 3 (12%) as well differentiated. In 4 (16%) cases differentiation was not reported. All resection margins were reported as being clear from dysplasia or cancer in 7 (28%) cases, radial resection margins were reported with dysplasia in 3 (12%) cases and with cancer in 15 (60%) cases, but this included the multiple piece EMRs. The deep margin was reported as being clear in 18 (72%) cases, with dysplasia in 1 (4%) case and with cancer in 6 (25%) cases. There were 15 (60%) patients with cancer invasion on the radial and/or deep margin of the EMR specimen, of these patients 9 (60%) had oesophagectomy and in the histologic assessment of these specimens, lymph node involvement was observed in 2 cases (22.2% of all oesophagectomies and 9.5% of all surviving and currently cancer-free patients). There was no residual cancer in 3 (33.3%) of the surgical specimens. Radical radio-chemotherapy was given in 1 (6.7%) patient and 5 (33.3%) patients did not have radical treatment for clinical reasons. There were 10 (40%) patients without cancer invasion of the EMR resection margins, of these 4 (40%) had oesophagectomy and 1 (10%) radical radio-chemotherapy. The histologic assessment of these surgical specimens showed residual cancer in 3 (30%) cases and high-grade dysplasia in 1 (10%) case. Of the 25 patients 5 (20%) met the criteria and had radio frequency ablation of the residual Barrett's oesophagus. Of the 13 (52%) patients who have had oesophagectomy 1 (7.7%) patient died of the deterioration precipitated by the oesophagectomy, and sadly in this case the oesophagectomy specimen did not show any residual cancer. Of the 12 (48%) patients who have not had oesophagectomy 3 (25%) died since their EMR, 1 (8.3%) of cardiac arrest, 1 (8.3%) of chronic obstructive pulmonary disease and 1 (8.3%) of advanced oesophageal cancer, 18 months after the EMR, and the 9 (75%) surviving patient are all cancer free on follow up investigations, one after radical chemo/radiotherapy. The median survival of all 21 (84%) patients currently alive is 25 months (range: 2-68 months; SD: 22.2).

Conclusion: In this retrospective analysis we have found that the clinical outcomes are very difficult to predict for patients with early adenocarcinoma and incipient invasion of the submucosa. Clinical decision making remains very challenging and has to be individualised for all patient, until further in depth studies gives us more useful prognostic factors.

Contact E-mail Address: shannonchan@surgery.cuhk.edu.hk

Results: From July 2015 to March 2017, forty-four patients were included in the study. Seventeen of the forty-four (38.6%) patients had histological confirmed cancer of the esophagus. There were sixteen patients who had normal finding and nine patients with esophagitis. The positive predictive value for malignancy (ECA 4 and 5) was 89.5%; the negative predictive value was 100%. Sensitivity was 100% and specificity was 92.6%. Similar findings were noted with IPCL on magnifying NBI. The positive predictive value for malignancy (IPCL 4 and 5) was 89.5%; negative predictive value was 100%. Sensitivity and specificity were also similar at 100% and specificity 92.6% respectively. To compare the diagnostic accuracy of endocystoscopy and magnifying NBI, the McNemar test was performed. The McNemar chi-squared statistic is NaN, and the McNemar chi-squared statistics with Yates correction of 0.5 is infinity, meaning that the two tests have the same diagnostic accuracy.

Conclusion: Endocystoscopy had a high positive predictive value and sensitivity for esophageal malignancy. Its diagnostic accuracy was comparable to magnifying NBI. It may be helpful as an adjunct for better characterization of esophageal lesions. However, further studies on interobserver variability is required.

Introduction: Early detection of esophageal cancers can significantly reduce the morbidity and improve the prognosis of these patients. A new prototype scope incorporating the endocystoscopy function into a magnifying endoscope has been designed. Previously, Inoue et al have published a pilot trial on evaluating the use of this endocystoscopy in various types of benign and malignant pathology in the esophagus. An endocystoscopic atypia (ECA) classification was proposed. The sensitivity and specificity of this classification system was evaluated.

Aims & Methods: All consecutive patients who had esophagogastroduodenoscopy (EGD) arranged for screening of the esophagus during the period July 2015 to March 2017 were recruited into the study. EGD with narrow band imaging and endocystoscopy were performed in these patients. During the procedure, the esophageal mucosa was stained with 0.5% methylene blue and then with crystal violet. The endocystoscopic findings were graded from 1 to 5 according to the Inoue et al's ECA classification. The esophageal mucosa was also evaluated with narrow band imaging (NBI) and the findings were classified according to the Intrapapillary capillary loop (IPCL) pattern classification. These findings were compared against the gold standard of histopathological diagnosis which was based on the Vienna classification.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Esophageal achalasia is considered to be a high-risk factor for superficial esophageal cancer. But there are few reports of endoscopic resection for this cancer, and the outcome is unclear. In our hospital, we have performed over 1300 Per-Oral Endoscopic Myotomy procedures for esophageal achalasia and related diseases. In this process, we diagnosed 10 superficial esophageal cancers in patients with achalasia. We performed endoscopic resection for all cases and report relatively long-term outcome.

Aims & Methods: We aimed to evaluate clinicopathological findings and outcomes of endoscopic resection for 10 achalasia-associated superficial esophageal cancer. This is a case series study at our hospital. Between August 2010 and February 2017, 10 achalasia patients with superficial esophageal cancer underwent endoscopic resection. We performed in all cases upper gastrointestinal endoscopy using lugol's solution and narrow band imaging, and we included all patients that had early cancers that were eligible for endoscopic resection in this series. At 2 and 12 months after treatment, we performed follow-up endoscopy in all cases. After this, we performed long-term endoscopic follow-up every year. In the case that the tumor invasion depth is to the muscularis mucosa (MM) on histopathology, we performed endoscopic follow-up every 6 months and CT scan.

Results: There were 6 men and 4 women and their average age was 61.7 years. 8 patients were diagnosed with lesions before POEM. We performed endoscopic resection (ESD/EMR;9/1) in all cases after POEM. None of the patients had a severe adverse event. The mean tumor diameter was 30 mm (range: 5-80 mm). The pathological diagnosis was 8 SCC, 2 high grade intraepithelial neoplasia. Out of the SCC cases, 7 were found with superficial lesion with depth of Tis-EP to T1a-LPM, and 1 with depth of T1a-MM, without lymphatic invasion (ly0) or venous invasion (v0). Follow-up surveillance mean term was 32 months (range: 1-

67months). Ectopic lesions were detected in 2 cases, and these patients underwent endoscopic resection. All patients survived in this term.

Conclusion: Endoscopic resection for achalasia-associated superficial esophageal cancer invasive to the MM on histopathology is safe and effective, and relatively long term outcome is good.

P1869 USEFULNESS OF TRIAMCINOLONE INJECTION TO PREVENT STRICTURE AFTER CIRCUMFERENTIAL ESOPHAGEAL ESD FOR SCC AND EAC

T. Oyama¹, A. Takahashi¹

¹Endoscopy, Saku Central Hospital Advanced Care Center, Nagano/Japan

Contact E-mail Address: oyama@coral.ocn.ne.jp

Introduction: ESD is a standard treatment for superficial esophageal cancer in Japan. Stricture is one of important complication of esophageal ESD, and it makes quality of life of the patient worse. Usefulness of Triamcinolone (TA) injection to prevent stricture after semi-circumferential ESD has been reported. However, usefulness of TA injection after circumferential esophageal ESD is still unclear.

Aims & Methods: The aim of this study is to clarify the usefulness of triamcinolone injection to prevent stricture after circumferential ESD. A total of forty-four patients treated by circumferential esophageal ESD from 2004 to 2016 in Saku Central Hospital Advanced Care Center were enrolled to this retrospective study. The patients treated from 2004 to 2009 were followed up without TA injection (Non-TA group). And, local injection of TA was performed for the patients after 2009 (TA group). The number of patient in Non-TA and TA group was 16 and 28, respectively. Age of both groups was 65 (30–83) and 61 (42–82) years old. The length of circumferential resection was 75 (50–10) and 76 (55–111) mm, respectively. There was no significant difference in the background of both groups. Fifty mg TA was injected into submucosal layer just after ESD, and TA injection was repeated in two-weeks interval by the ESD ulcer healed. When the length of circumferential ESD was 50 mm or longer, 100 mg Triamcinolone was injected just after ESD, and 50 mg TA injection was repeated in two-weeks interval. Fifteen mm endoscopic balloon dilatation (EBD) was performed when the scope couldn't pass the ESD ulcer. The primary endpoint was the number of balloon dilatation. The secondary endpoints were duration from ESD to ulcer healing, complications and the difference between Barrett's esophageal adenocarcinoma (EAC) and squamous cell carcinoma (SCC).

Results: 1. Number of EBD in Non-TA and TA group were 20 (13–33) and 5.1 (0–23), respectively ($p < 0.01$) 2. Duration from ESD to ulcer healing were 10 (3–23) and 6.9 (1–24) months, respectively. ($p = 0.47$) 3. Complications: Perforation rate due to EBD was 6.3% (1/16) and 3.6% (1/28). Both patients were treated by conservative therapy. 4. Difference between EAC and SCC: There were four EAC and 24 SCC patients in TA group. The number of EBD were 5.3 (5–11) and 5.4 (3–11), respectively. Duration of ulcer healing were 10 (4–14) and 6.5 (1–24), respectively. There was no significant difference between two groups.

Conclusion: Triamcinolone injection is safe and effective treatment to prevent stricture after circumferential ESD, not only for SCC but also for EAC.

P1870 OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL PHARYNGEAL SQUAMOUS CELL CARCINOMA

T. Oyama¹, A. Takahashi¹

¹Endoscopy, Saku Central Hospital Advanced Care Center, Nagano/Japan

Contact E-mail Address: aurevoireurope@yahoo.co.jp

Introduction: Superficial pharyngeal squamous cell carcinoma (SCC) has been increasing in Japan. And, such SCC could be treated by endoscopic submucosal dissection (ESD). However, the outcome of pharyngeal ESD is unknown.

Aims & Methods: The aim of this study is to clarify the outcome and prognosis of pharyngeal SCC treated by ESD. 89 pharyngeal SCC in 68 patients treated by ESD from Jan. 2006 to Jan. 2017 in Saku Central Hospital Advanced Care Center were enrolled to this retrospective study. CT and neck US were performed for the preoperative staging. All ESD were performed using a Hook knife under general anesthesia with tracheal intubation. Clip with line or forceps was used to make traction during ESD. Annual endoscopy, CT scan and neck US were performed as surveillance after ESD, and these examinations were recommended twice a year for the patients who had subepithelial (SEP) SCC. Male/Female was 67/1. Mean age was 67.1 (40–92). Mean size of tumor and specimen were 12.9 (1–50) and 26.8 (5–65) mm, respectively.

Results: 1. En bloc resection rate was 100%. 2. Complication: Delayed bleeding rate was 1.5% (1/68). Re-intubation was needed for the hemostasis. Dysphagia was shown in 4.4% (3/68). Two patients had mild dysphagia and improved in two weeks. The remaining one patient had severe dysphagia. The patient had a big SCC, 50 mm in size, and the SCC extend from light piriform sinus to aryepiglottic fold. The patient could keep vocal function. However, eating was impossible for mis-swallowing. 3. Invasion depth: Epithelial (EP) and subepithelial (SEP) SCC were 60% (53/89) and 39% (35/89), respectively. One case was inflammation. 4. The rate of lymph-duct involvement of EP and SEP were 0% and 5.7% (2/35), respectively. LNM was found in one of two patients who had lymph duct involvement, and treated by lymph node dissection. The other patient was followed up without additional therapy, and free from LNM for one year. 5. Venous involvement of EP and SEP were 0% and 2.9% (1/35), respectively. The

only patient who had venous involvement was 92 years old, and followed up without an additional therapy. 6. Local recurrent rate was 0%. 7. LNM rate of EP and SEP was 0% and 5.7% (2/35), respectively. One of two patients who had LNM was a 76-year-old male. He had SEP SCC without lymph duct involvement. A cervical LNM was diagnosed 6 months after ESD. Lymph node dissection and chemo-radio therapy (CRT) was performed for the patient. The patient died of other disease without recurrence of pharyngeal SCC. The other patient also had a cervical LNM and treated by lymph node dissection + CRT. The patient is alive without recurrence for 10 years after ESD. 8. Prognosis No patient died of pharyngeal SCC after ESD.

Conclusion: ESD is a safe and useful treatment for superficial pharyngeal SCC. However, surveillance of LNM is important for the patients who had SEP SCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1871 SHOULD ANTITHROMBOTIC AGENTS BE DISCONTINUED PRIOR TO ESOPHAGEAL ENDOSCOPIC SUBMUCOSAL DISSECTION?

N. Kawata, M. Tanaka, K. Takizawa, N. Kakushima, M. Yoshida, S. Ito, K. Imai, K. Hotta, H. Ishiwatari, H. Matsubayashi, H. Ono

Introduction: Endoscopic submucosal dissection (ESD) has been widely performed as a minimally invasive treatment for superficial esophageal squamous cell neoplasms (ESCNs) in Japan and Asian countries. According to the current guidelines[1], ESD is classified as a high bleeding risk procedure. However, these guidelines have not been fully validated.

Aims & Methods: The aim of this study was to identify the risk factors of bleeding associated with esophageal ESD, and to clarify whether antithrombotic agents increase the risk of bleeding for esophageal ESD. A total of 458 ESCNs in 411 patients who underwent ESD at our hospital from January 2013 to October 2016 were analyzed in this retrospective study. ESD was performed using an IT knife nano (Olympus, Tokyo, Japan). Hemostatic forceps (Coagrasper; Olympus, Tokyo, Japan) were used when hemostasis during ESD proved difficult with the IT knife nano. Longer hemostatic time during ESD was defined as more than 120 secs required for hemostasis with hemostatic forceps. We analyzed the relationship between risk factors for longer hemostatic time during ESD and the following factors using univariate and multivariate analyses: age (< 75 or ≥ 75 years), sex, body mass index (< 25 or ≥ 25), treatment for synchronous multiple ESCNs, previous radiation therapy, antithrombotic agents, lesion location (upper or middle or lower), lesion size (< 2 cm or ≥ 2 cm), lesion circumference ($< 3/4$ or $\geq 3/4$), and the endoscopist's experience of esophageal ESD (< 40 or ≥ 40 procedures).

Results: Twenty-nine ESCNs (6%) were treated by ESD without discontinuation of antithrombotic agents. Hemostatic forceps were used for 116 lesions (25%), median forceps use time was 73 secs (range: 8–1200 secs), and the median number of forceps application during procedures was 2 (range: 1–9 times). Of these, 41 lesions (9%) met our definition for longer hemostatic time. Univariate analysis revealed that lesion size (≥ 2 cm), lesion circumference ($\geq 3/4$), and the endoscopist's experience (≥ 40) were significantly associated with longer hemostatic time. Multivariate logistic regression analysis revealed that a lesion size ≥ 2 cm (OR 2.4 [95% CI 1.1–5.1], $P = 0.02$) was an independent risk factor for longer hemostatic time. Postoperative bleeding occurred 20 days after ESD in one patient (0.2%) receiving the continuous administration of warfarin and aspirin.

Conclusion: Our results suggest that continuous use of antithrombotic agents does not increase the risk of bleeding during esophageal ESD, and that postoperative bleeding was a rare occurrence. Discontinuation of antithrombotic agents may therefore not be necessary prior to esophageal ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: While definitive chemoradiotherapy (CRT) showed high efficacy for esophageal squamous cell carcinoma (ESCC), approximately 40% of patients develop local failure, resulting in poor long-term survival¹. However, there is no definitive biomarker which is useful to predict survival outcome after CRT for ESCC. Several studies have investigated the correlation of expression of CD24, cytokeratin 4 (CK4), or podoplanin (PDPN) with prognosis of patients with various malignant tumors who underwent surgical resection²⁻⁵. However, it remains unclear whether the expression of these proteins can predict the outcome of CRT for patients with ESCC.

Aims & Methods: The aim of this study was to clarify the predictive values of expression of CD24, CK4, and PDPN for ESCC patients who received CRT. Among patients with ESCC who received CRT or curative esophagectomy with extended lymph node dissection (OPE) as an initial treatment between 2005 and 2009 at our institution, cohorts were selected based on the following criteria: clinical stage II, III (UICC-TNM classification 6th edition), age of 75 years old or younger, ECOG Performance Status 0–1, and no prior or concurrent other cancers. The method of immunohistochemistry (IHC) was utilized to examine the protein expression of CD24, CK4, and PDPN in pretreatment biopsy specimens of ESCC. The cut-off values for CD24, CK4, and PDPN expression were used hazard ratio for overall survival (OS). The prognostic factor of CD24, CK4, and PDPN expression were statistically analyzed. OS was calculated from the date of CRT or OPE to the date of death or last follow-up, using the Kaplan-Meier method. The survival predictors identified by univariate analysis was assessed by multivariate analysis using a Cox's proportional hazards model.

Results: 148 ESCC patients (CRT group, n=83; OPE group, n=65) were analyzed. In the CRT group, 40 patients had stage II and 43 patients had stage III, and the 5-year OS was 52%. In the OPE group, 32 patients had stage II and 33 patients had stage III, and the 5-year OS was 66%. By univariate analysis, there were no significant clinical variables for OS in differences between the CRT and OPE group. The cut off value for CD24, CK4, and PDPN expression were 20%, 10%, and 20%, respectively. While the expression equal to the cut off value or more was defined as strong, the expression less than the cut off value was defined as weak. The frequency of strong protein expression was 50% for CD24, 12% for CK4, 65% for PDPN, respectively. In the CRT group, the OS of patients with strong CD24 expression was significantly better than that of patients with weak CD24 expression (P=0.015; strong/weak 5-year: OS 65%/43%). On the other hand, patients with strong CD 24 expression was poorer OS comparing with patients with weak expression in the OPE group, however there was no significant difference (P=0.286; strong/weak 5-year OS: 57%/74%). As for patients with strong CD24 expression, there was no significant difference between CRT group and OPE group (p=0.446), however there was significant difference between CRT and OPE group in patients with weak CD 24 expression (p=0.009). There were also no significant differences of the OS based on expression of CK4 or PDPN between the CRT and OPE group, respectively. Multivariate analyses revealed the strong CD24 expression in the CRT group (P=0.012; HR=2.787; 95%CI: 1.253–6.200) as an independent variable for favorable outcome.

Conclusion: CD24 expression was significantly associated with the survival outcome of patients with ESCC when they were treated with CRT. Furthermore, weak CD24 expression might be a useful predictive biomarker of poor outcome for CRT in ESCC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic treatment is a standard therapeutic approach for patients with T1a early esophageal cancer (EEC). In patients with 'high-risk' T1a cancer (e.g. advanced grading or invasion to blood/lymphatic vessels) and in patients with any submucosal (sm) invasion (T1b), surgery is recommended as a standard of care. However, recent data suggest, that endoscopic treatment might be curative in selected patients with 'high-risk' EEC.

Aims & Methods: The aim of this study was to assess outcomes of endoscopic treatment in patients with 'high-risk' EEC. 'High-risk' cancer was defined as any cancer with sm invasion or mucosal cancer with at least one of the following: poor differentiation (G3/G4), invasion to blood (A+) or lymphatic vessels (L+) and high tumor cell dissociation (TCD3). The main outcome measurement was tumor-free survival.

A single-center, retrospective analysis of prospectively collected data. Patients with EEC underwent endoscopic resection (ER) or endoscopic submucosal

dissection (ESD). Based on histopathological staging, patients with 'high-risk' EEC without contraindications were referred for surgery. Remaining patients continued in endoscopic treatment consisting of further sessions of ER and/or radiofrequency ablation if necessary. The patients have been followed up for a median of 39 months (range 2–156).

Results: A total of 56 patients with 'high-risk' EEC underwent endoscopic treatment: 21 patients (41%) had T1a cancer with 'high-risk' features and 35 patients (59%) had T1b cancer with sm invasion (sm1: 15, sm2: 9, sm3: 11); 45 patients had adenocarcinoma (EAC), 11 patients had squamous carcinoma (SCC); 19 patients were referred for surgery. A total of 37 patients (66%) continued in endoscopic treatment. Complete local remission (CLR) of neoplasia was achieved in 35/37 patients (95%). Two patients without CLR continued endoscopic therapy with palliative intent. Tumor generalization occurred in 2 patients (one of them achieved CLR) 24 months after endoscopic treatment (both patients had sm3 invasion, A+, L+) and these patients are undergoing oncological treatment. All remaining patients with CLR (n=33) have experienced neither local relapse nor generalization. One patient had to undergo surgery due to endoscopy related perforation. Tumor-free survival was 89% (CI 79–99%) in patients treated endoscopically and endoscopy related mortality was 0% (0/37). Among 19 patients who were referred for esophagectomy, one patient presented with tumor generalization revealed during the operation. The remaining 18 patients underwent esophagectomy; local residua of malignancy were present in 5/18 patients (28%). Lymph node (LN) metastases have not been detected in any patient among the 337 examined LNs. Surgery related mortality was 6% (1/18).

Conclusion: Endoscopic treatment provides long-term remission or cure in a considerable number of patients with 'high-risk' EEC and it may thus represent a valid alternative to surgery. Broadening of indications for radical endoscopic treatment of early EEC should be reconsidered.

P1874 DIAGNOSTIC ACCURACY OF ENDOSCOPIC ULTRASONOGRAPHY FOR ESOPHAGEAL SUBMUCOSAL GLAND DUCT INVOLVEMENT ACCOMPANIED BY EARLY ESOPHAGEAL CANCER

Y. Jie, L. Ying

Digestive Department, The Affiliated Drum Tower Hospital, Nanjing University Medical School, Nanjing, Jiangsu Province, Ch, Nanjing/China

Contact E-mail Address: 13770755008@126.com

Introduction: Normally, resided within the submucosal layer of esophagus, each esophageal submucosal gland will culminate in a single duct. The esophageal submucosal gland ducts (ESMGDs) can traverse the subepithelial connective tissue and muscularis mucosa, and deliver the acinar secretions to the esophageal lumen. However, the clinicopathological features of the esophageal submucosal gland duct involvement (ESMGDI) and its precursor lesion have not been comprehensively evaluated so far, and the series study focusing on endoscopic features of this lesion has not been reported widely. While since the 1990s, the esophageal lesions presumed to originate from ESGMDs had been described constantly in various case reports. Currently, in addition to the gold standard of histopathology, almost no more useful modality could be applied to this lesion. In our study, we considered that the ESGMDI had a correlation with early esophageal cancer, and we noted that the ESGMDI had special features under the endoscopic ultrasonography (EUS). The typical ultrasonic images of EUS could help diagnose ESGMDI.

Aims & Methods: In order to investigate the clinical value of EUS for diagnosing ESGMDI accompanied by early esophageal cancer, which were suggested by conventional endoscopy or biopsy, this study retrospectively analyzed the consecutive patients with early esophageal cancer diagnosed in the Endoscopy Center at the Affiliated Drum Tower Hospital, Nanjing, China from September 2009 to November 2016. The clinical data of 519 patients were included in this study, and all of them had already underwent EUS combined with Endoscopic Submucosal Dissection (ESD). The EUS preoperative diagnosis were compared with the results of postoperative pathology from ESD.

Results: According to the pathological results, all patients (371 males and 148 females, with a mean age of 67.5±4.5 years) had been diagnosed with early esophageal cancer with different invasive depth. Out of 519 patients, about 478 patients were not found ESGMDI by both examinations. Besides, postoperative pathology confirmed that 40 patients were identified with ESGMDI, 34 patients of which were completely consistent with the preoperative diagnosis of EUS. Approximately 98.7% (512/519) of ESGMDI were diagnosed exactly by EUS. Another six cases were estimated as false negative inaccurately, including two squamous cell carcinoma and four high-grade intraepithelial neoplasia. One case was regarded as ESGMDI by EUS while confirmed not by pathology. Therefore, the EUS values for sensitivity and specificity for the diagnosis of ESGMDI were 85.0% (34/40) and 99.8% (478/479) respectively. Furthermore, the positive predictive value was 97.1% (34/35), and the negative predictive value was 98.8% (478/484).

Conclusion: The esophageal submucosal gland duct involvement is a kind of lesion performed as a hypoechoic sonographic pattern located in the thickened mucosa. EUS has a satisfactory diagnostic accuracy for ESGMDI as well as good sensitivity and specificity.

PI875 PRETREATMENT NEUTROPHIL TO LYMPHOCYTE RATIO IS NOT A PREDICTOR OF RESPONSE TO NEOADJUVANT THERAPY IN ESOPHAGEAL CANCER

G. Pirozzolo¹, S.S. Gisbertz², O. De Simoni¹, A. Slaman², C. Castoro³, M. Scarpa¹, M.I. Van Berge Henegouwen²

Introduction: Preoperative Neutrophil to Lymphocyte Ratio (NLR) has been proposed as a prognostic marker in several solid tumors (Templeton 2014). A recent retrospective study of 60 patients showed the prognostic relevance of NLR as a predictor of response in esophageal cancer patients treated with chemoradiotherapy. The aim of this study is to assess the NLR prognostic strength in a retrospective series of two high-volume centers.

Aims & Methods: A retrospective review of two prospective esophageal cancer database was conducted. Neutrophil to lymphocyte ratio was defined as the pre-chemoradiotherapy serum neutrophil count divided by lymphocyte count. We dichotomized the NLR data using as cut-off values 2.5 and 3 respectively. Univariable logistic regressions were performed to determine the effect of NLR on response after neoadjuvant treatment. Survival curves were constructed with Kaplan Meier method and compared with the long rank test.

Results: We included 280 patients. The analysis of NLR as predictor of pathologic complete response (pCR) showed a OR of 0.963 (95% CI 0.531–1.746, p=901) and 1.161 (95% CI 0.647–2.081, p=0.617) considering as cut-off values 2.5 and 3 respectively. In our large series, NLR did not result as a predictive marker neither in terms of Overall Survival nor in terms of Disease Free Survival (p=0.997 and p=0.672 respectively).

Conclusion: Our results did not confirm NLR as a significant marker of pCR. Moreover, the survival analysis did not reveal significant differences using NLR as pre-treatment prognostic marker. The heterogeneity of treatments, the complexity of the disease, the absence of a validated and pre-defined NLR cut-off value in the available literature are the main limits to our analysis. Further studies are needed to assess the clinical relevance of NLR as a predictive marker of response to neoadjuvant treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI876 CAN THE USE OF A COMPUTER DECISION SUPPORT SYSTEM PREVENT COMPLICATED ULCER AMONG PATIENTS TREATED WITH NSAID OR ASPIRIN? A RANDOMISED CONTROLLED CLUSTER TRIAL IN GENERAL PRACTICE

J.M. Petersen¹, D. E. Jarbol², J. Hallas³, M. R. Munch², O.B. Schaffalitzky De Muckadell⁴, J.M. Hansen¹

Introduction: Background consumption of non-steroidal-anti-inflammatory drugs (NSAID) and Aspirin is high in Denmark and the majority of these drugs are prescribed in General Practice. Risk factors for complicated ulcer are well established and include NSAID, Aspirin, age, prior ulcer, *Helicobacter pylori*, anticoagulants, selective-serotonin-reuptake-inhibitors (SSRIs), Adenosine-Di-Phosphate (ADP)-inhibitors and glucocorticoids. Proton Pump Inhibitors (PPIs) reduce the risk of complication but preventive treatment with PPI is only given to a third of the people at risk. The mortality from an ulcer complication is 10% and above.

Aims & Methods: The aim was first in a randomised cluster design to test if a Computer Decision Support System (CDSS) - based on a risk profile for the individual patient - reduced the frequency of ulcer complications. Second to investigate if use of the CDSS changed the prescription pattern in general practice with regard to prescriptions of NSAID, Aspirin and PPI.

Results: Ninety-six GPs responsible for the treatment of 52,649 patients were randomised to the CDSS-group and 90 GPs responsible for the treatment of 43,861 patients to the control group. No significant differences were found between the two patients groups regarding peptic ulcer complications, uncomplicated ulcer, gastro-oesophageal reflux or usage of upper gastrointestinal(GI)-endoscopies. The patients' risk profile was identical in the two groups. During the intervention period lasting from April 2013 to September 2014 a significantly higher prescription rate of NSAID and PPI was found in the CDSS group. In addition a significantly higher co-prescription of NSAID and PPI was found in the CDSS group-particularly in high-risk patients. No significant difference was

found in co-prescription of Aspirin and PPI when comparing CDSS-group to the control-group.

Conclusion: Conclusion A CDSS based on a risk profile for the individual patient had no impact on the main outcomes ulcer complications, uncomplicated ulcer, reflux or endoscopies. Usage of CDSS increased the amount of co-prescription of PPI and NSAID in medium and high-risk groups. A similar pattern was not found for Aspirin. Triggering and the timing of the CDSS and its implementation in the Electronical Health Record should be optimized.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI877 ACCELERATION OF HEALING OF PREEXISTING GASTRIC ULCERS BY CARBON MONOXIDE RELEASING MOLECULE -2 (CORM-2). INVOLVEMENT OF HEME OXYGENASE, OXIDATIVE STRESS AND PROINFLAMMATORY MARKERS

T. Brzozowski, K. Magierowska, S. Kwiecien, M. Magierowski, M. Hubalewska-Mazgaj, D. Wojcik, R. Pajdo, A. Chmura

Physiology, Jagiellonian University Medical College, Cracow/Poland

Introduction: Carbon monoxide (CO) is produced endogenously in the body as a by-product of heme degradation via activity of the enzyme heme oxygenase (HO)-1. This gaseous mediator with multidirectional biological activity exerts antiproliferative, anti-inflammatory and immunomodulatory properties. A newly discovered class of compounds, named CO-releasing molecules (CORMs), is capable of liberating CO gaseous molecule that can be useful as pharmacological tool to assess the physiological role of CO under experimental conditions. CORM-2 was implicated in gastroprotection against formation of acute gastric lesions but the contribution of CO to the mechanism of gastric ulcer healing has not been fully elucidated.

Aims & Methods: We determined the effect of daily treatment with vehicle or CORM-2, on healing of preexisting gastric ulcers induced by serosal application of acetic acid (ulcer area = 28 mm²) in rats. Our second goal was to examine the mechanism of CO released from its donor by the determination of the CORM-2-induced alterations in gastric blood flow (GBF) at ulcer margin, the parameters of oxidative stress and the gastric mucosal expression of pro-inflammatory and anti-inflammatory factors. Groups of seventy rats with gastric ulcers (A-D) received daily treatment with A) vehicle (saline), B) CORM-2 in doses from 1 up to 10 mg/kg i.g., C) the HO-1 inductor, hemin (5 mg/kg i.p.), D) the HO-1 activity inhibitor, zinc protoporphyrin IX (ZnPP IX) (5 mg/kg i.p.). After 9 days of treatment, the ulcer area was measured by planimetry, the gastric blood flow (GBF) at ulcer margin was determined by Laser Doppler technique, plasma TNF-α and IL-1β levels were monitored by ELISA and IL-1β-, TNF-α, HO-1, HO-2, COX-1, COX-2, iNOS, cNOS mRNAs were analyzed by RT-PCR and Western blot. Gastric mucosal samples were collected for the assessment of MPO activity, level of reduced glutathione (GSH) and lipid peroxidation products (MDA + 4HNE) by spectrophotometry.

Results: Treatment with CORM-2 significantly reduced the area of gastric ulcers and significantly raised GBF at ulcer margin. The dose accelerating ulcer healing by 50% (ID50) and significantly raising GBF was 10 mg/kg as compared with vehicle-control animals. The administration of hemin significantly reduced the area of gastric ulcers and raised GBF at ulcer margin but the treatment with ZnPP IX significantly increased the area of gastric ulcers and significantly decreased the GBF at ulcer margin. The decrease in gastric ulcer healing by

CORM-2 was accompanied by a significant decrease in plasma levels of IL-1 β and TNF- α comparing to vehicle-control group. The expression of IL-1 β , TNF- α , COX-2 and iNOS mRNA was strongly upregulated in vehicle-treated gastric mucosa but expression of these factors was significantly attenuated in CORM-treated animals. The increased mucosal expression of mRNA for HO-1 but not HO-2 was detected in vehicle control group and these effects were ameliorated by treatment with CORM-2. The gastric mucosal MPO activity and themucosal content of MDA + 4HNE in gastric mucosa were elevated in vehicle-control group and these effects were significantly inhibited by CORM-2.

Conclusion: CO released from its donor CORM-2 accelerates the healing of pre-existing gastric ulcerations by the mechanism involving an increase in gastric microcirculation at ulcer margin, the inhibition of inflammatory response as manifested by the attenuation of enhancing synthesis of the proinflammatory markers IL-1 β , TNF- α , COX-2 and iNOS as well as by antioxidative properties of CORM-2 releasing CO limiting lipid peroxidation.

