Introduction: Raft-forming alginates may inhibit gastroesophageal reflux; however, remains unexplored effect of alginates on postprandial processes in the stomach.

Aims & Methods: 25 patients (14 F, age 23–69) with typical GERD symptoms, participated in this study. All patients underwent a 3-hour combined gastroesophageal pH-impedance monitoring with standardized breakfast (muffin and coffee). To determine the effect of alginates on postprandial reflux and pH in the esophagus and stomach, all patients underwent a repeat of similar monitoring the next day but in this case, they took alginate after breakfast. The difference in pH in the esophagus, in two parts of the stomach and the different types of gastroesophageal reflux (acid, low acid, alkaline, liquid, gas & mixed) was estimated. To evaluate the effects of raft-forming alginate on the severity of postprandial reflux in patients with GERD and for the postprandial stomach content.

Results: Monitoring with alginate showed significantly ($P < 0.05$) less number of acid [average values 5.42 ± 0.69 ($M \pm m$) vs. 3.33 ± 0.43 during 1st postprandial hour and 3.96 ± 0.8 vs. 1.82 ± 0.57 during 2nd postprandial hour] and gas [0.26 ± 0.06 vs. 0.08 ± 0.05 during 1st postprandial hour and 0.47 ± 0.35 vs. 0 during 2nd postprandial hour] gastroesophageal reflux, but increased of number low acid reflux [2.52 ± 0.46 vs. 3.91 ± 0.82 during 1st postprandial hour and 1.00 ± 0.42 vs. 2.16 ± 0.45 during 2nd postprandial hour; $P > 0.05$]. Also noted is a significant ($P < 0.05$) increase in the pH in the esophagus for 120 minutes after ingestion [average pH values 6.04 ± 0.27 vs. 4.86 ± 0.23 during 0–60 min., and 5.93 ± 0.25 vs. 4.15 ± 0.26 during 60–120 min.]. pH in the gastric cardia (a typical place of formation of postprandial acid pocket) showed significant ($P < 0.05$) higher values for the first 60 minutes after intake of alginate [pH 4.3 ± 0.37 vs. 3.04 ± 0.25], during 60–90 min. pH values wasn't significantly ($P > 0.05$) different [2.75 ± 0.45 vs. 2.43 ± 0.20]. In the stomach body no significant effect of the drug on pH was recorded [average pH values for stomach 2.56 ± 0.46 vs. 2.1 ± 0.18 during 1st postprandial hour and 2.29 ± 0.49 vs. 2.09 ± 0.18 during 2nd postprandial hour; $P > 0.05$].

Conclusion: Our findings demonstrate that raft-forming alginate is an effective means for the prevention of postprandial acid and gas reflux and to reduce the injurious effect of acid in the esophagus. At the same time alginate showed no effect on stomach content in the postprandial period, it means that the main mechanism of action is through the movement of postprandial acid contents of the stomach from the lower esophageal sphincter, but not the neutralization of stomach acid, unlike nonraft-forming antacids and PPIs.

Introduction: S-isomer (S) pantoprazole is more bioavailable and less dependent on cytochrome 2C19 than is racemic pantoprazole.

Aims & Methods: We aimed to evaluate the efficacy and safety of 10 mg S-pantoprazole for treatment of non-erosive reflux esophagitis (NERD). This study was designed as a multicenter, randomized, double-blind, placebo controlled trial. NERD was defined as reflux symptoms and normal endoscopy findings. Patients were allocated to take either 10 mg S-pantoprazole or placebo once daily for 4 weeks, after which reflux symptoms were reassessed. Recurrence of symptoms was assessed at 4 weeks after cessation of medication. The efficacy endpoints were complete relief of symptoms, improvement of reflux symptoms, and safety.

Results: Eighty-eight patients were randomly assigned to the S-pantoprazole group (25 males, 43.7 years old) and 86 to the placebo group (32 males, 43 years old), and 163 patients were subjected to a per protocol analysis. A higher proportion of patients in the S-pantoprazole group had complete symptom relief (34% vs. 14%, $P < 0.001$). In both groups, symptoms of heartburn, acid regurgitation and epigastric discomfort significantly improved after treatment compared with baseline; however, improvement of all symptoms was greater in the S-pantoprazole group compared to placebo group. Therapeutic gains in controls of heartburn, acid regurgitation and epigastric discomfort were 0.66, 1.82, and 0.57. The factors associated with poor symptom responsiveness to PPI were older age, female sex, greater body mass index and symptom severity in both groups.

Conclusion: S-pantoprazole (10 mg) was more efficacious than placebo in providing reflux symptom relief in patients with NERD, especially acid regurgitation

Disclosure of Interest: All authors have declared no conflicts of interest.

P0546 TAILORED THERAPY GUIDED BY MULTICHANNEL INTRALUMINAL IMPEDANCE PH MONITORING FOR REFRACTORY NON EROSIIVE REFLUX DISEASE: PRELIMINARY EXPERIENCE

N. Ranaldo, G. Losurdo, A. Morelli, A. Iannone, M. Barone, M. Principi, E. Ierardi, A. Di Leo

Contact E-mail Address: giuseppelos@alice.it

Introduction: Refractory non erosive reflux disease (NERD) is defined by absence of clinical response to a 12-week course of proton pump inhibitors (PPI) at full dose in absence of esophagitis. It accounts for about 20% of all NERD cases. 24-hour multichannel intraluminal impedance pH (MII-pH) monitoring should give useful patho-physiological information about refractory NERD. Therefore, our aim was to assess whether this technique could be useful to guide a "tailored" therapy to refractory NERD patients.

Aims & Methods: We retrospectively recruited patients undergoing MII-pH monitoring for refractory NERD. All patients had undergone upper endoscopy, and cases of esophagitis were excluded. No patient received PPI during MII-pH monitoring. Subjects were subgrouped into 3 categories according to Zerbib's classification: i) Acid reflux (exposure to pH < 4 for at least 1.1% of record time), ii) Non acid reflux (symptom association probability to pH > 4 reflux episodes > 95%) and iii) Functional heartburn (no pathologic reflux, with symptom association probability < 50%). MII-pH guided therapy was performed as follows: patients with acid reflux received PPI at double dose, patients with non acid reflux PPI at full dose plus alginates and patients with functional heartburn levosulpride 75 mg/day for 4 weeks. A visual analogue scale (VAS) ranging 0–100 was administered before and after such tailored therapy to evaluate overall symptoms. Responders were defined by VAS improvement of at least 10%. Comparisons between continuous variables were performed by ANOVA or paired/unpaired t-test where required, and Fisher's exact test was applied to categorical variables. Variables with statistical significance $p < 0.10$ at univariate analysis were analyzed by binomial multivariate regression analysis, aimed to investigate factors predictive of response to tailored therapy.

Results: Thirty-four patients with refractory NERD were selected (female:male ratio 20:14, mean age 47.4 ± 12.8). Twelve had acid reflux, 7 non acid reflux and 15 functional heartburn. Overall effectiveness of tailored therapy was 82.3% (28 out of 34), and it did not differ between subgroups (91.7% acid reflux, 71.4% non acid reflux, 80.0% functional heartburn, $p = 0.51$). At univariate analysis, therapy failure directly correlated with dysphagia (OR = 0.15, $p = 0.10$) and inversely with sensation of slow digestion (OR = 7.70, $p = 0.05$). However, at multivariate analysis, these parameters were not statistically significant. We found a mean VAS reduction of 30.2 ± 24.9 , which was similar between acid reflux (36.7 ± 22.7), non acid reflux (30.0 ± 27.7) and functional heartburn (25.0 ± 25.7), $p = 0.49$.

Conclusion: A tailored approach to refractory NERD, guided by MII-pH monitoring, demonstrated to be effective, independently from disease subtype. Therefore it should be advised to patients who complain of symptom persistence despite PPI therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0547 STW5 MODULATES TIGHT-JUNCTION GENE AND PROTEIN EXPRESSIONS IN REFLUX-ESOPHAGITIS - POSSIBLE RELEVANCE FOR TUMORIGENESIS

Introduction: STW5, a herbal combination preparation of nine different plant extracts (*Iberis amara* (L.), *Menthae piperitae* (L.) *Chamomilla recutita* (L.), *Glycyrrhiza glabra* (L.), *Angelica archangelica* (L.), *Carum Carvi* (L.), *Silybium marianum* (L.) Gaertn. *Melissa officinalis* (L.) und *Chelidonium majus* (L.)) has been extensively studied for the treatment of gastrointestinal disorders resulting in an recommendation in the German therapy guidelines for both upper and lower functional gastrointestinal disorders (1). We investigated the mode of action of STW5 in a rat model of reflux-esophagitis (RE) (2). RE is the most common condition treated by gastroenterologists with possible long-term implications such as Barrett's esophagus and esophageal adenocarcinoma.

Aims & Methods: We were especially interested in the tight junction proteins (TJ), which are multi-protein complexes in epithelial and endothelial cells known to contribute to the barrier-function, but recently discovered to play an important role in tumorigenesis (3). TJ proteins like ZO-1 and 2 participate in cell-cycle regulation, occludin (OCCL) regulates the mitotic entry via centrosome separation and correlates with decreased cell proliferation, claudins (CLDNs) are made responsible for increased proliferation of the crypt cells (3). CLDN 1, 3, 4, 5, 7, 10 and 16 have been found altered in various types of cancer and OCCL is regarded an anti -transformation protein (3).

Results: In our model, RE was induced by surgical methods and rats ($n = 6$ per group) were treated with STW5 (0.5 or 2 ml/kg) or the proton pump inhibitor (PPI) omeprazole (O) (30 mg/kg) as described earlier (2). RNA was isolated from defined tissue areas of the esophagi. In the inflamed tissue we found a simultaneous transcript down regulation of claudin 3 ($p < 0.0001$), confirmed by RT-PCR. Also claudin 4, claudin 23, OCCL, MARVELD2 and ZO1 were significantly downregulated ($p < 0.001$). The down regulation of ZO1 was seen by Western Blot, too. Transcripts of MarvelD1 and JAM 2 were increased. The

treatment of rats with STW5 (2 ml/kg) or O (partially) normalized the esophageal tissue transcripts of ZO1, CLDN3, CLDN23, OCCL, MARVELD1, 2 and JAM. **Conclusion:** Data demonstrate a reversal of inflammatory changes in the TJ-proteins by STW5 and O. They also suggest that inflammatory changes in TJ are consistent with TJ-protein modulations in tumorigenesis. Subsequent studies are necessary to better define the complex role of TJ in inflammatory processes and in tumorigenesis and the potential benefit arising from a treatment with STW5 or O.

Introduction: Chronic reflux, a risk factor for the development of Barrett's esophagus (BE), causes damage to the normal squamous epithelium of the esophagus, which eventually is replaced by a columnar type of epithelium. It has been shown that bile acids (BAs) play a role in the development of BE. The effect of different BAs in the refluxate has been poorly studied with respect to the pathogenesis of BE. Insights in the effects of the bile components in reflux can help provide more efficacious targets for preventing the development of metaplasia and the progression from BE to EAC. Before being released into the duodenum, BAs produced by the liver are conjugated with either taurine or glycine. BAs not only have detergent properties, but can also act as signaling molecules by activating the farnesoid X receptor (FXR) and G-protein coupled bile acid receptor (TGR5). Both receptors are upregulated in BE and EAC compared to normal squamous mucosa, suggesting a possible role in the progression of BE (De Gottardi 2006; Hong 2010).

Aims & Methods: The aim of the study was to analyze refluxates of BE patients and evaluate the effect of the different bile components on metaplastic gland development and bile receptor activation.

Results: Determination of the bile composition in refluxate of BE patients by HPLC showed the presence of both glyco-conjugated ($67.6 \pm 8.8\%$) and tauro-conjugated BAs ($31.5 \pm 9.1\%$). Only a low percentage of unconjugated BAs was found in the patient refluxates ($0.5 \pm 0.4\%$). Although unconjugated BAs were absent in our refluxates, others have shown their presence in GERD patients (Nehra 1999). Deoxycholic acid (DCA), a secondary bile, is formed through deconjugation by microbial enzymes present in the colon, but the increase in pH due to PPI use can cause gastric bacterial overgrowth, resulting in the presence of DCA in reflux (Theisen 2000). Each of the six conjugated bile components [glycocholic-, glycodeoxycholic-, glycochenodeoxycholic-, taurocholic-, taurodeoxycholic- and taurochenodeoxycholic acid] and DCA were tested individually in vivo for 16 weeks at 10 mM. All mice developed multi-layered glands at the SCJ (36/36). Overall, mice treated with glyco-conjugated BAs developed more glands compared to DCA treated or tauro-conjugated BAs. Also alcian blue expression, representing mucin production, was higher compared to DCA treated or tauro-conjugated BAs treated group. To investigate which bile components are able to activate bile receptors we transfected primary mouse esophageal keratinocytes with either TGR5 or FXR and treated the cells with different BAs. Activation of the receptors result in conformational changes, which can be detected by measuring fluorescence resonance energy transfer (FRET). Both DCA and all conjugated BAs were able to activate the membrane bound TGR5 receptor, as shown by a change in signal. DCA was able to activate FXR, while the addition of all conjugated BAs did not result in a signal change. **Conclusion:** The possibility of DCA to activate the FXR may result in the onset of different genes, which might result in the progression from BE to EAC.

Introduction: Barrett's esophagus (BE) is a metaplastic abnormality in patients with Gastro-esophageal reflux disease in which the normal stratified squamous epithelium in the esophagus is replaced by columnar epithelium. BE predisposes for esophageal adenocarcinoma. One underlying mechanism of BE is that columnar stem cells residing in the esophageal mucosa (e.g., in submucosal glands) or multipotent stem cells give rise to the columnar lining. Bone Morphogenetic Proteins (BMPs) are a family of growth factors that control tissue architecture, homeostasis and stem cell differentiation. In BE, BMP4 is upregulated in columnar cells.

Aims & Methods: Organoid cultures are widely used because they mimic *in vivo* differentiation of self-organizing stem cells and represent the perfect model to study stem cell interaction in basic and translational research. We developed an *in vivo* organoid model of human BE to investigate the potential to modulate the metaplastic process using an innovative anti-BMP2/4 llama-derived Dwarfbody[®] (DB). Endoscopic BE biopsies were implanted into immunocompromised mice intramuscularly and grown for a period of three months with DB or control. These structures were assessed histologically and immunohistochemically (IHC) using panels of squamous, intestinal and stem cell markers.

Results: BE organoids were lined by a columnar epithelial layer containing goblet cells and recapitulated the crypt and villous regions seen within BE glands. IHC validation confirmed that the xenograft structures were of human origin and expressed markers of intestinal differentiation (CK8, CDX2 and villin). In contrast, treatment with the BMP inhibitor lead to the formation of multi-layered squamous epithelium expressing both the stem cell marker p63 and the squamous marker CK5.

Conclusion: Preliminary results demonstrate that inhibition of BMP2/4 in this model enhanced the amount of squamous epithelium. These pre-clinical results may be translated to the clinical setting in order improve treatment of BE and as such prevent the development of esophageal adenocarcinoma.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0550 GASTRIC CARDIA GLANDS MANIFEST APPARENT BROAD DIFFERENTIATION POTENTIAL, AS EVIDENCED BY HOXA13 EXPRESSION, IMPLICATIONS FOR THE ORIGIN OF BARRETT'S ESOPHAGUS

V. T. Janmaat, M.j.m. Smits, M.J. Bruno, M.C.w. Spaander, M. P. Peppelenbosch
Gastroenterology & Hepatology, Erasmus Medisch Centrum, Rotterdam/Netherlands

Contact E-mail Address: v.janmaat@erasmusmc.nl

Introduction: Metaplastic phenomena in the upper gastrointestinal tract are still poorly understood. A prominent theory is that Barrett's esophagus originates from gastric glandular epithelium. However, in absence of evidence that the gastric stem cell has broad differentiation potential, this theory remains controversial. The gastroesophageal junction is a high prevalence area for metaplasia and subsequent cancer. Characteristic of this area are the gastric cardia glands which cover only the most proximal part of the anatomic gastric cardia. Recent evidence from human and mouse studies has shown Barrett's esophagus can originate from these gastric cardia glands.^{1, 2} If it can be shown that gastric cardia glands contain elements associated with positional misspecification, this theory could be substantially bolstered. *HOX* genes are a family of transcription factors that convey positional information. The 3' to 5' sequence of *HOX* genes corresponds to the sequence in which they act along the anterior to posterior axes of the gut. This property is termed collinearity and links clustering to function. In gastrointestinal physiology, *HOXA13*, a 5' member of the *HOXA* cluster, has an expression pattern restricted to the colonic epithelium. However, pathological metaplastic lesions of the esophagus and stomach are also characterized by *HOXA13* expression. This in parallel with the similarities of these lesions with physiological colonic morphology. Hence, investigating *HOXA13* expression in gastric cardia glands appears a rational strategy in assessing the potential of this gastric cardia epithelium to serve as the origin of Barrett's esophagus.

Aims & Methods: We aimed to determine *HOXA13* expression in physiological gastric cardia glands. Firstly, strips of tissue from surgical specimens containing squamous esophageal epithelium, gastric cardia glands, and oxyntic stomach glands, were collected. These were continuous strips, from proximal to distal, to preserve morphological information. Material from three patients was

selected, they suffered from either a neuroendocrine tumor, or decompensated achalasia, or an adenocarcinoma. Antibodies against *HOXA13* were found not to be specific. Therefore, RNA in situ hybridization by RNA-scope was performed to visualize *HOXA13* RNA. Secondly, a *Hoxa13GFP* x *C57BL/6J* heterozygous mutant mouse model was used. In these animals, the cardiac glands were analyzed directly for GFP expression using a fluorescence confocal microscope.

Results: All three patients showed *HOXA13* expression of a portion of gastric cardia epithelial cells. The squamous epithelium, the oxyntic epithelium, and the stroma did not show any signal. The signal is located relatively close to the base of the crypts of the cardiac glands. The *Hoxa13GFP* x *C57BL/6J* heterozygous mice showed GFP expression localized to the nucleus of some of the epithelial cells of the cardiac gland. No nuclear signal was detected in the squamous or oxyntic epithelium, nor in the stroma. The colonic epithelium of the mouse showed nuclear GFP signal. Rectal squamous epithelium was negative as well as ileal epithelium, in accordance with *HOXA13* collinearity in mouse and human. A littermate negative for *Hoxa13GFP* was analyzed and showed no nuclear GFP signal in either gastric cardia gland cells or in colon epithelial cells.

Conclusion: Gastric cardia gland epithelial cells in both human and mouse exhibit *HOXA13* expression. All other physiological upper gastrointestinal tract tissues are *HOXA13* negative in line with *HOX* gene collinearity in the gut. This dichotomy proves positional information in these glands is discordant with their actual location. These findings suggest that gastric cardia glands have a broad differential potential. This is consistent with an origin of Barrett's metaplasia in the gastric cardia and might be indicative of Barrett's not being a true transdifferentiation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: We have previously demonstrated that transcriptionally active high-risk HPV (hr-HPV) is strongly incriminated in Barrett's dysplasia (BD) and oesophageal adenocarcinoma (OAC) using mainly fresh frozen tissue.^{1–4} This study aimed to identify biomarkers of active HPV infection in Barrett's metaplasia, (BM)/BD/OAC by immunohistochemical staining (IHC) of formalin-fixed paraffin embedded (FFPE) tissue for aberrations of p53 and the retinoblastoma (pRb) pathway which are targets for the viral oncoproteins, E6/E7 respectively. **Aims & Methods:** Prospectively, BM(n=81)/BD(n=72)/OAC(n=65) FFPE specimens were subjected to IHC staining for pRb, p16INK4A, cyclin D1, p53 and RNA in-situ hybridization (ISH) for E6/E7 transcripts. HPV DNA was determined via PCR in fresh frozen specimens. Viral load measurement (real-time PCR) and Next Generation Sequencing of TP53 was also performed.

Results: Of 218 patients, 56 were HPV DNA positive [HPV16 (n=42), 18 (n=13), 6 (n=1)]. Viral load was low. Transcriptionally active HPV (DNA+/RNA+) was only found in the dysplastic and adenocarcinoma group (n=21). The majority of HPV DNA+/RNA+ BD/OAC were characterized by p16INK4A^{high} (14/21, 66.7%), pRb^{low} (15/21, 71.4%) and p53^{low} (20/21, 95%) and was significantly different to controls [combination of HPV DNA-/RNA- (n=94) and HPV DNA+/RNA- cohorts (n=22)] p53^{low} had the strongest association with DNA+/RNA+ oesophageal lesions (OR=23.5, 95% CI=2.94–187.8, p=0.0029). Seventeen HPV DNA+/RNA+ BD/OAC identified as p53^{low}, were sequenced and all but one exhibited wild-type status. pRb^{low}/p53^{low} provided the best balance of strength of association (OR=8.0, 95% CI=2.6–25.0, p=0.0003) and sensitivity (71.4%)/specificity (71.6%) for DNA+/RNA+ BD/OAC. Transforming infections i.e. viral positive BD/OAC lesions exhibiting p16^{high}/pRb^{low} was found in 47.6% of the RNA⁺ patients and 31.8% of RNA⁻ subjects.

Conclusion: Active HPV involvement in BD/OAC is characterized by wild-type p53 and aberrations of the retinoblastoma protein pathway. Transforming infections which are a feature of HPV driven lesions was identified in a significant proportion of virally positive BD/OAC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Barrett's oesophagus is defined as the replacement of the normal stratified oesophageal squamous epithelium with a metaplastic columnar intestinal-like epithelium. Dipeptidyl peptidase-4 (DPP4) is an integral membrane glycoprotein that is highly expressed on the small intestinal brush border. DPP4 is part of a larger enzyme family that also includes DPP8, DPP9 and fibroblast activation protein (FAP).

Aims & Methods: We aimed to characterise DPP4 enzyme activity in a panel of oesophageal metaplasia, dysplasia and cancer cell lines, and in Barrett's oesophagus patient biopsies. FLO-1, OE33 and JH-EsoAd1 (oesophageal adenocarcinoma), OE21 and TE7 (oesophageal squamous cell carcinoma), GihTERT, GohTERT, ChTERT (dysplastic Barrett's) and QhTERT (non-dysplastic Barrett's) were grown to confluence in T75 flasks using standard cell culture techniques. Oesophageal squamous tissue biopsies were collected from non-Barrett's patients participating in the Barrett's screening endoscopy program at Flinders Medical Centre (n=6). Duodenal and gastric tissue biopsies were also collected as positive and negative control tissue respectively. Membrane and soluble enzyme activity was determined in cell and tissue extracts by colorimetric enzyme assay using the DPP selective substrate H-Gly-Pro-pNA. Sitagliptin (a DPP4 selective inhibitor) and IG244 (DPP8/9 selective inhibitor) were used to define specific enzyme activity. Final enzyme activity was expressed as nm pNA released/min/mg protein. Data is expressed as mean ± standard error of the mean.

Results: Relatively high DPP activity was detected on the membrane of OE33 (13.92 nm pNA/min/mg protein), GihTERT (6.93 nm pNA/min/mg protein), GohTERT (2.65 nm pNA/min/mg protein) and QhTERT (1.80 nm pNA/min/mg protein) compared to all other cell lines, where activity was <1 nm pNA/min/mg protein. Addition of 1 mM sitagliptin completely inhibited enzyme activity in OE33 cells, indicating that membrane enzyme activity was specific to DPP4. Cytoplasmic DPP activity was highest in FLO-1 (3.77 nm pNA/min/mg protein) and ChTERT (2.39 nm pNA/min/mg protein). Addition of 1 mM sitagliptin did not reduce cytoplasmic DPP activity in FLO-1 cells, suggesting the presence of other peptidases. High DPP4 activity was detected in the membrane fraction of duodenal biopsies (45.90 ± 8.55 nm pNA/min/mg protein) compared to gastric (3.35 ± 1.59 nm pNA/min/mg protein) and oesophageal biopsies (0.65 ± 0.71 nm pNA/min/mg protein). In contrast, differential DPP activity was detected in the soluble fraction of all duodenal, gastric and oesophageal tissue biopsies. Using 1 μM sitagliptin, this was found to be specific to DPP4 in oesophageal samples, but likely derived from other peptidases in gastric and duodenal samples.

Conclusion: Our preliminary *in vitro* findings suggest a differential pattern of DPP activity in Barrett's metaplasia and dysplasia, which could have potential significance as a biomarker target for the continuum of Barrett's oesophagus. Human tissue sample collection is ongoing to define specific DPP enzyme activity and expression in tissue specimens from Barrett's metaplasia and dysplasia subgroups compared to normal, non-Barrett's tissue.

Introduction: Barrett's Oesophagus (BE) is an acquired condition resulting from oesophageal reflux that causes intestinal metaplasia. These mucosal alterations can progress to dysplastic lesions, which ultimately lead to oesophageal adenocarcinoma (EAC). The incidence of EACs is rising in the Western world and 5-year survival rates are below 20%. Hence, new diagnostic and prognostic markers are needed. Since elevated levels of interleukin (IL-) 22 and IL-17A producing cells are associated with a poor prognosis in colorectal cancer we wanted to investigate their influence in EACs.

Aims & Methods: None of the patients enrolled in this study received chemotherapy prior to surgery and all patients had pathologically confirmed BE. mRNA expression levels of interleukins in tumour tissue and non-malignant peritumoral samples of 39 patients were measured. Immunohistochemical analysis was conducted to investigate interleukins during the progression from BE to EAC. Interleukins were investigated by flow cytometry in freshly resected oesophageal cancer specimens and in its non-malignant peritumoral tissue (n=11). During routine endoscopy samples from healthy volunteers were obtained and analysed by flow cytometry as controls (n=5).

Results: During progression from BE to EAC an increase of CD4+ cells was observed. The number of IL-22+ cells and IL-17A+ cells as well as the number of FOXP3+ cells/mg tissue increased in oesophageal cancer and in its peritumoral tissue as compared to healthy controls. The relative amounts of IL-22+ and IL-17A+ cells decreased while an increase of FOXP3+ cells was observed. Also more IL-10+ cells/mg tissue were observed in the tumours. In accordance to the latter finding high IL-10 mRNA expression levels were associated with poor survival in EAC patients. Interestingly, high mRNA expression levels of IL-10 in the non-malignant peritumoral tissue also correlated with poor survival.

Conclusion: During progression from BE to EAC the infiltration of CD4+ immune cells increases. While the relative amount of pro-inflammatory cells decreases an accumulation of immunosuppressive cells was observed. Our data suggest that especially regulatory T cells influence overall patient survival in EAC. Notably, high levels of IL-10 in the non-malignant peritumoral tissue also demonstrated to be unfavourable for patient survival. Thus, a pro-tumorigenic field effect in yet unaltered oesophageal mucosa might contribute to local recurrences despite radical endoscopic or surgical resection.

P0554 DIFFERENT GLAND PHENOTYPES ARE CLONALLY RELATED IN BARRETT'S OESOPHAGUS AND GLAND PHENOTYPIC DIVERSITY IS INCREASED IN PATIENTS WHO HAVE PROGRESSED TO DYSPLASIA

Introduction: A range of complex glandular phenotypes exist in Barrett's esophagus (BE), but how these phenotypes are related and evolve is unknown. Genetic diversity is an established risk factor for cancer development in BE, yet as phenotype not genotype is selected for and as the gland is the unit of selection, we suggest that phenotypic diversity may confer a increased risk of cancer progression. Exploiting mutations in the mitochondrial genome (MtDNA) as a marker of clonality we have demonstrated that the glandular phenotypes seen in Barrett's represent an evolutionary pathway and that phenotypic diversity also leads to an increased cancer risk.

Aims & Methods: Biopsies from patients with a new diagnosis or surveillance for BE were obtained at endoscopy and frozen. Immunohistochemistry was performed on frozen sections for proteins including MUC5AC, MUC2, MUC6 and H⁺K⁺ ATPase to distinguish intestinal from gastric cell lineages. Individual glands were laser capture microdissected and DNA was extracted using the ARCTURUS® PicoPure® DNA Extraction Kit. Sanger sequencing of the entire mitochondrial genome was performed to determine the clonal relationships between different Barrett's gland phenotypes.

Gland phenotypes and phenotypic diversity was counted in archived FFPE cases of BE who had progressed to dysplasia versus those who had not (n=10 in each group – counts performed in a blinded fashion). Using the Shannon index as a measure of diversity, 5 distinct BO gland phenotypes were counted to determine if there was a significant increase in gland phenotype diversity in those biopsies taken adjacent to dysplastic glands compared to biopsies from patients who did not have dysplasia.

Results: In 2 separate cases specialised mature intestinal type glands were shown to be present expressing both MUC2 and MUC5AC. Furthermore, in the same section MUC5AC+ MUC2- cardia-like Barrett's glands and MUC5AC- MUC2+ mature intestinal-like Barrett's glands were also present. LCM sequencing of DNA extracted from each of these glands yielded an m.7148C > T mutation and m.10492T > C mutation respectively in each gland that was not present in the stroma. This is the first time that different gland phenotypes have been demonstrated to be clonal and suggests that Barrett's displays phenotypic as well

as genotypic evolution. Patients with dysplasia also show a significant increase in gland phenotype diversity (Shannon) per biopsy in adjacent to dysplasia glands compared with patients who do not have dysplasia.

Conclusion: BE is phenotypically diverse with a range of glandular phenotypes that are clonally related. An increase in phenotypic diversity may be a potential biomarker for predicting which patients are at risk of progressing from BE to cancer with implications for diagnostic and surveillance policy.

Introduction: The importance of skilled endoscopic assessment of Barrett's oesophagus (BO) has been clearly established and forms part of the British Society of Gastroenterology guidelines¹. Use of Prague classification when reporting on areas of BO improves standardisation, and adherence to the Seattle biopsy protocol (quadrantic biopsies every 2cm) when sampling Barrett's mucosa is thought to improve dysplasia detection². In East Kent Hospitals NHS Foundation Trust we have created a dedicated nurse-led BO surveillance endoscopy list with the aim of improving compliance with guidelines and the quality of biopsies taken. Here we present a retrospective observational study of patients who underwent upper GI endoscopy on a general endoscopy (GE) list compared with the dedicated BO endoscopy (DBO) list.

Aims & Methods: We searched our endoscopy software for patients who had had an indication for gastroscopy documented as BO and who had an endoscopy on a GE list from 2012–2013. The same search was performed for patients who were scoped on the DBO list from 2014–2016. Endoscopy reports were reviewed to assess the use of Prague classification and determine numbers of biopsies taken. Biopsy results were reviewed on our electronic pathology database.

Results: One hundred procedures for BO surveillance on GE lists were audited, comprising 65% male patients with median age 68 years; 60% were performed by a consultant gastroenterologist and the remainder were performed by other operators including surgical consultants and gastroenterology registrars. Of the 105 procedures on the DBO lists, 63% of patients were male, median age 70 years. Prague classification was used in 94% of endoscopy reports on the DBO lists compared with 5% on the GE lists. The Seattle biopsy protocol was observed in 70/94 (74%) cases on the DBO lists as opposed to 30/100 (30%) on the GE lists. Dysplasia detection rate (low grade, high grade or indefinite) was similar in both groups: 8/105 (7.6%) on the DBO list and 6/100 (6%) in the GE group. All (100%) of the dysplasia detected on the GE lists occurred in procedures performed by consultant gastroenterologists.

Conclusion: Our comparison shows that observance of Prague classification is significantly higher on the DBO lists when compared with GE lists (94% vs 5%), and compliance with the Seattle biopsy protocol is similarly higher (74% vs 30%). These are indicators of higher quality endoscopic surveillance on DBO lists. However, this did not translate to a different dysplasia detection rate which appeared to be more influenced by the endoscopy operator since all of the dysplasia detected on GE lists was identified by consultant gastroenterologists. We believe that this reflects the additional familiarity of guidelines and possible greater experience of endoscopists regularly taking BO biopsies. We therefore recommend that all Barrett's oesophagus patients have their surveillance endoscopies performed on dedicated BO endoscopy lists.

Introduction: Adherence to quality indicators and surveillance guidelines in the management of Barrett's esophagus (BE) promotes high-quality cost-effective care.

Aims & Methods: The aims of this study were to evaluate (1) adherence to standardized classification (Prague Criteria) and a systematic four-quadrant biopsy protocol, (2) identify predictors of practice patterns, and (3) to assess adherence to surveillance guidelines for non-dysplastic BE (NDBE). This was a Single-center retrospective study of endoscopies (EGDs) performed for BE between June 2008 to December 2015. Data on patient demographics,

procedure characteristics and histology results were obtained from a prospectively collected endoscopy database and chart review. Adherence to the use of Prague Criteria and systematic biopsy protocol were assessed based on operative report documentation. Guideline adherent surveillance EGD was defined as those performed within 6 months of the recommended 3–5 year interval. Uni- and multi-variate analysis were performed to identify predictors of practice patterns.

Results: A total of 397 patients (66.5% male; mean age 60.1 ± 12.5 years) had an index EGD during the study period. Adherence to the use of Prague Criteria and systematic biopsies were 27.4% and 24.1%, respectively. Endoscopists who perform therapeutic interventions for BE were more likely to use the Prague Criteria (OR: 3.16; 95%CI: 1.47–6.82) than those who do not. Longer time in practice (in years) was positively associated with adherence to Prague Criteria (OR 1.07; 95% CI: 1.02–1.12; p < 0.01) but with a lower likelihood of performing systematic biopsies (OR 0.91; 95%CI: 0.85–0.97; p < 0.01). Nearly 41% of patients with NDBE (11/27) underwent surveillance EGD sooner (range 1–24 months) than the recommended interval.

Conclusion: Adherence to quality indicators and surveillance guidelines in BE is low. Operator characteristics, including experience with endoscopic therapy for BE and time in practice predicted adherence to the use of Prague Criteria and systematic biopsies. Future efforts are needed to reduce variability in practice and promote high-value care.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0557 EXPRESSION OF TGF-β AND CD-44 IN AGE SPECIFIC SUBGROUP OF PATIENTS WITH ADENOCARCINOMA OF GASTRIC CARDIA

N. Lukavetsky, T. Fetsych
Oncology Department, Lviv Medical University, Lviv/Ukraine

Contact E-mail Address: lukavetsky@ukr.net

Introduction: Adenocarcinoma near the esophagogastric junction is one of the most lethal GI malignancies known. Surgical treatment of these cancers stay determinative factors of patient survival. Older persons often differ from the younger adult population in terms of biological and functional perspectives; as such, they may have particular needs which require an interdisciplinary approach and intervention, especially when faced with a cancer diagnosis.

Aims & Methods: The aim of this study was to detect expression of TGF-β and CD-44 in age specific subgroup. The expressions of TGF-β and CD-44 were evaluated immunohistochemically in 23 patients with adenocarcinoma of gastric cardia who underwent curative surgery (R0) without any neo/adjunct therapy. Additionally we analyzed control group of patients with non-cancer lesion or normal tissue of upper digestive tract (13 patients). We divided the patients into two groups. Group A consisted of 13 cancer patients and 7 control patients 65 years of age or older, while Group B consisted of 10 cancer and 6 control patients younger than 65 years of age. The two groups were comparable - there were no differences between the two groups regarding tumor stage.

Results: Elderly patients have statistically significant better survival (median 20.2 month) compared with younger patients (median 15.4 month) (p=0.045). The median survival rate of patients without TGF-β and/or CD-44 expression was significantly lower (7 m) than that of patients with positive expression (>15 m) (p=0.003). Regardless of patients age, CD-44 was significantly higher in the cancer tissue of elderly patients than in younger (p < 0, 035). But no significant difference was observed in the TGF-β expression between group A and group B cancers tissue (p=0.005).

Conclusion: The biology of tumors may be different in elderly patients, leading to a lower rate of tumor-related mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0558 BARRETT'S OESOPHAGUS PROFILE AND OUTCOMES IN A LARGE COHORT

Introduction: Barrett's oesophagus (BO) is considered a premalignant condition for oesophageal adenocarcinoma (OAC). Once diagnosed, interval endoscopic surveillance is recommended to promote early detection of dysplasia and cancer. Occurrence and incidence of dysplasia and cancer among BO vary across populations. Recent studies show BO patients mortality is mainly related to non-oesophageal cancer and cardiovascular morbidity.

Abstract No: P0556**Table:** Factors associated with the adherence to the use of Prague Criteria and systematic four-quadrant biopsies for BE evaluation

Clinical Variable	Prague Criteria				Systematic Biopsies

Aims & Methods: In this cross-sectional study, our aims were to describe the local BO clinical, endoscopic and histologic profile in our tertiary referral centre, and discover whether the Prague classification reporting requirements are filled. We identified and included all consecutive patients with oesophageal intestinal metaplasia (identified by the presence of goblet cells) from March 2009 to May 2015. All endoscopies and biopsy reports were reviewed: BO segment length, use of the Prague classification, endoscopic abnormalities, treatment modalities, and histologic findings of dysplasia. Participants were sent a clinical questionnaire, via which pertinent clinical data including personal and familial cancer history, were collected.

Results: Clinical profile- Our cohort consists of 406 patients, with a mean age of 60.9 ± 13.3 years, 69% were male. Endoscopic profile- Mean maximal BO length (Prague classification M) was 2.8 ± 1.9 cm (reported in 49.6% of endoscopies) Mean circumferential BO (Prague classification C) was 4.9 ± 3.1 cm (reported in 18.1% of endoscopies). Histologic profile- Low-grade dysplasia (LGD) was seen in 4.4% of patients, high-grade dysplasia (HGD) in 3%, intramucosal carcinoma (IMC) in 0.7%, and OAC in 2%. A subgroup of 250 patients underwent more than one endoscopy, allowing for prospective incidence analysis. They had 914 years of follow-up, with a mean number of endoscopies of 4.7 ± 3. The incidence rates of LGD, HGD, IMC, OAC per 1000 patient years were 20.8, 15.3, 2.2, and 7.6 respectively.

One hundred and fifty-five patients returned the questionnaire. In this subgroup analysis, we learned BO was diagnosed at 57.8 ± 12.5 years of age, with a mean duration of 4.9 ± 5.7 years. A personal history of non-oesophageal malignancy was reported in 15.4%. A family history of BO, OAC and non-oesophageal cancer were reported in 5.2%, 4.5%, and 35.4%, respectively.

Conclusion: Compared to the information gathered by Katz et al (1), we demonstrated a lower rate of LGD, but comparable rates of HGD and OAC. The personal and familial history of non-oesophageal malignancy was higher than the oesophageal malignancy rates. Our findings may support the importance of age appropriate non-oesophageal malignancy screening in BO patients. Physician compliance in reporting BO according to the Prague classification is lacking.

Factors associated with our local BO profile as well as the implication of family history requires further prospective studies

Disclosure of Interest: All authors have declared no conflicts of interest.

P0559 THE EFFICACY OF ENDOSCOPIC MUCOSAL RESECTION IN MANAGING EARLY NEOPLASIA IN BARRETT'S ESOPHAGUS, EXPERIENCES OF A TERTIARY REFERRAL CENTER IN THE UK

B. Eross¹, C. Clisby², B. Foria³, C. Gordon¹

¹Gastroenterology, Royal Bournemouth Hospital, Bournemouth/United Kingdom

²Endoscopy, Royal Bournemouth Hospital, Bournemouth/United Kingdom

³Pathology, Royal Bournemouth Hospital, Bournemouth/United Kingdom

Contact E-mail Address: xerobal@yahoo.it

Introduction: Endoscopic mucosal resection (EMR) is an established diagnostic and treatment tool in the management of Barrett's oesophagus (BO) with early neoplasia. Our objectives were to demonstrate EMR's efficacy in removing early neoplasia within BO and its usefulness in obtaining comprehensive histological specimens to accurately stage the early neoplasia and effectively deliver therapy.

Aims & Methods: We have conducted a retrospective analysis using our electronic database for endoscopic procedures for patients with BO, who underwent EMR

from October 2010 to December 2016. We analysed the resection margins for both en bloc and piecemeal EMRs. We compared the original histology from the referral endoscopy to the histology obtained from the EMR, to analyse any deviation and to demonstrate the importance of histological staging of the early neoplasia in BO. We also investigated the three-year survival in patients, who have had their EMR longer than 3 years ago, along with causes of death.

Results: A total of 99 patients underwent 134 EMR procedures and 259 EMRs, 84% were male, the mean age at first EMR was 71 years (SD = 8.2). 24 patients underwent 2 EMR procedures, 2 patients underwent 3 EMR procedures and 2 patients underwent 4 EMR procedures. The median length of the circumferential and maximum extent of the BO segments were 3 and 4 cm respectively (interquartile range (IQR) 2–4). 44 patients underwent 60 en bloc resections. After histologic assessment of these EMR specimens, 34 (56.7%) had clear deep and radial resection margins, 14 (23.3%) showed at least low-grade dysplasia at the radial margin, 2 (3.3%) at the deep margin and 8 (13.4%) at both margins. 2 (3.3%) were clear at the deep margin, but due to thermal damage the radial margins were indeterminate. Following the 60 EMRs there was no visible residual early neoplasia on the follow up endoscopy in 37 cases (61.7%). 55 patients underwent 74 piecemeal EMRs, of which 52 (70.3%) had clear deep margins on histologic assessment and 38 (51.4%) had no visible residual neoplasia on the follow up endoscopy. Pre EMR histology was available in 82 patients and it showed high-grade dysplasia (HGD) in 49 (59.8%), mucosal adenocarcinoma in 24 (29.2%) and low-grade dysplasia in 9 patients (11%). However the EMR histology resulted in altered grading in 59 (72%) patients, with 47 (57%) upgraded and 12 (14%) downgraded from the pre EMR histology and unchanged only in 23 patients (28%). The EMR histologies in the 82 patients showed HGD in 16 (19.5%) patients, intramucosal adenocarcinoma in 33 (40.2%), adenocarcinoma with submucosal invasion in 20 (24.4%) and LGD in 13 (15.9%). The remaining 52 EMRs were performed for visible lesions within BO without pre EMR histology result, predominantly for patients in the radiofrequency ablation program. The 3 year survival rate for 42 patients was 81%, 8 patients died, 5 due to cardiac failure, 1 due to a PE and 2 due to advanced oesophageal adenocarcinoma.

Conclusion: In this moderately sized retrospective study EMR has been proven to be an effective tool in managing early neoplasia within BO. It not only allows the potential complete resection of the visible early neoplasia (61.7% for en bloc and 51.4% for piecemeal EMR), but also gives a histological specimen with a more accurate grading of the neoplasia (upgraded in 57%, downgraded in 14% and unchanged in only in 23% of all EMRs), both aspects culminating in more effective and precise patient treatment. In all patients managed and assessed by EMR we have seen 19% mortality of which only 4.8% was cancer related.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0560 ADHERENCE TO BARRETT'S ESOPHAGUS SURVEILLANCE GUIDELINES: A SYSTEMATIC REVIEW AND META-ANALYSIS

Introduction: Barrett esophagus (BE) is a premalignant condition for esophageal adenocarcinoma (EAC) where recommended. Guidelines aim to reduce treatment variation and improve quality of care. Data on the extent to which level BE surveillance guidelines are followed are scarce.

Aims & Methods: The objectives of this systematic review and meta-analysis were to (1) quantify adherence to guidelines in BE surveillance and (2) identify factors that are associated with adherence. A systematic literature research was performed using EMBASE, MEDLINE, PubMed and Web of Science up to September 2016. Studies reporting adherence in at least one of the following four domains were selected: surveillance interval, biopsy protocol, landmark identification and histopathological information. Relevant publications were assessed using the STROBE statement for observational studies (<http://strobe-statement.org/>). Adherence was considered a prevalence ratio and reported as a percentage. Pooled data for the associated factors were reported as odds ratios with analysis of heterogeneity (I^2 statistic).

Results: From a total of 373 studies, 49 were eligible for this meta-analysis. For BE surveillance in non-dysplastic BE patients a prevalence ratio for adherence of 54% (95% confidence interval (CI) 45%;63%) was found and 41% (95% CI 37%;45%) in patients with low-grade dysplasia, but with large heterogeneity ($I^2=98\%$ and $I^2=100\%$). Adherence to the Seattle protocol was 47% (95% CI 33%;61%, $I^2=100\%$), length of BE was reported according to the Prague classification in 34% (95% CI 23%;44%, $I^2=98\%$) and in 51% (95% CI 27%;75%, $I^2=99\%$) of patients with a dysplastic BE the histology samples were reviewed by a second pathologist. Shorter BE length, an academic practice setting, younger age and the involvement of the clinical set-up incorporating a multifaceted intervention program were associated with better adherence. Endoscopists following the Seattle protocol detected more dysplasia.

Conclusion: Adherence to guidelines for the surveillance of BE is far from optimal and highly heterogeneous. A clinical set-up of a dedicated BE surveillance program is needed, for example follow-up within a research program, involvement of a dedicated nurse managing the program or guideline promotion by using posters stating recommendations. Besides initiating more and better studies to facilitate the creation of evidence based guidelines, more effort should be directed to stimulate and monitor the implementation of guidelines in clinical practice.

Introduction: Since squamous cell carcinoma in the esophagus confined to the muscularis mucosae (MM) or submucosa up to 200µm (SMI) has a risk of lymph node metastasis, it is defined as relative indication for endoscopic submucosal dissection (ESD) by the Japan esophageal society guideline. Although additional surgical treatment after ESD is recommended, long-term outcomes of ESD compared with surgery has not been clarified.

Aims & Methods: This study aimed to evaluate the long-term outcomes of ESD and surgery for cN0M0 relative indication lesions of ESCC. Between 2006 and 2016, patients with relative indication lesions of ESCC treated endoscopically or surgically in Okayama University Hospital were retrospectively analyzed. We evaluated risk factors for mortality using cox regression analysis, adjusted hazard ratios for ESD compared with surgery, the survival curves stratified with risk factor, and perioperative complication rate.

Results: 54 lesions in the ESD group and 51 lesions in the surgery group met the pathological criteria of relative indication for endoscopic resection. 10 patients underwent additional chemoradiation in the ESD group. 8 patients underwent additional chemotherapy and 1 patient underwent additional chemoradiation in the surgery group. Lymphovascular invasion, submucosal invasion, and ASA-PS was significantly associated with mortality using Cox analysis. Adjusted for lymphovascular invasion, submucosal invasion, and ASA-PS, multivariate Cox proportional hazard ratio of mortality for ESD compared with surgery was not significantly different (hazard ratio [HR], 0.76; 95% confidence interval [CI], 0.26–2.2; $P=0.61$). The survival curves for ESD and surgery stratified with each risk factor were not significantly different. Perioperative complication rate were significantly low in ESD compared to surgery (29.6% vs 49.1%; $P=0.047$).

Conclusion: ESD dose not compromise the long-term outcome compared to surgery. Further large number randomized controlled trials are necessary to confirm these results.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Patients with Fanconi anemia (FA) have an increased risk of developing esophageal squamous cell carcinoma. Data regarding endoscopic findings in patients with FA are lacking. Furthermore, there are no clear guidelines for endoscopic surveillance of patients with FA.

Aims & Methods: We aimed to describe the endoscopic findings among subjects with FA undergoing endoscopic surveillance and to determine the interval to development of esophageal cancer.

Results: Eight FA subjects with a median age of 22.2 years at first endoscopy (range 16–41) were identified. The median upper endoscopies number per patient was 5.5 (range 2–14) with a median time of follow-up of 4.5 years (range 1–9 years). All subjects (100%) had an endoscopic evidence of reflux esophagitis: 3 (37.5%) had mild and 5 (62.5%) had moderate-severe reflux esophagitis. Three subjects (37.5%) had complicated esophageal reflux disease (two subjects developed Barrett's esophagus and one subject had an esophageal stricture). Two subjects (25%) developed esophageal squamous cell carcinoma during follow-up, with interval time of 8 and 18 months from previous upper endoscopy. Both had tumor expression of p16 protein suggesting human papilloma virus (HPV) infection. The calculated standardized incidence ratio (SIR) for the development of esophageal squamous cell carcinoma is 5107.

Conclusion: FA patients are at an increased risk for developing esophageal cancer and reflux esophageal disease with associated complications. Larger, prospective studies are needed to determine the optimal interval for endoscopic screening in these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Multiple development of squamous cell carcinoma (SCC) in the upper aero-digestive tract is known as the “field cancerization phenomenon,” and alcohol is a definite carcinogen. Multiple dysplastic lesions in the esophagus are a useful predictor of the risk for the field cancerization. However, what causes the development of dysplastic squamous epithelium in the esophagus is still unclear.

Aims & Methods: The aim of this prospective cohort study was to identify associations between patients' lifestyle, including alcohol consumption, the genetic trait of aldehyde dehydrogenase-2 (ALDH2), and the development of dysplastic squamous epithelium in the esophagus. This is a post hoc analysis of the Japan Esophageal Cohort (JEC) study (UMIN1676). Patients with superficial SCC

treated by endoscopic resection were prospectively recruited from 16 hospitals throughout Japan. This cohort study was approved by the institutional review board at each hospital, and we obtained written informed consent from all patients. Using Lugol chromoendoscopy, we evaluated the dysplastic squamous epithelium in the esophagus. Lugol voiding lesion (LVL) was graded into 3 categories (A=no lesion; B=1 to 9 lesions; C=>10 lesions per endoscopic view). Endoscopic images obtained from eligible patients at study entry were centrally reviewed in a blinded fashion by three endoscopists to determine the grade of LVL. ALDH2 status was determined by questionnaire facial flushing after alcohol drinking (present and past flushing=inactive ALDH2, never flushing=active ALDH2). Lifestyle surveys were conducted using a self-assessment questionnaire. Data collected between July 2000 and Dec 2001 from a different cross-sectional cohort (n=1042; M/F=610/432) were used as an historical control.

Results: Between Sep 2005 and May 2010, 330 patients (M/F=278/52) were registered. The proportions of the different grades of LVL were A=50 (15.2%), B=174 (52.7%), and C=106 (32.1%). After adjusting for sex and age, controls and the LVL grade was associated with progressively higher proportions of heavy drinkers (8.4%, 24.8%, 26.2%, and 52.5%, respectively, $p < 0.0001$), frequently strong alcoholic beverages (2.3%, 7.2%, 11.8%, and 11.6%, respectively, $p < 0.0001$), heavy smokers (34.6%, 38.7%, 65.7%, and 70.8%, respectively, $p < 0.0001$), liking high-temperature food (4.6%, 19.6%, 20.8%, and 20.7%, respectively, $p < 0.0001$), not eating green-yellow vegetables almost every day (55.0%, 48.9%, 54.9%, and 71.1%, respectively, $p < 0.0001$), and not eating fruit almost every day (51.6%, 74.3%, 68.0%, and 75.3%, respectively, $p < 0.0001$). The risk of LVL grade B and C was strongly associated with the amount of alcohol consumption especially in inactive ALDH2. Odds ratio (OR) of LVL grade B associated with heavy drinking was significantly stronger in inactive ALDH2 (OR=47.5) than active ALDH2 (OR=12.8) ($p < 0.05$). OR of LVL grade C associated with heavy drinking was significantly stronger in inactive ALDH2 (OR=358) than active ALDH2 (OR=138) ($p < 0.05$).

Alcohol drinking	Controls (n=1042)	Grade A (n=50)	Grade B (n=174)	Grade C (n=106)	P
Never/rare	38.2%	25.1%	7.9%	4.7%	
Light	30.5%	15.0%	21.4%	8.9%	
Moderate	21.4%	30.1%	30.9%	25.7%	
Heavy	8.4%	24.8%	26.2%	52.5%	
Ex-drinker	1.4%	5.1%	13.6%	8.3%	<.0001
P, vs. controls	—	0.002	<.0001	<.0001	
Units/week (Mean \pm SE)	5.9 \pm 0.4	9.2 \pm 1.5	13.9 \pm 0.8	20.1 \pm 1.0	<.0001
P, vs. controls	—	0.037	<.0001	<.0001	

Conclusion: The development of dysplastic squamous epithelium in the esophagus was associated with the amount of alcohol consumption and genetic trait of inactive ALDH2.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Metachronous multiple squamous cell carcinoma (SCC) of the oesophagus and the head and neck often occurs in patients who previously underwent endoscopic resection (ER) for SCC of the oesophagus. This has become a problem regarding the curability of ER. Katada et al reported that alcohol abstinence significantly decreased the risk of developing a secondary SCC of the oesophagus, based on a prospective study of 330 patients from 16 hospitals¹. However, there are few studies that have investigated the risk of developing a secondary SCC of the oesophagus and the head and neck based on the genetic polymorphisms of alcohol dehydrogenase-1B (ADH1B) and aldehyde dehydrogenase-2 (ALDH2) which are closely associated with developing oesophageal SCC. No studies have evaluated the risk of developing a third (or more) SCC after ER for SCC of the oesophagus.

Aims & Methods: The study group included patients who underwent ER for SCC of the oesophagus at Hokkaido University Hospital. All patients were followed up by using endoscopic examination for ≥ 2 years. Overall, 126 patients were included in the study. The drinking and smoking histories before and after ER were carefully documented. To examine two single nucleotide polymorphisms

(SNPs) on ADH1B and ALDH2 genotyping, we obtained approximately 1 ml of saliva with a pipette or cotton swab before the endoscopic examination. The subjects were classified as rare drinkers who consumed <1 units/week, current drinkers who consumed 1 to 8.9 units/week (light drinkers), 9 to 17.9 units/week (moderate drinkers), or ≥ 18 units/week (heavy drinkers); alcohol consumption (1 unit=22 g, the ethanol content of one serving of sake). The physicians recommended all subjects to temperate in drinking and smoking. We retrospectively evaluated the risk of metachronous SCC of the oesophagus and the head and neck after ER for SCC of the oesophagus, based on the genetic polymorphisms for ADH1B and ALDH2 and the drinking and smoking histories.

Results: During a median follow-up period of 80 months (range, 24–228 months), a secondary SCC of the oesophagus and the head and neck was detected in 46 patients (36.5%). The high incidence groups had inactive heterozygous ALDH2 (rs671 GA, 36/83; $p < 0.05$), moderate and heavy drinkers (42/93; $p < 0.01$), continuous moderate and heavy drinkers after ER (21/35; $p < 0.01$). Multivariate analysis revealed that the inactive heterozygous ALDH2 (OR=2.24; $p < 0.05$), moderate and heavy drinkers (OR=3.54; $p < 0.05$) and continuous moderate and heavy drinkers after ER (OR=2.73; $p < 0.05$) were independently associated with the risk of developing a secondary SCC after ER. A third SCC was detected in 19 patients (15.1%), and the high incidence groups had inactive heterozygous ALDH2 (17/83; $p < 0.05$), moderate and heavy drinkers (19/93; $p < 0.01$) and continuous heavy drinkers after ER (10/16; $p < 0.01$). A fourth SCC was detected in seven patients (5.6%), who were all cases of continuous moderate and heavy drinkers after ER. Six of the seven patients had an inactive heterozygous ALDH2. We analysed the 63 patients with inactive heterozygous ALDH2 and moderate and heavy drinkers before ER based on their temperance history and found 38 patients in the temperance group (\leq light drinkers after ER) and 25 patients in the non-temperance group. The 3-year cumulative incidence rate of secondary SCC in the temperance and non-temperance groups revealed an incidence of 16.2% vs 49.8%, respectively ($p < 0.05$). The 5-year cumulative incidence rate of a third SCC revealed an incidence of 0% vs 28.3%, respectively ($p < 0.01$). The 7-year cumulative incidence rate of a fourth SCC revealed an incidence of 0% vs 16.9%, respectively ($p < 0.05$).

Conclusion: Among the patients who underwent ER for oesophageal SCC, an inactive heterozygous ALDH2 with a continue drinking habit were the significant risk factors of developing metachronous multiple SCC. These are the greater risk factors for developing a third (or more) SCC. Patients with an inactive heterozygous ALDH2 and a drinking habit should receive strict instruction for temperance.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0565 IS IT FEASIBLE TO TREAT ESOPHAGEAL SQUAMOUS CELL CARCINOMA WITH CLINICAL DEPTH OF MM/SM1 BY ENDOSCOPIC RESECTION?

K. Namikawa, T. Yoshio, A. Ishiyama, T. Tsuchida, J. Fujisaki
Gastroenterology, Cancer Institute Hospital Ariake, Tokyo/Japan

Contact E-mail Address: ken.namikawa@jfc.or.jp

Introduction: According to the Japanese guidelines for the treatment of esophageal cancer, T1a-EP or T1a-LPM squamous cell carcinoma (SCC) is definitive indication for endoscopic resection (ER) which is the first line treatment for them. T1a-MM or T1b-SM1 is a relative indication of ER, because 10–20% of the cases has metastasis in the previous analysis of operation cases. Recent advances in ER such as endoscopic submucosal dissection (ESD) and steroid injection for the prevention of stricture, provide us increasing opportunity to treat clinical MM/SM1 which means preoperative predicted invasion depth of MM/SM1. Recently we start to treat them because MM without lymphovascular invasion were reported to have very low risk of metastasis and occupy majority part of MM/SM1. There is no report about long term outcome of ER for clinical MM/SM1.

Aims & Methods: This study aimed to evaluate the clinical outcomes in patients having esophageal SCC with a predicted invasion depth of MM/SM1. We retrospectively reviewed 45 patients having esophageal SCC with a predicted invasion depth of MM/SM1. We predicted the invasion depth using conventional endoscopy, magnifying endoscopic classification of Japan esophageal society, and endoscopic ultrasound (EUS). The patients were diagnosed and treated at our hospital from 2010 to 2013. If pathological diagnosis after ER reveals T1b-SM2 or lymphovascular invasion, we recommended CRT or esophagectomy as additional therapy.

Results: The median age was 67 years (range, 39–81 years), including 37 males and 8 females. The median diameter of the tumor was 27 mm (range, 4–70 mm). The tumors were located in the cervical esophagus (n=2), upper esophagus (n=9), mid-esophagus (n=30), and lower esophagus (n=4). The number of tumors subclassified as types 0-I, 0-IIa, 0-IIb, and 0-IIc was 0, 7, 1, and 37, respectively. Forty cases were diagnosed as MM/SM1 using the Japanese Esophageal Society classification for magnifying endoscopy, and its accuracy was 62.5% (25/40). EUS was performed for 21 patients, and its accuracy was 68.8% (16/21). The patients underwent endoscopic mucosal resection (n=5) or ESD (n=40). In pathological diagnosis, LPM invasion was found in 14 patients, MM/SM1 invasion in 28 patients, and SM2 invasion in 3 patients. The overall accuracy rate of diagnosing MM/SM1 invasion was 62% (28/45). Among patients with MM/SM1 invasion, 20 had no lymphovascular invasion, and

they were not recommended additional therapy. The remaining eight patients had lymphovascular invasion, and they were recommended additional therapy. In total 33 cases were treated only by ER without additional therapy. Besides 97% (32/33) of those cases had no recurrence except for one case with a lymph node recurrence, which was successfully treated by additional CRT. The other 12 cases including cases with lymphovascular invasion or SM2 were recommended additional therapy. They underwent CRT (n=4), radiotherapy (n=3), or esophagectomy (n=3). No recurrence was observed after the abovementioned treatments. At the end of the follow-up, the 3-year overall and disease-specific survival rates were 91.1% and 100%, respectively. Considering ER for clinical MM/SM1, 76% of all cases were completed their treatment only with ER, and 24% of high risk case for metastasis were treated appropriately with additional therapy.

Conclusion: Conclusions: Our study suggests that ER is a valid treatment for esophageal SCC with a preoperative predicted invasion depth of MM/SM1.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0566 TRIAMCINOLONE INJECTION AND SHIELDING WITH POLYGLYCOLIC ACID SHEETS AND FIBRIN GLUE FOR THE PREVENTION OF POSTOPERATIVE STRICTURE AFTER ESOPHAGEAL ENDOSCOPIC SUBMUCOSAL DISSECTION: A RETROSPECTIVE COMPARISON OF TWO PILOT STUDIES AND A HISTORICAL COHORT

Y. Sakaguchi, Y. Tsuji, Y. Kataoka, I. Saito, K. Niimi, S. Ono, S. Kodashima, M. Fujishiro, K. Koike

Dept. Of Gastroenterology, University of Tokyo, Tokyo/Japan

Introduction: Triamcinolone injection is an effective and widely used method for preventing postoperative stricture after wide-spreading esophageal endoscopic submucosal dissection (ESD), but even with this method there is a stricture risk of 10–62%, and there is a need for an even more effective method. The objective of our study was to evaluate the efficacy of combining this method with the shielding method with polyglycolic acid (PGA) sheets and fibrin glue, another novel and effective method for the prevention of postoperative stricture.

Aims & Methods: 2 consecutive single-arm pilot studies were performed, and retrospectively compared with the results of a historical control group. After approval by the Institutional Review Board and trial registry, we enrolled patients with a diagnosis of superficial esophageal squamous cell carcinoma covering over half the circumference of the esophagus. In study group A (UMIN000014642), performed October 2014 to July 2015, immediately after the enrolled patients underwent esophageal ESD, a total of 40 mg of triamcinolone acetate was injected into the submucosal layer of the ESD defect, followed by adhesion of a PGA sheet to the post-ESD defect with fibrin glue. In study group B (UMIN000011058), performed July 2013 to September 2014, immediately after the enrolled patients underwent esophageal ESD, only adhesion of a PGA sheet to the post-ESD defect with fibrin glue was performed. As historical control group C, all patients at our institute who had undergone ESD for superficial esophageal squamous cell carcinoma covering over half the circumference of the esophagus during 2002 to June 2013 were extracted. After exclusion of patients who did not undergo follow-up for at least 3 months, and patients who underwent salvage surgery after non-curative ESD, statistical analysis of the incidence of postoperative stricture and required endoscopic balloon dilation (EBD) sessions in each of these 3 groups was performed.

Results: During the study period, 15 patients were enrolled in study A, 13 patients in study B, and 37 patients were extracted as group C. After exclusion, 11 cases in group A (2 circumferential, 9 semi-circumferential), 11 cases in group B (11 semi-circumferential), and 30 cases in group C (3 circumferential, 27 semi-circumferential) were analyzed. Although postoperative stricture occurred in all circumferential cases in group C, it was successfully prevented in 1 case of circumferential ESD in group A. A sub-analysis comparing the semi-circumferential ESD cases was performed. There were no significant differences in tumor size (A: 34.9 ± 8.1, B: 31.5 ± 7.0, C: 34.8 ± 13.8 mm) and operation times (A: 95.4 ± 23.8, B: 108.2 ± 33.1, C: 112.1 ± 50.3 min) in the 3 groups. Group A demonstrated the most effective results in both the incidence of postoperative stricture (A: 11.1%, B: 36.4%, C: 55.6%), and the number of EBD sessions required (median A: 0, B: 0, C: 3).

Conclusion: The combination of triamcinolone injection and the shielding method with PGA sheets and fibrin glue is a promising method for preventing stricture after esophageal ESD. Prospective studies for confirmation of efficacy and safety are required.

Introduction: Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are the first line treatment for superficial esophageal squamous-cell carcinoma (SCC). Comparatively to surgery, endoscopic resection is minimally invasive and associated with a lower morbidity and mortality.

Aims & Methods: Evaluation of the endoscopic resection efficiency for superficial esophageal SCC and long-term outcome. Primary outcome was recurrence rate after endoscopic resection defined as local recurrence or metastatic evolution. We conducted a retrospective multicenter study in 5 French tertiary care hospitals. All patients treated by EMR or ESD for histologically proven SCC were consecutively included. Esophageal SCC were defined as superficial after macroscopic evaluation including Lugol staining and endoscopic ultrasonography (EUS). Curative resection was defined as pT1a with free resection margins, without lympho-vascular emboli.

Results: Between 1998 to 2016, 132 patients were enrolled and 148 tumors were resected (EMR = 80, ESD = 68). The mean age was 63.9 [35.7–86.0] years-old and 108 (73%) patients were male. Mean tumor size was 15.0 mm in the EMR group and 35.0 mm in the ESD group (p < 0.001). The complete resection rate in the EMR and ESD groups were respectively 30% (24/80) and 100% (68/68) (p < 0.0001). The mean follow-up period was 22 months. The recurrence rate was 14.2% (19/80) in the EMR group and 2/68 in the ESD group, p = 0.001. At 12 months, recurrence-free survival rate was 84.4% and 74.6% at 24 months. Factors associated with recurrence in univariate analysis were: tumor size (p = 0.013), resection by EMR (p = 0.001), piecemeal resection (p = 0.016), and microscopic positive margins (p = 0.044). In multivariate analysis, risks factors for recurrence were: resection by EMR (OR = 7.315; IC [1.685–31.762]; p = 0.008) and tumor deep infiltration ≥ m3 (OR = 2.635; IC [1.065–6.519]; p = 0, 036). At 24 months, recurrence-free survival rate were 95.2% in ESD group, versus 59.8% in EMR group (p = 0.001). For infiltrating tumors ≥ m3, metastasis free survival rate at 24 months were 100.0% after complementary treatment by radio-chemotherapy, and 62.2% without complementary treatment (p = 0.042).

Conclusion: Endoscopic resection of superficial esophageal SCC is safe and efficient. According to our results, ESD should be preferred to EMR because it is associated with a higher curative rate and an increased recurrence free survival rate.

Introduction: Esophageal squamous cell carcinoma (ESCC) with invasion into the muscularis mucosae (MM) or submucosae up to 200-µm (SM1) has approximately 10% lymph node metastasis and is a relative indication for endoscopic resection (ER) as per the Japanese Esophageal Society (JES) guidelines. The consideration criteria for additional treatment of MM/SM1 ESCC are as follows: (1) lymphovascular invasion, (2) SM1, (3) positive vertical margin, and (4) diffuse pattern of infiltration (INFe). However, the clinical validity of the JES guidelines has not been established. We evaluated the curative conditions after ER for MM/SM1 ESCC based on long-term outcomes.

Aims & Methods: We recruited 98 patients with MM/SM1 ESCC who underwent ER between August 1992 and October 2013 and were followed up for more than 3 years at Hiroshima University Hospital. As per the JES guidelines, the e-curable group was characterized by en bloc resection lesions with pathological MM, tumor infiltration pattern (INF) a/b, VM0, ly0 and v0. We evaluated the clinicopathological characteristics of patients and lesions and the rates of overall survival, disease-specific survival, recurrence-free survival, lymph node recurrence and local recurrence in the e-curable and non-e-curable groups.

Results: We enrolled 98 consecutive MM/SM1 ESCC patients (88 males; mean age, 67 ± 9 years; e-curable group, 39 patients; non-e-curable group, 59 patients; mean follow-up period, 75 ± 44 months). There were no significant differences in the clinicopathological characteristics of the patients and lesions between the 2

groups. The proportion of patients with additional treatment after ER was significantly higher in the non-e-curable group (66%, 39/59) than in the e-curable group (23%, 9/39) ($p < 0.05$). Operation, radiotherapy, and chemoradiotherapy were administered to 3 (8%), 4 (10%), and 12 (5%) patients, respectively in the e-curable group and to 7 (12%), 22 (37%), and 10 (17%) patients, respectively in the non-e-curable group. The 5-year overall survival rates in the e-curable and non-e-curable groups were 97% and 75% ($p < 0.05$), respectively. The overall survival rate was significantly higher in the e-curable group. Three deaths (10%) occurred due to primary cancer. The other reasons were as follows: other organ cancer, 10 cases; heart failure, 4 cases; pneumonia, 3 cases; and others, 11 cases. The 5-year disease-specific survival rates in the e-curable and non-e-curable groups were 100% and 98%, respectively. The lymph node recurrence rates in the e-curable and non-e-curable groups were 3% (1/39) and 7% (4/59), respectively. The local recurrence rates in the e-curable and non-e-curable groups were 0% (0/39) and 7% (4/59), respectively. The 5-year recurrence-free survival rates in the e-curable and non-e-curable groups were 97% and 98%, respectively. The 5-year recurrence-free survival rates in the group with INFa and no lymphovascular invasion and in the group with INFb, INFc, or lymphovascular invasion were 100% and 87%, respectively. The recurrence-free survival rate was significantly higher in the group with INFa and no lymphovascular invasion than in the group with INFb, INFc or lymphovascular invasion.

Conclusion: Our outcome data support the clinical validity of the e-curative conditions after ER for MM/SM1 ESCC of the JES guidelines. However, MM/SM1 ESCC with INFa and no lymphovascular invasion may have more possible curative conditions after ER without additional treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0569 ENDOSCOPIC SUBMUCOSAL DISSECTION COMPARED TO LAPAROSCOPIC GASTRECTOMY FOR TREATMENT OF EARLY GASTRIC CANCER – A PROSPECTIVE RANDOMIZED TRIAL

P.W.Y. Chiu¹, A. Y. Teoh¹, E. Ng¹, V. Wong¹, H.C. Yip¹, J. C. Wu¹, S. Liu¹, S. K. Wong¹, F.K.L. Chan², J. Jy Sung³, J.Y. Lau¹

Introduction: The development of endoscopic submucosal dissection (ESD) allows en-bloc resection of early gastric cancer (EGC) with wide resection margins [1, 2]. En-bloc resection resulted in adequate resection margins and reduced local recurrence. When compared to gastrectomy, endoscopic resection should theoretically result in better perioperative outcomes and quality of life [3]. There is currently no study in the literature which directly compares laparoscopic assisted gastrectomy against ESD for treatment of intramucosal EGC. The objective of the study is to compare clinical, oncological and immunological outcomes of endoscopic submucosal dissection (ESD) against laparoscopic assisted gastrectomy (LAG) for treatment of early gastric cancer.

Aims & Methods: All patients with endoscopic diagnosis of early gastric cancer (EGC) and biopsy confirmed to be high grade dysplasia or adenocarcinoma were recruited. They received staging investigations including image enhanced endoscopy, EUS and CT and those predicted to be T1a (intramucosal) neoplasia were randomly assigned to receive ESD or LAG. ESD were performed according to the previously reported procedure, while LAG were performed with D1+8 lymphadenectomy. The baseline demographics, clinical perioperative outcomes, immunological and oncological outcomes were compared between the two groups. Primary outcome was rate of complication after operation.

Results: From 2011 to 2016, 36 patients with early gastric cancers were randomly assigned to receive ESD (n=18) or LAG (n=18). There was no difference between the two groups in terms of age, gender, ASA grade and baseline demographics (Table 1). ESD was associated with significantly shorter operative time (109.4 ± 55.4 vs 266.2 ± 47.8 mins, $p < 0.001$), hospital stay (4 (3–6) vs 8 (4–14) days; $p < 0.001$) and lower complication rate (1 (5.6%) vs 7 (38.9%); $p = 0.041$). There was no mortality at 30 days for the two groups, while those in ESD group tolerated full diet earlier (2 (1–5) vs 5 (3–12) days; $p < 0.001$). Patients who received ESD had significantly lower level of CRP as well as VAS pain scores on postoperative days 1, 2, 3 and 7 when compared to LAG. The median follow-up was 41.5 months for ESD group and 36 months for LAG group, and there was no difference in the cancer recurrence and overall survival. 27.8% of patients required re-intervention after ESD.