P1878 PROTON PUMP INHIBITORS INAPPROPRIATE USE IN PATIENTS ADMITTED IN A TERTIARY GREEK HOSPITAL CREATES SIGNIFICANT DIRECT COSTS BURDEN AND EXPOSURE OF PATIENTS TO THE RISK OF UPPER GASTROINTESTINAL COMPLICATIONS

G. Vlachonicolou, L. Bounou, A. Theodorou-Kanakari, S. Kalousios, M. Roma, E.A. Mavroedi, G. D. Dimitriadis, K. Triantafyllou
2nd Dept Of Internal Medicine And Research Institute, National and Kapodistrian University of Athens, Medical School, Athens/Greece

Contact E-mail Address: ktriant@med.uoa.gr

Introduction: There is evidence of proton pump inhibitors (PPIs) misuse in the community and in the hospitals causing significant direct and indirect costs burden for the health care system.

Aims & Methods: We aimed to evaluate the frequency of inappropriate PPIs administration in hospitalized patients, to measure the direct in-hospital costs of PPIs overuse and to calculate the number of patients exposed to the risk of upper gastrointestinal (UGI) complications due to medication underuse. This was a prospective, cross-sectional, prescription-indication drug-utilization, chart-review study in hospitalized patients with follow-up until discharge, in a tertiary 500 beds hospital in Athens, Greece. We recorded data of all patients admitted (intensive care, psychiatric, pediatric, obstetrics and day clinic admission were excluded) during three consecutive on-call days of the hospital in March 2017 regarding PPIs utilization before admission, during hospitalization and at discharge. We thereafter calculated the direct hospital costs of PPIs overuse and the number of patients at risk of UGI complications due to PPIs underuse for 1 year period, using a simulation model.

Results: We included data from 470 patients aged 67 \pm 19 yrs; 32.5% were prescribed a PPI before admission, 65.9% during hospitalization and 32.8% at discharge. PPIs overutilization was detected in 15.7%, 41.3% and 12.6% of the patients before, during and after the admission, while medications underutilization was detected in 10.2%, 8.1% and 9.5% of them, respectively. Admission at internal medicine and orthopedics clinics was associated with the highest unadjusted ORs (1.68 [95%CI 1.63–1.72] and 1.68 [1.59–1.78]) for PPIs misuse. 80% of the 193 over treated patients received PPIs iv (80% of them od, 20% bid) while the rest were treated with PPIs per os (90% of them od, 10% bid) during their 8 days of mean hospitalization length. This accounts for 1480 PPI iv and 344 PPI per os doses inappropriately given during the observation period. Taking into account in our simulation model that there are 90 on-call days of our hospital annually, the cost of each PPI dose is 3.435 and 0.235 euros for iv and per os preparations and assuming a similar to that of our sample case distribution for the next 12 months, we calculated the direct hospital costs burden of inappropriate PPIs use at 154940 euros per year. Using the same model, 1200 patients would be at risk of UGI complications annually, due to under prescription of PPIs at discharge.

Conclusion: Hospitalization does not represent an opportunity for optimization of PPIs utilization. On the contrary, the frequency of PPIs inappropriate use during hospitalization is higher than that before admission, causing significant direct costs for the hospital and exposing patients to the risks of UGI complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1879 CONTINUOUS INCREASE IN PREVALENCE OF FUNDIC GLAND POLYPS WITH THE LENGTH OF PROTON PUMP INHIBITORS USE. IS THERE ANY CLINICAL CONSEQUENCE?

R. Kroupa¹, M. Dastych¹, S. Konecny¹, J. Dolina¹

¹Department Of Internal Medicine and Gastroenterology, University Hospital and Faculty of Medicine Masaryk's University, Brno/Czech Republic

Contact E-mail Address: kroupa.radek@fnbrno.cz

Introduction: Proton pump inhibitor (PPI) usage is associated with an increased risk of development of fundic gland polyps (FGP). The trend of change in the prevalence with increasing length of PPI exposure over 5 years is not known. Theoretical risk of FGP seems to be very low for clinical consequence in management.

Aims & Methods: To evaluate the relationship between the length of PPI use and risk of fundic gland polyps. Prospective cohort study in patients referred for upper gastrointestinal endoscopy between years 2015–2016 was performed. The

length of PPI use was ascertained from direct patient interview and confirmed with medical records. The use of PPI in history not continuing at the time of endoscopy was also inquired. FGP were determined both endoscopically and histologically. Odds ratios for subsequent intervals of length of PPI use were calculated. Clinically relevant complications–dysplasia and bleeding from large polyps were recorded.

Results: During study period 1525 patients (mean age 59.2 years, 53% male) were included. Only 612 (40%) of patients had no history of any PPI use. Fundic gland polyps were identified in 170 patients (11%) and only 13 of them (7.6%) were without PPI use. The prevalence of FGP in subgroups of patients according to the length of PPI use was: 10.6% of 161 patients using PPI less than 1 year, 9.4% of 405 (1–4 years of PPI), 25.2% of 230 (5–9 years of PPI), 35.1% of 94 (10–15 years of PPI) and 47.8% of 23 patients using PPI more than 15 years. The appropriate odds ratios were 5.4 (CI 2.6–11.4), 4.8 (CI 2.5–9.1), 15.5 (CI 8.3–29.0), 24.9 (CI 12.4–49.9) and 42.2(CI 15.7–113.1) respectively, all with statistical significance ($p < 0.0001$). Only 1 case of low grade dysplasia within FGP was observed in the patient with familiar adenomatous polyposis. Polyps larger than 15 mm with signs of bleeding determined as a cause of sideropenic anemia were diagnosed in 6 patients.

Conclusion: The prevalence of FGP is permanently growing during prolonged use of PPI. Complex source of informations regarding history of PPI use identified quite low proportion of patient with FGP and without prior PPI use. Rather rare complications like bleeding from FGP might be clinically significant in increasing number of long term PPI users. The requirement of repetitive endoscopies and therapeutic interventions may burden gastroenterologists and sources.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1880 ENDOSCOPIC RESECTION OF ADVANCED AMPULLARY ADENOMAS: A SINGLE-CENTER 14-YEAR RETROSPECTIVE COHORT STUDY

S. E. Van Der Wiel, J.W. Poley, M.J. Bruno, A.D. Koch

Gastroenterology And Hepatology, Erasmus University Medical Center, Rotterdam/Netherlands

Contact E-mail Address: s.e.vanderwiel@erasmusmc.nl

Introduction: Adenomas of the ampulla of Vater are rare. Endoscopic ampullectomy has been recognized as a safe and reliable treatment of selective tumors of the ampulla of Vater and is associated with lower morbidity and mortality rates than surgical resection. However, the success rates for endoscopic ampullectomy range from 61 to 92 percent, with recurrence described in up to 33 percent of patients. Despite the increasing number of studies concerning endoscopic resection of ampullary tumors, data evaluating endoscopic resection of the more advanced ampullary adenomas are limited.

Aims & Methods: The aim of our study was to evaluate the technical success, complications and recurrence of endoscopic resection for treating patients with ampullary adenomas with intraductal extension (AIE), and patients with lateral spreading adenomas (LSA). Between January 2002 and November 2016, all patients referred to the Erasmus Medical Center, Rotterdam, for endoscopic resection of an ampullary lesion were retrospectively identified. Cases were selected by using ENDOBASE and we provided a search in the our local PALGA database. We included patients with a histological diagnosis of adenoma. Endoscopic resection was performed by 5 experienced endoscopists. Endoscopic success was defined as complete excision of the adenoma, irrespective of the number of attempts, and in the absence of recurrence. All patients underwent endoscopic follow-up. Early and late complications were registered.

Results: We included 84 patients, 56 patients (67%) had an adenoma confined to the ampulla (ACA), 17 patients (20%) had a LSA and 11 patients (13%) were treated for adenomas that demonstrated growth pattern with intraductal extension. Fifty-five percent of the patients were men and the median age was 65.4 years (range 32–89). The median lesion size was 24.6 mm (range 5–80) for patients with ACA, 34.8 mm (range 23–50) for LSA and 16.3 mm (range 10–20) for patients with an AIE ($P = 0.039$). Complications occurred in 26 patients (30.9%), of which hemorrhage was most seen in 17.9%, followed by perforation in 5.9% of the patients. Complications were equally divided over these three groups ($P = 0.775$). The mean follow-up duration was 31.1 months (range 0–129) for ACA, 23.1 months (range 0–127) for LSA and 11.9 months (range 0–37) for IEA ($P = 0.136$). Endoscopic resection was curative in 87.5% of patients with a localized adenoma, 82.3% in patients with a lateral spreading adenoma and in only 9.1% of patients with an intraductal extended tumor ($P < 0.000$). Recurrence occurred in 9 patients (10.7%), 5 of them had a localized adenoma, 3 patients with a lateral spread adenoma and 1 patient with an intraductal extended adenoma ($P = 0.875$).

Conclusion: Endoscopic ampullectomy is a safe and successful treatment in patients with an adenoma with or without a lateral spreading growth pattern. In case of an intraductal extended adenoma endoscopic success rates are significantly lower.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1881 FACTORS ASSOCIATED WITH TECHNICAL DIFFICULTY OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC CANCER WHICH MET EXPANDED INDICATION CRITERIA; POST HOC ANALYSIS USING DATA OF MULTI-INSTITUTIONAL PROSPECTIVE CONFIRMATORY TRIAL (JCOG0607)

Introduction: There are few reports about the technical difficulty of gastric endoscopic submucosal dissection (ESD) which were investigated through the prospective trial.

Aims & Methods: The aim of this study was to evaluate the factors associated with the technical difficulty of ESD for early gastric cancer (GC) which met expanded indication criteria using data from JCOG0607. The major inclusion criteria of JCOG 0607 was as follows: 1) histologically proven intestinal-type adenocarcinoma; 2) cT1aN0M0; 3) lesion without finding of ulcer (UL negative) and >2 cm in size, or UL positive and ≤3 cm in size; 4) age 20–75. ESD were performed by certified endoscopists or under the supervision of certified endoscopists who had experienced 100 cases or more. The difficult case was defined that ESD took 120 minutes (min) or longer, and/or developed perforation during procedure. Multivariate analysis was performed to investigate the clinical factors associated with technical difficulty of ESD.

Results: Between June 2007 and Oct. 2010, a total of 470 patients (pts) (male/female: 385/85, median age 65y-o (range: 40–75)) were enrolled from 29 institutions. Tumor location was upper (U) of stomach in 71, middle in 255, and lower in 144 pts, respectively. The median tumor size was 2.5 cm (range: 0.5–13), and 207 lesions were judged as UL positive whereas the other 263 were assessed as UL negative. And, 152 of 263 UL negative lesions were 3 cm or less in size, and the other 111 of them were larger than 3 cm. Median procedure time was 79 min (range: 14–462), and it took 120 min or longer in 127 pts. 12 pts developed perforation during ESD, and the procedure time took 120 min or longer in 9 of them. Therefore, 130 pts (27.7%) were classified in difficult case group. The proportion of difficult case was 23.2% (48/207) in UL positive and ≤3 cm cases, 18.4% (28/152) in UL negative and ≤3 cm, and 48.6% (54/111) in UL negative and >3 cm, respectively. Multivariable showed UL negative and >3 cm (vs. UL negative and ≤3 cm, odds ratio, 4.66; 95% confidence interval, 2.59–8.37, $p < 0.0001$) was the most significant factor associated with technical difficulty, and U of stomach, and age ≤60 were also associated with difficulty.

Conclusion: Lesion larger than 3 cm without finding of ulcer, U of stomach, age ≤60 were independent factors associated with technical difficulty of ESD for GC which met expanded indication criteria.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: mmizrahi@bidmc.harvard.edu

Introduction: Endoscopic ultrasound with fine-needle aspiration (EUS-FNA) is commonly used for the diagnosis of various gastrointestinal lesions. Recently, a novel fine-needle biopsy (FNB) system (SharkCore, Medtronic) was developed to acquire cohesive units of tissue to increase the diagnostic yield of EUS.

Aims & Methods: Our study objective was to compare the diagnostic yield of EUS-FNA using a conventional needle vs. EUS-FNB using the novel needle for gastric submucosal lesions. We conducted a prospective analysis of patients undergoing diagnostic EUS from November 2014 to October 2015. Each patient underwent 3 FNA passes followed by 3 FNB passes, without onsite cytologic evaluation. Data gathered included demographics, size and location of the lesion, needle size, and complications. Pathology and cytology were reviewed separately by two blinded, expert gastrointestinal pathologists. Diagnostic yield was defined

as the ratio between the number of significant findings detected by EUS tissue acquisition and the total number of EUS examinations performed for a given indication.

Results: During the study period 1487 EUS procedures were performed in our clinic. Thirty patients with gastric submucosal lesions were enrolled to participate in the study, 66% were female, mean age was 62 years (range 31–88). Mean lesion size was 27 mm (range 12–60 mm). Twenty-two-gauge needles were used in 14 cases (55%) and twenty-five-gauge needles were used in 12 cases (45%). Overall diagnostic yield for 3 needle passes was higher for FNB vs. FNA for gastric submucosal lesions (78% [N=20] vs. 44% [N=12], $P=0.04$). Analyzing each of the different passes, the diagnostic yield was: 61%, 67% and 78% with the first, second, and third FNB pass, respectively. In evaluation of tissue quantity and quality of FNB specimens, the mean tissue length was 7.3 ± 5.2 mm, with a mean lesional tissue proportion between 51 to 75% of the total tissue procured (determined as the percent of the surface are occupied by lesion over the surface area of the entire tissue on one slide). No complications occurred during the study period.

Conclusion: FNB using a novel core needle system is safe and effective for diagnosis of gastric submucosal lesions. When performed without on-site cytologic evaluation, EUS-FNB has a higher diagnostic yield than FNA and may represent an advance for endoscopic ultrasound guided gastrointestinal biopsies.

P1883 A COMPARISON OF SUBMUCOSAL TUNNELING ENDOSCOPIC RESECTION AND ENDOSCOPIC FULL-THICKNESS RESECTION FOR GASTRIC FUNDUS SUBMUCOSAL TUMORS

T. Duan, Y. Tan, X. Wang, L. Liang, D. Liu

Department Of Gastroenterology, The second Xiangya Hospital of Central South University, Changsha/China

Contact E-mail Address: tianyingduan@163.com

Introduction: Submucosal tumors (SMT) refer to protuberant lesion covered with intact mucosa, and most of SMT found in stomach are small and asymptomatic. While a half of these gastric SMTs are considered to be gastrointestinal stromal tumors (GIST) with malignant potential, especially for those with large diameters^[1]. One of the strategies for SMTs < 2 cm is periodical surveillance by esophagogastroduodenoscopy (EGD) and endoscopic ultrasonography (EUS), but it involves issues related to the patient's compliance and stress, cost-effectiveness, and the risk associated with repeated endoscopic procedures and delayed diagnosis of malignancy^[1]. Therefore, it is necessary to remove these SMTs and endoscopic resection could be considered as an alternative method. Endoscopic full-thickness resection (EFTR) is a safe and effective endoscopic method for gastric fundus SMT originating from the muscularis propria (MP) layer with a high rate of complete resection^[2]. Submucosal tunneling endoscopic resection (STER) is a novel endoscopic technique and has demonstrated to be safe and effective for the treatment of gastric SMTs^[3]. However, little is known about the comparison between STER and EFTR for treating SMTs in gastric fundus. In this retrospective study, we aimed to compare both endoscopic techniques for treating gastric fundus SMTs.

Aims & Methods: Both submucosal tunneling endoscopic resection (STER) and endoscopic full-thickness resection (EFTR) are effective methods for gastric fundus submucosal tumors (SMTs), however, little is known about the comparison between these two resections. The aim of this study was to compare the safety and efficacy of STER and EFTR for treating SMTs in gastric fundus. We retrospectively collected the clinical data about patients with gastric fundus submucosal tumors who received submucosal tunneling endoscopic resection or endoscopic full-thickness resection at our hospital from April 2011 to May 2016. Epidemiological data (gender, age), tumor size, procedure-related parameters, complications, length of stay, cost and follow-up data were compared.

Results: A total of 43 patients were enrolled, and 15 of them received submucosal tunneling endoscopic resection, while the other 28 cases received endoscopic full-thickness resection. There was no significant difference between the two groups in terms of gender, age, tumor size, en bloc resection rate, operation time, patho-histological results, hospital stay and cost ($p > 0.05$). However, patients who received endoscopic full-thickness resection had a longer suture time and needed more clips to close the gastric wall defect ($p < 0.05$). No recurrence was noted in the submucosal tunneling endoscopic resection and endoscopic full-thickness resection groups during a mean follow-up of 12.1 and 22.8 months, respectively.

Comparison of clinical characteristics and therapeutic outcomes between STER and EFTR

	STER (n = 15)	EFTR (n = 28)	P
Sex, M/F	5/10	13/15	0.407
Age, year	48.4 ± 11.2	53.4 ± 9.7	0.136
Concomitant disease, %	20% (3/15)	21.4% (6/28)	1.000
Tumor size, mm	19.0 ± 8.3	15.3 ± 7.0	0.126
Operation time, min	76.7 ± 38.0	63.3 ± 24.4	0.200
Suture time, sec	296.7 ± 97.0	383.4 ± 104.0	0.011

(continued)

Continued

Comparison of clinical characteristics and therapeutic outcomes between STER and EFTR

	STER (n = 15)	EFTR (n = 28)	P
No. of clips for suture	5.8 ± 1.4	7.6 ± 1.6	0.001
Complications, %	6.7% (1/15)	14.3% (4/28)	0.643
En bloc resection, %	6.7% (1/15)	3.6 % (1/28)	1.000
GIST/Leiomyoma/Schwannoma	11/4/0	25/2/1	0.173
Length of stay, d	6.1 ± 1.5	6.2 ± 2.0	0.856
Cost, USD	3260.9 ± 618.3	3237.5 ± 615.8	0.906
Follow-up time, mon	12.1 ± 12.2	22.8 ± 18.4	0.052

Conclusion: The treatment efficacy between submucosal tunneling endoscopic resection and endoscopic full-thickness resection for treating gastric fundus submucosal tumors was comparable, but submucosal tunneling endoscopic resection offers advantages over endoscopic full-thickness resection in terms of shorter suture time and smaller number of clips needed to close the gastric wall defect.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1884 COMPARISON OF THE DIAGNOSTIC YIELDS OF ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION FOR DUODENAL AND GASTRIC SUBEPITHELIAL LESIONS

K. Nakamura

Gastroenterology, St.Luke's International Hospital, Chuo-ku/Japan

Contact E-mail Address: nakaken@luke.ac.jp

Introduction: The progress of diagnosis and treatment for gastrointestinal subepithelial lesions (SELs) have been remarkable by the wide use of Endoscopic Ultrasound-Guided Fine Needle Aspiration (EUS-FNA) and the development of Laparoscopy and Endoscopy Cooperative Surgery. EUS-FNA is used widely for SELs that occur in the digestive tract. There are many reports on gastric SELs, but there are no studies on a large group of patients focusing on duodenal SELs.

Aims & Methods: The aim of this study was to investigate the usefulness and safety of EUS-FNA for duodenal SELs, comparing them with gastric SELs. Cross-sectional study was conducted using 41 patients who underwent EUS-FNA at tertiary medical center in Tokyo between April, 2012 and February, 2017. We divided into 2 groups: 6 patients with duodenal SELs (group D) and 35 patients with gastric SELs (group G), who were diagnosed as SELs located on the 4th layer by pre-operative EUS and were performed EUS-FNA consecutively. We retrospectively evaluated the patient characteristics and outcome of the technique on the subjects.

Results: Age (median, [range]); D: 61, [42–63], G: 60, [32–85]; male/female ratio: D, 1/5, G, 18/17; tumor size (median, [range])(mm): D, 16, [14–45], G, 24, [13–67]; type of needle (22-gauge/19-gauge): D, 5/1, G, 30/6 (One case was used two type of needles.); number of needle passes: D, 5, [4–5], G, 4, [3–7]; procedure time (median, [range])(min): D, 34, [22–52], G, 42, [20–67]; diagnostic yield: D, 100%, G, 91.4%; complication: D, 0%, G, 2.9%. There were no significant differences into 2 groups, but the size of duodenal SELs tended to be smaller than gastric SELs. Histological diagnosis of EUS-FNA using immunohistochemical analysis showed duodenal SELs were 5 GIST, 1 neurinoma, and gastric SELs were 25 GIST, 4 ectopic pancreas, 3 neurinoma, 3 indeterminate. Two of the indeterminates were followed up by CT, one was SEL like cancer diagnosed by conventional biopsy.

Conclusion: Although five of the six cases of duodenal SELs were small lesions of less than 20 mm, immunohistochemical staining was performed for all the cases, and diagnosis was made. EUS-FNA for duodenal SELs was as useful and safe as gastric SELs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1885 SHORT-TERM OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC CANCER IN ELDERLY PATIENTS AND LONG-TERM OUTCOME AFTER NON-CURATIVE RESECTION

H. Sakaguchi¹, Y. Ohara², T. Toyonaga², H. Kaku¹, K. Matsuoka¹, T. Sako¹, R. Ariyoshi¹, H. Abe², F. Kawara², S. Tanaka¹, T. Ishida¹, Y. Morita¹, E. Contact E-mail Address: valencia.0601@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is widely used as a standard treatment for superficial tumors in the GI tract and its safety has been established. Opportunities for elderly patients to undergo ESD for early gastric cancer is increasing due to the continued improvement in life expectancy. However, short-term and long-term outcome of ESD for elderly patients is still unclear because of the high frequency of comorbidities and possible increased risk of complications related to ESD in this population.

Aims & Methods: Therefore, we investigated the safety, efficacy and short-term outcome of gastric ESD for patients over 80 years old. Additionally, we evaluated the long-term outcome of non-curative resections according to both age groups. 1056 lesions in 886 patients treated with ESD between January 2011 and December 2015 in our hospital were retrospectively reviewed. They were classified into two groups; elderly group - older than 80 years old (246 lesions in 201 patients) and non-elderly group - 79 years old and younger (810 lesions in 685 patients). The patient demographics, lesion characteristics, short-term ESD outcome, complications (perforation, postoperative bleeding, postoperative delirium, and pneumonia), were examined and compared between the two groups. Concerning the long-term outcome of non-curative ESD, cases performed between 2011 and 2013 were assessed.

Results: The median age was 83 years old (range: 80–92) in the elderly group and 70 years old (36–78) in the non-elderly group. The ratio of female patients was significantly higher in the elderly group (30.9% vs. 17.0%; $p < 0.0001$). Comorbidities were significantly higher in the elderly group including heart disease (24.8% vs. 10.5%; $p < 0.0001$), lung disease (13.8% vs. 7.4%; $p = 0.002$) and dementia (3.3% vs. 1.0%; $p = 0.01$). Tumor location was not significantly different between the two groups. Median specimen and tumor size were the same in both groups with no significant difference: 43 mm and 15 mm, respectively. The en bloc resection rates (96.3% and 97.8%) and the curative resection rates (82.5% and 84.6%) were not significantly different. The perforation rates were not statistically different (2.44% and 3.21%). However, the postoperative bleeding rate (5.28% vs. 2.72%; $p = 0.05$), postoperative delirium (2.0% vs. 0.25%; $p = 0.009$) and pneumonia (2.0% vs. 0.25%; $p = 0.009$) were significantly higher in the elderly group. In multivariate analysis, age over 80 was not an independent risk factor for postoperative bleeding, however it was the independent risk factor for postoperative delirium and postoperative pneumonia. Nineteen elderly patients and 54 non-elderly patients with non-curative resections were followed-up for 3 years after ESD for the long-term outcome analysis. The percentage of patients who underwent additional surgery after ESD was 26.3% (5/19) and 51.85% (28/54) respectively ($p = 0.05$). Neither disease specific death nor progression to advanced gastric cancer was found in each age group. Overall survival rate 3 years after ESD was 68.4% and 85.2% respectively ($p = 0.17$).

Conclusion: ESD is a safe and effective treatment for early gastric neoplasia even in patients over 80 years old. However, because postoperative delirium and postoperative pneumonia were observed more often in the elderly patients, more careful attention to these conditions during perioperative care may be necessary. Elderly patients over 80 years, with non-curative resections, underwent less frequent additional surgery without any impact on the disease specific death and global mortality.

P1886 GASTRIC INTESTINAL METAPLASIA OUTCOMES: RESULTS FROM A 17 YEAR TERTIARY CENTRE UPPER GI SURVEILLANCE PROGRAMME IN IRELAND

M. Mc Nally¹, I. Cretu¹, A. O'Connor¹¹Trinity Academic Gastroenterology Group, Naas General Hospital, Kildare/Ireland

Contact E-mail Address: maireadnf@gmail.com

Introduction: Adenocarcinoma of the stomach is the second leading cause of cancer related death in the world. Gastric intestinal metaplasia (GIM) is an important intermediate stage in the gastric cancer cascade through a series of well-defined precursor lesions including nonatrophic gastritis, multifocal atrophic gastritis, intestinal metaplasia, and dysplasia. The prevalence of GIM is unclear in many parts of the world and few studies have evaluated the rate of progression to gastric cancer in patients with GIM. There is a lack of clarity in

published guidelines regarding appropriate surveillance of patients with GIM and there is wide disparity in the management of this premalignant condition.

Aims & Methods: This study aimed to analyze surveillance practice and characterize the natural history of this premalignant condition by identifying all patients with GIM on an upper GI surveillance programme and reviewing follow up data. This is a retrospective study of patients with GIM who are currently enrolled in an upper GI surveillance programme. Patients with a history of GIM identified at any time during an 18 year surveillance period (from 1998 to 2016) were included in the study. Patient characteristics, endoscopy data including histology, rates of *Helicobacter pylori* infection, Barrett's oesophagus association and outcomes were reviewed.

Results: 160 patients (including those with Barrett's oesophagus, GIM and family history of gastric cancer) were enrolled on the surveillance programme. 42 patients with GIM were identified—20 females (47.6%) and 22 males (52.3%). The mean age at which GIM was first diagnosed was 60.6 years (range from 17.9 to 71.5 years). 15/42 patients (35.7%) had co-existent Barrett's oesophagus and *Helicobacter pylori* was identified in 6/42 (14.3%). The follow-up period ranged from 0.5 to 17.3 years. 27 patients had repeat gastroscopies following initial diagnosis. 15 patients are still awaiting a repeat gastroscopy. A large degree of variability in the number and frequency of follow-up gastroscopies was observed. The average interval of follow-up gastroscopies was 3.3 years per person. 14/27 patients (51.8%) had no evidence of GIM on most recent gastroscopy. 7/27 patients (26%) had repeat findings of persistent focal GIM, 5/27 patients (18.5%) progressed to extensive GIM. No cases of dysplasia were recorded but 1 patient (3.7%) developed gastric cancer.

Conclusion: This study suggests a low apparent risk of progression of gastric intestinal metaplasia in a small western cohort. Further studies may be necessary to address if the applicability of published surveillance guidelines can be generalised to regions with low gastric cancer prevalence.

Disclosure of Interest: All authors have declared no conflicts of interest.

²Department Of Internal Medicine, Seoul National University Bundang Hospital, Seongnam/Korea, Republic of

Contact E-mail Address: tsm3wa@naver.com

Introduction: Previously we reported that direct family history of gastric cancer (GC) as a risk factor of GC and genetic polymorphisms of TGFB1 (transforming growth factor-β1) was associated with the development of GC in the first-degree relative of GC. The aim of this study is to investigate relationship between stage of gastric cancer and genetic polymorphism of TGFB1 regarding first-degree relative of GC.

Aims & Methods: From January 2006 to March 2017, 1090 gastric cancer patients were enrolled at Seoul National University Bundang Hospital in whom stage of GC was obtained from surgery, endoscopic submucosal dissection (ESD), endoscopic mucosal resection (EMR), and computer tomography (CT) and positron emission tomography (PET)-CT images. 203 patients (18.6%) had direct family history GC and 887 (81.4%) did not have. Genotype of TGFB1-509 was measured by the polymerase chain reaction-restriction fragment length polymorphism. Relationship between TGFB1 polymorphism and stage or GC tissue type was analyzed.

Results: Proportion of stage 1 & 2 was statistically higher in the group with direct family history GC (170, 83.7%) than without direct family history (660, 74.4%). (P=0.005). When GC stage was analyzed regarding direct family history and TGFB1 genetic polymorphism the ratio of gastric cancer stage I to TGFB1509 T carrier was significantly higher than that of stage II or higher (P=0.008), only in male. However, this difference was not found in female. In addition no

significant difference was found in GC patients without direct family history. Lauren classification and TGFB1 genotype did not show any statistically significant results even in the group with direct family history.

Conclusion: Family history of GC affects the stage of GC and the genotype of TGFB1-509 could be underlying mechanism in case of male. Survival analysis is undergoing.

Table: Differences of gastric cancer stage according to TGFB1-509 polymorphism and family history (Hx) of gastric cancer

		TGFB1-509	Stage 1 N (%)	Stage 2≤ N (%)	Total	P-value
Family Hx. (+)	Female	C/C	18 (78.3)	5 (21.7)	23	0.243
		T carrier	27 (64.3)	15 (35.7)	42	
	Male	C/C	20 (52.6)	18 (47.4)	38	0.008
		T carrier	76 (76.0)	24 (24.0)	100	
	Total	C/C	38 (62.3)	23 (37.7)	61	0.146
		T carrier	103 (72.5)	39 (27.5)	142	
Family Hx. (–)	Female	C/C	46 (61.3)	29 (38.7)	75	0.781
		T carrier	137 (63.1)	80 (36.9)	217	
	Male	C/C	91 (61.9)	56 (38.1)	147	0.568
		T carrier	289 (64.5)	159 (35.5)	448	
	Total	C/C	137 (61.7)	85 (38.3)	222	0.529
		T carrier	426 (64.1)	239 (35.9)	665

Introduction: Gastric adenocarcinoma and proximal polyposis of the stomach (GAPPS) has to been described recently only in a few families worldwide (only one in Europe so far). Three different point mutations in promoter 1B of the APC gene were identified as causal (c.-191T> C, c.-192A> G, and c.-195A> C). We diagnosed GAPPS in the second Czech white family (not related to that one published previously-ref. 1).

Aims & Methods: We diagnosed GAPPS across 3 generations in a new Czech white family. A genetic analysis of the family was performed.

Results: The Proband (a 43-year-old male) was endoscopically regularly surveyed from his 34 years of age because of fundic-gland polyposis with predominant involvement of the gastric fundus and body (with relative sparing of the lesser curve) and microcytic anaemia. Polyposis slowly progressed with the intestinal differentiated low-grade dysplasia in polypectomy specimens 10 years after the diagnosis. As the GAPPS criteria were fulfilled (ref. 2), he and his family underwent genetic testing and bi-directional Sanger sequencing of promoter 1B revealed a point mutation (c.-191 T> C). The same type of mutation was described in his father (63 years old), sister (41 years old), nephew (son of his sister, 6 years old), uncle (father's brother, 51 years old) and 2 cousins (uncle's daughters, 23 and 27 years old), all have been asymptomatic. No gastric cancer in the family history was mentioned. The Proband underwent preventive total gastrectomy, histology of the surgical specimen confirmed severe involvement of gastric body with fundic gland polyps, low-grade and focal high-grade dysplasia. The microcytic anaemia improved rapidly after surgery. The rest of family is scheduled for gastroscopy. The fundic-gland polyposis of similar distribution (with significantly lower number of polyps, without any dysplastic changes) was recently diagnosed in the 23-year-old cousin.

Conclusion: The second European family with GAPPS is presented. The recently described mutations in promoter 1B of the APC gene does not automatically mean a faster progression of the disease as suggested earlier. GAPPS can be presented with various phenotypes with a different course of disease, the prevalence can be higher than previously reported. Acknowledgement: The study was supported by the Research Project PROGRES Q40–15.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: ESD is one of the options of treatment even for lateral spreading (size is over 5 cm) esophageal squamous cell carcinoma (ESCC). Endoscopic diagnosis is developed by magnified endoscopy, however accuracy of diagnosis for lateral spreading ESCC is not high. Some patients have to undergo additional treatment because tumor is invaded to submucosal layer or lymphovascular invasion. On the other hand, wide resection by ESD could cause the delay of additional treatment because of the treatment for esophageal stricture after ESD. Thus, treatment strategy for lateral spreading ESCC has to include additional treatment after ESD. Aim of this study is to evaluate our treatment strategy for lateral spreading superficial ESCC.

Aims & Methods: From January 2010 to December 2014, 49 cases of lateral spreading superficial ESCC were resected by surgery or ESD. Diagnosis, treatment methods and outcomes are evaluated. Our indications for additional treatment after ESD are the cases of over pT1b (SM2) or lymphovascular invasion.

Results: In 49 cases of lateral spreading superficial ESCC, 32 cases were treated by ESD and 17 cases were treated by surgery. All lesions of 32 cases are completely resected by ESD. Average size of tumor treated by ESD is 59.4 mm (50–85 mm). Accuracy of estimated depth of invasion by endoscopy for ESD cases is 65.7%. Four of 32 cases of ESD underwent additional therapy (3 for surgery and 1 for CRT) because of pT1b (SM2) or lymphovascular invasion, and one case has lymph-node metastasis. Rate of stricture after ESD is 20.0% for sub-circumference ESD and 77.8% for circumference ESD instead of steroid injection. Average time and duration for control of esophageal stricture by Balloon Bougie is 13.5 times and 18 weeks. In 17 surgical cases, all cases are treated by thoracoscopic esophagectomy. Average size of tumor treated by surgery is 76.5 mm (50–130 mm). Accuracy of estimated depth of invasion by endoscopy for surgical cases is 47.1%. Seven cases in 17 (41.2%) have lymph node metastasis. Rate of lymph node metastasis is 42.9% for pT1a-MM, 100% for pT1b-SM1 and 42.9% for pT1b-SM2. One case died by recurrence after surgery and 48 cases were survived without any recurrences.

Conclusion: Accuracy of estimated depth of invasion by endoscopy for lateral spreading superficial ESCC is quite low compared to normal superficial ESCC. Most of strictures after sub-circumference ESD could be prevented by steroid injection. However control of strictures after circumference ESD is difficult. Thus, diagnostic ESD should not be performed for circumferential lesions of lateral spreading superficial ESCC for the patients who will select CRT for additional treatment, and CRT should be selected for first treatment of these cases. Long survival could be obtained by ESD or surgery for the patients of lateral spreading ESCC by our treatment strategy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1890 DIAGNOSTIC ACCURACY OF ENDOSCOPIC ULTRASONOGRAPHY FOR ESOPHAGEAL SUBMUCOSAL GLAND DUCT INVOLVEMENT ACCOMPANIED BY EARLY ESOPHAGEAL CANCER

Y. Jie, L. Ying

Digestive Department, The Affiliated Drum Tower Hospital, Nanjing University Medical School, Nanjing, Jiangsu Province, China, Nanjing/China

Contact E-mail Address: 13770755008@126.com

Introduction: Normally, resided within the submucosal layer of esophagus, each esophageal submucosal gland will culminate in a single duct. The esophageal submucosal gland ducts (ESMGDs) can traverse the subepithelial connective tissue and muscularis mucosa, and deliver the acinar secretions to the esophageal lumen. However, the clinicopathological features of the esophageal submucosal gland duct involvement (ESMGDI) and its precursor lesion have not been comprehensively evaluated so far, and the series study focusing on endoscopic features of this lesion has not been reported widely. While since the 1990s, the esophageal lesions presumed to originate from ESGMDs had been described constantly in various case reports. Currently, in addition to the gold standard of histopathology, almost no more useful modality could be applied to this

lesion. In our study, we considered that the ESGMDI had a correlation with early esophageal cancer, and we noted that the ESGMDI had special features under the endoscopic ultrasonography (EUS). The typical ultrasonic images of EUS could help diagnose ESGMDI.

Aims & Methods: In order to investigate the clinical value of EUS for diagnosing ESGMDI accompanied by early esophageal cancer, which were suggested by conventional endoscopy or biopsy, this study retrospectively analyzed the consecutive patients with early esophageal cancer diagnosed in the Endoscopy Center at the Affiliated Drum Tower Hospital, Nanjing, China from September 2009 to November 2016. The clinical data of 519 patients were included in this study, and all of them had already underwent EUS combined with Endoscopic Submucosal Dissection (ESD). The EUS preoperative diagnosis were compared with the results of postoperative pathology from ESD.

Results: According to the pathological results, all patients (371 males and 148 females, with a mean age of 67.5 ± 4.5 years) had been diagnosed with early esophageal cancer with different invasive depth. Out of 519 patients, about 478 patients were not found ESGMDI by both examinations. Besides, postoperative pathology confirmed that 40 patients were identified with ESGMDI, 34 patients of which were completely consistent with the preoperative diagnosis of EUS. Approximately 98.7% (512/519) of ESGMDI were diagnosed exactly by EUS. Another six cases were estimated as false negative inaccurately, including two squamous cell carcinoma and four high-grade intraepithelial neoplasia. One case was regarded as ESGMDI by EUS while confirmed not by pathology. Therefore, the EUS values for sensitivity and specificity for the diagnosis of ESGMDI were 85.0% (34/40) and 99.8% (478/479) respectively. Furthermore, the positive predictive value was 97.1% (34/35), and the negative predictive value was 98.8% (478/484).

Conclusion: The esophageal submucosal gland duct involvement is a kind of lesion performed as a hypoechoic sonographic pattern located in the thickened mucosa. EUS has a satisfactory diagnostic accuracy for ESGMDI as well as good sensitivity and specificity.

Introduction: Few major international guidelines consider pepsinogen tests as the best available non-invasive tests to detect precancerous lesions (in particular, corpus atrophy) in the stomach mucosa. Gastrin-17 (G-17) has been suggested as indirect marker for antral atrophy. Different tests are used in Europe and Asia. Recommendations from the European Commission expert group consider the need for additional studies before any screening with biomarkers can be recommended for implementation.

Aims & Methods: Generally healthy 40–65 years aged participants of the GISTAR pilot study referred for upper endoscopy according to the pilot study protocol were enrolled. Pepsinogen (Pg) I and II were assessed from plasma samples by two methods—ELISA (Biohit Plc.) and latex-agglutination (Eiken Chemical Co.) test systems. G-17 and IgG group antibodies to *H. pylori* infection were assessed by Biohit Plc. ELISA test systems. The following cutoff values were considered characteristic for atrophy: Pg I/II < 3 for ELISA, Pg I/II < 3 and PgI < 70 ng/ml for latex-agglutination, and G-17 < 1 pmol/l (in a plasma sample obtained in fasting condition). Biopsies were sampled and read by two independent pathologists according to the updated Sydney system. OLGA and OLGIM scoring systems were also applied. Cancer, dysplasia, OLGA/OLGIM III-IV taken together were considered high-risk lesions.

Results: Altogether 1044 subjects (55% females, mean age = 52, 67.7% with positive *H. pylori* antibodies) were included to the study. The sensitivity and specificity for detecting moderate to severe atrophy in the corpus for Biohit ELISA test was 47.2% and 92.3%, but for Eiken latex-agglutination test—81.1% and 62.1%, respectively. The corresponding values for G-17 to detect atrophy in the antrum were 29.2% and 58.9%. High-risk lesions were detected by Biohit ELISA pepsinogen test system with 22.8% sensitivity and 91.6% specificity, but with Eiken latex-agglutination test—with 67.4% and 62.5% sensitivity and specificity.

Conclusion: Due to the high specificity, pepsinogens (e.g. ELISA) could be potentially used for screening of precancerous lesions if relatively low sensitivity could be accepted. G-17 does not seem to provide any additional benefit.

Introduction: miRNAs are a group of small non-coding RNAs that dysregulate in various types of cancers [1–3]. They play a pivotal role in several pathological processes. Growing evidence show that miRNAs can act as either tumour oncogenes or suppressors in different types of cancers. Previous studies revealed that miR-211-5p could suppress melanoma proliferation, migration, and invasion [4]. However, the contrasting result suggested that miR-211-5p was a potential oncogene in non-small cell lung cancer by targeting SRCIN [5]. Therefore, the functional role of miR-211-5p is still unclear in the pathogenesis of gastric cancer.

Aims & Methods: We aimed to investigate and characterize the biological roles of miR-211 in the development of gastric cancer. The expression level of miR-211-5p was measured in paired primary gastric cancer with corresponding adjacent gastric mucosa by RT-PCR. Furthermore, we investigate the biological role of miR-211-5p in proliferation, apoptosis, migration of gastric cancer cell lines in vitro.

Results: The expression levels of miR-211-5p were significantly decreased in gastric cancer and low expression of miR-211-5p correlates with poor prognosis in gastric cancer patients. Ectopic expression of miR-211-5p suppressed proliferation, migration and induced apoptosis in gastric cancer cells in vitro. Bioinformatics and quantitative analysis revealed that FoxC1 might be a target of miR-211-5p. Downregulation of FoxC1 inhibited proliferation and migration of gastric cancer cells and Overexpression of FoxC1 partly abrogated the inhibitory effects of miR-211-5p on gastric cancer cell proliferation and motility.

Conclusion: We demonstrate that miR-211-5p acted as a tumour suppressor by targeting FoxC1 in gastric cancer and miR-211-5p might be a potential target for the treatment of gastric cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI893 CONGENITAL OR METAPLASTIC: EVALUATION OF GASTROESOPHAGEAL NEO-JUNCTIONS TO ASSESS CARDIAC TYPE EPITHELIUM ORIGIN

J. Castela, D. Vinha Pereira, S. Mão De Ferro, R. Casaca, R. Fonseca, P. Chaves, A. Dias Pereira

Núcleo Regional do Sul da Liga Portuguesa Contra o Cancro, Lisboa/Portugal

Contact E-mail Address: joanarocastela@gmail.com

Introduction: The dramatic rise in the incidence of gastroesophageal junction (GEJ) adenocarcinoma in the Western countries, has promoted an increased interest about the etiopathogenesis and natural history of GEJ. The cardiac epithelium (CE), which integrates the morphological spectrum of Barrett's esophagus, is frequently present in endoscopically normal GEJ in children and adults. Its congenital versus metaplastic origin still needs to be clarified. The gastroesophageal neo-junction after esophagectomy seems the ideal model to study the development of GEJ epithelia, reproducing "in-vivo" its natural history.

Aims & Methods: The aim of this study was to evaluate the prevalence of metaplastic CE in the gastroesophageal neo-junction. Prospective study of patients undergoing esophagectomy due to esophageal/GEJ neoplasia between November/2015 and November/2016. Upper gastrointestinal endoscopy (UGIE) (Olympus, GIF-HQ 190) was performed 3 months after surgery; the neo-junction was evaluated with white light and Narrow band imaging (NBI); protocolated biopsies were made (suspected areas of CE, randomized in the anastomosis if endoscopic absence of CE, 2 cm above and below the anastomosis). Endoscopic CE defined by the presence of circular pattern with NBI in the anastomosis. Histological evaluation performed by 3 pathologists with gastrointestinal expertise. A questionnaire for gastroesophageal reflux (GER) symptoms evaluation was applied.

Results: 20 patients were included (9 adenocarcinomas), 19 men, mean age 60 ± 11 years, 9 under proton-pump inhibitor and 10 with RGE symptoms. UGIE: unable to pass a standard scope in anastomosis due to stenosis: 3/20; esophagitis: 5/20; columnar epithelium of the esophagus: 1/20. Epithelium suggestive of CE: present in 17/20, suspect in 2/20 and absent in 1/20. Histologically: CE confirmed in 18/20 patients; additionally identified oxyntocardiac epithelium in 12/20 and intestinal metaplasia in 2/20. The endoscopic diagnosis of CE

revealed a sensitivity, specificity, positive and negative predictive value of 94.4%, 100%, 100% and 66.7%, respectively.

Conclusion: The identification of metaplastic CE in neo-junctions is a very frequent and early event and its presence corroborates the hypothesis of metaplasia, to the detriment of a congenital origin. The good endoscopic and histological correlation observed for CE will allow the definition of endoscopic patterns, essential for its recognition.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Duodenal adenomas are rare epithelial tumors and represent 25% of the benign lesions diagnosed in the small bowel. Non-ampullary sporadic duodenal adenomas (NASDA) are usually asymptomatic and their diagnosis is mostly incidental. NASDA are benign epithelial tumors with a potential for malignant transformation via the adenoma–carcinoma sequence; nevertheless this risk is lower compared to ampullary or duodenal adenomas in the context of genetic syndromes. Results of Endoscopic Mucosal Resection (EMR) of NASDA are assessed in a large series after long-term follow-up.

Aims & Methods: Consecutive patients undergoing EMR of NASDA between May 2002 and December 2016 were identified from an electronic database. Patients with a genetic polyposis syndrome (FAP or Peutz-Jeghers) and/or adenoma of the major or minor duodenal papilla were excluded. Preoperative biopsy were performed at operator discretion, considering that the majority of the patients were referred from other centers. In case of doubt for a possible involvement of the ampulla of Vater, duodenoscopy with a side-viewing endoscope was also performed. EUS was not systematically done before duodenal EMR. Size, site of the lesion, pre- and post-EMR histology, adverse events, local recurrence and survival rates were retrospectively analysed. En-bloc resection was preferred, when possible, for lesions <20 mm; bigger lesions were removed piecemeal. Blended "endocut" current was used in all the cases. All resected specimens were retrieved for histological examination. CO₂ insufflation was routinely used during duodenal EMR after 2013. Argon plasma coagulation was used to eradicate residual adenomatous tissue at discretion of the operator. Endoscopic follow-up was scheduled after 3, 6 and 12 months for the first year, and then yearly for up to 5 years.

Results: EMR of 75 NASDA was performed in 68 patients (56% en-bloc resection, 44% piecemeal). The mean size was 14.4 mm and 29.9 mm for lesions resected en-bloc and piecemeal, respectively. Histopathological findings were: low-grade dysplasia (n=27, 36%), high-grade dysplasia (n=34, 45.4%), high-grade dysplasia with focal adenocarcinoma (n=12, 16%), intramucosal adenocarcinoma (n=2, 2.6%). Pre-EMR biopsy tended to downgrade the lesion in 44.4% (16/36). Retroperitoneal perforations occurred in 3/75 (4.0%) procedures and were treated by surgical (n=2) or percutaneous (n=1) drainage; delayed bleeding was reported in 13/75 (17.3%) resections and was successfully managed by endoscopy (n=12) or radiologic embolization (n=1). There was no procedure-related mortality. Follow-up was available in 61/68 patients (89.7%) after a median time of 59 months (range 3–147) from resection. Residual and recurrent adenoma were diagnosed in 9 and 6 cases, respectively; all but one were successfully retreated endoscopically.

Conclusion: The present series reports the results of duodenal EMR for NASDA after more than 4-year median follow-up. When biopsies had been performed before duodenal EMR for NASDA, downstaging of the lesion was recorded more than 40% cases in our series, suggesting that biopsies are not routinely necessary before EMR. EMR for NASDA is effective with favorable long-term outcomes. The main limitation of duodenal EMR is the high incidence of residual/recurrent adenoma which was 27.3% in our series. Piecemeal EMR was

associated, in our series, with a higher incidence of residual/recurrent adenoma, when compared to en-bloc resection. These results are similar to those reported in the literature. Residual and recurrent duodenal adenomas were successfully retreated by EMR in all of them but one. Mortality related to NASDA was absent in our series after a median follow-up of 59 months (range 1–147). Management of adverse events after EMR for NASDA requires the availability of interventional radiologists and surgeons with experience in retroperitoneal surgery. In our experience colorectal adenomas was correlated to NASDA (33.3%), colonoscopy is considered part of the pre-EMR assessment when NASDA is diagnosed. A recall system and patient's compliance to endoscopic follow-up are mandatory to detect recurrences and their prompt treatment.

Introduction: Obestatin is a bioactive peptide with a well-defined function on cell proliferation mediated by the GPR39 receptor. Our data involve this system in several processes located in the stomach: from pepsinogen secretion in healthy stomach to malignant proliferation in gastric adenocarcinomas (1). A key step in obestatin signaling is the transactivation process GPR39-RTK through MMPs activation. This step could imply a key mechanism by which MMPs regulate these diseases. Numerous studies have shown that alterations in the expression and/or mutations in members of the family of receptors EGFR/Erbb are present in tumours, and these changes may contribute to the progression of cancer. In this sense, obestatin is added to the group of MMPs regulator factors, which have been implicated in diverse human diseases, such as inflammatory diseases and cancer (2,3).

Aims & Methods: The aim of the present study is to elucidate the detailed activation/regulation mechanism of GPR39-RTK cross-talk triggered by obestatin.

Results: Obestatin triggers phosphorylation of RTKs that belong mainly to the family of EGFR (EGFR, 126.7 ± 1.1%, insulin (InsulinR, 128.6 ± 1.3%), Trk (TrkC, 170.9 ± 4.6%), VEGF (VEGFR3, 114.9 ± 3.1%) and the ephrin receptors (EphA1, 135.8 ± 5.2%), both in AGS and KATO-III cell lines. Furthermore, we observed an augment in the expression of proteases in lysates and secretomes after obestatin treatment both in AGS and KATO-III cell lines. The most outstanding increments were located in the families of: ADAMs (ADAM9, 133.9 ± 0.1%; ADAM8, 406.9 ± 19.6%), CTSs (CTSB, 193.4 ± 3.9%; CTSV, 189.2 ± 4.9%), KLKs (KLK3, 358.4 ± 12.6%; KLK13, 365.1 ± 7.1%) and MMPs (MMP1, 690.6 ± 10.0%; MMP13, 273.1 ± 0.2%). In human tissues, the obtained data were heterogeneous. However, it was observed an overexpression for EphA1 and InsulinR in adenocarcinomas when compared to healthy stomach, while it was observed a decrease for Axl. Regarding the proteases, ADAMTS13 y PSEN1 were found overexpressed in healthy tissue compared to gastric adenocarcinomas. Besides, CTSX/Z/P expression augmented with the differentiation of the tumour.

Conclusion: These data corroborated obestatin involvement in proliferation, migration and apoptosis and in diverse oncogenic process. Besides, the GPR39-RTK crosstalk is not only limited to the EGFR, but instead depends on the existing RTKs present in the tissues, and regulated the expression of proteases involved in processes and pathways already described for obestatin.

Introduction: NSAIDs have demonstrated chemopreventive activity against gastrointestinal cancers but their toxicity limits their use as prophylactics. They have now been postulated as possible adjuvants to surgery or chemotherapy in order to prevent the formation of new lesions and reduce disease progression. Cancer cells enhance their resistance to the cytotoxic action of antineoplastic drugs by activating autophagy, which is a catabolic process that degrades superfluous and damaged organelles in the lysosome. We previously showed that indomethacin inhibits autophagy in gastric cancer cells by acting at a late stage in this catabolic process.

Aims & Methods: The aim of this study is to analyze whether indomethacin modulates lysosomal function and oxaliplatin-induced cell death in these cells. Gastric AGS cells were treated with increasing concentrations of indomethacin for 2, 6 and 20 hours. Lysosomal pH was assessed by using LysoTracker Red and acridine orange fluorescent probes (static cytometry). Cathepsin activity was determined by using Omnicathepsin fluorescence substrate. In cells treated with indomethacin for 2 hours LAMP2 immunostaining was also carried out. In another set of experiments AGS cells were treated with increasing doses of the antineoplastic drug oxaliplatin and indomethacin. Cell viability was measured by an MTT assay, the rate of apoptosis/necrosis was analyzed by means of the Apoptosis Detection Kit, and autophagy by p62 immunoblotting.

Results: Treatment of AGS cells with indomethacin decreased LysoTracker fluorescence in AGS cells after 2, 6 and 20 hours. Indomethacin also produces an acute reduction in lysosome-derived fluorescence of acridine orange after 2 and 6 hours of treatment. In addition, we observed a significant reduction of cathepsin enzymatic activity in cells treated with indomethacin for 6 or 20 hours. Furthermore, there was an altered distribution of LAMP2-positive dots from the perinuclear position observed in control cells to a peripheral position in cells treated with indomethacin. Taken together, these data suggest that indomethacin inhibits the activity of lysosomal acidic enzymes by increasing lysosomal pH. On the other hand, oxaliplatin decreased cell viability in a dose-dependent manner after 48 hours of treatment, and treatment of cells with indomethacin during the last 24 hours further decreased cell viability. In addition, indomethacin also increased the rate of apoptosis and necrosis in AGS cells treated with oxaliplatin. Finally, indomethacin blocked the autophagic degradation of p62 protein induced by oxaliplatin.

Conclusion: Indomethacin inhibits lysosomal function in gastric cancer cells. This could explain the inhibitory action on autophagy and the resultant increase in susceptibility to cytotoxic drugs.

PI897 HOXD10 METHYLATION IN PLASMA WAS POTENTIALLY SERVED AS BIOMARKER OF GASTRIC CANCER AND PRECANCEROUS LESIONS

L. Wang, L. Wang, M. Luo

The Second Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou/China

Contact E-mail Address: wanglj76@hotmail.com

Introduction: Gastric cancer (GC) is the fifth most common cancer and the third leading cause of cancer death worldwide. Our previous studies have demonstrated that HoxD10 functioned as a candidate tumor suppressor in GC, which is silenced through promoter hypermethylation. The diagnostic value of HoxD10 methylation in the plasma of GC patients was not determined.

Aims & Methods: We aim to evaluate whether HoxD10 promoter methylation in plasma could serve as noninvasive biomarker of GC. Methylated specific PCR (MSP) assays were used to measure HoxD10 promoter methylation in plasma of 38 healthy volunteers, 55 patients with gastric intraepithelial neoplasia (GIN), 123 GC patients and 17 GC after surgery patients.

Results: We demonstrated that the rate of HoxD10 methylation was 0% in healthy controls, 34.55% in GIN, 46.34% in GC and 17.65% in GC after surgery group, respectively. The methylation rate was significantly higher in GIN or GC than in the normal control group ($p < 0.01$). The methylation rate of the post-treatment group was significantly lower than that in the GC group ($p < 0.05$). In GC patients, HoxD10 promoter methylation was correlated to tumor invasion depth ($p < 0.05$), while no association was found in sex, age, tumor size, TNM stage, CEA level and *H. pylori* infection ($p > 0.05$).

Conclusion: It demonstrated that the HoxD10 promoter methylation rate in plasma dissociated DNA was increased with the progression from precancerous lesions to GC. Combined testing of HoxD10 methylation and CEA may be a great significant method for the early diagnosis of GC in high-risk populations.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The mechanisms of gastric carcinogenesis, especially of diffuse type of gastric cancer (GC) are poorly understood. The cancer stem cells (CSC) represent a particular fraction of cancer cells, considered at the origin of cancer and responsible for tumor development. The enteric nervous system (ENS) is a newly recognized component of tumor microenvironment and its role in carcinogenesis has been recently suggested. In particular, the role of acetylcholine (ACh), a major neuromediator released by enteric nerves, has been suggested in gastric carcinogenesis but its effect on gastric CSC remains to be established.

Aims & Methods: Our aim was to study the effect of ACh on gastric cancer cells, and in particular its capacity to induce the stem cell phenotype, and to study the mechanisms involved. Adenocarcinoma gastric epithelial cells MKN-45 were first cultured in adherent conditions in the presence of ACh (0.1–1–10 µM), before being cultured in non-adherent condition in order to favour expansion of CSC and formation of tumorspheres (T). The effect of ACh on T formation was evaluated under microscope by quantifying the number and size of T using the System snapshot file in INCell analyzer 2200/6000. The involvement of different cholinergic (muscarinic and nicotinic) receptors in ACh-induced responses was studied by pharmacological approach using selective agonists and antagonists. The role of nitric pathway was studied using SNP (NO donor) and L-Name (nitric oxide synthesis inhibitor). Finally, the effect of ACh on the expression of CSC and epithelial-mesenchymal transition (EMT) markers was studied by immunofluorescence, RT-qPCR and flow cytometry. Statistical analysis was performed by Man-Whitney test, Kruskal-Wallis test, or two-way non-parametric ANOVA test using SPSS16.0 F software

Results: ACh at concentrations of 0.1 and 1 µM significantly increased the number and size of T as compared to control conditions ($p < 0.001$). Bethanecol, a selective muscarinic receptor agonist, increased the number and size of T, while the stimulatory effect of ACh on T was significantly reduced by selective muscarinic receptor antagonist, atropine. Similarly, DMPP, a selective nicotinic receptor agonist, increased the number and size of T, while hexamethonium, a nicotinic receptor antagonist, significantly inhibited stimulatory effect of ACh on T ($p < 0.001$ as compared to ACh-stimulated cells). Interestingly, L-Name, significantly inhibited the effects of ACh on the number of T. Conversely, SNP, at 0.1 and 1 µM, increased the number and size of T. Finally, ACh induced the expression of CSC markers (CD44, ALDH) and EMT markers (Snail, Zeb1 and Vimentin) on gastric cancer cells.

Conclusion: This study shows that ACh induces CSC properties of gastric cancer cells of diffuse type via activation of muscarinic and nicotinic pathways. It also shows that ACh effects are, at least in part, mediated by nitric pathway. These results suggest that ENS may be a new actor in gastric carcinogenesis.

Introduction: CpG Island Methylator Phenotype (CIMP) has been identified as a distinct molecular subtype of gastric cancer, yet associations with survival are conflicting. A meta-analysis was performed to estimate its potential prognostic significance.

Aims & Methods: A systematic review of Embase, Medline, PubMed, PubMed Central and Cochrane databases related to CIMP in gastric was performed and the primary outcome measure was cumulative 5-year survival.

Results: A total of 967 patients from 10 studies were included, and the median rate of tumour CIMP-H was 40.9% (range 5.3–62.7%). Pooled analysis suggested that specimens exhibiting CIMP-H were associated with poorer 5-year survival (OR 1.49, 95% CI 1.11–2.01, $p < 0.05$). Significant heterogeneity was observed between studies ($I^2 = 88\%$, $p < 0.001$). Sub-analysis related to poor ($n = 5$) or improved outcomes ($n = 5$), revealed that CIMP was associated with both poor (OR 8.15, 95% CI 4.65–14.28, $p < 0.05$, study heterogeneity $I^2 = 52\%$, $p = 0.08$) and improved survival (OR 0.42, 95% CI 0.27–0.65, $p < 0.05$, study heterogeneity $I^2 = 0\%$, $p = 0.960$).

Conclusion: There was significant heterogeneity in the gene panels used to identify CIMP which may explain the survival differences. Consensus regarding CIMP methodology would be welcome to better facilitate the assessment of its prognostic value.

Introduction: The BreathID®Hp urea breath test (UBT) system provides several advantages over other ¹³C breath analyzers for the detection of *Helicobacter pylori* (*H. pylori*), including: higher accuracy, operator independence and immediacy of results. However, there are occasions when mailing or transporting saved breath samples may be preferable to real time analysis, especially in centers requiring a large quantity of automated analyses where continuous sampling from a single patient can provide a bottle neck preventing multiple other users from accessing the device.

Aims & Methods: To evaluate the sensitivity and specificity of a new BreathID®Hp Lab System (Exalenz Bioscience Ltd, Modiin, Israel), a ¹³C-UBT system using breath sampling bags, for the diagnosis of *H. pylori* in a multi-center international clinical study. A total of 257 subjects with evaluable results for UBT and biopsy [rapid urease testing (RUT) and histology] were enrolled into two study groups: 189 naïve subjects with unknown *H. pylori* status were included in the pre-therapy group, and 68 subjects who had completed eradication therapy comprised the post-eradication therapy group. To assess the stability of the breath samples in the breath sample bags, each pair of breath sample bags was analyzed at a different time point up to 14 days after collection. Analytical studies were conducted to evaluate the reproducibility and repeatability of the ¹³C-UBT results using a cut-off of 5 Delta Over Baseline (DOB).

Results: Among the pre-therapy subjects evaluated with the composite results from the two biopsy based methods (RUT and histology/immunohistochemistry), 176 results (37 positive, 139 negative) matched those of the UBT resulting in an overall agreement of 98.3% (95% CI: 95.2%; 99.7%) with a sensitivity of 100% (95% CI: 90.6%; 100.00%) and specificity of 97.9% (95% CI: 94.0%; 99.3%). The overall agreement between the UBT and the biopsy diagnosis in the post-eradication therapy cohort (55 negative, 13 positive) was 98.5% (95% CI: 92.1%; 100.0%). The sensitivity of the UBT in this cohort was 92.3% (95% CI: 66.7%; 98.6%) and its specificity was 100.0% (95% CI: 93.5%; 100.0%). The overall stability evaluated in samples of 191 (45 positive, 146 negative) subjects from the pre-therapy cohort was excellent, with positive agreement in 97.8% [95% CI (88.43, 99.61)] and negative agreement in 100.0% [95% CI (97.44, 100.0)]. Similarly there was uniformly high overall reproducibility of the test results over different batches, when analyzed on different days and under different storage conditions.

Conclusion: The validation studies of the BreathID®Hp Lab System described above show it is a highly accurate and dependable method for the diagnosis of *H. pylori* infection. Based on the current study, BreathID®Hp Lab System received on November 2016 U.S. Food and Drug Administration (FDA) marketing clearance for *H. pylori* bacterium detection.

Introduction: Linked color imaging (LCI), a recently developed endoscopic technique, emphasizes diffuse redness, which is a characteristic of *Helicobacter pylori* (Hp) infection. However, the diagnosis of Hp infection does not have objective indicators; it depends on medical doctors' experience. Therefore, it is necessary to construct objective indicators to diagnose Hp infection.

Aims & Methods: The aims of this study are to determine objective indicators for the presence or absence of Hp infection to support medical doctors' diagnoses by constructing an automatic diagnostic system. In the proposed system, first, a region with a high hue in LCI images is defined as a region of interest (ROI). Images with a wide ROI and images with a narrow ROI are classified as high and low hue images, respectively. As a result, LCI images are classified into two types in which inflammation due to Hp infection presents as red and purple. Then, the presence or absence of Hp infection is learned by machine learning for each type of LCI image. The feature values used in the learning process are the ratio of the ROI, the average and median hue values in high hue images, and the mode saturation value and the median and variance of the hue in low hue images. Then, the trained classifiers diagnose the presence or absence of Hp infection automatically. In this paper, the constructed system was evaluated using 128 images (32 patients) in which endoscopic examination (LCI observation) and Hp infection diagnosis were performed at Murakami Memorial Hospital of Asahi University. Furthermore, support vector machines were used as classify learners for diagnosis.

Results: In the previous system [1], 29 out of 32 cases were automatically diagnosed correctly. In contrast, all cases were automatically diagnosed correctly with the proposed system. This result demonstrates that classifying LCI images into two types based on color improves the accuracy of this system.

Conclusion: The proposed system can automatically diagnose the presence or absence of Hp infection with the same precision as medical doctors with sufficient experience. Therefore, the proposed system can support the diagnosis of medical doctors with less experience.

Introduction: γ -glutamyltranspeptidase (GGT) is a cell surface-associated enzyme that is not highly expressed in normal cell. However GGT is overexpressed in various type of human cancers. It is known that *Helicobacter pylori* (*H. pylori*) also produce GGT. Urano et al have developed an enzymatically activatable fluorescent probe, γ -glutamyl hydroxymethyl rhodamine green (gGlu-HMRG), which is nonfluorescent under a neutral pH and normal cellular environment, but turns to be highly fluorescent upon reaction with GGT¹⁾. Aim of this study is to consider if gGlu-HMRG can be useful for diagnosing infection *H. pylori*.

Aims & Methods: In this study, we investigated whether activation of gGlu-HMRG fluorescence detects a wild-type of *H. pylori* (WT) and a *ggt* gene-disrupted mutant of *H. pylori* (*ggt* mutant). In addition, we investigated whether activation of gGlu-HMRG fluorescence was suppressed in *H. pylori* culture solution which was co-incubated with an inhibitor of GGT (GGsTop). Furthermore, we applied gGlu-HMRG to biopsy specimens which were taken from antrum and corpus of stomach in *H. pylori* positive patients (n = 13) and *H. pylori* negative patients (n = 14). We then observed the increase of fluorescence intensity over time (1 min, 5 min, 10 min, 15 min). Fluorescence intensity was quantified by Image J2 software (National Institutes of Health, Rockville, Maryland)²⁾.

Results: Activation of gGlu-HMRG fluorescence was detected in WT strain, but was not in *ggt* mutant strain. Activation of gGlu-HMRG fluorescence was inhibited by GGsTop. There was significant difference of the increase of fluorescence intensity between *H. pylori* positive and negative both in antrum corpus of stomach (antrum p = 0.0008, corpus p = 0.047).

Conclusion: GGT-activated fluorescent probe can be useful for *H. pylori* infection diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1903 SEROLOGICAL CHANGES AFTER EQUIVOCAL *HELICOBACTER PYLORI*-SEROLOGY TEST FINDINGS DEPEND ON THE GASTRIC SECRETING ABILITY

J.H. Kim, S. Lee, S.P. Lee, J.H. Kim, I. Sung, H.S. Park, C.S. Shim
Internal Medicine, Gastroenterology, Konkuk University Hospital, Seoul/Korea, Republic of

Contact E-mail Address: kjhcess@gmail.com

Introduction: The serum anti-*Helicobacter pylori* (*H. pylori*) IgG and serum pepsinogen (PG) assays are widely used for gastric cancer screening. An equivocal serology test finding indicates IgG titer between the positive and negative test findings.

Aims & Methods: The study aim was to evaluate the long-term, follow-up result after an equivocal test finding on the serum anti-*H. pylori* IgG assay. Koreans above 18 years-old with an equivocal serum anti-*H. pylori* IgG assay finding were included. Subjects were excluded if they did not undergo *H. pylori* serology test, serum PG assay, and upper gastrointestinal (UGI) endoscopy on the same day at our center. Annual test findings were followed up using the same methods.