Table 1: - Outcomes of ESD vs Lap Gastrectomy

Parameters	Lap Gastrectomy	ESD	p value
Male (%)	7 (38.9)	11 (61.1)	0.317
Age (mean +/– SD)	62.5+/–10.4	61.7+/–11.2	0.899
ASA (I/II/III)	5/8/5	5/8/5	1.0
Comorbidities (Median)	2 (0–5)	1 (0–4)	0.505
Smoker (No/Ex/Current)	10/3/3	11/3/4	0.534

(continued)

Table 1 Continued

Parameters	Lap Gastrectomy	ESD	p value
Drinker (No/Social/Heavy)	12/1/3	14/2/2	0.480
Operation time (mins) (Median(range))	263.5 (165–365)	97.5 (30–195)	<0.001†
Hospital stay (days) (Median(range))	8 (4–14)	4 (3–6)	<0.001†
Days to resume full diet	5 (3–12)	2 (1–5)	<0.001†
Complications (%)	7 (38.9)	1 (5.6)	0.041†
30 days mortality	0	0	–
Reintervention (Gastrectomy/ESD/Reoperation)(%)	0(0)	5 (27.8)	<0.001†
Postop Day 1 VAS pain	49 (8–80)	23 (0–57)	0.013†
Postop Day 3 VAS pain	39.5 (6–65)	5 (0–37)	<0.001†
Postop Day 7 VAS pain	21 (0–53)	0 (0–10)	0.003†
Postop CRP Day 1	81.1 (54–249)	11.7 (2–46)	<0.001†
Postop CRP Day 3	110.3 (39.1–229.4)	22.8 (1.4–60.0)	<0.001†
Pathology T1a	12	14	
Pathology T1b	3	3	
Pathology T2	0	1	
Pathology T3	3	0	

Conclusion: Our prospective randomized study showed that patients treated by ESD had significantly lower complication rate and better perioperative outcomes when compared laparoscopic gastrectomy. ESD should be the first line treatment for intramucosal early gastric cancers.

Introduction: Pre-malignant conditions and lesions of the stomach (PCLS): atrophy, intestinal metaplasia and dysplasia are risk factors for the development of stomach cancer; therefore, its diagnosis is very important to identify patients with greater probability of this malignant neoplasm. The Clinical Guidelines recommend that during endoscopy procedure, to avoid an under diagnosis, biopsies of different areas of the stomach should be taken even when no lesion is evident in order to identify PCLS that are generally multi-focal. The initial identification of patients with this type of lesions and their subsequent stratification with the OLGA and OLGIM systems allows defining the subgroup of patients that merit follow-up because they have a higher risk of developing gastric cancer. However, there is a discrepancy between endoscopists, because it is now preferred to take biopsies directed at the lesions and not to do them systematically at fixed sites, so that no lesion is observed.

Aims & Methods: We aimed to evaluate and compare the prevalence of PCLS in biopsies taken from gastric mucosa with or without lesion during the endoscopic examination. A retrospective, cross-sectional study was performed on 356 dyspeptic patients. We reviewed the reports of esophagogastroduodenoscopies at the Trujillo Regional Teaching Hospital-Perú from October 2016 to March 2017. This study included reports which were consigned diagnosis with biopsies of different areas from the stomach. These biopsies were sent in different vials. Permission was obtained from the Hospital's research committee. Those reports that had a diagnosis of stomach cancer, gastrectomy, and those with not biopsy

or those in which the biopsies were still taken from the different anatomical areas were sent in a single vial were excluded.

Results: Only 148 patients were admitted to the study. The mean age was 49.7±3 years, 60% were female (CI: 52–67, 95%). 264 vials were sent with biopsies of the different areas of the stomach distributed as follows: 148 of antrum, 54 of angle and 62 of body. Only 48 (32.4%) patients had biopsies of antrum, angle and body. From 148 patients, 116 (78.4%) had an endoscopic diagnosis of normal gastritis or mucosa and 32 (21.6%) had endoscopic diagnosis of PCLS. From 116 patients with endoscopic diagnosis of gastritis or normal mucosa, LCPM was identified in 46 patients (39.6%) ($p < 0.001$) and 1 of them were low-grade dysplasia. From 32 of patients with suspected endoscopic PCLS, the diagnosis was confirmed with histology in 26 patients (81.2%). A total of 72 patients had PCLS vs. 32 who were initially suspected ($p < 0.01$), with a total prevalence of 48% (CI 40.7–56.6, 95%).

Conclusion: Pre-malignant conditions and lesions of the stomach (PCLS) can show as normal mucosa or gastritis during endoscopic procedure. 39.9% of patients who underwent endoscopic procedure with presumptive gastritis had PCLS. PCLS may be under-diagnosed if random biopsies are not taken. Therefore, taking biopsies from areas without suspected PCLS causes a change in the clinical management of patients, both for the initial diagnosis and for the staging according to OLGA and OLGIM systems.

Introduction: Prognosis of GC has a noticeable relation with its clinical stage. Atrophic gastritis (AG), intestinal metaplasia (IM) and dysplasia are well-recognized risk factors for intestinal type GC (GC). A large cohort study demonstrated that the annual incidence of GC were approximately 0.1% for patients with AG, 0.25% for IM and 6% for high-grade dysplasia, which were much higher than those with normal mucosal. In addition, long-term follow-up studies have confirmed that the extent/topography of mucosal atrophy parallels the risk of GC and it is on this ground that a system for staging gastritis, known as the Operative Link for Gastritis Assessment (OLGA) was created. It is widely accepted that serum PG level reflects the functional and morphologic status of gastric mucosal. While the gold standard for atrophy assessment is histology, the combination of serum pepsinogen and *Helicobacter pylori* (Hp) antibody, known as the ABC method, has been suggested as a predictive marker for patients with GC.

Aims & Methods: We aimed to discuss the correlation between the combination of Helicobacter pylori antibody and pepsinogen and OLGA/OLGIM staging system in gastric precancerous lesions risk assessment. A total of 331 patients were enrolled after the examination of endoscopy at Endoscopy Center, the First Affiliated Hospital of Zhejiang Chinese Medical University from October 2014 to December 2015. According to the result of gastroscopy, gastric secretion and serum *Helicobacter pylori* antibody test, patients were divided into four groups: Group A: Hp (-)PG (-), Group B: Hp (+)PG (-), Group C: Hp (+)PG (+) and Group D: Hp (-)PG (+). PG positive was defined as PGI≤70 μg/L and PGR≤7.0. According to the range and degree of atrophy/intestinal metaplasia, patients were divided into five groups on the basis of OLGA/OLGIM staging system. The levels of Hp infection rate, PG I, PG II and PGR were compared between different groups, and the correlation between ABC method and OLGA/OLGIM staging system were evaluated. Statistical analysis was accomplished by chi-square test and logistic regression modeling analysis.

Results: A total of 331 patients were enrolled. 214 patients were classified into group A, 106 patients into group B, 4 patients into group C and 7 patients into group D, respectively. According to the pathological results, 177 cases were non-atrophic gastritis and 154 cases atrophic gastritis. For OLGA staging system, 177 patients were divided into stage-0 group, 82 patients into stage-I group, 49 patients into stage-II group, 16 patients into stage-III group and 7 patients into stage-IV groups. The Hp infection rate was significant higher in patients with higher OLGA stages ($\chi^2 = 13.42$, $P = 0.006$). PGI and PGR level correlated inversely with the rising OLGA stages ($F = 2.127$, $P = 0.041$, $F = 4.350$, $P = 0.002$). For OLGIM staging system, 172 patients were divided into stage-0 group, 81 patients into stage-I group, 47 patients into stage-II group, 19 patients into stage-III group and 12 patients into stage-IV group. The Hp infection rate was significant higher in patients with higher OLGIM stage ($\chi^2 = 16.09$, $P = 0.003$) and the PGR level correlated inversely with the rising OLGIM stages ($F = 3.207$,

$P = 0.013$). Logistic regression modeling showed significant correlations between ABC methods and OLGA/OLGIM staging system ($P < 0.001$).

Conclusion: Serological ABC method and histological OLGA/OLGIM staging system are closely linked in gastric precancerous lesions risk assessment. Serum pepsinogen test could be applied for high risk population identifying and provide a recommendation for further endoscopy examination.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic treatment of sporadic duodenal adenoma is mainly performed in tertiary centers because it is technically challenging and associated with major complications (perforation 1–5% and delayed bleeding 10–15%). The aim of this study was to evaluate the safety and efficacy of the endoscopic treatment for non ampullary sporadic duodenal adenomas (SDA) in two tertiary centers in a large series and to try to determine the predictive factors of outcomes with a long follow-up.

Aims & Methods: This retrospective study was conducted in two tertiary centers between 12/2003 to 03/2016. All the patients who underwent at least one endoscopic treatment by EMR for SDA histologically proven were included. Patients with PAF and ampullary adenoma were excluded. All the following outcomes were systematically recorded in both centers: complete endoscopic resection, resection with negative lateral and vertical margins, recurrence, success of the endoscopic treatment and adverse events (Perforation, intra-procedural bleeding, delayed bleeding, others). There were analysed with multivariate analysis.

Results: 134 procedures were performed. The mean patient age was 65 years (33–85), 50.7% were women. The mean SDA size was of 20.7 mm (5–50 mm), mostly located in the second duodenum (61.2%), 64.9% of the adenomas had a villous component, 34.3% with high grade dysplasia and 7.5% with in situ or intramucosal. Discrepancy between biopsies and the final histology was demonstrated, 32% of the lesions being upgraded and 10.6% being downgraded. An EMR was performed in 98.5% of the cases with a complete endoscopic resection rate of 96.2% which was associated in multivariate analysis with the lesion size and depressed relief. The en-bloc resection's rate was of 44%. Vertical margins were negative in 91.8% of the cases. Negative lateral and vertical margins was associated in multivariate analysis with the lesion size and its en-bloc resection. Intraprocedural bleeding occurred in 5.9% of the case and was associated in multivariate analysis. Delayed bleeding occurred in 13.4% of the cases and was associated with a larger lesion size and the presence of high-grade dysplasia or adenocarcinoma. usual use of antiplatelet or anticoagulant did not increase the risk of bleeding after pre operative management. A prophylactic hemostasis was realized for 61.9% of the procedure, by clips alone or associated in 72.3% of the cases. Prophylactic clipping reduced significantly the risk of delayed bleeding. Perforation occurred in 3.7% of case. Median follow-up was of 31.2 months with at least one follow-up endoscopy (78.3%). Final success of endoscopic treatment occurred in 83.8% of the case. 30 patients had a recurrence (28.6%). 13 among them being successfully retreated with endoscopy, 12 still receiving endoscopic treatment with multiple sessions, and 5 were referred to surgery. In multivariate analysis, the main risk factor for recurrence was the lesion size.

Conclusion: Endoscopic treatment of SDA appears to be effective and relatively safe in tertiary centers. All the bleeding complications were endoscopically controlled and their occurrence could be reduced with clipping prophylactic hemostasis. Perforation is rare. Recurrence rate is frequent and associated with piecemeal resection but can be endoscopically managed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Additional surgery should be recommended in patients with non-curative endoscopic resection for early gastric cancer (EGC). However, this decision has been often hesitated according to patient's condition such as advanced age or comorbidities. After the recognition of recurrence, the salvage surgery has been considered difficult. However, little has been reported on it.

Aims & Methods: The aim of this study was to clarify the results of salvage surgery for recurrence after non-curative ESD for EGC using data from multicenter retrospective study (EAST study*). Of 15,785 patients who underwent ESD for EGC at 19 participating institutions from January 2000 to August 2011, 1969 patients who failed to meet the current curative criteria for ESD were retrospectively reviewed. Among 1969 patients enrolled into EAST study, 1064 patients underwent additional surgery, and 905 patients were observed without any additional treatment. We evaluated first site of recurrence, clinical course after salvage surgery, and long-term survival on non-treatment group. Recurrence was classified regional LNM, and distant metastasis.

Results: Over a median follow-up period of 64 months, recurrence was detected in 27 patients. Among them, 2 patients were excluded from this study due to missing data. First sites of recurrence were only local site (intra-gastric relapse 3, regional LNM 7), and distant metastasis 15 (60%). The first treatments for recurrence were endoscopic treatment 1, salvage surgery 7 (28%), chemotherapy 6, and best supportive care 11. Only one patient was alive without any recurrence for 31 months after salvage surgery. And one patient died of acute myocardial infarction just one month after salvage surgery. In the remaining 5 patients, recurrence was detected at 0, 2, 3, 5, 30 months after salvage surgery, and all of them died of gastric cancer. Median survival time of all 25 patients with recurrence was 5 months from recurrence. And median survival time of 7 patients who underwent salvage surgery was only 7 months from salvage surgery.

Conclusion: More than half of recurrence after non-curative ESD without additional surgery were distant metastasis, and the survival rate after salvage surgery was quite low.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Due to the increase of elderly patients who are often receiving antithrombotic therapy for cardio- and cerebrovascular diseases, postprocedure bleeding after endoscopic treatments for early gastric lesions has become one of the major concerns of therapeutic endoscopists. The Japan Gastroenterological Endoscopy Society (JGES) and other related associations published the Guidelines for Gastroenterological Endoscopy in Patients Undergoing Antithrombotic Treatment in 2012¹. According to the guideline it is not necessary to suspend an antiplatelet agent before endoscopic treatments including endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD) if the agent is not combined with other antithrombotic drugs (monotherapy). On the other hand it is recommended that anticoagulants should be substituted with heparin before EMR/ESD. The aim of this study is to clarify the efficacy of the recommendations of the guideline.

Aims & Methods: In this study 888 early gastric lesions in 783 patients who underwent EMR/ESD at our hospital between January 2012 and March 2017

were retrospectively analysed. Postprocedure bleeding was defined as: (1) hematemesis or melena for which an emergency endoscopy was required and (2) bleeding which were confirmed with a repeat endoscopy after a drop ≥ 2 g/dL of haemoglobin level.

Results: The total number of patients undergoing antithrombotic therapy was 78, out of which 38 patients were taking antiplatelet agents only, 29 were taking anticoagulants only, and 11 were taking the both. The antithrombotics were suspended in 22 cases (Group A), substituted with heparin in 18 (Group B), and kept continued in 38 (Group C). Postprocedure bleeding was encountered in 31 out of 783 cases (4.0%), 21 of which occurred in patients on antithrombotic therapy (21/78: 27%) whereas 10 of which occurred in those without (10/752: 1.3%). A univariate analysis between the patients with postprocedure bleeding and those without concerning such variables age, gender, the diameter and number of the resected lesions, use of antithrombotics, and the expertise of the operating endoscopist revealed that only the use of antithrombotics was significant risk factor for the postprocedure bleeding (odds ratio = 15.926, 95% confidence interval: 7.415–34.208, $p < 0.01$). However, the rate of postprocedure bleeding was not significantly different among Group A, B and C. Among the 21 bleeding patients with antithrombotics, the agent had been suspended or substituted with heparin before EMR/ESD in 10 and had been continued without suspension in 11. There was no significant difference of bleeding rate between the two groups.

Conclusion: The use of antithrombotics was a significant risk factor for the postprocedure bleeding after EMR/ESD for early gastric lesions. The rate of bleeding was not significantly different regardless if the antithrombotics were suspended, substituted with heparin, or continued without suspension.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0575 FACTORS AFFECTING CURATIVE ENDOSCOPIC RESECTION OF EARLY GASTRIC CANCER IN THE ENVIRONMENT OF POPULATION-BASED SCREENING

Y.G. Mun¹, H.H. Lee², D.H. Kang¹, J.M. Park¹, K.Y. Song³, M. Choi¹

Introduction: Since population-based screening for gastric cancer in Korea was implemented in 2002, endoscopic treatment of early gastric cancer (EGC) has been popularized. Most patients with early neoplasm have no alarming symptoms/signs. In addition, the strategy for detecting factors predicting curative endoscopic resection of EGC is becoming important, because the general population is aging and considering the quality of life after treatment.

Aims & Methods: This study investigates factors affecting curative endoscopic resection of EGC in the era of population-based screening for gastric cancer. The subjects consisted of patients newly diagnosed with stomach cancer at Seoul St. Mary's Hospital between May 2011 and May 2016. All patients completed questionnaires about symptoms, social history, family history, knowledge of national cancer screening program, the reason for screening and the interval between endoscopy screening examinations for gastric cancer.

Results: Of a total of 469 patients, 147 (31.3%) had a curative endoscopic resection, 260 (55.4%) had a curative surgical resection and 62 (13.3%) were in non-curative surgical resection or an inoperable state. The patients with curative endoscopic resection had minimal abdominal symptoms and fewer alarm symptoms/signs (a family history of gastric cancer, anemia, and clinically important weight loss), whereas alarm symptoms were more common in patients with advanced cancer. In multivariate analysis, regular surveillance endoscopy was only the factor predicting the curative endoscopic resection [Odd ratio (95% CI) 6.099 (2.532 ~ 14.933), $p = 0.000$]. In addition, the proportion of curative endoscopic resection was significantly higher in the 1-year [(Odds ratio (95% CI) 10.381 (4.081 ~ 26.405), $p = 0.000$), 2-year endoscopy interval groups [(Odds ratio (95% CI) 3.161 (1.106 ~ 9.035), $p = 0.032$)] than patients who had no endoscopy within 2 years.

Conclusion: Most patients with the curative endoscopic resection have minimal abdominal symptoms and no alarming symptoms/signs. Regular surveillance endoscopy was the only factor predicting the curative endoscopic resection of gastric cancer. In addition, more frequent endoscopic surveillance could help to early detect gastric cancers with curative endoscopic resection.

Introduction: Atrophic gastritis and intestinal metaplasia are the cancerization field in which gastric cancer (GC) develops in case of intestinal type. The OLGA and OLGIM staging systems have been suggested to provide risk estimation for GC.

Aims & Methods: The aim of this study is to evaluate the usefulness of OLGA and OLGIM staging according to Lauren's histological classification of GC in considering with other risk factors of gastric cancer. From January 2006 to December 2015, 607 GC patients and 677 control subjects were enrolled who underwent esophagogastroduodenoscopy. Biopsies were taken from the greater and lesser curvatures of the antrum and mid-body, respectively. The OLGA and OLGIM stage (0-IV) was recorded by combining antral with body atrophy scores using the Updated Sydney System. Stage III and IV OLGA or OLGIM was classified as high-risk stage group and Stage 0-II as low-risk group. *H. pylori* infection was assessed by modified Giemsa stain, rapid urease test and culture and was defined by a positive result on any of these tests. Multivariate logistic analysis was performed for the age, sex, smoking, alcohol and family history of GC.

Results: GC patients had more high-risk OLGA stages (25.9%) than controls (6.8%, $P < 0.001$) and high-risk OLGIM stages (18.3%) than controls (4.9%, $P < 0.001$). In the multivariate logistic analysis, Old age [odds ratios (ORs), 1.932; $P = 0.004$ and 2.584; $P < 0.001$ for ages in the 40~59 and >60, respectively], family history of GC (OR, 2.119; $P < 0.001$), and *H. pylori* infection (OR, 1.963; $P < 0.001$) were independent risk factors for GC in the diffuse type as well as intestinal type (Table). High-risk OLGA stages were significantly associated with increased risk of GC in comparison to low-risk (OR, 3.778; $P < 0.001$): intestinal-type (OR, 4.318; $P < 0.001$) and diffuse-type (OR, 2.920; $P < 0.001$) (Table). High-risk OLGIM stages were also significantly associated with increased risk of GC in comparison to low-risk (OR, 3.306; $P < 0.001$): intestinal-type GC (OR, 3.051; $P < 0.001$) and diffuse-type GC (OR, 3.981; $P < 0.001$).

Conclusion: High-risk OLGA and OLGIM stages were useful for intestinal type as well as diffuse type. This usefulness will be increased when combined with *H. pylori* status and family history of GC in regions with high prevalence of GC. Analysis regarding specific interaction among these three factors is undergoing.

Introduction: The association between body mass index (BMI) and digestive cancer mortality is not conclusive in East Asians.

Aims & Methods: We evaluated the relationship between BMI and digestive cancer mortality, using prospective cohort data by the National Health Insurance Service in Korea, which consisted of more than one million subjects. A total of 510, 148 Korean adults were followed-up until 2010. The adjusted hazard ratios (HRs) of cancer mortality were calculated using a Cox model.

Results: During follow-up, 7774 total deaths occurred from digestive cancer. HR for digestive cancer mortality across seven BMI categories. Below 25 kg/m², the HRs of death for each 5 kg/m² increase in BMI were 0.43 (95% confidence interval [CI]=0.32-0.58) for esophagus cancer, 0.70 (0.62-0.79) for stomach cancer, and 0.77(0.65-0.90) for colorectal cancer. Over 25 kg/m², the HRs of death for each 5 kg/m² increase in BMI were 1.30 (95% CI=1.04-1.64) for colorectal cancer, 1.28 (1.07-1.53) for liver cancer, and 1.28 (0.96-1.71) for gallbladder cancer and biliary tract cancer. BMI were not associated mortality from small intestine cancer and pancreatic cancer.

Conclusion: Low BMI were predictors of mortality from esophageal cancer and stomach cancer. High BMI were predictors of mortality from liver cancer and gallbladder cancer and biliary tract cancer. Both low and high BMI were predictors of mortality from colorectal cancer. Further research is needed to evaluate whether interventions involving weight change (loss or gain) reduce the risk of cancer or improve the survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0578 RISK FACTORS FOR LYMPH NODE METASTASIS OF ULCERATIVE TYPE INTRAMUCOSAL EGC

T. Kim, T.J. Kim, H. Lee, J.H. Lee, J.J. Kim
Department Of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: attack836@naver.com

Introduction: Endoscopic submucosal dissection (ESD) is not currently accepted as an alternative treatment to surgery in ulcerative type EGC due to relatively higher probability of lymph node metastasis (LNM). This present retrospective analysis examined the correlation of various histologic factors with the presence of lymph node metastasis in ulcerative type EGC.

Aims & Methods: A retrospective analysis on 200 patients with ulcerative type EGC who underwent radical gastrectomy with D2 lymph node dissection. Several clinicopathologic factors were investigated to identify predictive factors for LNM: tumor size, histopathologic type of tumor, lymphovascular invasion and depth of invasion. Multivariate logistic regression analysis was performed to evaluate the risk factors for LNM.

Results: The total rate of LNM was 15.5% (31/200). The rate of LNM was 2.1 % (2/95) in the lesions confined to the mucosa and 27.6 % (27/105) in those that had infiltrated the submucosa. On univariate analysis, depth of invasion ($p=0.047$) and lymphovascular invasion ($p < 0.001$) were significant associated with LNM. However, there was no significant association between tumor size, histopathologic type of tumor and LNM. On multivariate analysis, only lymphovascular invasion ($p < 0.001$) was significantly associated with LNM. There was no significant association between tumor size and lymph node metastasis in ulcerative type EGC.

Conclusion: Ulcerative EGC confined to the mucosa could be considered for candidate for curative ESD due to the low risk of LNM. This finding should be confirmed by more data from other centers, which focus on LNM after ESD in ulcerative type intramucosal EGC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0579 THE FEASIBILITY STUDY USING KUMC ROBOTIC MANIPULATOR IN ENDOSCOPIC SUBMUCOSAL DISSECTION

Introduction: Gastrointestinal cancers are one of the most common malignancy worldwide. Especially endoscopic submucosal dissection (ESD) for early

gastrointestinal cancers have been considered as the current standard cancer treatment. However, lack of counter traction during ESD procedure is one of major difficulty. To overcome this problem, we developed new endoscopic technique using robotic manipulator and conducted study about efficacy and safety in vitro animal study.

Aims & Methods: A novel robotic suture manipulator is composed of control panel and a working arm, which grasp and move objects at the end of scope. A total of 10 porcine stomachs were used for the test. Porcine stomachs were assigned randomly to 2 groups and ESD was performed on mucosa of stomach using conventional technique and new endoscopic technique with robotic manipulator. Endoscopic experts and novice endoscopists performed ESD in 2 parts (antrum & body) of stomach. During procedure, robotic manipulator lifts up dissected tissue of stomach to make better visibility. Procedure time, complete resection rate, and complication such as perforation was recorded.

Results: The average procedure time for the robotic manipulator and conventional ESD was 42 minutes and 45.9 minutes. In novice endoscopists, the average procedure time using robotic manipulator is faster than conventional ESD group (47.5 min vs 55.3 min, $p < 0.05$). Both endoscopic expert and novice endoscopist completed the ESD procedure for en bloc resection of target lesions using KUMC robotic manipulator. There was no difference in complete resection rates between two groups. No complication such as perforation was occurred in both groups during the procedures. There was no difference depending on resected location in stomach.

Conclusion: The robotic manipulator, which can perform ESD more easily showed feasible result comparing with conventional ESD. ESD using robotic manipulator could be helpful, especially in novice endoscopists. This research proposes a novel approach for safe and feasible method during ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0580 DEVELOPMENT OF NOVEL ENDOSCOPIC IRREVERSIBLE ELECTROPORATION ABLATION DEVICE

G. Min¹, S.J. Choi¹, W. Kim¹, I.K. Yoo¹, S.H. Kim¹, J.M. Lee¹, H.S. Choi¹, E.S. Kim¹, B. Keum¹, H.S. Lee¹, H.J. Chun¹, C.D. Kim¹, Y.T. Jeon¹

Introduction: Irreversible electroporation (IRE) is a promising novel technique for the ablation of tumors. An advantage of IRE is its mechanism to remove undesired cells by affecting the cell membrane without thermally destructing blood vessels, nerves and the surrounding tissues. Several clinical trials for applying IRE to human organs such as liver, pancreas, and kidney are conducted and studies about IRE ablation for gastrointestinal tumors also have been conducted recently. Here, we developed new endoscopic IRE device, and studied about its effectiveness and feasibility in animal model.

Aims & Methods: Newly developed endoscopic IRE ablative catheter works with single channel of endoscope. A pair of dipolar electrodes consist of pre-shaped f 0.63 mm nitinol wire and the distance between each electrode is 10 mm. The electrodes are loaded within braided tube for stent delivery system then deployed when IRE catheter put in stomach through the endoscope. We performed endoscopy and IRE ablation was done on pig's stomach mucosa by using endoscopy with newly developed IRE catheter. We divided pig's stomach into 2 parts (antrum & body), and IRE ablation was applied on each part of the stomach. Pigs were sacrificed after 24 hours, and we collected their stomachs with surgical technique. Following fixation, tissues were stained with H&E.

Results: Ten male Yorkshire pigs and in vitro stomachs were used in this study. The tissue with H&E stain showed diffuse cell death 24hr after IRE ablation.

BMI, body mass index; CI, confidence interval; GB, gallbladder; HR, hazard ratio. ^a Hazard ratios were calculated using Cox proportional hazards models after adjustment for age at baseline (continuous variable), smoking status (current smoker, former smoker, never-smoker, and missing smoking status), alcohol consumption (frequency; five or more times/week, one to four times/week, less than one times/week, past drinker [no alcohol for a year], never-drinker, or missing information), monthly household income (Korean won [KRW], 1 United States dollar = 1170 KRW as of August 1, 2004; <500,000, 500,000–990,000, 1,000,000–1,490,000, ≥1,500,000, missing information), and physical activity (yes, no). HRs were not presented for causes with less than 10 deaths.

Consistent with the mechanism of action of IRE on the cell membrane only, there was complete cell death within the IRE lesions without intervening live cells. But there was no difference in histology depending on gastric part in which ablation was applied. During the study, no complication was observed in pigs in 24 hours after ablation.

Conclusion: The new endoscopic IRE device, which can perform IRE ablation on gastrointestinal tract using endoscopy showed safe and feasible result.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0581 DIAGNOSIS OF MICROVASCULAR PATTERN IS MORE IMPORTANT THAN MICROSURFACE PATTERN TO DELINEATE GASTRIC CANCERS DETECTED AFTER H. PYLORI ERADICATION BY MAGNIFYING ENDOSCOPY

T. Iwasaki, K. Uchita, K. Kojima, S. Iwamura
Kochi Red Cross Hospital, Kochi/Japan

Contact E-mail Address: space-rendez-vous@sings.jp

Introduction: It is difficult to delineate gastric cancer that is detected after successful eradication of *Helicobacter pylori*. One reason is reportedly the difficulty in identifying the demarcation line between the cancerous lesion and non-cancerous gastric mucosa due to a mixture of non-neoplastic epithelial-lined structure inside the neoplasm. However, almost all previous studies have only used magnification endoscopy (ME) at low power magnification which could evaluate microsurface pattern (MSP) but could not evaluate microvascular pattern (MVP)1). The highest power magnification was necessary to evaluate MVP accurately2), and the diagnostic efficacy of ME in delineating the gastric cancers might not have been accurately assessed in these studies.

Aims & Methods: The aim of this study was investigating diagnostic efficacy of ME with narrow band imaging (NBI) in delineating the gastric cancers after eradication HP, using ME at highest power magnification, and classifying ME features of the marginal area according to the vessel plus surface classification system (VSCS) to realize which was more important ME findings MSP or MVP to detect demarcation line. Endoscopic examination was performed using a magnification endoscope (GIF-H260Z; Olympus Medical Systems Co, Tokyo, Japan) and NBI system (EVIS LUCERA Spectrum system; Olympus Medical Systems Co, Tokyo, Japan). Endoscopic imaging procedures were performed at low-power magnification followed by highest power magnification. On the day of ESD, the resection line was marked 3–5 mm outside of the margin of the lesion. A lesion meeting all of the following criteria was defined as a lesion with successful delineation: (1) the demarcation line of the lesion is endoscopically identified with a high level of confidence; (2) According to histopathological findings, the lesion is confined within the resection line. The diagnostic accuracy of ME-NBI in delineating the lesions was evaluated. On the other hand the ME findings of the marginal area in each lesion were classified in terms of microsurface pattern (MSP) and microvascular pattern (MVP) according to the VSCS to identify the findings that were useful in delineating the lesions in patients with differentiated-type early gastric cancers. The classification according to the VSCS was made in the marginal area with the least irregular findings.

Results: Of 178 consecutive lesions of differentiated-type early gastric cancer treated with endoscopic submucosal dissection (ESD) between August 2013 and March 2017, the study included 59 lesions that were detected after successful *H. pylori* eradication. The result of ME-MBI findings are summarized in the table. Gastric cancer was successfully delineated in 98.3%(58/59) of the lesions with irregular MSP and/or irregular MVP with a demarcation line. Among the ME findings of the demarcation line, irregular MSP and irregular MVP were present in 67.7%(40/59) and 93.2%(55/59), respectively, according to the VSCS, with a higher percentage of lesions with irregular MVP than those with irregular MSP. In addition, there was no finding which was irregular MSP and regular MVP, but 27.1%(16/59) was regular MSP and irregular MVP, which indicated that the ME findings of MVP was more important than MSP. One lesion showed regular MSP or regular MVP without a demarcation line in a portion of the marginal area, resulting in unsuccessful delineation.

	Regular MVP	Irregular MVP	Absent MVP
Regular MSP	1(1.6%)	16(27.1%)	0(0%)
Irregular MSP	0(0%)	37(62.7%)	3(5%)
Absent MSP	0(0%)	2(3.3%)	0(0%)

Conclusion: The accuracy of ME with NBI in delineating gastric cancer detected after *H. Pylori* eradication was 98.3%, which was higher than the values reported previously. In addition, the MVP as visualized by ME appeared to be a more reliable marker than MSP. These results indicate a meticulous observation of the MVP under maximal magnification to be crucial for the delineation of gastric cancer detected after eradication of *H. pylori*.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic forceps biopsy (EFB) is the gold standard for gastric epithelial tumor diagnosis. However, definitive diagnosis is often difficult, and some cases are diagnosed as gastric indefinite neoplasia (GIN), which corresponds to category 2 in the revised Vienna classification. GIN lesions require short periods of follow-up.¹ The most appropriate forceps size for gastric biopsy has yet to be determined. In the Japanese Classification of Gastric Cancer, diagnoses of GIN are attributed, at least partly, to the small size of biopsy specimens.² Since specimens yielded by small biopsy forceps are small, the use of small biopsy forceps is expected to increase the rate of GIN diagnoses.

Aims & Methods: The relationship between forceps size and the frequency of GIN was investigated. The patients in this cohort were divided into two historical groups. The first group comprised patients evaluated during the period when standard biopsy forceps (StF) were used (April 2010–March 2011), and the second comprised patients evaluated during the period when small biopsy forceps (SmF) were used (April 2011–March 2013). Standard caliber endoscopy was used for all esophagogastroduodenoscopy (EGD). We count the number of GIN and gastric carcinoma lesions. Patient characteristics, lesion characteristics (e.g., site, macroscopic appearance, and color tone), endoscopist experience level, biopsy sample size were investigated in both groups diagnosed as GIN. The clinical courses of GIN cases were followed for 3 years, and the timing of EGD after the GIN diagnosis and the final pathological result were investigated.

Results: Among the 8420 patients who underwent EGD in the first period, 2,584 (30.7%) underwent gastric biopsy with StF. Among the 15,968 patients who underwent EGD in the second period, 4204 (26.3%) underwent gastric biopsy with SmF. Gastric carcinoma was diagnosed in 7.93%(205/2584) and 7.54%(317/4204) of the StF and SmF groups, respectively ($P=0.556$). GIN was diagnosed in 0.73%(19/2583) and 1.25%(52/4204) of the StF and SmF groups, and the difference was significant ($P=0.048$). The two groups diagnosed as GIN did not differ significantly in terms of the patient characteristics, the lesion characteristics, endoscopist experience level and biopsy related hemorrhage. The mean minor-axis lengths of the biopsy samples were 1.50 ± 0.50 mm and 1.38 ± 0.40 mm in the StF and SmF groups, respectively. The SmF group samples tended to be shorter ($P=0.088$). In both groups, 40% of the final diagnoses were epithelial neoplasias; no significant differences were observed.

Conclusion: SmF use may increase the rate of GIN. Thus, SmF use should be avoided with a standard caliber endoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Stomach cancer is a leading cause of cancer-related deaths in the world. It well knows that stress play an important role in the cancer. However, for the role of stress in cancer initiation is contradicted and debatable. Other natural factors such as nitrites, which are widely presented in daily food, are actively discussed as carcinogenic to humans. But, there is no clinical and epidemiological evidences that nitrosamines itself can induce the stomach cancer.

Aims & Methods: For the better understanding of carcinogenic effects of daily stress and nitrites in development of stomach cancer, here we studied the role of these factors in adenocarcinoma in stomach of rats. The experiments were carried out with male adult rats ($n=200$). To examine the role of stress and nitrosamines in gastric mucosal injuries we used: 1) the model of chronic social stress (overpopulation during 9 months); 2) the daily using of toluidine (2 g/kg) in food and water with nitrites (2 g/l); 3) the combined effects of stress + nitrosamines. The

upper endoscopy was performed using our in-house custom-made multichannel endoscopy system. Histological assay performed to analyze the changes in the gastric tissues.

Results: Using upper gastroscopy, we studied the stomach tissues during 9 months of lining of rats in chronic stress. There were no changes in the gastric mucosa during the first two months. In the third month 35% (7 of 20) of animals demonstrated multiple small peptic ulcer (n=11). These changes progressed during other time of observation. 9 months of experiment. So, this time all rats showed peptic ulcers both types with significant increase in the number of ulcers (small, n=21 and large, n=9). Thus, this series of experiments clearly showed that chronic stress plays provoking role in the peptic ulcer formation in the stomach of rats. The deleterious effects of nitrosamines on the gastric mucosa observed 4 months after the beginning of daily using of toluidine and nitrites in 75% of rats (15 of 20). These rats showed symptoms of atrophic gastritis. Other 25% (5 of 20) of animals did not demonstrate any changes in gastric mucosa. Thus, this series of experiments markedly showed that effect of long-term eating low-dose nitrosamines induced of atrophic gastritis in the stomach of majority of rats. Using similar protocol of the first and second parts of experiments, we observed the changes in the stomach tissues during 9 months. The same scenarios of typical gastric injuries induced by stress and nitrosamines were observed in rats, i.e. they showed development of peptic ulcers and atrophic gastritis. But, 7 months after the start of experiment, these pathological changes of gastric tissues were associated with intestinal metaplasia of goblet cells, which is the pre-cancer symptom. In 9 months of study, symptoms of gastric adenocarcinoma were observed in 82% of rats (131 of 160). Tumor lesions was accompanied by the migration of metastatic tumor cells through the bloodstream in the liver. The number of metastatic nodes varied from 1 to 5.

Conclusion: Thus, in our research we clearly show that only combination of two pro-cancer factors such as stress and nitrosamines cause development of gastric cancer with metastasis in the liver while the presence of these factors alone contribute mucosal injuries without oncological changes in the stomach.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cyclooxygenases 1 (COX-1) and 2 (COX-2) are key enzymes in mediating the conversion of arachidonic acid into prostaglandins which are important regulators of the immune inflammatory response in the gastrointestinal mucosa^{1, 2}. COX-1 is constitutively expressed in most cell types and involved in maintaining gastric mucosal homeostasis, whereas COX-2 is induced by proinflammatory and mitogenic stimuli and involved in several relevant mechanisms of gastric cancer (GC) development.

Aims & Methods: Since variants in the PTGS1 and PTGS2 genes may modify the expression or function of their encoded enzymes COX-1 and COX-2, the aim of our study was to assess the relevance of environmental factors and several functional PTGS1 and PTGS2 gene polymorphisms on GC risk and phenotype in a Caucasian population in Spain. Methods: DNA from 603 unrelated Spanish patients with primary GC and 603 sex- and aged- (± 5 years) matched cancer-free healthy controls was typed for 10 single nucleotide polymorphisms (SNPs) in the PTGS1 (+50C/T, and +644C/A) and PTGS2 (−1195A/G, −765G/C, −297C/G, +3050G/C, +8473T/C, +9850A/G, +10335G/A, and Val511Ala) genes by PCR, RFLP and TaqMan assays. *H. pylori* infection and CagA/VacA antibody status were also determined by western blot in patients and controls.

Results: *H. pylori* infection with CagA strains (OR: 1.99; 95% CI: 1.55–2.54), smoking habit (OR: 1.77; 95% CI: 1.22–2.57) and positive family history of GC (OR: 3.02; 95% CI: 1.99–4.60) were identified as independent risk factors for GC. Concerning gene polymorphisms, no differences in carriage, genotype, and allele frequencies of the PTGS1 and PTGS2 gene polymorphisms were found between GC patients and controls. However, when GC patients were stratified according to the localization of the tumor, we found that carriers of the PTGS2 -1195 (rs689466) G allele were significantly more frequent in the group of cardia-GC patients than in controls (46.8% vs. 32.8%; OR: 1.77; 95% CI: 1.06–2.95). Moreover, carriers of the PTGS2 GGGTAG haplotype that contains the PTGS2-1195G allele, were also more frequent in the group of cardia-CG patients than in controls (41.3% vs. 32.1%; OR: 1.73; 95% CI: 0.86–3.49). Finally, no differences in carriage, genotype, and allele frequencies of the PTGS1 and PTGS2 gene polymorphisms were found when GC patients were categorized according to gender, age, smoking habit, *H. pylori* infection, CagA/VacA antibody status, family history of GC, and histological subtype of the tumor.

Conclusion: Our data show that the PTGS2-1195A/G (rs689466) gene polymorphism is involved in defining the genetic basis of the susceptibility to cardia-gastric cancer in a South-European population.

Introduction: Gastric cancer (GC) contributes a heavy burden to the global health, especially in Asian countries. Early diagnosis is crucial to improve patients' outcome, but reliable biomarkers are desperately needed. In our previous studies, we established several endogenous fluorescence spectra of gastric juice for GC diagnosis and screening [1, 2], isolated and identified three fluorescence candidates (aromatic amino acids, AAAs), which can be used to distinguish GC from non-neoplastic gastric diseases (NGD) regardless of the stage [3, 4]. However, the characteristic biosignature for the whole metabolic spectra of gastric juice free amino acids (GJFAAs) in GC patients remain unclear. Although many investigators had reported on the changes of amino acids' concentrations in the peripheral blood, urine and tissues of GC patients [5, 6].

Aims & Methods: In order to determine the metabolic patterns of GJFAA in GC and NGD patients, gastric juice samples were collected from GC patients (n=47) and age-matched NGD patients (n=83) from December 2015 to May 2016, and then measured by an automatic amino acid analyzer. Orthogonal partial least squares discriminant analysis (OPLS-DA) and Mann-Whitney U test are used for data analysis. The diagnostic value of GJFAAs was evaluated by ROC curve. Furthermore, significantly altered metabolic pathways were identified by pathway analysis using public databases such as KEGG and MetaboAnalyst 3.0.

Results: GJFAA profiles significantly differed between the GC and NGD patients. A total of 14 kinds of GJFAAs, whose first principal component of variable importance in the projection (VIP) value exceeding 1 and P-value less than 0.05, were screened as differential GJFAAs. Compared with the NGD patients, GC patients had higher levels of threonine, serine, alanine, valine, methionine, isoleucine, leucine, tyrosine, phenylalanine, lysine and arginine,

together with lower levels of phosphoserine, ethanolamine phosphate and urea (Table 1). The 14 GJFAAs revealed diagnostic values with AUC from 0.666 to 0.868, and the combined AUC of them reached to 0.902 (95% CI, 0.846–0.959) for the diagnosis of GC. Importantly, their AUCs were from 0.649 to 0.857, and the combined AUC reached to 0.880 (95% CI, 0.792–0.969) for the diagnosis of early GC. Particularly, leucine, threonine and serine are the most altered three GJFAAs between the two groups, whose fold change more than 2 and AUC value greater than 0.8. Moreover, the combined AUC of the 3 non-AAAs was 0.869 (95% CI, 0.805–0.934) for the diagnosis of GC. It was slightly higher than that combined with 3 AAAs 0.841 (95% CI, 0.773–0.908). Additionally, the pathway of aminoacyl-tRNA biosynthesis metabolism was excessively activated, which significantly responsible for the above metabolic alternations in GC.

Table 1: Differential GJFAAs between GC and NGD patients and their discriminating performance

Number	Abbreviation	Median GC	Median NGD	P-value	VIP	FC	AUC	95% CI
AA01	PSer	0.028	0.037	0.002	1.054	0.768	0.666	0.561–0.771
AA03	PEtN	0.007	0.018	<0.001	1.028	0.606	0.718	0.615–0.820
AA04	Urea	0.178	0.604	<0.001	1.058	0.486	0.804	0.729–0.880
AA06	Thr	0.022	0.007	<0.001	1.489	2.431	0.835	0.764–0.907
AA07	Ser	0.016	0.005	<0.001	1.420	2.671	0.831	0.759–0.903
AA12	Ala	0.033	0.016	<0.001	1.238	1.973	0.783	0.702–0.865
AA15	Val	0.025	0.013	<0.001	1.025	1.763	0.717	0.621–0.814
AA17	Met	0.017	0.007	<0.001	1.178	2.148	0.797	0.718–0.877
AA18	Ile	0.026	0.007	<0.001	1.343	2.674	0.812	0.736–0.887
AA19	Leu	0.075	0.020	<0.001	1.626	2.697	0.868	0.803–0.933
AA20	Tyr	0.066	0.026	<0.001	1.580	1.926	0.833	0.765–0.902
AA21	Phe	0.069	0.032	<0.001	1.415	1.754	0.802	0.720–0.883
AA31	Lys	0.044	0.015	<0.001	1.091	2.321	0.804	0.725–0.883
AA32	Arg	0.036	0.008	<0.001	1.332	2.722	0.772	0.686–0.859

P-value, Statistically significant difference using Mann-Whitney U test; VIP, variable importance in the projection; FC, Fold Change; AUC, area under the ROC curve; 95%CI, 95% confidence interval.

Conclusion: GJFAA profiles may be helpful for improving GC diagnosing even in the early stage and for providing more information about its metabolism. Leucine, threonine and serine, three non-AAAs, warrant further validation as alternative metabolic biomarkers for GC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0587 THE ASSOCIATION BETWEEN MMP-2/9 AND TYPE IV COLLAGEN AND THE LEVELS OF AROMATIC AMINO ACIDS IN GASTRIC JUICE OF GASTRIC CANCER PATIENTS

J. Liu, Y. L. Zhou, R. S. Lin, Z. Jin, J. Y. Han, Y. Xue, E. X. Yan, M. L. Meng

Contact E-mail Address: liujian-825@163.com

Introduction: It is reported that aromatic amino acids (AAAs) in gastric juice could be used as potential diagnostic biomarkers to screen gastric cancer (GC) [1–3]. However, the underlying mechanism remain elusive [4]. Our group had conducted a series of explorations on the reasons to cause such phenomenon before. The candidate molecules: 1) L- type amino-acid transporter 1 (LAT1), which is involved in the enhancement transport of amino acids and the accumulation of AAAs near cancer foci; 2) intracellular amino-acid-metabolizing enzymes, such as indoleamine 2, 3-dioxygenase (IDO) and monoamine oxidase (MAO); 3) proteins involved in intracellular protein degradation or autophagy, (e.g., SQSTM1/p62) had been examined [5]. However, because of the difference in the expression of the above proteins in different pathological classifications of GC tissues, it is impossible to explain the phenomenon that the elevation of AAAs' levels in gastric juice in almost all types of GC patients.

Aims & Methods: To investigate the role of proteolytic enzymes matrix metalloproteinase -2/9 (MMP-2/9) in the abnormal elevation of AAAs' concentrations in

gastric juice of GC patients, gastric mucosal specimens and gastric juice samples were simultaneously collected from 29 GC patients and 91 age- and gender-matched non-neoplastic gastric disease (NGD) patients. The expression levels of MMP-2/9 and type IV collagen (Col IV) in gastric mucosal tissues were examined by immunohistochemical staining while the levels of AAAs in gastric juice were measured by liquid chromatography-tandem mass spectrometry (LC-MS/MS). Furthermore, the association between them was evaluated by Spearman correlation analysis.

Results: On the one hand, the expression intensity of MMP-2/9 in GC group were significantly higher than those in NGD group, while Col IV was markedly lower than that in NGD group ($P < 0.001$ for all). Moreover, there was a positive correlation between the expression level of MMP-2 and MMP-9 ($\rho = 0.439$, $P < 0.01$), but they were both negatively correlated with Col IV ($\rho = -0.454$, $P < 0.01$; $\rho = -0.392$, $P < 0.01$). On the other hand, significantly higher levels of AAAs in gastric juice were observed in GC patients than those in NGD individuals ($P < 0.001$ for all). Ultimately, the expression levels of MMP-2/9 in gastric mucosal tissues were both positively correlated with the concentrations of AAAs in gastric juice (MMP-2 $\rho = 0.262$, 0.295, and 0.293, respectively, $P < 0.01$ for all; MMP-9 $\rho = 0.457$, 0.455, and 0.417, respectively, $P < 0.001$ for all), but Col IV was negatively correlated with them ($\rho = -0.283$, -0.280 , and -0.273 , respectively, $P < 0.01$ for all) (Table 1).

Table 1: Relationship between the expression levels of MMP-2/9 and Col IV in gastric tissues and the levels of AAAs in gastric juice

Variable	MMP-2	MMP-9	Col IV
Tyrosine	0.262**	0.457***	-0.283**
Phenylalanine	0.295**	0.455***	-0.280**
Tryptophan	0.293**	0.417***	-0.273**

** represents significant correlation using Spearman correlation analysis when the confidence level was 0.01; *** represents significant correlation using Spearman correlation analysis when the confidence level was 0.001.

Conclusion: The overexpression of MMP-2/9 resulting in the degradation of Col IV in basement membrane and extracellular matrix may lead to the variation of AAAs' levels in gastric juice of GC patients.

Introduction: Gastric cancer (GC) is the fourth most common type of cancer and the second leading cause of cancer related death. The gold standard for diagnosis is the esophagogastroduodenoscopy (EGD) with targeted biopsies.

Aims & Methods: Retrospective, observational and descriptive study in patients diagnosed of gastric cancer from January 2013 to December 2016 in the area of Ciudad Real (Spain). Missing rate of gastric cancer was defined as the percentage patients who had a negative EGD three years before the diagnosis of CG. A survival analysis was performed with Kaplan Meier curves, mainly focussing on the influence of missing rate for gastric cancer. We studied the features related to EGD that could lead this issue.

Results: 162 patients were included, 65% male with a mean age at diagnosis of 72 years. Intestinal type was the most common histology (76%). A rate of 6.8% missing of gastric cancer was detected with an average of 20 months in delay of diagnosis. However, the survival rate was similar between patients with and without a previous EGD (7.08 vs 5.05 months $p = 0.60$). Among the patients who passed away, a longer delay period was observed comparing to patients who were still alive (6 months vs. 25 months; $p = 0.006$). In the aforementioned subgroup, biopsies were taken in 72% with gastric atrophy in all these cases. *Helicobacter pylori* infection was detected in 50% of them. 55.6% of the EGDs were carried out without sedation. At no point chromoendoscopy was performed, pictures were taken and withdrawal times were not reflected.

Conclusion: Despite the fact that EGD is by far the most effective method to diagnose gastric cancer, 1 out of 10 cancers or premalignant lesions are not figured out. Therefore, it is of utmost importance to put in place quality protocols in EGD that may help to increase the diagnosis of early gastric cancer, and by this way, improve the survival rate of these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Several studies have demonstrated serum PGII level as a marker of the functional gastric mucosa, and a marker of some tumor including the gastric cancer. However, the modulation of the protein and its role in cancer is not fully understood. The aim of this study was to analyse the polymorphisms in the TATA BOX region, which provides a binding site for the transcription factor for the PG2 gene, in association with the PG2 circulating level and clinical parameters in population at risk for GC and in GC patients.

Aims & Methods: Gastric function of 180 patients (67 GC, 71 first-degree relatives of GC patients (FDR-GC) and 42 autoimmune chronic AG (ACAG)) was assessed by gastropanel test. We investigated the PG2 TATA BOX polymorphism frequencies in relation to serum PG2 (sPG2) expression level, HP-positivity and risk for GC. TATA BOX DNA fragments were amplified by PCR and analyzed by the capillary-electrophoresis (GeneMapper software). Association among clinical data and PG2 polymorphisms were estimated by Receiver operating characteristic (ROC) curve and linear regression analyses.

Results: After ROC curve analysis, the sensitivity to discriminate GC at 15 ng/mL PG2 cut-off was 70.15% and 79, 65% sensibility and sensitivity, respectively (AUC: 758, $p < 0.0001$). We obtained 26 different PG2 TATA box fragments (from 308 bp to 479 bp). These fragments were grouped into 4 sized categories (1 = 308–400 bp; 2 = 401–436 bp; 3 = 437–438 bp; 4 = 439–479 bp). A positive correlation among the increase of PG2 sized fragments and the sPG2 level was found in the GC group (linear regression $y = 16, 4381 + 2, 6846 x$, $p = 0.02$).

Conclusion: Accordingly to the literature, we confirm sPG2 level as a marker discriminating between GC and individuals at risk for GC (i.e. ACAG and FDR) in our series. In addition we reported a correlation between the shortest PG2 TATA BOX fragments and the lower PG2 level. Since highest PG2 level was related to the GC condition, our data suggest that carriers having longer TATA BOX region may produce higher sPG2 level than patients with shorter region. The clinical significance of the differences in PG2 level associated with the TATA BOX fragments, by interfering with the transcriptional factor and then with the expression of the corresponding gene, are under investigation. This study will be important to deeper understand the physiopathological PG2 role in GC.

P0590 HELICOBACTER PYLORI INFECTION ASSOCIATED WITH NONALCOHOLIC FATTY LIVER DISEASE: A LARGE-SCALE COHORT STUDY

T. Kim, T.J. Kim, H. Lee, J.J. Kim

Department Of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: attack836@naver.com

Introduction: Previous studies suggested a link between *Helicobacter pylori* (*H. pylori*) infection and nonalcoholic fatty liver disease (NAFLD), yet large-scale longitudinal studies are lacking to elucidate this association.

Aims & Methods: A cohort study of 17,028 adults without NAFLD at baseline, who participated in a repeated health screening examination including an *H. pylori*-specific immunoglobulin G antibody test, was conducted to evaluate the association between *H. pylori* and NAFLD development. Fatty liver was diagnosed by ultrasonography.

Results: During the 83,130 person-years follow-up, participants with *H. pylori* infection had a higher rate of incident NAFLD than those who were uninfected. In a multivariable model adjusted for age, sex, body mass index, smoking status, alcohol intake, regular exercise, year of screening exam, and education level, the hazard ratio (HR) for NAFLD development in participants with *H. pylori*-infection compared to those without infection was 1.21 (95% confidence interval [CI], 1.10–1.34). The association persisted after further adjustment for metabolic variables, inflammatory marker, and liver enzymes. The association between *H. pylori* and NAFLD was still evident in an analysis using fatty liver index as a surrogate marker of NAFLD. In addition, the association between *H. pylori* infection and incident NAFLD did not differ across clinically relevant subgroups evaluated.

Table 1: Development of nonalcoholic fatty liver disease (NAFLD) by *H. pylori* status

	Person-years	Number of Incident cases	Incidence density (per 1,000 person-years)	Age- and sex-adjusted HR (95% CI)	Multivariable-adjusted HR ^a (95% CI)
<i>H. pylori</i> (–)	34,960.7	1301	37.2	1.00 (reference)	1.00 (reference)
<i>H. pylori</i> (+)	48,169.3	2080	43.2	1.14 (1.06–1.22)	1.21 (1.10–1.34)

^aEstimated from Cox proportional hazard models adjusted for age, sex, body mass index, year of screening exam, smoking status, alcohol intake, regular exercise, and education level. *H. pylori*, *helicobacter pylori*; HR, hazards ratio; CI, confidence intervals.

Conclusion: *H. pylori* infection was significantly associated with the development of NAFLD, independent of metabolic and inflammatory risk factors. *H. pylori* infection may play a pathophysiologic role in NAFLD development, indicating that *H. pylori* eradication might play a role in reducing risk of NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0591 HELICOBACTER PYLORI INFECTION STATUS IN HUMAN IMMUNODEFICIENCY VIRUS-POSITIVE PATIENTS

S. Kato, T. YamadaY, Fujii, A. Shoji, R. Kiyota, K. Shinkai, T. Tashiro, A. Ishihara, T. Iwasaki, S. Tanaka, H. Hasegawa, Y. Sakakibara, S. Nakazuru, H. Ishida, E. Mita

Gastroenterology&hepatology, Osaka National Hospital, Osaka/Japan

Contact E-mail Address: seiya_heckle_0728@yahoo.co.jp

Introduction: *Helicobacter pylori* infects the gastric mucosa and causes chronic gastritis via the immunoreaction of the host. By contrast, the human immunodeficiency virus (HIV) infects CD4-positive T lymphocytes and destroys the immune system of the host. Some studies pointed out that the *H. pylori* infection rate is lower in HIV-positive patients. This is because in these patients, *H. pylori* is incidentally eradicated by the course of antibiotic therapy for HIV infection and because the supply of nutrients to *H. pylori* is prevented by the decrease in the number of CD4 lymphocytes.

Aims & Methods: We enrolled 290 HIV-positive patients who underwent esophagogastroduodenoscopy in our Hospital between January 2013 and September 2016. As end points of *H. pylori* infection examination, we retrospectively examined for the presence of gastric mucosa atrophy, *H. pylori* infection, *H. pylori* eradication and comorbidity. As end points of HIV infection examination, we quantified the number of CD4 lymphocytes and the titer of HIV and investigated the presence of acquired immunodeficiency syndrome (AIDS). Based on these data, we examined the relationship between *H. pylori* and HIV infections.

Results: Of the 290 patients, 281 were men and 9 were women, whose median age was 46 years (range, 22–82 years). Ninety patients had atrophic gastritis or stomach or duodenal ulcer, of whom 40 underwent examination for *H. pylori* infection. The median number of CD4 lymphocytes in the 21 *H. pylori*-positive cases was 505/μL (range, 108–952/μL). The titer of HIV ranged from non-detection to 90,900 copies/mL, and one patient had AIDS. Meanwhile, the median number of CD4 lymphocytes in the 19 *H. pylori*-negative cases was 331/μL (range, 15–998/μL), the titer of HIV ranged from non-detection to 1,590,000 copies/mL, and three patients had AIDS. *H. pylori* eradication therapy was applied in 18 of 21 *H. pylori*-positive cases. The success rate of primary *H. pylori* eradication was 37.5% (6/16 patients) and that of secondary eradication was 70% (7/10 patients). In addition, 2 (7.7%) of the 26 patients with stomach or duodenal ulcer needed urgent hemostasis. Five (6.7%) of the 74 cases of atrophic gastritis had gastric cancer, of which two were undifferentiated stomach cancers.

Conclusion: In our study, the number of CD4 lymphocytes was higher in the HIV-positive patients with *H. pylori* infection, implying that the high CD4 count was suggested to be associated with persistent *H. pylori* infection. In addition, the success rate of *H. pylori* eradication was shown to be insufficient in HIV-positive patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0592 *HELICOBACTER PYLORI* INFECTION REDUCES THE RISK OF BARRETT'S OESOPHAGUS AND IT IS INDEPENDENT FROM THE GEOGRAPHICAL LOCATION, A META-ANALYSIS

B. Eross¹, N. Farkas², K. Márta³, P. Hegyi¹

¹Centre For Translational Medicine, University of Pécs, Pécs/Hungary

²Institute Of Bioanalysis, University of Pécs, Pécs/Hungary

³Institute For Translational Medicine, University of Pécs, Pécs/Hungary

Contact E-mail Address: xerobal@yahoo.it

Introduction: In Western European and Northern American populations a decreasing prevalence of *H. pylori* infection has been observed, along with an increasing prevalence of Barrett's oesophagus and an increasing incidence and prevalence of the adenocarcinoma of the oesophagus and gastro-oesophageal junction. In previous meta-analyses, *H. pylori* infection has been proven a protective factor against Barrett's oesophagus, but some individual studies suggested the opposite.

Aims & Methods: Our aim was to scrutinise all data available on the relationship between *H. pylori* infection and Barrett's oesophagus prevalence, to see, if *H. pylori* has a protective role for Barrett's oesophagus and if it is dependent from the geographical location. A meta-analysis was performed using the preferred reporting items for systematic review and meta-analysis protocols (PRISMA-P). We conducted a systematic search in PUBMED, EMBASE and COCHRANE databases from inception to December 2016, for the keywords of Barrett's, Barrett's metaplasia, Barrett metaplasia, Barrett's oesophagus, Barrett's oesophagus, Barrett oesophagus, Barrett oesophagus, Helicobacter pylori, *H. pylori*, *H. pylori* and Helicobacter. We also used information from the references of relevant publications to find further eligible studies. We have conducted a meta-analysis of the data from all studies included. We used the random effect model by DerSimonian and Laird.

Results: We have found 568 articles in PUBMED, 741 in EMBASE and 15 in COCHRANE databases. After exclusion of the articles without sufficient data on the prevalence of *H. pylori* and Barrett's oesophagus, we have identified 83 articles with detailed data, suitable for statistical analysis. This meta-analysis involved 98 665 patients with Barrett's oesophagus and 720 800 patients without Barrett's oesophagus. The statistical analysis from all 83 studies from five continents and 27 countries showed a protective effect of *H. pylori* for Barrett's oesophagus on four continents, but not in Africa, overall Odds Ratio=0.63 (95% CI:0.55, 0.71). The OR and 95% CI values were 0.34 (0.17, 0.67) for Asia, 0.71 (0.55, 0.91) for Europe, 3.05 (0.59, 15.73) for Africa, 0.60 (0.51, 0.71) for North-America, 0.95 (0.56, 1.64) for South-America and 0.56 (0.39, 0.80) for Australia. The OR and 95% CI values were 0.84 (0.43, 1.64) for Eastern Europe; 0.68 (0.52, 0.90) for Western Europe and 0.71 (0.55, 0.91) for all of Europe, suggesting that the protective role of *H. pylori* infection is not different across Europe.

Conclusion: This large meta-analysis has given further evidence, that *Helicobacter pylori* infection has a protective role for Barrett's oesophagus and this protective role is independent from the geographical location, apart from Africa. In view of the decreasing prevalence of *H. pylori* in developed countries and the epidemiological rise of Barrett's oesophagus and adenocarcinoma, it would be important to conduct further large, prospective, multinational studies on the effect of *H. pylori* infection on Barrett's oesophagus.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: *Helicobacter Pylori* (*H. Pylori*) has been implicated in worsening outcomes in patients with hepatic encephalopathy. This is believed to be the result of its urease enzyme that increases the production of ammonia. Small studies so far have yielded contradictory results on whether the presence of *H. pylori* worsens treatment outcomes in hepatic encephalopathy. Therefore, the aim of this study was to assess the impact of *H. pylori* on mortality, morbidity and resource utilization among patients with hepatic encephalopathy using a national database.

Aims & Methods: This was a case-control study using the National Inpatient Sample 2013, the largest publically available inpatient database in the United States. All patients with an ICD-9 CM code for a principal diagnosis of hepatic encephalopathy were included. There were no exclusion criteria. Patients positive for *H. pylori* were identified using the appropriate ICD-9CM codes. The primary outcome was all cause mortality. The secondary outcome was resource utilization as measure by use of abdominal imaging (CT scan and ultrasound of the abdomen), length of hospital stay (LOS), total hospitalization charges and costs.

Multivariate regression analyses were used to adjust for the following confounders: Age, sex, race, income in patients' zip code, Charlson Comorbidity Index, hospital region, location, size and teaching status.

Results: A total of 55,360 patients with hepatic encephalopathy were included in the study, of which 20 had *H. pylori* infection. The mean patient age was 60 years and 42% were female. After adjusting for confounders using multivariate analysis, patients with and without *H. pylori* had similar adjusted odds of mortality (adjusted Odds Ratio (aOR): 1.71, 95% CI: 0.62–4.74, p=0.30). As far as resource utilization, patients with and without *H. pylori* had similar adjusted odds of abdominal imaging (aOR: 3.02, 95% CI: 0.88–10.40, p=0.08), LOS (adjusted mean difference: 1.7 days, 95% CI: –0.02–3.42, p=0.52), and total hospitalization charges (adjusted mean difference: \$16588, 95% CI: -\$4499 - \$37675, p=0.12). However, patients with *H. pylori* had higher adjusted total hospitalization costs compared with patients without *H. pylori* (adjusted mean difference: \$6128, 95% CI: \$1141 - \$11115, p=0.01).

Conclusion: Presence of *Helicobacter Pylori* has no impact on inpatient mortality among patients with liver cirrhosis and hepatic encephalopathy. In addition, the presence of *Helicobacter Pylori* is not associated with any increase in resource utilization among this patient population, with the exception of total hospitalization costs. It is surprising to note that, although total hospitalization costs differed between the two groups, they received the same total hospitalization charges from admitting hospitals.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0594 ERADICATION THERAPY FOR *HELICOBACTER PYLORI* – AN IMPORTANT TOOL TO IMPROVE THE HEART FUNCTION IN PATIENTS WITH CORONARY HEART DISEASE

Introduction: Literature data involves *Helicobacter Pylori* (HP) as a pro-inflammatory and pro-coagulant risk factor for ischemic coronary heart disease^{1, 2}, but the benefit of the curative treatment against HP infection and its repercussions on heart function were not explored sufficiently.

Aims & Methods: We aimed to investigate the role of HP eradication therapy in patients with different stages of heart insufficiency (HI) and coronary heart disease (CHD). 290 patients with CHD admitted in Cardiology and Gastroenterology Departments of St. Andrew Apostle Constanta were explored for HP infection status and found positive. The infection was determined by HP-Ag in faces, urea breath test or endoscopic biopsy. The CHD was assessed by electrocardiography (ECG) and HI was staged according to NYHA classification. According to the implementation of eradication therapy for HP, we divided the patients in two equal groups, matched by age, gender and severity of HI: one group of 145 patients with treatment and the other group of 145 patients without eradication therapy. We compared the heart function improvement after treatment for HP in both groups. We also compared the evolution of PCR, fibrinogen, IL-6 and other inflammatory cytokine.

Results: The eradication therapy for HP with one PPI and two antibiotics associated with cardiac treatment, improved the clinical status based on NYHA criteria in 118 patients with at least 1 stage decrease in NYHA staging compared with only 52 patients from the group with cardiac treatment but without eradication therapy (p=0.03). The laboratory finding also revealed a favorable course of pro-inflammatory tests in treated patients compared with untreated patients, regarding protein C-reactive, leucocytes, IL-6 and fibrinogen (p=0.019, p=0.037, p=0.08, respectively p=0.005, ss).

Conclusion: HP should be one of the treatment targets when managing infected patients with CHD, the eradication therapy being along with cardiac treatment important steps to improve the cardiac function.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: *Helicobacter pylori* infection has become more and more resistant to conventional first-line treatment regimens. So, there is a considerable interest in evaluating new antibiotic combinations and regimens. Nitazoxanide is an anti-infective drug with demonstrated activity against protozoa and anaerobic bacteria including *Helicobacter pylori*.

Aims & Methods: This work is designed to evaluate the efficacy and safety of a unique triple Nitazoxanide containing regimen as a treatment regimen in Egyptian patients with *Helicobacter pylori* infection.

Methods: Two hundred and twenty four patients with upper Gastro-intestinal tract (GIT) dyspeptic symptoms in whom *Helicobacter pylori* induced GIT disease was confirmed were included in the study. They have been randomized to receive either Nitazoxanide 500mg bid, Clarithromycin 500mg bid and Omeprazole 40mg twice daily for 14 days or Metronidazole 500mg bid, Clarithromycin 500mg bid and Omeprazole 40mg twice daily for 14 days. Laboratory evaluation for *Helicobacter pylori* antigen within the stool was done 6 weeks after cessation of *Helicobacter pylori* treatment regimens to assess the response.

Results: The response to treatment was significantly higher in group 1 of Nitazoxanide treatment regimen than group 2 of traditional treatment regimen. One hundred and six cases (94.6%) of 112 patients who completed the study in group 1 showed complete cure while only 63 cases (60.6%) of 104 patients who completed the study in group 2 showed the same response according to per-protocol (PP) analysis ($p < 0.001$). The regimen was well tolerated by all the patients enrolled in the study.

Conclusion: Nitazoxanide-containing triple therapy is a promising therapy for the first-line eradication of *Helicobacter pylori*. (ClinicalTrials.gov Identifier: NCT02422706)

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There is some evidence that prior use of macrolides is a useful predictor of the likelihood of standard triple therapy failure in *H. pylori* eradication (Lim SG, et al. *Dig Liver Dis* 2016). The goal of this study is to evaluate whether previous intake of various macrolide antibiotics can predict failure to eradicate *H. pylori* using first-line clarithromycin-containing regimens.

Aims & Methods: Between February 2014 and June 2016 a total of 250 patients with *H. pylori* infection were prospectively included in a study whose goal was to assess the eradication rates obtained with first-line clarithromycin-containing regimens in our health area. Patients were randomly assigned to one of two regimens: A/Triple therapy (PPI, amoxicillin, clarithromycin, optimized with a double dose of PPI) for 10 days; and B/Concomitant therapy (PPI, amoxicillin, clarithromycin, and metronidazole administered concurrently) for 10 days. The eradication was evaluated by the Stool antigen test or with the Urease test in those patients with a gastroscopy performed after the treatment. A total of 113 patients in the group A (58 women; Median age: 54 years; Range: 21–79) and 106 patients in the group B (56 women; Median age: 49 years; Range: 18–81) completed the study protocol. The electronic medical records of the patients, which contain information regarding all the medication prescribed to the patient during the previous 12 years, were reviewed and the intake of macrolides (clarithromycin, azithromycin and erythromycin) was registered.

Results: 89/219 patients (40, 6%) had received at least one treatment with macrolides during the previous 12 years. *H. pylori* eradication rates with the two treatment regimens are shown in Table 1.

Table 1: *H. pylori* eradication rates in patients with and without previous intake of macrolides.

	Previous use of Macrolides	No previous use of Macrolides	p
A: Triple therapy (n = 113)	24/45 (53, 3%)	65/68 (95, 5%)	<0, 0001
B: Concomitant (n = 106)	37/44 (84, 1%)	61/62 (98, 4%)	0, 0085
Total (n = 219)	61/89 (68, 5%)	126/130 (96, 9%)	<0, 0001

Conclusion: Previous use of macrolide antibiotics predicts a low response to triple and to concomitant clarithromycin-containing regimens. In addition, our study shows that in patients without previous use of macrolides triple therapy achieves per-protocol eradication rates over 90%.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Due to increasing prevalences of clarithromycin resistance in *H. pylori* infection, current guidelines recommend quadruple therapies as first-line therapy^{1, 2}. Bismuth quadruple therapy (BQT) has been proven superior to standard triple therapy in clinical trials³, however little is known about the efficacy of BQT in clinical routine practice.

Aims & Methods: In a prospective single center cohort study we analyzed consecutive patients in whom three-in-one capsule BQT (Pylera® + omeprazole) has been prescribed between 1/2013 and 12/2016. All patients were instructed in a standardized fashion and a prospective follow-up was planned. In a subgroup of patients, genotypic susceptibility testing for clarithromycin and levofloxacin by PCR was carried out on gastric biopsies before treatment. Treatment outcome was assessed by 13C urea breath test or by histology not earlier than 4 weeks after end of treatment.

Results: Three-in-one capsule BQT has been prescribed in 322 patients (mean age 41 years (18–80), 65% female, 26% active smoker). 71% of patients had a migrational background including Southern-/Eastern Europe, Eurasia/Central Asia, Southeast-Asia, Africa, and Central/South America. PCR results were available in 163 patients (50.6%) and identified resistance to clarithromycin and levofloxacin in 29 (17, 8%) and 20 (12, 3%) of cases, respectively. BQT was administered as firstline, secondline and rescue treatment in 74%, 17% and 9% of cases, respectively. 5 patients discontinued treatment prematurely due to side effects (1, 8%) and 43 patients were lost to follow-up (13, 4%). By modified intention-to-treat and per-protocol analysis the *H. pylori* eradication rates were 94, 9% (95% CI: 92.1–97.5%) and 96.7% (95% CI: 94.4–98.8%), respectively. The low number of treatment failures (n=9) did not allow to identify risk factors for failure.

Conclusion: Three-in-one capsule bismuth quadruple therapy is highly effective and safe for treatment of *H. pylori* infection in clinical routine practice, irrespective of the patient's migrational background or the number of previous treatment failures.

Introduction: Background: Eradication of *Helicobacter pylori* (*H. pylori*) infection represents a clinical challenge. The current requirements demand eradication rates above the 90%, which has made that the use of triple treatment including clarithromycin or metronidazole had been gave up on those countries, such as Spain, with high resistance rates. Quadruple therapy with a proton pump inhibitor (PPI) plus a single three-in-one capsule containing bismuth subcitrate potassium, metronidazole, and tetracycline (BMT) have shown high eradication rates in clinical trials.

Aims & Methods: We aimed to evaluate the efficacy and safety of a PPI-bismuth based quadruple therapy in patients diagnosed of *H. pylori* infection in a clinical setting of a Private Hospital, located at the North of Madrid (Spain). A prospective and real-life study was conducted, between March 2016 to February 2017, on consecutive patients with confirmed *H. pylori* infection eradication indication. Patients were treated for ten days with a galenic preparation containing bismuth subcitrate potassium 140mg, metronidazole 125mg, and tetracycline 125mg, three capsules four times daily, and esomeprazole 40mg twice daily and probiotic during 30 days. The primary endpoint was *H. pylori* eradication rate, defined as one negative urea breath test performed, at least 28 days, after the end of treatment. Intent-to-treat (ITT) efficacy analyses included all patients who received study medication and took at least one dose of study medication; patients without an observed outcome were considered as treatment failures. Per protocol (PP) analyses, which excluded patients who did not complete the study or who had major protocol violations, were also conducted to confirm the ITT results.

Results: A total of 100 patients, 60 (60.0%) women and 40(40.0%) men, who fulfilled the respective demands of the inclusion and exclusion criteria, were enrolled consecutively. Five of these were lost to follow-up. Mean (standard deviation) [95% confidence interval] age was 47.1 (15.4) [44.0 to 50.2] years. Twenty-five (25.0%) patients had a prior history of using medications to treat *H. pylori* most often clarithromycin, amoxicillin, and PPI. In the ITT population, the eradication rates were the 90.7 % (68/75) and the 80.0% (20/25) depending on whether the PPI-BMT treatment was administered as first-line or as rescue therapy, respectively. In the PP population, the eradication rates were the 98.6% (68/69) and the 95.2% (20/21) in those patients treated with PPI-BMT as first-line or as rescue therapy, respectively. Eighteen (18.0%) patients reported at least one adverse event.