Results: Of the 7,178 subjects who underwent the serum assays and UGI endoscopy on the same day, 274 (3.8%) subjects showed an equivocal *H. pylori* serology test finding. Of the 98 followed-up subjects, 58 (59.2%) showed sero-positive finding at the mean follow-up period of 30.6 \pm 12.4 months. Subjects with seroconversion showed a higher initial serum PG I (p = 0.023) and PG II (p = 0.036) levels than the subjects without seroconversion.

Conclusion: An equivocal *H. pylori* serology test finding is not rare (3.8%) in Korean adults, and 60% of the equivocal subjects show seroconversion within 3 years. Higher seroconversion rates in the subjects with high PG I and PG II levels suggest that intact gastric secreting ability play a role for the survival of *H. pylori*. Therefore, equivocal subjects with increased serum PG levels should be considered as a potential seropositive subjects.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Several *H. pylori* (HP) infection related gastric findings (mucosal atrophy, metaplastic change, diffuse redness, spotty redness and nodular change of the antrum etc.) are so important sign of HP infection on endoscopic examination. On the other hand, we have confused with various newly endoscopic findings (patchy redness and map-like redness etc.) were seen on the post-eradicated stomach. On this time, we have found out a new other ultimate useful finding showing HP infection related gastritis at gastric cardia (EG junction) including present and post HP infection. The endoscopic image of gastric cardia is the first gastric view through the esophagus on each endoscopic examination.

Aims & Methods: Our aim of this study is to elucidate possibility of judgement with only this cardiac endoscopic view about presence or absence with HP infection. We have found out so useful and specific cardiac image (We call Whale Shark Sign: WSS) closely related to HP infection. We have examined the presence of WSS on 4, 268 cases that have been able to overviewed on their endoscopic profiles. We have judged the presence of HP infection with serum HP antibody titers on each case. The 3,233 cases their serum HP antibody titers were measured from Jan. 2012 to Oct. 2016. A total of 2,810 patients (HP positive) were enrolled. Fisher's exact test was used in all statistical analyses. The judgement of HP present or past infection was done more than serum HP antibody 3 U/ml to avoid false negative results.

Results: Mean age of patients was 52.4 years old. In case of WSS positive, all their serum HP antibody titers showed more than cut-off level (3 U/ml). This means that the presence of WSS closely related to HP related gastritis. The positive predictive value (PPV) of WSS was surprisingly high (98%). According to this high PPV, we can think WSS positive cases are high risk of gastric carcinoma. This WSS mean that the presence of irregular gastric mucosal surface pattern and the presence of lymphoid hyperplasia, that showing HP infectious stomach. Especially presence of lymphoid hyperplasia at gastric cardia is most important specific sign of HP related gastritis. This lymphoid hyperplasia at gastric cardia were recognized small round whitish nodules on white light endoscopy. And this was more emphasized with image-enhanced endoscopy (Narrow Band Imaging: NBI), it looks like Whale Shark. This WSS sign is very simple and easy for every gastroenterologist. It is so useful to know gastric cancer risk at gastric entrance (cardia) with the presence of very easy simple sign.

Conclusion: We have been able to judge the presence of HP infection with only cardiac endoscopic images (WSS), we should take care of seeing the presence of

WSS sign. Since this sign is very easy and simple, everyone will be able to judge the presence of HP infection and gastric cancer risk.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The diagnosis of *Helicobacter pylori* (H.p.) infection is currently made by means of non-invasive (Urea Breath Test or HpSA) or invasive (gastric biopsy or culture) methods. Serological assessment of H.p. infection by using levels of IgG is not recommended. Pepsinogen II (PGII) is validated in the literature as a non-invasive marker of gastric inflammation. Aim of the study was to assess in a population of dyspeptic patients the clinical availability of PGII determination in singling out subjects infected by H.p. in comparison with non-infected ones.

Aims & Methods: A cohort of 880 consecutive dyspeptic patients (F 439; mean age 55.5 ys; range: 29.83 ys) were enrolled in the study. Exclusion criteria: previous surgery, previous H.p. eradication therapy, concomitant PPI. In all patients the diagnosis of H.p. infection was made by means of upper GI endoscopy and at least one of these two methods: UBT, HpSA. All patients underwent blood sample for determination of serum levels of PGII (Biohit Oy; Finland; normal values: 2–15 µg/l). In a group of 670 pts a course of antibiotics (triple, concomitant or sequential therapy) to cure H.p. infection was performed and PGII levels were assessed at baseline (T0) and after two months (T1) from the end of the antibiotic therapy. The search for the most appropriate cut-off of PGII in diagnosis of H.p. infection was assessed by using the ROC curve method.

Results: 430 out of 860 dyspeptic patients (F 245; mean age 52.3 ys; range 32–69 ys) showed an H.p.-related gastritis (group1) in comparison with 430 (F 261; mean age 57.3 ys; range 38–74 ys) resulted negative for H.p. infection (group 2). The mean value of PGII in group 1 was 20.9 ± 6.1 opposite to 7.2 ± 1.7 in group 2; p < 0.0001. 415 out of 670 patients treated with antibiotics schedules were cured from H.p. infection, opposite with 255 non-eradicated ones. In the group of cured patients, the PGII values at T0 were 16.5, in comparison with 8.6 at T1; p < 0.001. The cut-off for PGII in the diagnosis of H.p. infection, by comparing the 430 H.p. positive pts and the 430 negative ones with method of ROC curve identified the mean value of 10.6 µg/l, youden index J = 0.997.

Conclusion: serum PGII levels seem able to perform diagnosis of H.p. infection in dyspeptic patients, as well as the efficacy of antibiotics treatment for H.p. eradication, being 10.6 µg/l the best cut-off in singling out infected from non-infected subjects.

Disclosure of Interest: All authors have declared no conflicts of interest.

Abstract No: P1903. Table: Different characteristics of the subjects with an equivocal *H. pylori* test finding according to the repeated *H. pylori* serology test findings

Variables	Seropositive finding on the follow-up test (n = 58)	Seronegative or equivocal finding on the follow-up test (n = 40)	p-value
Age (years-old)	52.1 ± 9.8	54.0 ± 11.2	0.386
Gender (male)	43 (74.1%)	23 (57.5%)	0.084
Follow-up period (months)	32.1 ± 13.0	28.6 ± 11.3	0.165
Past <i>H. pylori</i> eradication	6 (10.3%)	10 (25.0%)	0.054
Initial serum pepsinogen I level (ng/ml)	61.2 ± 32.0	48.5 ± 15.6	0.023
Initial serum pepsinogen II level (ng/ml)	12.3 ± 8.6	9.3 ± 3.5	0.036
Initial serum pepsinogen I/II ratio	5.5 ± 1.5	5.5 ± 1.4	0.985
Body mass index (kg/m ²)	24.6 ± 3.4	23.8 ± 2.6	0.231
Cigarette smoking Current smoker Past smoker Non-smoker	18 (31.0%) 16 (27.6%) 24 (41.4%)	5 (12.5%) 13 (32.5%) 22 (55.0%)	0.101
Alcohol drinking Heavy drinker* Social drinker Non-drinker	5 (8.6%) 40 (69.0%) 13 (22.4%)	6 (14.3%) 23 (59.5%) 11 (26.2%)	0.451
Upper gastrointestinal symptom	18 (31.0%)	10 (25.0%)	0.516
Recent intake of drug(s)	14 (24.1%)	8 (20.0%)	0.629
Comorbidity Hypertension Diabetes mellitus Others	17 (29.3%) 5 (8.6%) 19 (32.8%)	13 (32.5%) 4 (10.0%) 13 (32.5%)	0.736 0.816 0.979

Statistically significant values are highlighted in bold. Continuous variables are shown as mean value ± standard deviation using the Student's *t*-test. Categorical variables are shown in frequency (%) using the Chi-square test or Fisher's exact test. *Criteria for heavy drinking was ≥ 15 drinks/week for men and ≥ 8 drinks/week for women. Social drinker was defined as those who drink alcohol, but less than heavy drinkers.

P1906 CAN THE UREA BREATH TEST PREDICT *HELICOBACTER PYLORI* ERADICATION?

Introduction: The Urea Breath Test (UBT) is considered the gold standard non-invasive test for detection of *Helicobacter pylori* infection in Ireland. In Ireland, eradication rates for standard clarithromycin-based triple therapy have fallen below the 80% deemed acceptable for a given treatment. With this in mind, it is important to optimise management of *H. pylori* infection. It has been suggested that the DOB value is reflective of the amount of bacteria present in the stomach and could predict whether the infection is eradicated.

Aims & Methods: The aim of this study was to determine whether there is an association between DOB and eradication of *H. pylori* infection in an Irish cohort. Treatment naïve adult patients undergoing UBT were included. Patients were deemed to be *H. pylori* positive if a Delta Over Baseline (DOB) value of >4.0 % was obtained. Positive patients were categorised into low (<16 %), intermediate (16–35 %), and high (>35 %) DOB groups. A random subset of positive patients was given clarithromycin-based triple therapy for 7 days. A follow-up breath test was performed at least 8 weeks post-treatment to confirm eradication of *H. pylori* in all patients. The three DOB groups were compared with respect to age, gender and eradication rates.

Results: Out of 860 of UBTs assessed (mean age 43.5 ± 15.2 years, 39% male), 289 (33.6%) were *H. pylori* positive (mean age 43.1 ± 14.9 years, 41.9% male). Of the total positive patients, 91 (31.5%) returned for a follow-up UBT to confirm eradication of *H. pylori*. When patients were categorised into low, intermediate and high UBT groups, there was no significant difference in age and gender between the three groups (p=0.06 for age, p=0.3 for gender). Eradication rates in the low, intermediate and high UBT groups were 70.5%, 63.0% and 50.0% respectively (p=0.3). Patients were then categorised according to eradication status. When eradication was successful, the average DOB value was significantly lower, at 20.6 % compared to 29.8% when eradication was unsuccessful (p=0.03, 95% CI 0.69 to 17.5). 46 (50.5%) patients were given clarithromycin-based triple therapy for 7 days. When this subset of patients was categorised into low, intermediate and high UBT groups, eradication rates were 76.2%, 75% and 70% respectively. When these rates were compared to respective rates in those whose treatment was not known, no difference was observed. The subset was also categorised according to eradication status. When eradication was successful, the average DOB value was lower, at 22.0% compared to 25.8% when eradication was unsuccessful (p=0.6). Similarly, when these DOB values were compared to respective values in those whose treatment was not known, no difference was observed.

Conclusion: As the DOB value increases in the UBT, the eradication rate of *H. pylori* decreases, regardless of treatment regimen. When categorised according to eradication status, the DOB value was significantly lower when eradication was successful (20.6 % vs 29.8%, p=0.03). The DOB value could be a useful value in stratifying patients with *H. pylori* infection; especially as histology and antimicrobial resistance information is unavailable in patients undergoing non-invasive testing for *H. pylori* infection.

P1907 HIGH-DOSE CAM WITH VONOPRAZAN (P-CAB) PLUS AMX TRIPLE THERAPY REGIMEN IS THE STRONGEST *H. PYLORI* ERADICATION THERAPY EVEN IF CAM RESISTANCE

T. Yamasaki¹, T. Sakurai¹, J. Mitobe¹, M. Mitsunaga¹, Y. Amano², Y. Tokai³, M. Chibai⁴, M. Saruta¹

Introduction: Success or failure of Amoxicillin (AMX) and Clarithromycin (CAM)-based *H. pylori* (HP) eradication therapy mainly depends on sensitivity of CAM for HP. In Japan, we are permitted to prescribe AMX and CAM as antibiotics of 1st eradication. So far now, several proton pump inhibitors (PPIs) have been used in HP eradication therapy, most of reports said that the success rate of eradication approximately from 70 to 80% on AMX and CAM-based triple therapy regardless of CAM dose (400 or 800 mg/day) in Japan. Recently the ratio of CAM resistance in Japan comes up to over 30%, we have to overcome CAM resistance. On the other hand, recently it is considered that the stability of continuous gastric acid suppression is one of most important factors. At the point of gastric acid suppression, we expect stronger acid suppressive drug rather than PPIs. Since Feb. 2015 we have used P-CAB (Potassium-Competitive Acid Blocker) instead of PPIs in AMX and CAM-based HP eradication therapy to improve success rate of eradication.

Aims & Methods: The aim of this study is to elucidate effects of CAM dose on success rate of P-CAB Vonoprazan (VPZ) and one of PPI Rabeprazole (RPZ) based triple therapy regimens (VAC, RAC).

This study is a multicenter center (7 hospitals), prospective case study from Jan. 2012 to Oct. 2016. A total of 1,310 patients (HP positive) were enrolled. Mean age of patients was 52.4 years old. Fisher's exact test was

used in all statistical analyses. Regimen of VAC (400 or 800) was VPZ (40 mg/day) b.i.d., AMX (1,500 mg/day) b.i.d. plus CAM (400 or 800 mg/day) b.i.d. for 7 days. Regimen of RAC (400 or 800) was RPZ (20 mg/day) b.i.d., AMX (1,500 mg/day) b.i.d. plus CAM (400 or 800 mg/day) b.i.d. for 7 days. The judgement of success or failure on eradication was done with urea breath test on 3 months later after eradication therapy to avoid false negative results.

Results: Success rate of VAC 800 showed significantly high (416/428=97.2%, PPS) rather than VAC 400 (373/423=88.2%, PPS) (p<0.001). The average success rate of VAC regimens was 92.7% (789/851, PPS). On the other hand, success rate of RAC 800 showed high (190/245=77.6%, PPS) rather than RAC 400 (140/198=70.7%, PPS) (p=0.125). The average success rate of RAC regimens was 74.5% (330/443, PPS). The average success rate of VAC regimens (789/851=92.7%) were significantly high rather than the average success rate of RAC regimens (330/443=74.5%) (p<0.001). These results suggest that using high dose CAM with VPZ (P-CAB) plus AMX regimen might be the strongest *H. pylori* eradication triple therapy regimen to overcome CAM resistance.

Conclusion: High-dose CAM with Vonoprazan (P-CAB) plus AMX triple therapy regimen is the strongest *H. pylori* eradication therapy even if CAM resistance. We will be able to expect significantly high success rate (more than 97%) as HP 1st eradication therapy.

Introduction: Bismuth is a heavy metal which has antimicrobial activity through regulating iron uptake profile of bacteria. *Helicobacter pylori* (*H. pylori*) is also highly susceptible to bismuth. So the Korean guideline preferably recommends the regimen contains bismuth for the patients who failed on *H. pylori* eradication with the primary regimen consists of proton pump inhibitors, amoxicillin, and clarithromycin. Rifaximin is one of derivatives of rifamycin with antimicrobial activity against *H. pylori*. It can achieve high concentrations within the gastrointestinal tract and remains active in acidic environment. So rifaximin has been studied as a treatment for persistent *H. pylori* infection. Rifaximin has been prescribed for replacing the bismuth of the regimen concurrently uses PPI, metronidazole, and tetracycline in Soonchunhyang University Hospital, Seoul for a while. So we reviewed the clinical outcomes of the 2 different regimens.

Aims & Methods: From May 1st 2003 to October 31st 2015, six thousand and five hundred ninety-five patients were treated their *H. pylori* infection in Soonchunhyang University Hospital, Seoul. And their prescriptions and result of eradication were retrospectively reviewed on the medical records. The patients had clarified pre-and post-eradication result, which can be assured by the rapid urease test or the urea breath test performed within 100 days of eradication were enrolled. And statistical analyses were performed to the patients who had second-line treatment to compare the efficacy of the bismuth containing regimen and the rifaximin containing one.

Results: During the periods over 12 years, two thousand and seven hundred patients were prescribed the standard triple eradication regimen and 2,109 (78.11%) patients showed the successful treatment result. One hundred twenty-six of treatment failure group were consecutively treated with second-line regimens. Thirty-five patients were prescribed the bismuth-containing regimen and 34 (97.14%) of them showed successful eradication result. Other 91 patients were treated with the rifaximin-containing regimen and showed 92.31% of eradication rates. These treatment success rates are not different significantly in statistics. (Fishers' exact test, p-value = 0.442)

Conclusion: Alternative rifaximin containing regimen of second-line *H. pylori* treatment didn't showed inferiority on standard bismuth-containing one. This suggest that the use of rifaximin is possible in the patients who are not suitable to bismuth use and failed with primary eradication.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1909 COMPARISON OF 10-DAY STANDARD TRIPLE THERAPY AND LEVOFLOXACIN BASED THERAPY FOR *HELICOBACTER PYLORI* ERADICATION: RANDOMIZED CONTROLLED TRIAL

M.K. Kang, S. Lee, M.C. Kim, K.H. Kim, K.O. Kim, B.I. Jang, T. Kim

Introduction: Standard triple therapy (STT) has been widely used in *Helicobacter pylori* infection, but eradication rate is decreasing because of clarithromycin resistance. Recently, Levofloxacin-based therapy (LBT) has been evaluated to overcome the low eradication rate of standard triple therapy and reported eradication rate over 80%.

Aims & Methods: We compared the efficacy and safety of STT group and LBT group for Koreans. Between April 2014 and April 2016, 49 patients in the STT group (amoxicillin 1 g bid, clarithromycin 500 mg bid and esomeprazole 20 mg bid for 10 days) and 48 in the LBT group (levofloxacin 500 mg bid, amoxicillin 1 g

bid and esomeprazole 20 mg bid for 10 days) were enrolled, prospectively. *H. pylori* eradication rate as the primary endpoint and serious adverse effects as the secondary endpoint were defined.

Results: *H. pylori* eradication rate as the primary endpoint was higher in the LBT group than in the STT group, but there was no statistically significant difference between the two groups (82.0% vs. 84.8%, $P=0.927$). Serious adverse effects as the secondary endpoint tended to be more frequent in the LBT group, but there was no significant difference (6.1% vs. 15.2%, $P=0.267$). The overall rates of adverse effects were not different between two groups.

Conclusion: In comparison of *H. pylori* eradication rate of our study, LBT was not significantly higher than STT, but it may be an alternative treatment if STT eradication rate is lowered in Korea.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1910 TREATMENT OF *HELICOBACTER PYLORI* INFECTION: WILL TAILORING THERAPY FIRST TIME OVERCOME INCREASING FAILURE OF STANDARD TRIPLE THERAPY?

D. Brennan, M. Hussey, D. Tighe, C. O'Morain, S. Smith, D. McNamara
Trinity Academic Gastroenterology Group, Trinity College Dublin, Dublin/Ireland

Contact E-mail Address: dbrenna9@tcd.ie

Introduction: In Ireland, *Helicobacter pylori* infection has become increasingly resistant to commonly used antibiotics, such as clarithromycin. Concurrently, eradication rates for standard clarithromycin-based triple therapy have fallen below the 80% deemed acceptable for a given treatment.

Aims & Methods: The aim of this study was to compare eradication rates of standard clarithromycin-based triple therapy with those of tailored therapy based on antimicrobial susceptibility as a first-line treatment for *H. pylori* infection. Treatment-naïve adult patients undergoing endoscopy were prospectively recruited. Biopsies from *H. pylori*-positive patients (assessed by CLO test) were processed for sensitivity testing by E-testing and genotyping by the GenoType HelicoDR assay (Hain). Patients randomly received either clarithromycin-based standard triple therapy or tailored treatment based on antibiotic sensitivities, for 7/14 days. A follow-up breath test was performed at least 8 weeks post-treatment.

Results: To date 889 patients have undergone endoscopy and 186 (21%) were *H. pylori* positive. Infected patients were significantly younger (mean age 53 vs 49 years, $p=0.002$) and tended to be male (43% vs 53%, $p=0.02$). Of 186 *H. pylori*-positive patients, 112 (60%) were treatment naïve. Culture of *H. pylori* was successful in 57% (64/112) of samples and primary clarithromycin resistance was 47% (30/64) by E-test. Genotypic resistance data was available for 93% (104/112) patients and 55% (61/104) strains were clarithromycin resistant. Thus far, 99 (88%) treatment naïve patients have been enrolled in the study, 92 (93%) have completed the study. Of these, 45 (46%) have received standard triple therapy and 54 (54%) have received tailored therapy. In the tailored arm, 25 (46%) patients received standard triple therapy, 14 (26%) received levofloxacin-based triple therapy, 12 (22%) received a PPI and combination of antibiotics based on their sensitivities (e.g. levofloxacin, clarithromycin, rifampicin, tetracycline or metronidazole), and 3 (6%) bismuth quadruple therapy. The eradication efficacy of tailored therapy by intention-to-treat analysis was higher at 74% (40/54) compared to 67% ($n=30/45$) for standard therapy ($p=0.5$). The eradication efficacy by per-protocol analysis was also higher, at 82% (40/49) for tailored versus 70% (30/43) for standard therapy ($p=0.2$). Patients in each arm were further categorised by clarithromycin resistance status, phenotypically by E-test or genotypically by GenoType HelicoDR when culture was unsuccessful. Of note, in clarithromycin resistant patients, tailored therapy achieved a better eradication rate per protocol analysis than standard triple therapy (83% vs 57% per protocol, $p=0.09$).

The eradication rates of standard triple therapy and tailored therapy according to clarithromycin resistance status

		Standard Arm (n=45)		Tailored Arm (n=54)	
		Resistant strains (n=22)	Sensitive Strains (n=23)	Resistant strains (n=26)	Sensitive Strains (n=28)
Eradication Rate	ITT analysis	12/22 = 55%	18/23 = 78%	19/26 = 73%	21/28 = 75%
	PP analysis	12/21 = 57%	18/22 = 82%	19/23 = 83%	21/26 = 81%

Conclusion: In those who are sensitive to clarithromycin, standard clarithromycin-based triple therapy achieves an acceptable eradication rate of approximately 81%. However, a high primary clarithromycin resistance rate was observed in this study (47%). In those who are resistant to clarithromycin, prescribing a regimen based antibiotic susceptibilities increases eradication rates to 83%, compared to those treated with standard triple therapy (57%, $p=0.09$).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1911 TREATING *HELICOBACTER PYLORI* INFECTION SECOND TIME ROUND: IS TAILORING THERAPY BASED ON ANTIMICROBIAL SUSCEPTIBILITY THE BEST OPTION?

D. Brennan, M. Hussey, D. Tighe, C. O'Morain, S. Smith, D. McNamara
Trinity Academic Gastroenterology Group, Trinity College Dublin, Dublin/Ireland

Contact E-mail Address: dbrenna9@tcd.ie

Introduction: Due to increasing prevalence of antibiotic-resistant *Helicobacter pylori*, the number of patients who require rescue treatment (after 1 or more failed eradication attempts) is increasing. The Irish *Helicobacter pylori* Working Group consensus for the diagnosis and treatment of *H. pylori* infection in adult patients in Ireland recommendeds that second-line and subsequent treatments depend on the first-line treatment and should not be the same treatment. First-line treatment for *H. pylori* is not standardised in Ireland, therefore it's difficult to recommend a specific rescue treatment. Prescribing a tailored regimen based on antibiotic sensitivities upon first eradication failure may be most effective.

Aims & Methods: The aim of this study was to examine the efficacy of a tailored regimen based on antimicrobial susceptibility as a rescue treatment for *H. pylori* infection. Patients previously treated for *H. pylori* and undergoing endoscopy were prospectively recruited. Biopsies from *H. pylori*-positive patients (CLO test) were processed for sensitivity testing by E-testing and genotyping by the GenoType HelicoDR assay (Hain). Patients received treatment based on antibiotic sensitivities, for 7/14 days. A follow-up breath test was performed 8 weeks post-treatment.

Results: Of 889 gastroscopies done between April 2013- February 2017, 186 (20.9%) were *H. pylori* positive. Of these, 74 (39.8%) were previously treated: 39 (52.7%) received one prior treatment and 35 (47.3%) received >1. Thus far, 55 patients have agreed to participate and been eligible for the study; 44 (80%) patients have completed the study. 27 (49%) patients have received levofloxacin triple therapy; 14 (26%) a PPI and 2 antibiotics based on their sensitivities; 10 (18%) bismuth quadruple and 4 (7%) clarithromycin triple therapy. The efficacy of tailored treatment by intention-to-treat and per protocol analysis was poor, at 47.3% (26/55) and 59.1% (26/44) respectively. Patients who received one previous treatment were significantly more likely to achieve eradication than those who received >1 previous treatment (76.2% vs 43.5%, $p=0.04$).

Conclusion: Rescue eradication rates are disappointing. Eradication rates in patients who received more than one previous treatment were significantly lower than those who had just one previous treatment (43.5% vs 76.2%, $p=0.04$). This emphasizes the importance of eradicating *H. pylori* infection the first time round, before more virulent or antimicrobial resistant strains are selected for.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: *Helicobacter pylori* (Hp) successful eradication has been considered since it contributes to several gastrointestinal disorders. Sequential therapy has been used widely as the first approach in Hp eradication therapy (HpET). However, its fails in 10–45%. The addition of probiotics has been considered because of potential benefit in the improvement of efficacy and reduction of side effects during HpET.

Aims & Methods: We aimed to evaluate the effect of probiotics, as adjuvant to sequential HpET on treatment efficacy, side effects and patient compliance. This was a prospective study of total of 1159 patients followed in a gastroenterology outpatient clinic. Selected patients undergone Hp screening for unexplained gastrointestinal symptoms or disorders with HpET indication. Compared patients undergone sequential therapy (10-day treatment of 5 days of pantoprazole + amoxicillin followed by further 5 days of pantoprazole + clarithromycin + metronidazole-G1:n=85) and patients with additional supplement of *Lactobacillus reuteri*protektis therapy 2tablets/day in previous two weeks and during treatment (G2:n=77), since it was approved for this indication. Screening Hp test and indication, eradication rate, auto-reported side effects and patient compliance were evaluated.

Results: Of 265(22.9%) patients underwent screening Hp test, 147(55.5%;147/265) were positive, being the majority obtained by gastric biopsy (86.0%;n=228). The mean age was 58.6 ± 15.8years with women predominance (60.8%;n=161). The main indications for Hp screening were dyspepsia (27.9%), epigastric pain (24.2%), gastroduodenal peptic ulcerous disease(19.2%) and gastroesophageal reflux disease (15.8%). At gastric biopsies, chronic gastritis was present in 61.5% (n=163), gastric atrophy in 17.0% (n=45) and intestinal metaplasia in 7.9% (n=21), with Hp mild colonization in most cases (58.5%;76/130). Eradication rate was significantly higher in patients who had probiotic supplement (G1–74.1%vsG2–92.2%; $p=0.002$;OR=4.132). No significant difference was verified between two groups in relation to side effects (G1–15.3%vsG2–9.1%; $p=0.094$) or patient non-compliance (G1–2.4%vsG2–

0.0%; $p=0.106$). However, significantly higher rates of diarrhea were noted in treated group without probiotics (G1–5.9%vs0.0%; $p=0.031$;OR = 1.063). Of G2 patients, 19(24.5%) performed sequential therapy first, with eradication rate improvement of 78.9%(15/19). The remaining cases that didn't respond were submitted to 14-day of quadruple therapy with PPI+amoxicillin+metronidazole+levofloxacin with success.

Conclusion: Co-adjutant sequential therapy with probiotic *Lactobacillus reuteri protectis*, within previous two weeks to final of treatment, is associated with higher HpET rate, initially or after sequential therapy failure, and lower rate of diarrhea-associated treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1913 THE IMPACT OF *CLOSTRIDIUM BUTYRICUM* MIYAIRI-588 ON *HELICOBACTER PYLORI* ERADICATION THERAPY

S. Takayama, O. Handa, R. Mukai, Y. Suyama, A. Majima, Y. Onozawa, O. Dohi, T. Okayama, N. Yoshida, K. Kamada, K. Katada, K. Uchiyama, T. Ishikawa, T. Takagi, H. Konishi, Y. Naito, Y. Itoh

Introduction: As a country with high incidence of gastric cancer, the elimination of *Helicobacter pylori* (HP) is useful strategy for the prevention of gastric cancer in Japan. And the eradication therapy for HP-infected gastritis was approved as an insurance indication since 2013, and virtually all HP-infected patients were subject to eradication. In Japan, triple therapy using proton pump inhibitor (PPI)/amoxicillin (AMPC)/clarithromycin (CAM) has been used as a regimen for the primary eradication therapy. Since HP has rapidly acquired the resistant character against CAM, the eradication rate has gradually been decreasing. Recently, vonoprazan (VPZ), a novel potassium competitive acid blocker, has been approved for HP eradication therapy. Recently, higher HP-eradication ratio by VPZ+AMPC+CAM than PPI based triple therapy has been reported. However, there might be some concern for the use of VPZ; higher serum gastrin, decrease in the diversity of intestinal microbiota and increase in colitis. Therefore, PPI-based triple therapy is still used, and additive effect of probiotics has been reported in these therapy.

Aims & Methods: The aim of this study is to investigate the effect of probiotics, *Clostridium butyricum* Miyairi-588 (Miya-BM®:MBM) on PPI-based triple therapy comparing the eradication rate and side effect with VPZ-based triple therapy. From January 2015 to December 2016, patients who received HP primary eradication therapy in our hospital were retrospectively evaluated. They were divided into three groups; 1) patients who received PPI+AMPC+CAM therapy (PPI group), and 2) patients who received VPZ+AMPC+CAM therapy (VPZ group), 3) patients who received PPI+AMPC+CAM+MBM therapy (PPI+MBM group), and the eradication rate and side effects were evaluated.

Results: The number of patients enrolled in this study were 468; 150 cases in the PPI group, 271 cases in the VPZ group and 47 cases in the PPI+MBM group. Successful rate of HP eradication was 81.7% in the PPI group, 89.8% in the VPZ group and 89.1% in the PPI+MBM group. The eradication rate in VPZ group was significantly higher than PPI group. However, the eradication rate of VPZ group was not significantly higher than that of PPI+MBM group. The rate of side effect was 14.7% in the PPI group, 10.0% in the VPZ group and 19.1% in the PPI+MBM group, and there was no significant difference between 3 groups.

Conclusion: The study shows that *Clostridium butyricum* Miyairi-588 can have additive effects in PPI-based triple therapy for HP.

²Gastroenterology, HMIMV RABAT, Rabat/Morocco

Contact E-mail Address: hanaeboutallaka@gmail.com

Introduction: The eradication of *Helicobacter Pylori* remains crucial because of constantly evolving data. The recent recommendations of Maastricht V stipulate that the concomitant quadritherapy and the bismuth quadruple therapy are more efficient than the sequential therapy because of a higher rate of eradication (90% vs 82%), but with more important side effects. The aim of our study is to investigate the effects of the *Saccharomyces boulardii* supplementation to the sequential therapy on *Helicobacter pylori* eradication rate and associated therapy side effects.

Aims & Methods: One hundred ninety nine patients with *Helicobacter pylori* infection documented on a histological study of gastric biopsies were enrolled from May 2013 to May 2016, on a single center, prospective, controlled and randomized study, performed in the Gastro Enterology II department on the military hospital of Rabat. Using a permuted block randomization, our patients were assigned to one of the following groups: a control group receiving the

standard sequential therapy, and an experimental group receiving in addition of sequential therapy, 500mg of *Saccharomyces boulardii* (Ultralevures®) orally and daily during the ten days of regimen. All the patients were reviewed in the end of the therapy to evaluate the adherence to treatment and the incidence and severity of side effects. The eradication of *Helicobacter pylori* was evaluated by 13C-urea breath 4 to 6 weeks after the end of the protocol. Statistical analysis was performed by the software SPSS 20.0. A model of logistic regression was performed to analyse the effects of *Saccharomyces boulardii* supplementation on eradication rate and side effects.

Results: There was no significant difference between the two groups on age (middle age = 44.3+/-13.8years vs 43+/-13.2years), gender (Sex ratio M/ F = 1.15 vs 1.05), medical antecedents, smoking, endoscopic and histological datas. In Intention To Treat ITT and Per Protocol PP analysis, the eradication rate was significantly higher in the experimental group (86.6% ITT, 87.5% PP), comparing to the control group (78.2% ITT 74.7% PP), $p=0.02$. Moreover, the *Saccharomyces boulardii* supplementation allowed a significant reduction of the incidence of overall side effects (RR = 0.26, IC 95% [0.14–0.47], $p < 0.001$), and the incidence of antibiotic-associated diarrhea (RR = 0.07, IC95%[0.028–0.20], $p < 0.001$). The incidence of nausea and vomiting, dizziness, asthenia and metallic taste was also lower in the experimental group, although the differences were not statistically significant. In the multivariate analysis, the *Saccharomyces boulardii* supplementation is associated with an optimization of the eradication rate (RR = 2.4, IC95% = [0.19–1.09], $p=0.02$), and with a reduction of the antibiotic-associated diarrhea AAD (RR = 0.07, IC95% = [0.02–0.26], $p < 0.001$).

Conclusion: Our study shows that the *Saccharomyces boulardii* treatment during sequential therapy in *Helicobacter pylori* regimen is associated with a significant reduction of side effects and particularly the antibiotic-associated diarrhea, and allows an optimization of the eradication rate of *Helicobacter pylori*.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1915 “CONCOMITANT” OR “SEQUENTIAL” THERAPY FOR THE ERADICATION OF *HELICOBACTER PYLORI*: WHICH REGIMEN COMES FIRST IN MOROCCO?