Conclusion: In patients with confirmed *H. pylori* infection, 10 days of treatment with a quadruple regimen of bismuth, metronidazole and tetracycline plus esomeprazole provides high eradication rates not only as first-line but also as rescue therapy, with an acceptable safety profile.

Introduction: Most *Helicobacter pylori* (Hp) infections are asymptomatic but 15% of those infected with Hp will eventually experience dyspepsia symptoms or peptic ulcer.

Aims & Methods: We aimed to evaluate the cost effectiveness of population screening and eradication for *Helicobacter pylori* (Hp). This was a cost effectiveness analysis and cost utility analysis alongside randomized controlled trial with 13-years follow-up, with a random sample of the general population from the county of Funen, Denmark. 20,011 individuals aged 40–65 were randomized and invited in 1998–99; 12,530 were enrolled and of these 8658 individuals have been successfully followed up at 1, 5, and 13 years after intervention. Questionnaires included Gastrointestinal Symptom Rating Scale and the quality of life instrument SF-36. From SF-36 responses an SF-6D score was derived and used for calculation of quality adjusted life years (QALY). EQ-5D-5L was incorporated in the last follow-up. The intervention was an invitation to Hp screening by in-office blood test; positive tests were validated by 13C-Urea Breath test. Those with a positive 13C-Urea Breath test received eradication therapy. The Hp prevalence was 17.5%. Main outcome measure was incremental cost per quality adjusted life year (QALY) and Life-years gained. The evaluation has a National Health Sector perspective.

Results: There was no significant difference in index scores and in mean QALY between groups. Hp population screening and eradication with 13-years follow-up was not effective in regards to quality of life and the cost of screening was

higher than not screening (14,327DKK (95%CI: 4155–24,499)). The probability of being cost-effective was 80% with a willingness to pay of 400,000 DKK per life-year gained. When including only peptic ulcer disease related costs the probability was 85% a willingness to pay of 100,000DKK per life-year gained.

Conclusion: Hp population screening and eradication with 13-years follow-up was not effective in regards to quality of life and the cost of screening was higher than not screening.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0600 A SEVEN-DAY TRIPLE THERAPY CONTAINING A POTASSIUM-COMPETITIVE ACID BLOCKER COMPARED WITH PROTON PUMP INHIBITORS, AMOXICILLIN AND CLARITHROMYCIN FOR FIRST-LINE *HELICOBACTER PYLORI* ERADICATION IN JAPAN: A SINGLE-CLINIC RETROSPECTIVE STUDY

S. Yojiro

Sadamoto GI Clinic, Kitakyushu/Japan

Contact E-mail Address: sadamotoy@yahoo.co.jp

Introduction: This study was evaluated the effectiveness and safety of Vonoprazan, a potassium-competitive acid blocker (P-CAB) compared with proton pump inhibitors (PPIs) for a first-line *Helicobacter Pylori* (*H. pylori*) eradication.

Aims & Methods: We retrospectively analyzed data from first-line *H. pylori* eradication treatment (vonoprazan or PPIs with 400mg clarithromycin and 750mg amoxicillin twice daily for 7-day) ($n=1393$) between April 2008 and February 2017 at Sadamoto GI clinic, Japan. Patients who received 7-day P-CAB therapy (vonoprazan 20mg twice daily; $n=498$) were compared with those who received 7-day PPI therapy (lansoprazole 30mg; $n=216$, rabeprazole 10mg; $n=331$, esomeprazole 20mg; $n=348$ twice daily). Eradication rates were calculated by intention-to-treat (ITT) and by per-protocol (PP). Compliance and adverse events were also assessed for each study group.

Results: ITT and PP analysis of the first-line *H. pylori* eradication for vonoprazan, lansoprazole, rabeprazole, and esomeprazole were 75.5%/86.8%, 63.9%/76.2%, 68.0%/79.5%, and 63.2%/70.8%, respectively. The vonoprazan eradication rates were significantly higher than those of these PPIs ($P < 0.05$), respectively. There was no significant difference in the adverse events between the two therapies.

Conclusion: 7-day P-CAB based triple therapy is more effective than 7-day PPI based triple therapy as a first-line *H. pylori* eradication without differences in tolerability.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0601 AN OPEN-LABEL, RANDOMIZED CONTROLLED TRIAL OF VONOPRAZAN VERSUS ESOMEPRAZOLE AS PART OF FIRST-LINE TRIPLE THERAPY FOR *HELICOBACTER PYLORI* INFECTION

Introduction: Vonoprazan (VPZ) is a novel, orally bioavailable, potassium-competitive acid blocker for the treatment and prevention of acid-related gastrointestinal diseases. A phase III study revealed that VPZ is superior to lansoprazole as part of first-line therapy for *Helicobacter pylori* (HP) infection when combined with 400 or 800 mg/day clarithromycin (CAM).

Aims & Methods: The aim of the current study was to evaluate the efficacy and safety of VPZ, CAM (400mg/day), and amoxicillin (ABPC; 1500mg/day) triple therapy in post-marketing use in Japan. A randomized, open-label, single-center study was conducted to verify the superiority of VPZ to esomeprazole (EPZ) as part of first-line triple therapy in patients with HP infection. Three hundred and forty-nine Japanese patients with HP infection diagnosed using a rapid urease test were enrolled between June 2015 and October 2016. The patients were randomly allocated to VPZ group (VPZ 40mg/day, ABPC 1500mg/day, CAM 400mg/day) or EPZ group (EPZ 40mg/day, ABPC 1500mg/day, CAM 400mg/day) with stratification according to endoscopic findings of gastric/duodenal ulcer/scar and CAM resistance determined via a microbial sensitivity test. The eradication rates were evaluated using the urea breath test 8 to 12 weeks after cessation of therapy.

Results: Three hundred and forty-five patients (177 men, 168 women; mean age 64.7 years [range 27–89 years]; VPZ group, 169; EPZ group, 176) completed the study. One patient in the VPZ group and three patients in the EPZ group discontinued the treatment because of adverse events. One patient in the VPZ group and three patients in the EPZ group were lost to follow-up. There was no significant difference in the overall first-line eradication rate between the two groups (81.7% [138/169] in the VPZ group vs. 74.4% [131/176] in the EPZ group [$P=0.10$]). Furthermore, there was no significant difference in the first-line eradication rate in patients with CAM-sensitive HP (87.2% [82/94] versus 84.6% [77/91] in the VPZ and EPZ groups, respectively, [$P=0.60$]), although the eradication rate was significantly higher among patients with CAM-resistant HP in the VPZ group than that in the EPZ group (73.6% [39/53] vs. 55.6% [35/63], [$P=0.044$]). The first-line eradication rate in the patient with high estimated glomerular filtration rate (eGFR; ≥ 100 ml/min/1.73m²) was significantly lower than that in the patients with low eGFR (< 60 ml/min/1.73m²; 86.4% [32/37] in

the patients with low eGFR, 65.3% [34/53] in the patients with high eGFR [$P = 0.034$]), and it was significantly higher in the VPZ group than that in the EPZ group (79.3% [23/29] versus 50% [11/13], respectively, [$P = 0.025$]). The first-line eradication rate in continuous smokers was significantly lower than that in non-smokers (81.0% [187/231] in non-smokers vs. 64.3% [27/42] in continuous smokers [$P = 0.016$]). However, there were no significant differences between the VPZ and EPZ groups in non-smokers (84.2% [96/114] versus 77.8% [91/117], respectively, [$P = 0.21$]) and in continuous smokers (84.2% [12/16] versus 57.7% [15/26], respectively, [$P = 0.33$]). Furthermore, the first-line eradication rates in both groups were not influenced by age, sex, body mass index, drinking habit, and the endoscopic findings of gastric/duodenal ulcers/scars. There were no significant differences with regard to adverse effects between the two groups.

Conclusion: In contrast to the previous reports, the first-line eradication rate of VPZ-based triple therapy with 400 mg/day CAM and 1500 mg/day ABPC was similar to that of EPZ-based triple therapy in all groups except in patients with CAM-resistant HP and high eGFR. It is necessary to determine the most appropriate conditions that will maximize the therapeutic effect of VPZ-based triple therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

²College Of Medicine, Fu-Jen Catholic University, New Taipei City/Taiwan

Contact E-mail Address: dtmed046@pchome.com.tw

Introduction: The impact of amoxicillin resistance on the efficacy of regimens containing amoxicillin for *Helicobacter pylori* (*H. pylori*) eradication remains inconclusive. Therefore, we aimed to investigate whether the efficacy of amoxicillin containing regimen is affected by amoxicillin resistance and to identify the optimal breakpoint of amoxicillin resistance.

Aims & Methods: This was a post-hoc analysis of five randomized trials conducted in Taiwan from 2007 to 2016. Patients who received amoxicillin-containing regimens were recruited. The minimum inhibitory concentrations (MICs) were determined by agar dilution test. Meta-analysis was performed to assess the risk ratio of eradication failure in amoxicillin resistant strains compared to susceptible strains of seven different regimens. We further performed pooled analysis and logistic regression in patients treated with clarithromycin triple therapy to identify the optimal breakpoint of amoxicillin resistance.

Results: A total of 2339 patients with available data of amoxicillin MICs were enrolled. Meta-analysis showed that the presence of amoxicillin resistance was consistently associated with increased risk of treatment failure of amoxicillin-containing regimens at different breakpoints (RR [Risk ratio]: 1.41, 95% CI [confidence interval]: 1.12–1.78, $P = 0.004$ when cut at 0.5 mg/ml). The heterogeneity was low ($I^2 = 0\%$, $p = 0.615$). Pooled analysis also showed that amoxicillin resistance was an independent risk factor of treatment failure of clarithromycin triple therapy at different breakpoints. The best correlation was observed when the breakpoint of amoxicillin resistance was ≥ 0.125 mg/ml (Kappa coefficient 0.298), at which the resistance rate was 11.1% (110/990).

Conclusion: The efficacies of amoxicillin containing regimens are affected by amoxicillin resistance and the optimal breakpoint of MIC is ≥ 0.125 mg/ml.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Previous genome-wide association studies showed that genetic polymorphisms in toll-like receptor (TLR) 1 and protein kinase AMP-activated alpha 1 catalytic subunit (PRKAA1) were associated with gastric cancer (GC) or increased *Helicobacter pylori* (*H. pylori*) infection susceptibility.

Aims & Methods: The aim of this study was to evaluate associations between TLR1 and PRKAA1 genes polymorphisms and *H. pylori* infection, atrophic gastritis (AG) or GC in European population. Single-nucleotide polymorphisms (SNPs) were analyzed in 1178 subjects (511 controls, 340 AG patients and 327 GC patients) from 3 gastroenterology centers in Germany, Lithuania and Latvia. Patients with AG and controls were from the out-patient departments, who underwent upper endoscopy because of dyspeptic symptoms and had no history of malignancy. GC patients had histopathological verification of gastric adenocarcinoma and were recruited from out-patient and stationary departments. Genomic DNA was extracted from peripheral blood mononuclear cells. TLR1 C > T (rs4833095) and PRKAA1 C > T (rs13361707) were genotyped by the real-time polymerase chain reaction. *H. pylori* status was determined by testing for anti-*H. pylori* IgG antibodies in sera. Associations between SNPs and presence of *H. pylori* infection were evaluated using logistic regression analysis. The same analysis with adjustment for sex, age and *H. pylori* infection status was used for evaluation of associations between gene polymorphisms and AG or GC. The Bonferroni-corrected alpha level was set at 0.025 (0.05/2 SNPs).

Results: We observed similar distribution of TLR1 and PRKAA1 genotypes in *H. pylori* positive and negative cases. Moreover, no significant differences in the frequencies of all polymorphisms between AG patients and controls were found. TC genotype of TLR1 gene was more prevalent in GC patients compared to control group (22.3% and 29.7% respectively, $P = 0.018$). Logistic regression analysis revealed that polymorphism in TLR1 gene was associated with increased risk of GC. Carriers of TC genotype had higher odds of GC when compared to TT genotype (OR = 1.89, 95% PI 1.26–2.83, $P = 0.002$). Similar association was observed in a dominant model for TLR1 gene, where comparison of CC + TC vs TT genotypes showed an increased risk of GC (OR = 1.86, 95% PI 1.26–2.75, $P = 0.002$). No association between genetic polymorphism in PRKAA1 gene and GC was observed.

Conclusion: TLR1 rs4833095 SNP is associated with increased risk of GC in population of European descent, while polymorphism in PRKAA1 gene is not linked with the presence of GC. Both genetic polymorphisms showed no associations with *H. pylori* infection susceptibility and risk of AG.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0604 ASSOCIATION BETWEEN GASTRIC ADENOCARCINOMA OF THE FUNDIC GLAND TYPE AND *H. PYLORI* INFECTION

M. Matsueda, H. Kinugasa, K. Miyahara, M. Nakagawa

Internal Medicine, Hiroshima City Hiroshima Citizens Hospital, Hiroshima/Japan

Contact E-mail Address: maaaaayu0917@gmail.com

Introduction: Gastric adenocarcinoma of the fundic gland type (GAFG) is gastric adenocarcinoma with low-grade atypia occurring in the mucosa of the fundic gland without atrophy, and is recognized that it is not related to *H. pylori* (*Hp*) infection. However, GAFG is also found in *Hp*-infected and past *Hp*-infected patients, as well as in *Hp*-uninfected patients. It can not deny the relationship between the progress of GAFG and *Hp* infection.

Aims & Methods: Ten lesions of GAFG resected endoscopically or surgically in our hospital from December 2010 to October 2016 were classified as *Hp*-uninfected ($n = 3$)/past *Hp*-infected ($n = 5$)/*Hp*-infected ($n = 2$), and each endoscopic and clinicopathological features were examined.

Results: Median age of *Hp*-infected/past *Hp*-infected/*Hp*-uninfected were 65/71/54.5 years old, respectively, male ratio were 100/80/0%, occupied site U area were 33/80/50%. There was no difference between the 3 groups in these parameters. However, a significant difference in the rate of submucosal invasion is recognized between the *Hp*-uninfected and past *Hp*-infected group and the *Hp*-uninfected group (submucosal invasion was found at 0/80/100%, $p = 0.035$). According to endoscopic features, background mucosa of gastric fundus gland mucosa without atrophic change was found in 100/100/100%, whitish color in 67/60/50%, submucosal tumor shape in 67/60/0%, dilated vessels with branching architecture in 100/100/50%. The association with *Hp* infection was not clear. In immunohistochemical staining, MUC6 positive, Pepsinogen-I positive, MUC2 negative, CD 10 negative in all cases, whereas the rate of MUC5AC positive was significantly higher in the *Hp*-infected group as 0/20/100% ($P = 0.045$). We reported that black pigmentation is recognized in GAFG (stomach and intestine 50: 1521–1531, 2015), but no association between *Hp* infection and black pigmentation was observed. On the other hand, the rate of PPI administration divided pigmentation ($n = 6$)/no pigmentation ($n = 4$) are 50/0%, and it is suggested that the pigmentation in GAFG may relate with PPI ($p = 0.091$).

Conclusion: Hp infection is suggested to be related to the invasion depth of GAFG and the MUC5AC prevalence, which is also an important profile in GAFG cases. Pigmentation in GAFG is found frequently, but it may be related to taking PPI.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0605 MUCIN EXPRESSION IN THE SMALL BOWEL OF CELIAC DISEASE – A SYSTEMATIC REVIEW AND META-ANALYSIS

Y. Niv¹, R. Shamir²

¹Dept. Of Gastroenterology, Rabin Medical Center, Tel Aviv University Gastroenterology, Petach Tikva/Israel

²Gastroenterology, Schneider Children Hospital, Petach-Tikva/Israel

Contact E-mail Address: yniv@clalit.org.il

Introduction: Mucins, heavily glycosylated glycoproteins, synthesized by mucosal surfaces and have an important role in healthy and malignant states. Changes in mucin synthesis, expression and secretion may be a primary event or may be secondary to inflammation and carcinogenesis.

Aims & Methods: Since untreated celiac disease (CD) is associated with intestinal malignancy, we aimed to assess the current knowledge about mucin expression in the small bowel of CD patients, and to look for a possible association between mucin profile and gluten-free diet. English Medical literature searches were conducted for “mucin” and “celiac”. Observational studies were included. Meta-analysis was performed by using Comprehensive meta-analysis software. Pooled odds ratios and 95% confidence intervals were calculated.

Results: Out of 18 titles initially generated by the literature searches, 3 observational studies that fulfilled the inclusion criteria remained eligible for meta-analysis. They included 58 patients and 68 controls from 3 countries (Finland, Japan, USA). Mucin expression was significantly increased in small bowel mucosa of CD patients than in normal small bowel mucosa [OR 10.789, 95%CI (1.062–109.634), $p = 0.044$] (random-effect model). Heterogeneity was significant: $Q = 9.470$, $df (Q) = 3$, $P = 0.024$, $I^2 = 68.323\%$. ORs for MUC2 and MUC5AC expression in the small bowel mucosa of untreated CD patients were 1.143, 95%CI 0.060–21.870, $P = 0.929$ and 21.429, 95%CI 3.883–118.255, $P < 0.0001$, respectively.

Conclusion: We found that expression of certain mucin genes in the small bowel mucosa of CD patients may serve as a diagnostic tool, and assist in surveillance programs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0606 HEPATIC ABNORMALITIES ASSOCIATED WITH CELIAC DISEASE

D. Tagzout¹, A. Tebaibia², N. Oumnia³, N. Benfenatki³

¹Medicine, University Hospital Center, Tizi Ouzou/Algeria

²Medicine, University Hospital Center, Algiers/Algeria

³Medicine, Hospital University center, Algiers/Algeria

Contact E-mail Address: tagzout.d@gmail.com

Introduction: Celiac disease (CD) is a gluten-sensitive enteropathy that resolves with gluten-free diet (GFD). It's now considered as multisystem disorder. A number of studies have shown the occurrence of liver diseases at a higher frequency in patients with CD compared with that in the general population. Cryptogenetic hypertransaminasemia is observed in about half of celiac patients not following GFD with reversibility in the majority of cases after 6 to 12 months of GFD (1). Other liver abnormalities such as autoimmune hepatitis, cholestatic liver diseases, cirrhosis can be observed.

Aims & Methods: The aims of our study are to report the prevalence of liver diseases during CD and to describe the characteristics, etiologies and response to GFD of these liver disorders. Prospective multicentric study including 154 celiac patients (42 H; 112 F); middle age: 36, 1 ans \pm 13, 6, recruited over a period of 18 months from 01-01-2013 to 30-06-2014 and followed at least over a period of 12 months. Hepatic abnormalities were investigated with an etiologic assessment. The evolution of liver disorders after GFD was assessed.

Results: The prevalence of hepatic disorders in celiac patients is estimated at 18.1% ($n = 28$). A cryptogenetic hypertransaminase is found in 12.3% of cases ($n = 19$). This diagnosis was retained after a negative etiologic assessment of hepatic cytolysis in patients at a diagnosis of CD. Severe hepatic pathologies are associated with CD in 5.8% ($n = 9$) of cases, and in almost all cases in the hepatic cirrhosis stage. Cirrhosis is cryptogenetic in 55.5% (5/9) of cases and secondary to an autoimmune origin in 44.5% (4/9). Chronic hepatopathy revealed CD in 1.9% of the celiac population (3/154), two cases of autoimmune cirrhosis, one associated with pituitary insufficiency, and one case of cryptogenetic cirrhosis. The diagnosis of cirrhosis preceded the diagnosis of CD in 55.6% (5/9) of cases, and was contemporary and revealing the CD in 33.3% (3/9). In a single case (11.1%, 1/9), the diagnosis of cryptogenetic cirrhosis was made in a celiac patient diagnosed in childhood without the concept of GFD followed, 7 years after the diagnosis of CD. It's noted that hepatic cirrhosis occurred in the celiac population at a young age, on average 31.1 years. Cirrhosis is most often complicated (77.8%), with bleeding esophageal varices in 22.2% ($n = 2$) of the cases and

ascitic decompensation in slightly more than half of cases 55.6% ($n = 5$). Hepatoceellular insufficiency was noted in 66.7% of cases. Specific management of hepatic cirrhosis has been established with ligation of esophageal varices in 2 patients after bleeding esophageal varices until eradication of varices. A treatment with β blockers was prescribed in primary prophylaxis of digestive bleeding by rupture of oesophageal varices in 4 patients. Diuretic therapy and aspiration of the ascites fluid are performed in cirrhotic patients with ascites. A GFD is established in addition to the specific management of liver cirrhosis. Liver tests were standardized in 100% of patients with cryptogenetic transaminasemia followed GFD. The chronic liver disease was often decompensated and the hepatic signs for cirrhosis were in the foreground masking the response to GFD.

Conclusion: It is recommended to look for hepatic abnormalities during CD and even to think of the diagnosis of CD in front of liver cytolysis syndrome without obvious etiology and in the presence of a chronic cryptogenetic or dysimmune liver diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0607 CELIAC DISEASE ASSOCIATED WITH VASCULAR THROMBOSIS

D. Tagzout¹, A. Tebaibia², N. Oumnia², N. Benfenatki²

¹Medicine, Hospital University Center, Tizi Ouzou/Algeria

²Medicine, Hospital University Center, Algiers/Algeria

Contact E-mail Address: tagzout.d@gmail.com

Introduction: Celiac disease (CD) is a life-long autoimmune disease affecting multiple organs of genetically susceptible individuals. One of the extra intestinal manifestations of the disease is thromboembolic events like strokes and veins' thrombosis.

Aims & Methods: The aim of this work is to determine the prevalence and clinical characteristics of the thrombosis observed during CD. Prospective multicentric work involving 154 adult celiac patients (42H, 112F), with an average age of 36.1 years \pm 13.6, recruited between 01-01-2013 and 30-06-2014 with a minimum follow-up of 12 months. The diagnosis of CD was in all cases based on clinical, serological and histological arguments. Thrombotic complications were noted as well as their modalities of occurrence.

Results: Vascular thrombosis was noted in 13 patients (8.4%), and occurred almost exclusively in women (84.6%) (11 F - 2 H). There are 6 cases of portal cavernoma, one associated with lower limb thrombosis, 4 cases of stroke and 3 cases of thrombosis of the lower limbs. The diagnosis of thrombosis revealed the diagnosis of MC in 8 patients (61.5%) with an average delay of 11.6 months and extreme delays of 1 to 43 months. These include 4 cases of a portal cavernoma, one associated with deep limb thrombosis, 3 cases of stroke, and one case of deep thrombosis of the lower limbs. The diagnosis of CD was made on average 72 months after that of thrombosis in 4 patients (30.8%). In one case, thrombosis was complicated 39 years after diagnosis of CD diagnosed in childhood at the age of 5 years without gluten-free diet. The thrombophilia assessment was carried out in all patients and. The thrombophilia assessment was negative in 11 cases (84.6%). A S protein deficiency associated with the CD in one case and an antithrombin III deficiency in another case were detected. The use of oral contraceptives and in all cases a micro-dosed oestro-progestin was found in 7 women (63.6% of the women involved in thrombosis).

Conclusion: The diagnosis of CD must be evoked when there is a thrombotic disease without obvious cause, factors of thrombophilia may be present during the CD. Early CD diagnosis with respect to the gluten-free diet may prevent the development of this complication.

Introduction: Celiac disease (CD) is an organ-specific autoimmune disease, and both adaptive and innate immunity are involved in its development. Recent studies suggest the dysregulation Toll-like receptors (TLRs) in innate immunity can confer risk to autoimmune diseases such as CD.

Aims & Methods: In this study we investigated the TLRs 2, 4, 7, 9 genes expression in the Iranian patients with celiac disease compared with healthy control. Blood samples from 120 CD patients diagnosed according to the Iranian Society for Gastroenterology were collected and 120 healthy individuals were served as a control group during 2016. Also, among them, 20 duodenal biopsy specimens were collected randomly. Total RNA for both blood samples and biopsy specimens was isolated using a standard commercial kit. The mRNA expression of TLRs were quantified by relative qPCR with B2M as a reference gene.

Results: Significantly higher expression of TLR4 and TLR9 mRNA was observed in blood samples of CD patients compared to the healthy controls ($P < 0.05$); but there were no significant differences between expression of TLR2 and TLR7 mRNA compared to the controls. Furthermore, TLR4 and TLR2 expression level was increased in CD biopsy specimens compared to controls, whereas expression of TLR9 mRNA was decreased in CD patients. No significant differences in expression of TLR7 was observed in biopsy specimens.

Conclusion: The result of this study show that the alteration of TLR4 and TLR9 genes expression in intestinal mucosa of CD can be detected in PBMs in peripheral blood. Further, this data supports the potential implication of innate immune system in the pathomechanism of celiac disease.

²Gastroenterology, European Georges Pompidou Hospital Dept. of Gastroenterology, Paris/France

Contact E-mail Address: agathe.ravoux@live.fr

Introduction: Low bone mineral density (BMD) is common in celiac disease (CD).

Aims & Methods: The goals of the study were to identify the predictive factors of low BMD and of bone density variations. The medical files of 607 patients with CD at European Georges Pompidou Hospital were reviewed (2000–2015). Four hundred and four had an osteodensitometry and 133 had one before or until six months after beginning a gluten free diet (GFD). An univariate and multivariate analysis were performed for the different factors. The speed of variation of T and Z-score was calculated by the ratio between T and Z-score variation and the duration between these two measures.

Results: 46% of patients had osteopenia and 17.5% had osteoporosis. The predictive factors of low BMD in celiac patients were, in lumbar spine and forearm tests, male gender ($p < 0.001$), in lumbar spine and femoral neck tests, low body mass index (BMI) ($p < 0.001$) and in the three sites, old age at the diagnosis ($p < 0.001$). In the femoral neck, secondary hyperparathyroidism was a predictive factor of low BMD at celiac disease diagnosis ($p = 0.016$). The factors with an impact on gain of bone density were, in the forearm, female gender ($p = 0.034$) and in the femoral neck, the HLA-DQ2/DQ2 status ($p = 0.008$).

Conclusion: 64% of celiac patients had low BMD. The predictive factors were male gender, old age at diagnosis, low BMI and secondary hyperparathyroidism. The gain of bone density was better in woman and in HLA-DQ2/DQ2 patients whereas GFD had no impact.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0610 GLUTEN-FRIENDLY BREAD (GFB) INCREASES GUT MUCUS PRODUCTION AND MONOLAYER PERMEABILITY IN VITRO

G. Corona¹, M. Henderson¹, T. Bergillos-Meca¹, M. Roul¹, D. Musaico², C. Lamacchia², A. Costabile¹

Introduction: The mucus layer, covering the gastrointestinal mucosa, is considered the first line of defence against mechanical, chemical, or microbiological aggressions arising from the luminal contents¹. Among all different cell types of the intestinal epithelium, the goblet cells are specialised in the secretion of mucus constituent². As an example of failing barrier function, patients with coeliac disease (CD) have been reported to have altered intestinal barrier³. Human colonic mucus-secreting cells HT-29-16E are valuable tools to explore the effect of a specific treatment on permeability and mucus production by the human intestinal epithelium.

Aims & Methods: We investigated the new and innovative gluten detoxified bread (GFB; patent PCT/IB2013/000797⁴) effects on mucus production by means of Alcian blue staining in comparison to the control bread (CB). In addition, MUC2 and MUC3 were quantified by ELISA and the permeability of the intestinal epithelium monolayer was evaluated by trans-epithelial electrical resistance (TEER) measurement. The statistical analysis was conducted by one-way ANOVA followed by a Bonferroni post-hoc t-test.

Results: Mucin production by Alcian blue staining was expressed as % black pixels obtained from Image Tool software. GFB increased the secretion of mucin after 24 hours by Alcian blue staining (10.28 ± 1.82 ; $P \leq 0.01$), whereas CB did not (9.94 ± 0.67 ; $P = 0.05$). Higher MUC2 concentrations expressed as ng/ml were found on cells treated with GFB (10.82 ± 1.35 ; $P = 0.01$) compared to control, which was not found for CB (9.54 ± 0.18 ; $P = 0.05$). Additionally, greater TEER values, expressed as a percentage of initial TEER, were observed after 24 hours of incubation with GFB in comparison to the control (163.2 ± 33.8 , $P = 0.01$) which was not observed or CB (139.4 ± 28.8 , $P = 0.05$).

Conclusion: It could be concluded that GFB has a potential of inducing MUC2 secretion by intestinal epithelial cells and improving intestinal epithelium permeability *in vitro*. Such observed potential may effectively contribute to consequent benefits such as higher gut barrier defence, decreased susceptibility to infections and better absorption regulation, thus ameliorating such alterations in coeliac patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0611 IMMUNOHISTOCHEMICAL LYMPHOCYTE PATTERN OF NON CELIAC GLUTEN SENSITIVITY MAY SUPPORT THE INVOLVEMENT OF INNATE IMMUNITY

G. Losurdo, F. Pezzuto, C. Covelli, F. Fortarezza, A. Marra, A. Iannone, A. Amoroso, M. Barone, M. Principi, E. Ierardi, A. Di Leo

Introduction: Non celiac gluten sensitivity (NCGS) is a gluten-related enteropathy with distinct features compared to celiac disease. Patients with NCGS experience symptoms, such as diarrhea or abdominal pain, shortly after gluten exposure. Differently from celiac disease, serology is negative, and histological picture is characterized by no lesion or a mild enteropathy (Marsh 1 stage). Few studies have investigated possible histopathological characteristics of NCGS. An immune response against gluten elicited exclusively by innate immunity has been hypothesized. On these bases, we attempted to depict an immunohistochemical trait of NCGS by exploring markers of lymphocyte and innate immunity activation.

Aims & Methods: Duodenal biopsy samples of patients diagnosed of NCGS according to Salerno criteria were retrieved. Duodenal biopsy samples of positive controls (overt seropositive celiac disease at Marsh 1 stage) and negative controls (functional dyspepsia and normal microscopic picture) were selected. Immunohistochemistry for CD3 (intraepithelial lymphocytes), CD4 (T-helper lymphocytes), CD8 (T-cytotoxic lymphocytes) and CD1a (Langerhans cells) was performed. Cell count was carried out both in the epithelial layer (expressed as positive cells/100 enterocytes) and in the lamina propria (positive cells/mm²). Comparison of means was performed by ANOVA test with Bonferroni's post-hoc analysis.

Results: Twenty NCGS, 12 celiac patients (positive controls) and 16 negative controls were selected. CD3 positive intraepithelial lymphocytes in NCGS were expressed at intermediate levels (18.5 ± 6.4) between negative controls (11.9 ± 2.8) and celiac disease (40.8 ± 8.1 , $p < 0.0001$). CD4 T-helper lymphocytes were present only in lamina propria and NCGS had a lower level (31.0 ± 22.1) than controls (72.5 ± 29.5) and celiac disease (103.7 ± 15.7 , $p < 0.0001$). Intraepithelial CD8+ cells were similar between NCGS and negative controls (14.0 ± 7.4 versus 17.8 ± 4.2), but lower than celiac disease (34.0 ± 7.1 , $p < 0.0001$). CD1a+ Langerhans cells were over-expressed in the lamina propria of NCGS (1.9 ± 1.1) in comparison to celiac disease and negative controls (respectively 0.3 ± 0.8 and 0.4 ± 0.5 , $p < 0.0001$).

Conclusion: NCGS is characterized by a mild immunologic reaction, as shown by the slight increase in CD3 intraepithelial lymphocytes. The over-expression in the

lamina propria of Langerhans cells, which are antigen presenting cells mainly involved in innate immunity, seems to confirm previous hypotheses on the pathogenesis of NCGS. Additionally, this finding could represent an useful pathological feature of NCGS.

Introduction: Coeliac disease (CD) is estimated to affect up to 1 in 100 Australians (1). Although CD has a wide range of clinical manifestations, patients frequently present with gastrointestinal (GI) symptoms which overlap with functional GI disorders, particularly irritable bowel syndrome (IBS) and functional dyspepsia (FD); the prevalence of biopsy proven CD is higher in IBS (2) and in dyspepsia (3). Patients with CD have been shown to experience persistent GI symptoms despite long term treatment with a gluten-free diet (4).

Aims & Methods: The aim of this study was to define GI symptoms reported in an Australian cohort with a doctor diagnosis of CD and compare with those not reporting CD. A total of 3825 people (mean age 58.4 years, age range 18–100 years and 47.5% males) randomly selected from the Australian population returned a mail survey (Digestive Health & Wellbeing Survey, response rate = 45%) which contained questions on whether the participant had ever been told by a physician that they had CD, and questions regarding GI symptoms to establish whether they had co-existent functional GI disorders. Adherence to a gluten-free diet was not assessed. Prevalence of CD, FD and IBS are reported with 95% exact confidence intervals. The difference between symptoms in those with CD compared with the unaffected population was tested for significance by the Pearson chi-square test.

Results: The prevalence of doctor-diagnosed CD was 1.2% (95% CI 0.84–1.59) in this cohort. Subjects with CD reported significantly higher levels of GI symptoms than unaffected individuals, including abdominal pain associated with abnormal bowel habit, diarrhoea, bloating, distention, epigastric burning and early satiety (see Table). There was no significant difference observed in symptoms of post-prandial fullness, nausea, constipation, abnormal stool consistency, or straining with defecation. The prevalence of FD as defined by Rome III criteria in the CD cohort was 37.5% (95% CI 22.7–54.2) compared to 13.9% (95% CI 12.8–15.1) in the non-affected population (OR 3.7, 95% CI 1.9–7.1, $p < 0.001$). There was no significant difference in the prevalence of IBS in the affected compared with the non-affected cohort (30.8% versus 22.2%, $p = 0.2$).

Table: Gastrointestinal symptoms reported by patients with and without self reported coeliac disease (CD). Items reported as greater than one day per week (*) or greater than or equal to “often” (**)

Symptoms	self report CD - Yes	self report CD - No	p value
Abdominal pain associated with loose bowel motions **	16/37 43.2%	600/3234 18.6%	$P < 0.001$
More bowel motions associated with pain **	13/38 34.2%	504/3248 15.5%	$P = 0.002$
Bloating *	13/40 32.5%	436/3381 12.9%	$P < 0.001$
Distention *	12/40 30%	395/3371 11.7%	$P < 0.001$
Abdominal pain *	9/39 23.1%	362/3378 10.7%	$P = 0.014$
> 3 bowel motions per day **	7/40 17.5%	7/40 17.5%	$P = 0.046$
Epigastric burning *	8/40 20%	165/3380 4.9%	$P < 0.001$
Early satiety *	8/40 20%	230/3378 6.8%	$P = 0.001$

Conclusion: The prevalence of gastrointestinal symptoms and in particular functional dyspepsia are significantly higher in patients with a doctor diagnosis of CD than in the unaffected population. Studies show that biopsy proven coeliac disease in IBS is higher in IBS cohorts than healthy controls (2) and the value of screening with duodenal biopsy testing for CD in FD is concluded to be useful (3), this study supports these views

Disclosure of Interest: All authors have declared no conflicts of interest.

P0613 MALE GENDER AND UNDERWEIGHT ARE ASSOCIATED WITH OSTEOPOROSIS IN PATIENTS WITH NEW DIAGNOSIS OF COELIAC DISEASE

G. Galli, E. Lahner, L. Conti, G. Esposito, M.C. Sacchi, E. Di Giulio, B. Annibale

Department Of Medical-surgical Sciences And Translational Medicine, Sant'Andrea Hospital, University Sapienza, Rome/Italy

Contact E-mail Address: gloria.galli5@gmail.com

Introduction: Osteoporosis is a systemic skeletal disorder characterized by low bone mass and micro-architectural deterioration with increase of bone fragility and consequent fracture risk. About 50–75% of patients (pts) with untreated coeliac disease (CD) suffer from bone mass loss (osteopenia or osteoporosis). Despite this strong correlation, guidelines do not express with certainty on the need to undergo a dual-energy X-ray absorptiometry (DEXA) scan in every patient with new diagnosis of CD. Recently, the DEXA screening was suggested for CD peri-post menopausal females, males over 55 years, pts with overt malabsorption or with a history of fragility fractures. Studies on bone mineral density (BMD) in CD pts led to discrepant results, probably due to heterogeneous designs.

Aims & Methods: The aim of this study was to evaluate, in a cohort of consecutive newly diagnosed CD adults, the prevalence of BMD alterations at diagnosis time and to evaluate associated clinical features. From January 2004 to December 2016, 258 consecutive pts ($F = 72.4\%$) were diagnosed with CD. All pts were adults (median age 38, range 18–72 years), had atrophic disease and were invited to undergo a DEXA within 3 months from diagnosis to screen for osteoporosis ($T\text{-score} < -2.5$) or osteopenia ($T\text{-score} < -1$ and ≥ -2.5). A total of 214 (82.9%) pts underwent the DEXA scan and were included in the study ($F = 71.5\%$, median age 38, range 18–72 years). On the basis of DEXA results (codified according to WHO classification) pts were divided into 3 groups: pts with normal BMD, with osteopenia, and with osteoporosis. For each patient, reported risk factors for low BMD (underweight, alcohol intake, drugs, menopause, smoke) and serological PTH values were assessed. The signs/symptoms leading to CD and their duration before diagnosis, autoimmune/not-autoimmune comorbidities, familiarity for CD, previous fractures and serological assays (specific antibodies for CD, ferritin, cholesterol, triglycerides, and albumin) were also assessed. All the variables described were analyzed and compared between the 3 groups. Logistic regression was performed including into the model those independent variables which showed a significant difference at univariate analysis.

Results: At the DEXA scan, 85 (39.7%) and 129 (60.3%) pts had normal or low BMD, respectively. Among pts with low BMD, 91 (42.5%) had osteopenia and 38 (17.8%) osteoporosis. At logistic regression, clinical features significantly associated with osteoporosis were male gender (OR 4.7; 95%CI 1.3 to 17.4), underweight (OR 8.1; 95%CI 1.8 to 35.3) and increased PTH values (OR 5.1; 95% CI 1.4 to 18.8), while age ≥ 40 years and gastrointestinal symptoms at diagnosis time, menopause, alcohol intake and previous fractures were not associated. Clinical features significantly associated with osteopenia were underweight (OR 4.0, 95% CI 1.4 to 11.2) and increased PTH values (OR 2.6, 95%CI 1.1 to 6.4).

Conclusion: In newly diagnosed coeliac pts, the overall prevalence of BMD alterations was more than 60%, with osteoporosis in nearly 1/5. Osteoporosis was significantly associated with male gender, underweight and increased PTH. This study suggests that at CD diagnosis, DEXA scan might be of benefit, in particular in male underweight pts.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Coeliac disease (CD) affects 0.6–1% of the population worldwide (1). Wheat avoidance in the absence of CD is common, and studies report a population prevalence of self-reported wheat or gluten sensitivity (SRWS) of

up to 13% (2, 3). SRWS is defined as gastrointestinal (GI) or extra intestinal symptoms on ingestion of wheat or gluten-containing food (2, 3).

Aims & Methods: The aim of this study was to determine the prevalence of SRWS in an Australian population, define associated GI symptoms, and relate the diagnosis to demographic, lifestyle and medical factors. A total of 3825 people (mean age 58.4 years, age range 18–100 years and 47.5% males) randomly selected from the Australian population returned a mail survey (Digestive Health & Wellbeing Survey, response rate=45%) which contained questions on wheat avoidance, GI symptoms, demographic, medical and lifestyle factors. We defined SRWS as people who reported gastrointestinal symptoms on ingestion of wheat based foods, but did not suffer from doctor diagnosed coeliac disease, inflammatory bowel disease or bowel cancer. Prevalence of SRWS is reported with 95% exact confidence intervals. The association between SRWS prevalence and potential risk factors was reported using unconditional logistic regression. The degree of differentiation of SRWS from health was evaluated through the area under the receiver-operator-characteristic curve.

Results: The prevalence of SRWS in this cohort was 13.5% (455/3331, 95% CI 12.5–14.9%). Only 11% (50/455) of these subjects had received a doctor diagnosis of wheat or gluten intolerance. The most commonly reported GI symptoms (reported as more than weekly or often) associated with SRWS included abdominal pain relieved by bowel movements (54.5%), bloating (37.6%) and abdominal distention (30.8%). In a multivariate analysis, a diagnosis of SRWS was significantly associated with irritable bowel syndrome (IBS) and functional dyspepsia (FD) (Rome III criteria), female gender, and food allergy (see Table). Older age was negatively associated with SRWS. In this multivariate model, factors with no observed association included body mass index, depression, anxiety, sleep problems, proton pump inhibitor use, gastrointestinal infection, rheumatoid arthritis, scleroderma, migraine, Parkinson's disease, asthma, pollen allergy, animal allergy or psoriasis, diabetes and recent antibiotic use. The model provided useful although imperfect differentiation of SRWS from health (AUC = 0.76).

Table: Medical and demographic factors associated with a diagnosis of self-reported wheat sensitivity (SRWS).

	SRWS -YES	SRWS -NO	Odds ratio	95% CI, p value
Age: mean (SD)	51.9 (14.9)	59.3 (16.5)	0.98	0.98–0.99, p < 0.001
Female gender (total = 52.5%)	336/450 (74.7%)	1392/2854 (48.8%)	1.86	1.51–2.30, p < 0.001
Functional dyspepsia	128/466 (27.5%)	327/2865 (11.4%)	1.74	1.38–2.20, p < 0.001
Irritable bowel syndrome	248/453 (54.8%)	571/2866 (19.9%)	3.96	3.23–4.86, p < 0.001
Food allergy	56/455 (12.3%)	151/2878 (5.3%)	2.05	1.50–2.80, p < 0.001

Conclusion: SRWS has a prevalence of 13.5% in this Australian cohort. Those with SRWS are likely to report abdominal symptoms, including abdominal pain associated with abnormal bowel habits, bloating, or abdominal distention. SRWS is significantly associated with IBS and FD, younger age, female gender, and food allergy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pathogenesis of functional bowel disease is usually associated with disorders of visceral sensitivity and intestinal motility, which result from a dysfunction of the central nervous system, intestinal microflora and immune system

Aims & Methods: We aimed to highlight importance of intestinal enzymes (glucoamylase, maltase, sucrase and lactase) in the etiology and pathogenesis of functional bowel disease. 74 patients with functional bowel diseases in age from 18 to 50 years (36 men and 38 women) were examined. According to Rome IV criteria (2016), 21 had irritable bowel syndrome (IBS) with predominance of diarrhea, 33 - functional diarrhea, 6 - IBS with predominant constipation, 4 - functional constipation and 10 - mixed type of IBS. Activity of the mucosa enzymes of the small intestine was determined by Dahlquist-Trinder method in duodenal biopsies obtained during esophagogastroduodenoscopy.

Results: Lactase deficiency was identified in 87.8% of patients, maltase deficiency – in 48.6%, sucrase deficiency – in 51.3%, the glucoamylase deficiency – in 85.1%. The activity of all investigated enzymes was reduced in 23 (31.1%) patients with functional bowel diseases, failure of 1 to 3 enzymes detected in 47 (63.5%). Normal activity of enzymes was observed in 4 (5.4%) patients.

Conclusion: In 70 of 74 (94.5%) patients with functional bowel disease and a disorder of the stool, abdominal pain and flatulence, there was a decrease in the activity of intestinal enzymes, which may be a cause of intestinal symptoms.

Introduction: Epidemiological studies estimate a worldwide prevalence of CD of approximately 1:100 individuals, with a considerable proportion of patients remaining undiagnosed and untreated.

According to a study performed by the National Health and Nutrition Examination Survey in the United States, the prevalence of self-prescribed GFD in an unselected population of subjects aged 6 years or older was 0.5%.

Epidemiological studies report a prevalence of WA in American population of around 0.4% until 0.6%.

The diagnosis of WA is classically based on skin prick tests (SPT), in vitro specific Immunoglobulin E (sIgE) assays and functional assays. SPTs and sIgE in vitro assays are the first-level diagnostics for WA. However, they are affected by a low predictive value. In particular, their low sensitivity can be explained by the fact that the commercial test reagents are mixtures of water/salt-soluble wheat proteins that lack allergens from the insoluble gluten fraction. The association between food allergy and celiac disease (CD) is still to be clarified. Gluten-related disorders are an epidemiologically relevant phenomenon with a global prevalence that is estimated around 5%, drawing the attention of the scientific community.

Aims & Methods: We visited in our unit of celiac disease and gluten-related conditions during 2016 423 (F/M:312/111) new patients with clinical suspicion of CD. Of these 113 they were not celiac but were investigated for suspected non-celiac gluten sensitivity. After in vitro tests for the exclusion of celiac disease, to verify the real prevalence of food allergy particularly to wheat protein, in non celiac patient referred our unit for symptoms after gluten ingestion, all these patients underwent allergologic workup consists on: skin prick tests for foods including wheat (Alk-abello), LTP (lipid transfer protein) (peach Alk abello), alpha amylase, wheat flour, barley, corn, rice, grass pollen and histamine. Also they all performed patch tests for suspected allergy to nickel, if they reported reactions after a few hours of ingestion of gluten. Molecular-based allergy (MA) diagnostics could overcome some limitations of sIgE in vitro assay using wheat flour extracts. We have used omega-5 gliding (TRI a 19) and nsLTP (TRIa 14), gli admin, wheat, gluten that are available in the immunoCap assay, whereas the Alfa -amylase/trypsin inhibitor (TRI a A/TI) is available only in the microarray ISAC assay. The sIgE to omega-5 gliadin assay is highly reliable and now widely used to identify the patient with WDEIA.

Results: In our overall population, 113 (26.7%) non celiac patients had a history of immediate or not immediate reaction after ingesting gluten: the Allergologic tests found wheat protein sensitization in 14 patients of these (12.4%, 9 F). In addition we also found 5 (4.5%, 4F) patients with real allergy to wheat or wheat protein.

Conclusion: In our population 19/113 (16.8%) non celiac patient had real reaction after ingesting gluten: 14 (12.3%) had wheat protein sensitization and 5 (4.5%) had WA. These percentages are different and very high than that reported in the literature.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0617 A QUESTIONNAIRE-BASED SYMPTOM EVALUATION STUDY IN 381 PATIENTS DIAGNOSED WITH BILE ACID MALABSORPTION BY SEHCAT FROM 2003 TO 2016

H.R. Clausen, B. Damsgaard, J.F. Dahlerup, J. Agnholt, S.P. Jørgensen, K. Krogh

Department Of Hepatology And Gastroenterology, Aarhus University Hospital, Aarhus/Denmark

Contact E-mail Address: helenerasklausen@studmed.au.dk

Introduction: Excessive amounts of bile acids entering the colon cause chronic diarrhoea (bile acid diarrhoea (BAD)). Diagnosis of BAD is possible by measuring the retention level of orally ingested ⁷⁵Selenium homotaurocholic acid (SeHCAT). Standard treatment of BAD is bile acid sequestrants (BAS), such

as colestyramine. Short-term outcome of having BAD is well-described, but long-term effects remain unclear. The aim of the present study was to describe long-term symptoms, adherence to treatment and quality of life in a well-defined group of patients with BAD.

Aims & Methods: Between 2003 and 2016, 559 patients referred to our hospital for diarrhoea had abnormally low seHCAT retention levels (<15% at day 7). Questionnaires about medical history, bowel function, use of medication, and quality of life were sent to all patients.

Results: Among 559 patients, 381 (68.2%) responded ((242 women (63.5%), median age: 53 years (range 22 to 89), median age at diagnosis 47 years (range 16 to 85)). In 123 respondents (32.3%) BAD was due to ileal dysfunction (type 1), 199 (52.2%) had idiopathic BAD (type 2), and 59 (15.5%) had BAD due to cholecystectomy (type 3). At follow-up, 272 patients (73.9%) still reported bothersome diarrhoea and 244 (65.1%) regularly used antidiarrheal medication. Treatment included BAS in 45.1% while 32.3% of patients used other treatment. 184 patients (49.9%) reported that treatment had improved their symptoms, while 116 (31.4%) reported that they were the same, and 69 (18.7%) felt worse. Quality of life was still affected by diarrhoea in 242 patients (63.5%).

Conclusion: BAD must be considered as a chronic disease and despite correct diagnosis and treatment, most patients continue to have significant diarrhoea and reduced quality of life. This supports the need for further research in pathophysiology and new therapy principles.

Introduction: Chronic intestinal pseudo-obstruction (CIPO) is an intractable rare digestive disease manifesting persistent small bowel distension without any mechanical cause. Intestinal decompression is a key treatment, but conventional method including a trans-nasal small intestinal tube is invasive and painful. Therefore, a less invasive and tolerable new decompression method is urgently desired. We conducted a pilot study and assessed the efficacy and safety of percutaneous endoscopic gastro-jejunostomy (PEG-J) decompression therapy in CIPO patients.

Aims & Methods: Eight definitive CIPO patients (2 males and 6 females) were enrolled. All patients received PEG-J decompression therapy. The number of days with any abdominal symptoms in a month (NODASIM), body mass index (BMI), serum albumin level (Alb), and small intestinal volume before and after PEG-J were compared in all patients.

Results: PEG-J was well tolerated and oral intake improved in all patients. NODASIM has significantly decreased (24.3 vs 9.3 days/months) and BMI/Alb have significantly increased (14.9 vs 17.2 kg/m² and 2.6 vs 3.8 g/dl, respectively), whereas total volume of the small intestine has not significantly reduced (4.05 vs 2.59 L, $p=0.18$). Reflux esophagitis and chemical dermatitis were observed in one case but was successfully treated conservatively.

Conclusion: PEG-J decompression therapy can contribute greatly to improvement of abdominal symptoms and nutritional status in CIPO patients. Although sufficient attention should be paid to acid reflux symptoms, PEG-J has the potential to be a noninvasive novel decompression therapy for CIPO available at home. However, accumulation of more CIPO patients and long-term observation are needed.

Introduction: In genetically susceptible subjects, gluten exposure determines celiac disease, but it has also been shown that gluten ingestion could alter intestinal absorption even in patients with non-intestinal diseases (Doherty, *Lancet* 1981) and in healthy subjects (Levine, *NEJM* 1966). However, whether gluten causes intestinal alterations in healthy volunteers (HV) is still a matter of debate: in HV we recently demonstrated that gallbladder motility and gastric emptying were not affected by the ingestion of gluten, whereas a slight increase of intestinal fermentation was evident (Di Stefano, *DD* 2015). A cytotoxic effect of gluten on intestinal cell lines was also previously shown (Rivabene, *BBA* 1999). We recently demonstrated that in dyspeptic patients the ingestion of a standard meal induces both an inflammatory and an antioxidant response, correlated with symptom occurrence (Di Stefano, *UEGW* 2016). It is therefore possible that food-related

alterations of the intestine could be responsible for post-prandial activation of inflammation and anti-oxidant systems.

Aims & Methods: We therefore studied whether gluten intake induces alterations of post-prandial activation of inflammation and anti-oxidant systems. Twenty consecutive, non-smoking, normal-weight HV (8 females, mean age 27.9 ± 3.6 yrs) were enrolled. The presence of acute or chronic disorders was excluded in all of them. After an overnight fast and at the same time in the morning, all the subjects underwent evaluation of post-prandial modifications of serum levels of pro-inflammatory cytokines (IL-1 β , IL-6, TNF α), endogenous antioxidant system (uric acid), glucose, insulin and serum lipopolysaccharide (LPS), measured as putative factors responsible for inflammatory response. Serum samples were collected at fasting and every 30 minutes for a 4-hour period after an oral gluten load of 2 gr (in 10 HV) or 20 gr (in the other 10 HV). The presence and severity of symptoms such as epigastric pain, epigastric burning, fullness, early satiety, abdominal pain, abdominal distention, bloating, flatulence, nausea, vomiting, belching, heartburn, regurgitation, diarrhea, and headache, were evaluated by visuo-analog score at fasting and every 30 minutes in the post-prandial period.

Results: In comparison with mean fasting values, none of the measured parameters showed a significant increase in the post-prandial period after the ingestion of 2 gr of gluten. On the contrary, after the ingestion of 20 gr of gluten mean post-prandial values of TNF α and IL- β showed a significant increase (2.45 ± 1.75 pg/mL and 0.65 ± 0.31 pg/mL) as compared to mean fasting values (1.17 ± 1.49 pg/mL and 0.29 ± 0.15 pg/mL; $p < 0.05$). Mean post-prandial values of uric acid were also significantly higher (74.98 ± 33.02 nmol/mL) than fasting values (45.34 ± 10.08 nmol/mL; $p < 0.05$). No significant differences were detected in IL-6, glucose, insulin and LPS d after the ingestion of the 20 gr gluten oral load. Symptoms were absent after both oral loads.

Conclusion: The ingestion of a high, but not a low, oral load of gluten induces a significant post-prandial inflammatory response causing the activation of the main endogenous anti-oxidant system. In HV, these activations are not accompanied by a symptomatic response. Further studies are needed to investigate the inflammatory and anti-oxidant post-prandial response in patients with gluten-related disorders.

³Clinical Nutrition, Rome/Italy

Contact E-mail Address: cinzia.papadia@nhs.net

Introduction: Ketogenic Enteral Nutrition (KENTM) is a modification of Blackburn's protein-sparing modified fast, using a hypocaloric, ketogenic liquid diet. The study is about Ketogenic enteral nutrition (KEN) in overweight and obese patients receiving short treatment of the nutritional solution as 24-hour infusion. It is a retrospective analysis that examines safety, weight loss and body composition changes after three sequential 10-days cycles of KEN therapy. **Aims & Methods:** Anthropometric and bio-impedance data from 629 patients who underwent KEN were collected before and after completing a ten-day cycle. The study focuses on the change in outcomes from the first cycle to the second cycle and from the first cycle to the third cycle. The following outcomes were explored: weight, waist circumference, BMI, fat mass, lean mass, dry lean mass, phase angle, wellness marker, water mass as a percentage of total body weight. The cycle 1, 2 and 3 outcomes were analyzed using descriptive statistics (mean, standard deviation, n) summarizing the outcome at each cycle. Statistical tests were used to test for significant differences between paired cycle 1 and cycle 2 outcomes and also between paired cycle 1 and cycle 3 outcomes. For normally distributed outcomes, the paired t-test was used. Whereas for skewed outcomes, the Wilcoxon signed-ranks test was used. Scatter plots were used to plot percentage of excess weight loss against phase angle. The Pearson's correlation coefficient was calculated. Regression analysis for the outcome percent change in weight from cycle 1 to cycle 2 for phase angle and basal metabolic rate (BMR)/Weight ratio as predictors was carried out.

Results: The results suggested significant changes for all analyzed parameters. There were significant decreases in weight, waist circumference, BMI, fat mass, lean mass, dry lean mass and phase angle. Quantitative changes in lean mass and dry lean mass were negligible with respect to changes in fat mass. There was also a statistically significant increase in water mass as a % of total body weight and wellness marker from cycle 1 to cycle 3. The Pearson's correlation coefficients $r=0.18$, $p=0.004$ and $r=0.22$, $p=0.04$ indicated changes in cycle 1 and cycle 3 in percentage of weight excess to be significantly, positively correlated to phase angle. The multivariate linear regression model showed that for a 1 unit increase in BMR/weight there was a 3.3 percent decrease in percent change in weight. KEN treatment was overall well tolerated. 92% of patients on oral hypoglycaemics and 80% of patients on anti-hypertensive medication were able to discontinue their medication safely during KEN therapy.

Conclusion: KEN treatment is safe, well tolerated and results in rapid fat loss without detriment to dry lean mass.

Introduction: Obesity is a global disease and its management includes pharmacological therapy, nonabsorptive surgery and, Intra-gastric Balloon (IGB). Any form of therapy, including surgery, is flawed by weight regain in the long-term. IGB has gained popularity recently; however, there is a lack of studies addressing the use of IGB and its effect on weight control in the long-term. This is the first study that aimed to assess the weight regain in a large cohort of patients treated with IGB, with a time span from two to five years after the removal of the device.

Aims & Methods: All obese patients treated with IGB in a specialized obesity center, and that underwent balloon removal from June 2009 to June 2013 were invited to participate in the study. Exclusion criteria: pregnancy or bariatric surgery after balloon removal, impossibility to contact, and refusal to participate. Patients that agreed to participate were interviewed by a trained investigator in person and answered a questionnaire survey and had their body weight measured. Interviews started on July 2015 and ended on July 2016. Medical records of recruited patients were reviewed and the body weight at the moment of IGB introduction and removal registered. Patients were stratified by segment time-frame from balloon removal and interview date (2, 3, 4 and 5 years) and all intervening factors related to weight control, as well as behavior habits were analyzed and compared with logistic multivariate analysis.

Results: A total of 224 patients entered the study. Of these, 81.3% (182) were women. During the use of IGB, patients lost an average of 15% of their body weight; representing a mean loss of 66% of excessive weight. Between 2 and 5 years after removal of IGB, 67% (150) of the subjects had regained weight; the mean weight regain was 4 kg during this period. Most patients (62%) regained 10% to 19% of weight lost during treatment. The mean weight regain increased during follow-up, but without significant difference among groups: 2 years [n=10]: 4.66±4.91 kg; 3 years [n=83]: 8.66±6.96 kg; 4 years [n=54]: 9.99±8.44 kg and 5 years [n=3]: 19.96±12.24; (p=0.51). The lower the BMI at the beginning of treatment, the greater the weight regain after the IGB withdrawal. This correlation was inverse (r=-0.20) and significant (p<0.01). The correlation was stronger and more significant with patients who had withdrawn the balloon at two years (r=-.59, p<0.01) followed by those in which balloon withdrawal was undertaken four years before (r=-0.23, p=0.03). Weight regain group contained more individuals who did not perform psychological and nutritional follow-up and who were also sedentary, during and after treatment. Each year, after removal of IGB, the chance of regaining weight increased 1.5 times. No follow-up with a nutritionist after the procedure increased chance of weight regain in 1.8 times. Lack of follow-up with a psychologist during treatment had a weight regain 1.9 times increased. Multivariate logistic analysis determined risk factors for weight regain according to time span after IGB removal. After 2 years of balloon removal, the significant risk factor was lack of follow-up with a psychologist during treatment; increasing the chance of weight regain 1.13 times compared with those subjects that received psychological follow-up. An independent and significant risk factor for weight regain after 3 years of IGB removal was the lack of follow-up with a nutritionist after the use of IGB. Chance of weight regain was 3.36 times higher in this group than in individuals who did the nutritional follow-up. After 4 years of IGB removal, sedentary behavior was an independent and significant risk factor, increasing the chance of weight regain 3.86 times compared with physically active behavior.

% of weight regained *	2 years	3 years	4 years	5 years
<10%	20% (2)	15.6% (13)	18.5% (10)	33.3% (1)
Between 10 and 19%	70% (7)	62.7% (52)	59.3% (32)	66.7% (2)
Between 20 and 29%	10% (1)	14.5% (12)	14.8% (8)	0
Between 30 and 39%	0	2.4% (2)	1.9% (1)	0
Between 40 and 49%	0	1.2% (1)	5.6% (3)	0
Between 50 and 59%	0	2.4% (2)	0	0
Between 90 and 99%	0	1.2% (1)	0	0

Conclusion: IGB has a suboptimal long-term effect on body weight control after 2 to 5 years of balloon removal, with weight regain observed in up to two thirds of patients (66%). The following variables adversely affect long-term body weight control after IGB removal: lack of psychological support and nutrition counseling and sedentary lifestyle. A multidisciplinary team approach is of paramount importance to assist obese patients treated with IGB in order to effectively maintain long-term body weight control.

Introduction: The Duodenal-Jejunal Bypass Linear (DJBL) is an endoscopic device which prevents ingested nutrients absorption in the duodenum and first part of jejunum. The resultant effects are weight reduction and improvement in glycemic control in patients with type 2 diabetes mellitus (T2DM).

Aims & Methods: The aim of the current study is to assess weight and glycemic control changes resulted from the device implantation and a year after the device removal. Between February 2013 and September 2016, 51 diabetic patients were treated with DJBL in our center. This prospective observational study included 36 patients who completed at least 9 months of active treatment. However, adverse events and early removals were analyzed for the whole cohort. Blood tests, body weight and medications data were collected during scheduled visits and phone interviews. The primary end points were body weight and glycemic control changes a year after implantation. Secondary end points were the same parameters after device removal. The protocol was approved by the local ethic committee.

Results: Thirty six patients (52.8% male) were treated for at least 9 months with the device, 10 of which completed a whole year follow-up after device removal. At the end of 12 months post implantation, the average body weight and BMI dropped from 109.5±19.1 kg and 37.4±5.0 Kg/m² to 93.7±20.4 Kg and 31.3±3.4 Kg/m², respectively (P≤0.001). Although parameters increased up to 97.4±14.6 kg and 33.3±5.0 Kg/m² at the end of a year follow-up, both parameters remained significantly lower than the baseline (P<0.05). HbA1c was reduced during the treatment from 7.6±1.6% to 6.6±1.2% (P=0.02) and increased to 6.8±1.0% after 12 month follow-up (P=NS). Among 15 insulin-dependent patients (42%), insulin average dose was reduced by 65% (p=0.05), but the dose was doubled after a year follow-up. Interestingly, the glycemic control in this insulin-dependent population was difficult to maintain as evidenced by the increased HbA1c a year after the device removal (6.9±1.1 % to 7.3±1.1% p=0.585). In contrast, among non-insulin dependent patients, there was a non-significant decrease in HbA1C during the year post the device removal (6.5±1.3 to 6.4±0.8, P=0.812). Ten patients (19.6%) of the initial 51 treated suffered from adverse events, 4(7.8%) of which were categorized as severe ones (two major bleedings and 2 hepatic abscesses).

Conclusion: DJBL is an effective tool for weight reduction glycemic control among insulin and non-insulin dependent diabetic patients. Moreover, substantial metabolic achievements are preserved at least a year after device removal. Since DJBL bears a considerable amount of side effects, strategies to mitigate them are warranted.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0623 SYNBIOTIC (INULIN, LACTOBACILLUS, BIFIDOBACTERIUM AND SACCCHAROMYCES BOULARDII) IMPROVES FATTY LIVER DISEASE BY VIRTUE OF ITS ACTION ON LIPID PROFILES, LEPTIN, ADIPONECTIN, AND INFLAMMATORY BIOMARKERS

Contact E-mail Address: nazariikobylak@gmail.com

Introduction: NAFLD is the most important cause of chronic liver disease and is considered the hepatic manifestation of the metabolic syndrome associated with type 2 diabetes. The prevalence of NAFLD in the general population reaches 15–20% and it goes up to 76 to 90% in the obese population. The search of new non-toxic drugs for preventing the development of obesity is the most important challenge of modern science. The question about impact of probiotics and prebiotics on fat metabolism and obesity is being actively debated in the scientific literature. So the aim of the study was to investigate the effect of synbiotic (S) on development of experimental obesity in rats with NAFLD.

Aims & Methods: The study was carried out on 60 white rats, that were divided into 6 groups (I–III – males, IV–VI – females). I and IV groups were intact control (4-month old). Newborn rats of groups II and III s.c. in volume 8 µl/g were administered a saline or monosodium glutamate (MSG) (4 mg/g) at 2–10 days of life. Since the age of 1 month, rats of III and V group had been injected with water, rats III and VI groups - S (Inulin, Lactobacillus, Bifidobacterium and *Saccharomyces boulardii*) ("Opefera" World Medicine) in a dose of 1, 94 × 109 KOE + 2, 9 mg/inulin. Introduction had been performed with 2-week course for 3 months courses alternated with two-week breaks) for 3 months. In 4-month rats anthropometrical parameters and visceral adipose (VAT) tissue mass were estimated, and adiponectin in serum and leptin in VAT were measured by ELISA.

Results: In 4-month rats we diagnosed the changes of the anthropometrical parameters and significant increase of VAT mass that confirmed development of visceral obesity. In male rats, there were more pronounced changes. It was established that under condition of obesity caused by the introduction of MSG, the level of adiponectin in serum decreased but leptin in VAT was increased. S significantly improvement lipid profiles and histological state of liver: decrease of dystrophy, inflammation and necrosis and reduction of the NASH incidence.

Also consumption of S led to reduction of pro-inflammatory cytokines and leptin and increased anti-inflammatory cytokines and adiponectin.

Conclusion: Thus, the introduction of S reduced the obesity, that shows the effectiveness of therapy for the prevention of obesity.

P0624 IMPROVED EMPLOYMENT OF INTRAGASTRIC BALLOON FOR WEIGHT LOSS: A PRELIMINARY ANALYSIS

S.H. Kim, H.J. Chun, H.S. Choi, E.S. Kim, B. Keum, Y.T. Jeon, H.S. Lee, C.D. Kim

Department Of Internal Medicine, Division Of Gastroenterology And Hepatology, Korea University Anam Hospital, Seoul/Korea, Republic of

Contact E-mail Address: drchunhj@chol.com

Introduction: Endoscopic bariatric approaches are gaining traction as possible treatment modalities for obesity. Especially, intragastric balloon was demonstrated to be associated with a significant weight loss in obese patients. Despite many advances in the design and material of intragastric balloon devices, there still remains a need for improved devices which is safer, faster, and less expensive than before. In the present study, we evaluated feasibility of newly developed intragastric balloon.

Aims & Methods: We used a newly developed intragastric balloon with improved employment for this study. The intragastric balloon was supplied as delicately rolled up inside a thin silicon sheath and mounted by surrounding the endoscope. Endoscopic intragastric balloon placement and positioning was simply performed with direct vision. 10 pigs were submitted to the novel intragastric balloon placement. We evaluated feasibility of the intragastric balloon and compared procedure time between the novel intragastric balloon and End-ball (Endalis, Brignais, France) intragastric balloon.

Results: In all cases, the novel intragastric balloons were successfully placed under usual sedation of diagnostic endoscopy. The procedures were simple and fast; the mean insertion time was 41.314.3 and 153.8 134.8 sec in novel intragastric balloon group and end ball group, respectively. The mean inflation time was 412.46 and 512.83 sec in novel intragastric balloon group and end ball group, respectively.

Conclusion: This preliminary data suggest that the procedure with the new intragastric balloon attain technical improvements in the placement without severe adverse events. The new intragastric balloon could offer constantly effective procedure regardless of the ability of the endoscope practitioner.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0625 IS RE-IMPLANTATION OF THE DUODENAL-JEJUNAL BYPASS LINER VIABLE?

S. Guenther, A. Dienethal, J. Stein

Gastroenterology And Clinical Nutrition, DGD Clinics Sachsenhausen, Frankfurt/Main/Germany

Contact E-mail Address: j.stein@em.uni-frankfurt.de

Introduction: The endoscopically implanted DJBL is a 60 cm long, impermeable fluoropolymer device which prevents food from making contact with the proximal intestine, thus inducing considerable weight loss and improvement of type 2 diabetes mellitus (T2DM). Both weight and HbA1c levels have been reported to increase post explantation. The question remains as to whether it is possible to re-implant the DJBL, and what the results would be in terms of BMI (Body Mass Index) change and T2DM control.

Aims & Methods: The aim of this study was to investigate the safety, feasibility and effectiveness of DJBL re-implantation in patients who show a relapse in glucose levels after DJBL explantation. This prospective, observational study was conducted at the Department of Gastroenterology of DGD Clinics Sachsenhausen, Frankfurt (Germany) between 2014 and 2016. Five obese patients with T2DM and with a body mass index (BMI) ranging from 35–59 kg/m², who completed follow-up after their first implant and underwent removal of the DJBL after 12 months, were selected for re-implantation after an additional 4 months of follow-up. Weight loss, BMI, and HbA1c were analysed before reimplantation and twelve months thereafter.

Results: In all 5 patients, the DJBL was initially implanted and explanted without complications. Re-implantation and re-explantation were also performed without complications. Changes in body weight, BMI and glycated haemoglobin (HbA1c) are shown in Table 1.

Table 1: Body weight, BMI and HbA1c changes at different timepoints

Timepoint (months)	Mean weight in kg (±SD, range)	Mean BMI (±SD, range)	Mean HbA1c in % (±SD, range)
0	115.8 (45.4; 88–196)	40.9 (10.3; 35.3–59.2)	9.1 (1.3; 8–10.7)
6	97.4 (39.8; 72–164)	29.9 (2.2; 26.4–51.2)	7.6 (0.8; 6.6–8.3)
12	95.0 (38.8; 72–164)	33.5 (9.0; 29.549.5)	6.7 (0.9; 5.9–7.8)
16 (0)	97.1 (37.8; 75–164)	34.3 (8.6; 29.3–49.5)	7.7 (1.6; 6.2–9.9)
22 (6)	93.2 (40.6; 63–164)	32.8 (9.7; 24.6–49.5)	7.0 (1.0; 5.7–7.7)
28 (12)	92.5 (43.6; 61–160)	31.5 (9.1; 23.8–48.6)	7.0 (0.7; 6.3–7.7)

Conclusion: The results of this observational study show that re-implantation of the DJBL is viable and safe even only 4 months after explantation. After re-implantation, weight and HbA1c levels decreased once more.

P0626 THE COMPARATIVE EFFICACY OF OBESITY TREATMENTS IN YOUNG PEOPLE - A SYSTEMATIC REVIEW AND META ANALYSIS

S. S. Selvendran, N. Penney, N. Aggarwal, A. Darzi, S. Purkayastha
Surgery And Cancer, Imperial College London, London/United Kingdom

Contact E-mail Address: SS9612@ic.ac.uk

Introduction: Obesity in the young population is becoming increasingly prevalent. It is associated with short- and long-term consequences. Early and effective interventions are paramount. Current treatment options include: lifestyle modifications, pharmacological therapies, endoscopic treatments and bariatric surgery. However, the relative effectiveness of these treatments in this cohort remains unclear.

Aims & Methods: To systematically identify and meta-analyse studies evaluating treatments that reduce body mass index (BMI) in overweight and obese young people. A systematic literature review of EMBASE and MEDLINE databases was conducted. Studies were included/excluded based on pre-specified eligibility criteria. Included patients were 21 years or younger. Lifestyle modification and pharmacological therapy searches were restricted to randomised control trials.

Results: 16,372 studies were identified with 80 studies complete with sufficient data for meta-analysis. Bariatric surgery caused the most weight loss in the short- and medium-term [pooled estimate of mean BMI loss: 13.77 kg/m²]. Lifestyle modifications and pharmacological therapy had a more modest impact on weight [pooled estimate of mean BMI loss: 0.99 kg/m² and 0.94 kg/m² respectively]. Individual studies demonstrated that endoscopic treatment results in short-term BMI reduction, however insufficient data prevented meta-analysis.

Conclusion: This is the first systematic review and meta-analysis to comprehensively summarise and quantify the comparative efficacy of BMI reducing treatment options in the obese, young population. Currently, bariatric surgery is rarely considered in this young cohort. However, due to its high efficacy, physicians and patients should have a lower threshold for considering bariatric surgery when lifestyle and pharmacological interventions have failed. The non-surgical interventions provide smaller but statistically significant impacts on BMI reduction. There should be effective communication discussing the relative efficacy of all treatment options and their associated complications between those involved. This knowledge will assist clinicians in determining a holistic, patient-centred treatment programme for obese, young patients.

P0627 FOOD-DERIVED MICRORNA AND INFLUENCE ON THE FECAL MICRORNA EXPRESSION

J. Link¹, C. Langner¹, A. Canbay¹, P. Malferttheiner¹, A. Link¹

¹Department Of Gastroenterology, Hepatology And Infectious Diseases, Otto-von-Guericke University, Magdeburg/Germany

Contact E-mail Address: alinkmail@gmail.com

Introduction: Tumor development is a multistep process, which involves genetic and environmental factors. Diet is among the most important contributing factors and processed and red meat has been classified as carcinogenic for colorectal cancer. MicroRNAs (miRNAs) are functional, ubiquitously present molecules with great impact on tumor initiation and progression. Exogenous microRNA or xenomiRs have been identified in sera from different species suggesting an active cross-kingdom trespassing through biological barriers during digestive process.

Aims & Methods: In the present work, we evaluated whether miRNAs are present in various foods, and if miRNAs may be degraded through cooking and other forms of food processing. Furthermore, we tested if short-term vegetarian or meat-rich diet may influence human or plant-derived miRNA in feces and blood. For this purpose, six healthy subjects were asked to adhere to vegetarian or meat rich diet for 5 to 7 days and fecal and blood specimens were obtained at different time points. Plant-miRNAs were further investigated in gastric and colon mucosa. To evaluate the presence of miRNA in food, we selected several common foods prior and after cooking/processing. Quantitative real-time PCR was performed using TaqMan Assay.

Results: All analyzed microRNAs were present in all studied foods with highest expression for miR-21 followed by miR-16 and miR-155. Especially, hash, beef and salmon showed the highest miRNA expression, while lowest expression was found in cheese and milk. Food procession led to only marginal changes (max. 1.5-fold) in miRNA expression and thus demonstrating its stability against degradation. Short-term changes in diet (from usual to vegetarian and to meat-rich diet) in healthy subjects was not associated with variation in miR-21, miR-155 and miR-16 expression. Interestingly, in comparison to several previous reports, we repeatedly failed to detect any plant miR-168 in sera. However, vegetarian-diet was associated with a significant increase in miR-168 level in feces (up to 8-fold), while meat-rich diet was associated with slight decrease if compared to the starting time point (mean \pm SD 0.0031 \pm 0.002 for no diet vs 0.025 \pm 0.042 for vegetarian vs. 0.0016 \pm 0.00096 for meat-rich; $p = 0.03$ Kruskal-Wallis test, with $p > 0.05$ for Dunns multiple comparison test for vegetarian vs. meat-rich).

Conclusion: The results of this study show that various foods provide a great source of miRNAs, which remains stable despite processing. We further demonstrate that minor short-term changes in diet do not impact on the miRNA expression pattern in feces and blood supporting its value as biomarkers. A functional role of diet-induced increase in plant-derived miRNA expression needs further evaluation.

P0628 NEUROMEDIN U BLOCKS GASTRIC EMPTYING THROUGH VAGAL-DEPENDENT MECHANISMS AND IMPROVES ORAL GLUCOSE TOLERANCE

A. Jarry¹, N. Merah¹, M. Fiamma², L. Bodineau², A. Bado¹, J. Le Beyec¹, M. Le Gall¹

¹INSERM U1149, Paris/France

Introduction: The gut and brain peptide neuromedin U (NMU) is reported to decrease food intake and body weight, and to improve oral glucose tolerance suggesting that NMU could exert an incretin effect. NMU is thus considered as a promising candidate for the treatment of obesity and diabetes. However, and in contradiction with previous observations, NMU was recently presented as a “decretin” hormone able to decrease insulin secretion. The pathways through which NMU controls glycemia are thus uncertain and we sought to clarify some of NMU mechanisms of action on glucose homeostasis.

Aims & Methods: Oral (OGTT) and intraperitoneal (IPGTT) glucose tolerance tests were performed after an intraperitoneal injection of NMU or PBS in C57Bl6 mice that underwent a laparotomy or a truncular subdiaphragmatic vagotomy. During OGTT, blood was sampled to measure insulin secretion. [14]-C-glucose uptake was assessed in isolated intestinal loops in presence or absence of NMU. Gastric retention of a phenol red gavage and total intestinal transit time were evaluated after an intraperitoneal injection of NMU or PBS. Activation of vagus nerve neurons by intraperitoneal injection of NMU was assessed by cFos immunostaining on brainstem slides going through the nucleus of the solitary tract (NTS) and the dorsal nucleus of the vagus (DMV). Direct impact of NMU on pyloric contraction was assessed ex vivo in isometric chambers.

Results: A single intraperitoneal injection of NMU in C57Bl6 mice prevented the rise of glycemia following an oral but not an intraperitoneal load of glucose (OGTT versus IPGTT). Unexpectedly, during the OGTT, NMU injection prevented insulin secretion and only slightly improved peripheral insulin sensitivity. Furthermore intestinal [14]-C-glucose uptake in isolated intestinal loops was barely reduced by NMU addition (-17% $P < 0.05$ vs PBS). Actually NMU injection blocked gastric emptying (gastric retention of a phenol red gavage at 30 min: $+285\%$ $P < 0.0001$ vs PBS). This effect was partly prevented in vagotomized mice. In addition, injection of NMU induced c-fos expression in the nucleus of the solitary tract (NTS) of control but not vagotomized mice. In isotonic chambers, NMU directly induced pyloric contraction in a dose dependent manner (basal contraction $+21.7\%$ at 10^{-6} M).

Conclusion: These data demonstrate that a single intraperitoneal injection of NMU blocks gastric emptying directly by inducing pylorus contraction and indirectly via afferent vagal fiber activation. Through the blockade of gastric emptying, NMU reduces intestinal nutrient absorption and thus improves oral glucose tolerance. The gastric emptying blockade induced by NmU could also contribute to its anorexigenic effect.

P0629 LOW FODMAP DIET & PREBIOTIC GALACTOOLIGOSACCHARIDES IMPROVE IRRITABLE BOWEL SYNDROME SYMPTOMS AND RESPONSE TO LOW FODMAP DIET IS PREDICTED BY URINE METABOLOME, STOOL SHORT-CHAIN FATTY ACIDS AND VOLATILE ORGANIC COMPOUNDS: A RANDOMISED CONTROLLED TRIAL

Introduction: Dietary restriction of fermentable carbohydrates (low FODMAP diet, LFD) is effective at managing symptoms in 50–80 percent of patients with irritable bowel syndrome (IBS). Prebiotic B-galacto-oligosaccharide (B-GOS; HOST-G904) also reduce symptoms in IBS however the combination of the two therapies has not previously been investigated. What differentiates those who respond to the LFD from those who do not is unclear.

Aims & Methods: This randomised controlled trial aimed to investigate whether: 1) addition of prebiotic B-GOS could improve symptoms of IBS alongside the LFD; and 2) if urinary metabolites, faecal short-chain fatty acids (SCFA) or volatile organic compounds (VOC) could identify factors at baseline that predict response. Sixty-nine adults fulfilling Rome criteria for IBS were recruited to a 3-arm RCT: control (sham diet/placebo), LFD (LFD/placebo) or LFD plus B-GOS (LFD/B-GOS) for four weeks. Validated questionnaires (Global symptom question and gastrointestinal symptom rating scale) assessed GI symptoms (response) and urine and stool samples were collected for analysis at baseline and week 4. To examine the relationship between responders and non-responders, urine metabolomics (700 MHz ¹H-NMR), stool SCFA (gas liquid chromatography (GLC)) and stool VOC (GC-mass spectrometry) were analysed on samples at baseline and 4-weeks. Urine metabolomics spectra and VOC profiles were analysed using unsupervised principal component analysis (PCA) and supervised pattern recognition methods (orthogonal partial least square discriminant analysis (OPLS-DA)) or PLS-DA respectively. Stool SCFA were compared using t-tests, models of prediction were tested using receiver operator characteristic (ROC) curves.

Results: There was a significant difference in response rates (adequate relief) between control (30%), LFD (50%) and LFD/B-GOS (67%) ($p = .046$), with post-hoc differences specifically between control and LFD/B-GOS ($p = 0.015$). Individual IBS symptoms were more markedly improved in the LFD/B-GOS group compared to control. In the LFD group only, there was a significant difference in the urine metabolome between responders and non-responders at both baseline ($Q^2 = 0.296$ vs randomised -0.175) and at 4-weeks ($Q^2 = 0.485$ vs randomised -0.203). At baseline, there were significant greater stool isobutyrate between responders (51.4 mg/100g) and non-responders (31.9 mg/100g, $p = 0.04$), with ROC curves supporting this as a predictor of response (AUC = 0.747, $p = 0.063$). Finally, there was a significant difference in VOC profiles between responders and non-responders to the LFD at baseline ($p = 0.04$). VOC profiles, modelled by PLS-DA, reveal significant separation of VOC profiles across the three treatment groups at 4-weeks ($p = 0.02$).

Conclusion: Addition of B-GOS to the LFD improves symptoms in IBS. Urine metabolomics, stool SCFA and VOC profiling are relatively low-cost and non-invasive techniques that may predict response to the LFD as well as helping to further understand the underlying mechanisms. Prospective clinical trials to test these algorithms are warranted and may lead to personalised therapy for patients with IBS.

P0630 THE ANALYSIS OF PROTEIN CONSUMPTION PATTERNS IN PATIENTS WITH SIBO

V. Pilipenko, V. Isakov, A. Vlasova

Gastroenterology & Hepatology, Research Institute of Nutrition RAMS, Moscow/Russian Federation

Contact E-mail Address: pilipenkowork@rambler.ru

Introduction: Small intestinal bacterial overgrowth (SIBO) is common in patients with gastrointestinal diseases. SIBO symptoms are improved with antimicrobial treatment, but recurrence rate is high (approximately 40% for 9 months). Dietary modification is essential for prevention of recurrence of SIBO however there are no detailed studies of nutrition in SIBO patients. Protein consumption is considered important for SIBO, as the proteins from animal source are essential for growth of CH4/H2-producing microorganisms.

Aims & Methods: The aim of the study was to assess the protein consumption patterns in patients with different types of SIBO. Three-day food diary was collected from 574 patients, undergoing CH4/H2 lactulose breath test. The photographs used to estimate the size of the portions eaten. According to food composition and portion all dishes in food diary were converted into constituent products by food groups. Each food group were compared with the normal levels of a healthy diet pyramid based on daily calories (normal value = 1.0). According to the breath test results the patients were divided into 4 subgroups of different SIBO types (H2, CH4, H2 and CH4) and a subgroup with no signs of SIBO (Table 1).

Results: All types SIBO patients consumed less meat than control (no signs of SIBO), however patients with hyperproduction of CH4 only demonstrated highest consumption of fish, and it was a trend in patients with isolated H2-hyperproduction to consume more poultry than other groups. There were no differences between groups in consumption of processed meat foods or eggs.

Conclusion: There are specific animal protein consumption patterns related to the type of the SIBO, which can be used for the planning of dietetic interventions in patients for prevention of SIBO recurrence

⁴Center For Nutrition, Clinical Medicine, University of Bergen, Bergen/Norway

Contact E-mail Address: trinelarsen92@gmail.com

Introduction: Patients suffering from chronic radiation-induced small bowel disease (RISBD) after cancer treatment have similar symptoms as patients with IBS (irritable bowel syndrome), despite dissimilar pathological origin. RISBD is a common late effect after pelvic radiation therapy for gastrointestinal (GI), gynecological and urological cancer. The delayed development of ischemia, fibrosis, dysmotility and malabsorption in GI tissue, leads to IBS-like symptoms like abdominal pain, diarrhea, constipation and bloating. The low FODMAP (fermentable oligo-, di-, monosaccharides and polyols) diet (LFD) is a widespread management strategy for IBS. The aim of the conducted study was to investigate the effects of LFD on symptoms and health related quality of life (HRQOL) for patients with chronic RISBD.

Aims & Methods: In an open pilot study, 11 patients (mean age 46 years) with RISBD related IBS symptoms were instructed to follow LFD throughout a 4-week intervention period. IBS Severity Scoring System (IBS-SSS) and IBS Symptom Questionnaire (IBS-SQ) were used to assess symptoms. An Ad hoc questionnaire measured grade of tissue damage and typical RISBD complaints (fecal incontinence, rectal mucus and rectal bleeding). Short Form Nepean Dyspepsia Index (SF-NDI) and 12-item Short Form Health Survey (SF-12) were used to evaluate HRQOL. A 3-day food record was used to estimate baseline intake of FODMAPs, to reveal dietary changes and to assess adherence to the diet. All schemes were completed at baseline and at 4 weeks. The study included no control group.

Results: FODMAP intake was successfully reduced, and main additional changes in the diet were reduced intake of energy, carbohydrates and fiber. The adherence to the diet was high (mean 94.8%). IBS symptoms improved significantly based on mean total score of IBS-SSS and IBS-SQ, which changed from 310.2 ± 60.7 to 171.4 ± 107.2 ($p=0.001$) and 27.4 ± 4.1 to 15.7 ± 10.1 ($p=0.002$), respectively. The severity of abdominal pain, abdominal distension, belching/flatulence, constipation, diarrhea, early satiety, dissatisfaction with bowel habits and interference with life in general, improved significantly. Tendencies of improvement were also measured in comorbidity complaints (nausea, headache, backache, fatigue and muscle pain) and typical RISBD complaints. HRQOL improved based on SF-NDI total score, which changed from 30.5 ± 9.4 to 18.3 ± 8.2 ($p=0.001$) and based on mental ($p=0.047$) and physical ($p=0.134$) component summary score of SF-12.

Conclusion: The low FODMAP diet seems effective in alleviating IBS symptoms, and improving HRQOL in patients with RISBD. High compliance to LFD is possible with adequate diet counseling and continuous guidance. Further controlled studies with larger sample size should be conducted to verify our results and hopefully enable the implementation of LFD as a future management strategy for chronic RISBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0632 DIET SUPPLEMENTED WITH MEDIUM- AND LONG-CHAIN FATTY ACIDS DOES NOT AFFECT LOWER GI MOTILITY AND VISCERAL PAIN IN RATS

P. Mosinska¹, M. Martin-Ruiz², R. Abalo², J. Fichna¹

¹Biochemistry, Medical University of Lodz, Lodz/Poland

²Universidad Rey Juan Carlos, Alcorcon, Madrid/Spain

Contact E-mail Address: paula.mosinska@gmail.com

Introduction: Dietary interventions are gaining popularity in terms of alleviating symptoms experienced by patients with functional GI disorders (FGID), especially with irritable bowel syndrome (IBS). Available strategies rely on low intake

of foods high in short-chained carbohydrates, dairy products, wheat, spices etc. Although some studies indicate increased rectal sensitivity after duodenal lipid administration in patients with IBS and suggest delayed transit after high fat intake, the effects of dietary supplementation with different types of fatty acids in IBS have not been explored so far.

Aims & Methods: The aim of the study was to evaluate the differences in GI motor function and visceral sensitivity in rats exposed to diet supplemented with either medium-chain- (MCFA) or long-chain fatty acids (LCFA). Male Wistar rats were fed with control diet (A), and diet supplemented with 3.5 % coconut oil (B) (abundant with MCFA) or 3.5 % evening primrose oil (C) (abundant with LCFAs) for 4 weeks. The effects of each diet on GI motility were measured radiographically after contrast administration (p.o; X rays were taken 0–8 h before and after feeding, on day 0 and day 28, respectively), and by performing the colon bead expulsion test. Temporal changes in the size of the stomach and caecum of each rat were analyzed based on digitalized X-rays, using an image processor. Visceral sensitivity was assessed with abdominal withdrawal reflex to colorectal distension. Body weight gain and food/water ingestion were measured throughout the experiment.

Results: Diet supplementation in neither group B nor group C affected the GI motor function in comparison to control group (A). The number of contractions and the mean time of each contraction in response to colorectal distension measured during each 5 min for 40 min were higher in the control group (A), when compared to either B or C groups but the differences were not statistically significant. No changes in morphometric measurements of stomach and caecum, the body weight gain or food/water consumption were found.

Conclusion: Diets differing in MCFAs or LCFAs contents did not induce marked effects on GI motility and visceral pain in rats. Available data and the results obtained herein suggest that the amount of FAs intake, rather than the types of FAs may provoke IBS symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Glucagon and insulin are pancreatic peptides essential for the control of glucose homeostasis. Pancreatectomy in human leads to a loss of plasma insulin while glucagon is still detectable, suggesting the existence of an extra-pancreatic source of glucagon. More specifically, in pancreatectomized patients, glucagon secretion is increased when glucose is administered orally, a release that

Abstract No: P0630

Table 1: Consumption of protein products in SIBO patients.

Food	No SIBO n = 65	H2 SIBO (> 20ppm) n = 312	CH4 SIBO (> 12 ppm) n = 77	H2/CH4 SIBO n = 123	Significance

is similar to the oral glucose-stimulated secretion of glucagon-like peptide 1 (GLP-1). GLP-1 is an incretin hormone secreted by enteroendocrine L cells (EEC) from the distal gut. GLP-1 and glucagon, both originate from the same proglucagon precursor, differentially processed by prohormone convertase 2 (PC2) into glucagon in pancreatic α cells and by prohormone convertase 1/3 (PC1/3) into GLP-1 in EEC.

Aims & Methods: We hypothesized that, after pancreatectomy, proglucagon can also be processed into glucagon in EEC. We developed a 75% subtotal pancreatectomy model in C57Bl6 mice. Control (Ct) mice underwent a laparotomy. Post-surgery, blood glucose levels were measured daily and oral glucose tolerance tests (OGTT) were performed after 1 week. Insulinemia and glucagonemia were also measured in fed and fasted mice and during OGTT. After 2 weeks, animals were sacrificed and the remnant pancreas was sampled for glucagon and insulin immunostaining and for alpha- versus beta-cell mass quantification. Proximal and distal intestinal segments were sampled for morphometric analyses as well as measurement of proconvertase and proglucagon mRNA levels. Colonic segments were incubated in a glucose-enriched medium for one hour and glucose-induced secretions of glucagon and GLP-1 were measured in the supernatant.

Results: As soon as one day post-surgery, pancreatectomized (Px) mice developed a hyperglycemia that maintained for over a week (351 mg/dl in Px mice vs 140 mg/dl in Ct mice, $P < 0.05$, 5 days post-surgery). This hyperglycemic state was accompanied by an oral glucose intolerance (area under the curve +278% in Px mice, $P < 0.01$ vs Ct mice, 1 week post-surgery). During, OGTT, intestinal glucose absorption increased (slope between 0 and 15 min +69.9% in Px mice $P < 0.01$ vs Ct mice, 1 week post-surgery). Glucagonemia increased in fasted pancreatectomized mice (+146.6% in Px mice $P < 0.01$ vs Ct mice 1 week post-surgery). After sacrifice, alpha cell mass was decreased in the remaining pancreas (-79.25% in Px mice $P < 0.05$ vs Ct mice, 2 weeks post-surgery). However an increased ability of the proximal colon to secrete glucagon *ex vivo* was observed (+290.6% in Px mice $P < 0.05$ vs Ct mice, 2 weeks post-surgery). In pancreatectomized mice, an hypertrophy of the duodenum was associated with an increase in crypt depth (+77.7%, in Px mice $P < 0.05$ vs control mice, 2 weeks post-surgery) and villus height (+53.8% in Px mice $P < 0.05$ vs control mice, 2 weeks post-surgery).

Conclusion: These data establish an ability of the whole gut to adapt in response to pancreatectomy. The upper intestine (duodenum) become hyperplastic and may contribute to the increased intestinal capacity to absorb glucose. The distal intestine (colon) is able to produce glucagon and may participate to the development of the reported hyperglucagonemia.

Introduction: A probiotic formula to be functional and reliable should: i) contain viable cells, ii) have a reproducible composition, iii) to be taxonomically defined. Here we detail the consistency of the multispecies probiotic product VSL#3, which has been produced for the last 20 years and is marketed globally for threatening Inflammatory Bowel Disease, Pouchitis and other intestinal diseases (Mimura et al 2004; Reiff et al., 2009).

Aims & Methods: To show consistency in the quality, viability and composition of the multispecies probiotic product VSL#3 various batches of the multispecies probiotic VSL#3 were analyzed in detail and derived from productions in the USA and Italy. The product batches have been tested using a series of microbiological, phylogenetic and genomic methods. The microbiological analysis included plating on selective media, cell counting and viability analysis by Flow Cytometry (FCM) using fluorescent dyes that allowed high throughput separation and quantification of live, dead and damaged cells (ISO 19344 IDF 232, 2015). A metagenetic approach, based on *16S rRNA* gene profiling, was used to define the bacterial community structure of different productions batches. In addition, *Lactobacillus helveticus* and *L. acidophilus* S-layer proteins, which are known to exert anti-inflammatory effects by reducing the activation of NF- κ B on the intestinal epithelial Caco-2 cell line, have been extracted and visualized on SDS-PAGE (Konstantinov et al., 2009; Taverniti et al., 2013). Moreover, urease activity of *Streptococcus thermophilus*, known to exert positive effect human health by competing with the undesired urease-positive bacteria of the human microbiota (Mora and Arioli, 2014), was quantified using a spectrophotometric-, and flow cytometry-based assay.

Results: The different test batches were all found to contain a common bacterial community structure based on the presence of the following species *Streptococcus thermophilus*, *Lactobacillus acidophilus*, *Lactobacillus paracasei*, *Lactobacillus plantarum*, *Lactobacillus helveticus*, *Bifidobacterium breve* and *B. animalis* subsp. *lactis*. The stability of the batches was confirmed by FCM and viable cells were always above the value of 2×10^{10} event/g. The *Lactobacillus helveticus* and *L. acidophilus* S-layer protein SlpA was detected in each VSL#3 batches tested thus highlighting that this relevant immunomodulatory factor was not subjected to degradation during the shelf-life of the product. Likewise, urease activity of *S. thermophilus* was stable in all VSL#3 batches along the shelf-life.

Conclusion: In conclusion, stability, molecular and taxonomic comparative analysis shows that VSL#3 is reliably and reproducibly produced in different parts of the world.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Soybean oil intravenous lipid emulsion (IVLE) is also known as conventional lipid is rich in linoleic acid (ω -6 PUFA). ω -6 PUFA may exaggerate inflammatory response and indirectly detrimental in the critically ill patients^{1, 2}. To overcome this, the use of alternative IVLEs such as medium chain triglycerides (MCT), fish oil and olive oil alone or in combination with soybean oil IVLE have been used to lower the content of ω -6 PUFA. Most studies on alternative IVLEs have been conducted in the critically ill patients, elective surgical patients and cancer patients. No previous studies have evaluated the clinical outcomes of several different IVLEs in non-critically ill patients in acute hospital setting.

Aims & Methods: The purpose of this study is to determine whether there is a difference in clinical outcome amongst patient who received conventional soybean oil IVLE versus alternative IVLEs in non-critically ill patients in acute hospital setting. All patients on parenteral nutrition (PN) were identified in a prospective compilation database from July 2007 to September 2010 and were analysed retrospectively. Patients were analysed based on the IVLE received, namely soybean oil based (Lipofundin-N 20%, type 1), MCT oil based (Lipofundin MCT/LCT 20%, type 2), olive oil based (ClinOleic, type 3) and fish oil containing (Lipidem, type 4). Patients must receive PN for at least 5 days in general ward or high dependency unit not requiring invasive/non-invasive ventilator support or inotropes support. Exclusion criteria included patients who received less than 5 days of PN, intensive care unit (ICU) patients, PN started in ICU and continue in general ward or HDU, PN restarted in less than 3 days after receiving PN in ICU, patient on invasive/non-invasive ventilator support or inotropes support and home PN patients.

Results: 537 patients were started on PN and 388 patients were included in the study. 90 patients were on type 1 (soybean based) IVLE, 60 patients were on type 2 (MCT based) IVLE, 141 patients were on type 3 (olive oil based) IVLE and 97 patients were on type 4 (contain fish oil) IVLE. Baseline characteristic were similar in four groups of IVLEs. Majority of PN were initiated in patients admitted under surgical team. There were no difference in terms of mortality, readmission and infection rate between conventional and alternative IVLE as a group, odd ratio (OR) was 0.66 (CI 0.36–1.24; $p = 0.16$), 1.71 (CI 0.84–3.73; $p = 0.15$) and 0.90 (CI 0.55–1.49; $p = 0.73$) respectively (as shown in table 1). The length of stay in log-scale was significantly lower in alternative IVLE as a group ($p = 0.03$). There were no difference in terms of mortality, readmission and infection rate between conventional IVLE versus each of the alternative IVLE. Length of stay was only statistically significantly lower for olive oil based IVLE (Type 3) when compared to conventional IVLE ($p = 0.05$).

Table 1: Clinical outcomes with conventional IVLE versus alternative IVLE as a group

	Conventional	Alternative (As a group)	OR (95% CI)	P Value
Mortality Yes (N) No (N)	21 70	49 248	0.66 (0.36–1.24)	0.16
Readmission Yes (N) No (N)	12 58	65 183	1.71 (0.84–3.73)	0.15
Infection Yes (N) No (N)	41 50	126 171	0.90 (0.55–1.49)	0.72
Length of stay (Mean (SD) in log-scale)	3.58 (0.59)	3.43 (0.57)		0.03

Conclusion: Length of stay was significantly lower in alternative IVLE compared with conventional IVLE. However, there were no clinical difference in terms of mortality, readmission and infection between conventional and alternative IVLE in non critically ill patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Percutaneous endoscopic gastrostomy (PEG) is currently the method of choice for medium- and long-term enteral feeding and is nowadays one of the most common endoscopic procedures performed worldwide. To date, data on complications and mortality rates are generally retrospective and only few prospective studies have been published on small number of patients.

Aims & Methods: We aimed to prospectively evaluate the complication rates and the mortality of patients after PEG insertion or PEG replacement. This is a multicenter prospective cohort study. Between 15th September 2015 and 15th September 2016, all patients that underwent PEG insertion or replacement, were included. Details about patient's characteristics, ongoing therapies, comorbidities, indication for PEG placement/replacement, informed consent form signature were collected. Early and late (30 days) complications and mortality were assessed.

Results: 912 patients (426 [46.7%] male) were enrolled in 34 centers. Patients mean age was 72y (SD16.01, range 18–99). ASA status was 1 in 4.0%, 2 in 23.4%, 3 in 58.4%, 4 in 14.1%. PEG 1st placement was performed in 582 (64%) patients. Indications were: dysphagia for cerebrovascular diseases in 33.3%, degenerative neurological illness in 21.3%, dementia in 14.6%, head and neck cancer in 14.4%, management of patient after the discharge in 8.9%, nutritional support in oncological patients in 3.4%, medication administration in 1.5%, gastric decompression in 0.2%. The informed consent form was signed by a relative (without legal guardianship) in 49.6%, patient in 28, 2%, legal guardian in 16%, medical director in 6, 2% of patients. The majority of patients (63.2%) had antiplatelet and/or anticoagulant concomitant therapy. Anesthetist was present in 47.7% of procedures and sedoanalgesia was the more common modality for sedation (69.8%). The complication and mortality rate were 4.6% and 7.8%, respectively. The most frequent complication was infection (2.4%), followed by bleeding (1.4%), tube dislodgment (0.4%), buried bumper syndrome (0.2%). PEG replacement was carried out in 330 (36%) patients. The indications for PEG replacement were obstruction/malfunction/deterioration of the tube in 52.9%, tube dislodgment in 26.4%. Endoscopic procedure was necessary in 9.7% of cases. The informed consent

was signed by relative (without legal guardianship) in 66.3%, patient in 10.5%, legal guardian in 16.25%, medical director in 7% of patients. Thirty-days mortality was 2.4%.

Conclusion: Our data confirm that PEG placement is a safe procedure with a mortality rate at 30 days of 8%. To our knowledge this is the largest prospective study on the use of PEG. Surprisingly in more than 50% of patients the consent form was not properly signed, leading to possible medico-legal consequences. Moreover, in 9% of the cases PEG was placed for an early discharge (more than for real clinical indication).

P0637 MEDICAL REGISTRAR REPORTING OF CHEST X-RAYS FOR NASOGASTRIC TUBE POSITION: HOW CAN IT BE MADE SAFER?

M. Tierney, Z. Leach, C. Sibley, C. Rutter, C. Pither, T. Smith
 Nutrition, University Hospitals Southampton, Southampton/United Kingdom

Contact E-mail Address: maeve.tierney@nhs.uk

Introduction: Nasogastric tube (NG) feeding is an essential part of in-patient care. Tubes can be placed at the bedside with no need for specific equipment or sedation. However placement of NG tubes is not without risk and avoiding the introduction of substances into the respiratory tract through a misplaced NG tube was highlighted as a UK National Patient Safety Agency alert in 2005. In 2011 the NPSA made this a 'never event'. The only acceptable methods of checking the position of an NG tube are: pH < 5.5 on aspirate or confirmation on chest x-ray (CXR) by competent medical staff. Reporting a CXR for NG tube position is a frequent request particularly for junior doctors out of hours. Practise varies across the UK - some trusts require NG checking to be done only by senior clinicians (medical registrars or consultants) and some only allow reporting by a consultant radiologist. We assessed documentation of NG position on CXR by medical registrars from the region to find out if documentation was adequate, as would be expected of senior clinicians. NPSA guidance suggests four points should be documented in the medical notes to confirm NG position: 1. Does the tube follow the contours of the oesophagus and avoid those of the bronchi? 2. Does the tube clearly bisect the carina or the bronchi? 3. Does it cross the diaphragm in the midline? 4. Is the tip clearly visible below the left hemi-diaphragm? All four criteria were met in only 17.6% of responses and answers were considered incorrect in 20.5%. An aide-memoir sticker with an abbreviated version of the above four points, time, date, doctor signature and whether tube is safe to use or not with Yes/No answers, is used on some wards in Southampton and we assessed whether its use would improve quality of reporting both a correctly placed and misplaced NG tube.

Aims & Methods: Medical registrars from first to final year of specialist training and from various specialties were presented with a CXR showing a correctly sited NG tube and were asked to complete a sticker answering yes or no, to check position and whether it was safe to use. Following this they were presented with a CXR showing an incorrectly sited NG tube and asked to use the sticker to assess position. The CXR was projected and anonymous responses collected after sufficient time for the group to complete both stickers.

Results: 31 complete responses were obtained for the correctly sited tube with 58% stating that it should be used and 42% that they would not use the tube without further review. 10 incomplete responses were obtained and therefore 86% of responses met NPSA guidance for reporting CXR for NG position. 28 complete responses were obtained for the incorrectly sited tube and 100% stated that the tube should not be used.

Conclusion: Use of the sticker increased compliance with NPSA guidance for CXR reporting for NG tube position from 17.6% to 86%. The misplaced tube was correctly reported and not used in 100% of responses. The correctly sited tube was reported as safe to use in 58%. The CXR used was of an anonymous real patient and was slightly rotated to reflect a real-life scenario which meant the tube was slightly off the midline. In this real-life scenario some trainees would be happy to make a judgement considering these factors and others may be cautious and follow the sticker statements exactly prompting further review by radiology or removal of the tube. Overall this increases patient safety and avoids use of a misplaced tube in accordance with UK guidance. We intend to roll out use of the sticker on all wards which use NG tubes to rapidly improve documentation and patient safety. The other option we may consider is developing a pathway for radiology consultants to report all these CXRs before the NG tube is used; however, this is likely to take considerable time and is unlikely to be available out of hours.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0638 MICRONUTRIENT MONITORING IN HOME PARENTERAL NUTRITION PATIENTS: AN AUDIT OF PRACTICE IN A REGIONAL REFERRAL CENTRE

M. Tierney, L. Bakewell, E. Buse, C. Rutter, C. Pither, T. Smith
Nutrition, University Hospitals Southampton, Southampton/United Kingdom

Contact E-mail Address: maeve.tierney@nhs.net

Introduction: Intestinal failure patients by definition have reduced ability to absorb fluid and macronutrients through the gastrointestinal tract. Type two intestinal failure patients require months of intravenous nutrition (parenteral nutrition) for weeks or months either in hospital or at home. Type three intestinal failure patients generally require long-term parenteral nutrition (PN), which is given at home (HPN) and may be life-long. In addition to a reduction in the ability to absorb macronutrients, patients on long-term PN have a reduction in absorption of micronutrients (copper, zinc, selenium and manganese) and vitamins (A, B12, D and E) which are required for metabolism and enzymatic reactions at a cellular level. PN is routinely supplemented with micronutrients and should be sufficient. Toxicity can occur at high levels and deficiency can cause a variety of symptoms. ESPEN guidelines recommend that serum vitamin and trace element levels be checked at baseline and at least once per year. NICE guidelines specify more frequent monitoring for in-patients and that selenium, manganese and vitamin D should be checked three to six monthly in HPN patients. Some trace elements (copper and zinc in particular) are affected by acute illness. Current local practise is to avoid checking levels until there is evidence that inflammation or infection has resolved.

Aims & Methods: Our aim was to audit the frequency of micronutrient screening in our cohort of HPN patients. All type two and three intestinal failure out-patients were included. Current in-patients were excluded due to the effect of acute illness on micronutrient levels. Patients on parenteral fluid rather than nutrition were excluded as current guidelines give recommendations for HPN patients and do not specify recommendations if fluid alone is required. A search of the blood results system was performed for all micronutrient results from one full year to the date of the search. Results were recorded in spreadsheet format and analysed. Many patients live out of the region; however, many local trusts do not have the laboratory facilities to check micronutrient levels so they tend to be done in Southampton. If no results were available on the Southampton system then the local hospital was contacted for local results if available.

Results: 57 home parenteral nutrition patients were identified. 51 (89.5%) of these patients had micronutrients checked at some point during their care. 44 of 49 (89.7%) had micronutrients checked within one year (two of the 51 had only recently so did not have results within a year). 32 (61.5%) of those who had micronutrients checked had them done within the last six months. 6 patients had never had micronutrients checked. One had them requested just prior to the time of audit but results were not yet available. Two were out of area and had not been to clinic within the past year. One of these commenced PN in 2015 and found it difficult to attend clinic. The other had not been seen in clinic due to an administrative error and has now been seen with micronutrients requested. Two further patients had never had micronutrients checked due to a persistently raised CRP.

Conclusion: Despite a lack of clarity between guidelines about the frequency of monitoring of micronutrients, it is recommended that HPN patients receiving long-term intravenous nutrition should have regular monitoring to reduce risk of deficiency or toxicity. The majority of our cohort of HPN patients had micronutrients checked annually and over half were checked six monthly. This is compliant with ESPEN guidelines; however, we need to aim for 100%. We have introduced a template to use in clinic to trigger review of results and request micronutrients when required. Alongside this we have introduced a virtual ward round to remotely review all out-patients regularly and plan ahead to request blood tests when required. Following the introduction of these measures we will repeat the audit to find out if the situation has improved.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0639 CLINICAL NUTRITION - ARE WE IGNORANT OR NEGLIGENT?

T.M.A. Gan, R. Asokkumar, E. Salazar
Gastroenterology And Hepatology, Singapore General Hospital, Singapore/Singapore

Contact E-mail Address: aaron.gan2@mohh.com.sg

Introduction: Early recognition and delivery of nutritional care by physicians has been shown to improve outcomes in malnourished hospitalized patients. However, physicians encounter multiple barriers in providing appropriate nutritional care. While comprehensive international guidelines and nutritional training in medical education have been introduced to overcome these barriers, there appears to be a discrepancy in practice amongst physicians despite the availability of these resources.

Aims & Methods: We aim to assess the knowledge and attitudes of physicians towards clinical nutrition in a large tertiary teaching hospital in Singapore. An anonymous questionnaire comprising 15 multiple-choice questions from standard nutrition textbooks was administered. The questionnaire was designed to

assess (a) recognition of nutritional needs of hospitalized patients, (b) knowledge on principles of clinical nutrition, and (c) application of nutritional intervention in common clinical practice. We included consultants, fellows and residents working in units where nutritional problems were common. Finally, we conducted a separate 5-question opinion survey to assess each participant's nutritional training and exposure, based on a 5-point Likert scale ranging from "strongly agree" to "strongly disagree".

Results: A total of 305 physicians volunteered to participate in this study. Forty (13%) did not reveal their specialty or staff grade and were excluded from analysis. The remaining 265 responders comprised 77 (29%) consultants, 58 (22%) fellows, and 130 (49%) residents. Amongst them, 232 (87%) were from medical disciplines and 33 (13%) from surgical disciplines. The median aggregate score (out of a maximum score of 15) obtained by consultants, fellows and residents was 6.0 ± 2.2 (range 2–12), 7.0 ± 1.8 (range 3–11), and 7.0 ± 1.8 (range 1–10) respectively. All 3 grades of physicians achieved less than 50% of the maximum possible score. No significant difference in median aggregate score was observed between physicians from medical disciplines (6.5 ± 1.9) and those from surgical disciplines (7.0 ± 1.8). However, gastroenterologists performed significantly better than non-gastroenterologists (median aggregate score 9.0 ± 2.2 vs 6.0 ± 1.8 , $p < 0.001$). In the opinion survey, a majority of physicians (63%) believed that nutrition-related teaching was inadequate during residency training and 44% felt that clinical nutrition was accorded insufficient attention during ward rounds. Only 33% of responders reported that they performed nutritional screening on admission, and a mere 10% were confident in providing nutrition counselling to malnourished patients. Interestingly, their overall performance was not different from that of other participants (see Table 1).

Table 1: Median aggregate scores by grade, specialty and response in opinion survey

	Median aggregate score \pm SD	Range	P value
Physician Grade			
Consultants (n = 77)	6.0 ± 2.2	2.0–12.0	0.617
Fellows (n = 58)	7.0 ± 1.8	3.0–11.0	
Residents (n = 130)	7.0 ± 1.8	1.0–11.0	
Specialty			
Medical disciplines (n = 232)	6.5 ± 1.9	1.0–12.0	0.193
Surgical disciplines (n = 33)	7.0 ± 1.8	2.0–10.0	
Gastroenterologists (n = 25)	9.0 ± 2.2	3.0–12.0	<0.001
Non-gastroenterologists (n = 240)	6.0 ± 1.8	1.0–11.0	
Performed nutrition screening on admission			
Agreed (n = 81)	7.0 ± 2.0	1.0–12.0	0.321
Disagreed (n = 99)	7.0 ± 2.2	2.0–11.0	
Confident in providing nutrition counselling			
Agreed (n = 23)	7.0 ± 2.0	3.0–10.0	0.467
Disagreed (n = 137)	7.0 ± 2.0	2.0–11.0	

Conclusion: Our study highlights that knowledge on nutrition and its clinical application to hospitalized patients remains inadequate across all physician grades, especially amongst non-gastroenterologists. The current state of clinical nutrition-related teaching during residency training falls short of achieving its goals, and may need re-examination.

Contact E-mail Address: zaheernabi1978@gmail.com

Introduction: Per-oral endoscopic myotomy (POEM) is a novel treatment modality for achalasia cardia (AC). The studies are limited in paediatric population. **Aims & Methods:** In this study our aim was to analyse the feasibility, safety and efficacy of per-oral endoscopic myotomy in children. We retrospectively evaluated the data of all children (≤ 18 years) who underwent POEM at our institution from September 2013 to February 2017. All POEM procedures were performed under general anaesthesia in an endoscopy suit. Technical feasibility, safety and efficacy were analysed. Clinical success was defined as Eckardt score ≤ 3 . Objective parameters including timed barium swallow and high resolution manometry were assessed and compared before and after POEM.

Results: Thirty children (15-boys, 15-girls) with mean age of 14.1 ± 3.32 (4–18) years, underwent POEM during the specified period. The sub-types of AC were type I (8), type II (19) and type III (1). Eight children had prior treatment with pneumatic balloon dilatation. POEM was successfully performed in all children. Anterior myotomy was performed in majority of children 23 (76.7%). Mean total length of myotomy was 10.9 ± 2.25 cm, with 7.9 ± 2.09 cm on esophageal and

3.03±0.67 cm on gastric side. Mean operating time was 76.7±45.5 (30–240) minutes. Mild gas related adverse events requiring temporary discontinuation of procedure and/or drainage procedure were encountered in eight (26.7%) children (capno-peritoneum-4 and retro-peritoneal carbon dioxide -4). There was significant reduction in mean LES pressure after POEM (36.25±16.5 vs 11.47±5.06, $p=0.0001$). Significant improvement of esophageal emptying on timed barium esophagogram (>50%) was documented in 94.4% children. At median follow up of 504 days (30–1290) clinical success was noticed in 29 children (96.7%). Mean Eckardt score before and after POEM were 6.8±1.63 and 0.86±0.77, respectively ($p=0.0001$). Gastrosocopy revealed erosive gastroesophageal reflux in five children at 1 year (27.8%).

Conclusion: Conclusion-POEM is safe and effective for children with achalasia cardia. POEM can be safely performed in an endoscopy suit in paediatric patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Because of high prevalence of gastric malignancies in the adult population, high *Helicobacter pylori* (Hp) prevalence in Armenia is suspected. Rising antibiotic resistance of Hp both in children and adults lead to decrease of effectiveness of standard eradication therapy [1, 2]. The aim of this study is to determine frequency of Hp antibiotic resistance in Armenian children.

Aims & Methods: 47 children with suspected gastroduodenal disease (GDD), hospitalized in Arabkir MC, were selected from April to December 2016 (23 boys and 24 girls, average age 8.98±4.10). Hp-associated GDD were diagnosed according to clinical, endoscopic and histological criteria. Antral biopsy was cultured on 5% sheep blood Columbia agar and selective Hp media. Antibiotic susceptibility test was done by disk diffusion method.

Results: Hp-associated GDD was diagnosed in 40 patients out of 47: 37 (92.5%) had gastritis and/or duodenitis, 3 (7.5%) had peptic ulcer disease (PUD). Seven out of 47 children were excluded from the study due to both histology and culture negative for Hp. Thirty-four (85%) were treatment-naïve patients and 6 (15%) had received eradication therapy previously. Main clinical symptoms were recurrent epigastric pain 34 (85%), nausea 28 (70%) and vomiting 13 (32.5%). By endoscopy erosive gastritis and/or duodenitis was seen in 18 (45%), non-erosive gastritis in 16 (40%), PUD in 3 (7.5%), normal mucosa in 3 (7.5%). Rapid urease test was positive in all antral biopsies (100%). Histology showed chronic gastritis and/or duodenitis in 28 (70%), atrophic gastritis in 5 (12.5%), gastric glandular dysplasia in 2 (5%), gastric metaplasia of duodenal mucosa in 3 (7.5%), normal mucosa in 2 (5%). Hp was positive in 38 (95%) and negative in 2 (5%). Cultures were positive for Hp in 14 of 40 patients (35%). Susceptibility test was possible in 12 Hp strains from available 14: all but to 2 were resistant to metronidazole (83.3%), 4 to clarithromycin (33.3%), 3 double resistant to both metronidazole and clarithromycin (25%), and 66.6% to doxycycline. All strains were susceptible to amoxicillin and levofloxacin (100%), 6 strains were tested and found susceptible to rifampin.

Conclusion: These data indicate a high rate of resistance to conventional triple therapy antibiotics: metronidazole (83.3%) and clarithromycin (33%). High resistance to doxycycline also was seen, despite limited use of this antibiotic in Armenian paediatric practice. High susceptibility to rifampin might be useful for further development of specific eradication schemes for Armenia. High frequency of both erosive and non-erosive gastritis as well as high rate of gastric atrophy and dysplasia in these patients were noticed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: da@amamed.ru

Introduction: Children's gastric microbiota in the presence or absence of *H. pylori* (HP) has not been studied well.

Aims & Methods: We aimed to study the composition of the microbiota in the biopsy material of the antral part of the stomach, according to the 16S-rRNA sequencing, of children with chronic gastritis, in the presence or absence of HP, and also to compare it with the histological data. Biopsy materials of mucous tunic from antral part of the stomach were taken from 16 children aged 10–17 with chronic gastritis and after the preliminary extraction the biopsy materials were examined using the method of sequencing with a pair of oligonucleotide primers, which are specific for the conservative regions of the 16S-rRNA gene, on the Life Technologies Ion Torrent sequencer using the 318v2 chip. Bioinformatic processing was conducted using the QIIME package. The results were compared with the data from the histological examination of the biopsy materials from the same part of the stomach as well as with the results of diagnosis using rapid urease test AMA RUT Expert with digital Reader.

Results: 8 out of 16 patients were identified as HP(+) positive, 2 of them had HP in small amounts, 6 of them – in significant amounts. The dominant types of bacteria in the stomach of all children were Proteobacteria, Bacteroidetes, Firmicutes; in a lesser extent – Actinobacteria, Cyanobacteria, Fusobacteria. 64.1% of HP(+) patients' microbiome was constituted of HP, among Proteobacteria it reached 75–99%, the amount of other bacteria herewith shortened, and the species diversity decreased. Non-helicobacter microbiota of children with small amount of HP was almost identical in composition as HP(-) patients', the amount of other microbes was more numerous and diverse, also within Proteobacteria. The signs of inflammation in mucous coat of the stomach in case of HP presence were more pronounced than in HP absence, they correlated with the amount of HP.

Conclusion: Microbiome of the children's stomach is diverse, it is similar to adults'. The infection from HP inhibits another microbiota and it is accompanied with the signs of mucous coat inflammation, which correlates with the amount of HP.

P0643 FEATURES OF CHRONIC GASTRITIS CAUSED BY CO-INFECTION OF *HELICOBACTER PYLORI* AND EPSTEIN-BARR VIRUS IN PEDIATRIC PATIENTS

E. Spivak, R. Levit

Pediatric, Medical State University, Yaroslavl/Russian Federation

Contact E-mail Address: spivak58@mail.ru

Introduction: It is known that co-infection of the gastric mucosa with highly pathogenic Hp strains and the Epstein-Barr virus is a risk factor for the development of severe gastritis and gastric adenocarcinoma. However, the characteristics of such co-infection in children are not sufficiently studied.

Aims & Methods: The aim of this study is to estimate the role co-infection of highly pathogenic strains of *Helicobacter pylori* and Epstein-Barr virus in pediatric patients with chronic gastritis Patients and methods. 190 children aged 8–16 with chronic Hp-associated gastritis were studied. All the patients underwent clinical and laboratory examinations and endoscopy. Gastric biopsies were taken and inflammation graded according to the Sydney system. Polymerase chain reaction (PCR) was used to detect the presence of Epstein-Barr virus (EBV), *Helicobacter pylori* (Hp) and its highly pathogenic strains in the gastric mucosa of the patients.

Results: Persistent EBV infection was found in 83 children (43.7%) with chronic gastritis of the antral and (or) gastric body areas. *Helicobacter pylori* strains that possess the virulence factors (cytotoxin-associated gen A (CagA), vacuolating cytotoxin gen A (VacA), induced by contact with epithelium (IceA), and blood group antigen-binding adhesion (BabA) were detected in 49 patients (25.8%). In most cases, the association of two or more virulence factors in one patient was observed. It was found that 39 pediatric patients had co-infection of the highly pathogenic strains of Hp and EBV. The study revealed no significant effect of the variant of the gastric mucosa infection on the clinical manifestations of gastritis – the nature of intoxication, abdominal and dyspeptic syndromes. At the same time, the endoscopic and morphological data analysis has revealed a severe gastritis with the development of pangastritis and signs of gastric mucosa atrophy observed mainly in the antral region, in patients with co-infection (highly pathogenic strains of Hp + VEB). In addition, by correlation analysis, we found that the increase and development of the inflammatory process in the gastric mucosa was mostly influenced by the presence of CagA-positive strains of *H. pylori* in combination with EBV. We found that children infected by EBV without highly pathogenic Hp strains had mild mononuclear and polymorphonuclear cell infiltration without atrophy.

Conclusion: Co-infection with highly pathogenic Hp strains and the Epstein-Barr virus in pediatric patients is significantly associated with severe gastritis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0644 *HELICOBACTER PYLORI* INFECTION AND SPECIFIC IMMUNOGLOBULIN E ANTIBODIES TO FOOD ALLERGENS IN SYMPTOMATIC CHILDREN ADMITTED IN A DIGESTIVE ENDOSCOPY UNIT

V. Hurduc, B. Luiza, P. Doina

Pediatric Gastroenterology, Victor Gomoiu Clinical Children Hospital, "Carol Davila" University of Medicine and Pharmacy, Bucharest/Romania

Contact E-mail Address: v_hurduc@yahoo.com

Introduction: *Helicobacter pylori* is one of the most widespread bacterial infections worldwide, therefore nowadays its prevalence was decreasing, mostly in developed countries. There are some studies which support that *H. pylori* could favor the development of food allergy.

Aims & Methods: To assess the relationship between *H. pylori* infection and specific immunoglobulin E (Ig E) antibodies to food allergens in symptomatic children. We conducted a prospective study of 394 symptomatic children (249 girls, age range 6 months-18 years), mostly with uninvestigated dyspepsia requiring an endoscopic evaluation in our unit, from January 2015 to December 2016. All patients were evaluated for *H. pylori* infection by at least two standard invasive tests and for specific immunoglobulin E antibodies to major food allergens (R-biopharm, Germany). The nutritional status of patients was assessed in all cases by the new World Health Organization (WHO, 2007) growth charts. EPI-INFO version 7 was used for statistical analysis. A two sided p-value less than 0.05 was considered statistically significant.

Results: Active *H. pylori* infection was documented in 246 (62.3%) cases. The allergic sensitization to at least one of the food allergens was identified in 134 of 394 patients (34%). The majority of Ig E positive children (109 of 134 cases; 81.3%) were positive for cow's milk followed by egg (17.9%), wheat (7.46%), peanut (4.5%), soybean (3.73%). The allergic sensitization to food allergens was associated with abnormal levels of specific Ig E antibodies to common inhalatory allergens in 55 of 134 cases (41.04%). Regarding the association of *H. pylori* infection with an elevated serum Ig E level to at least one of the food allergens tested, there was no significant correlation ($p = 0.14$). 77 of 134 (31.30%) patients positive for food specific Ig E antibodies were *H. pylori* infected and 57 of them (38.55%) were *H. pylori* negative (Fisher exact test = 0.08). The assessment of the patients nutritional profile in relationship with *H. pylori* infection and food allergy not revealed a statistically significant effect on the two ends of the poor nutritional status (undernutrition and overnutrition).

Conclusion: The recent decline of *H. pylori* infection is not evident in our study. There was no association between *H. pylori* infection and Ig E mediated food allergy. Undernutrition and overnutrition were not associated with the *H. pylori* infection and food allergy in our patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0645 CURRENT STATUS OF THE FIRST AND SECOND LINE THERAPY FOR *HELICOBACTER PYLORI* INFECTION IN SYMPTOMATIC CHILDREN: A SINGLE CENTER STUDY

V. Hurduc, B. Luiza, P. Doina

Pediatric Gastroenterology, Victor Gomoiu Clinical Children Hospital, "Carol Davila" University of Medicine and Pharmacy, Bucharest/Romania

Contact E-mail Address: v_hurduc@yahoo.com

Introduction: Current evidence suggests the decline of the eradication rates of *H. pylori* in children treated with standard first line therapy, partly determined by its antibiotic resistance.

Aims & Methods: To evaluate the effectiveness of current first and second-line therapy recommendations for *H. pylori* eradication in children. We conducted a prospective open-label study of 158 symptomatic children (age range 6 months-18 years; 106 girls) who required a first upper digestive endoscopy over the past year. Active *H. pylori* infection was documented in 122 of the 158 investigated children (77.2%). Infected children were randomly assigned to receive either a 7-14 days standard empiric triple therapy consisting of esomeprazole (ESO) plus amoxicillin (AMO) and clarithromycin (CLA) or metronidazole (MET), either a sequential therapy for 10-14 days. Bismuth salts are not easily available in our country. Eradication efficacy was assessed by follow-up endoscopy 4-8 weeks after the end of anti-*H. pylori* therapy by at least two different invasive tests. In patients failing to be cured through the first treatment a second alternative was applied (a triple therapy based on quinolones or metronidazole either sequential therapy) associated with antibiotic susceptibility testing. The primary and secondary outcomes were the rate of *H. pylori* eradication after the first and second line therapy, by intention to treat (ITT) and per-protocol (PP) analysis. Statistical analysis was performed with EPI INFO 7. The differences between eradication rates were analysed by χ^2 test and the Odds Ratio ($p < 0.005$ was considered statistically significant).

Results: Patients with *H. pylori* infection were treated with an initial empiric first line standard therapy ($n = 52$) or a sequential therapy ($n = 70$). Of the 122 children, 9 patients were lost to follow-up (7.38%). Overall *H. pylori* was eradicated in 87/122 children (71.32% for ITT analysis versus 76.99% for PP analysis). The first eradication rates were significantly higher using the sequential therapy (55/70 cases; 78.57% for ITT analysis and 55/64 cases; 85.93% for PP analysis) compared with standard first line triple therapy (32/52 cases; 61.53% for ITT analysis and 32/49 cases; 65.30% for PP analysis). The ITT and the PP eradication rates were significantly higher with sequential treatment (OR = 0.43; 95% CI: 0.19-0.97; $p = 0.04$; $\chi^2 = 3.43$; $p = 0.06$ for ITT analysis and OR = 0.30; 95% CI: 0.12-0.77; $p = 0.013$; $\chi^2 = 5.55$; $p = 0.01$ for PP analysis). A second-line therapy was recommended in 26 of cases with an overall eradication rate of 80.76% (21/26 cases) for ITT analysis and respectively 87.5% (21/24 cases) for PP analysis. The choice of second line therapy was tailored by antimicrobial

susceptibility only in some cases (15/26 cases; 57.7%). The eradication rates for PP analysis were: 90% (9/10 cases) for triple therapy based on MET; 80% (8/9 cases) for triple therapy based on quinolones and 80% (4/5 cases) for sequential therapy.

Conclusion: This endoscopic series reveals a high rate of *H. pylori* infection (77.2%). The sequential therapy achieved a significantly higher rate of eradication than the standard empiric triple regimens regardless of using ITT (78.57% versus 61.53%) or PP (85.93% versus 65.30%) analysis. The eradication rates for the second-line therapy was significantly higher (87.5% for PP analysis) compared with the first-line empiric standard therapy (76.99% for PP analysis).

Introduction: Imbalanced gut microbiota is suggested to be involved in the pathogenesis of coeliac disease (CD). In many CD patients, despite a long-term treatment with a gluten-free diet (GFD), the intestinal dysbiosis is not completely restored. Prebiotics, substances of the unique ability to shape intestinal microbiota are promising, low-risk GFD supplement to remedy the intestinal dysbiosis in CD patients.

Aims & Methods: The aim of the present study was to assess the effect of prebiotic oligofructose-enriched inulin (OEI) administration on the quantitative gut microbiota characteristics of CD children following a strict GFD for ≥ 1 year. A randomized, placebo-controlled 12-weeks dietary intervention was conducted on 34 CD children (62 % female, mean age 10 years) on GFD who were randomly assigned to prebiotic (OEI; 10 g/day) or placebo group (maltodextrin; 7 g/day). Before (baseline) and after the intervention, the anthropometric (weight, height) and biochemical blood parameters (C-reactive protein, creatinine, aspartate aminotransferase, alanine aminotransferase), quantitative gut microbiota characteristics (by real-time PCR) and concentration of short-chain fatty acids (by gas chromatography with a flame ionization detector) were assessed.

Results: Thirty CD patients completed the study. After 12-weeks intervention, the biochemical blood parameters reminded normative in all CD patients, and the gut microbiota counts within each experimental group did not differ from their counts at baseline. However, in comparison with placebo group, Bifidobacterium counts was significantly ($p < 0.01$) higher in CD children consuming OEI-supplemented GFD. Moreover, the counts of *Clostridium leptum* group in children of prebiotic group did not show the decreasing tendency along with the time of GFD as it was observed in placebo group. These changes were reflected in total bacteria number after the intervention that was constant in prebiotic group but tended to fall in placebo group. Microbiota counts corresponded well with microbial metabolic activity. In comparison with placebo group, the concentration of short-chain fatty acids increased significantly in prebiotic group (50.27 vs. 69.95 $\mu\text{mol/g}$, $p < 0.05$), mainly due to a significantly higher acetate formation (28.82 vs. 44.06 $\mu\text{mol/g}$, $p < 0.05$).

Conclusion: A long-term administration of OEI in GFD prevents from a gut dysbiosis observed along with the duration of the GFD, and maintains a constant quantity of beneficial bifidobacteria. Moreover, the administered of OEI in GFD stimulates activity of gut microbiota observed as the increased SCFA formation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Treatment for celiac disease (CD) is a lifelong strict gluten-free diet (GFD). Patients should be followed-up with dietary interviews and serology as CD markers to ensure adherence to the diet. However, none of these methods

offer an accurate measure of dietary compliance. Presence of gluten related substances in faeces proves that transit through gastrointestinal tract happened and confirms gluten ingestion.

Aims & Methods: Detection of gluten immunogenic peptides (GIP) in stools as a marker of GFD adherence in CD paediatric patients was evaluated and compared against traditional methods of GFD monitoring.

A prospective, non-randomized, multi-centre follow-up study, 2 years long, including 64 CD patients started on GFD when diagnosed was conducted (age range 0–18 years).

Faecal GIP was quantified by enzyme-linked immunosorbent assay (ELISA). Anti-tissue transglutaminase (anti-tTG) IgA and anti-deamidated gliadin peptide (anti-DGP) IgA antibodies were measured simultaneously, during basal and follow-up visits at 0, 6, 12 and 24 months. Correlations between faecal GIP and serum antibodies were established by Cochran's and Friedman tests.

Results: 62 patients (97%) had detectable GIP levels in stools, during basal visit, before initiation of the GFD, whereas 20.3% of the patients were found to have positive GIP after treated with a GFD. Dietary transgressions were more frequent in children over 8 years of age. 46.1% of them showed more than one detected transgression. Anti-tTG IgA remained in high concentrations in 48, 34 and 20% of the patients at 6, 12 and 24 months of follow-up. Anti-DGP was positive in 13, 4.5 and 0% of cases when tested at 6, 12 and 24 months follow-up. Both serological methods did not correlate with GIP in stools ($p < 0.05$).

Conclusion: The GIP ELISA enabled direct and quantitative assessment of gluten exposure early after ingestion. Detection of GIP in stools revealed lack of accuracy of traditional serological methods to verify GFD compliance in CD paediatric patients. The antibodies can take several months or even years to decrease after initiation of the GFD and reduction (but incomplete suppression) of gluten intake appeared to be sufficient to decrease antibodies in sera. Faecal GIP could be a useful tool: 1) on the diagnosis of CD, to ensure that a sufficient amount of gluten has been ingested to allow a correct CD diagnosis. 2) on treatment, for monitoring of short-term and long-term GFD compliance. 3) on the differential diagnosis of unresponsive CD versus dietary non-compliance.

Introduction: There are sporadic reports of occurrence of intussusception in celiac disease but no systematic study yet. The prevalence and natural history of intussusception in children with celiac disease is not known.

Aims & Methods: We prospectively studied the prevalence and natural history of intussusception in newly diagnosed celiac disease in children. From January 2010 to October 2013, 150 children, diagnosed to have celiac disease on the basis of positive celiac serology (IgA tissue transglutaminase/anti-endomysial antibody) and duodenal biopsy showing villous atrophy, were prospectively recruited in this study. Abdominal ultrasonography was done before starting gluten-free diet and repeated in those who had intussusception, on day three and then weekly till the resolution of intussusception.

Results: A total 167 children were diagnosed to have new onset celiac disease during the study period. Out of them 150 were recruited in the study and 17 were excluded; 15 did not get an ultrasonography before starting gluten-free diet and two children were consuming gluten-free diet prior to presentation to our hospital. The median age of 150 children with celiac disease was 72 (range, 16–204) months and 79 (53%) were boys. Their median duration of symptoms was 18 months (range, 1–136 months). Diarrhea was presenting symptoms in 119 (79%) of cases. A total 45 intussusceptions were detected in 37 (24.7%) children. Majority (86.5%) had single intussusception and the most common site was ileo-ileal (46.7%), followed by jejuno-jejunal intussusception (40%). Out of 45 intussusceptions, 43(95%) involved small bowel. All but one had asymptomatic intussusception. On gluten-free diet, intussusception resolved spontaneously within 7 days in 24 (65%), within 14 days in 31 (84 %) and within 28 days in 34 (92%) cases, and none required surgical or hydrostatic reduction. On

univariate analysis, younger age, low weight z score, presentation with diarrhea, abdominal distension, rickets, lower serum albumin, more severe villous atrophy and refeeding syndrome were found to be significantly more common in children with intussusception as compared to children without intussusception. On multivariate analysis abdominal distension (Odds ratio: 3.9, 95% Confidence Interval: 1.3–11.9) and hypoalbuminemia (Odds ratio: 1.8, 95% Confidence Interval: 1.2–2.7) were found to be significantly associated with intussusception.

Conclusion: Intussusception is frequently (25%) seen in children with newly diagnosed celiac disease, generally asymptomatic and resolves spontaneously on gluten-free diet. It is often associated with more severe disease. As spontaneous resolution is the rule for intussusception in the setting of pediatric celiac disease, attempt for reduction (either surgical or hydrostatic) should be deferred unless indicated otherwise.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0651 META-ANALYSIS: PROTON PUMP INHIBITORS MODERATELY INCREASE THE RISK OF SMALL INTESTINAL BACTERIAL OVERGROWTH

T. Su, S. Chen

Department Of Gastroenterology, Sir Run Run Shaw Hospital, Zhejiang University, Institute of Gastroenterology, Zhejiang University, Hangzhou/China

Contact E-mail Address: 18770085122@163.com

Introduction: PPIs have become one of the most commonly prescribed classes of medications.¹ Although PPIs are generally well tolerated, accumulating evidence suggests that PPIs have long-term risks.² One potential risk of PPI use is development of small intestinal bacterial overgrowth (SIBO), which is defined as > 10⁵ bacteria colony-forming units (CFU) per mL upon culturing upper gut aspirates. However, this is controversial due to conflicting results from prior studies.^{3–8}

Aims & Methods: The aim of this meta-analysis was to evaluate the association between use of PPIs and the risk of SIBO. We systematically searched the online PubMed, Embase, Cochrane Library databases and Web of Science for relevant articles before November 2016. Two researchers identified and extracted data independently. The pooled analysis was performed using generic inverse-variance random-effects model. Subgroup and sensitivity analysis were conducted to assess the stability and heterogeneity of the pooled results. The risk of publication bias was evaluated by examining funnel plot asymmetry, Egger's test and Begg's test. All statistical analyses were performed using Stata software version 13.0.

Results: A total of nineteen articles met the eligibility criteria for the meta-analysis. The pooled odds ratio (OR) showed a statistically significant association between increased risk of SIBO and PPI use (OR = 1.71 95% CI:1.20–2.43). No statistically significant publication bias was found based on the Egger's test ($p = 0.149$) or Begg's test ($p = 0.115$). Furthermore, subgroup analyses demonstrated an association between SIBO and PPI use in studies that employed small bowel aspirates culture and glucose hydrogen breath tests (GHBT) as diagnostic tests for SIBO. However, when the pooled analysis was limited to studies recruiting irritable bowel syndrome (IBS) patients as study population, no statistically significant association between PPI use and SIBO was observed, which suggests that PPI use does not affect the risk of SIBO among IBS patients.

Conclusion: Our meta-analysis suggests that the use of PPI moderately increases the risk of SIBO, which highlights the need for appropriate prescription of PPIs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Nowadays food allergy continue to increase, especially in westernized countries and is now recognized as a worldwide problem. Transforming growth factor- β 1 (TGF- β 1) is a profibrotic cytokine, which plays an important role in promoting the structural changes in food allergy. Also for patients with food protein - induced enterocolitis syndrome TNF- α appears to have an important role.

Aims & Methods: The aim was to determine the significance of the Transforming Growth Factor - β 1 (TGF - β) and Tumor Necrosis Factor - α (TNF - α) in children with food protein induced enterocolitis syndrome. It was examined 38 patients with FPIES at the age from 4 months to 3 years, the average age was 19 ± 4 months. The control group consisted of 11 healthy children of the same age. The determination of TGF- β 1 and TNF - α in serum was performed by an enzyme-linked immunosorbent assay kits from Bender Medsystem (Austria).

Results: The level of TGF- β 1 in patients with FPIES exceeded the norm and was respectively 33.5 ± 1.6 ng/ml, at norm 20.2 ± 2.1 ng/ml, $p < 0.001$. The indices of TNF - α were also increased and amounted to 8.8 ± 1.3 ng/ml in comparison with the norm 4.2 ± 0.67 ng/ml $p < 0.001$. For our patients it was characterized by an increase in specific antibodies IgE to cow's milk in 18 (47.3%) children. In these cases disease was more severely with vivid clinical manifestations (indomitable vomiting, stool with blood, expressed weight deficit). Also among of patients in this group TGF- β 1 level was significantly higher than in the control group, amounting to $42, 01 \pm 7.5$ ng/ml. TNF - α indicators were also increased: 11 ± 1.2 ng/ml.

Conclusion: It is believed that TGF - β 1 inhibits allergic inflammation, but in our observations, an increase in its values was established, especially in the group of children with high specific IgE levels to cow's milk. It is likely that an increase in TGF - β 1 stimulates the release of TNF - α , which supports chronic inflammation in allergic diseases.

Introduction: Newborns' birth weight is influenced by maternal factors (mother's weight at the onset of pregnancy, gestational weight gain - GWG), genetic, obstetrical and environmental factors, but also socio-economical ones. Excessive GWG, mother's increased BMI and the adipose tissue mass determine a bigger birth weight and increase the risk of newborns' obesity. Glutathione S-transferases (GSTs) is an oxidative stress-related gene which is associated with and ist complications.

Aims & Methods: The aim of the study was to investigate the role of mother-child GTS1 and GTM1 polymorphisms as independent risk factors for newborn's weight, but also to establish correlations between these polymorphisms and anthropometrical parameters, and bioimpedance (BIA) ones, respectively. We assessed the anthropometrical parameters in both mothers and their newborns (BMI- body mass index, MUAC - medium upper arm circumference, TST - tricipital skin thickness, weight - W), BIA parameters in mothers, but we also determined the clinical, paraclinical and genetic parameters in both mothers and newborns.

Methods: We performed a cross-sectional study on 202 mothers and their newborns in a Clinic of neonatology & Gynecology and Obstetrics from Romania.

Results: We noticed that in newborns with $W > 3000$ gr there was a significant statistical correlation between weight and mother's GST1 polymorphism ($p = 0.046$), birth at term ($p < 0.001$), with mother's percentage of fat mass assessed by BIA ($p < 0.001$), and multi parity, respectively ($p < 0.001$). We obtained a tendency towards correlations between $W > 3000$ gr and basal metabolism rate ($p = 0.063$), and GWG seemed to be a protective factor for this W ($p = 0.072$). We also found that GSM1 in newborns was a risk factor with tendency towards statistical significance in newborns with increased birth weight. We did not find any interaction effect between newborns' and mothers' GST1

and GSM1 polymorphisms and anthropometrical parameters ($p = 0.545$ for MUAC, and 0.664 for TST), or paraclinical parameters.

Conclusion: Mother's GSTM1 is an independent risk factor for newborns' $W > 3000$ gr, while mother's GWG seems to be a protective factor for $W > 3000$ gr. Further studies are needed in order to determine the clear role of this polymorphisms in newborns' obesity risk. This research was supported by the Research Grants of the University of Medicine and Pharmacy Tirgu Mures, Romania - "The role of genetic determinism of the mother in child's obesity correlated with measurements of bioimpedance and anthropometry" no.275/4/11.01.2017.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0654 SARCOPENIA IN CHILDREN WITH INTESTINAL TRANSPLANTATION

R. Hegarty, J. Hind, D. Thangarajah

Paediatric Liver, GI And Nutrition Centre, King's College Hospital, London/ United Kingdom

Contact E-mail Address: anthiburt@gmail.com

Introduction: Deficits in lean mass and muscle measures are well described in children with chronic disease e.g. childhood inflammatory bowel disease[1]. Sarcopenia is a poor prognostic biomarker in adults with advanced cancer, liver transplantation and in children with acute lymphoblastic leukaemia [2–4]. Psoas muscle cross sectional area (PCA) has been shown to correlate with whole body muscle mass and can be measured from axial imaging [5]. Little is known about sarcopenia in children with intestinal transplantation (IT). Sarcopenia is a poor prognostic biomarker in adults with advanced cancer, liver transplantation and in children with acute lymphoblastic leukaemia. Psoas muscle cross sectional area (PCA) has been shown to correlate with whole body muscle mass and can be measured from axial imaging [5]. Little is known about sarcopenia in children with intestinal transplantation (IT).

Aims & Methods: The primary objective was to determine whether children who had IT show differences in total PCA when compared to healthy controls. The secondary objective was to investigate association of PCA and survival after IT. A retrospective, case note review of children who had IT at a single centre since inception in 2009 to May 2016. Controls were identified from abdominal trauma series. Total PCA (mm²) was measured using direct techniques of magnetic resonance imaging or computed tomography at the level of the anterior superior iliac spine. To correct for body size, PCA index was derived for all subjects: PCA divided by height. PCA index was then described according to outcome. Statistical analysis was carried out using Social Sciences (SPSS) version 23.

Results: 16 patients (9 male) underwent IT at our centre. Post-transplant axial imaging was available for 12(6 males), median age 6.2[3.6 to 12.9] years patients in whom the diagnoses (n): Chronic intestinal pseudo-obstruction(3), gastroschisis(3), intestinal ischaemia(1), intestinal lymphangiectasia (1), volvulus (1), progressive familial intrahepatic cholestasis (1), Hirschsprung's disease (1) and intestinal failure of indeterminate aetiology(1). One patient was excluded from analysis as she was a bilateral amputee. Children who had IT had a significantly lower PCA and PCA index than controls; median PCA index ($\times 10^{-3}$ mm²) [IQR] in IT vs controls; 4.71[3.68 to 6.10] vs 9.55 [8.44 to 11.33], $p < 0.05$. There was a trend toward higher PCA index in those who survived (n = 9) compared to those who did not (2).

Conclusion: Children who underwent IT had sarcopenia of the psoas muscle in comparison to healthy controls. In IT patients who died there was a trend toward psoas muscle sarcopenia. This study adds to the evidence that body core muscle is consistently deficient in children with chronic disease and is the first to comment on children with IT. This small study provides the basis to develop PCA as a prognostic marker in children with transplantation.

Introduction: Primary lactose intolerance (PLI) is a frequent condition caused by a genetically programmed and progressive loss of lactase expression. It is considered that PLI is the ancestral variant, while lactase persistence is caused by 2 polymorphisms: the dominant C/T13910 and G/A22018. Homozygotes (CC or GG) have undetectable lactase levels. In clinical practice only half of people with PLI have symptoms. However, some studies showed that PLI subjects have lower dairy intake.

Aims & Methods: To investigate whether genetic predisposition to PLI influences the quality of life and dairy intake in a group of Romanian children. We conducted a prospective study, recruiting consecutive children evaluated in our unit in May-August 2016. Our study population included 87 children aged 6–17 years (mean age 10.64 ± 3.51 years), 45 (51.72%) girls. We used strip genotyping to identify genetic predisposition to IPL. Subjects were asked to complete a validated quality of life questionnaire and a dairy intake questionnaire. We used Spearman's test to evaluate the correlation between IPL and quality of life and dairy intake.

Results: (51.7%) subjects had a CC genotype. 30 (34.5%) subjects had a GG genotype. Our results were consistent with Hardy-Weinberg equilibrium. We found no correlation between homozygosity for PLI and dairy intake (CC: $r = -0.06$, $p = 0.54$; GG: $r = -0.01$, $p = 0.86$). We found no correlation between either CC, or GG homozygosity and quality of life ($r = -0.11$, $p = 0.3$ and $r = -0.1$, $p = 0.34$).

Conclusion: In our group genetic predisposition to IPL followed European trends. It did not influence quality of life and dairy intake.

Introduction: CUX1 (CUTL1) is a transcription factor belonging to homeobox proteins. It is responsible of driving the transcription of genes deputed to many cellular functions like proliferation, differentiation and cell death. It has been shown that its role can change and drive tumorigenesis. Up to now, its role is unknown in hepatic stellate cells. W

Aims & Methods: We focused on CUX1 activity in hepatic stellate cells undergoing hypoxic stress. LX-2 cells were treated with 100 ng/ml CoCl₂ or kept at 37°C at low oxygen (<0.5%). Expression of hypoxia markers and activation markers was performed by RT-qPCR. Western blotting was performed to analyze the protein level of CUX1 and HIF1α. Transfection with plasmid containing a promoter sequence for HIF1α was performed simultaneously with CUX1 knock-down.