A. Ait Errami, Z. Samlani, S. Oubaha, K. Krati
Hepatogastroenterology, CHU Mohammed VI, Marrakech/Morocco

Contact E-mail Address: adil.ae@hotmail.fr

Introduction: *Helicobacter pylori* (*H. pylori*) infection, the major cause of peptic ulcer disease, is a bacterial infection that can lead to inflammation and ulcers in the lining of the stomach and the upper part of the small intestine. It has been proved that curative treatment of *H. pylori* infection markedly reduces relapse of peptic ulcers, bleeding, and gastric cancer. The decline of *Helicobacter pylori* (*H. pylori*) eradication rates with standard triple therapy resulted in a search for novel therapies for first-line therapy of *H. pylori* infection

Aims & Methods: The objective of this study is to compare, in Morocco, an African country, the efficacy rates of the concomitant versus the sequential *H. pylori* eradication therapy. Our prospective randomized study included 164 patients with newly diagnosed *H. pylori* infection, randomized to receive a 14-day concomitant or 10-day sequential therapy. Treatment outcome was assessed by C13-urea breath test at least 4 weeks after therapy. Intention to treat (ITT) and per protocol (PP) analysis of the eradication rates were performed. Secondary end points included patient compliance and safety.

Results: The concomitant therapy group achieved statistically significant higher eradication rates when compared with the sequential treatment group, both in the ITT and in the PP analysis (86.6% versus 79.9%, $p=0.002$, and 90.6% versus 72.1%, $p=0.001$, respectively), after adjusting for age, gender, smoking status, and the presence or not of ulcer and/or non-ulcer dyspepsia. Both groups displayed excellent compliance rates (99.5% for the concomitant therapy group and 96.2% for the sequential therapy group, $p=0.067$). Regarding treatment safety, major adverse events that led to the discontinuation of both regimens were few, with no statistical difference between the two groups (6.2% for the concomitant therapy group and 3.1% for the sequential therapy group).

Conclusion: Concomitant therapy led to statistically significant higher eradication rates over sequential therapy. Both therapies showed excellent compliance and an acceptable safety profile. The 14-day quadruple concomitant scheme should be the adopted for first-line *H. pylori* eradication in Morocco.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1916 PROSPECTIVE COMPARATIVE STUDY OF TWO FIRST-LINE REGIMENS FOR *HELICOBACTER PYLORI* ERADICATION: 14-DAYS NON-BISMUTH QUADRUPLE OPTIMIZED CONCOMITANT THERAPY VERSUS 10-DAYS BISMUTH-CONTAINING QUADRUPLE THERAPY USING A THREE-IN-ONE CAPSULE

Introduction: The Maastricht V/Florence Consensus Report recommends bismuth quadruple or non-bismuth quadruple concomitant therapies as first-line treatments for *H. pylori* infection, in areas where clarithromycin resistance is high (>15%). Head-to-head studies between both therapies are needed.

Aims & Methods: We aimed to compare compliance, efficacy and adverse effects of two first-line *H. pylori* eradication therapies in a high clarithromycin resistance

area, and in clinical practice. A prospective study was performed in a Spanish center recruiting consecutive naïve adult patients, candidates to *H. pylori* eradication. Omeprazole 40mg, Clarithromycin 500mg, Amoxicillin 1g and Metronidazole 500mg, all drugs b.i.d, for 14 days (OCAM); or Omeprazole 20mg b.i.d and 3-in-1 capsule with Bismuth 140mg + Tetracycline 125mg + Metronidazole 125mg, 3 capsules q.i.d, for 10 days (3-1-OBMT) were prescribed according to physician criteria. Compliance was assessed by striking the consumed doses in a patient filled template, and adverse effects using a specific questionnaire with a 1–3 intensity scale. Efficacy was determined by 13C-urea breath test. A descriptive study and analysis of efficacy by intention to treat (ITT) were performed. Cases with poor therapeutic compliance (<80%) or no available data were excluded in per-protocol (PP) analysis. Chi2, Student's t, and Mann-Whitney U tests with significance level $p < 0.05$ were applied. The protocol was approved by the Ethics Committee.

Results: 216 patients (63.43% women; mean age 51.53 -range 19–84 years-) were included. OCAM were prescribed in 103 and 3-1-OBMT in 113. No differences in age, sex and functional dyspepsia as indication to eradicate were observed between groups. Main indications for treatment were functional dyspepsia (39.35%), gastroduodenal ulcer (19.44%) and non-investigated dyspepsia (13.89%). Compliance was <80% in 11 patients and unknown in 7. The efficacy outcome was unavailable in 9 subjects. Compliance $\geq 80\%$ was obtained in 96% with OCAM and in 93.53% with 3-1-OBMT ($p=0.64$). The ITT rates were 82.52% vs 85.84% ($p=0.63$), and PP 89.47% vs 96.04% ($p=0.13$), for OCAM and 3-1-OBMT respectively. The outcomes of adverse effects (frequency, number, duration and intensity) are shown in the Table.

	Frequency [%]	Number [Mean (SD)]	Days [Mean (SD)]	Maximum Intensity [%]			
				None	Mild	Moderate	Intense
OCAM	96.97	4.08 (2.49)	10.07 (4.6)	3.41	20.45	22.73	53.41
OBMT	91.51	3.92 (2.6)	6.02 (3.43)	7.14	19.39	40.82	32.65
p-value	0.17	0.70	<0.0001	0.0149			

Conclusion: In a high clarithromycin resistance area, 14-days OCAM and 10-days 3-1-OBMT regimens achieve high and similar compliance and efficacy rates, but 3-1-OBMT provides a superior safety profile.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: We have detected a large increase of urea breath test (UBT) requests for *Helicobacter pylori* (Hp) diagnosis by primary care physicians (PCP). In this way, most Hp-infected patients are now being managed at primary care level. However, little is known about outcomes of Hp infection by PCP.

Aims & Methods: 1. To evaluate and compare the eligibility of UBT indications, treatment regimens and eradication rates between PCP and gastroenterology specialist (GS). 2. To evaluate the effect of introduction of specific counselling to PCP in the management profile of Hp infection. First, we prospectively included 500 consecutive UBT indicated by PCP (250) and GS. Appropriate UBT indications were considered those included in the 3rd Spanish Consensus Conference on *Helicobacter pylori* infection (1). Hp treatment prescribed and eradication rates were collected retrospectively. Finally, we analyzed another consecutive 240 UBT and treatment outcomes after the introduction of specific counselling to PCP (a personal letter with the accepted indications for UBT and treatment issued by their referent GS). Statistical analysis was performed using SPSS (version 22.0).

Results: We have analyzed 740 UBT (500 pre-intervention and 240 post-intervention). 66.89% women, mean age of 48.94 \pm 16.6 years. Most (68.4%) of pre-intervention UBT were performed for the initial diagnosis of Hp infection, and the rest were indicated after previous eradication treatment. Inappropriate indication of UBT in the pre-intervention cohort was significantly higher in those test requested by PCP compared to GS (36.4% vs 7.2%; $p < 0.001$). Also, inappropriate treatment regimens were significantly higher in the PCP group (65% vs 26.4%; $p < 0.0001$). Consequently, eradication rates were significantly lower in PCP compared to GS group (57.1% vs 81.1%; $p < 0.001$). A significant increase in the adherence to appropriate treatment regimens (71% vs 35%; $p < 0.0001$) and eradication rates (78% vs 57.1%; $p < 0.0001$) were observed in the PCP group after the implementation of specific counselling based on national guidelines.

Conclusion: Hp infection management at primary care level is inappropriate with very low Hp infection eradication rates. The introduction of a specific counselling to PCP has significantly improved these outcomes. These data should encourage the implementation of interventional strategies in order to reduce the actual increase in antibiotic resistance.

Disclosure of Interest: All authors have declared no conflicts of interest.

SMALL INTESTINAL III - HALL 7_

P1918 VALPROATE AND CHIR 99201 AMELIORATES RADIATION-INDUCED INTESTINAL EPITHELIAL INJURY IN MOUSE MODEL

Y. Kim, J.S. Shin

Internal Medicine, Division Of Gastroenterology, Korea Cancer Center Hospital, Seoul/Korea, Republic of

Contact E-mail Address: younjoo282@gmail.com

Introduction: Radiation-induced gastrointestinal syndrome (RIGS) stems from the clonogenic loss of crypt cells and villi depopulation and results in mucosal barrier disruption, bacterial invasion, inflammation and sepsis. Valproate (VPA) is the one of the popular anti-convulsants, recently its Notch signal modulatory effect has been reported. Notch signal pathway is the essential to maintain intestinal stem cells and to differentiate to secretory cells such as goblet cells. Moreover, It has been reported that combination of VPA and CHIR 99021 (GSK3B inhibitor) has powerful proliferative effect for intestinal stem cells, such as Lgr 5+ cells. One of the major difficulties for RIGS studies is the fact that crypts are not easily accessed and cultured with traditional means. Ex-vivo culture techniques for single crypt or a stem cell derived enteroid, with essential features of the in vivo tissue architecture, have been recently developed. Thus, we have adopted the 3D-cultured enteroids for RIGS ex-vivo model, and proved the effect of VPA and SCFAs for RIGS.

Aims & Methods: We have adopted the 3D-cultured enteroids for RIGS ex-vivo model, and proved the effect of VPA and SCFAs for RIGS. To culture enteroid, ten centimeters segments of jejunum were procured from 9–13 week-old C57BL/6 mice. Crypts were isolated by EDTA chelation, suspended in Matrigel and grown in culture media containing epidermal growth factor, noggin, R-spondin 1. After 1 day in culture, the enteroids were treated (or not) 3 mM CHIR 99021 (GSK3B inhibitor) and 1 mM VPA. On day 3, the enteroids were irradiated as a dose dependent manner. The evaluation of irradiated enteroids was performed by measuring MTT assay, budding efficiency of enteroid, and EdU staining. On post-irradiation Day 2 and Day 7, RT-PCR was performed.

Results: Enteroid from mouse had multiple crypts ('budding') with well-differentiated goblet, Paneth cells, +4 stem cells (quiescence stem cells, BMI1 is expressed), Lgr5+ stem cells. In the response of radiation, irradiated enteroid decreased proliferation rate in a dose dependent manner, as measured by MTT assay and budding efficiency of enteroids. Irradiated enteroids with VPA + CHIR 99021 could maintain their +4 stem cells even in 10 Gy of irradiation, lethal dose of mouse intestinal epithelium., and they were able to proliferation. Combination of VPA + CHIR 99021 did not have an effect on paneth cells, enterochromaffin cells and goblet cells.

Conclusion: VPA and CHIR 99021 may ameliorate RIGS in ex-vivo mouse enteroid, through +4 reservoir stem cell preservation and stimulatory action for epithelial proliferation. Considering their clinical application such as safety, they could be possible strategy for prevention and treatment of RIGS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Celiac disease (CD) is an important health problem worldwide. It is characterized by a high prevalence (1%), non specific morbidity, long-term complications and epidemiological progression. However, mass screening is not recommended. Currently, the strategy of 'Targeted screening,' defined as screening of high-risk groups, is widely practiced and recommended by learned Societies, in particular, in relatives of CD patients. In the world, targeted screening studies related to CD showed prevalence ranging from 4.2 to 13%.

Aims & Methods: The main aim of our study is to determine the prevalence of CD in the first degree relatives in Algerian population. This was a descriptive-transversal study with prospective recruiting. This is a screening of first-degree relatives of patients known and treated for CD. Relatives are screened by using antitransglutaminase (TTG) antibodies in the serum. Upper digestive endoscopy and duodenal biopsy are performed in all sero-positive relatives and graded as per Marsh modified by Oberhuber classification to confirm the diagnosis. 546 first degree relatives of 107 families are included in our study.

Results: Among the 546 first-degree relatives, we have 18.5% of parents, 57.5% of siblings and 24% of children; 44 cases have positive anti TTG antibodies. The prevalence of CD among first-degree relatives is 8.1% with Confident Interval (CI) at 95% [5.8–10.4]. The prevalence of CD in first-degree relatives with positive serology and positive duodenal biopsy is 7.3% with CI at 95% [5.2–9.4]. Histo-pathological study of duodenal biopsies of new cases, detected by targeted screening, shows 5 cases of Marsh I, 5 cases Marsh IIIa, 27 cases Marsh IIIB and 3 cases Marsh IIIC. 44 patients are screened with CD; they are divided as follows: 9% Parents (4 mothers), 11% of children (son 3 and 5 girls) and 72% of siblings (brothers and 23 sisters 9). The average age of screening cases is 31.8 years with CI at 95% [27.2 to 36.4] and extremes of [3–71] years. The mean duration of symptoms before diagnosis is 3.4 years, with CI at 95% [2.8 to 4.0] years. Among the 44 new cases detected by targeted screening, whereas 11.4% are asymptomatic, 88.6% are symptomatic. This is a classical form in one case and atypical form in 86.4% of cases.

Conclusion: The present work entitled "Prevalence of celiac disease in relatives" is the first screening study of CD in the first-degree relatives carried out in Algeria. Among the 546 first-degree relatives, it is showed that 44 patients present positive serology which corresponds to the prevalence of CD in first degree relatives of 8.1% with CI at 95% [5.8–10.4]. Our investigation supports the idea that the development of an extensive screening approach is needed to promote early diagnosis and to prevent complications of CD in first-degree relatives.

P1920 LONG-TERM HEALTH AND LIFESTYLE OUTCOMES IN ADULT CELIAC DISEASE PATIENTS DIAGNOSED IN CHILDHOOD BECAUSE OF CLINICAL SUSPICION OR BY SCREENING

L. Kivela¹, S. Alin², S. Kröger², K. Kaukinen², K. Kurppa²

¹Tampere Center For Child Health Research, University of Tampere and Tampere University Hospital, University of Tampere/Finland

²School Of Medicine, University of Tampere, Tampere/Finland

Contact E-mail Address: laura.kivela@fimnet.fi

Introduction: Celiac disease affects 1–2% of population, but due to diverse presentation most patients remain unrecognized. Diagnostic efficiency could be improved by screening of at-risk groups, but long-term benefits of this approach are unclear. To shed light to this issue, we compared a variety of celiac disease-related and other parameters in large cohorts of adult patients diagnosed in childhood either because of clinical suspicion or by screening.

Aims & Methods: A questionnaire about current health and lifestyle, adherence to gluten-free diet (GFD) and follow-up of celiac disease was sent to 564 adults with a childhood diagnosis. Further, the participants fulfilled validated Gastrointestinal Symptom Rating Scale (GSRS) and Psychological General Well-Being (PGWB) surveys for symptoms and quality of life. Clinical and histological presentation at diagnosis and other relevant medical data were confirmed from patient records. All variables were compared between screen-detected and clinically detected patients.

Results: Altogether 235 (42%) adults completed the questionnaires. At diagnosis, screen-detected patients (n=49) were older (11.3 vs 8.8 yr, p=0.016) and had less symptoms (44% vs 85%, p<0.001) and poor growth (17% vs 51%, p<0.001) than clinically detected patients (n=186). They also had a trend to have less often total villous atrophy (18% vs 32%, p=0.075) and anemia (18% vs 32%, p=0.072). The groups did not differ in gender, current age (median 26.5 vs 27.1 yr, p=0.245), time from the diagnosis, self-experienced health or concern about health, clinical symptoms, strict GFD (74% vs 80%, p=0.161), lifestyle restrictions caused by GFD, presence of celiac disease-related complications, physical activity, fertility or GSRS and PGWB scores. However, screen-detected patients smoked less (4% vs 15%, p=0.037) and had more often celiac disease in relatives (78% vs 58%, p=0.011).

Conclusion: Diagnostic approach and presentation of celiac disease in childhood do not seem to affect the long-term health outcomes or attitude towards the

disease in adulthood. Lack of difference in the dietary adherence and lifestyle restrictions gives further support for active screening and early diagnosis of celiac disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1921 REVIEW OF SERVICE PROVISION OF NATIONAL INSTITUTE FOR HEALTH AND CARE EXCELLENCE (NICE) RECOMMENDED QUALITY STANDARDS FOR COELIAC DISEASE AT A BIG DISTRICT GENERAL HOSPITAL

F.K. Shaikh, D. Vani, M. Sprakes, F. Greenhalgh

Gastroenterology, Mid Yorkshire Hospitals NHS Trust, Wakefield/United Kingdom

Contact E-mail Address: sheikh177@yahoo.com

Introduction: In the UK, 1 in 100 people are affected with coeliac disease. NICE published quality standards (QS134) for coeliac disease in October 2016 based on NICE guidelines NG20 (September 2015). This quality standard covers the recognition, assessment and management of coeliac disease in children, young people and adults. The quality standard is expected to contribute to improvements in the diagnosis of coeliac disease, growth in children and young people, health-related quality of life, incidence of osteoporosis, intestinal lymphoma, vitamin D deficiency, and iron deficiency

Aims & Methods: We audited our departmental practices against NICE quality standards for coeliac disease. It is a retrospective data analysis of patients, 16 years and above, with positive coeliac serology from April 2016 to September 2016. The main parameters examined were source of referral, value of tissue transglutaminase (tTG) antibodies, type of referral (new or follow up), timing of OGD (less than or more than 6 weeks), whether or not seen by dietician, offer of annual review, and DEXA scan.

Results: Total of 95 cases were examined. The General Practitioner was the main source of referral for tTG antibody (76%) test followed by gastroenterology outpatients (OP) (13%), 2% each was shared by surgical OP and inpatient gastroenterology services. Other referrers contributed 3% each. 88% (84 out of 95) positive tTG results was more than 20 U/ml. 53 out of 95 (56%) were new referrals, 30 (31%) were follow-up and 12 (13%) referrals had no further record on system. 11 of 53 (21%) new patients had OGD in less than 6 weeks; 30 of 53 (56%) had OGD in more than 6 weeks, 22 of 95 (23%) had no record of OGD on system. 56 of 95 (59%) patients had dietician review. 26 of 95 (27%) were offered or had annual review. 42 of 95 (44%) had DEXA scan to assess bone density.

Conclusion: The incidence and prevalence of coeliac disease in our study are 30.28 per 100,000 persons-years and 8 per 100,000 population respectively. The data demonstrates that Mid Yorkshire NHS Trust is not providing required service standards for optimum care of coeliac patients in the Mid Yorkshire region. We need to keep in mind that some gastroscopies would have been performed in the primary care sector, the records of which were not available on our system. This factor could have potentially affected our results. Due to several constraints in our service provision, time frames stipulated in the NICE guidance are challenging as evidenced by the audit results. In spite of our unique local access to endoscopy units in primary care, we are still not able to deliver the required standards of care. Given the potential disease sequelae of coeliac disease, such as osteoporosis and lymphoma, it is important that these issues are addressed by the development of local referral and management pathways to ensure that all coeliacs are captured, investigated, and followed up appropriately.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: liisa.viitasalo@uta.fi

Introduction: In nonresponsive celiac disease (NRCD) the symptoms and duodenal damage persists despite a gluten-free diet (GFD). We have previously shown an association between dysbiotic microbiota and persistent symptoms in treated CD (1). Furthermore, serum microbial antibodies to *Saccharomyces cerevisiae* (ASCA), *Pseudomonas fluorescens*-associated sequence (I2) and *Bacteroides caccae* TonB-linked outer membrane protein (OmpW) were found to be gluten-sensitive (2) and present already at early stages of CD development (3). We hypothesized that increased seroreactivity to microbial antibodies is associated also with NRCD.

Aims & Methods: Serum ASCA, I2 and OmpW were measured in 20 CD patients with persistent villous atrophy and mucosal inflammation despite strict GFD and negative celiac serology (NRCD group). Corresponding GFD responsive patients served as CD controls (58 samples at diagnosis and 55 on GFD) and

80 healthy blood donors as non-CD controls. Kruskal-Wallis test was used to compare antibody titers and Dunn-Bonferroni for post hoc pairwise comparisons.

Results: At least one serum microbial marker was positive in 80% of NRCD patients, in 97% of untreated and 87% of treated CD patients and in 44% of non-CD controls. NRCD patients had the highest frequency of ASCA positivity (64% vs 52%, 20% and 0%, respectively) and also significantly higher ASCA IgA (median 14.5 U/ml) and IgG (32.5 U/ml) titers than treated CD patients (7.0 U/ml, 13.0 U/ml) and non-CD controls (4.5 U/ml, 5.8 U/ml). There was no difference in ASCA between NRCD and untreated CD. The frequencies of I2 (65%) and OmpW (45%) were lower in NRCD than in untreated CD (86%, 59%, respectively), while I2 titers were higher in NRCD (median absorbance 0.76) and untreated (1.0) and treated (0.83) CD than non-CD controls (0.32). OmpW was elevated in untreated (1.1) and treated (0.94) CD patients compared with non-CD controls (0.79).

Conclusion: Seropositivity and high titers of ASCA were associated with NRCD and might thus serve as additional follow-up tool for histological recovery in CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: High levels of reactive oxygen species (ROS) and impaired antioxidant defense systems lead to oxidative stress (OxS) and tissue injury in different intestinal and extraintestinal conditions, including celiac disease (CD). A possible effect of gluten ingestion on intracellular oxidative imbalance has been suggested.

Aims & Methods: The first aim of the study was to investigate the effects of OxS in CD, evaluating the levels of ROS and oxidative damage biomarkers in sera of naïve patients (N-CD), coeliac patients on a gluten-free diet (GFD) including responders (CD-GFD) or non-responders (NRCD) to dietary treatment. The second aim was to look for new serological biomarkers corresponding to morphological/functional alterations detected in biopsies according to Marsh-Oberhuber classification. Finally, a possible correlation between ROS production and/or biomarkers of OxS and/or hematological data was investigated. Analysis were conducted on small intestinal biopsy specimens and peripheral blood samples of celiac patients (N-CD, CD-GFD and NRCD). The methods included Electron Paramagnetic Resonance (EPR) technique for ROS detection, High Performance Liquid Chromatography (HPLC) analysis of erythrocytes glutathione (GSH), enzymatic assays for oxidative damage biomarkers (lipid peroxidation measured by thiobarbituric acid-reactive substances (TBARS) method; protein oxidation, measured by a protein carbonyl (PC) assay kit; total

antioxidant capacity (TAC), measured by an enzymatic kit; nitric oxides metabolites in sera, assessed by the Griess method).

Results: Overall, blood samples and biopsies from 54 patients affected by CD were collected (44 F; median age 43.98 ± 13.44 years; range 19–80 years; 17 N-CD, 18 CD-GFD and 19 NRCD). Hemoglobin and haematocrit levels were significantly lower in NRCD and N-CD than in CD-GFD group ($p < 0.05$). In our study, a significantly increased production of ROS, lipid peroxidation and oxidized protein levels, plasma nitrate concentrations were reported in NRCD and N-CD compared to CD-GFD. On the contrary, the TAC and GSH levels were significantly decreased in N-CD and NRCD groups compared to CD-GFD. Data are summarized in Table 1. A significant direct relationship between Marsh subtypes and ROS production rate ($R^2 = 0.19$; $p < 0.001$), TBARS ($R^2 = 0.20$; $p < 0.001$) and PC ($R^2 = 0.17$; $p < 0.001$) was found by Pearson's product-moment correlation while an inverse correlation between Marsh subtypes and TAC ($R^2 = 0.23$; $p < 0.001$) and GSH ($R^2 = 0.34$; $p < 0.0001$) was identified. In all groups of patients, at higher ROS production rate levels corresponded to greater plasma TBARS concentrations and lower erythrocytic GSH levels.

Conclusion: Several defense mechanisms are implied in maintaining the cell integrity and tissue homeostasis. According to our results, the presence of higher levels of ROS, oxidative damage biomarkers and nitric oxides metabolites in naïve and non-responders patients suggest an implication of OxS in the functional and histological damage of CD. In parallel, the antioxidant capacity of celiac patients with the active form of the disease is significantly reduced. On the contrary, in patients responding to GFD, the pro-oxidant/antioxidant balance seems to be greatly recovered.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1924 CIRCULATING EXTRACELLULAR VESICLES, A NOVEL MECHANISM OF ENDOCRINE CELLULAR CROSS-TALK, ARE INCREASED IN NEWLY DIAGNOSED CELIAC DISEASE PATIENTS

K. Efthymakis, G. Bologna, P. Lanuti, C. Pipino, A. Milano, F. Laterza, P. Simeone, A. Bonitatus, A. Pandolfi, M. Marchisio, S. Miscia, M. Neri
Department Of Medicine And Ageing Sciences And Center For Excellence On Ageing And Translational Medicine (cesi-met), "G. D'Annunzio" University and Foundation, Chieti/Italy

Contact E-mail Address: efkn78@gmail.com

Introduction: Extracellular vesicles (EVs) have been recently hypothesized to represent a major peripheral mechanism of cellular cross-talk. EVs carry surface receptors and proteins characteristic of their cells of origin and shuttle molecules (proteins, RNAs, microRNAs) potentially controlling physiological and pathological systemic processes. Recent studies have demonstrated an increased number of circulating EVs in a variety of conditions characterized by multi-organ impairment and/or damage such as insulin-resistance, atherosclerosis and obesity. Celiac disease (CD) is an immune-mediated inflammatory enteropathy, elicited by gluten ingestion in genetically susceptible individuals. It is frequently associated with a variety of systemic conditions both autoimmune and potentially immune-mediated in nature.

Aims & Methods: The aim of this study was to assess and characterize patterns of circulating EVs in newly diagnosed CD patients. We enrolled consecutive adult anti-tTG positive, biopsy proven CD patients. Circulating EVs were identified untouched on whole blood samples by a no-lyse/no-wash method, combined with EVs volumetric count (FACSVerse, BD), based on a novel six-colour flow cytometry panel, in order to identify and enumerate both the whole EV compartment and different EVs subpopulations. Data are expressed as mean ± SD and statistical differences were evaluated by means of T-test.

Results: We evaluated 12 celiac adults (mean age = 42.9 ± 19.1 vs. 40.8 ± 15.9 years, F/M = 4:1) at diagnosis and 12 age- and sex-matched healthy controls. Histology was considered positive for lesions of grade ≥ B1 according to the Corazza-Villanacci classification. Mean anti-tTG levels at diagnosis were 6.9 ± 3.5 times ULN. Mean number of total circulating EVs was significantly higher in CD than in controls (59895 ± 72482 vs 14383 ± 10018 EV/microL, $p = 0.035$). Subgroup analysis showed that EpCAM+ EVs, of epithelial origin, and CD41+ platelet-derived EVs were not significantly different between CD and controls (894 ± 1004 vs. 548 ± 1237 and 3052 ± 1563 vs. 1734 ± 1810 respectively, $p = ns$). On the contrary, CD45+ EVs, of leucocyte origin, showed a significantly higher number in CD patients vs. controls (460 ± 492 vs. 119 ± 150 $p = 0.026$).

Abstract No: P1923

Data on levels of ROS and oxidative damage biomarkers in sera of naïve patients (N-CD), coeliac patients on a gluten-free diet (GFD) including responders (CD-GFD) or non-responders (NRCD) to treatment.

	N-CD	NRCD	CD-GFD	P value
ROS production ($\mu\text{mol} \cdot \text{min}^{-1}$)	0.21 ± 0.03*	0.22 ± 0.04^	0.17 ± 0.03**	*^ < 0.05
TAC levels (mM)	1.07 ± 0.30*	1.16 ± 0.47^	1.68 ± 0.54**	* < 0.01, ^ < 0.05
GSH levels ($\mu\text{mol} \cdot \text{L}^{-1}$)	534.40 ± 37.46*	507.80 ± 81.73*	634.00 ± 187.80**	* < 0.001, ^ < 0.0001
Peroxidized lipid levels (μM)	3.59 ± 0.67*	3.46 ± 0.87^	2.82 ± 0.47**	* < 0.01, ^ < 0.05
Oxidized proteins levels ($\text{nmol} \cdot \text{mg}^{-1}$ protein)	1.42 ± 0.43*	1.23 ± 0.53^	0.91 ± 0.20**	* < 0.001, ^ < 0.05
Plasma nitrates concentrations ($\mu\text{mol} \cdot \text{L}^{-1}$)	99.74 ± 30.76*	54.61 ± 14.57^	22.21 ± 6.92**	* < 0.001, ^ < 0.01

Conclusion: Celiac disease patients at diagnosis show higher numbers of circulating EVs than age- and sex-matched controls. Phenotypical assessment suggests that this increase is not primarily driven by epithelial or endothelial damage. On the contrary, the increased numbers of leucocyte-derived EVs, suggest their potential implication in systemic signaling.

P1925 COELIAC DISEASE AND REPRODUCTIVE DISORDERS: IS THERE ANY CORRELATION

H. Boutallaka, I. Benelbarhadi, F.Z. Ajana
Medecine C, Ibn Sina University Hospital, Rabat/Morocco

Contact E-mail Address: hanaeboutallaka@gmail.com

Introduction: The coeliac disease is an autoimmune enteropathy induced by the ingested gluten proteins (Corn, barley, rye), that occurs in people who are genetically predisposed primarily affecting the small intestine inducing atrophic lesions, which are regressive with a gluten-free diet. The classic form is actually a minority of patients. The extradigestive forms are currently the most found, with varied manifestations including reproductive disorders. The aim of our study is to evaluate the frequency of these disorders in the coeliac disease and their evolution under gluten-free diet.

Aims & Methods: It's a single-center, retrospective and descriptive study including 241 patients with coeliac disease enrolled within period of 17 years from 1995 to 2016 in the department of Gastroenterology « Medecine C » in Ibn Sina University Hospital.

Results: About 241 patients suffering from coeliac disease, 58 patients presented reproductive disorders, either 28.9%. Recruiting 53 women and 5 men, with a sex ratio M/F of 10/6. The mean age was 32.25 years ranging from 13 to 59 years old. The diagnosis of coeliac disease was based on: Histology (severe or partial Villous atrophy with intraepithelial lymphocytosis exceeding 30%), the antiendomysial antibodies and/or antitransglutaminase antibodies positive. The reproductive disorders were never isolated but always associated with digestive or extradigestive signs at the time of the diagnosis of coeliac disease. These disorders were manifested by: retarding puberty in 11 cases (19%), secondary amenorrhea in 13 cases (22.4%), Metrorrhagia in 12 cases (20.6%), absence of development of secondary sexual characters in 8 cases (12.5%), spontaneous abortion in 7 cases (10.9%), menometrorrhagia in 4 cases (13.8%), primary sterility in 5 cases (8.6%), precocious menopause in 6 cases (10.3%), premature labour and/or IUGR in 3 cases (5%), primary amenorrhea in 2 cases (3.4%), and intrauterine Foetal death IUFD in one case (1.7%). All our patients benefited from a gluten-free diet. 15 patients were excluded from the study, 2 patients died, and 12 patients are still under follow-up. Of the 29 patients stayed, the evolution of the reproductive disorders under gluten-free diet was good in 26 cases (90%), with normalization of the cycles in 15 cases. The cycle was returned in 6 cases, development of secondary sexual characters in 2 cases, fertility was returned in one case, one case developed her cycle after primary amenorrhea, and one case was delivered a baby in term after a repeated premature deliveries. The evolution was good in 3 cases as regard missed abortion four years after the gluten-free diet in 1 patient, and amenorrhea continued in 2 cases.

Conclusion: Reproductive disorders related to the coeliac disease were frequent and variable. In our study, these disorders well responded to the gluten-free diet in 90% of cases, and these disorders were reversible under gluten-free diet.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1926 SEVERITY OF MUCOSAL DAMAGE AND TISSUE TRANSGLUTAMINASE ANTIBODY LEVELS CORRELATE WELL IN ADULT CELIAC DISEASE IRRESPECTIVE OF CLINICAL FEATURES

R. Maxim¹, A. Trifan², A. Plesa², S. C. Oana Cristina¹, I. Ciortescu², I. Gîrleanu², C. Stanciu³

Introduction: Celiac disease (CD) is a chronic immune-mediated enteropathy that occurs in genetically predisposed individuals. The clinical phenotypes ranges from classical gastrointestinal manifestations to only atypical signs, thus making the clinical diagnosis a challenge. The aim of the study was to investigate the relationship between duodenal histology, specific antibody levels and clinical presentation in adult CD Romanian patients.

Aims & Methods: Study design: retrospective retrieval of information prospectively entered into a structured database including 81 adult patients diagnosed with CD hospitalized at the Institute of Gastroenterology and Hepatology, "St. Spiridon" Hospital, Iasi between January, 2012- December, 2016 admitted with symptoms of abdominal disturbances (diarrhoea, heartburn, nausea, vomiting, regurgitation, abdominal pain). Demographic, clinical, serological, and histological characteristics of individuals with CD were reviewed.