Results: LX-2 cells treated for 6 hours with CoCl₂ or low oxygen showed an over-expression or a restoration of COL1A1 and ACTA2 after knock down of CUX1. Additionally, CDKN1A, CDKN1B, VEGFA and HIF1α were up-regulated in LX-2 cells previously transfected with siCUX1. Protein level of CUX1 was significantly down-regulated, whereas HIF1α protein was strongly up-regulated by hypoxia condition. Transcriptional activity of HIF1α is not correlated with CUX1 expression.

Conclusion: CUX1 controls the activation of hepatic stellate cells. Its knock down promotes the hypoxia response. CUX1 could represent a key factor for

controlling liver fibrogenesis. Its role in a liver fibrosis scenario needs to be further investigated.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0657 HEPATIC FIBROBLAST GROWTH FACTOR-21 AND OMENTIN-1 MRNA LEVELS IN MORBIDLY OBESE WOMEN WITH NON-ALCOHOLIC FATTY LIVER DISEASE

Introduction: Fibroblast growth factor-21 (FGF21) and omentin-1 have been recognized as potent antidiabetic agents, with potential hepatoprotective activity. **Aims & Methods:** The aim of this study was to evaluate hepatic FGF21 and omentin-1 mRNA expression, and their serum levels as predictive markers of liver injury and insulin resistance in morbidly obese women with NAFLD. The study included 56 severely obese women who underwent intraoperative wedge liver biopsy during the bariatric surgery. Hepatic FGF21 and omentin-1 mRNA was assessed by quantitative real-time PCR, while their serum concentration with commercially available enzyme-linked immunosorbent assays.

Results: FGF21 serum level was significantly higher in patients with more extent steatosis (grade 2 and 3) compared to those without or with mild steatosis (grade 0 and 1) ($p = 0.049$). However, ROC analysis showed poor discriminant power for FGF21 serum level in differentiation between more and less extensive steatosis with AUC = 0.666. There was evident tendency to higher levels of hepatic FGF21 mRNA in patients with lobular inflammation and fibrosis, and to lower levels in the case of ballooning degeneration and steatosis. There was positive mutual correlation between hepatic FGF21 and omentin-1 mRNA levels ($r = 0.73$; $p < 0.001$). Fibrosis stage was associated with serum glucose and HOMA-IR ($p = 0.03$ and $p = 0.02$, respectively). Serum omentin was not associated with histopathological features. Hepatic omentin-1 mRNA levels exerted the tendency to be lower in patients with advanced steatosis and hepatocyte ballooning.

Conclusion: In conclusion our study, which focused on hepatic FGF21 and omentin-1 mRNA expression, confirmed a marked expression of both molecules in the liver of morbidly obese patients with NAFLD. mRNA levels were affected by histopathological abnormalities. More extent steatosis was associated with evident change in serum FGF21 concentration in morbidly obese women with NAFLD. The vast amount of fat, both visceral and subcutaneous in severely obese patients may affect FGF21 and omentin-1 serum levels.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0658 LOUREIRIN B INHIBITS THE PROLIFERATION OF HEPATIC STELLATE CELLS VIA DOWN-REGULATING FRIZZLED-4

Z.

Dept. Of Gastroenterology, First Peoples Hospital, Kunming/China

Contact E-mail Address: song4715@163.com

Introduction: Liver fibrosis is the result of repeated healing repair and interstitial reconstruction after chronic liver injury. Activation of hepatic stellate cells represents a critical event in fibrosis because these cells become the primary source of extracellular matrix in liver upon injury. Inhibiting HSCs' activation, proliferation, extracellular matrix production and promoting HSCs' apoptosis are the important therapeutic approaches of liver fibrosis.

Aims & Methods: We aimed to investigate the anti-liver fibrosis ability of louriirin B and the molecular mechanisms involved it. After hepatic stellate cells

(HSCs), which were separated from Sprague-Dawley rat, were treated with different concentrations of lousirin B, MTT assay was employed to determine HSCs proliferation, western blot were used to test the expressions of Frizzled-4 receptor protein and α -SMA. In addition, enzyme-linked immunosorbent assay (ELISA) was performed to measure the content of α -SMA, TGF- β 1 and VEGF in the cultured HSCs' supernatant, and reverse-transcription PCR (RT-PCR) were utilized to detect the expressions of Frizzled-4 and α -SMA genes.

Results: MTT test showed that the proliferation of HSCs was inhibited significantly with a time and dose dependent relationship by the treatment of lousirin B with the half maximal inhibitory concentrations of 0.180 μ g/ μ L (IC_{50} = 0.180 μ g/ μ L). Western blot analysis showed that the expressions of Wnt receptor Frizzled-4 protein and α -SMA were obviously lower in the group of lousirin B treatment than that in the control group. Moreover, the Loureirin B also inhibited α -SMA ($p < 0.01$), TGF β 1 ($p < 0.01$) and VEGF ($p < 0.05$) secretion in the cultured HSCs' supernatant in different degree by the ELISA assay, and RT-PCR results revealed that Loureirin B down-regulated the expressions of Frizzled-4 and α -SMA genes in the level of mRNA.

Conclusion: CONCLUSIONS: The Loureirin B mediated anti-hepatic fibrosis by inhibiting the proliferation of HSCs through restraining the Wnt signaling pathway.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Macrophages play a pivotal role in the pathogenesis of non-alcoholic steatohepatitis (NASH) and are a major component of inflammatory cells infiltrated in NASH. However, the precise mechanism of how macrophages contribute to the pathogenesis of NASH remains unexplored.

Aims & Methods: We aimed to characterize the role and molecular regulators of macrophages in NASH and the therapeutic effects of macrophage depletion on NASH. C57BL/6 wildtype (WT) mice and transgenic *LysM-Cre/DTR* mice were fed with methionine-and-choline-deficient (MCD) diet for 5 weeks to induce steatohepatitis. Hepatic macrophages were depleted in WT mice by injecting liposomal clodronate (i.p. 50 mg/kg/week) and in *LysM-Cre/DTR* mice by injecting diphtheria-toxin (DTox) (i.p. 100 ng/mice). Primary macrophages were isolated from bone marrow of WT mice. For the *in vitro* study, mouse immortalized hepatocytes AML-12 were cultured with primary macrophage conditioned medium and mouse primary macrophages were cultured with AML-12 hepatocytes conditioned medium to evaluate the interaction between macrophages and hepatocytes in steatohepatitis. A series of assays including cytokine profiling assay, DNA binding activity, flow cytometry and Western blot were performed.

Results: Hepatic macrophage marker CD68 expression was significantly higher in human NASH patients compared with normal controls ($P < 0.001$). Steatohepatitis was established in WT mice and *LysM-Cre/DTR* mice fed MCD diet, concomitant with significantly enhanced hepatic macrophage infiltration as indicated by F4/80 staining. Macrophage depletion by liposomal clodronate or DTox attenuated steatohepatitis in both animal models. This was also associated with reduced hepatic necroinflammation, oxidative stress, hepatic triglyceride accumulation, and secretion of pro-inflammatory cytokines in both liposomal clodronate-treated WT mice and DTox-treated *LysM-Cre/DTR* mice as compared to the corresponding control mice. Macrophage depletion was also accompanied by the reduction of neutrophils, which together can reduce inflammation. Upregulated macrophages were associated with the increased expression of hepatic pro-inflammatory cytokines including interleukin (IL)-1 α , IL-1 β , IL-12, IL-17, Granulocyte-macrophage colony-stimulating factor, Monocyte chemoattractant protein-1 (MCP-1) and macrophage inflammatory protein 1 α (MIP-1 α), and the activation of NF- κ B and JNK signaling pathways in the liver. Macrophage-induced steatosis was mediated by increased hepatic lipogenesis through inducing liver X receptors (LXR α and LXR β), sterol regulatory element binding protein-1c and carbohydrate-responsive element-binding protein. Moreover, autophagy deficiency and endoplasmic reticulum (ER) stress were involved in macrophage-induced steatohepatitis as indicated by p62/SQSTM1 accumulation and increased GRP78 and p-IRE1 α expression. For the *in vitro* study, macrophage conditioned medium significantly promoted lipid accumulation in AML-12 hepatocytes. On the other hand, MCD-cultured hepatocytes medium promoted primary macrophage polarization to M1 phenotype as well as the production of pro-inflammatory cytokines (TNF- α and MCP-1).

Conclusion: We demonstrated that macrophages contribute to the progression of NASH through promoting inflammation, lipogenesis, autophagy impairment, ER stress and also through a crosstalk with hepatocytes. Similarly, macrophage

depletion has mitigation effects on NASH and may provide a potential treatment approach of steatohepatitis.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is considered the hepatic manifestation of metabolic syndrome, with simple liver steatosis being capable of gradually progressing to inflammation, fibrosis, cirrhosis and even hepatocellular carcinoma. Still, disease pathogenesis is complex and no targeted therapies have yet been approved for NAFLD. Bile acids (BAs) constitute a wide class of steroid molecules with pleiotropic functions, contributing to the homeostasis of lipids and glucose. In the liver, they specifically modulate nuclear receptors from the NR1 subfamily, such as Farnesoid X Receptor (FXR) and Liver X Receptor (LXR), thus tightly regulating bile acid synthesis and oxidation and storage of triglycerides.

Aims & Methods: Our aim was to screen BA derivatives for their potential to selectively activate FXR, thus protecting liver cells against free fatty acid (FFA)-induced lipid accumulation and lipotoxicity. Nineteen novel BA derivatives were analyzed by *in silico* molecular docking studies for FXR binding affinity, further evaluated in human cells using a FXR reporter assay. Assessment of FXR-dependent gene and protein expression was analyzed upon incubation of primary mouse hepatocytes and HepG2 cells with selected BA derivatives. In parallel, BA derivatives were co-incubated with oleic and palmitic acids (2:1) for assessment of cellular cytotoxicity and intracellular lipid accumulation.

Results: From the compound library, five BA derivatives showed stronger activation of FXR, comparing with their natural precursors. Incubation of HepG2 cells with FFAs led to a ~25% reduction in cell viability and ~35% increase in cell death, with a dose-dependent accumulation of lipid droplets. Pre-incubation of cells with selected derivatives efficiently prevented FFA-induced cell death and lipid accumulation. Finally, incubation of both HepG2 cells and primary mouse hepatocytes with BA derivatives strongly induced FXR, RXR, SHP, BSEP, FGF19 and VLDLR mRNA levels, and repressed PARP1, LXR, SREBP1-c and CYP7a1 mRNA expression. Molecular docking studies and FXR reporter assays confirmed ligand affinity to FXR. Furthermore, chenodeoxycholic acid (CDCA)-based derivatives were potent activators of FXR at lower concentrations comparing with the parent molecule.

Conclusion: In conclusion, we identified novel BA derivatives that directly modulate liver nuclear receptors, such as FXR and LXR, thus protecting liver cells against lipotoxicity and preventing FFA accumulation. These new molecules may be used as scaffolds for the development of targeted therapies for NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: NAFLD is currently classified in non-alcoholic fatty liver (NAFL) and non-alcoholic steatohepatitis (NASH). It is a liver disease related to metabolic syndrome with rising socio-economic impact worldwide. NAFLD is defined by significant lipid deposition in hepatocytes that is unrelated to alcohol consumption. This high prevalence of liver disease occurs after a protracted inflammatory status caused by insulin resistance derived from high consumption of fructose-rich goods as shown by the multi-parallel hit theory. Autophagy is a self-digesting mechanism that helps the cells to overcome stress conditions derived by nutrient deprivation and massive storage, e.g. lipid and proteins. Autophagy dysfunction has been implicated in lipid accumulation related diseases. Up to now, it is not fully understood the role exerted by autophagy in liver diseases not related to alcohol.

Aims & Methods: Here, autophagy has been analyzed in a mouse model of NAFL/NASH and in human *in vitro* model. Liver specimens were collected from 24 weeks old FLS and FLS-ob/ob mice. Liver tissue was snap frozen and kept at -80°C. RNA and proteins were isolated. RT-qPCR and western blotting was performed. HepG2 cells were incubated for 24h with 2 mM oleic acid (OA)

alone and in combination with 100 pM Bafilomycin and 2 mM Caffeine. RT-qPCR and western blotting was performed also. Real time fluorescence monitoring of HepG2 cells stably expressing ectopic MAP1LC3B-GFP-RFP-tag was performed with Incucyte.

Results: FLS-ob/ob mice, representing a NASH mouse model, showed an over-expression of the autophagy markers BECN1, MAP1LC3B, SQSTM, UVRAG, TFEB, PRKAA 1_1 and PRKAA 2_1 in comparison with FLS mice that represent the NAFL model. Furthermore, the protein level of BECN1 and MAP1LC3B was down-regulated in FLS-ob/ob mice, whereas SQSTM and UVRAG resulted over-expressed. Interestingly, the phosphorylated form of AMPK α was found up-regulated in FLS-ob/ob mice, while FLS mice did not show a quantifiable expression of P-AMPK α . AMPK α was found stably expressed in both FLS-ob/ob and FLS mice. HepG2 cells treated with oleic acid showed a down-regulation of BECN1, MAP1LC3B, UVRAG and SQSTM proteins. AMPK α and its phosphorylated form resulted unvaried. Interestingly, Caffeine treatment caused a stronger reduction of autophagy markers, including the reduction of P-AMPK α also. The combination of Caffeine and OA had an additive effect compared to single compounds by causing a stronger reduction of autophagy markers protein level. Bafilomycin caused a reduction of MAP1LC3B and UVRAG only. Its combination with OA caused a stronger reduction of protein level. HepG2 MAP1LC3B-GFP-RFP showed an increase of red fluorescence after 48 h of treatment with 2 mM OA.

Conclusion: Autophagy mechanism is significantly activated in FLS-ob/ob mice, that lack of Leptin expression, and in HepG2 treated with OA, supporting that autophagy is strongly implicated in NASH. Targeting autophagy could represent a valid future therapeutic strategy for patients affected by NASH. Further studies are needed to better understand the role exerted by Leptin during autophagy in NASH.

Introduction: Non-alcoholic fatty liver disease (NAFLD) pathogenesis associates with intracellular lipid accumulation in the liver. In addition, recent evidence supports a functional role for both mitochondrial dysfunction and microRNAs (miRNA/miRs) in NAFLD pathogenesis. In particular, deregulation of mitochondrial dynamics proteins, like mitofusin-2 (Mfn2) is frequently observed in obese and diabetic patients.

Aims & Methods: Our aims were to profile global liver miRNA expression changes during NAFLD progression and correlate them with the development of mitochondrial dysfunction in both experimental and human NAFLD. C57BL6 mice were fed either a standard or a fast food (FF) diet for 25 weeks; or a methionine- and choline-deficient (MCD) diet for 2 and 8 weeks. miRNA profiling was performed using liver RNA from 8 weeks MCD-fed mice, in TaqMan MicroRNA arrays. qPCR array data was analyzed using the HTqPCR package in Bioconductor. Liver biopsies were obtained from patients with simple steatosis or NASH. mRNA and protein expressions were analyzed by qRT-PCR and immunoblotting, respectively. miRNA targeting was evaluated by dual-luciferase reporter assays.

Results: Both FF- and MCD-fed mice developed NASH-like features, including liver steatosis, inflammation and insulin resistance; as well as progressive steatohepatitis, severe liver damage and fibrosis. Strikingly, liver Mfn2 protein levels significantly decreased in both models ($p < 0.05$). Inversely, expression of Drp1, a mitochondrial fission protein, was found increased ($p < 0.05$). Other mitochondrial proteins, such as the voltage-dependent anion channel (VDAC), presented no expression changes. In human patients, Mfn2 protein levels decreased from steatosis to NASH ($p < 0.05$). Microarray profiling indicated that liver miRNAs are significantly modulated during NAFLD progression. Specifically, 25 miRNAs were found significantly increased in the liver of MCD-fed mice, while, inversely, 27 miRNAs were decreased. Curiously, in silico analysis revealed that several of the up-regulated miRNAs could target Mfn2 in, at least, one Mfn2 3'UTR binding site. Binding of miRNAs to Mfn2, including miR-34a, was validated in HepG2 cells using a dual-luciferase reporter vector containing the Mfn2 3'UTR. Finally, overexpression of miR-34a in C2C12 muscle cells lead to Mfn2 inhibition and insulin resistance ($p < 0.05$).

Conclusion: In conclusion, mitochondrial dysfunction, particularly downregulation of Mfn2, plays a key role in human and experimental NAFLD and is targeted by miRNAs, like miR-34a. A better understanding of the network of miRNAs targeting mitochondrial proteins during NAFLD may help in the development of novel targeted therapies for metabolic diseases associated with mitochondrial dynamics dysfunction. (Supported by PTDC/BIM-MEC/0895/2014, SFRH/BD/104160/2014, FCT, PT and Gilead Sciences International Research Scholars Program 2015).

P0663 GRANULOCYTE COLONY STIMULATING FACTOR IN DECOMPENSATED LIVER DISEASE - OUR EXPERIENCE IN A TERTIARY HOSPITAL IN NEPAL

S. Thapaliya

Department Of Gastroenterology, Tribhuvan University Teaching Hospital, Institute of Medicine, Maharajgunj, Kathmandu/Nepal

Contact E-mail Address: sabinthapaliya@gmail.com

Introduction: Alcoholic Hepatitis, Decompensated Chronic Liver Disease and Acute-on-Chronic Liver Failure form a bulk of in-patients in Nepal. Mortality is quite high in these presentations despite all the medications currently available in our country. Prednisolone and Pentoxifylline are not up to the mark in terms of both short and long-term outcomes¹. The only option that remains is liver transplant, which is not readily available in our country, and even if available in the near future, needs at least some months for planning and preparation and is costly. G-CSF (Granulocyte Colony Stimulating Factor) has shown both morbidity and mortality benefit in some studies in these groups of patients^{2, 3, 4}. By comparing the outcomes in those receiving and not receiving G-CSF, we can suggest G-CSF therapy to reduce mortality and morbidity in these patients. Although most of the studies done in the role of G-CSF in ACLF (Acute-on-Chronic Liver failure) and decompensated CLD (Chronic Liver Disease) have used 5µg/Kg/dose of G-CSF subcutaneously for ≥ 10 doses², our study has used fixed dosage of 300µg of G-CSF subcutaneously twice a day for a total of 3 days (6 doses).

Aims & Methods: We aimed to study the role of G-CSF in the treatment of alcoholic hepatitis, Decompensated CLD and ACLF. From January 2016 to December 26, a total 49 patients with alcoholic hepatitis, decompensated chronic liver disease and acute-on-chronic liver failure admitted in TUTH (Tribhuvan University Teaching Hospital) were studied. Patients were randomized (in a 1:1 ratio) to either the 'GCSF + SMT' (Standard Medical Therapy) group (cases) or the 'SMT-alone' (control) group according to computer-generated random numbers. Patients in G-CSF group received G-CSF 300µg twice daily for 3 days (total 6 doses). Mortality rates at 1 month and CTP (Child Turcotte Pugh) and MELD (Model for End stage Liver Disease) scores at enrollment and at Day 30 were compared in the two groups.

Results: A total of 49 patients [median age: 49 (range: 27–73) years, 70% males] were included in the study. 24 of them received G-CSF along with SMT and 25 received SMT alone. Baseline characteristics were similar in both the groups. The 3-day GCSF therapy did not lead to any significant adverse effects. At one month, in GCSF + SMT group, 4 had died whereas in SMT alone group 15 had died. 83% survived in GCSF group whereas only 40% survived in control group ($P = .002$). Also significant improvement in CTP and MELD scores was seen in the group treated with GCSF at one month after therapy. Also, there were fewer complications of sepsis, hepatic encephalopathy and renal impairment in the GCSF group compared to the SMT alone group.

Conclusion: GCSF therapy improves survival and clinical outcome in patients with alcoholic hepatitis, decompensated chronic liver disease and acute-on-chronic liver failure. It may be useful in patients who do not have access to transplant services and also to the patients awaiting transplantation to prevent worsening during the waiting period. Further studies are needed to explore whether lower doses (total 6 doses) of GCSF are as effective as higher doses (total 10 doses).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cirrhosis and its complications are common causes of death among patients with end-stage liver disease. Liver transplantation as a definitive treatment is limited by shortage of donors and high cost. Autologous bone marrow

mononuclear layer containing stem cells is a novel approach for regeneration of liver cell which can be a therapeutic option for those patients.

Aims & Methods: To determine the outcome after intrasplenic or intrahepatic injection of autologous bone marrow stem cells (ABMSC) transplantation in patients with liver cell failure secondary to chronic hepatitis C infection. Sixty chronic hepatitis C patients with liver cell failure were prospectively enrolled. They were classified into 3 groups; group I: 20 patients underwent (ABMSC) injected intrasplenic. Group Ia: 10 patients underwent (ABMSC) injected intrasplenic after trans differentiation into hepatocytes with regular amount of growth factor. Group Ib: 10 patients underwent (ABMSC) injected intrasplenic after trans differentiation into hepatocytes with the double amount of growth factor. Group II: consisted of 20 patients underwent (ABMSC) injected intra hepatic (right portal branch). Group IIa: 10 patients underwent (ABMSC) injected intrahepatic after trans differentiation into hepatocytes using regular amount of growth factor. Group IIb: 10 patients underwent (ABMSC) injected intrahepatic; after trans differentiation into hepatocytes with the double amount of growth factor. Group III: (Control Group): consisted of 20 patients received traditional supportive treatment for chronic liver cell failure and symptomatic treatment of ascites and bleeding abnormalities. All groups of patients were followed regularly for nine months clinically, biochemically and ultrasonographically. Fatigue was assessed by the modified fatigue impact scale questionnaire before, during and at end of the study.

Results: Our study included 60 patients (78.33% males) with mean age \pm SD (49.9 \pm 6 years). Patients who had ABMSC injection showed improvement in clinical parameters as bleeding tendency, ascites, lower limb edema and hepatic encephalopathy. There was statistically significant improvement in serum albumin level and prothrombin time in group I and group II in comparison group III. There was also statistically significant improvement in Child-Turcotte-Pugh in group I and group II in comparison group III at the third month and this was maintained till the end of the study. Fatigue improved in all patients who had ABMSC. There was improvement in serum albumin, ascites, lower limb edema, bleeding tendency and physical activity. Also there was improvement in MELD score and performance status.

Conclusion: Stem cell transplantation has a beneficial effect on synthetic functions of the liver and possibly improves survival and quality of life of patients with end stage liver disease. Autologous bone marrow transplantation is safe and beneficial technique in treatment of in patients with liver cell failure secondary to chronic hepatitis C infection.

Introduction: It is well known that severe liver disease requires a liver transplantation to be treated. But liver transplantation is not available in many countries. An alternative treatment can be a transplantation of autologous bone marrow derived cells which can stimulate liver regeneration. Proliferating cell nuclear antigen (PCNA) shows nuclei of dividing cells and may be useful for calculating proliferation index.

Aims & Methods: The aim of this study was to evaluate changes of proliferation intensity of liver cells in patients with alcoholic liver cirrhosis after autologous peripheral blood mononuclear cell (PBMC) transplantation. This uncontrolled open-labeled clinical trial was approved by Ethical committee of Ministry of Health of the Republic of Tatarstan, Russia. Eleven patients took part in the study, they received granulocyte colony-stimulating factor injections for 5 days for PBMC mobilization. On the 6th day PBMCs were collected and injected into the celiac trunk. Liver biopsies were obtained three times from each person on next time-points: before transplantation of PBMCs into the celiac trunk (initial), three and twelve months after the procedure. Liver biopsy specimens were embedded in paraffin and stained immunohistochemically with antibodies against PCNA. The PCNA labeling index was calculated as the number of PCNA-labeled nuclei for 1000 hepatocyte nuclei in each specimen and the results were expressed as percentage ratios. Statistical analysis was done by Wilcoxon signed-rank test using Statistica v.12 software. p value <0.05 was considered significant.

Results: Before the transplantation of PBMCs 28.3 \pm 18.3% of all the hepatocytes expressed PCNA without any topographic prevalence. Three months after the transplantation the proportion of proliferating hepatocytes increased up to 36.7 \pm 24.8%. Twelve months after transplantation of PBMCs we found hepatocytes proliferation to be 2 times higher than before the procedure. Proportion of proliferating hepatocytes reached 50.2 \pm 17.0% (p=0.04). Great increase in hepatocytes proliferation intensity coincided with biochemical improvements of serum bilirubin, ALT and alkaline phosphatase.

Conclusion: Our study showed that proposed treatment was safe and effective. We can conclude that after transplantation of autologous PBMCs proliferation of hepatocytes greatly contributes to the liver regeneration and improvement of

blood biochemical data in patients with alcoholic liver cirrhosis. However, effect of our treatment is not constant and requires repeated PBMC transplantation.

P0666 ASSOCIATION BETWEEN NONALCOHOLIC FATTY LIVER DISEASE AND METABOLIC SYNDROME IN APPARENTLY HEALTHY KOREAN ADULTS

K.M. Sohn¹, Y.J. Jeon²

¹Gastroenterology, Hansol Hospital, Seoul/Korea, Republic of

²MedGene Lab, Seoul/Korea, Republic of

Contact E-mail Address: dr.sohnkm@gmail.com

Introduction: The prevalence of non-alcoholic fatty liver disease (NAFLD) has increased and several studies have shown that there is an association between NAFLD and metabolic syndrome (MetS). The aim of this study was to determine how much impact the risk factors of metabolic syndrome has on ultrasonographic fatty liver, especially NAFLD.

Aims & Methods: A total of 41,258 adults who underwent routine comprehensive health evaluations, including abdominal ultrasonography, were selected. We calculated the adjusted prevalence ratios (PRs) for components of MetS (high blood pressure (BP), impaired fasting glucose, low high-density lipoprotein cholesterol (HDL-C), and high triglycerides (TG) according to NAFLD.

Results: NAFLD was found in 13.8% of non-obese subjects and 52.3% of obese subjects. NAFLD was associated with most components of MetS in both obese and non-obese subjects. However, non-obese NAFLD patients had significantly higher PRs for certain components of MetS than did obese patients, especially among women. Body mass index, waist circumference, fasting blood glucose, triglyceride, HDL-C and aspartate aminotransferase, alanine aminotransferase, γ -glutamyl transpeptidase levels all affected NAFLD independently. The prevalence of metabolic syndrome was increased in mild (40.8%) and moderate (57.8%) NAFLD groups. When odd ratio (95% CI) for NAFLD group was compared to the contrast group, there was an increased risk of metabolic syndrome with odd ratio of 12.8 (95% CI, 9.1 ~ 17.0).

Conclusion: NAFLD and its severity has a close connection with MetS and also with each risk factors of MetS. Therefore, assessment for concurrent MetS among NAFLD patients is considered to be necessary.

Disclosure of Interest: All authors have declared no conflicts of interest.

²National Center for Global Health and Medicine, Tokyo/Japan

Contact E-mail Address: maduniln@yahoo.co.uk

Introduction: Obesity is a global problem. Data from the South Asian region is limited.

Aims & Methods: In a cohort follow-up study we investigated obesity among urban, adult, Sri Lankans [selected by age-stratified random sampling from Ragama-MOH area, Gampaha District; initial screening 2007 (aged 35-64 years); re-evaluation 2014 (aged 42-71 years)]. On both occasions structured interview, anthropometry, liver ultrasound, biochemical and serological tests were performed. Total body fat (TBF) and visceral fat percentage (VFP) were assessed by impedance in 2014. General-obesity (GO) was BMI > 25 kg/m². Central-obesity (CO) was waist circumference (WC) > 90 cm males and WC > 80 cm females. Non-alcoholic fatty liver disease (NAFLD) was diagnosed on ultrasound criteria, safe alcohol consumption and absence of hepatitis B/C markers. Multinomial logistic regression was fitted to assess associations.

Results: In 2007 (n=2967), 614(20.7%) were overweight [51.9%-women], 1161(39.1%) had GO [65.9%-women] and 1584(53.4%) had CO [71%-women]. Females (p < 0.001), raised-TG (p < 0.001), low-HDL (p < 0.001), diabetes (p < 0.001), hypertension (p < 0.001), NAFLD (p < 0.001), and low household income (p < 0.001) were significantly associated with prevalent GO and CO respectively. Additionally, increased-age (p=0.05), low-educational level (p < 0.001) and unhealthy eating (p < 0.001) were associated with prevalent CO. Inadequate physical activity was not associated with either. 2137(72%) attended follow-up in 2014. Of those who were initially non-obese who attended follow-up, 189/1270(14.9%) [64% women] had developed GO (annual-incidence 2.13%) and 206/947(21.9%) [56.3% women] had developed CO (annual incidence 3.12%) after 7 years. TBF and VFP significantly correlated with incident GO and CO (p < 0.001). Females gender (OR-1.78, p < 0.001; 2.81, p < 0.001) and NAFLD (OR-2.93, p < 0.001; OR-2.27, p < 0.001) independently predicted incident GO and CO respectively.

Conclusion: The prevalence and incidence of GO and CO were high in this cohort. Both incident GO and CO were associated with female gender and

lean-NAFLD with lean-NAFLD being the strongest predictor of future development of GO.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0668 THE USE OF THE FATTY LIVER INDEX TO DETERMINE THE PREVALENCE OF FATTY LIVER DISEASE (HEPATIC STEATOSIS) IN AN IRISH POPULATION

L. Reynolds, L. Rabbitt, C. Goulding

Acute Medical Unit, University Hospital Galway, Galway/Ireland

Contact E-mail Address: laura93reynolds@gmail.com

Introduction: Worldwide, the prevalence of fatty liver disease (FLD) is increasing, particularly in countries with rising obesity rates, such as Ireland. Studies suggest that up to 25% of those with FLD can progress to non alcoholic steatohepatitis (NASH) and be at risk of its sequelae, including cirrhosis and hepatocellular carcinoma. Indeed, NASH is now the second most common indication for liver transplantation in the US. Despite this alarming data, there is no prevalence data for Ireland in relation to FLD.

Aims & Methods: We aimed to use a simple screening tool, the Fatty Liver Index (FLI) to identify those at risk of having fatty liver disease (FLD) amongst all comers presenting to an Acute Medical Unit (AMU) and to use this data as an indicator of prevalence of FLD in Ireland.

Methods: In this prospective cohort study, all patients attending the Acute Medical Unit (AMU) were invited to take part. Their height, weight and waist circumference were measured, and triglycerides (TG) were added to their 'routine AMU blood panel', which also included measurement of gamma glutamyl transferase (GGT). Exclusion criteria were as follows: known liver disease, excess alcohol intake (>17 units per week for males, >11 units per week for females), age <18 years, pregnancy, active malignancy. The Fatty Liver Index (FLI), an algorithm based on Body Mass Index (BMI), waist circumference, TG and GGT was used to stratify patients into groups based on risk of having FLD. A FLI score of >60 is highly suggestive of having FLD, a score of 30–60 is indeterminate and a score of <30 is considered low risk for FLD. Ethical approval for this research was granted by the ethics committee of UHG.

Results: Data was completed on 316 participants; 58 were excluded, the majority due to either a history of alcohol excess or known liver disease. A total of 258 participants were therefore evaluated; 50% were male. One hundred and sixteen (45%) participants scored >60 on the FLI; 57.3% of which were male. Only 16% of males had a FLI <30, compared with 44% of females. Males had a significantly higher FLI than females; 60.9 vs. 43.12 ($p < 0.0001$). Those with FLI >60 had a mean weight=93.5kg and BMI=31.5, vs. 64.9kg and 22.4 respectively for those with FLI <30 ($P > 0.0001$). There was a statistically significant difference in all parameters measured between all 3 groups ($p < 0.0001$), apart from height, although there was a trend toward lower height in the FLI <30 group, most likely due to the fact that it was 73% female. When only males were looked at, there was no height difference between the 3 groups. Those with a FLI >60 were older than those with FLI <30, 54.6 vs. 48 ($p = 0.01$).

Conclusion: In this study looking at prevalence of fatty liver in Ireland, 45% of participants were found to be at high risk, and 70% were at high or indeterminate risk. Worryingly, only 16% of males fell into the low-risk group. Apart from weight, GGT, TG and BMI this study also showed age and male sex to be significant risk factors for developing fatty liver. This group clearly needs follow up to further evaluate and manage their fatty liver.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Bisphenol A (BPA) is an endocrine disrupting chemical, a heterogenic group of chemicals usually found in food packaging or insecticide residues on vegetable crops, associated with type 2 diabetes mellitus (T2DM), cardiovascular disease and liver enzyme abnormalities, and in general with the whole blood glucose homeostasis.

Aims & Methods: We have evaluated BPA plasma and urine levels in non-alcoholic fatty liver disease (NAFLD) patients compared to healthy subjects and we evaluated the possibility to eliminate this environmental factor after a BPA-free diet regimen. Furthermore, we evaluated, in human HepG2 cells, the effects of exposure to different BPA concentrations on both oxidative stress induction and cell proliferation. We enrolled sixty patients with histologic diagnosis of NAFLD with or without T2DM, before a BPA-free diet, and healthy subjects, by subjecting them to evaluation of body composition using bioimpedance analysis. In vitro, the proliferation of BPA-exposed HepG2 cells at two different concentrations (0.025 and 0.05 μ M) was evaluated, both at high (H-HepG2), in order to

simulate human hyperglycemia, and at low (L-HepG2) glucose concentrations, for 48 h. Lipoperoxidation was also assessed by TBARS assay.

Results: BPA levels were significantly higher in 60 NAFLD subjects, both in urine and in plasma ($p < 0.0001$) if compared to controls and, among this group, it appeared to be higher in 30 non-alcoholic steatohepatitis (NASH) patients compared to 30 simple steatosis (NAFL) ones ($p < 0.05$), independently from the presence of T2DM. After following a BPA-free diet for one month, NAFLD patients showed a significant reduction of BPA circulating levels ($p < 0.05$) without a significant reduction of urine levels, which represents the only way to eliminate BPA amount released into circulation by the adipose BPA reservoir. In fact subjects with a higher fat percentage in body composition showed higher BPA levels in plasma and urine. In our population study, NASH patients showed a higher fat percentage in body composition in comparison to NAFL ones. Only H-HepG2 cells treated with BPA (0.05 μ M) increased proliferation compared to controls at 48 h ($p < 0.0001$). Moreover, BPA increased TBARS levels at 48 h in H-HepG2 cells versus controls.

Conclusion: Our study reveals a possible role of BPA as an environmental factor involved in the progression of NAFLD, particularly in obese and/or T2DM patients.

Introduction: The clinical implications of non-alcoholic fatty pancreas disease (NAFPD) are still the topic of debate in human studies. It has been shown that fatty infiltration in pancreas correlates with metabolic risk factors and may represent significant manifestation of metabolic syndrome (MeS) in association with nonalcoholic fatty liver disease (NAFLD). The aim of our study was to determine the association of fatty pancreas (FP) in NAFLD patients with features of MeS and to determine a simple new noninvasive scoring system for FP prediction in NAFLD patients.

Aims & Methods: We conducted cross-sectional study that included 143 subjects with NAFLD classified into two groups according to the severity grade of FP as follows: patients with non fatty pancreas and grade I light FP ($n = 59$) and patients with grade II severely and grade III highly FP ($n = 84$). Patients were analyzed for diagnostic criteria of MeS, underwent sonographic examination with adiposity measurements and liver biopsy. Liver fibrosis was evaluated semi-quantitative according to the METAVIR scoring system and using non-invasive markers of hepatic fibrosis (NAFLD fibrosis score (NFS), BARD score, Fibrosis-4 score (FIB-4), AST to Platelet Ratio Index (APRI)).

Results: Of these 143 patients with NAFLD, 84 had criteria for metabolic syndrome (MeS), while there was no significant difference in frequency among FP groups. Out of all clinical and laboratory characteristics, no statistical differences were registered in demographic data, lifestyle factors, body mass index (BMI), systolic and diastolic blood pressure, presence of hypertension and dyslipidemia, values of insulin, high density lipoprotein (HDL) and triglycerides. Waist circumference (WC) showed significant difference among groups, indicating WC as a possible marker for higher risk of FP in NAFLD patients ($P = 0.018$). Diabetes mellitus (DM) was more frequent in patients with severely FP ($P = 0.02$), with greater portion of patients with HOMA-IR > 3. Higher values of fasting plasma glucose, total cholesterol, serum amylase and lipase were associated with presence of highly fatty pancreas ($P = 0.052$, $P = 0.007$, $P = 0.014$; $P = 0.024$, retrospectively). Values of hemoglobin A1c (HbA1c) > 6% were significantly associated with NAFLD patients with severely FP, highlighting its impaired function in MeS ($P = 0.008$). While no significant difference was found in the use of statins and hypertensives, higher number of patients with severely FP did not use antidiabetic agents and association was registered among NAFLD patients with use of metformin and glimepirid and the first FP group ($P = 0.035$). Out of all visceral fat amounts, only measures of mesenteric fat were associated with severely FP ($P = 0.013$). Results of our study determined highly significant association of NAFLD and NAFPD. Neither NAFLD non-invasive markers nor histological reports of liver fibrosis showed significant association with presence of fatty pancreas. In multivariate analysis of FP predictors in our study cohort, logistic regression approach was used. Model of predicting occurrence of FP was designed from multivariate logistic regression analysis. The probability was estimated with the equation: $0.627 + 0.640 * 0.593 * \text{glucose (fasting glucose level)} - \text{cholesterol level (total cholesterol)} + 0.058 + 1.585 * \text{serum lipase} * \text{ultrasonography level of liver steatosis}$. According to the score values for different cut off levels, best ability in the prediction of severely FP has shown the score value above 6.5.

Conclusion: Our study demonstrated that pancreatic fat infiltration due to its impaired function presents an additional factor that contributes to aggravation of MeS manifestations, affects glucose metabolism and severity of NAFLD. Interestingly, significant association was registered among NAFLD patients

with use of antidiabetic agents and the absence of highly fatty pancreas, indicating its potential protective role. Simple new noninvasive scoring system was designed from multivariate logistic regression analysis to estimate the occurrence of severely FP in NAFLD with best ability in the prediction in score values above 6.5.

²Transplant Research Center, Shiraz/Iran

Contact E-mail Address: eshraghiana@yahoo.com

Introduction: Non- alcoholic fatty liver disease (NAFLD) is a rapidly growing disease worldwide. The pathogenesis of NAFLD is not well recognized. Thyroid is totally involved in regulation of lipid and carbohydrate metabolism, body weight, and energy homeostasis. Therefore, the role of thyroid hormones in pathogenesis of hepatic steatosis is anticipated.

Aims & Methods: This study aimed to investigate thyroid hormone abnormalities in euthyroid subjects with hepatic steatosis. A cross sectional study was conducted between September 2012 and September 2015 at Namazi hospital, Shiraz, Iran. Study subjects were healthy individuals who had undergone liver biopsy for evaluation of liver histology as a routine pre-transplant checkup before living related liver transplantation. Liver function tests, age, gender, weight, height, fasting plasma glucose, thyroid hormones, and lipid profile were recorded. Liver biopsy specimens were reviewed by an expert pathologist for hepatic steatosis and steatohepatitis. Individuals with a history of chronic liver disease, hepatitis B or C infection, hepato-biliary cancers, those with >20 grams/day alcohol consumption, and individuals receiving medications causing hepatic steatosis were excluded from the study.

Results: A total of 210 individuals (130 women and 80 men) were included. Seventy six individuals (36.19 %) had hepatic steatosis and 19 individuals had steatohepatitis (9.04 %) in liver histology. Mean age of individuals with and without hepatic steatosis were 32.9±6.69 and 31.8±6.72 years respectively (P=0.26). In univariate analysis higher weight, triglyceride, total cholesterol, alanine aminotransferase (ALT), alkaline phosphatase, fasting blood sugar (FBS) and thyroid stimulating hormone (TSH) were associated with hepatic steatosis (P<0.05). Serum T4 and T3 were not associated with hepatic steatosis (P>0.05). In regression analysis, higher FBS, higher alkaline phosphatase, higher ALT and higher TSH (OR=1.36; 95 % CI: 1.02–1.80, P=0.03) were independent predictors of hepatic steatosis. In regression analysis, higher serum TSH was independently associated with steatohepatitis compared to those without steatohepatitis (6.83±6.04 mIU/L and 2.10±1.27 mIU/L) (OR=2.11; 95% CI: 1.45–3.07, p<0.001). A cutoff value of 3.75 mIU/L for TSH was predictor of presence of steatohepatitis in liver biopsies (sensitivity = 75%; specificity = 89 %; AUC = 0.754; P=0.004).

	Odds Ratio (OR)	95 % Confidence Interval (CI)	P-Value
Weight	1.05	0.96–1.16	0.245
Triglyceride	1	0.98–1.01	0.989
ALT	1.007	0.93–1.08	0.867
TSH	2.11	1.45–3.07	<0.001

Conclusion: Higher serum TSH is associated with hepatic steatosis and steatohepatitis in euthyroid subjects. Thyroid hormones may have crucial role in hepatic steatosis and may be targeted for treatment of NAFLD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Glucosidase II is part of the functional pathway of co-translational protein translocation and maturation in the endoplasmic reticulum. It is implicated in autosomal dominant polycystic liver disease (ADPLD) and autosomal dominant polycystic kidney disease (ADPKD). The β -subunit of glucosidase II, encoded by *PRKCSH*, has been identified as one of the causative genes of ADPLD. Recent data suggest that the α -subunit of glucosidase II (*GLI2*), encoded by *GANAB*, is associated with ADPKD and ADPLD. We aimed to identify *GANAB* mutations in an independent cohort of patients with the primary phenotype of polycystic liver disease (PLD) and to predict the influence of these mutations on glucosidase II function.

Aims & Methods: We identified genetic mutations in *GANAB* using molecular inversion probe (MIP) analysis in a cohort of PLD patients. Both patients with ADPKD and ADPLD were included for analysis. Mutations identified with MIP analysis were validated using Sanger sequencing. Bioinformatics prediction tools (PolyPhen-2, Align GVGD, SIFT, MutationTaster) were used to predict the functional significance of the mutations. YASARA&WHAT IF were used for analysis of the structural effects of the mutations. Primary cholangiocytes obtained from a patient with *GANAB* mutation (c.2515C>T) were used to study loss of heterozygosity.

Results: We identified and validated 6 new bona fide *GANAB* mutations in 7 unrelated families. These are 2 frameshift (c.687delT and c.11_16delTAGCGG), 1 splicing (c.2691-28C>G), 2 nonsense (c.2509C>T and c.2656C>T) and 1 missense (c.1835G>C) mutation. In silico analysis showed c.687delT and c.11_16delTAGCGG are located in N-terminal domain of the protein. These mutations probably lead to a total defective protein. c.1835G>C is located in the active site of the protein. It is predicted to disrupt the composition of the active site and reduce enzymatic activity. The remaining mutations (c.2691-28C>G, c.2509C>T and c.2656C>T) are located in the distal C-terminal domain, which interacts with *PRKCSH*. The mutations could result in early termination of this domain. It is speculated this disrupts the ability of the two subunits to interact. Western Blot showed no differences in *GLI2* expression in an ADPLD patient with *GANAB* mutation c.2515C>T compared to primary cholangiocytes obtained from a patient without PLD. This indicates in this patient no loss of heterozygosity occurs in cholangiocytes lining the hepatic cysts.

Conclusion: We describe six novel *GANAB* mutations that can cause PLD in a mixed population of ADPKD and ADPLD patients. These mutations are found in functionally important domains of α -subunit of glucosidase II, which may lead to impaired enzymatic activity of the complex. In contrast to other PLD related genes no loss of heterozygosity was found for *GANAB* in cyst epithelium.

Introduction: In patients with morbid obesity, dietary treatment and physical activity are the first line of treatment, but if not responding, bariatric surgery is the only validated alternative. The main surgical procedures are sleeve gastrectomy (SG) and gastric bypass (GBP), and they are chosen in function of BMI, age and comorbidity. Both techniques have proven effective in weight loss. It is known that liver fibrosis evaluation with Point Shear Wave Elastography (pSWE) is difficult in these patients.

Aims & Methods: To study the difference between SG and GB and their impact on main clinical and laboratory hepatic metabolic indicators and scores 6 and 12 months after the intervention and pSWE at 12 months. We studied 68 obese subject candidate to bariatric surgery (45 female, 23 male). 28 underwent GBP and 40 SG. Blood tests, physical examination were assessed before surgery, after 6 months (68 patients) and after 12 months (51 patients) and pSWE after 12 months.

Results: In the comparison between GBP vs SG there was a statistically significant difference in the reduction in Fatty Liver Index (61% vs 37%, p=0.015), waist circumference (26% vs 18%, p=0.045), BMI (34% vs 28%, p=0.016), total cholesterol (23% vs 0, 05%, p=0.001), ALT (increased by 15% in GBP, decreased by 27% in SG, p=0.023) while no differences were observed in the other indicators considered. Ferritin level increased (52%) in SG and decreased (25%) in GBP (p=0.02). No difference was observed for pSWE.

Conclusion: This study showed some significant differences in clinical and laboratory terms between the two types of intervention, in fact GBP seems to have a more powerful effect on weight loss and all related markers: all steatosis scores (FLI, HSI, LAP), BMI, waist circumference. This can be explained by better malabsorptive effect of this intervention and by a lower BMI starting point for reasons related to the intervention technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Polycystic liver disease (PLD) occurs in the setting of 2 different genetic disorders: autosomal polycystic liver disease (ADPLD) and autosomal polycystic kidney disease (ADPKD). These patients may develop hepatomegaly as a result of multiple fluid-filled cysts. It is unclear whether PLD severity differs between ADPLD and ADPKD. Height adjusted liver volume (htTLV) reflects with symptomatic disease and diminished quality of life. We assessed hepatomegaly with htTLV, as an objective parameter, in a large cohort of ADPKD and ADPLD patients

Aims & Methods: PLD patients, defined by >10 liver cysts on radiological imaging, were included in the international PLD registry. The cases were identified from clinical records at the University Leuven (Belgium), Seoul National University Hospital (South-Korea) and Radboud University Hospital Nijmegen (the Netherlands). For this cross-sectional analysis, we selected patients when height adjusted total liver volume was measured prior to liver reducing therapy. We performed univariate and multivariate analyses to explore risk factors associated with severity of disease.

Results: Out of a total 1674 patients in the PLD registry, 1222 patients (1110 ADPKD, 112 ADPLD) could be selected. In the ADPKD + PLD group height adjusted liver volume is significantly lower compared with ADPLD patients (1050 ml/m vs 1922 ml/m; $p = .000$). Females have higher htTLV than men in both ADPLD and ADPKD. Severe disease (htTLV > 3.200 ml/m) is more prevalent in ADPLD. Diagnosis, gender and age are independent predictors for severity of disease.

Conclusion: In this cohort more ADPLD patients had moderate to severe PLD compared to those with ADPKD. Longitudinal studies are needed to further explore the differences in national course of PLD phenotype between ADPLD and ADPKD patients and to identify new risk factors.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0675 CARDIOVASCULAR RISK DEVELOPMENT MODEL FOR THE (ATYPICAL) PATIENT WITH NON-ALCOHOLIC FATTY LIVER DISEASE

Introduction: Non-alcoholic fatty liver disease (NAFLD) affects about 1 billion people worldwide. Those with non-alcoholic steatohepatitis (NASH) among NAFLD patients have increased mortality rates compared to the general population, with cardiovascular diseases being the leading cause of death. Identifying patients at risk of developing cardiovascular events is of major importance, both in terms of prognosis, as in the terms of therapeutic attitude.

Aims & Methods: Our aim was to quantify the risk of developing atherosclerosis as a main cardiovascular risk factor, in NAFLD patients and to identify a screening strategy for those patients. We included patients with NAFLD and metabolic syndrome (MS) into 2 arms: with NAFLD and MS, and with NAFLD without MS. NAFLD diagnosis was based on clinical, biological and ultrasound determinations. We used Fibromax for evaluating the hepatic modifications (presence of NASH, the degree of steatosis and the stage of fibrosis); F3-F4 counted as advanced fibrosis). We performed ultrasound measurement of the carotid intima-media thickness (in the common carotid artery, 1 cm before the bifurcation). Values above 0.07 cm were considered pathologic and values above 0.12 cm were considered as atherosclerotic (ats) plaques. Routine antropometric and laboratory determinations were performed.

Results: We included 95 patients with NAFLD, from which 53 were with MS and 43 were without MS. In all patients with NAFLD, with and without MS, there was a correlation between the value of intima-media thickness and the presence of NASH ($p = 0.025$), the degree of steatosis ($p = 0.027$) and the severity of fibrosis ($p < 0.001$). Patients with NAFLD and MS had higher values of the intima-media thickness than those with NAFLD, but without MS ($p = 0.002$).

In all patients with NAFLD, there was a correlation between the presence of ats plaque and advanced fibrosis ($p < 0.001$). The sex of the patients ($p = 0.638$) and the level of total cholesterol ($p = 0.438$), LDL cholesterol ($p = 0.505$), HDL-cholesterol ($p = 0.458$), and triglycerides ($p = 0.911$) were not correlated with the presence of ats plaque, nor on the entire group of patients or on each arm. In the logistic model for the prediction of the risk of developing ats plaque, we included presence of NASH, the grade of steatosis, the stage of fibrosis, body mass index, abdominal circumference and creatinine clearance level. In this model, the stage of fibrosis has been shown to be a predictor with a positive effect on the presence of ats plaque ($p = 0.004$, adjusted OR = 7.19, CI[1.86;27.72]). This model correctly classified 90.9% of patients with ats plaque and 91.7% of patients without ats plaque.

Conclusion: NAFLD patients were found to be atypical for the development of cardiovascular risk. Staging of fibrosis has proved to be an important prognostic factor. On the other hand, identifying NAFLD patients with ats plaques might select the patients in which liver biopsy might be indicated for better characterization of the liver disease. Screening and aggressive treatment of cardiovascular risk factors should be done in every NAFLD patient.

Introduction: Liver biopsy is the reference standard for diagnosing and staging non-alcoholic fatty liver disease (NAFLD). Steatosis grade and fibrosis stage are typically reported using semi-quantitative scores. Inter- and intra-observer variability in the current scoring systems may impact upon histological staging, and consequently upon the interpretation of responses to interventions in clinical trials.

Aims & Methods: We developed an automated method for steatosis and fibrosis quantitation using biopsies of NAFLD patients. We further validated Liver Stiffness Measurements (LSM) and controlled attenuation parameter (CAP) in this group, using quantitative assessment as reference. 246 consecutive patients with biopsy-confirmed NAFLD and transient elastography within 3 months of the biopsy were evaluated. Biopsies were independently scored by two histopathologists and digitalised at 2x magnification. Areas of steatosis and fibrosis were annotated manually using the NDP.view2 to facilitate machine learning. Each image was then analysed by the automated software: fat percentage (fat%) and Collagen Proportionate Area (CPA) computed by the software were compared with the manual annotation. They were also correlated with LSM and CAP.

Results: There was an excellent concordance between manual and automatic measurements, with inter-class correlation coefficient, ICC = 0.98, (95%CI = 0.96-0.99, $p = 0.0001$). There was good correlation between fat% and steatosis grade, but with significant overlap between groups. Results were similar between CPA and fibrosis stage. LSM was significantly associated with CPA (Rho = 0.8, $p = 0.001$). CAP score correlated significantly with fat% (Rho = 0.45, $p = 0.002$) and effectively diagnosed steatosis > 5% (AUROC 0.82, 95% sensitivity, 60% specificity), but could not distinguish between grades.

Conclusion: We have developed an automated software, using low-resolution images to provide a rapid, easily performed, objective assessment of steatosis and fibrosis in NAFLD, with excellent correlation with experts' annotation. Objective measures would be helpful in the assessment of therapeutic response in clinical practice and in clinical trials for patients with non-alcoholic fatty liver disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0677 THE IMPORTANCE OF FIBROSIS SCORES AND TRANSIENT ELASTOGRAPHY IN NAFLD EVOLUTION

Introduction: Today, nonalcoholic fatty liver disease (NAFLD) is the most prevalent form of liver disease and it is an increasingly frequent cause of cirrhosis. Although several factors have been associated with the disease, the biological basis of the histological diversity of severity of NAFLD remains unknown. Several relatively noninvasive parameters have been identified as predictive for advanced fibrosis stage in patients with NAFLD, but none of them has sufficient sensitivity or specificity to replace liver biopsy.

Aims & Methods: Aim of our study was to compare two non-invasive methods: fibrosis scores based on serum markers and transient elastography Fibroscan (TE). We included 152 patients with NAFLD, 40 males (26.31%) and 112 females with age from 23 to 79 years. 35 patients (23.02%) were overweight, 9 patients had normal weight and 24 (15.79%) had severe obesity. In all patients we calculated BMI and fibrosis scores: BARD, FIB-4 and NAFLD fibrosis score (NAFLD-FS). Blood samples were collected to determinate aminotransferases, glucose, albumin level, platelet count. The abdominal ultrasonography was performed by the same physician and steatosis was graded using a semi-quantitative scale of 1 (mild) to 3 (severe). TE was, also, performed by a single physician using conventional M probe or XL probe, with 10 valid acquisitions. We considered significant fibrosis (F2) when estimated cutoff of F2 was 7.1 kPa, severe fibrosis (F3) when cutoff value was 9.5 kPa, and cirrhosis (F4) with cutoff value ≥ 12.5 kPa.

Results: 86.84% patients had metabolic syndrome and 51.31% had diabetes mellitus. 40 patients had mild steatosis, 59 had moderate and 53 had severe steatosis. After we performed TE 69.07% of patients had no significant fibrosis, 14.47% had F2, 9.86% had F3 and 7.23% had F4. The area under the receiver-operating characteristic curve (AUROC) of TE was 0.823 (95%, 0.252–0.394) ($p < 0.0001$). Sensibility and specificity for cutoff 7.1 kPa was 0.74 respectively 0.79 to exclude significant fibrosis. NAFLD-FS correlated statistically significant with TE ($p < 0.0001$). BARD score did not correlate with TE and NAFLD-FS for significant fibrosis. FIB-4 correlated with TE for high degree fibrosis ($p = 0.004$).

Conclusion: NAFLD-FS, FIB-4 and TE can be used together to evaluate the progression of fibrosis in NAFLD and to select the patients for liver biopsy. In our study BARD score was not useful in detection of high degree fibrosis.

P0678 EFFECTS OF UDCA AND STATIN COMBINATIONS ON LIPID PROFILE IN NAFLD PATIENTS

S. S. Vyalov

Gastroenterology, Peoples Friendship University of Russia, Moscow/Russian Federation

Contact E-mail Address: svialov@mail.ru

Introduction: Dyslipidemia has an important role in NAFLD and inflammation progress and insulin resistance development. The studies suggested the role of UDCA in lipid profile correction. UDCA replaced bile acid balance and improved triglyceride and cholesterol levels in NAFLD patients, has immunomodulatory action.

Aims & Methods: The aim of study was estimation of the efficacy of different dosage of ursodeoxycholic acid (UDCA) with statin combination treatment in patients with NASH and NAFLD. There are 180 patients with NAFLD. It was divided into two subgroups: fatty liver (90 subjects) – patients with normal level of ALT, and nonalcoholic steatohepatitis (NASH, 90 subjects) – patients with elevated level of ALT (the median is 78.5 U/l). All patients was divided in 3 groups. The blood test, liver enzymes, lipid profile, HOMA-IR, Fibroscan and stool test was checked every 2 weeks of treatment. First group was taken UDCA 10 mg/kg/day + Statin. The patients of first group continue treatment for 3 months. Second group was taken UDCA 15 mg/kg/day + Statin. Third group were fed the low-lipid and low-glycemic index diet only (900 kcal/day). After 3 months of treatment patients of third group (diet only) add UDCA 15 mg/kg/day to treatment for extra 3 months.

Results: The subgroups did not show any difference in terms of initial total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), and triglycerides (TG). Analysis of the lipid spectrum showed a more intense dynamics in the group of patients taken UDCA combined with statin. After 3 months of follow-up there was a significant reduction in TC to 4.2 mmol/l, LDL-C to 1.8 mmol/l and TG to 1.2 mmol/l in the fatty liver subgroup, and TC to 4.1 mmol/l, LDL-C to 1.8 mmol/l and TG to 1.2 mmol/l in the NASH subgroup. Changes were similar in the subgroups. The level of total cholesterol, triglyceride and liver enzymes were decreased faster in group taken UDCA and statin independent from UDCA dosage. There are no side effects or liver enzyme elevation in group treated with UDCA and statins. In the NASH subgroup there was a significant decrease in ALT to 35 U/l. At the end of the first month of statin therapy combined with UDCA in the NASH subgroup a significant positive dynamics of ALT was found in patients with NASH (initially 78.5 U/l; after treatment decrease to 38.5 U/l). Stage of liver fibrosis was significant in patients taken UDCA and statin, as evidenced by the decrease in the index of fibrosis.

Conclusion: 3-month statin therapy in combination with UDCA showed significant lipid-lowering effects in patients with NAFLD, as well as normalization of ALT in the NASH subgroup. Among the patients who previously had not taken statins in the NASH subgroup, higher levels of TC and TG were observed. The same subgroup showed more evident lipid-lowering effects than the fatty liver subgroup during the first month of the treatment. There are no differences between the dosages of UDCA.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0679 EFFECT OF GRANULOCYTE COLONY-STIMULATING FACTOR (G-CSF) ON MORTALITY AND COMPLICATIONS VIZ. SEPSIS, ENCEPHALOPATHY, HEPATORENAL SYNDROME, AND GASTROINTESTINAL BLEED IN SEVERE ALCOHOLIC HEPATITIS-A RANDOMIZED CONTROLLED STUDY

A. Sharma

Gastroenterology And Hepatology, Fortis Escorts Hospital Jaipur, Jaipur/India

Contact E-mail Address: abhinav_11005@yahoo.com

Introduction: Severe alcoholic hepatitis has very high short-term mortality. Compared to standard medical therapy (SMT), GCSF improves clinical and biochemical profiles, morbidity and mortality in these patients. We evaluated efficacy of GCSF in modulating the disease course of severe alcoholic hepatitis over a period of 3 months in terms of mortality, morbidity by Discriminant function (mDF), Child-Turcotte-Pugh (CTP) and Model for End-Stage Liver Disease (MELD) scores and various complications viz. sepsis, GI bleed, encephalopathy, hepatorenal syndrome (HRS) in comparison to SMT. We also studied the mobilising effect of GCSF on bone marrow stem cells measured by counting CD34+ cells from peripheral blood.

Aims & Methods: The present study was performed to evaluate the safety and efficacy of GCSF on mortality and complications viz. sepsis, encephalopathy, hepatorenal syndrome (HRS) and gastrointestinal bleed (GI Bleed) and also to investigate whether G-CSF therapy could improve the indices of severity of liver disease, such as Discriminant function (mDF), Child-Turcotte-Pugh (CTP), Model for End-Stage Liver Disease (MELD) score in patients with severe alcoholic hepatitis. 50 patients with severe alcoholic hepatitis were randomly assigned to groups A and B (25 in each). Both groups were given SMT, while in addition, patients in group A were given 5 μ g/kg GCSF subcutaneous (10 doses for 5 days). We assessed survival, changes in CTP, MELD and mDF scores and the development of complications till 90 days.

Results: The baseline parameters in both groups were comparable. On day 6 group A had higher mean leukocyte and CD34 counts than group B ($p < .001$). On 90 days follow up 17 patients in group A (68%) and 9 in group B (36%) survived ($p = .04$). Mean changes for different scores were greater in group A than group B i.e. CTP (–41.97% vs –8.84%), MELD (–50.89% vs 10.09%) and mDF (–74% vs 18%) ($p < .001$). The percentages of patients who developed HRS, HE, or sepsis were lower in group A than in group B (28% vs 64%, 32% vs 64%, and 28% vs 68%, respectively) ($p < .001$). There was no significant difference in GI bleed in both groups.

Conclusion: In severe alcoholic hepatitis, GCSF therapy significantly improves the survival. It also significantly reduces CTP, MELD, and mDF scores and prevents the development of complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Steatosis/steatohepatitis is one of the most common liver diseases with increasing prevalence and results from excessive alcohol consumption (alcoholic liver disease) or as nonalcoholic fatty liver disease (NAFLD). The differential diagnosis is of paramount importance as they have different management and therapeutic approaches, being liver biopsy the gold standard for establishing the diagnosis. The distinction between these two entities without biopsy is

difficult due to the unreliable history of alcohol consumption and lack of sensitivity and specificity of a single marker. In order to overcome these difficulties, ANI (alcoholic liver disease/nonalcoholic fatty liver disease index) was created for a non-invasive determination of fatty liver diagnosis.

Aims & Methods: The aim of this study was to evaluate the reliability of ANI as a noninvasive method to distinguish NAFLD from ALD. A retrospective study between 2010 and 2015 in patients with definite diagnosis of NAFLD and ALD based on clinical, biochemical and histological criteria was performed. ANI scoring system in the differentiation of ALD and NAFLD was evaluated through the area under receiver-operating curve (AUROC). ANI score was calculated through Mayo Clinic formula.

Results: This study was carried out in 22 patients with ALD and 120 with NAFLD, 87 men (61.3%) with a median age of 51 ± 13 years. NAFLD patients presented a body mass index (BMI) of 28.9 ± 5.9 vs 23.9 ± 6 in ALD. ANI showed a sensitivity of 81% and specificity of 79% for the diagnosis of ALD with a cut-off value of -1.96 [AUROC 0.806 (0.715–0.898), $p < 0.001$]. ANI greater than -1.96 indicates a diagnosis of ALD whereas ANI less than -1.96 indicates a greater probability of NAFLD.

Conclusion: ANI scoring system is a non invasive diagnostic and reliable tool that may be used to distinguish NAFLD from ALD, decreasing the need for liver biopsy. ANI greater than -1.96 suggests the diagnosis of ALD and ANI lesser than -1.96 suggest NAFLD.

Introduction: Alcohol consumption is an accepted phenomenon in Western society, although harmful effects of excessive alcohol intake on health have been widely shown. Alcohol has a direct toxic effect on the liver, potentially leading to steatohepatitis and eventually liver fibrosis and cirrhosis. Excessive use is furthermore associated with obesity, hypertension, hypercholesterolemia and diabetes. Cessation of alcohol may reverse these effects to some degree. The biological effects of short-term abstinence from moderate alcohol consumption are not known.

Aims & Methods: A prospective interventional study in 16 healthy moderate drinkers (≤ 3 units alcohol/day or 21 units/week) who discontinued alcohol use for one month. Nine complete abstainers served as a control group. In both groups an extensive health evaluation was performed at three time points: at baseline (T0), at end of cessation (T4) and after one month of resuming alcohol intake (T8). Outcomes consisted of morphometrics (blood pressure, body mass index and body impedance analysis), transient and shear wave elastography to assess liver stiffness and computer assisted ultrasonography to assess liver fat. A blood panel consisted of liver enzymes, cholesterol, glucose and iron metabolism and inflammatory parameters. Several quality of life components were assessed with VAS scales.

Results: The intervention and control group were comparable on baseline in terms of age, gender and morphometrics. Prior to intervention the participants consumed on average 10.4 ± 4.5 units alcohol/week and when they resumed alcohol use, an average of 12.4 ± 5.1 units/week. During the intervention period, complete cessation was ascertained by blood parameters. Liver stiffness and liver fat percentage did not differ between both groups nor change within participants at any time point. Compared to baseline, GGT decreased at T4 (28 to 22 IU/L, $p = .001$) and increased at T8 to 26 IU/L ($p = .010$). AST showed a similar trend (T4: $p = .071$ resp. T8: 0.021). Cessation of alcohol also led to a significant drop in total cholesterol and LDL. Interestingly, subcutaneous fat decreased significantly at T4 (19.5 mm to 18.1 mm, $p = .008$). Ferritin was higher at baseline in drinkers compared to controls (median $107 \mu\text{g/L}$ (IQR 52 – 280) vs. $55 \mu\text{g/L}$ (IQR 21 – 100), $p = .027$) and decreased at T4 to $86 \mu\text{g/L}$ ($p = .053$). All parameters remained unaltered in the control group during all time points. Physical fitness improved significantly within drinkers after cessation of alcohol, other parameters of quality of life remained stable and were similar between groups.

Conclusion: Metabolic and biochemical changes within the liver, amelioration of lipid profile and improvement of physical fitness can be observed after one month of alcohol cessation in moderate drinkers. These pilot results should be further assessed in larger cohorts but already endorse the public message to subdue and possibly even altogether cease alcohol use.

Introduction: Gut-liver axis plays an important role in the pathogenesis of ALD. The metabolic products of intestine enter the blood through the damaged intestinal mucosal barrier and cause liver damage. Nowadays, probiotics have been used in the prevention and treatment of a variety of diseases, including ALD. It has become a hot spot for the study of regulating intestinal micro ecological balance and enhancing intestinal barrier function, to prevent alcoholic liver injury. In this study, ALD mice were given probiotics to observe the protective effects on ALD and explore the possible mechanism.

Aims & Methods: Gut-liver axis plays an important role in the pathogenesis of ALD. The metabolic products of intestine enter the blood through the damaged intestinal mucosal barrier and cause liver damage. Nowadays, probiotics have been used in the prevention and treatment of a variety of diseases, including ALD. It has become a hot spot for the study of regulating intestinal micro ecological balance and enhancing intestinal barrier function, to prevent alcoholic liver injury. In this study, ALD mice were given probiotics to observe the protective effects on ALD and explore the possible mechanism.

Results: HE and oil red O staining of liver tissues in alcohol group showed significant steatosis and inflammatory response, and probiotics treatment can reduce liver injury. Compared with the control group, the LPS of alcohol group was significantly higher than that of the control group (62.36 ± 3.05 vs 12.23 ± 1.19 pg/ml, $p < 0.05$) and TNF- α (779.4 ± 10.01 vs 272.4 ± 6.78 pg/ml, $p < 0.05$) was significantly increased. Probiotics can effectively ease endotoxemia (35.63 ± 1.84 vs 6.236 ± 3.05 pg/ml, $p < 0.05$) and inflammatory factors TNF- α (526.6 ± 25.04 vs 779.4 ± 10.01 pg/ml, $p < 0.05$) induced by alcohol. RT-PCR results showed that probiotics increased the expression of Reg3b and Reg3g ($P < 0.05$). Compared with the alcohol group, the mRNA levels of intestinal tight junction protein Occludin and Claudin-1 were increased with probiotics treatment ($P < 0.05$). However, compared with the alcohol group, the mRNA level of ZO-1 showed no significant difference ($P > 0.05$). WB results showed that the expression of Occludin and Claudin-1 increased in probiotic treatment group ($P < 0.05$).

In addition, Bacteroides ($p < 0.05$) and Bacteroides ($p < 0.05$) were significantly increased in the intestine of the alcohol group. While the Clostridium ($p < 0.05$), Lactobacillus ($p < 0.05$) and Coccidia ($p < 0.05$) were decreased. With the treatment of probiotics, the levels of Enterococcus ($p < 0.05$) and Enterobacteriaceae ($p < 0.05$) decreased, and the levels of Lactobacillus ($p < 0.05$) and Bifidobacterium ($p < 0.05$) increased.

Conclusion: Probiotics showed protective effects on ALD by reducing alcohol-induced endotoxemia and liver inflammatory injury as well as improving the intestinal mucosal barrier and restoring the intestinal micro ecological imbalance.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0683 THE OVERWEIGHT ROLE IN THE OCCURRENCE OF HEPATOTOXIC REACTIONS DURING CHEMOTHERAPY OF ACUTE LEUKEMIA

I. Skrypnyk, G. Maslova

Internal Medicine #1, Ukrainian Medical Stomatological Academy, Poltava/Ukraine

Contact E-mail Address: scrin69@yandex.ru

Introduction: Chemotherapy drugs have a direct hepatotoxic effect, which leads to multiple increase in the risk of liver injury in patients with acute leukemias (AL). The development of hepatotoxicity limits the chemotherapy (CT) providing in full doses.

Aims & Methods: We aimed to assess the overweight role in an increase of risk level of hepatotoxic reactions in AL chemotherapy dynamics. The study involved 84 patients with newly diagnosed AL (64 – acute myeloid leukemia (AML), 20 – acute lymphoblastic leukemia (ALL)), ECOG I-II, aged 24–67 years, 41(48.8%) women, 43(51.2%) – men. The body mass index (BMI) was determined, the liver function was assessed by the activity of alanine aminotransferase (ALT), aspartate (AST) aminotransferase, alkaline phosphatase (ALP), gamma-glutamyltranspeptidase (GGT), total bilirubin, total protein in the blood serum three times: at baseline and on the 28th and 56th day after starting induction of remission therapy, according to the ALL (prednisolone, doxorubicin, vincristin, asparaginase, cyclophosphamide, cytarabine, mercaptopurine) and AML (cytarabine, doxorubicin) treatment protocols. To assess the severity of hepatotoxic reactions

the CTCAE scale was used. Overweight was detected in 40 patients: BMI = 25–29.9 – in 29 (34.5%), BMI > 30 – in 11 (13.1%) patients. Depending on the overweight presence the patients were divided into 2 groups: I (n = 44) – patients with AL with normal body weight, II (n = 40) – patients with AL and overweight. **Results:** In AL patients of group I before the start of chemotherapy functional liver state was not significantly different from healthy people. In group II there was an increase of ALT activity in 1.5 times, AST – in 1.2 times, ALP and GGT in 1.4 times compared to the norm ($p < 0.05$) and reached grade I level, and no change in bilirubin and total protein levels. On the 28th day of treatment in 3 (6.8%) patients of group I the violation of the functional liver state was revealed, which was characterized by the increased activity of ALT in 1.5 times, AST – in 1.2 times, ALP – in 1.3 times, GGT – in 1.5 times compared to normal levels, that consistent with grade I level, the bilirubin and total protein levels remained in the normal range. In group II hepatotoxicity was detected in 19 (47.5%), which was characterized by the increased activity of ALT and AST in 2.3 and in 2.2 times respectively, GGT and ALP in 1.9 and 2.4 times respectively, the level of total bilirubin increased in 2.1 times ($p < 0.05$), of which in 17 (42.5%) patients hepatotoxic reactions were of grade I and in 2 (5%) – of grade II level, with no statistically significant changes in protein synthesis liver function. On the 56th day of treatment in 7 (15.9%) patients of group I the violation of the functional liver state was revealed, which was characterized by the increased activity of ALT in 1.8 times, AST – in 1.3 times, ALP – in 1.6 times, GGT – in 1.9 times compared to normal levels, the bilirubin and total protein levels remained in the normal range, that consistent with grade I. In group II hepatotoxicity was detected in 26 (65%), which was characterized by the increased activity of ALT and AST in 2.6 and in 2.3 times respectively, GGT and ALP in 2.6 and 3.7 times respectively, the level of total bilirubin increased in 3.6 times ($p < 0.05$), of which in 10 (25%) patients hepatotoxic reactions were of grade I and in 16 (40%) – of grade II level.

Conclusion: The presence of the overweight results in a significant increase in the frequency and degree of hepatotoxic reactions in patients with AL during chemotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0684 RESEARCH ON FERROPTOSIS IN HEPATOCYTE INJURY INDUCED BY ALCOHOLIC

Y. Wu, T. Liu, G. Zhang

Xiangya Hospital, Central South University, Changsha/China

Contact E-mail Address: liuting818@126.com

Introduction: Alcohol abuse and alcohol dependence have become the world's growing public health problems. With the improvement of living standards in China, alcohol consumption is growing and the incidence of alcoholic liver injury also increased year by year. However, the mechanism of alcohol-induced liver injury is not clear yet, and its pathogenesis is mainly related to oxidative stress, lipid peroxidation, cytokines and mitochondrial dysfunction. Ferroptosis is an iron-dependent cell death and its inhibitors can improve cell biochemical and morphological changes^[1]. The presence of Ferroptosis in liver injury induced by alcohol has not yet been reported.