Results: The study group included 81 adult patients with a female: male ratio of 3:1, 60(71.1%) female patients, mean age 40.02 ± 12.14 years. A total of 48.1% patients presented with gastrointestinal (GI) complaints and 51.9% of patients presented mostly with non-GI manifestations, and advanced age of symptom onset in the latter category (38yrs vs 47yrs). Marsh-Oberhuber classification was

used to assess mucosal injury and Marsh 3c lesions were found in 25 (30.9%) cases. When assessing the serological parameters, IgA anti-tissue transglutaminase (IgA-tTG) antibody (61.45 ± 76.458 u/mL vs 162.02 ± 106.179 u/mL, $P=0.001$) and IgA anti-gliadin antibodies (IgA-AGA) levels (61.83 ± 69.41 u/mL vs 77.15 ± 71.02 u/mL, $P=0.001$) correlated with intestinal villous atrophy (Marsh 3a and 3c) in CD patients by Spearman rank correlation. Among symptoms, abdominal distention and diarrhea were associated with abnormal histology. Hemoglobin levels were evaluated and anemia was diagnosed in 61.7% patients among patients with elevated IgA-tTG levels ($r=-0.316$; $P=0.004$), IgA-AGA ($r=-0.301$; $P=0.006$) and Marsh 3b-3c lesions ($P=0.0048$). Among biological markers included in the statistical analysis, low iron levels (cut off 30mg/dl), hypocholesterolemia and low protein levels were associated with Marsh 3b lesions ($P=0.006$) and elevated tTG-IgA titers ($r=-0.384$; $P=0.001$). **Conclusion:** IgA-tTG and AGA levels correlate with duodenal villous atrophy in adult CD patients. An IgA-tTG titer >160 was nearly always associated with severe CD histopathology. GI and non-GI symptoms are not reliable predictors of CD.

Introduction: Celiac disease is an immunologically-mediated enteropathy that triggered by the intake of gluten-containing foods in genetically predisposed individuals. It causes intestinal and extraintestinal problems. Extraintestinal findings are observed in many systems. The prevalence of extraintestinal findings in the cardiovascular system of celiac disease is not clearly known and the correlation between them has not been yet obviously explained. There is also no data in the literature regarding the association of patent foramen ovale (PFO) and celiac disease, which is 10–25% common in the general population. We performed an echocardiography study to determine the frequency of accompanying cardiac findings in our patients with celiac disease. In this article, we aimed to share the frequency of the PFO detected in celiac patients with high results.

Aims & Methods: Between May-June 2015, 65 patients who applied to the gastroenterology clinic of Derince Education and Research Hospital and followed up with celiac diagnosis were identified. The sociodemographic characteristics, celiac disease diagnosis duration, symptoms and complaints, accompanying diseases, drug use histories, hemogram and biochemical parameters of these patients were recorded. The patients underwent saline contrast transthoracic echocardiography in the cardiology clinic. Patients' data were recorded. The obtained data were evaluated with appropriate statistical methods.

Results: Sixty-five celiac patients were included in the study, 21 (32.3%) male and 44 (67.7%) female. The mean age of the patients was 41.5 ± 14.1 years. PFO was detected in 39 (60%) of the patients. There was no difference in the incidence of PFO in between male and female patients. (61.9% and 59.1% respectively, $p=0.829$). Compared with the frequency of PFO in the general population, the incidence of PFO in celiac patients was higher. (25% and 60% respectively)

Conclusion: As a result, the incidence of PFO is more prevalent in celiac patients than in the general population. For this reason, the evaluation and treatment of the PFO, which may be the cause of cerebrovascular disease in clinical follow-up of patients, are required. In addition, the high incidence of PFO in celiac patients suggests that celiac disease is a factor affecting the development of patients from intrauterine period. Because our patients did not undergo transesophageal echocardiography, this rate may be less than real exist. For this reason, further evaluation is required with a wider patient group and by transesophageal echocardiography.

P1928 USEFULNESS OF BULB BIOPSY SAMPLES IN CELIAC DISEASE DIAGNOSIS IN ADULTS

D.V. Balaban¹, A. Popp², J. Taavela², K. Laurila², M. Mäki², M. Jägingä¹

¹Carol Davila" University of Medicine and Pharmacy, Bucharest/Romania

Introduction: Currently available celiac disease (CD) guidelines recommend sampling of both the bulb and distal duodenum for diagnostics. This has been reinforced by the recent data on ultra-short CD [1]. However, it has been previously shown in pediatric CD that bulb specimens are frequently of poor quality and that morphological injury is common in the duodenal bulb in non-celiac patients also, and it can lead to false-positive diagnoses [2]. Our aim was to address the same issue in adult CD, using the same validated morphometric methods [3].

Aims & Methods: We prospectively recruited cases of clinically recommended upper GI endoscopy; all patients also had signs and symptoms of CD and were checked for CD serology (serum tissue transglutaminase 2 antibodies and endomysial antibodies) and biopsy sampled according with current

recommendations. Paraffin embedded biopsy samples were assessed for villous height (VH), crypt depth (CrD) and VH to CrD ratio (VH:CrD). The corresponding frozen duodenal samples were assessed for duodenal IgA deposits targeting transglutaminase 2 (TG2-IgA), density of CD3 (cut-off 37 cells/mm epithelium) and $\gamma\delta$ T cell receptor bearing intraepithelial lymphocytes/IELs (cut-off 4.3 cells/mm epithelium). The study was approved by the Local Ethical Committee.

Results: Altogether 41 patients, mean age 45 ± 14 years, 61% female, were recruited. Among these, 21 were finally diagnosed as adult CD (mean tTG 156 U/l, median EMA 1:500, and crypt hyperplastic mucosal lesion in distal duodenum) and the rest 20 were non-CD controls (serum negative and normal on distal duodenal biopsy). All patients were on a gluten-containing diet. Quality of bulb biopsy samples was unsatisfactory and unreadable in 67% of CD cases and 50% of controls, even after reorientations and recuttings. All CD patients had, when measurable, VH:CrD < 2 in the anatomical bulb (average 0.31, range 0.02–0.61). On the other hand also non-CD controls had a crypt hyperplastic diseased bulb mucosa in 80% of patients (average VH:CrD 1.65, range 0.7–4.1), but the injury was not that severe as in CD ($p = 0.0006$). Inflammation was significantly higher in CD compared to controls (CD3 81.87 vs. 34.05, $p < 0.01$; $\gamma\delta$ IELs 29.12 vs. 6.44, $p < 0.01$). Bulb IgA deposits were positive in all CD patients and was able to discriminate CD cases from disease controls.

Conclusion: As reported in children, bulb biopsy samples in adults are frequently of poor quality and not reliable for accurate histological measurements. Also, interpretation of results from bulb samples should be done with caution, as non-CD patients may have mild injury in the bulb lining and could be misinterpreted as CD. Assessment of bulb TG2-IgA subepithelial deposits is a powerful tool to confirm CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Celiac disease (CD) is a chronic inflammatory disorder triggered by the ingestion of gluten in genetically susceptible people. The prevalence varies in between European countries and averages at 1% within whole Europe. It is anticipated that the number of undetected and therefore untreated cases is high. Since untreated CD is associated with a high morbidity, further diagnostic modalities to uncover undiagnosed coeliacs are currently explored. In this setting, we evaluate SimtomaxTM, a POCT detecting deamidated gliadin peptide antibodies, with the goal to identify patients at need for duodenal biopsies prior to gastroscopy. Thus, the goal was to establish a test allowing to guide the endoscopist in his decision to collect duodenal biopsies.

Aims & Methods: Prospective investigator-initiated multi-center study in six adult gastroscopy and two pediatric gastroscopy centers in Berlin and Brandenburg, Germany, approved by the local ethical committees. Finger prick blood of patients registered for gastroscopy and eligible for the study (exclusion: defective coagulation, established celiac disease or on gluten-free diet) was analyzed by the POCT (IgA and IgG for deamidated gliadin peptides; SimtomaxTM test, Tillots, Switzerland). Test results were compared with duodenal histology (Marsh classification). In POCT-positive individuals transglutaminase-IgA serology was performed.

Results: Analysis was performed at $n = 721$ adult patients (average age: 48 yrs) and $n = 108$ pediatric patients (average age: 11 yrs). In the adult cohort 45 POCT-tests were judged as “positive”. Within the POCT positives, 6 Marsh III case were detected. None of the 676 POCT-negative individuals revealed CD. Therefore, the prevalence of CD in this population was 0.8%. The POCT-specificity in this group was 94% (95%-CI 92–96%), the sensitivity was 100% (95%-CI 51–100%). In the pediatric cases 21 POCTs were judged as “positive” with 13 being true-positive. Of the 87 negative POCTs, 68 were true-negative, but 4 were false-negatives. Thus, the prevalence of CD in the pediatric gastroscopy was 16%. However, sensitivity in this group was only 76% (CI 50–93%) and specificity 91% (CI 83–96%). Examiners at various centers suggested, that “faint” bands in the POCT analysis might contribute to interpretation failures.

Conclusion: A screening test-like a POCT in CD-needs to perform optimally especially in sensitivity. In the adult population all CDs were detected by the

POCT. However, the CD prevalence in this group was low. In the pediatric group the test revealed a critically lower sensitivity, either due to a sensitivity problem with this serology in the pediatric population or secondary to a suboptimal IgA band expression of the POCT.

P1930 QUALITY STANDARDS IN COELIAC DISEASE: A RETROSPECTIVE EVALUATION IN A SINGLE SPECIALIST CLINIC

M. Fitzpatrick¹, S. Nichols², E. Soilleux², S. Travis³

¹Translational Gastroenterology Unit, Nuffield Department of Medicine, University of Oxford, Oxford/United Kingdom

²Department Of Nutrition And Dietetics, John Radcliffe Hospital, Oxford/United Kingdom

³Gastroenterology Department, John Radcliffe Hospital, Oxford/United Kingdom

Contact E-mail Address: mebfitz@gmail.com

Introduction: Quality standards in coeliac disease management were recently published by the National Institute for Health and Care Excellence¹. These specify a new 6-week target for the time from referral to endoscopy, which was previously covered by the 18-week referral to treatment (RTT) pathway². They also state that all newly-diagnosed patients should discuss a gluten-free diet with a specialist dietician. We retrospectively evaluated practice in the Oxford University Hospitals NHS Foundation Trust coeliac clinic against these criteria, and against national guidelines (duodenal bulb sampling at endoscopy and screening for nutritional deficiency)³.

Aims & Methods: The medical records of 110 patients referred to our clinic between September 2015 and September 2016 were examined. The date of referral and endoscopy were recorded, along with relevant demographic, clinical and laboratory information. Data were collected and analysed in Microsoft Excel.

Results: Eighty-five patients (68% female, median age 34) were seen with suspected or newly-diagnosed coeliac disease, of whom 76 (89%) were referred with positive coeliac serology and would be subject to the 6-week target. Six patients declined or delayed endoscopy, and endoscopy or referral information were not available for 4 patients. For the remaining 66 patients, median time from referral to endoscopy was 12 weeks 2 days (SD 37 days), with 59 patients (89%) within 18 weeks, but only 11 patients (17%) within 6 weeks (Figure 1). Duodenal bulb biopsies were taken at endoscopy in 31 patients (44%). A diagnosis of coeliac disease was made in 74 (87%) of all patients referred, of whom 67 (90%) were referred to a specialist dietician. Haematinics (iron studies, vitamin B12 and folate) were measured in 67 patients (90%), bone densitometry was measured in 51 patients (69%) and all patients were offered a follow-up appointment in the coeliac clinic. Iron deficiency was found in 31 patients (45%) of patients tested, folate deficiency in 12 patients (18%), vitamin B12 deficiency in 5 patients (7%) and vitamin D deficiency in 23 patients (38%). Osteoporosis was diagnosed in 5 patients (10%) and osteopenia in 10 patients (20%).

Conclusion: Appropriate dietician referral, specialist follow-up and screening for nutritional deficiency and bone disease occur within the Oxford coeliac disease service. Compliance with recommended biopsy protocols was only 44%. Whilst most referrals met the previous 18-week RTT pathway, few would have met the new quality standards.

P1931 MANAGEMENT OF OCCULT OBSCURE GASTROINTESTINAL BLEEDING PATIENTS BASED ON LONG-TERM OUTCOMES

S. Kuniyama¹, S. Oka², S. Tanaka¹, A. Tsuboi², I. Otani², K. Chayama²

¹Department Of Endoscopy, Hiroshima University Hospital, Hiroshima/Japan

²Department Of Gastroenterology And Metabolism, Hiroshima University Hospital, Hiroshima/Japan

Contact E-mail Address: sayokok@hiroshima-u.ac.jp

Introduction: We previously reported that small-bowel capsule endoscopy (CE) is effective in diagnosing small-bowel lesions with occult obscure gastrointestinal bleeding (OGIB) (*Gastroenterol Res Pract*. 2013). However, there is no consensus regarding the management of occult OGIB patients without bleeding source lesions.

Aims & Methods: We aimed to consider management of occult OGIB patients based on the long-term outcomes. A total of 357 consecutive occult OGIB patients (203 men; mean age: 59.7 years) who underwent CE at Hiroshima University Hospital before March 2016 and whose entire small-bowel could be observed and followed-up by CE for at least 12 months, were enrolled. We examined each patient to confirm the positive CE findings rate, the detection rate of bleeding source lesions, the details of bleeding source lesions, the overt

bleeding rate with or without treatment, the rate of anaemia exacerbation (hemoglobin levels decreased >2.0 g/dL), 5 year overall survival rate (OS), and 5 year disease specific survival rate (DSS). Occult OGIB was defined as recurrent or persistent iron deficiency anaemia with or without a positive faecal occult blood test and no bleeding findings by esophagogastroduodenoscopy and colonoscopy.

Results: The positive CE findings rate was 44% (157/357) and the detection rate of bleeding source lesions was 27% (98/357). All of the treated bleeding source lesions (Group A) were as follows: angiodysplasia 61 patients (Yano-Yamamoto classification Type 1a 37 patients, Type 1b 24 patients), non-specific ulcer 10 patients, nonsteroidal anti-inflammatory drugs-induced ulcer 8 patients, hemangioma 5 patients, Crohn's disease 3 patients, primary cancer 2 patients, metastatic cancer 2 patients, gastrointestinal stromal tumour 2 patients, malignant lymphoma 2 patients, others 3 patients. Lesions that were not regarded as bleeding source and were followed-up without treatment (Group B) were as follows: angiodysplasia 25 patients (Type 1a without oozing 25 patients), erythema 31 patients, others 3 patients. There were no patients with overt bleeding in Group B. Although 6 patients (10%) had anaemia exacerbation in Group B, they had angiodysplasia (Type 1a) that was not a bleeding source lesion. OS in both Group A and Group B was 90%. DSS in Group A was 99% and in Group B was 100%. One patient in Group A died of a primary small-bowel cancer.

Conclusion: Long-term outcomes with occult OGIB patients were good except malignant tumor, because overt bleeding and/or anaemia exacerbation did not occur within the follow-up period. Thus, occult OGIB patients without bleeding source lesions, including Type 1a angiodysplasia without oozing, and erythema, are unnecessary to follow-up with CE in occult OGIB patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1932 A PILOT STUDY EXPLORING THE VALUE OF FAECAL IMMUNOCHEMICAL TEST (FIT) WHEN INVESTIGATING ANAEMIA OR OCCULT GASTROINTESTINAL BLEEDING WITH SMALL BOWEL CAPSULE ENDOSCOPY

D. Tighe¹, C. Judge¹, P. Walsh², M. Kelly², A. O'Connor¹, N. Breslin¹, B. Ryan¹, G. Boran², D. McNamara¹

¹Department Of Gastroenterology Trinity Academic Gastroenterology Group (TAGG), AMNCH Tallaght, Dublin/Ireland

²Department Of Clinical Chemistry, AMNCH Tallaght, Dublin/Ireland

Contact E-mail Address: donaltighe83@gmail.com

Introduction: Small bowel capsule endoscopy (SBCE) is a very useful method of investigating iron-deficient anaemia, or occult gastrointestinal (GI) bleeding. It can help diagnose sources of anaemia or bleeding, such as angiodysplasia, small bowel Crohn's disease, polyps, lymphoma, and malignant lesions. There is however a need to improve the diagnostic yield, particularly where resources and access to capsule endoscopy are restricted. Faecal immunochemical test (FIT) has an established role, in investigating large bowel bleeding, and is incorporated into a number of bowel cancer screening programmes.

Aims & Methods: The aim of our study was to investigate whether FIT could help predict likelihood of small bowel bleeding or other significant pathology at time of small bowel capsule endoscopy. This was a prospective pilot study, performed at our centre from September 2016-April 2017. Indications for enrolment were patients referred for SBCE with the indication of anaemia or occult GI bleeding. Baseline patient characteristics were obtained including age, gender, history of renal disease, transfusion requirements and use of antiplatelet/anti-coagulants. Patient haemoglobin (Hb) level was checked on the day of SBCE where possible. Patients were asked to return one completed FIT for further analysis. A cut of 50 ng/ml was chosen, as this is the standard cut-off used, in the Irish National Bowel Cancer Screening programme.

Results: A total of 40 patients were enrolled, mean age 55.4 years (range 18–77), 64% were female. A total of 27.6% of patients were on anti-platelet agents or anti-coagulants. 34% of patients had a blood transfusion within the last year. Mean Hb for the cohort was 12.8 g/dL (range 7.8–15.9 g/dL). The average FIT reading was 459 ng/ml (range 0–4426 ng/ml). 30% of patients had a FIT level >50 ng/ml. 46% of patients, had positive findings at SBCE. 9/12 (75%) of patients with a FIT level >50 ng/ml had positive findings at capsule endoscopy compared to 5/28 (17.8%) for FIT <50 ng/ml, p value = 0.002, 95% C.I. 0.29–0.86 O.R. 0.16. These included 4/12 (33%) new cases of Crohns, 3/12 (25%) angiodysplasia, 3/12 (33%) non-IBD enteritis, 1/12 (16.7%) small bowel tumour, and 1/12 (16.7%) melaena, with no clear source. In addition there was a good correlation between FIT and Haemoglobin levels. 60% of patients with FIT >50 ng/ml were anaemic (Hb <11.5 g/dL), compared to 17% with FIT <50 ng/ml, p value = 0.02 95% C.I. 0.09–0.76 O.R. 0.14. Combining Hb and FIT levels, was also informative and predictive of small bowel pathology. 83% of patients, who were anaemic and had a FIT >50 ng/ml had clinically significant findings at SBCE compared to 21% pick up rate in patients with normal Hb and FIT levels, p value = 0.05 95% C.I. 0.22–1.03 O.R. 0.05. Overall the sensitivity for a FIT >50 ng/ml for detecting small bowel pathology was 83% with a specificity of 92%, giving a positive predictive value of 83.3% (95% C.I. 56%–95%). Antiplatelet usage was not predictive of a positive FIT, as 16.7% of patients with a FIT >50 ng/ml were on anti-platelet agents, compared to 83.3% who weren't.

Conclusion: FIT is useful at predicting clinically significant small bowel pathology at the time of capsule endoscopy. It may help better identify and prioritise patients who would best benefit from referral.

Introduction: The features of the portal hypertension enteropathy (PHE) vary from mild mucosal changes to varices with or without bleeding. The prevalence and the correlation of factors that predict the development of PHE are not fully understood.

Aims & Methods: Our aim in this study is to examine the prevalence of the different manifestations portal hypertensive enteropathy and it's correlation with the Child-Pugh score (CTP) in cirrhosis using video capsule endoscopy (VCE). At a single center, we performed a retrospective chart review study of patients between the age of 18 and 80 with cirrhosis, who had VCE study between January 2010 and January 2016. Based on the published literature, we divided the portal hypertensive enteropathy lesions in our study into vascular lesions (arteriovenous malformation (AVM), red spots, bleeding or varices) and mucosal lesions (mild inflammatory changes or severe inflammatory changes which are a mosaic, congested and friable mucosa).

Results: 100 patients with cirrhosis had a VCE study. The mean age was 62.82 years. Male gender was predominant with a 64%, while the Caucasians represented 82% of the cohort. The most common etiologies of the cirrhosis were chronic alcohol abuse followed by chronic hepatitis C virus (HCV) and non-alcoholic steatohepatitis (NASH) table 1A. The average MELD score was 13.86(± 0.66). VCE detected small bowel lesions in 71% of the patients while the features of portal hypertensive enteropathy were found in 65% from the total cohort. AVMs and Inflammatory changes were the most common findings, followed by bleeding. 13 patients found to have two or more lesions by VCE. More than 50% of the lesions were vascular in nature (table 1A). The percentage of the CTP A, CTP B and CTP C was 46%, 42% and 12% respectively. The odds of finding portal hypertensive enteropathy in decompensated cirrhosis is twice that in compensated cirrhosis (odd ratio of 2.0) table 1B. 45 patients had negative EGD exam for any active bleeding, esophageal varices (EV), portal hypertensive gastropathy (PHG) or gastric varices (GV). 31 of them (69%) had features of portal hypertension enteropathy in their VCE. table 1B.

Table 1A

	Number & (%)
Total number of patients	100
Causes of cirrhosis:	
Congestive Hepatopathy	4(4%)
Cryptogenic	8(8%)

Introduction: Small-bowel capsule endoscopy (SBCE) have been useful in managing obscure gastrointestinal bleeding. We previously reported that the use of oxicams and diclofenac was associated with an increased risk of nonsteroidal anti-inflammatory drug (NSAID)-induced small-bowel injury (*Aliment Pharmacol Ther* 2014). However, the etiology and temporal development of drug-associated small-bowel bleeding (SBB) has not been well characterized.

Aims & Methods: The aim of this study is to determine the risk of drugs associated with overt SBB using a case-crossover design. The Japanese Association for Capsule Endoscopy developed a prospectively recorded database of outpatients and inpatients who underwent SBCE at 18 medical centers in Japan, and data were collected from 1052 patients with obscure gastrointestinal bleeding (OGIB) between December 2010 and June 2016. This database includes patient characteristics, drugs used, SBCE findings, and final diagnosis. Drugs used were identified during a “case period” 4 weeks before the overt SBB, and a “control period” 24–5 weeks before the overt SBB. Drug adherence was classified into 4 groups: 1) 100%, 2) 50% or higher, 3) lower than 50%, and 4) 0%. Using conditional logistic regression, odds ratios (ORs) and 95% confidential intervals (CIs) were estimated using Mantel-Haenszel estimator in discordant cases.

Results: Of 1052 patients with OGIB (male/female: 678/374, age of onset: 68 ± 87), 455 with SBB (male/female: 291/164, age of onset: 70 ± 91) were enrolled. Final diagnoses were vascular lesions (n = 169, 37%), followed by inflammatory lesions (n = 148, 33%), drug injuries (n = 64, 14%: NSAID 47, aspirin 15, both 1, anticancer drug 1), tumors (n = 48, 11%: malignant 32, benign 16), diverticula (n = 13, 3%), etc. Data from 133 patients on 346 drugs which could be identified 24 weeks before overt SBB were analyzed. ORs (95% CIs) of enteric-coated aspirin (n = 51), warfarin (n = 27), clopidogrel (n = 24), and loxoprofen (a propionic acid derivative, n = 21) were 5.7(1.3–24.3), 3.7(0.8–16.6), 313406(2.3E-145–4.3E + 155), and 18.0(2.3–139.6). Aspirin-associated SBB was caused by aspirin-induced injuries, angiodysplasias, Meckel's diverticula, and polyps. Loxoprofen-associated SBB was caused by mostly loxoprofen-induced injuries.

Conclusion: Enteric-coated aspirin, clopidogrel, and loxoprofen were identified as agents causing overt SBB during a relatively short period after administration.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1935 META-ANALYSIS REVEALS SIMILAR REBLEEDING RATES AMONG EASTERN AND WESTERN POPULATIONS UP TO FIVE YEARS AFTER INDEX VIDEO CAPSULE ENDOSCOPY EXAMINATION FOR OBSCURE GASTROINTESTINAL BLEEDING

G. Tziatzios, P. Gkolfakis, G. D. Dimitriadis, K. Triantafyllou
2nd Dept Of Internal Medicine And Research Institute, National and Kapodistrian University of Athens, Medical School, Athens/Greece

Contact E-mail Address: kttriant@med.uoa.gr

Introduction: Video capsule endoscopy (VCE) is the first-line diagnostic modality for obscure gastrointestinal bleeding (OGIB) investigation and different re-bleeding rates have been published among Western and Eastern studies.

Aims & Methods: Aim of this meta-analysis was to examine the differences in re-bleeding rates in patients with OGIB after index VCE, as measured in Western and Eastern studies. A comprehensive literature search in MEDLINE was conducted to identify all studies examining re-bleeding rate after VCE for OGIB. Meta-analysis assessed the pooled proportion of re-bleeding events after VCE for OGIB according to study's origin (Western vs. Eastern) as the primary end point. Pooled odds ratios for re-bleeding after positive vs. negative index VCE and after long (> 24 months) vs. short (< 24 months) follow-up in the two studies origins, comprised the secondary endpoints. Study outcomes effect sizes were calculated using RevMan 5.3 software random effect model and they are presented as rate[95%CI] or OR[95%CI]. Heterogeneity was measured using the I² statistics and publication bias risk was examined with Funnel plots inspection.

Results: Thirty-eight (14 Eastern and 24 Western) studies were included in the analysis with 5197 patients followed from 6 to 52 months. We detected significant heterogeneity with no evidence for publication bias in the meta-analyzed studies. While the overall, pooled rate of re-bleeding after VCE was 25(21–29)%, I² = 93%, similar re-bleeding rates were detected among Eastern and Western populations [22(16–28)%, I² = 93% vs. 28(22–35)%, I² = 95%]. The re-bleeding risk after positive compared to negative VCE index examination was higher [1.89(1.10–3.24), I² = 72%] in Eastern population studies, while a similar difference was not detected in the Western studies [1.46(0.72–2.94), I² = 88%]. When only studies with short-term follow-up were analyzed, the OR of re-bleeding after positive vs. negative VCE was 1.23[0.58–2.61], I² = 77% and 1.93[0.90–4.13], I² = 71% in Western and Eastern studies, respectively. For studies with long-term follow-up, no significant difference in the OR of re-bleeding after positive vs. negative index VCEs was detected either in the East [2.03(0.96–4.29), I² = 71%] or in the West [2.29(0.46–11.37), I² = 96%].

Conclusion: Our analysis shows that patients undergoing VCE for OGIB have similar re-bleeding rates in the East and in the West, regardless of the length of the follow-up. An increased re-bleeding risk after positive vs. negative index VCE was noted only in studies originating from the East.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1936 LONG-TERM OUTCOMES AFTER NEGATIVE DOUBLE-BALLOON ENTEROSCOPY FOR SUSPECTED OVERT SMALL BOWEL BLEEDING (OBSCURE-OVERT GASTROINTESTINAL BLEEDING)

R. Hashimoto¹, T. Matsuda¹, M. Nakahori¹

¹Dept. Of Gastroenterology, Sendai Kosei Hospital, Sendai/Japan

Contact E-mail Address: rinhashimoto@gmail.com

Introduction: There are very few reports about long-term outcomes in patients with negative balloon assisted enteroscopy for suspected overt small bowel bleeding (obscure-overt gastrointestinal bleeding).

Aims & Methods: The aim of this study is to evaluate long-term outcomes and risk factors of re-bleeding after negative double balloon enteroscopy (DBE) for suspected overt small bowel bleeding. We investigated 297 patients undergoing DBE for suspected overt small bowel bleeding between December 2004 and April 2016 at Sendai Kousei Hospital. Prospectively collected data were reviewed, and 83 patients (27.9%) showed negative results in the first antegrade and/or retrograde DBE. For these patients, letter and telephone interviews were conducted in April 2017. As a result, a cohort of 64 patients could be followed. The primary outcome measurement is overt rebleeding and necessity for clinical assessment after negative DBE.

Results: Rebleeding was observed in 19 of 64 patients (29.7%) with 76 months follow-up period. The mean period during the first DBE and the first rebleeding episode were 11.6 months(2day-48months). Three patients showed rebleeding after more than three years of the first DBE. At the time of rebleeding, emergent endoscopy including DBE (within less than 48 hours) and/or contrast-enhanced computed tomography (CECT) was performed in all patients. The bleeding source was identified in 17 of 19 patients (89.4%). The bleeding source were duodenum (n = 8), jejunoleum (n = 7) and colon (n = 2), respectively. One

patient died due to uncontrollable duodenal bleeding. Blood transfusion before the first DBE was associated with rebleeding (odds ratio 22.5, $p=0.0005$), but total enteroscopy rate, use of capsule endoscopy, use of anti-thrombotic agents and use of NSAIDs were not associated with rebleeding.

Conclusion: Rebleeding after negative DBE for suspected overt small bowel bleeding is not rare. Blood transfusion before the first DBE may predict rebleeding. Emergent endoscopy including DBE and concomitant CECT use could help the diagnosis on re-bleeding.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1937 DOES DISCONTINUATION OF ANTITHROMBOTIC AGENTS AFFECT DIAGNOSTIC YIELD OF SMALL BOWEL CAPSULE ENDOSCOPY IN PATIENTS WITH OBSCURE GASTROINTESTINAL BLEEDING?

T. Watanabe¹, S. Shimada¹, Y. Nadatani¹, K. Otani¹, F. Tanaka¹, Y. Nagami¹, N. Kamata¹, H. Yamagami¹, T. Tanigawa¹, M. Shibato¹, T. Miyazaki², S. Nakamura², Y. Fujiwara¹

²Department Of Inflammatory Bowel Disease, Division Of Internal Medicine, Hyogo College of Medicine, Nishinomiya/Japan

Contact E-mail Address: watanabet@med.osaka-cu.ac.jp

Introduction: Capsule endoscopy (CE) is a useful and noninvasive modality for investigation of the small intestine, and currently, it has become the first-line modality for the diagnosis of obscure gastrointestinal bleeding (OGIB). Use of antithrombotic agents including antiplatelets and anticoagulants is associated with gastrointestinal bleeding. Antithrombotic users account for a large portion of patients with OGIB, and those with OGIB often undergo CE. It should be noted that some patient with over OGIB discontinue antithrombotic agents at the time of CE, which may affect endoscopic findings.

Aims & Methods: To examine the effect of discontinuation of antithrombotic agents on the diagnostic yield of CE, and to assess the predictive factors associated with positive CE findings in patients using antithrombotics who develop overt OGIB. Between March 2004 and December 2015, 130 consecutive patients (75 male; mean age, 71.9 years) taking antithrombotics who underwent CE for overt OGIB were enrolled, whereas patients who underwent double-balloon endoscopy prior to CE were excluded. Findings were considered positive if the observed lesions could explain the bleeding, while findings including isolated red spots and a single small polyp were considered negative. The primary endpoint was the difference in the rate of positive CE findings between patients who continued and those who discontinued antithrombotic agents. Furthermore, a propensity score analysis was performed to reduce the effects of selection bias and potential confounding factors. The secondary endpoint was to assess the predictive factors for the positive CE findings by using multiple logistic regression.

Results: Of the 73 patients who continued antithrombotic agents, 36 (49.3%) patients had positive findings in the small intestine (ulcer/erosion [$n=24$], angioectasia [$n=7$], tumor [$n=4$], and blood pooling [$n=1$]), while of the 57 patients who discontinued these agents, 35 (61.4%) patients had positive findings (ulcer/erosion [$n=17$], angioectasia [$n=11$], tumor [$n=3$], and blood pooling [$n=4$]). The rates of positive CE finding did not differ between the two groups. Even after propensity score matching, discontinuation of antithrombotic agents did not affect the rate of positive CE finding. In multivariate analysis, the lowest hemoglobin level before CE examination was an independent predictive factor associated with positive CE findings. The odds ratio per 1 g/dL increase in the lowest hemoglobin level was 0.84 (95% confidence interval, 0.71–0.98). However, other factors, including sex, age, and discontinuation of antithrombotic agents, were not associated with positive CE findings.

Conclusion: Discontinuation of antithrombotic agents did not affect the diagnostic yield of CE in patients with overt OGIB, and lowest hemoglobin level was associated with positive CE findings

Disclosure of Interest: All authors have declared no conflicts of interest.

P1938 EFFICACY OF REBAMIPIDE TO PREVENT LOW-DOSE ASPIRIN-INDUCED SMALL INTESTINAL INJURY

S. S. Vyalov

Gastroenterology, Peoples Friendship University of Russia, Moscow/Russian Federation

Contact E-mail Address: svialov@mail.ru

Introduction: Long-term use of low-dose aspirin (LDA) is associated with development of peptic ulcers, gastrointestinal bleeding, enteropathy. For prevention of LDA-induced gastroduodenal mucosal injury, proton pump inhibitor (PPI) are the first-line therapy according to several guidelines. However, gastric acid suppressants, like PPI, do not prevent small intestinal mucosal injury. The latest clinical trials showed that rebamipide stimulates the production of prostaglandins, thereby preventing mucosal injury. This could improve mucosal breaks in small intestine in patients receive LDA.

Aims & Methods: We aimed to investigate the protective role and efficacy of rebamipide for prevention low-dose aspirin-induced small intestinal mucosal injury and enteropathy. Subjects comprised patients undergoing longlife low-dose aspirin therapy prescribed by cardiologist. Patients with a high-risk of gastrointestinal bleeding were excluded. This trial was performed as a randomised open-labelled clinical study with the permission of an institutional

review board. The trial was included 100 patients (50 cases in each group) received enteric-coated low-dose aspirin 100mg. The Group PPI received LDA plus pantoprazole 40mg, the Group RBD received plus rebamipide 300mg. Before starting therapy, we checked the background characteristics of each patient (H.pylori, use of LDA, NSAID, bismuth, PPI; and endoscopic findings). Gastroduodenoscopy and capsule endoscopy were performed, and the fecal occult blood reaction and fecal calprotectin levels were measured before, two and four weeks after drug administration. After the therapy, we have asked physicians and patients about medication compliance and side effects. Capsule endoscopy was then repeated. The primary endpoint was the change in the number of mucosal breaks from baseline to 4 weeks. The secondary endpoints were the rates of side effects.

Results: The fecal calprotectin levels increased significantly in Group PPI, they did not increase in Group RBD. The mean number of small intestinal mucosal injuries by capsule endoscopy in Group PPI increased significantly up to 3.9 after 4 weeks of LDA treatment. There was not detected new small intestinal injuries in Group RBD. Stomach ulcer, bleeding or stenosis were not found in any subject. There were no significant differences in the presence of fecal occult blood in both groups. There were no significant side effects in Group RBD.

Conclusion: In conclusion, rebamipide is effective and sufficient for preventing mucosal injury of the small intestine induced by low-dose aspirin. These results show the gastroprotective and enteroprotective effects of rebamipide, suggesting that it may be a good choice in low-dose aspirin users with gastrointestinal toxicity that is not suppressed by acid suppressants alone.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Capsule endoscopy allows high-quality imaging of the small bowel. Newer capsule with a panoramic viewing mode is available and might increase the detection rate of bleeding lesions in patients with obscure gastrointestinal bleeding. Furthermore, an improved patient acceptance rate is expected.

Aims & Methods: In a randomized prospective comparative multi-center study, patients with obscure gastrointestinal bleeding were included and examined either with Capsocam SV-1 or with Pillcam SB 3. Detection of bleeding lesions, transit and evaluation time and adverse events were evaluated. Physicians were interviewed about their experience with both capsules and the evaluation software. A detailed subject questionnaire analyzed acceptance of each capsule system. Three months after initial capsule endoscopy follow-up procedures were documented.

Results: One hundred eighty-one patients with obscure gastrointestinal bleeding were recruited into the study. After exclusion of 28 patients 153 patients were randomized and Capsocam SV-1 ($n=78$) or Pillcam SB 3 ($n=75$) was administered. Capsocam SV-1 detected more cases of bleeding (31/79, diagnostic yield 39.7%) compared to Pillcam SB 3 (26/75, diagnostic yield 34.6%, n.s.). Transit time of both capsules was not different. Evaluation time with Pillcam SB

3 was superior to CapsoCam SV-1 (27 min. vs. 40 min, $p=0.01$). 95% of the physicians were satisfied with each capsule system and evaluation software. The acceptance rate of the patients to retrieve the CapsoCam SV-1 was high. Adverse events/SAEs were 17.9%/1.3% with CapsoCam SV-1 and 16%/0% with PillCam SB 3. Re-bleeding rate was 28.75% within 3 months.

Conclusion: Both capsules allow high-quality imaging of the small bowel. CapsoCam SV-1 detected more lesions, however, relevant bleeding sources were visualized by both capsules. Physician's satisfaction was high with both capsule systems and evaluation software. Patient's acceptance with CapsoCam SV-1 was unexpectedly high. SAEs were 0% with PillCam SB 3 and 1.3% with CapsoCam SV-1.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Chronic mesenteric ischemia (CMI) is the result of insufficient mucosal perfusion of the gastrointestinal tract, mostly caused by atherosclerotic stenosis of the mesenteric arteries. Other causes of CMI are vasculitis, median arcuate ligament syndrome or non-occlusive ischemia (NOMI) due to decreased cardiac output or hypo-oxygenation. The diagnosis of CMI remains challenging as chronic abdominal pain is common and mesenteric artery stenoses are frequently observed in the general population but not necessarily related. Harki et al.(1) designed a score chart to predict the risk of CMI based on a cohort of CMI suspected patients. This score chart consists of patient characteristics (female 1 pt, weight loss 1 pt, cardio-vascular disease 1 pt) and radiologic evaluation (50–70% celiac artery (CA) stenosis 1 pt, >70% CA stenosis 4 pts, 50–70% superior mesenteric artery (SMA) stenosis 1 pt and >70% SMA stenosis 3 pts). A total score of 0–2 pts predicts an absolute risk of CMI of 0–21%, 3–6 pts a 22–46% risk and ≥7 pts a risk of >79%. We aimed to validate this prediction model in a prospective large multicenter patient cohort.

Aims & Methods: Patients suspected of CMI referred to two Dutch specialized CMI referral centers were included consecutively from January 2014 to August 2016. After diagnostic work-up of medical history taking, mesenteric CT-angiography or MR-angiography, and a mucosal ischemia test (visible light spectroscopy or tonometry), all patients were discussed in a specialized CMI multidisciplinary meeting resulting in an expert based consensus diagnosis. All patients with a CMI consensus diagnosis were planned for treatment (revascularization for occlusive disease and medication for NOMI). A definitive diagnosis of CMI was made if successful treatment resulted in durable symptom relief. The score chart to predict the risk of CMI was computed for each patient.

Results: A total of 246 patients were included and consensus diagnosis of CMI was made in 108 (44%) patients, which resulted in 96 (39%) patients with a definitive diagnosis of CMI after a positive response therapy. A definitive diagnosis of CMI was made in 9% of the patients with low risk, in 40% of the patients with intermediate risk and in 94% of the patients with high risk of CMI according to the score chart, respectively. Etiology and vascular lesions are specified for each risk group in the table. The discriminative ability of the score chart was strong (C-Statistic 0.87).

	Low risk (0–2 pts) $n=91$	Intermediate risk (3–6 pts) $n=107$	High risk (≥7 pts) $n=48$
Diagnosis			
Consensus diagnosis CMI	9 (9.9%)	53 (49.5%)	46 (95.8%)
Definitive diagnosis CMI	8 (8.8%)	43 (40.2%)	45 (93.8%)
Vascular lesion			
No significant vascular lesion [#]	73 (80.2%)	20 (18.7%)	0 (0.0%)
Single vessel	17 (18.7%)	69 (64.5%)	5 (10.4%)
CA stenosis	11 (64.7%)	50 (72.5%)	5 (100.0%)
SMA stenosis	0 (0.0%)	18 (26.1%)	0 (0.0%)
IMA stenosis	6 (35.3%)	1 (1.4%)	0 (0.0%)
Multi vessel	1 (1.1%)	18 (16.8%)	43 (89.6%)
CA and SMA stenosis	0 (0.0%)	7 (38.9%)	19 (44.2%)

(continued)

Continued

	Low risk (0–2 pts) $n=91$	Intermediate risk (3–6 pts) $n=107$	High risk (≥7 pts) $n=48$
CA and IMA stenosis	0 (0.0%)	3 (16.7%)	1 (2.3%)
SMA and IMA stenosis	0 (0.0%)	7 (38.9%)	1 (2.3%)
CA, SMA and IMA stenosis	1 (1.1%)	1 (5.5%)	22 (51.2%)
Etiology			
No sign. vascular lesion [#] , no ischemia	68 (74.7%)	19 (17.8%)	0 (0.0%)
Atherosclerosis	7 (7.7%)	53 (49.5%)	42 (87.5%)
MALS	8 (8.8%)	32 (29.9%)	2 (4.2%)
MALS and atherosclerosis	0 (0.0%)	0 (0.0%)	3 (6.3%)
Vasculitis	0 (0.0%)	1 (0.9%)	0 (0.0%)
NOMI	5 (5.5%)	1 (0.9%)	0 (0.0%)
NOMI and atherosclerosis	3 (3.3%)	0 (0.0%)	1 (2.1%)
NOMI and MALS	0 (0.0%)	1 (0.9%)	0 (0.0%)

Conclusion: The score chart for CMI based on patient characteristics and anatomy is a reliable tool to discriminate the risk of CMI and useful for clinical decision-making, for example to adopt a wait-and-see policy in patients with a low risk and immediate vascular intervention in patients with high risk of CMI.

Introduction: Isolated stenosis of the celiac artery (CA) or the superior mesenteric artery (SMA) is frequently detected in patients with abdominal complaints. These patients may suffer from chronic mesenteric ischemia (CMI) causing nonspecific abdominal complaints as postprandial pain, nausea or diarrhea. However, the existence of single artery mesenteric ischemia is a topic of continuous clinical debate and reports on the effectiveness of single mesenteric artery revascularization are scarce. We evaluated the long-term clinical success rates for single CA or SMA revascularization in patients with gastrointestinal symptoms and confirmed mucosal ischemia.

Aims & Methods: Data were collected from all 97 consecutive patients with gastrointestinal symptoms and a single mesenteric artery stenosis referred to the outpatient clinic of our tertiary care institution for analysis of CMI between January 2006 and October 2010. All patients underwent a standardized diagnostic work-up for CMI at baseline consisting of medical history taking and physical examination, imaging of the gastrointestinal arteries with either CT- or MR-angiography and/or conventional catheter angiography, and a functional test for detecting mucosal ischemia using either tonometry or visible light spectroscopy. All cases were discussed in a multidisciplinary meeting attended by a vascular surgeon, interventional radiologist and gastroenterologist, all specialized in CMI, leading to an expert based consensus diagnosis. Patients with consensus diagnosis of CMI underwent surgical or endovascular revascularization. The primary outcome was clinical response to revascularization, defined as relief of presenting symptoms as experienced by the patient.

Results: Consensus diagnosis of CMI was obtained in 62/97 patients and all consensus patients were revascularized. Isolated CA stenosis was present in 55/62 patients (89%) (31 vascular disease; 24 median arcuate ligament syndrome, MALS) and isolated atherosclerotic SMA stenosis in 7 patients. After a mean follow-up of 5.5 ± 3.0 years, 42/62 patients (68%) experienced sustained symptom relief. Responders to revascularization had a BMI increase during follow-up in contrast to the non-responders ($+0.43 \pm 2.5$ versus -1.06 ± 2.4 kg/m², $p=0.033$). Response to revascularization was not related to lesion localization (CA 67% versus SMA 71%, $p=0.825$) or lesion etiology (MALS 63% versus vascular disease 71%, $p=0.483$). See table.

CA = celiac artery; SMA = superior mesenteric artery; MALS = median arcuate ligament syndrome

	Symptom relief	No symptom relief
All patients	42/62 (68%)	20/62 (32%)
Vascular lesion		
CA stenosis	37/55 (67%)	18/55 (33%)
SMA stenosis	5/7 (71%)	2/7 (29%)
Etiology		
MALS	15/24 (63%)	9/24 (38%)
Vascular disease	27/38 (71%)	11/38 (29%)

Conclusion: Revascularization of the CA or SMA provides long-term symptom relief in 68% of patients with chronic gastrointestinal symptoms and confirmed mucosal ischemia due to single mesenteric artery stenosis. This provides the opportunity to help patients with otherwise unexplained, refractory abdominal complaints.

P1942 UNDERUTILIZATION OF ENDOSCOPIC ARGON PLASMA COAGULATION FOR TREATMENT OF BLEEDING GASTROINTESTINAL ANGIODYSPLASIAS: AN INTERNATIONAL MULTICENTRE COHORT STUDY

K. Grooteman¹, M. Matheeuwsen¹, G. Holleran², E. Van Geenen¹, D. McNamara², J.P.h. Drenth¹

Introduction: Endoscopic argon plasma coagulation (APC) is the first-line treatment in patients with iron deficiency anaemia or overt bleeding resulting from gastrointestinal angiodysplasias. In the minority of patients active bleeding angiodysplasias are seen during endoscopy, but in contrast non-bleeding angiodysplasias can be an incidental finding. This can make the decision whether to treat endoscopic detected angiodysplasias with APC difficult.

Aims & Methods: The aim of this study is to investigate the need for repeat endoscopies with APC in patients with angiodysplasias who were left untreated during the index endoscopy performed for iron deficiency anaemia or overt bleeding. We initiated an international, multicentre cohort study to collect clinical, laboratory and endoscopic data from angiodysplasia patients. Cases were identified through a systematic search in endoscopy reports from 2010–2015 with follow-up until July 2016. Inclusion criteria was endoscopic detection of angiodysplasia in the context of overt bleeding or iron deficiency anaemia. Exclusion criteria were other vascular anomalies and angiodysplasias as incidental finding. The primary outcome was repeat endoscopy with APC.

Results: A total of 197 patients with proven angiodysplasia as cause for anaemia or bleeding were included (mean age = 68 years; 58% male). Median follow-up was 37 months (range 18–57). In 52% of the cases (n = 103) APC treatment for bleeding angiodysplasia(s) was performed at the index endoscopy. Repeat endoscopy with APC was necessary in 17 patients (18%) in whom angiodysplasias were detected but left untreated during the index endoscopy. Median time between index and repeat endoscopy was 21 weeks. A total of 48 patients (51%) who received a purely diagnostic index endoscopy were in need of other treatment modalities (e.g. iron supplementation, blood transfusion, stop anticoagulants). Anaemia and/or overt bleeding resolved spontaneously in 24 patients (26%).

Conclusion: A substantial proportion of patients with clinical symptomatic angiodysplasia bleeding do not receive APC at the index endoscopy and continue to be dependent on iron supplementation, blood transfusion or undergo repeat endoscopy with APC.

Introduction: Digestive manifestations in systemic diseases including vasculitis and granulomatosis is broad and can affect any segment of the digestive tract and related organs. The clinical symptoms are not specific and it can be challenging for diagnosis. The other difficulty remains the interference of digestive side effects of medication used.

Aims & Methods: We aimed to review various digestive manifestations of systemic diseases. This was a retrospective study from Feb 2009 to Sep 2016 in

internal medicine and gastroenterology departments. The exclusion criteria was incomplete data considering the diagnosis of the systemic disease.

Results: patients were included, sex ratio 0.38 (101 F/39 M), mean age at inclusion was 40 years old [13,79]. The following chart summarize the% of digestive manifestations by disease:

Systemic disease	Number of cases	Digestive manifestations (%)
Systemic Lupus erythematosus	49	10.36%
Systemic sclerosis	27	8.33%
Behcet's disease	27	4.39%
Sjogren syndrome	14	7.37%
Wegener's granulomatosis	2	21.60%
Antiphospholipid Anti body Syndrome	3	22.58%
Amyloidosis	1	45.16%
Churg-Strauss syndrome	2	20.96%
Dermatomyositis	2	25.80%
Microscopic Polyangiitis	1	0%
Horton's disease	2	8.06%
Takayasu arteritis	3	3.22%
Cryoglobulinemic vasculitis	2	0%
Henoch-Schönlein purpura	3	30.10%
Leucocytoclastic vasculitis	2	12.9%

Patients symptoms and clinical findings were: Abdominal pain in 32 cases (22.9%), Nausea and vomiting in 7 cases (5%), stool modification 15 cases (10.7%), jaundice in 4 cases (2.9%), dysphagia in cases (7.1%), hepatomegaly in 4 cases (2.9%), splenomegaly in 8 cases (5.7%), ascitis in 13 cases (9.3%), digestive bleeding 17 cases (12.1%). Laboratory findings: elevated liver enzymes 18 cases (15.9%), alkaline phosphatase elevation 15 cases (19.2%). Radiological findings: 17 ascitis (14.4%), 12 digestive thickening (10.16%), 6 hepatomegaly (5.08%), 14 splenomegaly (11.86%), 2 portal cavernoma (1.6%), 3 portal thrombosis (2.5%), 4 esophageal distension (3.4%), acalculous cholecystitis in 2 cases (1.6%), 2 portal hypertension (1.6%), steatosis in 3 cases (2.5%), 3 hepatic angioma (2.5%), acute pancreatitis in 2 cases (1.6%), 2 mesenteric ischemia (1.6%), 1 Budd-Chiari (0.8%), 1 hepatic carcinoma (1.8%). Upper gastrointestinal Endoscopy findings: hiatus hernia in 3 cases (8.6%), esophagitis in 11 cases (31.4%), esophageal varices in 2 cases (5.7%), Gastritis in 37 cases, duodenitis in cases 16 cases, ulcers in 3 cases (8.6%), 4 celiac disease (11.42%). Lower GI endoscopy: Crohn's disease in 1 case (8.3%), ulcerative colitis in 1 case (8.3%), 1 hyperplastic polyps (8.3%), 2 colitis (16.6%). Esophageal manometry: motility disorder in 4 cases. The most used drugs were immunosuppressive drugs, steroids and hydrochloroquine, all causing digestive side effects mainly abdominal pain.

Conclusion: The digestive involvement is around 10% of cases in the most represented systemic diseases, the main symptom is abdominal pain probably related to medication, endoscopic modifications are mainly non specific but we found some association with celiac disease and IBD. Liver involvement was noticed in 15% of cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1944 CHANGES IN LEVELS OF VITAMIN D IN OBESE PATIENTS SUBMITTED TO BARIATRIC SURGERY

A. Vaz¹, R. Guerreiro², D. Sousa¹, P. Queirós³, T. Gago¹, J. Roseira³, H. Guerreiro¹

¹Gastroenterology, Centro Hospitalar do Algarve, Faro/Portugal

²Clinical Pathology, Centro Hospitalar do Algarve, Faro/Portugal

³Gastroenterology, Centro Hospitalar do Algarve, Portimão/Portugal

Contact E-mail Address: anam_vaz@hotmail.com

Introduction: An association between obesity and vitamin D deficiency has been reported in several studies. This may be explained, among other things by the sequestration of the fat-soluble vitamin D in the adipose tissue. Bariatric surgery, including Roux-en-Y gastric bypass (RYGB) is an effective treatment for more extreme cases of obesity, promoting significant weight loss and consequently reduction in some obesity-related health problems. However, the problem of vitamin D deficiency doesn't seem to be solved after RYGB and can even be exacerbated by the changes in digestion and absorption of this nutrient after the surgery.

Aims & Methods: The aim of this study was to analyze the prevalence of vitamin D deficiency (VDD) and vitamin D insufficiency (VDI) in a population of obese patients, before and after being submitted to RYGB. We included patients patients selected to undergo RYGB for obesity. We measured anthropometric values and the levels of 25-hydroxy-vitamin D (25(OH)D) before and 1 year after the procedure. VDD was defined as serum 25(OH)D < 20 ng/mL and VDI as serum 25(OH)D concentrations between 20–30 ng/mL. Levels of 25(OH)D > 30 ng/mL were considered normal.

Results: We included 39 patients. Thirty-two were females (82.1%) and the mean age was 43.6 ± 11.3 years. The mean BMI before surgery was 41.6 kg/m². There was a significant decrease in BMI after surgery and, on average, the mean total body weight loss was 34% and the mean excess BMI loss was 90%. Before

bariatric surgery, 52.3% of patients had VDD and 36.8% had VDI. After surgery, the number of VDD increased to 71.1% ($p=0.079$). The mean levels of 25(OH) D decreased significantly from 19.8 ng/mL before surgery to 16.6 ng/mL after surgery ($p < 0.05$). There was no correlation between the amount of weight loss and the changes in the levels of 25(OH)D in our study.

Conclusion: There is a high prevalence of vitamin D deficiency in obese patients eligible for bariatric surgery. The level of deficiency tends to increase after RYGB. This population of patients should, therefore, be offered an adequate level of vitamin D supplementation, especially after the procedure.

²Dept. Of Gastroenterology, Usuy Clinic, Florianopolis/Brazil

³Bariatric Endoscopy, Gastro Obeso Center, São Paulo/Brazil

Contact E-mail Address: ricfittipaldi@hotmail.com

Introduction: Bariatric surgery is established as an excellent therapy for obesity. However, lower degrees of overweight without surgical indication also impact on patients' health and quality of life, and the intragastric balloon (IGB) may be a treatment option.

Aims & Methods: We aimed to assess the efficacy of excess weight treatment with an IGB in patients with overweight and grade I obesity at EndogastroRio Clinic. A total of 717 patients were analyzed. A liquid filled IGB was used. The patients had initial body mass index (BMI) between 27 and 34.9 kg/m². The level of significance was set at $p < 0.05$.

Results: Results 615 patients were women. 131 patients had overweight and 586 had grade I obesity. Mean age was 37.97 years (17–75). Weight loss results and treatment success rates are shown on table 1. Percent excess weight loss (%EWL) was higher in overweight group ($p < 0.0001$) and percent total body weight loss (%TBWL) was higher in the grade I obesity group ($p=0.0009$). 96 (73.28%) overweight patients and 132 (22.52%) grade I obesity patients reached a normal BMI (< 25 kg/m²).

	Total group (n = 717)	Overweight (n = 131)	Grade I Obesity (n = 586)
Body weight(kg)			
Baseline	88.55 ± 10.14	78.90 ± 6.56	90.67 ± 9.56
Final	73.20 ± 10.78	66.73 ± 8.13	74.62 ± 10.73
Reduction	15.35 ± 6.49	12.16 ± 4.76	16.05 ± 6.53
%TBWL	17.36 ± 7.08	15.51 ± 6.11	17.76 ± 7.11
BMI(kg/m2)			
Baseline	32.05 ± 2.04	28.73 ± 0.94	32.78 ± 1.38
Final	26.46 ± 2.43	24.26 ± 1.85	26.95 ± 2.51
Reduction	5.59 ± 2.36	4.46 ± 1.86	5.83 ± 2.37
Excess weight (kg)			
Baseline	19.77 ± 6.04	10.52 ± 2.7	21.81 ± 4.45
Final	4.42 ± 7.44	-1.65 ± 5.09	5.77 ± 2.37
%EWL	83.97 ± 41.89	122.77 ± 57.89	75.36 ± 31.33
%TBWL			
< 10%	106(14.78%)	22(15.27%)	83(14.16%)
≥ 10%	611(85.22%)	109(83.21%)	503(85.84%)
%EWL(n;%)			
< 25%	32(4.46%)	2(1.52%)	30(5.12%)
≥ 25%	685(95.54%)	129(98.48%)	556(94.88%)
BMI(n;%)			
< 25 kg/m ²	213(29.71%)	96 (73.28%)	132(22.52%)

* $p < 0.0001$ for all comparisons between values at baseline and at the end of the study. IGB = intragastric balloon; BMI = body mass index; TBWL = total body weight loss; EWL = excess weight loss. Success rates (criteria: $\geq 10\%$ TBWL or $\geq 25\%$ EWL)

Conclusion: Endoscopic treatment of obesity with an IGB shows to be an excellent therapeutic option to non elective patients for bariatric surgery according to BMI criterion

P1947 SPATZ3® ADJUSTABLE INTRAGASTRIC BALLOON TREATMENT: A BRAZILIAN MULTICENTRIC EXPERIENCE

R.J.F. Fernandez¹, C.F. Diestel¹, M. Galvao Neto², A. F. Teixeira¹, E. Usuy³, S. Barrichello¹

¹Dept. Of Bariatric Endoscopy, Endogastro Rio, Rio de Janeiro/Brazil

²Bariatric Endoscopy, Gastro Obeso Center, São Paulo/Brazil

³Dept. Of Gastroenterology, Usuy Clinic, Florianopolis/Brazil

Contact E-mail Address: ricfittipaldi@hotmail.com

Introduction: Intragastric balloons (IGB) are already used worldwide in the treatment of overweight and obesity, with established success. The Spatz3® adjustable balloon brings the possibility of balloon volume control during all the treatment, possibly reducing the risk of early removals due to intolerance and greater weight loss when compared to traditional IGBs.

Aims & Methods: We aimed to analyze the initial 25 months results regarding weight loss and complications with Spatz3® adjustable intragastric balloon in Brazil. In this retrospective longitudinal study were included patients submitted to Spatz3® adjustable IGB treatment between October 2014 to April 2017 in four private clinics in Brazil. The IGB Spatz3® was filled with a standard volume of 600 ml that was downward or upward adjusted when necessary. The patients presented a minimum body mass index (BMI) of 27 kg/m². Were analyzed the complications of Spatz3® treatment and BMI reduction, percent total body weight loss (%TBWL) and percent excess weight loss (%EWL). Data were analyzed using descriptive statistic and the Student t test. The level of significance was set at $p < 0.05$.

Results: 422 patients underwent implant Spatz3® balloon in the period. The complications (14.28%) at the present study were: early balloon removal (6.89%), gastric ulcer (3.94%), spontaneous deflation (1.48%), gas production inside the balloon (0.98%), gastric perforation (0.23%) and Malory Weiss Syndrome (0.23%). There was no death at the present study. Twenty-eight patients underwent downward adjustment due to intolerance (mean volume reduction: 162.86 mL) and all of them kept in the treatment (no early removals). 180 patients have completed the treatment (minimum 9 months of gastric balloon stay). The BMI decreased from 37.69 to 31.51 kg/m² ($p < 0.0001$), body weight decreased from 107.67 to 90.16 kg ($p < 0.0001$) and excess weight diminished from 36.79 to 19.27 kg ($p < 0.0001$). Eighty-six patients underwent upward adjustment. The adjustment resulted in a further mean weight loss of 4.2 kg (-9 to 20 kg), the range of upward volume was 281.73 ± 66.58 ml (100–420 ml) and the moment of the procedure was 7.06 ± 1.64 months. The group of patients that did the upward adjustment don't have a higher %TBWL, %EWL or a higher BMI reduction when compared to the group that did not ($p=0.4413$, $p=0.9245$, $p=0.2729$, respectively).

	Total (n = 180)	With adjustment (n = 86)	Without adjustment (n = 94)
Body weight (kg)			
Baseline	107.67 ± 23.65	108.66 ± 25.12	106.76 ± 22.3
Final	90.16 ± 22.53	90.41 ± 23.39	89.94 ± 21.83
Reduction	17.51 ± 11.67	18.26 ± 10.99	16.83 ± 12.28
% TBWL	16.22 ± 9.74	16.81 ± 9.09	15.68 ± 10.33
BMI (kg/m ²)			
Baseline	37.69 ± 6.16	38.26 ± 6.56	37.16 ± 5.77
Final	31.51 ± 6.11	31.55 ± 6.11	31.29 ± 6.14
Reduction	6.18 ± 4.07	6.51 ± 3.91	5.87 ± 4.21
Excess weight (kg)			
Baseline	36.79 ± 19.07	38.15 ± 20.15	35.58 ± 18.04
Final	21.79 ± 19.33	19.89 ± 18.45	23.25 ± 19.39
% EWL	56.68 ± 40.12	56.98 ± 34.18	56.41 ± 42.86
%TBWL			
< 10%	52 (28.89%)	19 (22.09%)	33 (35.11%)
≥ 10%	128 (71.11%)	67 (77.91%)	61 (64.89%)
% EWL (n;%)			
< 25%	40 (22.22%)	16 (18.6%)	24 (25.53%)
≥ 25%	140 (77.78%)	70 81.4%)	70 (74.47%)
BMI (n;%)			
23–28 kg/m ²	21 (11.67%)	10 (11.63%)	11 (11.7%)

Conclusion: This study shows that Spatz3® IGB treatment is an effective procedure for weight reduction, without mortality but with higher morbidity rates when compared to tradition IGBs. Even more, the downward adjustment shows to be effective in preventing the early balloon removal, although the upward adjustment does not show to be able in providing a greater weight loss.

Disclosure of Interest: M. Galvao Neto: I declare that I had received personal fees from FRACTYL LABS, GI WINDOWS, APOLLO ENDO SURGERY, GI DYNAMICS, ETHICON ENDO SURGERY, not related to the present study. All other authors have declared no conflicts of interest.

P1948 VOMITING FREQUENCY AFTER INTRAGASTRIC BALLOON PLACEMENT AND INTRAVENOUS HYDRATION REQUIREMENT

⁵Bariatric Endoscopy, Faculdade de Medicina do ABC - Hospital Mário Covas, São Paulo/Brazil

Contact E-mail Address: sergio.barrichello@healthme.com.br

Introduction: The endoscopic treatment of obesity and over weight with intragastric balloon (IGB), is a safe and effective option. Nausea and Vomiting are the most commons side effects after IGB implant.

According to A. Scudero Sanches, 71.1% of patients experience nausea and 57.9% had vomiting. Iñaki Imaz et al, in a systematic review with more than 3000 patients showed that nausea and vomiting are the fifth leading cause of early accessory explantation. The reported symptoms are more common in first 3 days post implant.

Regarded as one of the major causes of gastric balloon early removal, is important to evaluate in daily practice the frequency of patients requiring intravenous hydration to quell nausea and vomiting during the first day os the accessory use.

Aims & Methods: Evaluation of Frequency of vomiting and number of patients requiring intravenous hydration (HEV) after gastric balloon placement. This was a retrospective analysis of medical records of 340 obese and over weight patients treated with intragastric balloon, between November 2015 to December 2016 in the bariatric endoscopy division of the Mario Covas Hospital in São Paulo. The implant was performed by 3 endoscopists with experience in bariatric endoscopy, all procedure were performed under moderate sedation and anesthetist's care. The patients used omeprazole 40mg once a day, and antiemetic drugs (dimenhydrinate) 8/8 hours the first 5 days as well. The data recorded were about the numbers and frequency of vomiting and if there was need for intravenous hydration during the first three days after intragastric balloon implant

Results: There were 340 patients treated with intragastric balloon between 2015 and 2016.

The present study showed 74.41% vomiting until the third day after placement of the BIG, and it is in accordance with literature. Those 252 patients who had vomiting, 67.58% presents frequency of 0 to 5 times per day and 32.42% of the group 5 to 10 times per day. Approximately 9.48% of the patients required intravenous hydration and there were no early explant.

Conclusion: Gastric balloon causes vomiting in the early days post implant in 74.41% of patients and cause dehydration requiring Intravenous fluid therapy in 7.06% of all patients who underwent implantation of gastric balloon (IGB).

Safety and effectiveness of the intragastric balloon for obesity. A meta-analysis. Imaz I, Martínez-Cervell C, García-Alvarez EE, Sendra-Gutiérrez JM, González-Enríquez J. Obes Surg. 2008 Jul;18(7):841–6. doi: 10.1007/s11695-007-9331-8. Epub 2008 May 6. Review. PMID:18459025

All other authors have declared no conflicts of interest.

Patients' body mass distribution had a clear improvement, with a significant increase in the percentage of Fat-Free Mass. A significant reduction of the basal metabolic rate of 1893.24 to 1694.67 was noted. Endoscopic approach with gastric balloon provides a significant weight loss and helps patients acquiring healthy habits

Introduction: Endoscopic methods, especially the intragastric balloon (IGB), have been shown to be effective for the treatment of excess weight.

Aims & Methods: We aimed to assess the efficacy and complications of excess weight treatment with a non adjustable IGB.

A liquid-filled IGB with a volume of 600 to 700 ml was used. The patients had a minimum initial body mass index (BMI) of 27 kg/m2 and were followed up by a multidisciplinary team consisting of a nutritionist, a doctor and a psychologist. For statistical analysis, the patients were divided into groups according to sex and degree of excess weight (overweight and grade I, II and III obesity). Data were analyzed using descriptive statistical methods, the Student t-test, and analysis of variance followed by the Tukey post-test. The level of significance was set at $p < 0.05$.

Results: A total of 5874 patients were analyzed. The incidence of complications was 7.32% ($n = 430$), as listed below: 299 (5.09%) early IGB removal, 58 (0.98%) absence of weight loss or weight gain. The incidence of gas production inside the balloon was 0.20% ($n = 12$) and the incidence of leakage was 0.54% ($n = 32$); pregnancy was 0.32% ($n = 19$); gastric perforation was 0.06% ($n = 4$); upper digestive bleeding was 0.05% ($n = 3$); Wernick Korsakoff syndrome due to excessive vomiting was 0.01% ($n = 1$), pancreatitis and esophagus perforation was 0.01% each ($n = 1$). Of the 5444 remaining patients, 4081 (74.9%) were women and 1363 (25.1%) were men. Mean age was 38.38 years. The patients showed a significant weight loss, with a significantly lower final BMI (mean: 30.08 ± 5.06 kg/m2) than the initial BMI (mean: 36.94 ± 5.67 kg/m2) ($p < 0.0001$). Mean BMI reduction was 6.85 ± 3.06 kg/m2 (range: 0.25–29.79). Mean percent total body weight loss (TBWL) was $18.42 \pm 7.25\%$ and mean percent excess weight loss (EWL) was $65.66 \pm 36.24\%$ (range 3.99–336.14). The weight loss in kilograms was 19.13 ± 8.86 . The treatment success rate (%EWL > 25) was 93.0%, as follow: overweight was 99.0%, grade I obesity was 95.83%, grade II obesity 93.65% and grade III obesity was 86.09%. Percent EWL was higher in the overweight group (OVW) (131.54%EWL), followed by grade I obesity (G1O)(76.67%), grade II obesity (G2O) (56.01%) and grade III obesity (G3O) (45.45%) sequentially ($p < 0.0001$). Percent EWL was also higher in women (69.71%EWL) than in men (53.39%EWL) ($p < 0.0001$). Results are better shown in table 01.