Aims & Methods: We aim to investigate the presence of Ferroptosis and the expression of glutathione peroxidase 4 (GPX4)^[2] in alcoholic liver injury by establishing a cytological model of acute alcoholic liver injury and animal model of alcoholic liver injury, and further elucidating the pathogenesis of liver injury caused by ethanol. 1. By recovering human primary hepatic cell lines to establish a model of acute alcoholic liver injury, Fer-1 and erastin were used to intervention, DMSO control. 2. The biochemical indexes ALT, Fe, GSH and MDA were detected by the kit. The expression of GPX4 in liver cells was detected by qRT-PCR and Western Blot. 3. To establish an animal model of alcoholic liver injury, Fer-1 and erastin were used to intervention, DMSO control. HE staining and electron microscopy were used to observe the changes of liver tissue morphology.

Results: 1. Acute alcoholic liver injury cytology model showed that in the untreated group, the Fe content is 0.809 ± 0.140 nmol/mg, GSH 14.978 ± 0.398 nmol/mg, MDA 3.402 ± 0.546 nmol/mg; The content of Fe in the alcoholic model group was 1.059 ± 0.005 nmol/mg, GSH 6.826 ± 0.013 nmol/mg and MDA 8.598 ± 0.669 nmol/mg, which was statistically significant compared with the untreated group ($P < 0.05$). The content of Fe in Ferroptosis inhibitor Fer-1 group was 0.889 ± 0.007 nmol/mg, GSH 11.11 ± 0.413 nmol/mg, MDA 5.465 ± 0.317 nmol/mg, compared significantly with alcoholic liver model group ($P < 0.05$). The expression of GPX4 mRNA in the untreated group, alcohol model group and Ferroptosis inhibitor group was 2.041 ± 0.236 , 1.420 ± 0.219 , 1.693 ± 0.294 respectively. The protein level of GPX4 respectively were 9.65 ± 1.453 , 1.36 ± 0.770 and 4.04 ± 0.709 . The results of the above analysis showed that there was significant difference between alcoholic model group and Ferroptosis inhibitor group at both mRNA and protein level of GPX4 ($P < 0.05$). 2. Liver microelectrography showed that the size of mitochondria in liver cells of untreated group was normal. The mitochondrial atrophy and membrane density were increased in the liver alcoholic model group, suggesting that Ferroptosis occurred in the liver injury induced by alcohol. The size of the mitochondria was normal and the mitochondrial ridge was seen in the liver of the Ferroptosis inhibitor group.

Conclusion: 1. Ferroptosis exists in alcohol-induced liver injury. 2. The acute alcohol liver injury cell model showed GSH content decreased, Fe and MDA content increased and the expression of GPX4 decreased in both protein and mRNA levels. Ferroptosis inhibitor Fer-1 could improve the above biochemical changes and the expression of GPX4. 3. In the animal model of alcoholic liver injury, electron microscopy showed that there was Ferroptosis in mouse liver cells, which showed that the mitochondria of the liver cells were smaller and

the mitochondrial membrane density was increased. The Ferroptosis inhibitor Fer-1 could improve the above mitochondrial morphological changes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0685 AMANITA PHALLOIDES HEPATOTOXICITY: 20-YEAR EXPERIENCE IN A GASTROENTEROLOGY INTENSIVE CARE UNIT

C. Atalaia Martins, J. Carvalho, R. Ferreira, P. Amaro, M. Ferreira, L. Tomé Gastroenterology, Centro Hospitalar e Universitário de Coimbra, Coimbra/Portugal

Contact E-mail Address: catarinatalaiamartins@gmail.com

Introduction: Ingestion of amatoxin-containing mushrooms is a rare medical emergency. Amatoxin can cause massive hepatocyte necrosis and acute liver failure. Liver transplantation can be life saving but liver transplantation criteria are complex and not consensual. Mushrooms poisoning is associated with a high mortality rate.

Aims & Methods: We conducted a retrospective analysis of demographic, clinical, therapeutic and prognostic data of all patients with *Amanita phalloides* poisoning admitted to a Gastroenterology Intensive Care Unit (GICU) of a tertiary hospital between 1997 and 2017.

Results: A total of 27 patients were included: 55.6% were male and the mean age was 53 ± 15 years old (range, 16–75). The most frequent initial symptoms were vomiting (100%), diarrhea (88.9%) and abdominal pain (74.1%). The mean time between ingestion and onset of symptoms was 10.1 hours and GICU admission was 50.9 hours. At admission 33.3% presented hepatic encephalopathy (25.9% grade 1; 3.7% grade 3 and 3.7% grade 4). Laboratory characterization at admission: mean INR was 4, total bilirubin 3.5 mg/dL, creatinine 1.9 mg/dL and factor V 25.8%. The different criteria for emergent liver transplantation were assessed: 37% (n = 10) met Clichy's criteria, 59.3% (n = 16) met King's College criteria, 33.3% (n = 9) met Ganzer criteria and 40.7% (n = 11) met Escudie criteria. Overall, 59.3% fulfilled criteria for liver transplantation: 25.9% on admission and 33.3% during hospitalization. Regarding specific medical treatment: 92.6% received silibinin, 59.3% acetylcysteine and 48.1% penicillin. In the group of patients with emergent liver transplantation criteria, 63% were effectively transplanted. In the sub-group of patients who met criteria but were not transplanted (n = 6): in 66.7% (n = 4) the reason was absence of donor, in 16.7% (n = 1) there was liver function recovery and in 16.7% (n = 1) a contraindication was found (irreversible intestinal ischemia diagnosed intraoperatively). The mortality in this sub-group was 83.3%. The mortality rate in transplanted patients was 60%. All patients without emergent liver transplantation criteria survived.

Conclusion: *Amanita phalloides* poisoning has a severe and rapidly progressive presentation, often with indication for liver transplant. Patients are admitted late in GICU. Mortality rate remains high even in transplanted patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Binge drinking is a common pattern of alcohol consumption among young population. At present few data are available on the possible relationship between binge drinking and alcohol use disorder (AUD) in adolescent. The aim of this study was to assess drinking habits, patterns of alcohol consumption, smoking habits, use of illicit drugs, the prevalence of binge drinking and AUD among young students. The correlation between binge drinking and AUD was also investigated.

Aims & Methods: This study was performed on 2704 subjects attending high school. Questionnaires regarding socio-demographic data, anthropometric characteristics, pattern and amount of alcohol intake, smoking habits, use of illicit drugs, and physical activity were administered to students. Moreover Italian versions of AUDIT, STAI-Y1, STAY-Y2 and ZUNG scale were administered.

Results: Alcohol intake was reported by 2126 students (79%); among them 1278 (60%) reported at least one episode of binge drinking in the last year and 715 (34%) in the last month. According to AUDIT questionnaires, a diagnosis of AUD was made in 165 (6%) subjects. The prevalence of AUD was higher in subjects that reported binge drinking behavior than in those that did not report binge drinking ($p < 0.0001$).

Conclusion: Alcohol consumption and abuse among young students is alarming. Binge drinking behavior among young students seems to be very common and it seems a risk factor for the development of AUD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Severe alcoholic hepatitis (SAH) remains a condition which bears high mortality and morbidity rates, as well as high healthcare costs. This is why adequate selection of patients who would benefit the most from corticotherapy is of utmost importance. Although serum biomarkers are available (Maddrey Discriminant Function - MDF), the diagnostic of SAH relies on liver biopsy. Previous metabolomic studies have shown a core metabolic phenotype

represented by decreased serum lysophosphatidylcholines (LPC) and increased serum bile acids that occurs relatively early in liver diseases regardless of etiology, and remains stable in their evolution, including liver cirrhosis and hepato/cho-langiocarcinoma (1). Our previous work also showed that decreased LPC levels are associated with alcoholic liver disease (ALD).

Aims & Methods: The aim of the study was to assess the metabolic profile of patients with ALD and to identify potential new biomarkers associated with severity. Between December 2015 and September 2016, 64 patients with biopsy proven AH were included (38 with SAH - MDF ≥ 32 and 24 with non-severe AH - MDF < 32). Fasting serum was stored at -80 degrees after centrifugation at 5000 rpm for 10 minutes. Specific purification protocol metabolomic analysis was performed using Thermo Scientific UHPLC UltiMate 3000 system, equipped with a Dionex quaternary pump delivery system and a Bruker Daltonics MaXis Impact MS detection equipment (version 2012). *Biostatistical analysis* The chromatograms obtained were processed using CompassDataAnalysis_4.2 software (Bruker, Germany) and about 3000–4000 molecular masses were identified. Those data were further processed using ProfileAnalysis (Bruker, Daltonics): time alignment, normalization by sum of bucket values in analysis, 80% bucket filter, internal recalibration, etc. The matrix obtained was further processed by MetaboAnalysis, to analyze samples through univariate and multivariate statistical analysis.

Results: Univariate and multivariate statistical analysis by MetaboAnalysis identified 10 potential biomarkers. Among them, LPC (18:0) showed good discrimination for SAH (AUC = 0.804) with significantly lower values as compared with non-severe AH (0.38 fold change, $p = 6 \times 10^{-11}$).

Conclusion: SAH appears to have a different metabolic profile, mainly due to changes in lysophosphatidylcholine metabolism. Targeted metabolomic studies are required in order to confirm the results and to evaluate the possible applications in current clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute kidney injury (AKI) is a common complication in patients with decompensated liver cirrhosis. Recently, the International Club of Ascites (ICA) defined new diagnostic criteria: the ICA-AKI criteria.

Aims & Methods: This study aims to identify patients hospitalized for acute decompensation of cirrhosis with AKI, according to the ICA-AKI criteria, and to determine if its application leads to greater prognostic accuracy.

Methods: Retrospective analysis of hospitalized patients in a gastroenterology department for acute decompensation of cirrhosis, without acute-on-chronic liver failure, between January 2014 and December 2015. Identification of AKI patients according to ICA-AKI criteria. Compared the hospital length of stay, severity of liver disease and in-hospital and short-term mortality among patients with and without AKI. Compared the accuracy of the conventional criteria vs. ICA-AKI criteria in the prediction of mortality.

Results: 161 patients included, 85.7% male, mean age of 65 ± 10.8 years. Average length of stay of 11.6 ± 9.5 days. 39.8% of patients had AKI on admission or during hospitalization according to the ICA-AKI criteria (60.9% in stage 1, 20.3% in stage 2 and 18.8% in stage 3). Patients with AKI according to ICA-AKI had longer hospitalizations (14.55 vs. 9.78 days, $p < 0.05$), higher severity of hepatic disease quantified by the MELD and MELD-Na scores (17.62 vs. 12.83 511, $p < 0.05$ and 17.61 vs. 12.83 $P < 0.05$) and higher in-hospital, 28 and 90-day mortality when compared to patients without AKI (23.4 vs. 6.2%, $p < 0.05$, 31.3 vs. 9.3%, $p < 0.05$, 42.9 vs. 23.7%, $p < 0.05$). There was a statistically significant association between the presence of infection and the development of AKI ($p < 0.05$). The ICA-AKI area under the curve (AUC) to predict in-hospital, 28 and 90-day mortality was significantly higher than the AUC of conventional criteria (0.682 vs 0.533; 0.678 vs 0.588; 0.618 vs 0.509, $p < 0.05$).

Conclusion: The ICA-AKI criteria allow the identification of decompensated cirrhotic patients in whom a worse prognosis is predicted. Thus, they constitute a useful tool in daily clinical practice.

Introduction: The pathophysiology of hepatic encephalopathy is not fully understood. A nationwide nested case-control study was conducted to investigate risk factors in the development of hepatic encephalopathy (HE) among patients with liver cirrhosis (LC) in Taiwan.

Aims & Methods: A total of 913 patients with incident HE and 3499 patients without HE (control) were identified from a cohort of liver cirrhosis ($n = 14,428$) using the population-based, Longitudinal Health Insurance Database 2000 in 1997–2012. Controls were matched to case patients on age at LC diagnosis (± 2 years), sex, Charlson Comorbidity index score, year of LC and follow-up time at 1:1 ratio. A multivariate logistic regression model for HE was developed to explore the relative contribution of various risk factors, including patient

demographics, infections, cirrhosis-related complications (hepatocellular carcinoma, decompensated cirrhosis), *H. pylori* therapy, and peptic ulcer bleeding. A Cox regression model for all-cause mortality was performed.

Results: 714 cases of HE and matched to 714 controls were enrolled in the analysis. Infections (adj. OR, 3.41, 95% CI, 2.7–4.31, $p < .0001$) and frequency of infections yearly (≥ 3 : adj. OR 11.26, 95% CI, 5.7–22.22; 1–3: adj. OR 2.82, 95% CI, 2.26–3.53) were significantly associated with increased risk of HE. *H. pylori* infection (13.31% vs. 8.68%, $p = 0.0052$) and sites of infections such as pneumonia (14.99% vs. 10.50%, $p = 0.0111$), peritonitis (14.29% vs. 2.52%, $p < 0.0001$), sepsis (25.63% vs. 9.52%, $p < 0.0001$), urinary tract infection (18.77% vs. 11.20%, $p < 0.0001$), biliary tract infection (7.14% vs. 3.22%, $p = 0.0008$) and cellulitis (11.62% vs. 3.98%, $p = 0.0207$) increased risk for HE. HE (adj HR, 0.90, 95% CI, 0.76–1.06, $p = 0.02$) and infections (adj. HR, 1.13, 95% CI 0.93–1.38, $p = 0.23$) increased hazards of death but did not reach statistical significance.

Conclusion: This is the first reported case-control study of HE in Taiwan. The study provides further evidence that infections are strongly associated with HE development among patients with liver cirrhosis; risks for HE vary by relative frequencies and sites of infections. These data provides important information relevant to the prevention and management of cirrhotic patients at risk for HE.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0690 SEPSIS-3 CRITERIA ARE MORE ACCURATE THAN SIRS CRITERIA IN PREDICTING IN-HOSPITAL MORTALITY IN PATIENTS WITH CIRRHOSIS AND BACTERIAL INFECTIONS

S. Piano, M. Tonon, G. Chies, A. Romano, E. Vettore, M. Stanco, C. Pilutti, A. Brocca, P. Angeli

Introduction: Patients with cirrhosis have a high risk of sepsis, which confers a poor prognosis. Systemic inflammatory response syndrome (SIRS) criteria have several limitations in cirrhosis. Recently, new criteria for sepsis (Sepsis-3) have been suggested in the general population (increase of Sequential Organ Failure Assessment [SOFA] ≥ 2 points from baseline). Outside the ICU, the qSOFA (at least 2 among: alteration in mental status, systolic blood pressure ≤ 100 mmHg, or respiratory rate ≥ 22 /min) was suggested to screen sepsis. These criteria have never been evaluated in cirrhotic patients.

Aims & Methods: The aim of our study was to assess the ability of Sepsis-3 criteria in predicting in hospital mortality in patients with cirrhosis and bacterial infections. Consecutive patients with cirrhosis and bacterial/fungal infections were prospectively included. Demographic, laboratory and microbiological data were collected at diagnosis of infection. Preadmission SOFA was assessed using preadmission data as provided for acute kidney injury criteria. Patients were followed-up until death, liver transplantation or discharge.

Results: 259 patients were included (Age = 61 ± 12 years, MELD-score = 20 ± 7). The most common infections were urinary tract infection (33%), spontaneous bacterial peritonitis (23%) and pneumonia (14%). SIRS, qSOFA and Sepsis-3 criteria were found in 34, 23 and 64% of patients, respectively. During the hospitalization 19% of patients died. Sepsis-3 and qSOFA had significantly greater discrimination for in-hospital mortality (AUROC = 0.784 and 0.732, respectively) than SIRS (AUROC = 0.606; $p < 0.01$ for both). In multivariate analysis, Sepsis-3 (OR = 5.71; $p = 0.007$), qSOFA (OR = 3.11; $p = 0.004$), CLIF-C-AD score (OR = 1.05; $p = 0.007$), C-reactive protein (OR = 1.62; $p = 0.014$) and nosocomial infections (OR = 2.15; $p = 0.058$), were found to be independent

predictors of in-hospital mortality. Patients with Sepsis-3 had higher incidence of acute-on-chronic liver failure (36 vs 11%; $p < 0.001$), septic shock (15 vs 0%; $p < 0.001$) and transfer to the ICU (16 vs 2%; $p = 0.001$) than those without Sepsis-3. Similar findings were found for qSOFA.

Conclusion: Sepsis-3 criteria are more accurate than SIRS criteria in predicting the severity of infections in patients with cirrhosis. qSOFA is a useful bedside tool to assess risk for worse outcomes in these patients. Patients with Sepsis-3 and positive qSOFA deserve more intensive management and strict surveillance.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0691 A SUBCLINICAL HIGH TRICUSPID REGURGITATION PRESSURE GRADIENT IS A RISK FACTOR FOR SURVIVAL AFTER LIVING DONOR LIVER TRANSPLANTATION

A. Ohyama, A. Takaki, Y. Umeda, T. Yasunaka, R. Yoshida, D. Nobuoka, F. Ikeda, H. Okada, H. Onishi, H. Shiraha, S. Nakamura, T. Yagi

Introduction: Portopulmonary hypertension (POPH) is characterized by pulmonary vasoconstriction, while hepatopulmonary syndrome (HPS) is characterized by vasodilatation. Given that HPS could be resolved after orthotopic liver transplantation (OLT) even when hypoxemia were severe ($\text{PaO}_2 < 50 \text{ mmHg}$), implications for OLT is accepted not only for deceased donor LT (DDLT), but also to living donor related LT (LDLT). However, the post-OLT course of POPH complicated patients are often unsatisfactory and severe ($\text{mPAP} > 45$ to 50 mmHg) patients are considered as an absolute contraindication for OLT. The International Liver Transplant Society Practice Guidelines indicate that, unlike HPS, there are no data to support the concept that POPH (treated or untreated) should be an indication for OLT. Furthermore, the Practice Guidelines recommend that patients with $\text{mPAP} < 35 \text{ mmHg}$ be indicated for OLT, and PA-targeted therapy should be initiated in patients with $\text{mPAP} \geq 35 \text{ mmHg}$. However, almost all of the patients in these articles had received DDLT, and no such analyses have been for LDLT patients. Given that left or right lobe LDLT grafts are smaller than DDLT grafts, PH-induced hepatic venous pressure might result in a strong congestive impact on the LDLT grafted liver. Although patients with confirmed POPH and HPS are rare, relatively pulmonary hypertensive patients and mild HPS patients may be more common.

Aims & Methods: The present objective is to investigate the clinical impact of subclinical PH on the inevitably small survival in grafted living donor OLT (LDLT). We recruited 84 OLT candidates for liver cirrhosis in a retrospective cohort study. Patients exhibiting a tricuspid regurgitation pressure gradient (TRPG) $\geq 25 \text{ mmHg}$ (median) on echocardiography were categorized as potentially having PH (subclinical PH; $n = 34$). The mean pulmonary artery pressure (mPAP) measured after general anesthesia with $\text{FIO}_2 0.6$ ($\text{mPAP-FIO}_2 0.6$) was also included as advisory data. Patients exhibiting $\text{pO}_2 < 80 \text{ mmHg}$ and an alveolar-arterial oxygen gradient (AaDO_2) $\geq 15 \text{ mmHg}$ were categorized as potentially having HPS (subclinical HPS; $n = 29$). The clinical course after LDLT was investigated according to subclinical PH or HPS.

Results: Subclinical PH was correlated with a worse 1-year survival ($p = 0.003$). Subclinical PH ($p = 0.012$) and older donor age ($p = 0.008$) were correlated with a poor 40-month survival. Although a higher $\text{mPAP-FIO}_2 0.6$ was expected to correlate with a worse survival, a high $\text{mPAP-FIO}_2 0.6$ was not a significant risk factor for the post-LDLT survival. When the post-LDLT survival was investigated according to the TRPG and $\text{mPAP-FIO}_2 0.6$ status, it was worst in patients who had a high TRPG and low $\text{mPAP-FIO}_2 0.6$. The patients with a high $\text{mPAP-FIO}_2 0.6$ and low TRPG showed a good survival, probably because co-existing HPS released the regurgitation pressure.

Conclusion: In cirrhosis patients, $\text{mPAP-FIO}_2 0.6$ may not accurately reflect the congestive pressure to the liver, as the pressure might escape via a pulmonary shunt. Subclinical high TRPG is an important marker for predicting congestive pressure to a grafted small liver, resulting in a worse survival after LDLT.

P0693 CARVEDILOL VERSUS PROPRANOLOL EFFECT IN THE PRIMARY PROPHYLAXIS OF VARICEAL BLEEDING IN CIRRHOTIC PATIENTS WITH PORTAL VEIN THROMBOSIS

I. Gîrleanu¹, A. Trifan¹, C. Cojocariu¹, A.M. Singeap¹, C. Sfarti¹, O. Stoica¹, S. Chiriac¹, T. Cucuureanu¹, C. Stanciu²

²Institute of Gastroenterology and Hepatology, Iasi/Romania

Contact E-mail Address: gilda_iri25@yahoo.com

Introduction: Portal vein thrombosis (PVT) is recognized as an independent factor of variceal bleeding. Beta blockers are the mainstay treatment to prevent variceal bleeding in cirrhotic patients. Carvedilol has been shown to be equal to propranolol in preventing first bleeding in cirrhotic patients, however, the efficacy of this policy in patients with PVT is unknown.

Aims & Methods: The aim of this study was to evaluate the efficacy of carvedilol versus propranolol in primary prophylaxis of variceal bleeding in cirrhotic patients with occlusive portal vein thrombosis. Between January 2014 and December 2015, cirrhotic patients with occlusive non-malignant PVT were enrolled in a tertiary center. PVT was suspected by Doppler ultrasound and confirmed by computed tomography. Cirrhotic patients with esophageal varices and no previous variceal bleeding were randomized to carvedilol 6.125 mg daily or Propranolol 40 mg daily. End points were esophageal variceal bleeding or death.

Results: During the study period forty eight patients were evaluated. Twenty one and twenty seven patients were randomized in carvedilol and propranolol arms respectively. Mean age was 49 ± 12.2 years; 33 (68.7%) were males; 60.4% had viral cirrhosis; mean Child-Pugh score was 7.2 ± 2.6 and mean follow up was 12.3 ± 9.1 months (range 1–29 months). All the patients had occlusive non-malignant PVT, most of them involving only the trunk, and grade 2 or 3 esophageal varices. Both carvedilol and propranolol groups had comparable variceal bleeding rates (14.2% vs. 14.8%, $P = 0.002$), bleed related mortality (9.5% vs. 11.1%, $P = 0.027$) and overall mortality (23.8% vs. 22.2%, $P = 0.004$) respectively. Adverse events in carvedilol group were hypotension ($n = 2$), requiring cessation of therapy, while and dyspnea ($n = 3$) resolved spontaneously. In the propranolol group there was 1 adverse event that required discontinuation of treatment (grade 2 atrio-ventricular block).

Conclusion: Our study suggests that carvedilol is probably not superior to propranolol in preventing first variceal bleeding in cirrhotic patients with occlusive PVT, and they both can be used as primary prophylaxis.

Introduction: The ALBI score was recently developed to assess the severity of liver dysfunction, taking into account albumin and bilirubin levels. We aimed to assess its prognostic performance in patients with liver cirrhosis complicated with upper gastrointestinal bleeding (UGIB) while comparing it with Child-Pugh (CP) and MELD scores.

Aims & Methods: Retrospective unicentric study, including consecutive adult patients with cirrhosis admitted for UGIB between January 2011 and November 2015. Clinical, analytical and endoscopic variables were assessed and ALBI, CP and MELD scores at admission were calculated. Statistical analysis was performed using SPSS v21.0 and MedCalc v.16.4.3, and a two-tailed p value < 0.05 was defined as indicating statistical significance.

Results: Included 111 patients with a mean age of 57 ± 12 years, 76.6% were males. Liver cirrhosis was most frequently alcoholic (89.2%) and the most common etiology for UGIB was variceal hemorrhage, in 75.5% of patients. During the first 30 days of follow-up 12 patients (10.8%) died, and during the 1st year of follow-up another 10 patients died (1st year mortality of 19.8%). When comparing the three scores, regarding in-stay and 30 days mortality, only ALBI score showed statistical significant results, with an area under the curve (AUC) of 0.82 ($p < 0.01$) for both outcomes. Regarding 1st year mortality, AUC for ALBI, CP and MELD scores, were 0.71 ($p < 0.01$), 0.64 ($p < 0.05$) and 0.66 ($p = 0.02$), respectively, while for global mortality AUC were 0.75 ($p < 0.01$), 0.72 ($p < 0.01$) and 0.72 ($p < 0.01$), respectively. When comparing the AUC of the three scores, no significant differences were found regarding 1st year mortality and global mortality.

Conclusion: In our series, ALBI score accurately predicted both in-stay and 30 days mortality (0.82 ($p < 0.01$)), while CP and MELD scores weren't able to predict these outcomes. All scores showed a fair prognostic prediction performance regarding 1st year and global mortality. These results suggest that ALBI score is particularly helpful in the assessment of short term outcomes, with a better performance than the most commonly used scores, and may assist the clinician in the stratification of care at admission and maybe even in the referral to liver transplant.

Introduction: Despite the progress in the treatment of cirrhosis, infections remain a common problem, being responsible for the great majority of morbidity and mortality in these patients.

Aims & Methods: The aim of this study was to identify predictive factors for infection in the first hospitalization for decompensated cirrhosis (DC). Retrospective analysis of patients with the first hospitalization for DC between January of 2009 and March of 2016. Demographic, clinical and biochemical data was compared between patients with and without proven infection in the first hospitalization for DC.

Results: From the 179 patients with a first hospitalization for DC, 6% had ascites on admission, 45.8% had upper gastrointestinal bleeding, 38.5% had jaundice, and 28.5% had hepatic encephalopathy. Regarding medication, 29.6% of the patients were taking proton pump inhibitors (PPI), 22.3% had beta-blockers prescribed, and 1.7% were on prophylactic antibiotic. In those 53 patients with proven infection, spontaneous bacterial peritonitis was the most common infection (34%), followed by urinary tract infection (30.2%) and pneumonia (13.2%). Infected patients presented with jaundice ($p = 0.03$), severe ascites ($p = 0.009$), use of PPI ($p = 0.003$) and acute-on-chronic liver failure ($p = 0.006$) more frequently than those without infection. Additionally, infected patients presented with significantly increased values of C-reactive protein ($p < 0.001$), INR ($p = 0.04$), creatinine ($p = 0.013$) and MELD scores ($p = 0.001$). Mortality rates were higher in infected patients at 30-day (4.0% vs. 9.4%), 3 months (7.9% vs. 18.9%), 6 months (12.7% vs. 24.5%) and 1 year (22.2% vs. 26.5%). In the multivariate analysis, the use of PPI was independently associated with an increased risk of infections (OR = 2.3; 95% CI 1.052–5.173).

Conclusion: Almost a third of patients will develop infections right at the first hospital admission for decompensated cirrhosis, which are associated with higher short and long-term mortality rates. As PPI more than double the risk of infection, the indication for the use of these drugs should be strictly reviewed and their interruption considered in cirrhotic patients.

Contact E-mail Address: vincistein00@gmail.com

Introduction: Critical flicker frequency (CFF) values ≤ 39 Hz identify cirrhotic patients with minimal hepatic encephalopathy (mHE) and predict their risk of developing overt hepatic encephalopathy (oHE). However, these results have been obtained in cirrhotics with advanced liver disease suffering a previous episode of liver decompensation (74% of patients) or oHE (14% of patients).

Aims & Methods: Herein, we evaluated the effectiveness of CFF in predicting the first episode of oHE in compensated outpatients undergoing a long-term follow up. A total of 134 selected patients and 150 healthy subjects were evaluated using CFF. A CFF value was considered normal when > 39 Hz and pathological when ≤ 39 Hz. At baseline, we evaluated demographic characteristics, laboratory tests, model for end-stage liver disease (MELD) score, and Child-Pugh class in all patients. Then, they were followed up for 31.5 ± 18.9 months and received clinical examinations and laboratory tests every six months.

Results: At baseline, all controls had a CFF > 39 Hz with a mean value significantly higher than that observed in 93 patients with CFF > 39 Hz ($p < 0.001$), while the remaining 41 patients showed a CFF ≤ 39 Hz. Our analysis demonstrated a significant inverse correlation between CFF and MELD ($r = -0.33$, $p = 0.0003$), while the prevalence of CFF values ≤ 39 Hz significantly increased with the progression of the Child-Pugh class ($p = 0.003$). Interestingly, the CFF value at baseline was predictive of the first episode of overt HE both by log-rank test ($p < 0.001$) and Cox regression analysis (HR = 5.623; 95%CI = 2.433–12.991; $p < 0.001$).

Conclusion: We demonstrated, for the first time, that CFF predicts the first episode of oHE in a population of compensated cirrhotics that never experienced oHE. Cirrhotic patients should be routinely screened by CFF to identify patients at risk of oHE.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The Fontan circulation causes some degree of hepatic congestion by its nature of anatomical reconstruction. This may lead to liver fibrosis or even cirrhosis, but to what extend is unknown. A profound hepatic evaluation, incorporating several non-invasive and invasive modalities, in an asymptomatic Fontan patient cohort may further elucidate this.

Aims & Methods: Consecutive patients with a Fontan circulation are prospectively included for screening of liver fibrosis. This screening consists of a blood panel including biomarkers, liver ultrasonography, transient elastography (Fibroscan), contrast-enhanced liver MRI or CT-scan and liver biopsy. Liver biopsies were systematically scored with the Fontan specific fibrosis score. Mild fibrosis was defined as a maximum score of 2 on sinusoidal and portal fibrosis component, severe fibrosis as score 3 or 4 on at least one component. Non-invasive markers for portal hypertension (PHT) such as presence of collaterals and splenomegaly on imaging, platelet count ($N/\mu Lmm^3$)/spleen diameter (mm) ratio (PSR) and von Willebrand factor (VWF) were measured.

Results: From November 2015 until March 2017, 52 Fontan patients were included (mean age 27 ± 7.5 years, 60% male). The majority of patients had one or more elevated liver enzymes (elevated GGT in 68%, median $67 \mu mol/l$ IQR 51–107). Median platelets were $174 \times 10^9/l$ (IQR 147–213) and mean VWF $104 \pm 23\%$. Mean liver stiffness was 21.8 ± 9.3 kPa. The majority (77%) of ultrasonographies showed no sign of cirrhosis or splenomegaly (mean spleen size 11.9 ± 1.8 cm). However, 54% of advanced imaging (MRI or CT-scan) showed cirrhosis, 23% congestion and in 21% signs of PHT were observed. Of 33 patients with histology, none were without fibrosis or sinusoidal dilatation and cirrhosis was present in 21%. Of these only 57% also showed signs of cirrhosis on imaging. Of all patients with signs of PHT on imaging only one (13%) patient had histologically confirmed cirrhosis whereas five (63%) had mild fibrosis. Liver stiffness was equal in patients with mild (22.3 ± 9.2) compared to severe fibrosis (25.3 ± 12.1) ($p = .458$). Median PSR in patients with mild fibrosis was 1557 (IQR 1139–1910) and 1233 (IQR 1045–1451) in severe fibrosis ($p = .114$). VWF was comparable between groups (99 ± 12 vs. $105 \pm 20\%$, $p = .241$). Patients with severe fibrosis were not older (resp 28 ± 7 vs. 26 ± 6 years, $p = .555$) nor had a longer duration of the Fontan circulation (22 ± 5 vs. 21 ± 4 years, $p = .644$).

Conclusion: All Fontan patients are at risk of developing severe liver fibrosis, irrespective of age, duration of Fontan circulation and even when asymptomatic. Portal hypertension may occur in the absence of severe fibrosis. Assessment by solely non-invasive modalities may both under- and overestimate the incidence of fibrosis. For generalizability of the current findings, Fontan patients should be prospectively assessed with multimodality assessment in larger cohorts.

Introduction: Probiotics has been recently used to treat cirrhotic patients with any grade of acute or chronic hepatic encephalopathy (HE). Herein, we evaluated the efficacy of Lactobacillus Rhamnosus GG (LGG) on the treatment of minimal HE (mHE) in compensated cirrhotics.

Aims & Methods: 134 patients were screened by critical flicker frequency (CFF) to diagnose mHE. Among them, 41 patients were CFF+ (≤ 39 Hz) and were

randomized to placebo or LRGG treatment, for 2 months. In all intention to treat and per protocol patients, demographic characteristics, laboratory test, model for end-stage liver disease (MELD) score, and Child-Pugh class were evaluated.

Results: CFF value increased in both LRGG and placebo groups at the end of treatment. However, in the former group CFF value significantly increased as compared to placebo (46.5 ± 5.7 vs. 41.1 ± 4.6 Hz, $p=0.015$), thus indicating a better therapeutic outcome on mHE. Moreover, mHE reversal was achieved in 75.0% vs. 35.7% of the patients from LRGG and placebo groups, respectively ($p=0.047$).

Conclusion: For the first time, we demonstrate that LRGG improves mHE (expressed by a significant CFF increase).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Hepatitis C virus infection is a pressing national problem in Egypt. HCV carries a variable clinical course in different patients. The human Toll like receptors (TLRs) family consists of ten receptors that are critically important for innate immunity. TLRs recognize and respond to diverse microbial molecules and enable the innate immune system to discriminate among groups of pathogens and to induce an appropriate cascade of effector responses. Toll-like receptors 3 and 7 are recognition receptors that allow the innate immune system binding to RNA materials. The genetic polymorphism of these receptors has a direct role on the outcome of many diseases.

Aims & Methods: The aim of this study was to assess the association between genetic polymorphism of TLR 3 and Sex- linked TLR 7 alleles with HCV infection outcome in Egyptian families using high resolution techniques. A total of 135 Egyptian families (622 individuals) were recruited in this study from upper and lower Egypt (East and West delta). We compared the risk of allele carriage of selected markers in different groups. These groups included spontaneous virus clearance (SVC) (108 subject), chronic HCV (CHC) patients (216), and negative control (298) individuals. The rs3775291 (C/T) was genotyped for TLR3. While the rs3853839 (C/G) was genotyped for TLR7 by real time PCR using TaqMan[®] allelic discrimination kit (Applied Biosystems) according to the manufacturer's protocol. The distribution of the TLR7 rs3853839 (C/G) polymorphism was assessed separately in female and male subpopulations of the study due to the X-linked nature of the TLR7 gene.

Results: As regard TLR3 the frequency of the C allele was 88.5%, 83.4% and 71.06% for the SVC, control and CHC groups respectively. While the allele frequency of the T allele was found to be 11.5%, 16.5%, 38.9% in SVC, control, and CHC groups respectively. When these alleles were compared between the 3 studied groups, The T allele of TLR 3 rs3775291 was found to be significantly higher in chronic HCV group when compared to both spontaneous clearance (SVC) and control groups [OR 15.285 (95% CI 2.04 to 114.08, corrected P (Pc) <0.02) and OR 5.17 (95% CI 2.30 to 11.64, Pc < 0.0003)] respectively. As regard the sex-linked TLR-7 it was found that the frequency of the C allele was 69.5%, 69.1% and 46.3% for the SVC, control and CHC groups respectively. While the frequency of the G allele was found to be 30.95%, 30.9%, 53.7% in SVC, control and CHC groups respectively. When the association of these alleles with HCV infection outcome was studied in the female and male subpopulations it showed

that: The C allele of TLR 7 rs3853839 in the female subpopulation was significantly higher in both HCV spontaneous clearance (SVC) and control groups when compared to chronic HCV group [OR 0.42 (95% CI 0.21 to 0.82, Pc < 0.0372) and OR 0.40 (95% CI 0.23 to 0.71, Pc < 0.0054)] respectively. The same results was also reported in the male subpopulation as the same allele was found to be significantly higher in both HCV spontaneous clearance (SVC) and control groups when compared to chronic HCV group [OR 0.289 (95% CI 0.14 to 0.59, Pc < 0.0021) and OR 0.17 (95% CI 0.1009 to 0.28, Pc < 0.0001)] respectively.

Table(1): Association of the allele T of TLR3 rs3775291 polymorphism among the studied groups.

	control Vs spontaneous	CHC vs Spontaneous	CHC vs control
Odds ratio (OR)	2.9517	15.2857	5.1786
95% CI	0.3648 to 23.8807	2.0481 to 114.0824	2.3038 to 11.6406
z statistic	1.015	2.659	3.979
P	0.3102	0.0078	0.0001
Pc	0.9306	0.0234	0.0003

Conclusion: The risk of development of chronic HCV infection was associated with T allele carriage of TLR3rs3775291 SNP. While the carriage of C allele of TLR7 rs3853839C allele was associated with spontaneous HCV clearance in both male and female subpopulations in Egyptian families.

Introduction: Th17 cells are involved in liver fibrosis by activating hepatic stellate cells (HSCs). We aimed to investigate whether HSCs could regulate the function of Th17 cells and the relevant mechanism.

Aims & Methods: Sixty-five patients diagnosed with chronic hepatitis B (CHB) were enrolled in this study. To unravel the effect of HSCs on T cells, naïve CD4⁺T cells and Th17 cells were sorted from CHB patients and cultured with or without activated-HSCs, and cytokines expression and genes transcription were analyzed. In addition, the regulatory mechanism of HSCs was also investigated.

Results: ELISA and qRT-PCR showed that Th17 cells from CHB patients were more pathogenic via the expression of IL-17A, IL-23R, RORC, CCL20 and CCR6, and meanwhile, they could activate the primary HSCs. The co-culture experiment indicated that activated HSCs dramatically promoted the proliferation of CD4⁺T cells in a time- and dose-dependent manner. In addition, they could also induce the naïve CD4⁺T cells into Th17 cells which had a more pathogenic phenotype. Moreover, activated-HSCs-mediated induction of Th17 cells might depend on IL-1β and IL-6 release as well as COX-PGE2 pathway.

Conclusion: Th17 cells cooperated with HSCs in a proinflammatory feedback loop provide us a more understanding of the pathogenic role of Th17 cells in the chronicity of HBV infection.

Introduction: Living donor liver transplantation (LDLT) has become the only life-saving treatment option for patients with end stage liver disease secondary to HCV infection in Egypt, unfortunately recurrence of infection is nearly universal,

resulting in cirrhosis and graft failure within 5 years after transplant. Different studies have been published studying efficacy and safety of direct acting antiviral (DAA) drugs in treatment of HCV infection post-liver transplantation. We aimed to evaluate the efficacy and safety of treatment with DAA drugs early post-transplant period in LDLT recipients with HCV genotype 4

Aims & Methods: The study was descriptive retrospective analysis on twenty-six LDLT patients with HCV genotype 4 treated with DAA drugs (fifteen patients received Sofosbuvir 400mg and weight based Ribavirin dose for 24 weeks, eight patients received Sofosbuvir 400mg and Daclatasvir 60 mg for 24 weeks and three patients received Sofosbuvir 400mg and Simeprevir 150 mg for 12 weeks) in the early post-transplant period who were transplanted during the period from January 2014 till December 2015 at Egyptian tertiary center for organ transplantation

Results: Twenty-six patients completed the treatment course, sustained virological response (SVR) at week 12 was achieved in 80.8% (21/26) of recipients, 100% (11/11) for Sofosbuvir- Daclatasvir and Sofosbuvir- Simeprevir group versus 66.7% (10/15) for Sofosbuvir-Ribavirin group ($p < 0.05$). No major side effects had been reported, anemia developed in patients received ribavirin respond to treatment with erythropoietin and reduction of the ribavirin dose.

Conclusion: Use of Daclatasvir/Sofosbuvir or Simeprevir/Sofosbuvir in early treatment of HCV genotype 4 post living donor liver transplant recipient achieved higher rates SVR than Sofosbuvir/Ribavirin.

Introduction: Direct antiviral agents (DAAs) have led to high sustained virological responses (SVR) in HCV patients. However, genotype 3 patients respond to treatment in a suboptimal way.

Aims & Methods: This study aims to identify which of the several treatment schedules recommended for genotype 3 would constitute the best option. Twenty-four Italian centers were involved in this real-life study where HCV genotype 3 patients treated with DAAs. To expand the number of cases, we conducted a systematic review of literature on the outcome of genotype 3 patients treated with DAAs.

Results: A total of 233 patients with HCV genotype 3 were enrolled. Cirrhotic patients accounted for 83.7%. Overall, the SVR12 rate was achieved by 205 subjects (88.0%); the SVR rates were 78.8% after sofosbuvir/ribavirin, 92.5% after sofosbuvir/daclatasvir ± ribavirin, and 100% after sofosbuvir/ledipasvir (7patients). No difference of rate of SVR was observed in cirrhotic and non cirrhotic patients (92.2vs94.4) using a combination regimens of NS5A and NS5B inhibitors. The systematic review of literature provided data of 3311 patients: the mean weighted SVR12 rate was 84.4% (CI:80.4–87.8); the rates varied from 79.0%(CI:70.9–85.3) with sofosbuvir/ribavirin, to 83.7% (CI:66.2–93.1) with sofosbuvir/ledipasvir, and to 88.2% (CI:83.3–91.7) with sofosbuvir/daclatasvir.

Conclusion: Our results reinforce the concept that HCV genotype 3 should no more considered difficult to treat individuals. The optimal therapeutic regimen for these patients appears to be the combination sofosbuvir/daclatasvir, administered for 12 weeks without the use of RBV in non cirrhotic patients. In cirrhotics the meta-analytic approach suggests to extend therapy at 24 weeks.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0704 IMPROVEMENT OF LIVER STIFFNESS VALUES MEASURED BY TRANSITION ELASTOGRAPHY AFTER CHRONIC HEPATITIS C TREATMENT WITH DIRECT ACTION ANTIVIRALS AND EVOLUTIVE CORRELATION OF THROMBOCYTOPENIA AND PRESENCE OF ESOPHAGEAL VARICES

M. Perez Ferrer¹, I. Maestro Prada¹, A. Mcgee², J.L. Castro Urda¹, L.A. Castillo Hererra¹, C. Garcia Ramos¹

²Epidemiology, Hospital Universitario Mostoles, Mostoles/Spain

Contact E-mail Address: miguelperrer@gmail.com

Introduction: An improvement in liver stiffness (LS) measured by transient elastography (TE) has been observed in patients with chronic hepatitis C treated with direct action antivirals (DAA).^(1, 2) The Baveno VI guidelines⁽³⁾ propose that patients with compensated advanced chronic liver disease (cACLD), LS measurement <20 kPa and a platelet count >150000/μL can avoid screening endoscopy as their combination is highly specific for excluding clinically significant oesophageal varices (EV). These criteria have been validated recently.^(4, 5, 6)

Aims & Methods: The aim of this study was to quantify LS regression both quantitatively (measured in Kilopascals) and qualitatively (Stages of F0-F4 fibrosis) in a stationary phase after the sustained virological response (SVR) in patients with cACLD (F4). The secondary objective was to assess whether this improvement in LF measurements has a clinical correlation with changes in platelet numbers and the presence of varices according to Baveno VI criteria.

Results: 84 patients (49 men and 35 women) with cACLD were included in the study. Median TE on baseline (BL) prior to DAA treatment was [mean (range), 23.86 (12.5–75) kPa] and decreased to [mean (range), 15.6 (4.8–75) kPa] at SVR 24 and [mean Range), 16.19 (3–62.7) kPa] at SVR > 54. Both were statistically significant, showing a decrease in LS about 30% between BL and SVR24 and about 33% between BL and SVR > 54. We did not find statistically significant differences between SVR 24 and SVR > 54. Regarding the probability of qualitative improvement of the LS (improve from F4 to F3 or less) the AUC was 0.8 with 17.9 kPa as the cut-off point which has a Sensitivity of 0.76 and Specificity of 0.81. NPV = 78.12, PPV = 78.57. 32 patients with highly suggestive cACLD (LS > 15 kPa) underwent upper endoscopy (UE): 10 (32%) had varices (5 small EV and 5 big EV), 17 (53%) fulfilled the Baveno VI criteria (3 with small EV and 4 with small) EV. There were only 3 cases of EV misdiagnosed by Baveno VI Criteria. We did not find any significant differences in platelet levels or in the regression of varices.

Characteristics	Main Cohort n = 84
Age mean (st)	60 (9.8)
Male-sex (%)	49 (58.3%)
Aetiology of liver disease (%)	HCV 100%
Platelet count × 103/mm3 Baseline mean (st)	149.21 (59.62)
Platelet count × 103/mm3 SVR 54 mean (st)	168.15 (60.33)
Fibrosis Stage F0–I in SVR 54 n (%)	8 (12.7%)
Fibrosis Stage F2 in SVR 54 n (%)	12 (19.5%)
Fibrosis Stage F3 in SVR 54 n (%)	13 (20.63%)
Fibrosis Stage F4 in SVR 54 n (%)	30 (47.62%)
Liver Stiffness (kPa) Baseline [n = 84]mean (st)	23.86 (12.63)
Liver Stiffness (kPa) SVR 24 [n = 59] mean (st)	15.6 (12.14)
Liver Stiffness (kPa) SVR 54 [n = 63]mean (st)	16.18 (10.99)
Patients who underwent Upper Endoscopy n (%)	32 (38.01%)
Patients with varices (VE) (any size) [n = 32] n (%)	10 (31.25%)
Patients fulfilling Baveno criteria [n = 32]n (%)	17 (53.15%)
Patients with high-risk VE [n = 32] n (%)	5 (15.6%)
Patients fulfilling Baveno criteria with high-risk VE [n = 32] n (%)	4 (12.5%)

Conclusion: There is a significant improvement in LS data after treatment with DAA both at SVR24 and SVR > 54. This improvement seems to be more likely to happen in patients with lower TE values (in our study 17.9 kPa). We did not have enough available data in our study to support that this improvement in LS measured by TE has a relevant impact on the clinical management of the patient. The Baveno VI criteria are a useful tool in daily practice to avoid unnecessary UE. Further investigation with larger samples is needed.

Contact E-mail Address: joana.rita.carvalho@gmail.com

Introduction: The therapeutic regimens for chronic hepatitis C are now tending to be shorter and ribavirin free, more cost-effective and with fewer adverse effects.

Aims & Methods: We aimed at comparing the 8 weeks versus the 12 weeks regimen of ledipasvir plus sofosbuvir in patients with hepatitis C virus (HCV) genotype 1 infection without cirrhosis, treatment naïve, HCV RNA <6000000 UI/mL. We included 281 patients (pts) with genotype 1 and RNA <6000000 UI/mL treated with ledipasvir plus sofosbuvir in the recommended dose: 120 pts - 8 weeks (group 1) and 161 pts - 12 weeks (group 2). The fibrosis stage was evaluated by transient elastography (Fibroscan®, Echoscans, Paris) considering F4 > 12.5 kPa. Patients with undetectable RNA after 12 weeks of treatment were considered cured – sustained virologic response (SVR).

Results: No significant demographic and clinical differences were found between the two groups with the exception of the fibrosis stage (table). Two hundred and forty-four patients concluded the treatment; the SVR was 99% in group 1 and 100% in group 2, without differences between the two groups (p=0.275). Thirty three patients are still in follow up: group 1–15 pts and group 2–18pts. The reported adverse effects were mild in both groups (fatigue, insomnia, headache and pruritus) but more frequent in group 2 (p=0.046).

Patients characteristics	8 weeks n = 120	12 weeks n = 161	p
Average age (years)	50.4 (20–81)	53.6 (19–86)	0.473
Male sex, n (%)	62 (51.7%)	89 (55.3%)	0.548
Genotype (n)			
1a	74	94	0.579
1b	44	66	0.462
1 and 1a/1b	1 + 1	1 + 0	
Average RNA ± SD (UI/mL)	903275 ± 1093067	1826591 ± 1611806	0.348
Initial transient elastography (n)			
F0/F1	111	105	<0.001
F2/F3	8	56	<0.001
F4	1	0	0.246
Previous treatment with INF ± Ribavirin			
Yes	8	0	0.001
No	112	161	<0.001
HIV co-infection	1	14	0.004
RNA – week 4, n° (%)			
Undetectable	86 (71.7%)	124 (77.0%)	0.307
<15 UI/mL	13 (10.8%)	13 (8.1%)	0.430
Virologic response			
SVR, n° (%)	103 (99.0%)	141 (100.0%)	0.275
No response (no compliance) *	1	0	*
Awaiting response (in follow up)	15	18	0.734
Lost for follow up	1	2	0.742
Mild adverse effects, n (%)	7 (6%)	21 (13%)	0.046

* Patient retreated with ledipasvir + sofosbuvir + ribavirin during 12 weeks with SVR

Conclusion: In patients with chronic HCV genotype 1 infection and RNA <6000000 UI/mL, the 8 weeks regimen of ledipasvir plus sofosbuvir without ribavirin has similar high cure rates with less adverse effects.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Although the conventional IFN-based therapy has made a significant achievement in treating patients with hepatitis C virus (HCV), including the preventive effect of hepatocarcinogenesis after achieving sustained virological response (SVR), patients intolerant of IFN, such as those with advanced age or liver cirrhosis (LC), could not savor its privilege. The appearance of direct-acting antivirals (DAAs) provided almost every patient with the chance to receive the treatment for HCV infection without any serious adverse effects (AEs). In addition, SVR could be highly expected in more than 95% of patients treated with DAAs. However, the preventive effect of DAAs for the future hepatocarcinogenesis following eradication of HCV remains unknown. In our facility, the administration of DAAs to patients with HCV infection led to 97% (153/157) of SVR, among which 5.9% (9/153) of patients developed hepatocellular carcinoma (HCC) within 2 years after achieving SVR.

Aims & Methods: We evaluated the clinical features of patients developing HCC after confirming SVR with DAAs against HCV. One hundred and fifty-three patients achieving SVR defined as negative HCV-RNA 12 weeks after cessation of DAA (oral combination therapy with Daclatasvir/Asunaprevir, Ombitasvir/Paritaprevir/Ritonavir, Sofosbuvir/Ledipasvir, or Sofosbuvir/Ribavirin) were enrolled in this study (Age 69.2±0.8, male/female 71/82, genotype1/2 122/31, chronic hepatitis/LC 124/29, PLT 15.3±0.5 10³/μL, ALT 44.9±3.5 IU/L, FIB-4 index 3.9±0.2, APRI 1.3±0.1, Wisteria floribunda agglutinin positive Mac-2-binding protein (WFA(+)-M2BP) 3.3±0.5 COI, AFP 12.1±2.4 ng/mL, PIVKA-II 29.8±4.5 mAU/mL). All patients were divided into 2 groups (A: 9 patients with HCC developing after SVR achievement, B: 144 without HCC after SVR achievement). Serum parameters (PLT, WFA(+)-M2BP, FIB-4 index, APRI, ALT, Alb, AFP, PIVKAI) and age were evaluated between 2 groups.

Results: In group B, significant declining (pre-DAA treatment/the time of achieving SVR) was observed in ALT(44.8±3.6/19.5±1.1 IU/L), AFP(11.9±3.1/4.1±0.3 ng/mL), WFA(+)-M2BP(3.2±0.5/1.9±0.3 COI), FIB-4 index(3.7±0.2/3.0±0.2) and APRI(1.2±0.1/0.7±0.05), and significant increase in Alb(4.1±0.04/4.3±0.04 g/dL) and PLT(15.4±0.5/16.1±0.5 10³/μL). In group A, significant declining was observed only in ALT (45.1±10.9/16.7±2.2 IU/L). This result indicates that DAA treatment significantly ameliorates parameters related with hepatic fibrosis as well as hepatic inflammation in group B, however, it led to the significant amelioration only in those related with hepatic inflammation in group A. Next, focusing on parameters after achieving SVR, WFA(+)-M2BP (A:3.4±0.6/B:1.7±0.2 COI) and FIB-4 index (5.7±1.6/3.0±0.2) were significantly higher and Alb (3.8±0.2/4.3±0.04 g/dL) was significantly lower in group A comparing with group B. When dividing group A into 2 groups (C: new occurrence/D: recurrence), AFP(3.0±1.3/6.2±1.8 ng/mL), WFA(+)-M2BP (2.0±0.8/3.8±0.7 COI), FIB-4 index (3.6±2.4/6.3±2.0) and APRI (0.6±0.4/1.1±0.3) were higher and Alb(4.3±0.1/3.6±0.3 g/dL) and PLT (20.9±13.2/13.4±3.4 10³/μL) were lower in group D than group C, although no significant difference was seen between 2 groups. This result suggests that there might be more patients with progressive hepatic fibrosis in group D comparing with group C. Finally, while univariate analysis showed WFA(+)-M2BP, FIB-4 index and Alb were significantly associated with the development of HCC after achieving SVR with DAA against HCV, multivariate analysis revealed only Alb was the significantly independent factor contributing to HCC development after SVR achievement.

Conclusion: Low level of serum albumin as well as the progression of hepatic fibrosis could be associated with the development of HCC after confirming SVR with DAA to HCV.

P0707 EARLY OCCURRENCE OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH HEPATITIS C VIRUS TREATED WITH DIRECT-ACTING ANTIVIRALS

S. Hai, E. Hatano, T. Okada, Y. Asano, N. Uyama, K. Suzumura, M. Tada, I. Nakamura, K. Iida, H. Sueoka, H. Iwama, A. Kurimoto, R. Ito, H. Nishida, J. Fujimoto

Introduction: Direct-acting antivirals (DAAs) are novel antiviral drugs for hepatitis C virus (HCV) and have enabled the achievement of a high rate of sustained

virological response (SVR) [1]. However, the impact of DAAs on the occurrence of hepatocellular carcinoma (HCC) and HCC recurrence after curative hepatic resection of HCC has been recently discussed [2, 3], but remain unclear.

Aims & Methods: The clinical data of 97 patients who underwent curative hepatic resection for primary HCC with HCV at our department between January 2012 and March 2017 were reviewed to clarify the impact of DAAs on HCC occurrence and recurrence. SVR was defined as no detection of HCV RNA in the serum at 24 weeks after the cessation of antiviral therapy.

Results: SVR was achieved in 21 patients treated with interferon (IFN)-based regimens and in 9 with DAAs at hepatectomy. Between the two groups, there were no significant differences in the clinical characteristics, including the age, prevalence of diabetes mellitus, drinking history, preoperative liver function, operative procedures, tumor size and presence of liver cirrhosis, but the median duration from the date of SVR to the date of HCC incidence was significantly shorter in patients treated with DAAs (14 days, range: -123 to 235 days) than in those treated with IFN-based regimens (324 days, range: 35 to 4190 days). In particular, HCC was detected within 24 weeks after the cessation of antiviral therapy in 3 patients treated with DAAs. After hepatectomy, SVR was achieved in 21 (DAAs: 16 patients, IFN-based regimens: 5 patients) of the 67 patients without SVR when hepatectomy was performed, and the 1- and 3-year disease-free survival (DFS) rates were 93.3% and 83.0% in patients after SVR treated with DAAs (n=25), 90.9% and 71.8% in patients with IFN-based regimens (n=26) and 57.8% and 19.7% in patients without SVR (n=46), respectively, regardless of the timing of hepatectomy, respectively. The DFS rate was significantly higher in patients with SVR than in those without SVR ($p < 0.01$), but was not markedly different according to the antiviral treatments ($p = 0.504$).

Conclusion: While DAAs were able to reduce the DFS rate, the early occurrence of HCC in patients after SVR treated with DAAs is more frequent than that among patients treated with IFN-based regimens. Therefore, careful follow-up with imaging series is needed even for patients with SVR treated with DAAs.

P0708 EFFICACY AND SAFETY OF SOFOSBUVIR AND RIBAVIRIN IN HCV POSITIVE PATIENTS WITH RENAL IMPAIRMENT

M.O. T. Butt

Gastroenterology And Liver Transplant, Shifa International Hospital, Islamabad, Islamabad/Pakistan

Contact E-mail Address: mosamabutt2016@gmail.com

Introduction: Hepatitis C virus infection is a leading cause of chronic liver disease affecting more than 170 million people worldwide. HCV infection in the setting of renal impairment is not uncommon. Despite the major developments in the treatment of HCV, treatment of this sub group of patient with impaired renal function is still a challenge.

Aims & Methods: The aim of this study is determine the efficacy and safety of sofosbuvir and ribavirin in HCV positive patients with renal impairment. All consecutive patients of with HCV related liver disease with creatinine clearance less than 50 ml/min were included in the study. Data was collected for tolerability, efficacy and on treatment adverse events. All the patients received Sofosbuvir and dose adjusted Ribavirin according of CrCl. Virological response was checked at 1 month (RVR), 3 months (EVR) and at the end of treatment.

Results: A total of 31 patients were included in the study were 31 out of which 17(54.8%) were male. Mean age was 52.23 ± 17.6 years while the mean BMI was 25.0 ± 4.50 kg/m². 10 (32.25%) patient were on regular hemodialysis. 26 (83.9%) patients had CTP-A while 5 (16.1%) had CTP-B disease. Majority of the patients 22 (71 %) were genotype 3 while 7 (22.6 %) were genotype 1. 24 (77.4 %) patients were treatment naïve, while those who were treatment experienced, 3 patients received each Interferon and Peg interferon therapy. Treatment was stopped in 2 (6.5%) patients because of disease decompensation while 3 (9.7%) were lost to follow up. ETR was achieved in 25 (96.1%) out of 26 patients who completed treatment. Similarly 12 (80 %) out of 15 patients have achieved SVR-12 so far. During the therapy 10 (32.3%) patients had adverse events, 6 (19.4 %) suffered from depression while 4 (12.9 %) developed grade II anemia.

Conclusion: In resource constraint population where newer DAAs are not available, combination of sofosbuvir and low-dose ribavirin in patients with renal impairment seems to be better tolerated and efficacious in terms of achieving the virological response.

Contact E-mail Address: drucicureanutudor@gmail.com

Introduction: Chronic hepatitis C infection is a systemic disease, one of the leading causes towards cirrhosis and hepatocellular cancer and it is to be considered nowadays a major health-related quality of life (HRQoL) burden.

Aims & Methods: The aim of this study was to assess HRQoL impairment of hepatitis C virus (HCV) infection among a broad sample of compensated HCV cirrhotic patients. We conducted a prospective study between January 1st 2016 to January 31, 2017, in a tertiary center, in which we included 110 patients with compensated HCV cirrhosis, aged between 50 and 75, with no history of neuropsychiatric illness but associated comorbidities (diabetes type 2, hypertension, dyslipidemia). The patients were completely evaluated according to the national protocol. Health status and fatigue of our patients were evaluated using the FACIT- F (version 4) and SF-36 survey. Respondents with HCV compensated cirrhosis were compared with a control group matched for age and sex with no prior history of HCV infection on the Mental (MCS) and Physical (PCS) Component Summary scores.

Results: Unadjusted comparisons between subjects infected with HCV (n = 110) and controls (n = 60) revealed that HCV patients had lower FACIT- F utility scores (43.2 ± 0.8 vs 49.5 ± 0.5 , $P < 0.05$). Severe fatigue was present in 30% (33 patients) of the HCV group compared to 11.6 % (7 patients) in controls. Subgroup analyses of respondents age 60 years and older revealed lower MCS score in HCV patients compared to controls (41.95 vs. 49.72 , $p < 0.05$). Control group registered higher PCS score (53.30 vs 45.2 , $P < 0.05$) compared to the study group.

Conclusion: Although the results were obtained on a small group we observed that in untreated patients with chronic HCV infection, HRQoL is significantly impaired due to fatigue severity and age. Our result underline the need for effective antiviral treatment to decrease the burden of fatigue in this segment of population.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0710 SOFOSBUVIR IN COMBINATION WITH RIBAVIRIN IN GENOTYPE 3 HEPATITIS C PATIENTS WITH CIRRHOSIS. AN EXPERIENCE FROM TERTIARY CARE HOSPITAL

A. A. Langhah

Gastroenterology Section, Medical Unit Iv, Jinnah Postgraduate Medical Centre, Karachi/Pakistan

Contact E-mail Address: draliakbar12@gmail.com

Introduction: Hepatitis C virus (HCV) is the most common cause of cirrhosis in this part of the world. Advent of Directly acting antivirals (DAAs) like Sofosbuvir (SOF) has dramatized the treatment and is the corner stone in treatment of (HCV). Most trials have been conducted in HCV genotype 1 and data for Interferon free regimen in genotype 3 (GT-3) is limited especially in cirrhotics.

Aims & Methods: We aimed to evaluate the safety and efficacy of SOF plus Ribavirin (RIB) in patients with compensated and decompensated cirrhosis. This is a prospective real-world cohort study of HCV with compensated or decompensated cirrhosis. Efficacy was assessed by Sustained Viral Response after 06 months of completion of treatment. Adverse events were recorded on designed proforma on serial follow-up visits.

Results: The cohort consisted of 91 consecutive patients out of which 41 were compensated cirrhotics and 50 had decompensated cirrhosis. The mean age was 53.4 ± 11 years. Males were 47 (51.6%) and females were 44 (48.4%). Mean CTP and MELD score were 7.71 and 9.21 respectively. In compensated cirrhosis, SVR was achieved in 25 (84%) treatment naïve patients compared to treatment experienced patients where 5 (80%) achieved SVR. In decompensated cirrhosis SVR was achieved in 22 (77.3%) treatment naïve patients, whereas 13 (76.9%) patients achieved SVR in treatment experienced group. In 72% patients with cirrhosis, there were no side effects whereas most common adverse event was fatigue and drop of Hemoglobin by 1.0 gm/dl. Furthermore, CTP and MELD scores decreased to 6.9 and 8.7 respectively after treatment.

Conclusion: Sofosbuvir in combination with Ribavirin in GT-3 HCV patients achieved good SVR in compensated cirrhosis than decompensated cirrhosis whereas fatigue and drop of Hb were the most common adverse effects.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0711 RECURRENCE OF HEPATOCELLULAR CARCINOMA (HCC) IN PATIENTS WITH COMPENSATED LIVER CIRRHOSIS AND HCC TREATED WITH PARITAPREVIR/OMBITASVIR/RITONAVIR, DASABUVIR WITH RIBAVIRIN: A NATIONAL COHORT STUDY

Introduction: New direct-acting antivirals (DAA) have changed the management of HCV infection by being effective in more than 90% of cases [1, 2]. Unfortunately, it has been reported an unexpected high rate of HCC early recurrence following DAA treatment, but more data are needed [3–5].

Aims & Methods: From a national prospective cohort, enrolling 3717 Romanian patients with hepatitis C virus compensated liver cirrhosis who received reimbursed DAA with Paritaprevir/Ombitasvir/ritonavir, Dasabuvir and Ribavirin (OBV/PTV/r + DSV + RBV) for 12 weeks, from December 2015 to August 2016, we analyzed 21 patients with previous HCC. Most of them were treated through surgical resection (9/21), followed by radiofrequency ablation (RFA) 6/21, transarterial chemoembolisation (TACE) 5/21 and only one percutaneous ethanol injection (PEIT). The patients received DAA treatment only if they had no cancer relapse 6 months after their last therapy session for HCC. All these patients were evaluated through CT scan or MRI 3 to 6 months after having finished their DAA therapy. The median follow-up is 6 months (3–12). Data were obtained from the Romanian National Health Agency.

Results: Two female patients decompensated and died because of acute liver failure (9.5%), the first one after having finished the 12 weeks therapy, and the other one in week 7 of DAA therapy. This cohort was 52% females, median age 64 years (51–77), 76% IFN pre-treated, 50% associated NASH, 67% with severe necroinflammatory activity (severity score 3–Fibromax), 30% with co-morbidities, 24% with Child Pugh A6. The median MELD score was 9 (6–11). SVR was reported in 19/21 as per protocol analysis (90.5%). Recurrence rate of HCC was 29%, higher in males (40%) than females (18%), higher in patients treated with TACE (40%) than in those with hepatic resection (33%), and the lowest risk of recurrence was encountered in RFA (17%). These differences were not statistically significant because of the small sample size. The pattern of recurrence was: intrahepatic growth (1 patient), new intrahepatic lesion (1 nodule in 2 patients, up to 3 nodules less or equal to 3 cm in 1 case) and infiltrative ill-defined hepatocellular carcinoma in 2 patients. We found no correlation between the HCC-free interval of time and recurrence rate ($p=0.62$).

Conclusion: Early recurrence rate of HCC in treated patients with compensated liver cirrhosis that received DAA with OBV/PTV/r + DSV + RBV was 29%, significantly increased compared to the natural recurrence rate. This rate is higher in males (40%) and in patients treated with TACE (40%).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Shear wave elastography (SWE) has been used in clinical practice as a noninvasive method to diagnose liver fibrosis by measuring tissue stiffness.

Aims & Methods: The usefulness of SWE in the diagnosis of esophagogastric varices (EGVs) associated with portal hypertension was evaluated. 550 patients who underwent measurements of liver stiffness (LS), spleen stiffness (SS) and EGV evaluation between January 2011 and July 2016 were included (no varices, n = 340; esophagus only, n = 107; stomach only, n = 14; esophagus and stomach,

n = 89). Virtual Touch Quantification (VTQ) was used for measurements of LS and SS, and the spleen index (SI) was calculated. EGVs were evaluated according to forms and red colour sign (RC sign) based on the General Rules for Study of Hypertension in Japan.

Results: LS, SS and SI showed significant increase in accordance with the severity of forms ($p < 0.01$). The area under the receiver operating characteristic curve (AUROC) of LS, SS and SI for detecting EGVs were 0.8526, 0.9048, 0.8199, with the cut off values 1.67 m/s, 2.81 m/s, 18.5cm², respectively, and SS showed usefulness in detecting EGVs. When LS, SS and SI were compared for their ability to detect EGVs which were <F2 or with RC sign positive, LS, SS and SI were significantly higher for EGVs which require treatment ($p < 0.001$). The AUROC of LS, SS and SI for detecting EGVs which require treatment were 0.8131, 0.8693, 0.8270, respectively. All modality showed good detecting ability, and SS particularly showed better performance. When each modality was compared in detection of gastric varices, LS and SS were significantly higher with the presence of gastric varices, but SI did not show a significant difference. The AUROC of LS, SS and SI for detecting gastric varices were 0.7359, 0.8611, 0.6470, respectively, and SS showed a superior detecting ability while LS and SI showed decreased abilities.

Conclusion: LS, SS and SI were all useful in detecting EGVs and predicting the presence of EGVs which require treatments. SS particularly showed the highest diagnostic ability.

Introduction: Nonalcoholic fatty liver disease (NAFLD) is the most common liver disorder in developed countries with a global prevalence of approximately 25%. NAFLD represents a spectrum of disorders and starts with benign steatosis (NAFL, $\geq 5\%$ hepatic steatosis but may lead to nonalcoholic steatohepatitis (NASH), inflammation with hepatocyte injury with or without fibrosis, which may lead to cirrhosis. Liver biopsy still is the gold standard for staging steatosis. The BRUNT score stages steatosis in 4 categories ($\leq 5\%$, 5–33%, 34–66%, $\geq 66\%$), which provides a limited sensitivity to detect changes in steatosis content. For evaluation of treatment and disease activity a quantitative and preferably non-invasive tool is needed urgently. Therefore we developed and tested a computer aided ultrasound (CAUS) protocol for the non-invasive assessment of hepatic steatosis using ultrasound (US) B-mode images, which showed high predictive values (area under the curve (AUC) up to 0.95) in cows and similar correlations in a human pilot study. The current study was conducted in order to assess the predictive values of CAUS in staging hepatic steatosis in-vivo.

Aims & Methods: Consecutive patients indicated for a liver biopsy received a simultaneous transabdominal US examination (Siemens Acuson X150; Siemens Healthcare GmbH, Erlangen, Germany, with CH5-2 transducer). Currently 205 patients with liver biopsies and QUS images are included. Biopsies were qualitatively scored using the Brunt-score for steatosis grading. Metavir, Ishak and/or Roenigk scores were used for disease specific fibrosis staging. All US images were further post-processed using the CAUS method. In CAUS corrections are applied for the: look up table (linearization); beam-profile; attenuation caused by the superficial tissue layers. Furthermore segmentation of large blood vessels and bile ducts is performed automatically. Finally echo-level and texture parameters are estimated on average and as a function of depth by estimation of slope and intercept of a linear fit.

Results: Best correlating CAUS parameter with BRUNT steatosis stage was found to be the residual attenuation coefficient (RAC, $R=0.79$, $p < 0.01$). Parameters used in the multiple linear regression analysis using the leave one out method were: Residual attenuation coefficient (RAC=slope of the mean echo level (MU)); MU; slope of the Signal to noise ratio; and the lateral speckle size. AUC for HS was found to be 0.95 ($n=71$) with a sensitivity and specificity of 86% and 85% respectively, which are in line with previously performed studies. 87% of the included patients were found to have NASH with fibrosis. However, no significant correlations of the CAUS parameters to a pure fibrosis-group ($N=106$) was found.

Conclusion: CAUS is able to classify steatosis accurately and does not suffer from the presence of fibrosis, making CAUS a feasible tool for screening and evaluation of hepatic steatosis.

Introduction: Recently, fusion imaging technology has been reported as useful for radiofrequency ablation (RFA) and various models of ultrasound equipment have been developed to include fusion imaging systems. The 3D Sim-Navigator (HITACHI) is a navigation system that can be used in real-time virtual sonography (RVS) by simulating and navigating the 3D positions of electrodes. As an addition, the 3D Sim-Navigator is now equipped with a new system that shows the predicted ablative area. This function indicates the electric field that occurs around the electrodes as the predicted ablative area on MPR images. The E-field Simulator (E-field) can manage various electrodes, such as monopolar and bipolar RF systems. E-field can be used to predict the ablative areas from not only a single electrode but also multiple electrodes, which was difficult to do in the past. We therefore examined the accuracy of E-field on 3D Sim-Navigator.

Aims & Methods: We evaluated 10 nodules treated using a bipolar RF system (CelonPOWER; Olympus Medical Systems) with multiple electrodes and 72 nodules treated using a monopolar RF system (VIVARF system; STARmed) between April 2016 and March 2017 prospectively. We compared the major and minor axes of maximum axial ablative area for 72 nodules ablated by the monopolar RF system on both E-field and post-RFA contrast-enhanced computed tomography (CT). We then compared ablative volumes of 10 nodules ablated by the bipolar RF system on E-field and on post-RFA contrast-enhanced CT. Finally, we compared treatment efficacy using a grading system (J Gastroenterol 2013 Aug;48(8):951–65.) on E-field and on post-RFA contrast-enhanced CT.

Results: On the evaluation of maximum axial ablative area by monopolar electrodes, major and minor axes were smaller on E-field than on CT, but these differences were not significant. On the evaluation of ablative volume by bipolar electrodes, the correlation coefficient for ablative volumes on E-field and CT was greater than 0.96. On comparing treatment efficacy using the grading system, the degree of agreement between E-field and CT was 0.691 and the weighted kappa coefficient was 0.929.