Introduction: While monitoring weight loss in patients undergoing very low calorie diets (VLCD), regardless of which method used, mostly patients experience significant weight reduction, but also a significant fat-free mass (FFM) loss. The fat-free mass loss is associated a decrease in basal metabolic rates, a fact confirmed in patients undergoing treatment with intragastric balloon (IGB).

Aims & Methods: Retrospective study was conducted with analysis of medical records of obese patients treated with intragastric balloon between 2013 to 2015 in a supplementary health service. Patients were evaluated at three different moments: before intragastric balloon placement, 45 days post implant and after BIG removal (30 days).

Results: We evaluated 29 patients, mean age of 40.07 years (± 10.35 years), pre-treatment weight 97.44 kg (± 16.70 kg), pre BMI 35.51 kg/m2 (4.3 kg/m2) and a bioimpedance showing a % of fat-free mass (FFM) of 63.15 and 36.84% fat mass (FM) with a metabolic pretreatment rate of 1893.24 (± 337.21). Forty five days after gastric balloon placement, bioimpedance avaluation showed 64.9% of Fat-Free Mass, 35.1% of Fat Mass and metabolic rate in 1731, associated with a weight loss of 9.46 kg or 27.37% overweight In the third assessment, there were a significant improvement in BMI, weight and metabolic rate with $p < 0.05$. The final metabolic rate was 1694.67, FFM was 69.7% with 30.3% of FM, a reduction about 17% of the initial weight with the decrease of 44.29% overweight.

Conclusion: Intragastric balloon was effective as minimally invasive treatment of obesity and over weight.

	n = 5444

Introduction: Many factors contribute to the development of irritable bowel syndrome (IBS) including the altered visceral perception, intestinal low-grade inflammation and psychosocial factors. Recent research has revealed a relationship between intake of FODMAPs (Fermentable Oligosaccharides, Disaccharides, Monosaccharides, and Polyols) and abdominal complaints. A diet low in FODMAPs can reduce symptoms in patients with IBS but mechanisms were poorly understood.

Aims & Methods: We aim to explore the role of FODMAPs in triggering IBS symptoms by investigating visceral sensitivity, intestinal inflammation and short chain fatty acid (SCFA) in stress induced IBS mice model. Fructo-oligosaccharide (FOS) as one of the most frequently exposed FODMAPs in daily life was used in this study. Mice were subjected to water avoidance stress (WAS condition; 1 h/day for 10 days) or sham stress (basal condition; 1 h/day for 10 days) with an oral gavage of saline or saline solution containing FOS (8 g/kg) for 2 weeks. Then visceral sensitivity was measured by abdominal withdrawal reflex (AWR) in response to colorectal distension (CRD) and histologic analyses were used to evaluate mucosal inflammation. Immunohistochemistry, reverse transcription, and gas chromatography were used to estimate mucosal mast cell, levels of cytokines (IL-6, IL-23, TNF- α , IL-10, IL-1 β) and SCFA, respectively.

Results: Stress induced visceral hyperalgesia and low-grade inflammation in WAS mice as a model of IBS. In WAS condition, increased visceral sensitivity and mucosal mast cell (12.3 ± 2.61 vs. 8.33 ± 3.55 , $P < 0.01$) were observed in FOS-administered mice compared with saline-administered mice. In WAS condition, cytokine expression were mediated by FOS with increased IL-23 (3.17 ± 2.11 -fold, $P < 0.05$) in ileum and IL-1 β (2.45 ± 1.55 -fold, $P < 0.05$) in colon compared with saline. In addition, the average concentrations of acetic (2.48 ± 0.62 vs. 1.04 ± 0.10 , $P < 0.01$), propionic (0.48 ± 0.09 vs. 0.33 ± 0.0 , $P < 0.01$), butyric (0.27 ± 0.09 vs. 0.19 ± 0.003 , $P < 0.05$) and total SCFA (3.61 ± 0.89 vs. 1.79 ± 0.17 , $P < 0.01$) significantly increased in FOS-administered mice compared with saline-administered mice in WAS condition. In basal condition, no difference of visceral sensitivity, intestinal inflammation and SCFA were observed between mice treated with FOS or saline.

Conclusion: Oral gavage of FOS leads to both an increase in visceral sensitivity and gut inflammation in stress induced IBS mice. These effects are link with the production of SCFA in the gut which involved in the regulation of sensitivity and intestinal immune activation. These findings support the hypothesis that visceral hypersensitivity and intestinal inflammation aggravated by certain FODMAPs may be responsible for IBS symptom generation, and indicate an alternative mechanism of the efficacy of the low-FODMAP diet for IBS patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Several formulations consisting of live lactic acid bacteria, including bifidobacteria, are marketed as probiotic products. However, these products are often poorly defined and insight into their mode of action is lacking. This hampers further application in treating diseases, limits comparative studies, and prevents predicting their efficacy. We have previously addressed this by providing genomic and functional characterization of single commercial strains (Kainkainen et al 2009, Douillard et al 2013, Tytgat et al 2016). The multispecies product VSL#3 is marketed globally for treating colitis ulcerosa, pouchitis, and irritable bowel syndrome. To provide a rational basis for understanding the function of VSL#3 and generate a baseline for future studies, the genomes of all 8 strains that make up this multispecies product were determined and used to predict their function. The strains were provided by the facility which is currently producing both the single strains and the blend mix (CSL-SACCO System, Zelo Buon Persico - Lodi-ITALY).

Aims & Methods: The individual strains of multispecies product VSL#3 were cultured on MRS-based media and DNA was extracted using established methods. The DNA was subject to paired-end Illumina sequencing using a HiSeq2000 platform, assembled and annotated as previously described (Douillard et al 2013).

Results: The next generation sequencing provided high quality genomes of all 8 strains that are components of the multispecies product VSL#3. Detailed phylogenetic and genomic analysis confirmed the species composition to be as indicated in the VSL#3 product specification and showed the 8 strains of this multispecies product to belong the species *Streptococcus thermophilus*, *Lactobacillus acidophilus*, *Lactobacillus (para)casei*, *Lactobacillus plantarum*, *Lactobacillus helveticus*, *Bifidobacterium breve* and *B. animalis* subsp. *lactis* (this species included two strains). The species *L. paracasei* and *L. casei* are highly related and in need for further official taxonomic resolution. The annotated genes of the assembled genomes were used to identify genes involved in potential probiotic functions. Full sets of genes for the production of tight adherence pili were observed in the *Bifidobacterium* spp. and are known to produce pseudopilins that we recently identified to mediate microbe-host crosstalk, promote intestinal integrity, and influence host cell development (O'Connell Motherway et al 2011). Moreover, a series of signaling proteins were identified in the genomes of the *Lactobacillus* spp., including surface layer proteins and sortase-dependent pili proteins that we showed to interact with the mucosal surfaces and dendritic cells (Konstantinov et al 2008; Kankainen et al 2008; Tytgat et al 2016).

Conclusion: The genomic analysis of the VSL#3 strains confirmed the product specifications, defined the baseline genetic coding capacity, and predicted a number of probiotic mechanisms that could explain the efficacy of this multispecies product.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Disease prevention and high public awareness are fundamental to reduce morbidity, mortality and health-related costs. Extensive research led to identification of causes of gastrointestinal (GI) diseases, nevertheless it is still difficult to get population involved. The goals of our pilot campaign are: (a) to raise awareness about GI diseases, risk factors, signs, symptoms, in order to convince people to change behavior and to prompt them with concerns to visit doctors as early as possible; (b) to facilitate communication between healthcare providers and population; (c) to determine the knowledge of health personnel about the appropriate diagnostic investigations. Any information we can share may also benefit patients and their families, in recognition of the many people who suffer with the pain and discomfort caused by GI disorders.

Aims & Methods: We organized population-based events, out of health facilities, during which: (a) giant inflatable anatomical models of GI organs that can be visited inside, were installed; (b) educational panels and brochures were set and explained both inside and outside the models; (c) videos illustrating endoscopic exams and histopathology examinations were projected and discussed; (d) clinical cases, also mimicking patient encounter, were simulated.

Results: We started an innovative strategy focused on the keywords: multidisciplinary team, scientific rigor but simple words, people attraction, curiosity inducing communication, in Parma and neighbouring Cities. Specialists in Gastroenterology, Anatomic Pathology, Radiology, Surgery, Biochemistry, Nutrition, together with pre- and post-graduate Students, discussed various aspects of gastrointestinal diseases. Selected people were examined by ultrasonography. Municipality and civil society were also involved to ensure organizational efficiency. The most discussed topics regarded dyspepsia, gastritis, helicobacter pylori infection, gastroesophageal reflux disease, alcohol abuse, cirrhosis, hepatitis, irritable bowel syndrome, intestinal polyp and polyposis, GI cancer, food allergy and intolerance, optimal nutrition in health and disease. The event performed in the main square of Parma lasted two full consecutive days and was attended by about 3,000 people, most of which also filled a questionnaire. A total of 120 ultrasound examinations were performed. In neighbouring Cities the events were organized for one day; as a consequence, the number of participants was lower in proportion, but very satisfactory.

Conclusion: The events were educational and enjoyable for all age groups. The interactive approach and the environment out of health-care centres facilitated population to feel comfortable and eager to learn, as well as clinical cases simulation provided a valuable entertaining experience. This strategy of raising public awareness of GI diseases seems promising, we are refining the model for a national campaign.

Introduction: Amino acids are essential metabolites which play a role as protein constituents. Moreover, amino acids and their metabolites feature in regulation of anabolic and catabolic metabolism, detoxification processes, and act as neurotransmitters. Concentration of circulating amino acids reflects about dietary protein intake and can be an indicative of malnutrition. Changes in the amino acid homeostasis are observed in coeliac disease (CD) [1] due to malabsorption caused by enteropathy but also because of the treatment with gluten-free diet (GFD) shown to be low in the important nutrients.

Aims & Methods: A randomized, placebo-controlled interventional trial was designed to assess the influence of an oligofructose-enriched inulin (OEI) as a supplement of GFD on plasma profile and urine excretion of amino acids in CD children strictly following GFD at least 1 year. We randomized 34 children diagnosed with CD into a group receiving 10 g of OEI daily and a placebo (maltodextrin) group during a 12-week nutritional intervention. Amino acid profiles in urine and plasma was analysed via EZ:Faast™ derivatisation method followed by gas chromatography/mass spectrometry detection.

Results: At the baseline and after supplementation, 22 and 27 amino acids were identified in plasma and urine, respectively in both groups of children. Significantly higher levels ($p < 0.05$) of alanine, serine, asparagine, glutamine, threonine, phenylalanine, lysine, histidine, α -aminoadipic acid, α -aminopimelic acid, hydroxylysine and cystine were determined in urine of OEI group after intervention as compared to the baseline and placebo group. The analysis of amino acid profiles in plasma samples showed a significant increase ($p < 0.05$) of majority of amino acids in both OEI and placebo groups after intervention. However, the concentrations of glutamine and glutamic acid were significantly higher ($p < 0.05$) in the OEI supplemented group.

Conclusion: Our study showed that supplementation of GFD with OEI impacts the amino acid homeostasis in CD children. OEI in GFD increased a total concentration of amino acids in both urine and plasma. Higher excretion of amino acids in urine accompanied with increased amino acid content in plasma may indicate the improved absorption or/and stimulated de novo synthesis of proteins. Increase in the concentration of glutamine can stimulate recovery of the intestinal mucosa by itself or by the involvement in the synthesis of citrulline known as negatively correlated with intestinal mucosal damage [1], therefore we can suspect that OEI added to GFD can help in restoring of the intestinal barrier integrity.

Disclosure of Interest: All authors have declared no conflicts of interest.

The research was supported by statutory funds of the Department of Chemistry and Biodynamics of Food in the IAR&FR PAS and by the National Science Centre, Poland (project number: 2016/21/N/NZ9/01510).

P1955 LONG-TERM TRENDS IN HEMATOLOGICAL AND NUTRITIONAL STATUS AFTER GASTRECTOMY FOR GASTRIC CANCER

J. Kim

General Surgery, The Catholic University of Korea, Seoul/Korea, Republic of

Contact E-mail Address: doctor2003@catholic.ac.kr

Introduction: The quality of life and nutritional management after gastrectomy are major issues for gastric cancer patients, as is oncological surveillance. Weight loss usually follows gastric resection, with reported losses ranging from 10% to 30% of the preoperative weight. This loss has been attributed to inadequate oral intake, malabsorption, rapid intestinal transit time, and bacterial overgrowth. Timely, appropriate nutritional intervention can minimize diet intolerance, weight loss, and micronutrient deficiencies that often follow surgery.

Aims & Methods: This study investigated long-term trends in hematological and nutritional parameters after gastrectomy for gastric cancer and evaluated the influence of the reconstruction type on these trends. The medical records of 558 patients who underwent curative gastrectomy with standard lymph node dissection for stage I gastric cancer between January 2006 and December 2013

were reviewed. The hematological and nutritional parameters evaluated included hemoglobin, ferritin, vitamin B₁₂, total protein, albumin, total cholesterol, triglyceride, and calcium. The patients were followed up for 6 months postoperatively and then annually until death, cancer recurrence, or follow-up loss.

Results: In the long term, ferritin and triglyceride gradually decreased after gastrectomy, while the other parameters decreased slightly or were stable. In the comparisons according to reconstruction type, the Roux-en-Y group had the lowest levels of hemoglobin, ferritin, vitamin B₁₂, total protein, albumin, and total cholesterol beginning 6 months postoperatively compared with the Billroth I and II groups. However, only ferritin and vitamin B₁₂ had significant differences in the 5-year cumulative incidences of deficiency according to the reconstruction type, whereas albumin, triglyceride, total cholesterol and calcium did not.

Conclusion: Although malabsorption and malnutrition are common in patients after a gastrectomy, most nutritional parameters were stable or decreased slightly in the long-term and were not markedly influenced by the reconstruction type or extent of gastrectomy. Therefore, for more accurate nutritional assessment after gastrectomy, multidirectional monitoring should be considered rather than simply measuring biochemical parameters.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1956 EVOLUTION OF REPRODUCTIVE DISORDERS RELATED TO CELIAC DISEASE UNDER GLUTEN -FREE DIET

A. Aomari¹, M. Firwana¹, A. Amjahdi¹, I. Benelbarhadi²

¹CHU Rabat, Rabat/Morocco

²Rabat, Ibn Sina Hospital, Rabat/Morocco

Contact E-mail Address: ayoub.medinterne@gmail.com

Introduction: Celiac disease is an autoimmune enteropathy induced by the ingestion of gluten. The classical form has become a minority. Currently, the most frequent forms of presentation are extradigestive with various manifestations, among others, reproductive disorders. The aim of our study is to assess the frequency of these disorders in celiac disease and their evolution under gluten-free diet.

Aims & Methods: Descriptive retrospective study of 173 patients with celiac disease followed in the department of diseases of the digestive tract medicine c of the Ibn Sina Hospital in Rabat, over a period of 18 years.

Results: In 173 patient with celiac disease, 58 patients had reproductive disorders. there are 53 women and 5 men. The average age was 32.25 years; the diagnosis of celiac disease is based on histology and serology. The reproductive problems were never isolated but always associated with other digestive signs at the time of diagnosis of celiac disease. These disorders are represented by: delayed puberty in 11 cases, secondary amenorrhea in 13 cases, irregular menstrual in 12 cases, absence of development of secondary sex characteristics in 8 cases, spontaneous abortions in 7 cases, menometrorrhagia in 4 cases, primary sterility in 5 cases early menopause in 6 cases, premature delivery in 3 cases primary amenorrhea in 2 cases and intrauterine fetal death in 1 case. All our patients have had a gluten-free diet. 15 Patients lost to follow-up, 2 patients died, and 12 patients undergoing follow-up. The remaining 29 patients, the evolution of reproductive disorders under gluten-free diet was favorable in 26 cases (90%), with the normalization of cycles in 15 cases, resumption of cycles in 6 cases development of secondary sex characteristics in 2 cases, fertility resumption in one case, initiation of cycles after primary amenorrhea in one case and delivery of a newborn at term after premature deliveries in one case. The evolution was unfavorable in 3 cases with the notion of miscarriage 4 years after the start of the gluten-free diet in one patient and the absence of cycle resumption in 2 cases.

Conclusion: The reproductive disorders associated with celiac disease are frequent and varied. In our study, these disorders responded very well under a gluten-free diet conducted in 90% of the case. these disorders are thus reversible under this diet.

Introduction: High -fat diet induces depression and anxiety, alters gastrointestinal motility in rats but operative mechanisms are not clear. Vagal nerve conducts physiological information about luminal content to the higher brain centres.

Aims & Methods: Is there any role of vagal afferent nerves on high fat diet (HFD)-induced alterations in cognitive functions and gut motility? Ten-week old male Sprague-Dawley rats (n=38) were treated with either perivagal 1% capsaicin (n=19) or vehicle (10% Tween 80 in oil) (n=19). After 3 weeks of recovery, rats were pair-fed with chow (fat 2-7%) (n=18) or HFD (% 45 fat) (n=20) for 5 weeks until decapitation. In between 4th and 5th weeks of HFD rats were subjected to open field tests (anxiety and depression-like behaviour); novel object recognition, passive avoidance tests (memory). Food and water intake were measured after 16 hrs. of food and 24 hrs. of water deprivation. Weight of faeces for 16 hrs. and transit time with charcoal were measured. Data was expressed as mean standard deviation, comparison between groups were done with two-way ANOVA.

Results: VAD increased body weight significantly ($p < 0.05$) during feeding period irrespective of fat content of the diet. Fat content and VAD had no effect on 1 hr food intake after food deprivation. HFD decreased water intake ($p < 0.0075$), VAD blunted this effect ($p < 0.05$). Both HFD and VAD decreased faeces weight significantly ($p < 0.0001$ and $p < 0.05$ respectively) but there was not any change in intestinal transit. HFD impaired short-term memory ($p < 0.02$), whereas VAD compromised spatial learning ($p < 0.04$). HFD rats were more anxious in OFT ($p < 0.01$).

Conclusion: HFD-induced alterations in memory and anxiety were not affected by VAD but VAD blunted effect of HFD on water intake and faeces weight, suggesting that their operating mechanisms are different. VAD by itself impaired spatial memory that requires further investigation.

Introduction: Total gastrectomy can profoundly influence patients' nutritional status and controversy surrounds the various nutritional options available post-operatively, namely total parenteral nutrition (TPN), or enteral nutrition (EN) either via the nasogastric or feeding jejunostomy (JJE) route. The aim of this review was to determine the optimal nutritional route after total gastrectomy for cancer.

Aims & Methods: PubMed, MEDLINE and the Cochrane Library (January 1985 to January 2017) were systematically searched for randomized controlled trials comparing various nutritional routes after total gastrectomy. The primary outcome measure was overall morbidity.

Results: Six studies involving 353 patients (median age 62 years, 217 males, 170 TPN, 96 NJ, 87 JJE) who underwent total gastrectomy were analysed. Overall morbidity was significantly greater in patients after TPN compared with EN [odds ratio (OR) 1.95, 95% Confidence Interval (CI) 1.16-3.28, $p=0.01$]. There was a trend towards greater mortality in patients who received TPN compared with EN (OR 1.90, 95%CI 0.64-5.70, $p=0.25$). When EN was sub-analyzed according to NJ or JJE, morbidity was significantly greater in patients who received TPN compared with JJE (OR 4.59, 95%CI 1.74-12.10, $p=0.002$) but not in patients who received NJ feeding (OR 1.23, 95%CI 0.64-2.36, $p=0.53$).

Conclusion: Enteral nutrition in the form of feeding jejunostomy was associated with lower morbidity compared with TPN following total gastrectomy for cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Patients on home parenteral nutrition (HPN) are exposed to a life-long risk of catheter-related bloodstream infections (CRBSI), which threaten catheter and patient survival. Both taurolidine 2% and saline 0.9% solution are used as catheter lock solutions (CLS) to prevent CRBSI. The optimal agent however, remains unclear. We hypothesized that taurolidine as CLS is superior to saline in preventing CRBSI in HPN patients.

Aims & Methods: We hypothesized that taurolidine 2% as CLS is superior to saline 0.9% in preventing CRBSI in HPN patients. This multicenter double blinded trial randomly assigned HPN patients to use either the CLS taurolidine 2% or saline 0.9% for one year. Primary outcome was the number of CRBSI/1000 catheter days. Secondary outcomes included time to CRBSI or catheter removal due to CRBSI, number of catheter removals due to CRBSI, exit-site infections, catheter occlusions, and (serious) adverse events.

Results: Of 105 randomized patients, 102 were enrolled as modified intention-to-treat population. With taurolidine, 5 CRBSI occurred during 15318 catheter days. In the saline arm 18 CRBSI occurred over 12493 catheter days. CRBSI/1000 catheter days were 0.33 and 1.44 in the taurolidine and saline groups, respectively (relative risk, 0.23; 95%CI, 0.07 to 0.63; $P=0.002$). The cumulative proportion of CRBSI-free patients after one year was 88% in the taurolidine group and 49% in the saline group ($P=0.002$). The number of catheter removals due to CRBSI was two (4%) in the taurolidine group and eight (16%) in the saline arm ($P=0.049$). The cumulative proportion of patients without a catheter removal due to CRBSI was higher in the taurolidine group ($P=0.025$). Exit-site infection and catheter occlusion rates were similar in both groups. Except for occurrence of CRBSI ($P=0.002$), there was no difference in (serious) adverse events between groups. Drug-related adverse events were rare and generally mild to moderate.

Conclusion: Taurolidine 2% decreased the risk for CRBSI by more than four times in HPN patients compared to saline 0.9%. Given its favorable safety profile and lack of evidence for altering microbial susceptibility, taurolidine locking therefore seems a key strategy to prevent CRBSI.

P1960 REPAIR OF DAMAGED CENTRAL VENOUS CATHETERS SUBSTANTIALLY PROLONGS DEVICE SURVIVAL IN PATIENTS ON HOME PARENTERAL NUTRITION

Y. Wouters¹, R. Vissers¹, W. Kievit², G. Wanten¹

¹Radboudumc, Nijmegen/Netherlands

Introduction: Patients with severe intestinal failure depend on life-long home parenteral nutrition (HPN) support. Repeated central venous catheter (CVC) loss due to complications, including mechanical damage, compromises vascular access. It remains unclear whether repair of damaged CVCs is an effective strategy to extend catheter life, avoid surgical replacement and maintain venous access.

Aims & Methods: The objective of this study was to characterize patients who underwent catheter repair and to evaluate effects on catheter survival and describe complications. This study concerns a retrospective analysis of all catheter repairs that were performed in HPN patients in the Radboud University Medical Center between January 2000 and May 2017. Primary endpoint was the difference in catheter survival in the presence or absence of catheter repair. To this end, a non-parametric survival analysis was performed. Secondary outcomes included localization of catheter damage and frequency of repair-related complications within 1 month after catheter repair.

Results: A total of 50 repairs in 38 CVCs of 32 HPN patients were included in the analysis. 16 CVCs (32%) were damaged at the distal end, near the screw thread of the catheter, 25 CVCs (50%) at the junction between the rigid and flexible part of the catheter, and 9 CVCs (18%) at the flexible part of the catheter. The mean time to catheter repair after placement was 2.2 years (95% CI = 1.55–2.89). The mean catheter survival after repair was extended by 1.4 years to 3.6 years (95% CI = 2.69–4.46; $p = 0.01$). No repair-related complications occurred within 1 month after catheter repair.

Conclusion: Repair of damaged CVCs significantly extends catheter life in HPN patients and maintains venous access. Catheter repair is a safe procedure.

P1961 LONG-TERM CLINICAL OUTCOMES OF PATIENTS ON HOME PARENTERAL NUTRITION USING TAUROLIDINE CATHETER LOCKS

Y. Wouters¹, B. Roosenboom², W. Kievit¹, G. Wanten²

¹Radboudumc, Nijmegen/Netherlands

²Department Of Gastroenterology And Hepatology, Radboud University Nijmegen, Nijmegen/Netherlands

Contact E-mail Address: Yannick.Wouters@radboudumc.nl

Introduction: Catheter-related complications (CRCs) in home parenteral nutrition (HPN) patients are a threat to both catheter and patient survival. Taurolidine 2%, an antimicrobial catheter lock solution (CLS), is an effective agent for the prevention of catheter-related bloodstream infections (CRBSI).

Aims & Methods: The aim of this retrospective study was to evaluate long-term clinical outcomes of our HPN patient cohort that uses the CLS taurolidine. Between 2008 and 2016, all adult HPN patients requiring a central venous catheter (CVC) or port-a-cath (PAC) who used taurolidine as CLS were included. CRC incidence rates/1000 catheter days were described. Kaplan-Meier analysis was used to determine the time until a first CRC. Cox proportional hazard analysis was performed to identify risk factors for a first CRC.

Results: In 221 HPN patients, 658 CVCs (418 Hickmans, 172 PACs, and 28 non-tunneled CVCs) were inserted, comprising 261252 catheter days. Median survival for Hickmans, PACs and non-tunneled catheters was 175 (43–544), 310 (61–827) and 14 (7–19) days, respectively. During eight years of follow-up, 176 CRBSI occurred and 80 catheter-related occlusions (CRO). CRBSI and CRO rates/1000 catheter days were 0.74 and 0.34, respectively. In 47% and 32% of patients, at least one CRBSI and CRO occurred, respectively. Median time to a first CRBSI or CRO was 246 (54–817) and 215 catheter days (5–2070). Numerically, but not significantly, CRBSI and CRO rates decreased over time. The sole use of intravenous fluids was associated with a significantly lower risk for CRBSI (RR 0.32). Twenty patients reported adverse events (5 grade 1, 13 grade 2 and 2 grade 3) which were possibly related to the use of taurolidine.

Conclusion: This study describes the largest cohort of HPN patients to date on long-term taurolidine 2% as CLS. Overall, CRC incidence rates were low when compared with the literature. We found no evidence for a decreased effect of taurolidine over time.

Introduction: Patients with short bowel syndrome (SBS) exhibit substantial disturbances in gut microbiota composition, which implicates significant alterations of intestinal metabolome.

Aims & Methods: The aim of this study was to perform genetic and metabolomic analysis of stool samples collected from SBS patients totally dependent on parenteral nutrition (TPN). We analysed the stool samples from 8 healthy individuals and 8 patients with SBS dependent on TPN. Faecal microbiota composition was assessed by sequencing of variable V3 and V4 regions of 16S rRNA gene using Illumina MiSeq TM platform. Library preparation, template preparation and template sequencing was performed according to manufacturer's protocols. Obtained data were filtered by quality and length and processed for alpha and beta diversity analyses using QIIME software package. SCFA profile was measured using solid phase microextraction (SPME) coupled to gas chromatography and high resolution mass spectrometry employing time of flight mass analyser (Pegasus GC-HRT; LECO, USA). D-lactate content was determined using Megazyme kit.

Results: Weighted Unifrac analysis revealed significant differences between control and TPN subjects. In healthy controls, most abundant phylum was Firmicutes (64.2 ± 7.5%), followed by Bacteroidetes (22.5 ± 9.1%) and Actinobacteria (8.9 ± 4.5%). Proteobacteria were found only in one control sample. In TPN group, Firmicutes represented 66.4 ± 29% of microbiota but Bacteroidetes were absent and Actinobacteria significantly reduced (1.6 ± %). Proteobacteria were found in all samples (23.6 ± 15%). The most abundant metabolites in control stool samples were short - chain fatty acids (SCFA): acetate, propionate and butyrate. In the TPN group, lactate predominated significantly, while SCFA were absent in the intestinal content of these patients.

Conclusion: Long-term dependence on total parenteral nutrition results in dysbiosis of the intestine residuum characterized by extinction of Bacteroidetes and appearance of Proteobacteria. This shift was reflected by the changes in the composition of prevailing metabolites in stool.

P1963 COMPARING RISKS OF ADVERSE EVENTS ASSOCIATED WITH PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) PLACEMENT BETWEEN THE MODIFIED INTRODUCER TECHNIQUE AND THE OVERTUBE ASSISTED PULL TECHNIQUE

H. Matsui¹, H. Inomata¹, H. Horiuchi¹, N. Tamai¹, K. Sumiyama¹

¹Department Of Endoscopy, Jikei University School of Medicine, Tokyo/Japan

Contact E-mail Address: hiro24tht80@yahoo.co.jp

Introduction: Techniques of percutaneous endoscopic gastrostomy (PEG) placement can be divided into two techniques, the pull technique or the introducer technique. Although the development of the pull technique greatly improved procedural safety for the gastrostomy placement, the pull technique, in which the PEG catheter is delivered through the oral cavity and the hypopharynx, inevitably contaminates the peristomal site. A series of studies directly comparing the newly developed modified introducer technique using a blunt cannula compared with the conventional pull technique demonstrated that the modified introducer technique was more preferable regarding procedure related adverse events.^{1,2} Meanwhile, use of an overtube while guiding the catheter into the stomach in pull technique succeeded the reduction of the bacterial implantation. It is still unclear if the modified introducer technique or the overtube assisted pull technique would reduce risks of adverse events.

Aims & Methods: In this study, we retrospectively investigated risks of adverse events associated with the modified introducer technique and the overtube assisted pull method. Outcomes of patients who underwent the PEG placement from Jan 2013 to Oct 2016 at Jikei University Hospital were analyzed. The following data were collected from clinical records: age, gender, technique of PEG, reasons for PEG, lab tests and prognostic nutritional index (PNI).

Results: During the study period, 236 PEG placements were done in 234 patients. The average age was 69.3 ± 12.5. The modified introducer technique was applied in 167 procedures (70.8%) and the overtube assisted technique was applied in 69 procedures (29.2%). The PEG was placed aiming for nutrition supports for cancer patients in 132 procedures, cerebrovascular accident in 51 procedures, aspiration pneumonia in 32 procedures, and others such as infection and disuse atrophy in 21 procedures. Age (the overtube assisted pull technique > the modified introducer group), Gender and preoperative serum C-reactive protein level were significantly different between the two groups ($p < 0.05$). Overall, adverse events were observed in 19 (8.1%) procedures, although there was no procedure related mortality in the both groups. The risks of clinically significant adverse events were not different between the two groups. There was no significant difference in the types and the rate of adverse events between the two groups. However, severe peristomal bleedings were observed only in the modified introducer technique group. Four patients required suture placements and 3

patients required blood transfusion for the peristomal bleeding. In a univariate analysis, age, the rate of aspiration pneumonia as the reason for the PEG placement were higher in patients encountering adverse events ($p < 0.05$) (table 1). Also, serum platelet level, serum albumin and the rate of nutrition supports for cancer as the reason of the PEG placement was lower in patients encountering adverse events ($p < 0.05$). In a multivariate analysis, lower serum platelet level was solely recognized as a relevant predictive factor for adverse events ($p < 0.05$). The types of the technique used were not relevant to risks of adverse events.

Clinical backgrounds of patients with and without adverse events.

	with adverse events (n = 19)	without adverse events (n = 217)	p
Age (mean \pm SD)	77.4 \pm 7.9	68.6 \pm 12.6	$p < 0.05$
Sex (male/female)	13/6	162/55	n.s.
Technique for PEG (introducer/pull)	13/6	154/63	n.s.
Reasons for PEG (cancer/cerebrovascular accident/aspiration pneumonia/others)	5/5/6/3	127/46/26/18	$p < 0.05$
Lab tests (mean \pm SD)			
ChE (U/L)	184.9 \pm 60.8	214.9 \pm 78.9	n.s.

(continued)

Continued

Clinical backgrounds of patients with and without adverse events.

	with adverse events (n = 19)	without adverse events (n = 217)	p
TP (g/dL)	6.1 \pm 0.9	6.4 \pm 0.8	n.s.
Alb (g/dL)	2.9 \pm 0.6	3.1 \pm 0.6	$p < 0.05$
CRP (mg/dL)	1.5 \pm 2.0	2.0 \pm 3.3	n.s.
WBC (/ μ L)	7336.8 \pm 3162.1	6696.8 \pm 3086.6	n.s.
Hb (g/dL)	10.4 \pm 2.2	11.3 \pm 1.9	n.s.
Plt (/ μ L)	20.7 \pm 8.4	25.6 \pm 8.8	$p < 0.05$
TLC (/ μ L)	1400 \pm 797.9	1387.6 \pm 967.4	n.s.
PNI	35.7 \pm 8.5	38.4 \pm 8.5	n.s.

Conclusion: There was no significant difference in overall risks of adverse events between the modified introducer technique group and the overtube assisted pull technique group. However, the modified introducer technique may be associated with higher risks of severer adverse events. Especially, special care should be taken in patients with lower serum platelet level.

Disclosure of Interest: All authors have declared no conflicts of interest.