Conclusion: Ablative volume on E-field correlated well with that on post-RFA contrast-enhanced CT. Furthermore, good agreement was observed between the treatment efficacy based on E-field and post-RFA contrast-enhanced CT. E-field can be used to predict the ablative area from not only a single electrode, but also multiple electrodes, which was difficult to do in the past. The present results suggest that contrast-enhanced CT may become unnecessary for confirming therapeutic effects in the future.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The presence of fat droplets in the hepatocytes (micro- or macrovesicular hepatic steatosis) under condition of chronic diffuse liver disease (CDLD) increases the attenuation of ultrasound (US). A group of Ukrainian scientists proposed an original algorithm for real-time US attenuation measurement (attenuation coefficient measurement – ACM – patent UA №2014 111234).
Aims & Methods: From total of 3274 patients who underwent to comprehensive abdominal US (2015–2016) in our clinic, 949 have been diagnosed with fatty liver according to Hamaguchi criteria. All these patient we provide ACM (dB/cm) measurement on SoneusP7 device (Ultrasign, Ukraine), with a 1–6 MHz convex transducer in the right and left lobes. For diagnostic accuracy assessment (used CT as standard) and comparison with CAP measured by Fibroscan (Echosens, France) we included 142 patients for subanalysis. Evaluation of diagnostic accuracy of ACM performed using ROC-analysis.

Results: Depending on the stage of steatosis according to B-mode median, 25 and 75 quartiles for ACM were as follows: control group 1.57 (1, 32–1, 85); S1–1, 86 (1, 78–2, 11); S2–2, 26 (2, 20–2, 49) and respectively for S3–2, 7 (2, 40–2, 82) dB/cm. ACM value increase parallel the hepatic steatosis progression ($p < 0.001$), which was also accompanied with presence of very strong correlation between these parameters ($r = 0.814$, $p < 0.001$). In patient with NAFLD the association between maximum value of ACM and duration of T2DM and triglycerides (model 1, multiple correlation coefficient = 0.55; $R^2 = 0.26$; $p = 0.004$) and ALT (model 2, multiple correlation coefficient = 0.55; $R^2 = 0.25$; $p = 0.005$) were observed. After adjustment by the duration of T2DM the level of triglycerides ($r = 0.44$, $p = 0.012$) and activity of ALT ($r = 0.44$, $p = 0.012$) significantly correlated with ACM. The AUROC of ACM for steatosis diagnosis was 0.925 (95% CI 0.877–0.973). The optimal cutoff point was > 2.27 dB/cm, with sensitivity,

specificity, PPV and NPV respectively 91.5, 77.3, 84.6 and 83.8%. ACM value also significantly correlated with CAP ($r = 0.630$, $p < 0.001$).

Conclusion: The ACM as novel real-time ultrasound approach can be used for noninvasive hepatic steatosis diagnosis, allows clinicians to monitor disease progression and response to treatment.

Introduction: The aim of this paper is to evaluate the performance of CEUS as a first step in the evaluation of focal liver lesions (FLLs) in cirrhotic and non-cirrhotic patients.

Aims & Methods: A retrospective study was performed on a cohort of 2904 FLLs evaluated by CEUS between September 2009–December 2016, according to EFSUMB guide lines (2) in a tertiary center. 979 (33.7%) FLLs did not completely fulfill the EFSUMB-CEUS criteria thus needing to be confirmed by other imaging technique (contrast-enhanced CT, contrast-enhanced MRI) or histology. Lesions that were previously diagnosed have been excluded. Using CT, MRI and histology for the final diagnosis we calculated the specificity, sensibility and accuracy of CEUS for the difficult FLLs that challenged the examiner, in cirrhotic and non-cirrhotic patients.

Results: CEUS managed an overall correct diagnosis in 76.8% (752/979) of the lesions. From the 979 FLLs, 335 (34.3%), (67.7% HCC, 4.7% Hemangioma, 3.8% Metastasis, 18.2% Other benign lesions and 5.3% Other malignant lesions), were detected in liver cirrhosis (LC) and 644 (65.7%), (36.1% Metastasis, 19.5% Hemangioma, 6.8% HCC, 31.3% Other benign lesions and 6% Other malignant lesions) were in non-cirrhotic liver (NC). In LC CEUS performance for benign lesions was: 87.7% Se, 93.6% Sp and 90.4% Ac. For malignant lesions in LC, CEUS performed: 76.1% Se, 92.4% Sp and 83.8% Ac. In the NC group, CEUS performance for benign lesions was: 82% Se, 95.8% Sp and 88.4% Ac. and for malignant lesions was: 90.16% Se, 90.13% Sp and 89.4% Ac. CEUS performance on the most frequent lesions: Hepatocellular carcinoma (HCC) in LC: 65.2% Se, 86% Sp, 68.5% Ac. HCC in NC: 65.9% Se, 94.75% Sp, 92.1% Ac. Metastasis in LC: 30.7 Se, 97.3Sp, 92.9% Ac. Metastasis in NC: 78.5% Se, 91.2% Sp, 85.5% Ac. Hemangioma in LC: 68.7% Se, 95.6 Sp, 93.4% Ac. Hemangioma in NC: 77.2% Se, 96.1% Sp and 91.3 Ac.

Conclusion: CEUS is an accurate and reliable method as a first step in the evaluation of FLLs. Liver cirrhosis does not influence significantly CEUS performance.

Introduction: CUX1 (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of proapoptotic genes. Its aberrant expression in tumor turns its role as foe. It favors the expression of oncogenes and survival factors, especially in stress condition, thus supporting tumorigenesis.

Aims & Methods: Here, we show CUX1 activity during hypoxia in liver cancer cells. CUX1 was knocked down and its targets were analysed by RT-qPCR in HepG2 and Hep3B cells under hypoxic and/or normal culture condition. The hypoxia condition was established by 24h treatment with 150 μ M CoCl₂ or with 0.5% O₂ atmosphere. Hypoxia markers and CUX1 were analysed by RT-qPCR. Transfection with plasmid expressing a reporter sequence for HIF1alpha was performed in combination with CUX1 knock-down.

Results: Hypoxia determined the up-regulation of HIF1-alpha (Hypoxia inducible factor-1-alpha) and a stable or up-regulated expression of its inhibitor FIH-1 (SLC2A1) up to 24h prolonged hypoxia. VEGFA was significantly

overexpressed. Knock-down of CUX1 determined a significant down-regulation of HIF-1 α , FIH-1 and VEGFA. Interestingly, the expression of CDKN1A was only attenuated after CUX1 knock down and hypoxic stress. HIF1 α transcriptional activity is dependent by CUX1 expression.

Conclusion: CUX1 exerts an oncogenic role in liver cancer by sustaining the survival mechanism beyond hypoxia. CUX1 silencing results in suppression of the hypoxia inducible factor and its target VEGFA causing a block of cell cycle in liver cancer cells modulated by the stable expression of CDKN1A.

P0718 S-ADENOSYLMETHIONINE AFFECTS CELL CYCLE PATHWAYS AND SUPPRESSES PROLIFERATION IN LIVER CELLS

L. Yan, G. Zhang, Y. Chen

Department Of Gastroenterology, Xiangya Hospital, Central South University, Changsha/China

Contact E-mail Address: yanlu_152@163.com

Introduction: S-Adenosylmethionine (SAME) is a kind of common liver-protecting medicine. Recent studies have shown that SAME has the inhibitory effects on hepatocellular carcinoma (HCC). But the specific mechanism has not been elucidated.

Aims & Methods: Here, we examine the effects and relevant mechanism of SAME on human hepatocellular carcinoma cell HepG2 and mouse hepatocyte AML12. RNA sequencing (RNA-Seq) was used to identify the differentially expressed genes between HepG2 cells which were treated with SAME or not. And we used western blot and QRT-PCR to confirm some of these genes. MTS and flow cytometry-based assays were carried out in response to SAME treatment.

Results: A total of 472 SAME-related genes were identified by RNA-Seq. We found that differentially expressed genes were enriched in cell cycle related signaling pathway significantly by the KEGG and GO Pathway enrichment analysis. Through the construction of protein-protein interaction network, we observed the module associated with cell cycle is in the middle of the whole network. All these results implied that cell cycle pathway may play a very important role in the regulation of SAME effected on HepG2 cells. Then the RNA-Seq characterized genes involved in cell cycle (MCM3, MCM4, and E2F1) were confirmed by Western blot and QRT-PCR in HepG2 and AML12 cells. MTS analysis showed that SAME could diminish cell proliferation. And flow cytometry-based assays indicated that treatment with SAME altered cell cycle kinetic S phase cell cycle arrest.

Conclusion: Altogether, our data enforce the evidence of SAME possessing of antiproliferative action in liver cells, capable of up-regulating MCM3, MCM4 and E2F1 expression leading to cell cycle inhibition, and provide an important theoretical basis for the clinical chemoprevention and treatment in HCC of SAME.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0719 BRG1 PROMOTES HEPATOCARCINOGENESIS BY MODULATING CYCLINB, D, E AND MATRIX METALLOPROTEINASE 7

B. Kaufmann, B. Wang, M. Lu, N. Hüser, H. Friess, G. Von Figura, D. Hartmann

Klinikum rechts der Isar/Technische Universität München, München/Germany

Contact E-mail Address: benedikt_kaufmann@hotmail.com

Introduction: The chromatin remodeler complex SWI/SNF plays an important role in physiological and pathological processes. The role of BRG1, a catalytic subunit of the SWI/SNF complex, that is known to be mutated in hepatocellular carcinoma (HCC) remains unclear. The aim of this work is to investigate the role of BRG1 on cell growth, cell invasion and its effect on the expression of target genes.

Aims & Methods: We examined the expression of BRG1 in human tissue samples and HCC cell lines by qRT-PCR and Western Blot. We used siRNA to down-regulate BRG1 in human HCC cell lines. Cell growth and cell invasion of siRNA-treated cells was analysed by growth curves, colony formation assay and invasion assay. The expression of target genes after BRG1 downregulation was investigated by qRT-PCR.

Results: BRG1 was found to be significantly increased in HCC samples compared to non-HCC samples. After BRG1 downregulation by siRNA, cell growth and cell invasion decreased in HuH7 and HepG2 cell lines. A positive modulating effect by BRG1 was shown for the expression of CyclinB, D, E and MMP7 in either HepG2 or HuH7 cell lines.

Conclusion: Our results support the hypothesis that overexpression of BRG1 increases cell growth and cell invasion in HCC. Furthermore, the data highlight genes promoting proliferation and invasion that are being regulated by BRG1 during hepatocarcinogenesis. In particular, CyclinB, D, E and MMP7 appear to play a major role in this context and might be an important link between BRG1 expression and HCC development.

P0720 PROGNOSTIC ROLE OF NEUTROPHIL-TO-LYMPHOCYTE RATIO IN HEPATOCELLULAR CARCINOMA (HCC)

N. Elleuch, S. Jarak, A. Sabbek, A. Ben Slama, H. Jaziri, E. Hammami, B. Ahlem, K. Mehdi, J. Ali
Sahloul, Sousse/Tunisia

Contact E-mail Address: Elleuchghorbel.nour@yahoo.fr

Introduction: Inflammation may play an important role in progression, and a high neutrophil-to-lymphocyte ratio (NLR) has been reported as a poor prognostic indicator in several malignancies.

Aims & Methods: This study was aimed to investigate the prognostic value of NLR in patients with HCC. We performed a retrospective study including patients with hepatocellular carcinoma admitted in the hepato-gastroenterology department of Sousse between January 2010 and December 2015.

Results: A total of 76 patients were included in this study. Mean age was 59.8 (33–87 years). The sex ratio was 3.22 (M/F = 58/18). Hepatocellular carcinoma occurred on a liver of cirrhosis in the majority of cases (90.7%). The main causes of cirrhosis were hepatitis B virus infection (43 patients-62.3%), hepatitis C virus infection (11 patients-16%), non alcoholic steatohepatitis (6 patients-8.6%) and alcohol consumption (5 patients-7.2%). Our results showed that high NLR was associated with poor overall survival (OS) in HCC regardless of therapeutic choice ($P < 0.05$). Otherwise, high NLR was significantly correlated with the presence of vascular invasion ($P = 0.002$), lymph node metastasis ($P = 0.04$), tumor multifocality ($P = 0.01$) and higher incidence of AFP ≥ 200 ng/ml ($P = 0.04$).

Conclusion: Elevated NLR indicates a poor prognosis for patients with HCC. The NLR is a readily available and inexpensive biomarker, and its addition to established prognostic scores for clinical decision making warrants further investigation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0721 REIC/DKK-3 PROTEIN CONCENTRATION INDUCE THE POSITIVE EFFECT TO THE MORTALITY OF HEPATOCELLULAR CARCINOMA

A. Ohyama, D. Uchida, H. Shiraha, H. Sawahara, H. Kato, H. Okada
Gastroenterology And Hepatology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama City/Japan

Contact E-mail Address: at841205@gmail.com

Introduction: The Wnt/ β -catenin plays essential roles in the growth of hepatocellular carcinoma (HCC). The Dickkopf (Dkk) protein family (Dkk1-4) is known as Wnt signal antagonists, and reduced expression in immortalized cells (REIC)/Dkk-3 over-methylation is associated with poor prognosis of HCC patients. But the roles of REIC/Dkk-3 in inhibiting Wnt signaling remains still unclear.

Aims & Methods: In our previous study, REIC/Dkk-3 protein induced significant production of interferon gamma from lymphocytes incubated with pancreatic cancer cells, indicating that REIC/Dkk-3 protein might activate cancer immunity in the tumor-bearing patients.¹ We hypothesized that REIC/Dkk-3 expression was correlated with cancer immunity in HCC patients. Thus, we investigated the correlation between serum REIC/Dkk-3 protein level and the prognosis in HCC patient. We retrospectively studied 58 HCC patients who underwent primary liver resection for HCC admitted to our unit from 2008 to 2017. Patient serum was gathered before resection. Serum REIC/Dkk-3 protein level was measured by an enzyme-linked immunosorbent assay.

Results: 58 HCC patients were divided into two groups, 41 REIC/Dkk-3 high concentration group (protein level > 800) and 17 Dkk-3 low concentration group (protein level < 800), according to the presence of REIC/Dkk-3 proteins in the blood, as detected by ELISA spectrometry. There was no significant difference in age, sex, Child-Pugh score and HCC stage in the patient groups. REIC/Dkk-3 Protein tended to be declining in liver cancer patients with poor prognosis. ($p = 0.186$)

Conclusion: Our results demonstrated that the serum Dkk-3 protein levels might be a prognosis marker in HCC patients. Further study is necessary with more number of HCC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Fibrolamellar hepatocellular carcinoma (FL-HCC) has conventionally been considered to be a histologic variant of hepatocellular carcinoma (HCC), with distinct clinicopathologic features. It is a rare primary hepatic malignancy that was first described as a pathological variant of HCC by Edmondson in 1956 [1]. The etiology of FL-HCC remains unclear. It typically occurs in normal livers without underlying liver fibrosis or cirrhosis [2]. In contrast to HCC which usually found in the presence of cirrhosis or chronic hepatitis [3]. FL-HCC has been reported to occur in association with focal nodular hyperplasia (FNH) a type of benign liver lesion. Many series have mentioned that FL-HCC is less aggressive than conventional HCC [4]. However, other studies have failed to confirm the observation of a better outcome in FL-HCC [5]. Other studies reported that the survival was similar between common HCC and FL-HCC, and that may be related to the higher resectability rate which improve the survival of patients with FL-HCC [6].

Aims & Methods: The aim of this study was to evaluate the clinicopathological features and the surgical outcomes of patients with FL-HCC who were referred to our tertiary referral center over a 15-year period. This is a retrospective study including 22 patients with a pathologic diagnosis of FL-HCC who underwent hepatectomy over a 15-year period. Tumor characteristics, survival and recurrence were evaluated.

Results: There were 11 male and 11 female with a median age of 29 years (range from 21 to 58 years). Two (9%) patients had hepatitis C viral infection and only 2 (9%) patients had alpha-fetoprotein level > 200 ng/mL. The median size of the tumors was 12 cm (range from 5–20 cm). Vascular invasion was detected in 5 (23%) patients. Four (18%) patients had lymph node metastases. The median follow up period was 42 mo and the 5-year survival was 65%. Five (23%) patients had a recurrent disease, 4 of them had a second surgery with 36 mo median time interval. Vascular invasion is the only significant negative prognostic factor.

	FL-HCC (n = 22)
Number	
Single	19 (86%)
Multiple	3 (14%)
Size (cm)	Median 12 cm (range, 5–20)
Location	9 right, 10 left, 3 bilateral
Hepatic resection	
Hepatectomy	16 (73%)
Extended hepatectomy	4 (18%)
Localized resection	2 (9%)
Stage	
I	10 (45%)
II	5 (23%)
III	7 (32%)
IV	0
Nodal metastases	4 (18%)
Vascular invasion	5 (23%)
Positive safety margin	2 (9%)
Repeated hepatectomy	4 (18%)

Factor	No. (%)	Overall survival (month)	p. value
Age (year)			
< 40	16(73%)	86	0.4
≥ 40	6(27%)	72	
Gender			
Female	11 (50%)	84	0.6
Male	11(50%)	79	
Tumor size (cm)			
< 10	8(36%)	82	0.3
≥ 10	14(64%)	76	
Number			
1	19(86%)	89	0.2
> 1	3(14%)	77	
Hepatic resection			
Hepatectomy	16 (73%)	86	

(continued)

Continued

Factor	No. (%)	Overall survival (month)	p. value
Extended hepatectomy	4 (18%)	77	0.62
Localized resection	2 (9%)	79	
Nodal metastases			0.09
Negative	18(82%)	88	
Positive	4 (18%)	78	
Vascular invasion			0.03
Absent	17(77%)	92	
Present	5(23%)	58	
Safety margin			0.08
Negative	20(91%)	87	
Positive	2 (9%)	72	

Conclusion: FL-HCC has a favorable prognosis than common HCC and should be suspected in young patients with non cirrhotic liver. Aggressive surgical resection should be done for all patients. Repeated hepatectomy or excision of recurrent disease should be considered for these patients as it has a relatively indolent course.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Hepatocellular adenoma (HCA) is a rare benign tumor of the liver that typically presents in women within their reproductive years. The recent increase in the HCA prevalence is noticeably associated with the rising prevalence of obesity and the metabolic syndrome. Because of high risk of complications such as hemorrhage, rupture and malignant transformation, appropriate treatment strategy should be considered. Given the success of image-guided ablation in treating malignant hepatic tumors, there is increased interest in treating benign masses with percutaneous ablation.

Aims & Methods: To investigate the efficacy and safety of Microwave versus Radiofrequency Ablation in management of HCA. Out of 320 Patients presented with hepatic focal lesions over 1 year, data of 15 patients diagnosed to have HCA were collected retrospectively. The diagnosis of HCA in those patients was based on radiological findings using triphasic pelvi-abdominal CT, dynamic MRI or cytopathological examination of FNAC for those whose radiological findings were not conclusive. The size of the all tumors was ranged between 2.5 to 3.4cm. Tumors were selected for treatment by percutaneous ablation after review at a multidisciplinary that included radiologists, hepatologists, hepatobiliary surgeons. Decisions to pursue percutaneous ablation therapy were based on a multidisciplinary discussion of multiple factors, including patient preference, number and location of tumors impacting the extent of a possible liver resection and hepatic reserve and the decreased morbidity compared with surgery. The patients were divided into 2 groups: Group(A):included 7 patients (5 females, 2 males) underwent Radiofrequency Ablation. Group(B):included 8 patients (5 females, 3 males)underwent Microwave Ablation. Follow up was performed every 3 months over a period of 1 year.

Results: Microwave and Radiofrequency thermal Ablation had the same safety and efficacy in management of HCA with no evidence of residual tumour, tumor recurrence nor complications but Microwave thermal ablation was superior in large size tumors and needed only single skin puncture while Radiofrequency ablation needed more than single puncture in the same session.

Conclusion: Percutaneous ablation of HCA using Microwave or Radiofrequency thermal Ablation is safe, feasible and able to eradicate the targeted hepatic focal lesion and prevent known complications of HCA. Of note Microwave ablation is much more efficient in treating larger lesions through single puncture in contrast to Radiofrequency which needs more than one puncture.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Metabolic disorders, such as obesity and diabetes, are well known risk factors for hepatocellular carcinoma (HCC). Conversely, their impact on the natural history of HCC patients is not established.

Aims & Methods: This study aimed at evaluating the impact of metabolic disorders on clinical features, treatment and survival of HCC patients regardless of its etiology. We analyzed the Italian Liver Cancer (ITA.LI.CA) database regarding 839 HCC patients prospectively collected from 2009 to 2014. The following metabolic features were analyzed: BMI, diabetes, arterial hypertension, hypercholesterolemia and hypertriglyceridemia. According to these features, patients were divided into 3 groups: 0–1 metabolic features, 2 metabolic features, 3–5 metabolic features.

Results: As compared with patients with 0–1 metabolic features, patients with 3–5 features showed lower percentage of HCC diagnosis on surveillance (p 0.021), larger tumors (p 0.038), better liver function (higher percentage of patients with Child-Pugh A [p 0.007] and MELD < 10 [p 0.003]), higher percentage of metastases (p 0.024), and lower percentage of portal vein thrombosis (p 0.010). The BCLC stage and treatment options were similar among the 3 groups, with the exception of a less frequent access to locoregional therapies for BCLC stage B patients with 3–5 features (p 0.012). Overall survival and survival according to BCLC stage and/or treatment did not significantly differ among the 3 groups. Diabetic patients showed a lower survival (p 0.046). MELD score, HCC

morphology, nodule size, BCLC stage, portal vein thrombosis and metastasis were independent predictors of lead-time adjusted survival.

Conclusion: Our "real-world" study suggests that metabolic disorders shape the clinical presentation of HCC but do not seem to play a major role in setting the patient survival, except for diabetes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0726 LIVER VOLUME AS A PREDICTOR OF RISK FOR HEPATOCELLULAR CARCINOMA IN CHRONIC HEPATITIS C PATIENTS

N. Kang, J.W. Chung, J. Kim

Internal Medicine, Seoul National University Bundang hospital, Seong-Nam city/Korea, Republic of

Contact E-mail Address: namkyumd@gmail.com

Introduction: Chronic hepatitis C virus (HCV) infection pose risk for development of hepatocellular carcinoma (HCC), even after viral eradication with effective antiviral therapy. Therefore, risk prediction is clinically important for effective surveillance of chronic hepatitis C (CHC) patients, but studies are insufficient compared to chronic hepatitis B. The liver volume has been reported to correlate with the severity of liver cirrhosis, but it is not known whether decreased liver volume predicts the HCC risk in CHC.

Aims & Methods: The aim of this study was to assess the significance of liver volume in the prediction of HCC risk in CHC patients. A retrospective cohort of 101 CHC patients who received 4-phase dynamic CT imaging studies during surveillance was analyzed for liver volume and outcome of surveillance. Liver volumes were measured on portal venous phase of CT image and corrected for body weight and height: liver volume index (LVI) = ratio of the expected standard volume to the measured liver volume. Kaplan-Meier analysis with the log-rank test used to compare HCC. Cox proportional hazard analysis was used to identify the independent predictors of HCC risk.

Results: The cumulative incidence of HCC was 2.1%, 16.2% and 46.1% at 1, 4 and 8 years, respectively. The risk of HCC was significantly higher in patients with LVI > 1 ($P < 0.001$). Presence of liver cirrhosis was also associated with higher risk for HCC. ($P < 0.001$), whereas age, sex, alpha-fetoprotein and HCV RNA level were not significant predictors of HCC. Multivariate analysis show that LVI > 1 and presence of LC were independent predictors of HCC (HR: 63.53, CI: 3.24-1244.28, $P < 0.001$ /HR: 3.10, CI: 1.28-7.51, $P = 0.12$, respectively).

Conclusion: Decreased liver volume is an independent predictor of HCC in chronic hepatitis C. Liver volume index is useful in predicting risk of HCC in CHC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0727 HAND AND FOOT SYNDROME AS A PREDICTOR OF OUTCOME IN PATIENTS WITH HEPATOCELLULAR CARCINOMA TREATED WITH SORAFENIB

M. Ochi, A. Okawara, N. Kakinoki, T. Kamoshida, S. Hirai

Department Of Gastroenterology, Hitachi General Hospital, Hitachi City/Japan

Contact E-mail Address: masaochphi@hotmail.co.jp

Introduction: Sorafenib is a multi-tyrosine kinase inhibitor classified as a neo-vascularization inhibitor. A previous study indicated that the administration of a tyrosine kinase inhibitor, cetuximab, significantly prolonged the survival of patients with dermal disorder¹. However, few studies have reported the efficacy of sorafenib administration in patients with hand and foot syndrome (HFS).

Aims & Methods: In this study, we investigated the prognosis of sorafenib-treated patients with HFS. HFS grading was conducted according to the Common Terminology Criteria for Adverse Events (CTCAE) v.4.0. Patients with grade 1 or higher dermal disorder were regarded as having HFS, and grade 0 patients as not having HFS. For HFS evaluation, a double-check system was adopted: primary evaluation based on a specific evaluation sheet at the Pharmacists' Outpatient Clinic and final evaluation by physicians at the outpatient clinic. We examined the influence of HFS on the effects of treatment after the introduction of sorafenib in 42 patients with a history of multidisciplinary treatment, such as transcatheter arterial chemoembolization (TACE), between May 2009 and March 2017.

Results: Grade 1 or higher HFS was observed in 22 patients (53%), and it was absent in 20 (47%). Overall, the median sorafenib administration period was 2.1 months. In the HFS-free and HFS groups, it was 0.9 and 2.7 months, respectively ($p < 0.001$). Survival analysis was performed using the Kaplan-Meier method. Overall, the median survival was 5.2 months. In the HFS-free and HFS groups, it was 3.0 and 7.8 months, respectively ($p < 0.001$). Multivariate analysis showed that the presence of HFS (hazard ratio, 0.41; 95% CI, 0.19 to 0.88; $p = 0.023$) and administration period (hazard ratio, 0.45; 95% CI, 0.20 to 0.98; $p = 0.045$) were significant predictive factors. The following were not significant predictive factors: age, BCLC staging, dosage, and tumor markers.

Conclusion: The prognosis of hepatocellular carcinoma patients receiving sorafenib treatment was closely related to the presence of HFS and administration period. HFS was a predictor of outcome in patients with hepatocellular carcinoma treated with sorafenib. This study indicated that a multi-tyrosine kinase inhibitor, sorafenib, prolonged survival in patients with HFS, as demonstrated for cetuximab. HFS reduces the quality of life (QOL), and is a sorafenib administration-inhibiting factor. In our hospital, a system for patients to initially consult the Pharmacists' Outpatient Clinic, followed by the feed-back of grade-based

HFS control strategies to physicians at the outpatient clinic, was established. Skin control for sorafenib-treated patients with HFS may have prolonged the administration period, improving the prognosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0729 UNUSUAL METASTASIS OF HEPATOCELLULAR CARCINOMA

I. Nakhcha¹, I. Benelbarhadi², F.Z. Ajana¹

¹Service Medecine C Rabat Maroc, Hopital Ibn Sina Rabat, Rabat/Morocco

²Rabat, Ibn Sina Hospital, Rabat/Morocco

Contact E-mail Address: Ibtissamnakhcha2@gmail.com

Introduction: Hepatocellular carcinoma is the most common primary tumor of the liver and is estimated to cause more than a quarter of a million deaths each year throughout the world. Extrahepatic metastasis of HCC occurs in about 30-50% of patients, and it depends on HCC stages. The most frequent site is lung, followed by lymph node, bone, and adrenal gland. Extrahepatic metastases to unusually sites from HCC have been reported in a few case reports. We report cases of patients with unusual extrahepatic metastatic sites from HCC.

Aims & Methods: We carried out a retrospective study of 16 patients with unusual extrahepatic metastasis of hepatocellular carcinoma out of 1047 cases of HCC treated at the hepatogastroenterology department "Medicine C" of the IBN SINA University Hospital during the past 22 years. The diagnosis was suspected based on clinical signs and imaging data, and confirmed by histology when the biopsy of the metastasis was possible, were excluded from this study, patients with lung metastasis, lymph node and portal thrombosis.

Results: Our study included 16 patients, 10 men and 6 women with a mean age of 58.5 years ranging from 37 years to 75 years. 13 patients had cirrhosis due to hepatitis C virus, 1 patient had a cirrhosis due to viral B infection and 2 patients had HCC within an oncogenic liver. All patients had one or more HCC, ranging in size from 2 to 10 cm. The AFP was normal in 11 cases and elevated in 4 cases (>200 ng/ml). We collected 4 cases of adrenal metastases, 3 costovertebral metastases, 2 gastric metastases, 2 brain metastases, 1 cranial metastasis, 1 clavicular metastasis, 1 ovarian metastasis, 1 nasopharyngeal metastasis, and a case of metastasis in the path of percutaneous biopsy of HCC. In 4 cases the diagnosis of HCC and metastasis was synchronous while in 12 cases median time from diagnosis of hepatocellular carcinoma and extrahepatic HCC was 15.5 months. Therapeutic abstention was decided in 14 patients for the advanced stage of the disease. cutaneous metastasis was resected surgically and HCC occurring in healthy liver was treated by lumpectomy and upper pole gastrectomy in gastric metastasis. The average survival was estimated at 14 months with a decline of 17.3 months, 6 cases were lost to follow and 6 deaths occurred in our series.

Conclusion: The incidence of unusual and extrahepatic metastasis of HCC diagnosed during clinical course was not frequent. The diagnostic procedures for extrahepatic metastasis have not been standardized, however considering the substantial advances in treatment of HCC, the detection of extrahepatic HCC is crucial for patients to receive appropriate therapy, which ultimately determines patient survival.

Introduction: Hepatocholangiocarcinoma is a rare primary hepatic tumor combining features of both, cholangiocarcinoma and hepatocellular carcinoma (cHCC-ICC). Few data concerning the epidemiology of cHCC-ICC have been reported, mainly from surgical series in Asian and American populations.

Aims & Methods: The main objective of this retrospective multicenter study was to evaluate epidemiological features and overall survival of histologically proven advanced cHCC-ICC patients in a French population. Data from patients treated for histologically proven cHCC-ICC in six French university hospitals between 2008 and February 2017, were retrospectively collected. The main clinical, biological, therapeutic features and OS were reported. Statistical analysis was performed using Graph Pad Prism 6.

Results: Thirty patients were included (76.6% of men, median age 64 years [extreme 37-88]). Cirrhosis was associated in 33.3% of cases (Child-Pugh score A: 70%). Positive serology for hepatitis B virus and C was found in respectively,

5 (16.6%) and 2 (6.6%) patients; and 1 co-infection was observed. Chronic alcoholism was noted in 33.3%, diabetes and obesity (body mass index $\geq 30 \text{ kg/m}^2$) were both present in 26.6% of cases. Alpha-fetoprotein, Carbohydrate Antigen 19-9 and carcinoembryonic antigen serum levels were above normal in respectively 39% (median = $5.3 \mu\text{g/L}$ [2–21 479]), 50% (median = 21.8 IU/mL [4.5–20 000]) and 14% (median = $2.4 \mu\text{g/L}$ [2–88]) of cases. Six patients (20%) were initially treated by surgical resection. At the diagnosis of advanced non resectable disease, 66.6% of patients presented a multifocal hepatic lesions, 50% presented distant metastases (bones metastases (23.3%), lung metastases (20%) and peritoneal metastases (13.3%). Twenty-seven patients (90%) received first line of systemic treatment. Twenty-four patients were treated by chemotherapy: Gemcitabine (Gem) alone (n=1), Gem + oxaliplatin (n=12), Gem + oxaliplatin + bevacizumab (n=9), Gem + cisplatin (n=2). Two patients were treated by chemoembolization and 1 patient received sorafenib. Twenty-one (70%) and 4 (13.3%) patients received a second and third line of treatment, respectively. Median overall survival was 14.5 months.

Conclusion: Advanced cHCC-ICC appear to be aggressive tumors with a poor prognosis. Cirrhosis was associated in one third of patients. Systemic treatments are not standardized and must be evaluated in a dedicated study.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0731 A PROPOSAL FOR MODIFICATION OF BARCELONA CLINIC LIVER CANCER SYSTEM FOR HEPATOCELLULAR CARCINOMA STAGING BASED ON KOREAN MULTICENTER REGISTRY DATABASE

J. Cheong, H. Cho

Gastroenterology, Ajou University Hospital, Suwon/Korea, Republic of

Contact E-mail Address: jaeyoun620@gmail.com

Introduction: Barcelona Clinic Liver Cancer (BCLC) C stage is defined as patients with preserved hepatic function and one of those adverse predictors including performance status (PS) 1–2, vascular invasion (VI), or extrahepatic spread (EHS). Therefore, BCLC C demonstrates extreme heterogeneity because patients with PS 1–2 are categorized to BCLC C regardless of tumor burden, VI or EHS. This study aimed to modify BCLC system based on PS to derive more relevant staging system.

Aims & Methods: A total of 7501 subjects, who were registered in Korean Liver Cancer Study Group during the period 2008–2013, were analyzed. Kaplan-Meier analysis was used to compare overall survival (OS). The relative goodness-of-fit between staging system was compared by Akaike information criterion (AIC) and integrated area under the curve (IAUC).

Results: Two modified BCLC (mBCLC) systems (#1 and #2) were derived by reducing role of PS in BCLC system. The patients with PS 1 or 2 without VI or EHS were reassigned to stage 0, A, or B according to their tumor burden. Prognostic accuracy was compared between mBCLC systems and original BCLC by AIC and IAUC. As a result, mBCLC#2 system identified as most explanatory and desirable model for HCC staging by showing smallest AIC value (AIC=70088.01) and largest IAUC (IAUC=0.722), while original BCLC showed the biggest AIC value (AIC=70697.17) and smallest IAUC (IAUC=0.705). The mBCLC#2 stage C was further sub-classified into C1, C2, C3 and C4 according to the variables which selected by statistical and clinical importance. The C1-C4 sub-groups showed significant different OS distribution between groups ($P < 0.001$).

Conclusion: Modification of BCLC system based on PS derived accurate and relevant modified BCLC system for HCC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0732 HEPATIC LYMPHOMAS: A RARE ENTITY

R. Gaspar¹, A. Andrade¹, J. Santos-Antunes¹, R. Liberal¹, F. Carneiro², G. Macedo³

¹Gastroenterology, Hospital São João, Porto/Portugal

²Pathology Department Centro Hospitalar São João, Porto/Portugal

³Centro Hospitalar São João, Porto Medical School, Porto/Portugal

Contact E-mail Address: ruilopesgaspar@gmail.com

Introduction: Primary tumors of the liver, beyond hepatocellular carcinoma, are difficult to characterize and are associated with poor prognosis. Hepatic involvement in the lymphomatous process is uncommon and primary hepatic lymphomas are rare. The etiology is not yet known but it is thought that hepatitis B and C may be risk factors. The therapeutic approach is not yet fully defined.

Aims & Methods: The aim of this study was to evaluate the clinical manifestations, risk factors and prognosis in lymphomas with hepatic involvement. We conducted a retrospective study of patients diagnosed with hepatic lymphoma at our center between 2005 and 2016.

Results: During the 12 years, 36 hepatic lymphomas were identified, 27 primary hepatic lymphomas and 9 with secondary hepatic involvement. The mean age at diagnosis was 53.5 ± 14.6 years and 50% were males. Only one patient had hepatitis B and none had hepatitis C. The majority (94.4%) had symptoms at the time of diagnosis, with fatigue (83.3%), night sweats (61.1%) and loss of weight (61.1%) being the most common. The imaging presentation was of a single mass in 47.2% of cases, multiple masses in 30.6% and infiltrative mass in 22.2%. The most common lymphoma subtypes were diffuse large B-cell lymphoma (52.8%), MALT lymphoma (11.1%) and Hodgkin's lymphoma (11.1%). Survival at the end of one year was 63.8% and 27.8% at 3 years. Age > 60 years ($p=0.004$) was the only factor that was significantly associated with higher mortality.

Conclusion: Hepatic lymphomas are rare entities that may occur in different ways, with diffuse large B-cell lymphoma being the most common subtype. They presented a 3-year survival of only 27.8% and the age over 60 years was the only factor significantly associated with mortality.

Introduction: Microbiotas, as part of our bodies, actually affect the body's metabolism, defense and digestion. Gut microbiotas are the typical examples and they are mainly regulated by bile acids. Each bile acid has different properties,¹ and the inhibition or promotion effects of microbiotas are very diverse.² Each individuals have a characteristic microbial distribution and composition within the intestinal tract, presumably related to the composition of their respective characteristic bile acids.³ The bile acids, released into the intestinal tract, are mostly reabsorbed (about 95%) through the enterohepatic circulation and recycled. If a certain bile acid is continuously orally-supplied, the ratio of supplied bile acid to the total bile acid is gradually increased due to the continuous enterohepatic circulation. It has been reported that changes in the composition of intestinal bile acids cause dysbiosis,⁴ and it is presumed that an artificial change in the composition of bile acid can be an effective method of controlling the proliferation of target microbiotas.

Aims & Methods: First, we wanted to identify the effects of certain bile acids on each microbiotas. We observed the effect of bile acids in human body (cholic acid, deoxycholic acid, chenodeoxycholic acid, ursodeoxycholic acid) on microorganisms by the disk diffusion method, used for antibiotic susceptibility test. Second, we intended to observe actual intestinal microbial changes through the supply of specific bile acids in animal models. Specific bile acid (UDCA), which is commercialized, was fed to rats, and real time polymerase chain reaction (RT-PCR) was used to observe the changes of the colon microbiotas. Firmicutes and bacteroidetes, which consist more than 90% of total intestinal microbiotas, were analyzed.⁵ Next, to minimize the role of endogenous bile acid, we used bile duct ligation rat model. Next generation sequencing (NGS) method was used to analyze the changes of microorganisms according to the supplied amount of UDCA. Examinations were divided into three groups for 3weeks, considering the capacity of commercial UDCA product: control group; 10 mg/kg/day group; and 15 mg/kg/day group. Fecal contents were collected from cecum of sacrificed rats.

Results: Each bile acid formed various inhibitory or promoting regions in target strains. *Saccharomyces boulardii* and *Lactobacillus casei*, which are commercially available as probiotics, were mainly inhibited by hydrophobic bile acids. *Enterococcus faecalis* and *Klebsiella pneumoniae*, which are frequently observed in bile during biliary infections, did not form a large inhibitory zone of bile acids. *Escherichia coli*, which is occasionally found in the lower intestinal tract, proliferated more around bile acid. Other microorganisms, which cause opportunistic infections in various organs in the body, showed various patterns. As a result of relative quantitative analysis(RT-PCR) based on the control group, the ratio of Firmicutes to Bacteroidetes was decreased in the group treated with UDCA for 3 weeks. In the cholestatic model, NGS showed changes in the proportion of intestinal microbiota and an increase in diversity after 3 weeks of UDCA supply.

Conclusion: The effects of various kinds of bile acids on microbiotas are very diverse, and the oral administration of certain bile acids may cause changes in microbial environment in the intestinal tract. Finally, oral feeding of certain bile acids can be used as a therapeutic treatment for dysbiosis by controlling the microbial environment in the intestinal tract.

Introduction: Inhibition of microRNA-21 (miR-21) prevents necroptosis in the mouse pancreas. In turn, we recently showed that necroptosis contribute to hepatic necro-inflammation in the common bile duct ligation (BDL) murine model.

Aims & Methods: We aimed to evaluate the role of miR-21 in mediating deleterious processes associated with cholestasis. The functional crosstalk between miR-21 and necroptosis was investigated *in vitro*. miR-21 expression was evaluated in the liver of primary biliary cholangitis (PBC) patients. C57BL/6 wild-type (WT) or miR-21-deficient (*miR-21*^{-/-}) mice were subjected to BDL or sham surgeries, with biochemical, molecular and histological analysis of hepatic damage, fibrosis, necroptosis and bile acid metabolism, after either acute (3 days) or chronic (14 days) injury.

Results: Studies in *miR-21*^{-/-} primary mouse hepatocytes established a functional link between miR-21 and necroptosis through cyclin dependent kinase 2 associated protein 1 (CDK2AP1). miR-21 expression increased in the liver of PBC patients and BDL WT mice at both 3 and 14 days. Notably, under BDL, *miR-21*^{-/-} mice displayed decreased serum levels of liver injury markers compared with WT mice, accompanied by reduced hepatocellular degeneration, oxidative stress and pro-fibrotic gene expression. Hallmarks of necroptosis were decreased in the liver of BDL *miR-21*^{-/-} mice, via relieved repression of CDK2AP1. Further, *miR-21*^{-/-} mice displayed improved adaptive response in the expression of bile acid homeostasis-associated genes.

Conclusion: miR-21 ablation ameliorates liver damage and necroptosis in BDL mice; as such, inhibition of miR-21 should arise as a promising approach to treat cholestatic liver diseases. Supported by FCT, Portugal through grants PTDC/BIM-MEC/0895/2014 and UID/DTP/04138/2013, and fellowships SFRH/BD/91119/2012 (MBA), SFRH/BD/88212/2012 (PMR), and SFRH/BD/104160/201 (ALS).

P0735 IS COMPLETE STONE REMOVAL FOR CHOLEDOCHOLITHIASIS ALWAYS NECESSARY IN EXTREMELY ELDERLY PATIENTS?

N. Okuda, S. Sugimoto, H. Nakamura, H. Hisada, T. Temma, Y. Hashimoto, S. Hayashi, T. Ito, M. Takami, M. Yamamura, J. Oyamada, A. Kamei
Gastroenterology, Ise Res Cross Hospital, Ise City/Japan

Introduction: Endoscopic sphincterotomy, endoscopic papillary balloon dilation, and endoscopic papillary large balloon dilation are widely recognized as safe and effective treatments of choledocholithiasis. However, endoscopic stone removal does have some complications. Although the life expectancy of elderly patients has increased dramatically worldwide, little information is available on the necessity of complete endoscopic stone removal in extremely elderly patients.

Aims & Methods: The aim of this study was to evaluate the safety and efficacy of complete endoscopic stone removal in extremely elderly patients. We retrospectively evaluated all extremely elderly patients (older than 90 years) who had undergone endoscopic stone removal for choledocholithiasis at Ise Red Cross Hospital between January 2012 and December 2016. Included patients were divided into complete stone removal and incomplete stone removal (failure to achieve complete stone removal and insertion of a plastic stent) groups. We compared the complication rate, overall survival (OS), and disease-specific survival (DSS) rate between the two groups.

Results: In total, 67 patients were included in this study; 36 (54%) had complete stone removal and 31 (46%) had incomplete stone removal. The median age of the patients was 92 years (range 90–100 years), median follow-up period was 462 days (range 6–1449 days) and the male-to-female ratio was 15:52. Baseline characteristics (age, body mass index, performance status, and comorbidities), rate of complications (perforation, bleeding, hypoxemia, or decreased blood pressure

during the endoscopic procedure), and total number of endoscopic procedures did not significantly differ between the two groups. The median number of stones was one (range 0–5) and two (range 1–5) ($P=0.013$), while the median diameter of the largest stones was 9 mm (range 0–27) and 14 mm (range 5–32) ($P=0.001$) in the complete and incomplete stone removal groups, respectively. During the follow-up period, OS was 33.3% and 41.9% and DSS was 5.56% and 3.23% in the complete and incomplete stone removal groups, respectively. Kaplan-Meier analysis found no significant difference in OS and DSS between the two groups ($P=0.187$ and $P=0.581$, respectively).

Conclusion: Patients in the incomplete stone removal group tended to have more numerous and larger stones. This single-centre retrospective study revealed no significant difference in OS and DSS between the two groups. Complete stone removal might not be always necessary in extremely elderly patients aged 90 years and older.

P0736 THE EVALUATION OF TRANSPAPILLARY ENDOSCOPIC GALLBLADDER DRAINAGE WITH THE USE OF INTRADUCTAL ULTRASONOGRAPHY

K. Hayasaka, T. Ujihara, R. Nakahara, D. Murakami, T. Shimizu, S. Suehoro, Y. Katsuyama, H. Harada

Gastroenterology, New Tokyo Hospital, Chiba/Japan

Contact E-mail Address: dr25027@gk2.so-net.ne.jp

Introduction: The number of indications for endoscopic transpapillary gallbladder drainage (ETGBD) to acute cholecystitis patients has been increasing with the aging of the population and prescribing antithrombotic agents. ETGBD is one of the challenging procedure because it is difficult to identify the cystic duct (CD) orifice. From November 2015, we performed with ETGBD using intraductal ultrasonography (IDUS) complementarily. The CD orifice can be identified using IDUS, resulting in cannulation in to the CD. We investigated the success rate and clinical outcomes of ETGBD in combination with using IDUS.

Aims & Methods: ERCP was performed in 1000 patients (1400 times) at New Tokyo Hospital between July 2012 and December 2016. Among them, a total of 97 patients underwent ETGBD; 58 patients with IDUS and 39 without IDUS. In this study, we investigated the success rate of ETGBD retrospectively. The success of ETGBD was defined as cannulation into the gallbladder within two trials.

Results: The mean age and male proportion of patients in the group with IDUS was similar to that in the group without IDUS (74.5 ± 11.4 vs 73.3 ± 11.3 ; $P=0.600$ and $18/40$ and $13/26$; $P=0.828$). The procedure success rate was 78.4% (76/97) in total; 86.2% (50/58) in the group with IDUS and 66.7% (26/39) in the group without IDUS ($P=0.026$). Using IDUS under fluoroscopic image allowed all patients in the group with IDUS to identify the CD orifice. ETGBD procedures in eight patients were unsuccessful because of a highly flexion of the CD in seven patients and an obstruction of the CD orifice caused by tumor invasion in one patient. Although both groups developed mild pancreatitis (one patient in the group with IDUS, and two patients in the group without IDUS), no significant difference was observed in the two groups ($P=0.563$). All patients were successfully managed with conservative treatment. There were no any other complications in the two groups.

Conclusion: The success rate of ETGBD in the group with IDUS was significantly higher than that in the group without IDUS. IDUS is may be useful as a complementary option of endoscopic gallbladder drainage.

Introduction: Bile Duct Injury (BDI) following laparoscopic cholecystectomy is a persisting problem. The rendezvous procedure (RV) provides a combined endoscopic and percutaneous approach in order to re-establish bile duct continuity in complex BDI.

Aims & Methods: The aim of this study is to assess short-term and long-term outcomes of the RV. All consecutive patients with BDI referred to our tertiary referral center between 1995 and 2016 were analyzed retrospectively. RV procedure was performed when endoscopic stenting or PTC failed and when deemed feasible by a dedicated multidisciplinary team including a hepato-pancreato-biliary surgeon, gastroenterologist and interventional radiologist. Classification of BDI, technical success of RV, procedure-related complications and outcomes were assessed.

Results: Among a total of 812 patients, RV was performed in 47 (5.8%) patients, of which 31 (66%) were diagnosed with complete transection of the bile duct (type D/Strasberg type E injury). Primary success rate of RV was 94% (44/47 patients). Reasons for failure ($N=3$) were inability to pass a stricture and inability to make contact between the two wires. In 26/47 patients (55%) RV was the final successful treatment. In 17/47 patients (36%) RV acted as a bridge to

surgery; although the RV was initially successful, late complications (stenosis, stent dysfunction) required elective hepaticojejunostomy (HJ). Procedure-related adverse events occurred in 10 patients (18%) with cholangitis being the most frequent complication (N=4.7%). No life-threatening adverse events and no 30-day mortality occurred.

Conclusion: In experienced hands, RV is safe with a final non-surgical success rate of 55%. When endoscopic stenting fails in patients with complex BDI, RV can be considered as a viable treatment option before surgical repair.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0738 CHOLECYSTECTOMY AFTER ERCP CLEARANCE OF COMMON BILE DUCT STONES: DOES TIMING MATTERS? A PROSPECTIVE RANDOMIZED STUDY

E. Atif, E. A. Elhanafy, A. Elnakeeb

Gastroenterological Surgical Center, Mansoura University, Mansoura/Egypt

Contact E-mail Address: Dr.ehab.atif@gmail.com

Introduction: The time interval between endoscopic retrograde cholangiopancreatography (ERCP) and laparoscopic cholecystectomy (LC) is a matter of debate. This study was planned to compare early LC versus late LC.

Aims & Methods: This is a prospective randomized study on patients who are presented with concomitant gallbladder and common bile duct stone. The study population was divided into two groups; group (A) managed by early LC within three days after ERCP; and group (B) managed by late LC one month after ERCP.

Results: No significant difference between both groups as regards the conversion rate, the degree of adhesion, cystic duct diameter, and intraoperative common bile duct injury or bleeding. Recurrent biliary symptoms were significantly more in delayed LC group in 7 (12.71%) patient versus 1 patient in early LC (P=0.03).

Conclusion: No significant difference between both groups as regards the conversion rate. Recurrent biliary symptoms were significantly more in delayed LC while waiting LC. Morbidity was significantly more in delayed LC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0739 TRANSRECTAL GALLBLADDER PRESERVING CHOLECYSTOLITHOTOMY AND POLYPECTOMY BY PURE NOTES

B. Liu

Gastroenterology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou/China

Contact E-mail Address: 3217265358@qq.com

Introduction: Transcolonic and transrectal NOTES in human cases was greatly restricted by the fact of fecal contamination. We developed a detachable intracolonic balloon to help keep the colon sterile by blocking the colonic lumen. Although cholecystectomy is widely used for treating gallbladder polyps and gallstones, there is still a controversy about whether or not the gallbladder should be preserved. However, postcholecystectomy syndromes, such as bile duct injury and the correlation with colon cancer, remind us of the importance of gallbladder preservation.

Aims & Methods: Approved by the Independent Ethics Committee, we've completed 8 transrectal gallbladder preserving cholecystolithotomy (TRGPC) and 3 transrectal gallbladder preserving polypectomy (TRGPP) and 2 combined cases by pure NOTES. Moreover, 1 case of TRGPC was done by hybrid NOTES. As the figures show, the balloon was placed in the transverse colon to block the colonic lumen, and the distal colon cavity was disinfected with povidone-iodine solution. An incision was made on the anterior rectal wall 12–17 cm from the anus. The endoscope was advanced into the peritoneal cavity with liver and gallbladder identified. The bile was aspirated before an incision on the gallbladder wall was made. Stones and/or polyps were found inside of the gallbladder. Stone extractor and biopsy forceps were used to take out the stones. The polyps were coagulated and removed by electric biopsy forceps. The muscular layer and the adventitial layer were successively closed with endoclips. Peritoneal cavity lavage was performed with sterile saline. The rectal incision was closed with endoclips and endoloops tightly. At the end of the procedure, the balloon was pulled out after being deflated.

Results: The mean operation time (from incision making till the last clipping) was 180.5 min. (89–467 min.). 6 hours after anesthesia, the patients could drink water, and liquid diet was resumed 24 hours later. Postoperatively, 4 of the 14 patients felt mild abdominal distention which disappeared within 12 hours when they were able to get off the bed. For 1 patient with acute cholecystitis, a hybrid NOTES with laparoscopy was performed. Moreover, gallbladder drainage and peritoneal lavage were used, and the abdominal pain relieved soon. All the patients were discharged without any adverse events and all felt good during the follow-ups.

Conclusion: The usage of the detachable balloon can prevent the operative field from fecal contamination effectively. TRGPC and TRGPP by pure NOTES are suitable for both males and females. Transrectal route provides a novel alternative approach for the treatment of gallbladder polyps and gallstones. To our knowledge, this is the first human case series of transrectal gallbladder preserving cholecystolithotomy and polypectomy by pure NOTES. However, multicentered, prospective, controlled researches with more cases are needed in the future.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0740 KML001, AN ORAL ARSENIC COMPOUND, AS PALLIATIVE CHEMOTHERAPY IN ADVANCED BILIARY TRACT CANCERS AFTER FAILURE OF GEMCITABINE BASED CHEMOTHERAPY

J.H. Jo, I.R. Cho, H.S. Lee, M.J. Chung, J.Y. Park, S. Bang, S.W. Park, J. Chung, S.Y. Song

Department Of Internal Medicine And Institute Of Gastroenterology, Yonsei University Health System Dept. of Internal Medicine Dept. of Gastroenterology, Seoul/Korea, Republic of

Contact E-mail Address: woforce@naver.com

Introduction: Sodium metaarsenite (NaAs2O3; code name KML001) is an orally bioavailable arsenic compound with potential anti-cancer activity. However, the effect of KML001 has not been evaluated in patient with biliary tract cancers. We investigated the potential of KML001 as palliative chemotherapy in patients with advanced biliary tract cancers who non-respond to gemcitabine-based chemotherapy.

Aims & Methods: The study was designed to evaluate safety, tolerability and effectiveness of KML001 as palliative chemotherapy in advanced biliary tract cancer. Inclusion criteria were 1) inoperable or metastatic cholangiocarcinoma and gallbladder cancer, and 2) previous history of failure to gemcitabine-based chemotherapy. Exclusion criteria were 1) naïve patient to chemotherapy, 2) ECOG PS > 3, and 3) history of decompensated congestive heart failure, uncontrolled arrhythmia, and QT prolongation (QTc > 480 ms). KML001 (Kominex, Komipharm International Co., Ltd.) was administrated as 7.5 mg daily to eligible subjects. Every two months, patient took response evaluation by biliary CT scan.

Results: A total of 44 patients (21 females and 23 males) were enrolled prospectively between November 2011 and October 2014. Mean age of the patients was

61.5 years old. There were 17 patients (38.6%) with intrahepatic cholangiocarcinoma, 9 patients (20.5%) with perihilar cholangiocarcinoma, 7 patients (15.9%) with extrahepatic cholangiocarcinoma and 11 patients (25.0%) with gallbladder cancer. All patients had stage IV disease and median number of prior anticancer treatments of patients was 2 (range 1–5). After an average of 1.5 months of treatment (range 0.5–10.0 months), three patients (6.8%) presented stable disease as best overall response, 23 patients (52.3%) presented progression and 18 patients (40.9%) could not survive until response evaluation. Median progression free survival was 1.7 months (interquartile range (IQR) 0.8–2.3 months) and median overall survival from study-enroll was 2.5 months (IQR 1.4–4.9 months). During treatment, 25 patients (55.6%) could maintain tolerable general condition without increasing ECOG PS, and 35 patients (79.6%) could maintain or decrease the requirement for morphine as pain killer. During treatment, there were 12 cases (12/44, 27.3%) of severity grade 3 adverse events (AE) and no cases of grade 4 AE. Most common AE was ALT/AST elevation (11/44, 25%) followed by anemia (10/44, 22.7%). The major causes of the drop outs from study were due to disease progression or patient's death (30 cases, 66.7%), and there were only 5 cases (11.1%) who dropped out due to adverse drug reactions or severe AE.

Table 1: Treatment outcomes

Study period, mean, mo (range)		1.5 (0.5–10.0)
Progression free survival, mo (IQR)		1.7 (0.8–2.3)
Survival from study-enroll, mo (IQR)		2.5 (1.4–4.9)
Best response, n (%)	SD	3 (6.8%)
	PD	23 (52.3%)
	Not evaluated	18 (40.9%)
ECOG, n (%)	Increased	19 (43.2%)
	Maintain	25 (56.8%)
Morphin requirement, n (%)	increased	8 (18.6%)
	maintain	31 (72.1%)
	decreased	4 (9.3%)
Adverse event, n (%)	Grade 1	16 (36.4%)
	Grade 2	29 (65.9%)
	Grade 3	12 (27.3%)
	Grade 4	0 (0%)
Drop out cause, n (%)	- drug reaction	1 (2.3%)
	Adverse event	4 (9.1%)
	Patient's death	7 (15.9%)
	Disease progression	22 (50.0%)
	Withdrawal consent	5 (11.4%)
	Loss of follow-up	2 (4.5%)
	Poor general condition	3 (6.8%)

Conclusion: KML001 was safe and well tolerated in respects of adverse events. KML001 was also shown promising result in disease control and pain control. KML001 can be another palliative treatment option for patients with advanced biliary tract cancers who non-respond to gemcitabine based chemotherapy.

P0741 ENDOSCOPIC DRAINAGE OF MALIGNANT STENOSIS OF THE BILIARY CONFLUENCE: HOW MANY SEGMENTS SHOULD BE DRAINED TO IMPROVE THE PATIENT SURVIVAL?

F. Caillol¹, E. Bories², C. Zemmour³, C. Pesenti¹, J.P. Ratone¹, M. Giovannini¹

¹Endoscopy, Paoli Calmettes Institute, Marseille/France

²Paoli Calmettes Institute, marseille/France

³Statistics, Paoli Calmettes Institute, Marseille/France

Contact E-mail Address: fcaillol@free.fr

Introduction: ESGE stated in 2012 that more than 50% of the liver had to be drained in case of unresectable hilar liver stenosis, however it remains unclear if unilateral or bilateral palliative drainage has to be performed for this kind of stenosis. Our policy is to try to drain the most possible segments of the liver in case of hilar stenosis. The aim of our study was to evaluate the efficiency of hilar drainage in function of the number of segments drained.

Aims & Methods: The study is a retrospective analysis of a prospective registry of drainage of malignant stenosis of the hilum. Drainage were performed by 5 operators performing ERCP, EUS-drainage, and per-cutaneous drainage. The choice of the technique was left to the appreciation of the operators. All techniques could be associated. A Ct-scan or MRI was performed before and after drainage to decide the plan of the drainage and to evaluate efficiency and quality of the drainage. All drainages were performed under general anesthesia in a intubated patient. The quality of the drainage was evaluated by calculation of the percentage of drained segments. This percentage was calculated by dividing

the number of liver segment drained with the number of liver segment. The number of liver segment was obtained by removing from the 8 classical liver segments with the segments resected in case of surgery, and/or the segments with invasion of more than 50% by tumor. The aim of the study was to evaluate the effect of the quality of the drainage on the patients survival. Quality of the drainage was defined by the percentage of liver segments drained.

Results: 60 (38 men) patients were included from 01/2015 to 07/2016. Mean age = 69.84 years old. The classification of the stenosis was type II for 17 (29%) patients, type III for 20 patients (34%), type IV for 22 (37%). Histology corresponded to CCK from 26 patients (43%), metastatic disease from colorectal cancer for 15 patients (25%) and others cancers for 19 (32%). Median follow-up was 8.5 months (5.5–16.5). The median of survival was 5 months (2.3–12.3). In unvaried and multi varied analysis there was a significant correlation between the percentage of segments drained > 80% ($p < 0.05$) and the survival. The other factor with impact on the survival was an invasion of the liver > 50% by tumor. There was no impact on the survival according to the different techniques used to drain the bile ducts. To confirm the efficiency of the quality of the drainage, a ROC curve was performed establishing a correlation between patients receiving chemotherapy and percentage of liver drained (area curve = 0.77 (0.65–0.88)).

Conclusion: The survival of patient with a malignant stenosis of the biliary confluence is highly correlate with the rate of the liver segment drained.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0742 SYSTEMATIC REVIEW AND META-ANALYSIS OF TRANSABDOMINAL AND ENDOSCOPIC ULTRASOUND FOR GALLBLADDER POLYPS

S. Z. Wennmacker¹, M. P. Lamberts², M. Di Martino³, J.P.h. Drenth², K. S. Gurusamy², C. J.h.m. Van Laarhoven¹

Introduction: Approximately 0.6% to 4% of cholecystectomies are for gallbladder polyps. The decision to perform cholecystectomy is based on presence of gallbladder polyp on transabdominal ultrasound (TAUS) or endoscopic ultrasound (EUS), or both. This decision is also influenced by whether the polyp is a true or pseudo polyp. Pseudo polyps are non-neoplastic and do not need surgery. True polyps are neoplastic, either benign (adenoma) or (pre)malignant (dysplastic polyp/carcinoma). True polyps usually need surgery, as they are thought to have malignant potential through the adenoma-carcinoma sequence. (Pre)malignant lesions should be operated sooner than benign lesions. There has been no systematic review and meta-analysis on the accuracy of TAUS and EUS in the diagnosis of gallbladder polyps, true gallbladder polyps and (pre)malignant polyps.

Aims & Methods: The aim was to determine and compare the accuracy of TAUS and EUS for diagnosis of gallbladder polyps, differentiating between true and pseudo polyps and differentiating between (pre)malignant and benign polyps. MEDLINE, EMBASE, Science Citation Index Expanded and the Cochrane library were searched. The search was not restricted based on language, publication status, or prospective or retrospective nature of the studies. Only studies with data on true positives, false positives, false negatives and true negatives for TAUS or EUS were included. Histopathology after cholecystectomy was the only accepted reference standard, except for studies on diagnosis of gallbladder polyp, for which follow-up by TAUS or EUS was also accepted as reference standard. Two authors independently screened abstracts, selected studies for inclusion and collected the data from each study. The quality of the studies was evaluated using the QUADAS-2 tool. If possible the bivariate model was used to obtain pooled estimates of sensitivity and specificity. Otherwise the principles of Takwiongi et al. for meta-analysis of sparse data were used.¹ Hierarchical summary receiver operating characteristics curve (HSROC) were used to test whether TAUS or EUS was superior. Post-test probabilities were calculated using the median prevalence (as pre-test probabilities) and summary positive and negative likelihood ratios.

Results: A total of 17 studies were included in this review. For diagnosis of gallbladder polyps six studies on TAUS were included. The sensitivities and specificity of the studies ranged from 0.45 to 1.00, and 0.91 to 0.98 respectively. There were no studies on EUS for this topic. For differentiating between true and pseudo polyps, seven studies were included. All seven studies reported on TAUS, four studies also reported on EUS. The sensitivities and specificities of the studies ranged from 0.47 to 1.00 and 0.51 to 0.98 for TAUS, and from 0.63 to 1.00 and 0.84 to 0.96 for EUS. For differentiating between (pre)malignant and benign polyps, five studies were included. Four studies reported on TAUS and three studies on EUS. The sensitivities and specificities of the studies ranged from 0.09 to 1.00, and 0.46 and 1.00 for TAUS and from 0.69 and 0.92, and 0.87 to 0.95 for EUS.

No studies were of high methodological quality. The results of the pooled sensitivities, specificities and post-test probabilities are shown in Table 1. HSROC analysis showed no significant difference between the diagnostic accuracy of TAUS and EUS for differentiating between true and pseudo polyps and for

differentiating between (pre)malignant and benign polyps ($p=0.174$ and $p=0.589$ respectively).

Conclusion: Diagnostic accuracy of TAUS for diagnosis gallbladder polyps is moderate and decreases further when differentiating between polyp types. TAUS would regularly provide false positive results, leading to unnecessary surgery. There was no evidence that diagnostic test accuracy of EUS was better than TAUS. Further studies of high methodological quality are needed to determine diagnostic accuracy of EUS and TAUS for differentiating between polyp types.

This abstract is based on a pre-peer review draft of a Cochrane Review.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In its early stages, gallbladder cancer is an asymptomatic disease, and is associated with a poor prognosis if found in an inoperable condition. Several investigators have reported the utility of contrast-enhanced ultrasonography (CEUS) in low mechanical index (MI) contrast mode using a microbubble contrast agent for gallbladder lesions. However, CEUS images with low MI setting are influenced by the echogenicity of background B-mode and cannot depict precise vessel images, in contrast with high MI contrast mode.

Aims & Methods: The aim of this study was to assess the diagnostic value of CEUS in high MI contrast mode for characterizing polypoid lesions of the gallbladder (PLG). Thirty-six patients with PLG, including 17 with gallbladder cancer and 19 with benign polyps, who underwent CEUS were enrolled. The institutional review board approved this study and informed consent was obtained. Perflubutane-based contrast agent and high MI contrast mode was used for CEUS. Two blinded readers retrospectively evaluated images obtained in B-mode and CEUS. Kappa values, which reflect inter-observer agreement. Subsequently, patients were stratified according to lesion size at the largest diameter, and the diagnostic accuracy for gallbladder cancer in B-mode and CEUS were assessed.

Results: Two patients with malignant PLG could not be evaluated in B-mode due to sludge. Kappa values for CEUS were graded as good or excellent, and were better than in B-mode. Age and size of malignant PLGs were significantly larger than benign lesions. In B-mode, 80% (12/15) of malignant PLGs exhibited heterogeneity ($p < 0.01$). On CEUS, malignant PLGs exhibited sessile-shape (76% [13/17]), dilated vessels (71% [12/17]), irregular vessels (82% [14/17]), and heterogeneous enhancement (59% [10/17]) ($p < 0.01$). Except for heterogeneous enhancement, all features remained significantly different after stratification according to size of PLG between 11 mm and 20 mm on CEUS. The sensitivity, specificity, and accuracy for diagnosis of gallbladder cancer was 80% (12/15), 79% (13/19), and 73% (25/34) in B-mode, 94% (16/17), 89% (17/19), and 92% (33/36) on CEUS, and 88% (7/8), 91% (10/11), and 89% (17/19) on CEUS after stratification according to size, respectively.

P0742

Table 1: Results of meta-analysis and post-test probabilities

Index Test	Target condition	Number of studies (patients)	Summary sensitivity (95% CI)	Summary specificity (95% CI)	Minimum, median and maximum prevalence of target condition = pre-test probability	Positive post-test probability (95% CI)	Negative post-test probability (95% CI)
TAUS	Gallbladder polyp	6 studies (16260 patients)	0.80 (0.55–0.98)	0.97 (0.95–0.98)	Minimum: 0.4% Median: 6.4% Maximum: 53.3%	0.10 (0.07–0.11) 0.65 (0.55–0.69) 0.97 (0.95–0.97)	0.00 (0.00–0.00) 0.01 (0.01–0.04) 0.19 (0.08–0.38)
TAUS	True gallbladder polyp	7 studies (1272 patients)	0.77 (0.48–0.92)	0.78 (0.59–0.90)	Minimum: 9.1% Median: 20.2% Maximum: 60.0%	0.26 (0.16–0.39) 0.47 (0.32–0.62) 0.84 (0.74–0.91)	0.03 (0.01–0.07) 0.07 (0.03–0.16) 0.31 (0.15–0.53)
EUS	True gallbladder polyp	4 studies (267 patients)	0.84 (0.54–0.96)	0.84 (0.70–0.92)	Minimum: 9.1% Median: 20.2% Maximum: 60.0%	0.35 (0.20–0.53) 0.57 (0.39–0.74) 0.88 (0.79–0.95)	0.02 (0.01–0.07) 0.05 (0.01–0.15) 0.22 (0.07–0.51)
TAUS	Dysplastic polyp/carcinoma	4 studies (1637 patients)	0.60 (0.22–0.89)	0.89 (0.76–0.96)	Minimum: 4.1% Median: 20.1% Maximum: 95.6%	0.19 (0.07–0.46) 0.59 (0.30–0.83) 0.99 (0.97–1.00)	0.02 (0.01–0.05) 0.10 (0.04–0.24) 0.91 (0.78–0.96)
EUS	Dysplastic polyp/carcinoma	3 studies (350 patients)	0.85 (0.56–0.96)	0.91 (0.75–0.97)	Minimum: 4.1% Median: 20.1% Maximum: 95.6%	0.28 (0.12–0.54) 0.70 (0.44–0.87) 0.99 (0.99–1.00)	0.01 (0.00–0.02) 0.04 (0.01–0.13) 0.78 (0.51–0.92)

Conclusion: CEUS in high mechanical index contrast mode was a useful modality for differentiating gallbladder cancer and benign PLGs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0744 ASSOCIATION OF CIRCULATING ADIPONECTIN LEVELS AND TUMOR STAGE IN BILIARY TRACT CANCER

A. Saray, B. Gogov, N. Zubcevic, D. Prohic, A. Mehmedović, A. Puhalić

Introduction: Multiple recent studies have indicated that some of adipose tissue-derived hormones may significantly influence the growth and proliferation of GI tumors including liver cancer (1, 2). However, the role of adipokines such as adiponectin and leptin in biliary tract cancer have not been well studied before. The aim of the study was to analyze plasma concentrations of adiponectin and leptin in cholangiocarcinoma (CC) patients and to compare these concentrations to clinicopathological parameters.

Aims & Methods: Baseline levels of adiponectin and leptin were determined in 38 consecutive patients with newly diagnosed cholangiocarcinoma and 38 healthy control subjects. The association between adiponectin and leptin and tumor stage was evaluated using nonparametric Spearman's correlation test. Control subjects were matched to case patients by age, sex and BMI. Survival analysis used the Kaplan-Meier curve and the Cox proportional hazards model.

Results: Overall median adiponectin concentrations were lower in CC patients versus control subjects (5.1 vs 9.3 mg/mL, $P=0.001$). In CC patients with T stage 2–4 ($n=22$) median adiponectin concentrations were significantly lower than in CC patients with T stage 1 ($n=16$) (3.8 vs 6.6 mg/mL, $P=0.001$). The mean leptin levels were not significantly decreased in CC patients ($P=0.45$). Adiponectin concentrations were inversely correlated with tumor T stage ($r=-0.811$, $P=0.01$) of CC patients. Higher adiponectin levels at baseline were associated with increased overall survival in T stage 2–4 patients (Cox F test = 2.139, $P < 0.05$).

Conclusion: This study identified an association between adiponectin levels and tumor stage suggesting a potential role for adiponectin in progression of cholangiocarcinoma. Furthermore these results suggest, for the first time, that serum adiponectin levels might represent a prognostic indicator in patients with CC. Our results support the hypothesis linking adipose-tissue derived hormones levels to growth of obesity-associated cancers (3). Adipokines appear to play an important role in risk prediction and management of cholangiocarcinoma patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0745 PRETREATMENT BODY MASS INDEX AND WEIGHT CHANGE DURING INITIAL PERIOD OF CHEMOTHERAPY AFFECT SURVIVAL OUTCOME IN ADVANCED BILIARY TRACT CANCER PATIENTS

Contact E-mail Address: schmeichel80@gmail.com

Introduction: Recently many studies have been conducted to investigate the association between obesity and survival in cancer patients. Cancer has a significant influence on the nutrient status of patients and obesity can affect on the pharmacokinetics of anti-cancer drugs. The impact of obesity on survival is known to vary in different cancers. Biliary tract cancer was less frequently analyzed and most of the studies were on the relationship between obesity and cancer incidence.

Aims & Methods: We performed this study to investigate the association between BMI and overall survival in advanced biliary tract cancer patients with chemotherapy. Between January 2005 and December 2015, two hundred and eighty-four patients who underwent chemotherapy for biliary tract cancer were retrospectively reviewed. The relationship between BMI (kg/m²) and overall survival (OS) was assessed. Based on World Health Organization BMI category and 2014 Clinical Practice Guidelines for Overweight and Obesity in Korea, BMI was classified as follows; underweight, <18.5 kg/m²; normal, 18.5–22.9 kg/m²; overweight, 23–24.9 kg/m²; obese, ≥25 kg/m².

Results: Median OS was 12.1 months for underweight patients, 10.5 months for normal patients, 16.1 months for overweight group, 13.6 months for obese patients, respectively. (p=0.047) Univariate analysis showed that BMI, local status of disease, operation, radiotherapy and ECOG performance were significantly associated with better survival. Compared with normal patients, overweight patients (BMI 23–24.9 kg/m²) had a reduced risk of mortality in multivariate analysis (HR 0.491, CI 0.334–0.721; 95% p=0.036). In the additional analysis for the effect of change in body weight and BMI to the overall survival, larger amount of change in body weight was associated with further decrease in overall survival.

Conclusion: Slightly overweight status and the maintenance of body weight during the initial period of chemotherapy is independent predictor of better overall survival in advanced biliary tract cancer patients with good performance status.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0746 THROUGH THE CATHETER BIOPSY METHOD FOR BILIARY CARCINOMA

T. Okuzono

Department Of Gastroenterology, Sendai Kousei hospital, Sendai/Japan

Contact E-mail Address: okuzonotoru@gmail.com

Introduction: To perform curative operation of biliary carcinoma, the pre-operative identification of exact proximal and distal margins is important. A biopsy forceps is conventionally inserted to common bile duct via duodenum ampulla guided with an antecedent guide wire. Cannulation of the bile duct with the biopsy forceps may sometimes be difficult in cases where no sphincterotomy is performed, placing the patient at risk of post-ERCP pancreatitis after multiple attempts to advance the forceps into the duct. Pancreatobiliary endoscopists have reported the biopsy methods.

Aims & Methods: The aim of this study was to assess the feasibility and safety of the biopsy methods. This was a retrospective review of bile duct biopsies with this new method conducted in Sendai Kousei hospital from February 2015 to October 2016. All patients who had biliary stenosis were included. Patients' demographic data, technical success, adverse events and the diagnostic accuracy were evaluated.

Results: A total of 95 biopsy procedures were performed in 40 patients. The technical success rate was 95% (90/95). Post-ERCP pancreatitis occurred in 1 of 40 patients (2.5%, 1 grade 1 patient). There were no other adverse events like perforation or bleeding. The diagnostic yield of mapping biopsy procedures was 100% (7 of 7 patients).

Conclusion: The new biopsy methods to biliary stricture were feasible and safe. It opens up exciting possibilities for endoscopic preoperative diagnosis of the biliary carcinoma.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Up to half of all patients with resectable PHC on imaging are found unresectable during exploratory surgery. Moreover, mortality is high in patients who do undergo resection for PHC.

Aims & Methods: The aim of this study was to identify patients at high risk for adverse outcomes of exploratory surgery and developing a preoperative risk score model to predict adverse outcomes in perihilar cholangiocarcinoma (PHC) patients undergoing exploratory surgery. Consecutive PHC patients who underwent exploratory laparotomy in two tertiary referral centers between 2002 and 2014 were identified. Baseline patient and tumor characteristics were collected from medical records. Adverse postoperative outcome was defined as unresectable disease at exploratory laparotomy, 90-day surgical mortality, or an R1 resection. A multivariable Cox proportional hazards analysis was performed to identify preoperatively available poor prognostic factors for an adverse outcome.

Results: In total, 331 patients underwent exploratory laparotomy with a median OS (95% confidence interval) of 20.7 (17.8–23.6) months. Adverse outcomes were found in 229 patients (69.2%): 145 patients (43.8%) had preoperative adverse outcomes of the exploratory surgery, 53 (16%) patients had postoperative adverse outcomes and 31 (9.4%) patients experienced both peri- and post-operative adverse outcomes. Median OS for patients with an adverse outcome was 13.1 months (11.3–15.0) compared to 50.9 months (39.6–62.2) in patients without adverse outcomes (p < 0.001). Cholangitis at or before first presentation (hazard ratio (HR) 2.38, 95% CI 1.16–4.99, p=0.0422), CA 19-9 above 1000 U/mL (HR 3.26, 95% CI 1.14–11.8, p=0.0195), and tumor involvement of the hepatic artery on imaging (HR 2.07, 95% CI 1.01–4.33, p=0.0492) were independent prognostic factors for an adverse outcome at exploratory laparotomy. A risk score based on these three factors identified patients with a substantial (49%), high (66%), and very high (87%) risk of adverse outcome.

Table 1: Calculation of prognostic score

Characteristic	Score
CA 19.9 (U/mL) ≥1000 U/mL	1
Cholangitis before or at presentation in referral center [#]	1
Hepatic artery involvement *	1
Risk group Substantial High Very high	Total score 0 1 2–3
Number of patients 41 74 69	Absolute risk 48.8% 66.2% 87.0%

Conclusion: PHC patients undergoing exploratory laparotomy have a high risk of an adverse outcome. A preoperative risk score for adverse outcome may help clinicians to inform patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Patients with perihilar cholangiocarcinoma (PHC) have few treatment options and a poor prognosis. Most staging models for patients with PHC have been developed for the minority of patients with potentially resectable disease and are not applicable to the vast majority of patients.

Aims & Methods: The aim of this study was to develop a prognostic score for all PHC patients using variables available at presentation. All consecutive patients with PHC (regardless of tumor stage and treatment) in two tertiary referral centers between 2002 and 2014 were identified and included. Baseline patient and tumor characteristics were collected from medical records. Cox proportional hazards regression was used for multivariable analysis. Age, BMI, bilirubin, CA 19-9, and tumor size were modeled as continuous covariates.

Results: A total of 674 patients were included of whom 342 (50.8%) had unresectable disease at presentation and 176 (26.2%) underwent exploratory laparotomy. Multivariable analysis identified age (HR 1.41 (95% CI 1.23–1.63)), BMI (HR 1.11 (95% CI 1.05–1.17)), serum bilirubin level (HR 1.45 (95% CI 1.21–1.71)), CA 19.9 serum level (HR 1.22 (95% CI 1.07–1.38)), tumor size (HR 1.33 (95% CI 1.14–1.56)), WHO performance status 3–4 (HR 1.48 (95% CI 1.10–1.95)), suspected distant metastases on imaging (HR 1.69 (95% CI 1.29–2.20)), unilateral HA involvement: HR 1.28 (95% CI 1.05–1.57), and main/bilateral HA involvement: (HR 1.61 (95% CI 1.21–2.14)) as independent prognostic parameters. Based on these factors, a prognostic score was created to predict survival for patients with PHC from the time of presentation. Discrimination using Kaplan-

Meier curves, and calibration curves revealed good predictive abilities. The risk scored identified patients with a 1-year survival probability ranging from 15–73%.

Conclusion: We developed a prognostic score to predict overall survival for PHC patients using eight independent poor prognostic factors available at presentation. This score may help to inform patients and guide individualized treatment decision making.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0749 THE OUTCOMES OF ERCP FOR THE PALLIATION OF MALIGNANT JAUNDICE IN ENGLAND BETWEEN 2001 AND 2015

P. Harvey¹, S. Baldwin¹, J. Mytton², F. Evison², P. Patel², N. Trudgill¹

Introduction: Malignant biliary obstruction has a poor prognosis unless secondary to a resectable primary cancer. Recent data on PTC for the relief of malignant obstruction in a palliative setting demonstrated a high early mortality. We have therefore examined outcomes of ERCP in inoperable malignant obstruction.

Aims & Methods: The Hospital Episode Statistics (HES) database contains diagnostic and procedural data for all hospital attendances in England. HES is linked to the Office for National Statistics (ONS) to provide mortality data. All subjects from April 2001 to April 2015 in England with an ICD10 code for cancer 2 years prior to ERCP or in the following 6 months were examined. Subjects undergoing a curative surgical procedure were excluded. Associations between demographics, co-morbidities, unit ERCP volume and mortality were examined by logistic regression.

Results: 49055 subjects were included in the study of whom 48.7% were male, median age 74.5 years (range 19–104). Pancreatic cancer was the most common aetiology (63.5%) followed by liver and intrahepatic bile duct malignancy (19.4%). Mortality was 4.16%, 10.9% and 19.6% for 7 day, in hospital and 30 day respectively. In multivariate analysis male gender (OR 1.14, (95% CI 1.08–1.20) $p < 0.001$); increasing by age quintile 64–71 (1.34, (1.23–1.47) $p < 0.001$), 72–77 (1.57, (1.44–1.72) $p < 0.001$), 78–83 (1.83, (1.68–2.00) $p < 0.001$), >83 (2.78, (2.55–3.03), $p < 0.001$); most deprived quintile (1.22, (1.12–1.33), $p < 0.001$); increasing co-morbidity score 1 to 5 (1.09, (1.02–1.16), $p = 0.012$), 6 to 10 (1.23, (1.12–1.35), $p < 0.001$) 11 to 15 (1.49, (1.33–1.66), $p < 0.001$), 16 to 20 (1.97, (1.70–2.28), $p < 0.001$), >20 (2.79 (2.39–3.25), $p < 0.001$); advancing year of ERCP 2013/14 (0.78, (0.68–0.90), $p = 0.001$), 2014/15 (0.85, (0.74–0.98) $p = 0.028$); and previous renal failure (1.92, (1.77–2.09), $p < 0.001$) were associated with increasing 30 day mortality. Asian ethnicity (0.82, (0.67–0.99), $p = 0.036$), Cancer of extrahepatic and unspecified parts of biliary tree (0.60, (0.55–0.65), $p < 0.001$) and upper tertile of unit ERCP activity (>230) per annum (0.86, (0.80–0.93), $p < 0.001$) were negatively associated with 30 day mortality.

Conclusion: Short-term mortality in subjects with malignant biliary obstruction following ERCP was high. A better prognosis was observed in; high-volume ERCP units, Asian ethnicity and extrahepatic primary cancers. Male gender, advancing age, increasing co-morbidity score, greater deprivation and previous renal failure predicted death at 30 days.

Disclosure of Interest: All authors have declared no conflicts of interest.

TUESDAY, OCTOBER 31, 2017

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a common chronic liver disease and in particular a health threat in obese children. Single nucleotide polymorphisms in genes encoding PNPLA3 (rs738409) and TM6SF2 (rs58542926) contribute to the development of NAFLD. It is however unknown whether liver pathology and cardiometabolic disturbances coincide in carriers and non-carriers of these risk alleles in an at-risk obese pediatric population. Therefore, we assessed cardiometabolic derangements, genetic predisposition for NAFLD and liver transaminase levels in children with overweight and obesity.

Aims & Methods: One hundred and seventy-four children (49% boys) from the Centre for Overweight Adolescent and Children's Healthcare (COACH) at the Maastricht University Medical Centre were genotyped for PNPLA3 I148M and TM6SF2 E167K. Anthropometric, cardiometabolic risk and liver-related parameters were determined.

Results: Anthropometric parameters did not differ significantly between carriers and non-carriers of the risk alleles. ALT and AST were significantly higher in

PNPLA3 G allele carriers as compared to the C allele carriers (ALT; CC 21, 00 (17, 00;28, 00); CG 26, 50 (18, 00;34, 50); GG 29, 00 (23, 00;51, 00) ($p = 0.004$) and AST; CC 24, 00 (19, 00;30, 00); CG 27, 50 (21, 00;40, 00); GG 30, 00 (26, 00;36, 00) ($p = 0.004$). The odds ratio for having ALT levels above the cut-off values increased for every PNPLA3 G allele, with an OR of 2.51 (1.22;5.18; $p = 0.013$) for the PNPLA3 CG genotype and 5.54 (1.53;20.02; $p = 0.009$) for the GG genotype, compared to the CC genotype. Carriers of the PNPLA3 risk allele did not show a deteriorated metabolic profile compared to non-carriers.

The TM6SF2 T allele carriers also showed a tendency towards increased transaminase levels, but a significantly healthier cardiometabolic profile, i.e. lower total cholesterol ($p = 0.024$), LDL cholesterol ($p = 0.015$) and triglyceride concentrations ($p = 0.003$) and a higher central retinal artery equivalent ($p = 0.020$) compared to the major allele carriers. Carrying the TM6SF2 T allele in addition to carrying the PNPLA3 'risk' allele, did not significantly increase the odds ratios for increased ALT concentrations. The prevalence of the metabolic syndrome did not differ between the different PNPLA3 genotype carriers nor between the TM6SF2 genotype carriers.

Conclusion: Despite significantly higher liver transaminase levels and a positive correlation between ALT levels and triglyceride and fasting insulin concentrations in PNPLA3 G allele carriers, these children did not have a more deteriorated cardiometabolic profile compared to non-carriers. The metabolic syndrome was not more prevalent in risk allele carriers. These results suggest that hepatic aberrations and metabolic disturbances apparently do not develop concordantly in this specific population. Furthermore, these children with a high liver health risk may not be identified by measuring cardiometabolic parameters.

Introduction: Pediatric chronic liver diseases are becoming a public health issue. Ultrasound based elastographic techniques have emerged as non-invasive methods of pediatric liver fibrosis assessment. The most recent are two dimensional shear-wave elastographic (2D SWE) techniques. While they are proved to be highly reproducible in children, there is still no consensus regarding the number of measurements to be performed for a high-quality evaluation.

Aims & Methods: We aimed to investigate the number of liver stiffness measurements (LSM) needed for a high-quality evaluation using a 2D SWE technique. We conducted a prospective study which included 73 children (age range: 3–17 years, mean age 11.73 ± 3.55 years, 37% girls, mean body mass index (BMI) 25.12 ± 7.38 kg/m²). We used the 2D-SWE.GE (Logiq E9, GE Healthcare, Chalfont St Giles- UK), with a C1-6-D probe. One examiner performed 10 LSM for each child. We randomly extracted 1 LSM, 2 LSM, 3 LSM and 5 LSM from all 10 and calculated their respective medians. We employed the Friedman test to compare the medians of 1, 2, 3, 5 and 10 LSMs. We used the interclass correlation coefficient (ICC) to assess the agreement between the medians of 1, 2, 3, 5 and 10 LSMs.

Results: Medians calculated from 1, 2, 3, 5 and 10 LSMs were similar (4.21 ± 1.05 kPa vs 4.22 ± 0.91 kPa, 4.25 ± 1.03 vs 4.2 ± 0.99 kPa vs 4.19 ± 0.99 kPa, $p = 0.94$). Furthermore, the agreement between medians calculated from 1, 2, 3, 5 and 10 LSMs was excellent (ICC = 0.960, 95% confidence interval: 0.944–0.974).

Conclusion: We suggest obtaining 5 LSM for a high-quality evaluation using this 2D SWE technique.

P0752 PERCUTANEOUS EMBOLIZATION OF VISCERAL ARTERY PSEUDO-ANEURYSMS – A TERTIARY CENTER EXPERIENCE

R. Chavan¹, J. Singh¹, Z. Nabi¹, R. Kalapala¹, D.N. Reddy¹

¹Gastroenterology, Asian Institute of gastroenterology, Hyderabad, Hyderabad/India

Contact E-mail Address: drdadhikachavan@gmail.com

Introduction: Visceral artery pseudo-aneurysms are rare, but potentially fatal if rupture. Pseudoaneurysm usually occurs most frequently after pancreatitis. Angioembolization with conventional trans-catheter approach is the standard treatment. Direct percutaneous embolization has been commonly used for treatment of peripheral artery pseudoaneurysm when trans-catheter approach is not feasible. However, very limited data is available regarding its safety and efficacy in visceral artery pseudoaneurysm.

Aims & Methods: We aimed to assess the technical feasibility, safety and effectiveness of direct percutaneous embolization as an alternative treatment option for visceral pseudo aneurysms. We retrospectively evaluated the data of patients who underwent percutaneous embolization at our institution from Feb 2007 to March 2017. All procedures were performed under ultrasound (US) guidance under local anaesthesia. Technical feasibility, safety and efficacy of percutaneous embolization were analysed. At 30 days follow up US with color Doppler/dual phase computed tomography was done to see for recurrence of pseudoaneurysm.

Results: 23 patients (18-male) with mean age of 34.47 ± 21.28 (7–72) years, underwent direct percutaneous embolization for visceral pseudoaneurysm. Most common aetiology for pseudoaneurysm was pancreatitis (16) followed by trauma (3), paracentesis (3) and surgery (1). The site of pseudoaneurysm was splenic artery (13), left gastric artery (3), hepatic artery (3), inferior epigastric artery (3) and gastroduodenal artery (1). Mean size of pseudoaneurysm was 1.8 ± 0.6 (1–3.5) cm. Reasons for choosing percutaneous approach over trans-catheter embolization included- technical difficulties in 11 patients, excess collaterals obstructing view of feeding artery in 5 patients, and recurrence after previous embolization in 6 patients. Agents used for embolization- glue with lipiodol (21), coil (1) and coil with glue (1). Mean procedural time was 11.3 ± 2.11 (8–16) minutes and fluoroscopy exposure time was 2.4 ± 1.34 (1–6) minutes. Percutaneous embolization was successfully performed in all patients (technical success-100%). Mild adverse events included - local site pain in 19 (80%) patients. Moderate adverse event included - splenic infarct in 5 patients, all of which responded to conservative management. There were no major adverse events and no occurrence of distant embolization. At median follow up of 910 days (30–3186) there was no recurrence of pseudoaneurysm (clinical success-100%).

Conclusion: Percutaneous embolization is safe and effective for treatment of visceral artery pseudoaneurysm. Percutaneous technique may be considered as an alternative to trans-catheter embolization in cases of challenging anatomy, multiple collaterals and recurrence after previous embolization precluding trans-catheter advancement.

Introduction: Chronic (CP) and autoimmune pancreatitis (AIP) are characterized by different inflammatory processes. Whether CP is a prerequisite for autoimmunity is still unclear. AIP is considered mostly a T-cell mediated disease; however, in induction of chronic pancreatitis macrophages play a pivotal role. Cyclin dependent kinase (cdk) inhibitors are critical regulators in inflammatory disease as they can influence proliferation, activation and differentiation of inflammatory cells, and apoptosis. In particular, p21 has been described as a mediator of inflammation and various autoimmune diseases by regulating T-cell activation and promoting macrophage development. We therefore examined the role of p21-mediated inflammation in AIP.

Aims & Methods: Human pancreas samples from CP and AIP patients were evaluated for p21 expression. To investigate the effects of p21 in pancreatitis, we intercrossed lymphotoxin overexpressing mice (*Tg(Elal-Lta, b)*) - a model to study CP and AIP - with p21 deficient (*p21*^{-/-}) mice. Infiltrating cells were visualized by immunohistochemistry, supported by gene expression analysis in an early and a progressive phase. Circulating autoantibodies and the presence of tertiary lymphoid organs (TLOs) were analysed to assess autoimmunity.

Results: p21 was upregulated in human CP patients but remained unchanged in AIP patients. p21 deficiency in LT mice (*LTP21*^{-/-}) prevented early pancreatic injury. *LTP21*^{-/-} mice had normal serum amylase, reduced inflammatory gene expression and cell influx. In acinar cells diminished proliferation and abrogated activation of non-canonical NF- κ B pathway was observed. In contrast, 12 months old LT mice with and without p21 had similar inflammatory gene expression and T & B cell infiltration. Interestingly, LT and *LTP21*^{-/-} mice had comparable tertiary lymphoid organs (TLOs), autoantibodies and elevated IgG levels. However, acinar cell proliferation, acinar-to-ductal metaplasia and acinar non-canonical NF- κ B pathway activation remained impaired in *LTP21*^{-/-} pancreata.

Conclusion: Our findings indicate that p21 is crucial for pancreatitis in LT-driven pancreatic injury. p21 is involved in early acinar secretion of inflammatory mediators that attract innate immune cells. However, p21 is not essential for humoral immune response, accountable for autoimmunity and lack of p21 does not rescue AIP development. Remarkably, p21 interferes with acinar NF- κ B signaling and renders acinar cells less susceptible to proliferation and transdifferentiation. We therefore suggest that chronic and autoimmune pancreatitis follow different inflammatory processes.

Introduction: Various forms of pancreatitis (e.g. severe acute pancreatitis, autoimmune pancreatitis type 2) are characterized by an infiltration of neutrophil granulocytes. Yet, despite sharing the feature of granulocytic infiltration, these diseases take opposing natural courses of disease. A novel function of granulocytes, the formation of aggregated neutrophil extracellular traps (aggNETs), has been described and called for a reevaluation of the specific role of neutrophils in pancreatitis. We were interested in the specific function of granulocytes in various models of pancreatic inflammation.

Aims & Methods: Experimental models of pancreatic inflammation were employed including caerulein-induced pancreatitis and a novel model of IL-17A-induced pancreatitis. The outcome of disease was characterized by immunohistochemistry, RNA expression and flow cytometric analyses.

Results: Transgenic systemic delivery of IL-17A alone can induce granulocytosis and neutrophil infiltration to the pancreas. Interestingly, neutrophils do not remain in the interstitium, yet enter the pancreatic ducts and form aggregates in the ductal lumen. Our experimental models further indicate that peptidyl arginine deiminase 4 (PAD4) is critical for intraductal aggregate formation and that PAD4-deficiency abrogates disease progression. Mechanistically, we identify the pancreatic juice as a strong instigator of neutrophil chromatin extrusion. Characteristic single components of pancreatic juice, such as bicarbonate ions and calcium carbonate crystals, induce aggregated NET formation.

Conclusion: Granulocytes aim to contain an inflammatory focus and enter pancreatic ducts with potentially detrimental consequences to dependent areas of the organ.

Introduction: Mitochondrial dysfunction is a hallmark of several disease pathogenesis including acute pancreatitis (AP). Our results suggest that mitochondrial damage is crucial in bile acid induced inhibition of pancreatic ductal HCO₃⁻ secretion, however the details of mitochondrial function and dysfunction in pancreatic ductal epithelial cells (PDEC) is not known yet.

Aims & Methods: The aim of our study was to characterize the mitochondrial distribution and function in PDECs under physiological and pathophysiological conditions. Guinea pig and Cyclophilin D WT and knock out (KO) mouse pancreatic ducts were used. Mitochondrial distribution was studied by electron microscopy (EM). Mitochondrial membrane potential ($\Delta\psi_m$) was measured by confocal microscopy and pancreatic ductal HCO₃⁻ secretion by microfluorometry.

Results: EM measurements revealed that the mitochondrial density is significantly higher on the apical side of the guinea pig PDEC compared to the middle or the basal segment in HEPES solution. The apical mitochondrial density increased further in CO₂/HCO₃⁻ buffered solution, or during the administration of 5 μ M forskolin. That was also confirmed by the $\Delta\psi_m$ measurements as we detected increased TMRM fluorescence on the apical side of the PDEC during stimulation. The genetic KO of cyclophilin D significantly reduced the loss of $\Delta\psi_m$ and protected pancreatic ductal HCO₃⁻ secretion during the administration of 500 μ M chenodeoxycholic acid.

Conclusion: Our results revealed that mitochondrial function has a central role in the function of PDEC presumably by providing ATP for fluid and ion secretion. On the other hand the opening of MPTP seems to be crucial in the bile acid induced toxicity offering a potential therapeutic target in AP.

Introduction: Infectious complications are main causes of mortality in severe acute pancreatitis (AP) (1). Most infections in AP are intestinal origin (2). The Nucleotide oligomerization domain 2 (NOD2) is a NOD-like receptor family member that senses and responds to bacterial wall peptides (3). Guenther et al. reported that p.R702W mutation was found to be associated with multi-organ failure and mortality in patients with AP (4). We aimed to investigate whether there is a correlation between NOD2 variants and AP severity in this study.

Aims & Methods: Group 1 (n=27) was healthy. Group 2 (n=36) and Group 3 (n=32) were composed of mild and severe pancreatitis patients according to the Atlanta 2012 classification (5). Four NOD2 variants and serum interleukin-6 (IL-6), Tumor Necrosis Factor- α (TNF- α) and lipopolysaccharide-binding protein (LBP) levels were studied.

Results: We detected p.R702W variant in 3 patients (3/32, 9.4%) in severe pancreatitis group, but this variant was not seen in the other two groups. 1007fs variant was found in 3, 3 and 1 patient in mild (3/36, 8.3%) and severe pancreatitis (3/32, 9.4%) groups, and in healthy group (1/27, 3.7%), respectively. There was no significant difference in the frequencies of NOD2 variants between groups. Serum IL-6, TNF- α and LBP levels were significantly higher in the severe pancreatitis group than in the healthy group and mild pancreatitis group (all p < 0.001). However, there was no significant difference between these cytokine levels and NOD2 variants.

Conclusion: Our results suggest that there may be a relationship between the presence of p.R702W variant and severe pancreatitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute pancreatitis (AP) has a wide clinical spectrum, ranging from mild cases to patients with high morbidity and a 3-5% mortality. Severity classifications used local and systemic complications to define different subgroups of patients, but it is important to ascertain which of them are independent determinants for the clinical course of the disease.

Aims & Methods: The aim of this study was to analyze which complications were independently associated to worse outcomes (time to oral refeeding, invasive treatment, ICU admission, hospital stay and mortality). Patients with AP were prospectively enrolled at 23 centers, 60% had biliary etiology, 17% necrotizing AP and 14% organ failure. Associations between possible determinants and outcome variables were assessed through binary logistic regression analysis (with adjustment for sex, etiology, Charlson comorbidity score (including age) and recurrent AP in the model).

Results: In total 1665 patients were included. Independent determinants of increased morbidity and mortality (vs category with lower risk) were: persistent organ failure (POF) vs transient organ failure (TOF), all local complications (especially combined peripancreatic and pancreatic necrosis) vs no local complications, infected necrosis vs sterile necrosis and multiple-organ POF vs single-organ POF. We found no independent effect for late (> 7th day) vs early POF nor POF associated to infected necrosis vs sterile POF.

Conclusion: Results of this study demonstrate that major determinants of severity to be included in a future classification of severity of AP are 1) local complications, where necrosis should be further categorized into infected vs sterile and 2) POF/TOF, with POF further categorized into multiple vs single POF.

Contact E-mail Address: inrae0428@yuhs.ac

Introduction: Pancreatic pseudocyst (PC) and walled-off necrosis (WON) are frequent complications of acute pancreatitis. Drainage procedure is required when symptoms and complications such as pain, biliary obstruction, or infection occur. With technological advances, endoscopic ultrasound (EUS)-guided drainage replaced surgical treatment and has become the standard treatment. We developed a novel fully-covered lumen apposing metal stent (LAMS) with anti-reflux valve for the purpose of preventing complications such as stent migration or reflux of bowel contents while improving the stent patency. The aim of this study is to investigate the efficacy and the rate of complications of EUS guided drainage using novel LAMS with anti-reflux valve for PC and WON.

Aims & Methods: We compared the treatment outcomes and the rate of complications of EUS-guided drainage using LAMS with EUS-guided drainage using plastic stents. Ten patients underwent EUS-guided drainage using the novel LAMS (LAMS group) and eighteen patients using conventional plastic stents (plastic stent group) from December 2013 to October 2016. A novel LAMS used in this study was designed to have bilateral flare ends, 4 anti-migration flaps (at each side) and a pair of 2 anti-reflux valves (inside the lumen). Technical success is defined as a successful placement of the stent without immediate complication and clinical success is defined as a resolution of the PC/WON and disappearance of the symptoms.

Results: Among 10 patients treated with LAMS, 4 patients had complicated PC and 6 patients had WON. In plastic stent group, 15 patients had complicated PC and 3 patients had WON. The median size of fluid collection before treatment was 69.5 mm (range, 48-214 mm) in LAMS group and 92.0 mm (56-253 mm) in plastic stent group. Median duration of stent placement was 47 days (1-355 days) in LAMS group and 55 days (1-216 days) in plastic stent group. Treatment outcomes of the LAMS group were not inferior despite the significantly higher proportion of WON patients in the LAMS group compared to the plastic stent group. There were no statistically significant differences in the technical success rate (90% versus 94.4%; p=0.595), clinical success rate (70% vs. 77.8%; p=0.491), resolution rate (76.8% vs. 80.7%; p=0.705), complication rate (40% vs. 50%; p=0.456). In LAMS group, 3 patients experienced mild fever and 1 patient showed peritonitis due to immediate stent migration. In plastic stent group, mild fever was developed in 4 patients, small amount of pneumoperitoneum was in 1 patients, self-migration of stent (after resolution of fluid collection) was in 2 patients. 3 patients showed serious adverse events - 1 patient in each group experienced peritonitis due to immediate stent migration and 1 patient in plastic stent group had active bleeding. Procedure time (30.7 minutes vs. 41.2 minutes; p=0.106) and fasting period after treatment (3.1 days vs. 2.1 days; p=0.344) were also not different between two groups.

Conclusion: For EUS-guided drainage, LAMS showed acceptable treatment outcomes and the rate of complications even in relatively more severe cases of pancreatic fluid collection. And no additional fasting period was required in the LAMS group compared to the plastic stent group. Further well-designed prospective studies are needed to validate these findings.

Introduction: Endoscopic ultrasound-guided transmural drainage (EUS-TD) has been shown to be a safe and effective minimally invasive treatment for walled-off necrosis (WON). However, in some cases, simple drainage is not sufficient to manage the symptoms of WON and step up approach such as direct endoscopic necrosectomy (DEN) and surgical necrosectomy may be required. The factors associated with the outcome of endoscopic treatment for WON remain unclear. **Aims & Methods:** This study aimed to retrospectively correlate the clinical characteristics of WON with the outcome of endoscopic transmural drainage. 49 patients (38 males; mean age 60.79 ± 13.44) with symptomatic WON treated by an attempted EUS-TD initially were enrolled in this study. The relationship between the outcome of treatment and the clinical characteristics including morphological feature and expansion of WON was evaluated.

Results: The mean size of WON was 126.63 ± 46.79 mm. EUS-TD was technically successful in 48/49 (97.9%) patients and 26 (54.2%) improved with EUS-TD alone while step up approach was needed in 19 patients. DEN, percutaneous drainage and surgery were done in 14, 2 and 3 patients, respectively. All patients with step up approach had successful outcomes. Three patients died before step up approach was performed, but death was not related with the procedure itself. The patients who needed step up approach had multi-locular ($p < 0.05$) and large size WON ($p = 0.02$) as compared to patients treated with EUS-TD alone. The extent of WON correlated significantly ($p = 0.001$) with the type of treatment. Gas bubbles sign within necrotic tissue on the abdominal CT imaging early after EUS-TD indicated the necessity of necrosectomy during the treatment ($p < 0.01$). Bleeding as adverse events was observed in 3 patients (6.2%). Two patients improved with conservative therapy and 1 patient underwent transcatheter arterial embolization.

Conclusion: The step up approach is safe and effective for the treatment of WON. Multi-locular, large size and extensive WON were important predictors for performing a step up approach. Gas bubbles sign within necrotic tissue after EUS-TD may help to perform necrosectomy.

Introduction: Patients with a first episode of acute pancreatitis can develop recurrent or chronic pancreatitis (CP). However, little is known about the incidence or risk factors for these events.

Aims & Methods: We performed a retrospective study of 489 patients with a first episode of acute pancreatitis from September 2012 - September 2015. We collected relevant information of disease course and follow up until June 2016. We classified these patients according to etiology, explore the relevant characteristics of recurrence episode and performed univariate and multivariate regression of possible risk factors.

Results: During a median follow-up of 30.4 months, 411 cases were followed up completely. The total recurrence rate was 27.5% (113/411), with a median recurrence interval of 6.5 (IQR 2.61–10.33) months. The recurrence rate and median recurrence interval of biliary group, hyperlipidemic group and other etiology group were 21.5% (57/265), 5.78 (IQR 2.52–9.92); 49.2% (30/61), 8.28 (IQR 5.35–16.30); 30.6% (26/85), 6.18 (IQR 2.60–9.07). To biliary AP, the recurrence rate of patients who underwent cholecystectomy less than two weeks after AP attack is lower than patients without cholecystectomy, and the difference was statistically significant. Logistic regression suggested that hyperlipidemic pancreatitis (OR = 2.133; 95% CI, 1.117–4.075; $P < 0.001$), pancreatic necrosis (OR = 2.52; 95% CI, 1.251–5.078; $P = 0.01$), smoking (OR = 2.918; 95% CI, 1.728–4.928; $P = 0.01$), complicated with diabetes (OR = 2.190; 95% CI, 1.282–3.741; $P = 0.04$) were independent risk factors for recurrence.

Conclusion: Quitting smoking, properly treating diabetes, hypertriglyceridemia and biliary disease, making close follow-up of patients complicated with pancreatic necrosis may reduce ARP attack.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: SChuklin@bigmir.net

Introduction: Clinical data has indicated that severe acute pancreatitis is a serious inflammatory disease with a systemic inflammatory response and multiple organ dysfunction. Acute renal injury caused by acute pancreatitis is a common complication that is associated with a high rate of mortality. Although the pathogenesis of acute necrotizing is not completely clear, the activation of inflammatory cytokines and coagulation are keys in the etiology.

Aims & Methods: We examined 155 patients with acute necrotizing pancreatitis. According to the international classification in 98 patients we diagnosed the moderate severe AP, and in 57 patients the severe AP. Disorders of kidney function were in 48 patients. We determined the creatinine level, indicators of hemostasis and inflammation.

Results: Analysis of the relationship of inflammation and hemostasis in patients with acute pancreatitis and renal dysfunction is accompanied by decreased of activated partial thrombin time ($F = 25.227$, $p < 0.00001$), increased of thrombin time ($F = 19.428$, $p = 0.00004$), fibrinogen concentration ($F = 4.6046$, $p = 0.03568$), D-dimers level ($F = 28.456$, $p < 0.00001$), and level of soluble fibrin-monomer complexes ($F = 34.015$, $p < 0.00001$), lack of activity of antithrombin III ($F = 42.123$, $p < 0.00001$), increased synthesis of C-reactive protein ($F = 15.591$, $p = 0.00020$), excessive production of proinflammatory cytokines IL-2 ($F = 29.997$, $p < 0.00001$), IL-6 ($F = 21.076$, $p = 0.00002$), and TNF- α ($F = 25.643$, $p < 0.00001$). In acute pancreatitis patients with renal dysfunction was shown a direct correlation between severity of renal failure (SOFA score) and concentrations of IL-6 ($R = 0.416484$, $p = 0.000504$), CRP ($R = 0.510742$, $p = 0.000012$), D-dimers ($R = 0.321619$, $p = 0.008456$), soluble fibrin-monomer complexes ($R = 0.290750$, $p = 0.017868$), and duration of thrombin time ($R = 0.296007$, $p = 0.015814$).

Conclusion: The mechanism of the acute renal injury following acute necrotizing pancreatitis is complicated. The inflammatory cascades and hypercoagulable state are initiated this pathological process.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0762 A NEW IL13/IFN γ RATIO PREDICTS SEVERITY IN ACUTE PANCREATITIS

Introduction: Acute Pancreatitis (AP) may be severe in up to 20% of patients with substantial morbidity and mortality, which is related to a generalized inflammatory response. In some individuals, this severe inflammatory response is down-regulated; in others it escapes control. Our group has previously described a TH1 profile associated with poor prognosis in AP, and a TH2 profile associated with a mild or moderate condition.

Aims & Methods: Our aim was the development of an index for an early assessment of prognosis in AP. We analyzed 12 cytokines in 117 patients, upon

admission to hospital. A receiver operating characteristic (ROC) analysis was built at day 0 for the prediction of severity. Later, a multiple discriminant analysis was performed, using the Wilks lambda test, to identify the variables that differ most between patients with mild AP and moderate/severe AP. A ratio calculated using the most discriminant cytokines was studied in relation to severity and mortality.

Results: ROC curves showed that TH1 cytokines IL6, IFN- γ and TNF- α can be measured for the prediction of severe AP, while TH2 cytokines IL4, L13, GM-CSF, for the prediction of a mild or moderate condition. A stepwise analysis showed that IL13 and IFN- γ were the biomarkers which contributed most to the discrimination between mild and moderate/severe AP (Wilks' lambda = 0.855, $p < 0.0001$; Wilks' lambda = 0.747, $p < 0.0001$, respectively). We calculated the IL13/IFN γ index. This ratio was significantly higher in patients with mild AP when we compared between groups ($p = 7.36 \times 10^{-8}$). This difference was also observed between severe AP and the rest of patients ($p = 0.007$). The ROC curve was also modified, increasing the area under the curve (AUC), the sensibility and the specificity, in relation to AP severity.

Conclusion: We describe an IL13/IFN γ ratio that could be of great interest in the assessment of prognosis in AP. A high value of the IL13/IFN γ ratio at hospital admission is associated with a good prognosis of AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0763 CORRELATION BETWEEN POST-ERCP SERUM AMYLASE LEVELS AND CT FINDINGS IN ERCP-INDUCED PANCREATITIS: A PROSPECTIVE MULTICENTER OBSERVATIONAL STUDY

Introduction: According to the diagnostic criteria by Cotton et al.^[1], post-ERCP acute pancreatitis is defined as the persistence of serum amylase levels three times or higher than the upper limit of the standard for 18 ± 6 h after ERCP with persistent upper abdominal pain for 4 h or longer. However, the criterion of three times or higher than the upper limit was mostly based on retrospective studies, and has not been necessarily supported by imaging diagnosis. In this study, using CT findings as the gold standard of ERCP-induced pancreatitis, we investigated the cutoff serum amylase level that suggested ERCP-induced pancreatitis in a prospective multicenter study.

Aims & Methods: At five high-volume centers, 2078 patients examined by ERCP between April 2015 and May 2016 were prospectively followed. CT was performed in patients whose serum amylase level exceeded the institutional upper limit on the day after ERCP (after 12–20 h) to investigate the presence or absence of pancreatitis findings. Two expert radiological diagnosticians assessed the images blinded and judged the presence or absence of pancreatitis based on the Balthazar grade. Patients with a preexisting high amylase level, clinically diagnosed pancreatitis, and had a difficult imaging evaluation due to the presence of cancer before ERCP were excluded from analysis. Correlations of the serum amylase level after 2 h, that on the following day, abdominal pain under 4 h, and that persisting longer than 4 h with the presence or absence of pancreatitis were investigated using ROC analysis and the chi-square test.

Results: Amylase levels increased on the following day in 402 (21.5%) of the 1868 patients included, and 340 patients examined by CT were included in the analysis. ERCP-induced pancreatitis was diagnosed based on imaging in 204 patients (10.9%). The cutoff amylase level for judging the presence or absence of pancreatitis on the following day was 2.75 times higher than the institutional upper limit (sensitivity: 73.3%, specificity: 79.0%, positive likelihood ratio: 3.48, negative likelihood ratio: 0.34) with an AUC of 0.80. The cutoff level after 2 h was 2.73 times higher than the institutional upper limit (sensitivity: 45.6%, specificity: 79.7%, positive likelihood ratio: 2.24, negative likelihood ratio: 0.68) with an AUC of 0.63. Abdominal pain under 4 h was noted in 36 of the 204 patients in the pancreatitis group, and 12 of 136 patients in the non-pancreatitis group with a sensitivity of 17.7%; specificity, 91.1%; positive likelihood ratio, 1.99; and negative likelihood ratio, 0.90. Abdominal pain that persisted longer than 4 h occurred in 75 patients in the pancreatitis group and 12 in the non-pancreatitis group with a sensitivity of 36.7%; specificity, 91.1%; positive likelihood ratio, 4.12; and negative likelihood ratio, 0.69.

Conclusion: The appropriate cutoff serum amylase level for judging ERCP-induced pancreatitis on the day following ERCP is 2.75 times higher than the institutional upper limit. The diagnostic value of serum amylase levels 2 h after ERCP may be low. Regarding abdominal pain persisting for longer than 4 h, the specificity was high but the sensitivity was low. Therefore, setting a cutoff serum amylase level on the day after ERCP is very useful to diagnose ERCP-induced pancreatitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0764 CLINICAL EFFICIACY AND SAFETY OF EUS-GUIDED LUMEN-APPPOSING METAL STENT ASSISTED PANCREATIC WALL-OFF NECROSIS DRAINAGE: A REAL-LIFE EXPERIENCE IN A TERTIARY HOSPITAL

S.T. Law¹, C. De La Serna Higuera², M. Perez-Miranda², P. Gil²

²Gastroenterology And Hepatology, Rio Hortega, Valladolid/Spain

Contact E-mail Address: stl168@hotmail.com

Introduction: Recently, lumen apposing metal stent (LAMS) has been developed and employed in abscess drainage. However, its use is limited by its cost [1] and its safety rises concerns as apparently associated with more adverse events.[2] The aim of this study was to investigate the efficacy and safety of LAMS in endoscopic ultrasound (EUS)-guided pancreatic wall-off necrosis (WON) drainage.

Aims & Methods: *Patients* All consecutive patients with necrotizing pancreatitis with WON who underwent EUS-guided drainage using LAMS during the period of 1st Jan 2012 and 30th Jun 2016 were retrospectively retrieved from the institution database. Necrotizing pancreatitis and WON were defined as according to the revised 2012 Atlanta classification. Those encapsulated fluid collection outside the pancreas were excluded from this study. The following data were collected: patient demographics, EUS and microbiologic features of the necrosis, procedural characteristics and their outcomes. *Procedures* All procedures were performed by 2 endosonographers. Once the WON was identified, a 19-gauge needle was inserted with 0.035-inch guidewire to allow for insertion of the AXIOS device, which was then advanced to create the fistula tract by using the electrocautery tip. Once the delivery catheter was inside the WON, the distal and proximal flange of the stent were deployed subsequently under EUS and endoscopic guidance respectively. *Outcome measures* Primary outcome measures were: 1.technical success defined as stent deployment without any difficulty nor reposition; 2.clinical success defined as symptom resolution with the abscess size ≤ 2 cm on computed tomography (CT); Secondary measures are: 1. Stent revision due to its migration/dislodgment in case of unresolved abscess; 2.adverse events; 3.WON recurrence Data analysis Continuous variables were expressed as median and IQR. Categorical data were expressed as absolute numbers and percentages.

Results: The clinical characteristics of the patients and their WONs are shown in Table 1. In the cohort, the deployment of LAMS (AXIOS: 15×10 mm, $n = 38$; 10×10 mm, $n = 8$) was technically success in 45 (97.8%, 3 cases required 2nd attempt for proper deployment) cases while one case required to switch over to a fully-covered metal stent due to the lengthy insertion tract. 28(60.9%) cases were managed with necrosectomy (median 1, IQR 2) in which 15(32.6%) of them had concurrent nasocystic drainage prior to each procedure. 43(93.5%) patients were treated successfully while two refractory cases required superimposed insertion of a fully-covered tubular metal stent coaxially and one case required to switch over to percutaneously drainage. 20(43.5%) cases reported to have adverse events. Six patients experienced immediate bleeding during insertion of LAMS in which two related to process of necrosectomy; among them, one case required the superimposed insertion of a tubular fully covered metal stent coaxially to control the bleeding while the other five had bleeding stopped spontaneously. Delayed bleeding was reported in 4 cases:three were managed by local administration of adrenalin, one managed by arterial embolisation to the bleeding site and one with uncontrolled bleeding due to disseminated intravascular coagulopathy and then died of multiple organ failure. Ten cases were reported to have stent migration during management in which two cases were dislodged during necrosectomy while the others were found during follow-up.

Introduction: Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) is a common and serious adverse event following ERCP, with a reported incidence of 9.7% in unselected patients [1]. Given huge economic and clinical burden, effective approaches for post-ERCP pancreatitis prophylaxis remains a major priority for research. Nonsteroidal anti-inflammatory drugs (NSAIDs) have also been shown the potential efficacy in prophylaxis PEP across high-risk patients, especially for diclofenac or indomethacin [3–5]. Recently, a prospective, double-blind, controlled trial conducted by Levenick [6] and colleagues in the USA showed that the reduction in PEP using indomethacin was not as significant as previously reported. In fact, even more cases of pancreatitis occurred in indomethacin group compared with placebo group. Subsequently, a high-quality meta-analysis also concluded that there is no prophylaxis for the prevention of PEP among average-risk patients[7]. These findings raised the question that whether administration of rectal indomethacin should be recommended in average-risk patients.

Aims & Methods: We aimed to determine the beneficial effect of rectal indomethacin in the prevention of post-ERCP pancreatitis in average-risk of patients. We systematically searched PubMed, EMBASE, Web of science and Cochrane library before October 2016. Studies that evaluated rectal administration of indomethacin in the prevention of post-ERCP pancreatitis were included in the analysis. We adopted a random-effects model to calculate overall relative risk (RR) and 95% confidence interval (CI).

Results: We identified ten randomized clinical trials from initial search and finally included in the meta-analysis. Administration of rectal indomethacin significantly reduced the incidence of PEP in combined population (RR, 0.63; 95% CI, 0.50–0.77). There was no significant heterogeneity across included studies ($I^2 = 14.2\%$, $P = 0.31$). In subgroup analysis, rectal indomethacin was effective in both high-risk (RR, 0.49; 95%CI, 0.35–0.71) and average-risk (RR, 0.69; 95%CI, 0.55–0.86) patients and reduced the risk of mild and moderate to severe pancreatitis. The overall results remained unchanged and robust in sensitivity analyses. There was no evidence of significant publication bias among this meta-analysis.

Conclusion: Rectal administration of indomethacin is an effective approach to prevent the incidence of post-ERCP pancreatitis both in high-risk and average-risk population undergoing ERCP. However, more high-quality randomized controlled trials are needed to further investigate the optimal timing for administration of indomethacin.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute pancreatitis (AP) is one of the most common gastrointestinal diseases requiring hospitalization with an annual incidence of 13–50 cases per 100,000 persons. It is a potentially fatal disease with an overall mortality ranging from 2 to 8%. Both epidemiology and outcomes are variable according to the different countries. Furthermore, few studies have considered the impact of hospital units on AP outcomes.

Aims & Methods: To evaluate both the trend and outcomes of acute pancreatitis according to the admitting hospital units: Surgery, Internal/General Medicine, Gastrointestinal (GI) Unit, Intensive Care Unit (ICU). This is a retrospective

cohort study based on the anonymous computerized database of hospital discharges in the Veneto Region (North-East of Italy). The principal diagnosis of AP according to the International Classification of Diseases 9th revision, Clinical Modification (ICD 9-CM, code 577.0) of the hospital discharges was selected. The period from January 2001 to December 2015 was analysed. Veneto population was considered as the reference population (in the period, it varied from 4,529,823 to 4,927,527 inhabitants, with 51% females). Hospitalization, Length of stay (LOS), in-hospital mortality, need for surgery (according to the DRG 191-194, 199-201 which identified bilio-pancreatic surgery) were reported according to the admitting hospital Units. Statistics: Chi squared for trend and Odds Ratio (OR) were applied.

Results: During the analysed period, 23,389 overall hospitalizations for AP, annual hospitalizations of 32 patients/100,000 inhabitants and in-hospital mortality of 3.2% were observed. Characteristics of the patients were: mean age: 62.2 \pm 19.3ys, 54% Males (M); Female (F) mean age: 65ys \pm 19.3ys, male mean age: 59.4 \pm 19.3ys ($p < 0.05$). Hospitalizations was higher in males (M: 35.4, F: 28.4, OR 1.24 (95% CI: 1.20-1.27, $p < 0.05$) and it increased in a stepwise progression from youngest to oldest patients (from 4.4 to 151.2 $p < 0.05$); a similar trend was observed when considering in-hospital mortality (from 0.5 to 10.3%, $p < 0.05$). From 2001 to 2015, hospitalization (32.4 to 29.5, $p = 0.04$), in-hospital mortality (1.41 to 0.79, $p < 0.05$) and need for surgery (NFS: 5.6% to 3.0%, $p < 0.05$) trends decreased. Conversely, admission trends increased during the analysed period both in General Medicine (from 34 to 63, $p < 0.05$) and Gastrointestinal (GI) units (from 14 to 29, $p < 0.05$). The Overall in-hospital mortality was the lowest in GI Units with a NFS of 3.6% (see Table). In comparison to General Medicine Units, GI units were associated with a low in-hospital mortality (OR: 0.37, CI 95%: 0.28-0.49, $p < 0.05$) and an high NFS (OR: 2.88, CI 95%: 2.18-3.81, $p < 0.05$).

Admitting Hospital Unit (2001-2015)	Number of cases (%)	Lengths of stay (days)	In-Hosp. Mortality	NFS (%)
General Medicine (Non GI)	6,960 (30%)	13.5 \pm 10.7	4.3%	88 (1.3%)
Gastrointestinal (GI) Units	3,797 (16%)	12 \pm 11.2	1.7%	135 (3.6%)
Surgical Units	12,112 (52%)	13 \pm 13.6	2.7%	443 (3.7%)
Intensive Care Unit	520 (2%)	17.2 \pm 21.8	12.9%	42 (8.1%)

Conclusion: During the last 15 years in the Veneto Region, hospitalization rate, in-hospital mortality rate and need for surgery of acute pancreatitis significantly decreased. Conversely, admissions in both General Medicine and GI units increased. Management of AP in GI units seems to be related with a best outcome: lower in-hospital mortality and probably, more eligible patients for surgical treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0767 COMPARISON OF CLINICAL COURSE AND OUTCOME OF ACUTE PANCREATITIS, RECURRENT ACUTE PANCREATITIS, ACUTE ON CHRONIC PANCREATITIS

N. Berry, D. Sharma, J. Samanta, N. Dhaka, S. K. Sinha, R. Kochhar, R. Prasada, V. Gupta, T. Yadav
Gastroenterology, Postgraduate Institute of Medical Education and Research, Chandigarh/India

Contact E-mail Address: dibya.sharma@yahoo.com

Introduction: Recurrent acute pancreatitis (RAP) and acute on chronic pancreatitis (ACP) are likely to have less severe disease and local complications in comparison to acute pancreatitis (AP) possibly due to underlying chronic changes or fibrosis. However there is lack of literature regarding comparative studies between the natural course of disease and outcome of patients of AP vis-à-vis that of RAP and ACP.

Aims & Methods: This study was conducted to compare the clinical course and outcomes of patients with AP, RAP and ACP. 248 consecutive patients with diagnosis of AP, RAP or ACP were included during study period. Outcome measures studied were severity, organ failure (OF), persistent organ failure (POF), need for ICU stay, ventilator and dialysis, hospital stay, need for percutaneous catheter drain (PCD), surgery and mortality.

Results: Out of 248,158 (64%) patients had AP, 45 (18%) patients had RAP and 45 (18%) patients had ACP. 86 (54%) of AP, 4 (9%) of ACP and none of patients in RAP group had severe AP according to revised Atlanta classification ($p < 0.001$). On comparison of OF, 101 (63%; of whom 54% had POF) of AP, 6 (13%; of whom 9% had POF) of ACP and none of RAP patients developed OF ($p < 0.001$). PCD and surgery requirement were seen in 89 (56%) & 9 (6%) of

AP, 5 (11%) & 4 (9%) of ACP and none of RAP patients respectively ($p < 0.001$ & $p = 0.44$). Length of hospital stay (days) was significantly higher in AP and ACP as compared to RAP (18.80 \pm 14.5, 8.82 \pm 11.2, 3.36 \pm 4.4, $P < 0.001$) whereas ICU requirement was seen in significantly more patients in AP group (59; 37%) than in ACP (5; 11%) and RAP (0; 0%) ($p < 0.001$). 41 (26%) of AP, 2 (4.4%) of ACP, but none of patient with RAP needed ventilatory support ($p < 0.001$), while 13 (8%) of AP patients, 1 (2.2%) of ACP and none with RAP required dialysis ($p < 0.05$). Mortality in AP, ACP and RAP was 29 (18%), 2 (4.4%), 0 (0%) respectively ($p < 0.05$).

Conclusion: Patients with first attack of AP had more severe disease course as compared to those with ACP, while those with RAP had the least severe course.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0768 ACUTE PANCREATITIS IN PATIENTS WITH IPMNS: RETROSPECTIVE STUDY OF 346 PATIENTS OBSERVED FROM 2009 TO 2016

L. Brozzi¹, A. Amodio¹, F. De Marchi¹, R. Teresa Marzia¹, I. Breoni¹, P. Campagnola², S.F. Crinó¹, A. Gabbriellini³, L. Frulloni¹

Contact E-mail Address: lorenzo.brozzi89@gmail.com

Introduction: In literature the frequency of acute pancreatitis (AP) in patients with IPMNs varies between 12 and 65%, but most of studies are from surgical series and often pancreatitis occurred after surgery was included. Furthermore, most of the studies includes in the dictio of "symptomatic IPMNs" the presence of less severe disorders, such dyspeptic symptoms, making series unclear.

Aims & Methods: The aim of this study was to investigate the correlation between the presence of IPMN and acute pancreatitis to determine the frequency, evaluate the different characteristics from asymptomatic IPMNs patients, evaluate the possible differences between type and localization of IPMNs in occurrence of acute pancreatitis and his disease severity. A retrospective analysis was performed on all observed patients with IPMN-MD, IPMN-BD and mixed type at Gastroenterology Unit in the period between January 2009 and March 2016. In the study patients with an instrumental or histological diagnosis of IPMNs were included.

Results: We studied 346 patients (164 males and 182 females, mean age at the first report 61.6 \pm 12.2 years). At the time of radiological diagnosis, 45% were asymptomatic, 51% had had symptoms, while 4% of the data were missing: the frequency of AP (excluding biliary etiology) of all 346 patients with IPMN was 26%. AP was edematous in 85% of patients and necrotic in 15%. We found increased frequency in patients with PA with IPMN of the main pancreatic duct (MD and mixed), and unifocal type. The localization to the body seems to be more correlated with the presence of AP. The number of cysts (for IPMN-BD and mixed type) was significantly lower in patients who have had AP.

Conclusion: Our medical extraction series confirms that the PA is an event that occurs in 26% of patients with IPMNs, with a prevalence of the male sex, it is associated with a IPMN central and mixed type, predominantly localized to the body. The pancreatitis is not associated with malignancy in resected patients

P0769 APOLIPOPROTEIN B AND A-I RATIO PREDICTS SEVERE ACUTE PANCREATITIS

J. Kim, K.J. Lee

Internal Medicine, Yonsei University Wonju College of Medicine Dept. of Internal Medicine, Wonju/Korea, Republic of

Contact E-mail Address: jawkim96@yonsei.ac.kr

Introduction: Severe acute pancreatitis (SAP) has a considerable mortality and morbidity rate. Although many indices have been developed to classify the severity of acute pancreatitis (AP), there is no ideal method for predicting SAP. The ratio of apolipoprotein B to A-I (apoB/A-I) is associated with metabolic syndrome and inflammatory status.

Aims & Methods: This study aimed to investigate the association between severity of AP and serum apoB/A-I ratio. Patients with AP were prospectively enrolled at Yonsei University Wonju College of Medicine from March 2015 to August 2016. The severity of acute pancreatitis was assessed according to the revised Atlanta classification criteria (Atlanta 2012).

Results: Of 191 patients with AP, 134 (70.2%) were classified as mild AP, 42 (22%) as moderately severe AP, and 15 (7.9%) as SAP. The apoB/A-I ratio was highest in patients with SAP compared with those with mild and moderately severe AP ($P = 0.001$). The apoB/A-I ratio positively correlated with Atlanta classification, computed tomography severity index, and Bedside index for severity of AP. The apoB/A-I ratio showed the highest ability to predict SAP in patients with AP compared with apolipoprotein B or apolipoprotein A-I alone.

Conclusion: Serum apoB/A-I ratio appears to have value in predicting SAP in patients with AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The Scandinavian-Baltic-Pancreatic-Club database collects data from patients with chronic pancreatitis (CP) in Nordic countries. Grading of structural changes is important in the description of a CP cohort.

Aims & Methods: We aimed to characterise structural changes of the pancreas in patients with CP. Subjects with definitive or probable CP according to the M-ANNHEIM diagnostic-criteria were included. Structural changes were graded according to the M-ANNHEIM-classification. A subgroup was also scored by the modified Cambridge score. Clinical data on disease-duration, nutrition, exocrine function, pain, alcohol/smoking habits and frequencies of malnutrition and diabetes were collected. A grouping of the M-ANNHEIM score (A: Normal = 0, B: Minimal change = 1 + 2 and C: Moderate/Marked = 3 + 4) was performed for correlation to the clinical data.

Results: The database contains 932 patients (623 men). The M-ANNHEIM-score was present from 446 subjects and both imaging scores from 93 subjects. According to M-ANNHEIM subjects were graded as 0: Normal (8.1%), 1: Equivocal (22.9%), 2: Mild (12.1%), 3: Moderate (17.9%) and 4: Marked (39.0%). Correlation of the imaging scores: The imaging-scores demonstrated acceptable correlation ($\rho = 0.75$, $p < 0.001$) and good agreement (ICC = 0.71 (0.59, 0.8), $p < 0.001$). Agreement was best for groups with marked changes. The clinical parameters divided by M-ANNHEIM groups are presented in the table:

Clinical parameter	A: Normal	B: Minimal change	C: Marked
Disease duration (Years)	3.6(5.2)	4.6(5.8)	5.0(6.4)
Pain (VAS 0–100)	38.3 (39.2)	39.4 (36.5)	35.5 (35.3)
Nutrition (BMI kg/m ²)	24.2(5.0)	24.7(5.5)	23.7(4.7)
Malnutrition (%)	4	10	11
Faecal Elastase (µg/g)	35[17–168]	69[15–304]	45[15–142]
Diabetes (%)	37	43	39
Smoke (Pack years)	0[0–20]	0[0–25]	17[0–37]*
Alcohol (Lifetime years > 5units/day)	0[0–2.5]	0[0–18]	0[0–18]

* $p < 0.05$ (Kruskal-Wallis). No other differences reached significance. Values: mean (SD) or median [IQ-range]. Malnutrition: BMI < 18.5.

Conclusion: Subjects with marked structural changes had the highest lifetime smoke-doses. There was poor correlation of structural changes to the clinical features. The two imaging scores demonstrated acceptable correlation and agreement. Poor agreement in normal/minimal-change groups may reduce the value of the scores where they are most needed. The results are presented on behalf of the SBPC study group

Disclosure of Interest: All authors have declared no conflicts of interest.

P0771 OSTEOPATHY IS COMMON IN PATIENTS WITH CHRONIC PANCREATITIS, BUT IS NOT RELATED WITH VITAMIN D AND FECAL ELASTASE LEVELS (P-BONE STUDY)

S. Stigliano¹, A. Waldthaler², E. Martínez-Moneo³, S. Robinson⁴, M. Malvik⁵, A. Hedström⁶, A. Kaczka⁷, M. Scholde⁸, G. Delle Fave¹, P. Simon⁸, G. Capurso¹

Introduction: In patients with chronic pancreatitis (CP) malabsorption of vitamins D and K, alcoholism, smoking and inflammatory status contribute to low bone mineral density (BMD). A recent meta-analysis estimated the prevalence of osteoporosis (25%) and osteopenia (40%) in CP and highlighted limitations of the reviewed studies.

Aims & Methods: To evaluate the prevalence of osteoporosis and osteopenia in patients with CP and to investigate the correlation between BMD and CP features, and vitamin D and PEI. This is a multicentre cross-sectional study (P-BONE, a Pancreas 2000 project) on prevalent CP patients. The Diagnosis and severity of the disease was defined according to the M-ANNHEIM classification. Clinical information and biochemical variables were recorded; PEI was assessed by fecal elastase. Standardized Osteodensitometry was performed by dual energy x-ray absorptiometry (DEXA). Categorical variables were analysed by means of Fisher's exact test, and continuous variables by t-test. A logistic regression analysis was performed to identify risk factors for osteoporosis or osteopenia. The relationship between continuous variables was assessed with Pearson correlation coefficient.

Results: 211 consecutive CP patients were enrolled at 6 Centres (67% M; mean age 60 ± 13 years). Osteopenia was diagnosed in 42% and osteoporosis in 22% of cases. Aetiology was alcoholic in 43%, and 18% had severe CP. 56% of patients had PEI. The mean value of vitamin D was 20 ng/ml and 56% of cases had vitamin D insufficiency. There was no correlation between vitamin D levels, or elastase levels and t-score at either spine or femur. Alcoholic aetiology was associated with higher risk of having low levels of fecal elastase ($p = 0.02$) and with lower level of vitamin D ($p = 0.001$) but not with osteopenia or osteoporosis. Female sex and older age seems to be associated with a higher risk of developing osteoporosis (OR 4.5 95%CI 2–9.8 $p = 0.001$; OR 1.09 95% CI 1–1.3 $p = 0.01$) while a higher BMI is associated with a reduced risk of its occurrence (OR 0.8 95% CI 0.77–0.94 $p = 0.001$).

Conclusion: The present data confirm a high rate of osteopathy in CP patients. However, there was apparently no correlation between BMD, pancreatic exocrine function, severity of the disease or vitamin D levels. Other factors, such as vitamin K might deserve investigation for their possible relationship with bone mineral density in CP patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0772 NATURAL HISTORY OF PANCREATITIS ASSOCIATED WITH SPINK1 MUTATIONS

N. Muller¹, O. Hentic¹, F. Maire¹, P. Ruszniewski¹, P. Lévy², V. Rebours²

¹Beaujon Hospital, Clichy/France

²Service De Gastroenterologie-pancreatologie, Université Denis Diderot Hopital Beaujon, Service de Pancreatologie, Clichy Cedex/France

Contact E-mail Address: nelly.muller@aphp.fr

Introduction: SPINK1 is a gene coding for the inhibitor of the cationic trypsinogen. Heterozygous mutations prevalence is estimated at 2%. They are recognized as a risk factor for chronic pancreatitis. However few data are available regarding the natural history and the risk of complications in these patients.

Aims & Methods: A prospective monocentric study was carried out from 2000 to 2016 to describe the natural history of SPINK1 mutation related pancreatitis All patients referred for idiopathic acute and/or chronic pancreatitis with a SPINK1 mutation, were included and followed annually. Epidemiological, genetic, clinical and morphological data were collected.

Results: We included 158 patients. Mutations of SPINK1 were: heterozygous (65%), homozygous (8%) N34S, others (27%). Median age at first symptoms and diagnosis was 20 [2–73] and 29 years [3–76]. During follow-up (median length: 7.45 years), clinical manifestations were pancreatic pain (73%), pseudocyst (15%), acute pancreatitis (77%), cholestasis (6%), exocrine pancreatic insufficiency (EPI) (33%), diabetes (15%) and pancreatic adenocarcinoma ($n = 6.4\%$). Calcifications and ductal abnormalities were found in 56% and 62%. Endoscopic treatment and surgery were performed for 16% and 14% of the patients. Four patients died including 3 due to pancreatic cancer. The risk of pancreatic cancer at 55, 60, 70 and 75 years was 9.4%, 14.7%, 28.9% and 46.7%. Risk factors of cancer were calcifications ($p = 0.03$) and EPI ($p = 0.04$).

Conclusion: SPINK1 mutations should be searched for in young patients with idiopathic pancreatitis. Risk of pancreatic cancer is probably underestimated.

Cancer screening should be discussed especially in case of pancreatitis with calcifications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0773 EXOCRINE FUNCTION, NUTRITION AND ENZYME TREATMENT IN THE SCANDINAVIAN BALTIC PANCREAS CLUB DATABASE - PRELIMINARY DATA

Introduction: The Scandinavian-Baltic-Pancreatic-club database collects patients with chronic pancreatitis (CP) from Nordic countries. Description of exocrine pancreatic insufficiency (EPI) and consequences is important in characterization of CP cohorts.

Aims & Methods: Characterise EPI from CP in a Northern European cohort. Patients with definitive or probable CP (M-ANNHEIM diagnostic criteria) were included from nine centres. Demographic data, body-mass index (BMI), faecal elastase (FE), enzyme-doses and lab-parameters were collected. Values: Mean (SD) unless otherwise stated. EPI-classification grouped patients as follows: A: Normal, B-Mild: EPI not requiring enzymes, C-Proven: EPI requiring enzymes. **Results:** Included patients: 932 (623 men: 309 women). Missing EPI-classification: 46 patients. Included patients: 932 (623 men: 309 women). Missing EPI-classification: 46 patients.

Clinical parameter	(A) Normal	(B) Mild insufficiency	(C) Proven insufficiency
Exocrine pancreatic function (%)	33	16	51
Faecal Elastase (µg/g) (mean (SD)) p < 0.001	368 (161)	128 (144)	51 (69)
Nutrition: BMI (kg/m ²) (mean (SD)) p < 0.005	24.6(4.9)	23.7(4.3)	22.6(4.3)
Frequency BMI < 18.5 (%) p < 0.005	5		16
Vitamin D: Frequency < 25nmol/L (%) (I vs II) p < 0.005	7.4	23.7	17.6
Enzyme Treatment (lipase-units/day) (median [IQR range])*	0[0–75000]		120000 [75000–150000]
Hemoglobin: (median [IQR range] p < 0.05	11.8(2.7–3.0)		10.7(2.8)
Faecal Elastase and disease duration (years)**	<10: 143(175)		> 10: 91(118)

*p < 0.001. 9% received < 50000 lipase-units/day. 14 subjects having FE > 200 received enzymes, 48 subjects with FE < 100 received no enzymes.

**no age/sex differences in EPF

Conclusion: In our material frequency of EPI is higher than reported in the NAPS2 study (31%). Consequences of EPI were lower BMI, more frequent underweight, higher enzyme-doses and lower haemoglobin. Need for vitamin D supplements was highest in the group with mild EPI not receiving enzymes. Exocrine function was correlated with disease duration, but neither with age nor gender.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0774 FLUID AND HCO₃⁻ SECRETION AND CFTR ACTIVITY IS INHIBITED BY CIGARETTE SMOKE EXTRACT IN GUINEA PIG PANCREATIC DUCTAL CELLS

Introduction: Smoking represents an independent risk factor for the development of chronic pancreatitis (CP). It is well documented that secretion of pancreatic

ductal alkaline fluid (which is regulated mostly by the anion exchanger and CFTR) is diminished in CP.

Aims & Methods: In this study we would like to understand whether smoking has any effects on pancreatic ductal fluid and HCO₃⁻ secretion. Guinea pigs were exposed to cigarette smoke four times a day for 30 min for 6 weeks. The CFTR expression was analysed by immunohistochemistry. Pancreatic ducts were isolated from guinea pig pancreas. Cigarette smoke extract (CSE) was prepared by smoking of 15 cigarettes into 10 ml distilled water by a smoking machine. Intracellular Ca²⁺ concentration and pH were evaluated by microfluorimetry. Fluid secretion was measured by video microscopy. CFTR currents were detected by whole cell configuration of patch clamp technique.

Results: Cigarette smoking significantly diminished the expression of CFTR and the fluid and HCO₃⁻ secretion in guinea pig pancreas. CSE dose dependently decreased fluid and HCO₃⁻ secretion in guinea pig pancreatic ducts via inhibition of anion exchanger, Na⁺/H⁺ exchanger and Na⁺/HCO₃⁻ cotransporter and also forskolin-stimulated Cl⁻ current of CFTR Cl⁻ channel. CSE incubation altered the pattern of carbachol-induced Ca²⁺ signal in pancreatic ducts suggesting that some of the inhibitory effects may be regulated by calcium signalling.

Conclusion: Cigarette smoking and CSE inhibits pancreatic ductal fluid and HCO₃⁻ secretion and the activity of the CFTR which may play role in the smoke-induced pancreatic damage. This study was supported by OTKA, MTA, SZTA and UNKP.

Introduction: Rapid on-site cytologic evaluation (ROSE) for determining the suitability of a specimen often provides high efficacy of endoscopic ultrasound-guided fine needle aspiration (EUS-FNA). In our center, we propose an additional role of ROSE in histological diagnosis aimed at improving diagnostic accuracy.

Aims & Methods: From January 2009 and December 2015, 215 patients were evaluated who underwent both EUS-FNA for pancreatic solid lesions and surgery. We retrospectively compared the diagnostic performance of ROSE during EUS-FNA with the final diagnosis confirmed by surgically resected specimens. Diagnosis by ROSE using Diff-QuikTM was carried out by both a cytopathologist and an endoscopist.

Results: The median of needle passes required for ROSE was 1 (range, 1–5). Final diagnoses for the 215 lesions were pancreatic ductal adenocarcinoma (PDAC; n = 162), pancreatic ductal adenocarcinoma (PDASC; n = 9), pancreatic neuroendocrine tumor (pNET; n = 30), solid pseudopapillary neoplasm (SPN; n = 9), metastatic tumors (n = 4), and acinar cell carcinoma (ACC; n = 1). Primary lesions for metastatic tumors in the pancreas were renal cell cancer (RCC; n = 2), small cell lung cancer (SCLC; n = 1), and colon cancer (n = 1). ROSE could not diagnose 14 cases. When adenocarcinoma (including suspicious) was suspected by ROSE, ROSE diagnosed 94.6% (159/168) of adenocarcinomas. When special type tumor (pNET, SPN, RCC, SCLC) was suspected by ROSE, ROSE diagnosed 96.4% (27/28) of special type tumor.

Conclusion: All adenocarcinomas suspected by ROSE were malignant tumors. When special type tumor (pNET, SPN, RCC, SCLC) was suspected by ROSE, Diagnostic accuracy of ROSE was 96.4%. Diagnostic accuracy using ROSE is high agreement in final histological diagnosis. It is suggested that ROSE may also be useful for diagnosis of special type tumor.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) has one of the most dismal prognoses of all cancer types. Diagnostic techniques for early malignant lesions are limited, which shows an evident need to understand the pathomechanism leading to PDAC and find a suitable marker for early detection. Initial processes in PDAC development involve acinar to ductal metaplasia (ADM) with further neoplastic progression into four pancreatic intraepithelial neoplastic (PanINs) stages. After accumulation of mutations, these lesions will further evolve into PDAC. Gastrokine 1 & 2 (GKN1 & GKN2) are secreted proteins found almost exclusively in the stomach, where they are involved in gastric epithelial homeostasis. While current research focuses on the exploration of tumor-suppressive properties of GKN1 in gastric tumors, nothing is known about GKN function in other organs. A whole genome microarray of KrasG12D Ptf1aCre (KC) mice, a mouse model with predisposition to pancreatic cancer, revealed strikingly high gastrokine expression. We will further analyze the involvement of GKNs in the development and progression of PDAC and explore the possibility to use them as biomarkers.

Aims & Methods: GKN1 & GKN2 expression was confirmed by qPCR in human and mouse pancreas samples. The presence of GKN1 was verified by western blot and immunohistochemistry (IHC) in mouse pancreas. Mouse pancreatic juice and serum were analyzed by proteomic analysis. To investigate the role of GKNs in pancreatic carcinogenesis in vivo, we established mouse models by intercrossing KC mice with Gkn1^{-/-} and Gkn2^{-/-} mice respectively. The capacity of acinar cells lacking Gkn1 and Gkn2 to transdifferentiate into ductal lesions in vitro was tested.

Results: GKNs were upregulated during early stages of pancreatic carcinogenesis in mouse and peri-tumoral human pancreas. GKNs were absent in healthy pancreas and tumor tissue. IHC showed specific GKN1 expression in premalignant PanIN lesions, while GKN2 positive cells were also localized in the stroma. ELISA and proteomic analysis in mice confirmed the secretion of GKNs into pancreatic juice. Preliminary results from the first timepoint of analysis showed accelerated tumor development in GKN1^{-/-} KC mice. Wild type acinar cells transdifferentiated in vitro only in the presence of TGFα. On the contrary, Gkn1^{-/-} acinar cells transdifferentiated spontaneously, and resulted in a higher number of ADMs.

Conclusion: We identified for the first time specific gastrokine expression in pre-neoplastic lesions in human and mouse pancreatic tissue. The secretion into pancreatic juice during carcinogenesis could make gastrokine a potential biomarker for the detection of early pancreatic premalignant lesions. With our mouse models we will provide in vivo evidence on the role of GKNs as potential tumor suppressors in the pancreas.

Introduction: Pancreatic cancer is one of the deadliest malignancies and there are no effective therapies for it. According to a search of The Cancer Genome Atlas (TCGA), alterations in Kirsten rat sarcoma (KRAS), Tumour protein (TP)53, Cyclin-dependent kinase inhibitor (CDKN)2A and Cyclin-dependent kinase inhibitor (CDKN)2B are the most frequent genetic aberrations in human pancreatic cancer (91%, 63%, 53% and 34% of cases, respectively). Macroautophagy (hereafter referred to as autophagy) has been implicated in some of human diseases, and it plays a complex role in pancreatic cancer.

Aims & Methods: We aimed to investigate autophagy response in a new humanized genetically-modified adult mouse model of pancreatic cancer. To induce pancreatic cancer, lentiviruses expressing oncogenic KRAS^{G12D} and shRNA targeting tumour suppressors *Tp53*, *Cdkn2a* and *Cdkn2b* (lentiviruses-KTCC) were injected into pancreas of 9-week old adult mouse. Autophagy was detected by immunofluorescence staining for autophagic protein light chain-3 (LC-3) and Lysosomal-associated membrane protein 1 (LAMP-1). Additionally, the expression of autophagic protein LC3, autophagy related protein 7 (ATG7), LAMP-1 and P62 were determined by western blot. *In vitro*, pancreatic duct epithelial cells

of normal mice were primary isolated, LC3 was determined by immunofluorescence staining in the lentiviruses-KTCC infected primary cells.

Results: Mice developed pancreatic cancer ten weeks after lentiviruses-KTCC injection, both in macrography and histopathology analysed. The mRNA levels of autophagic genes *Atg7* and *Atg12* were up regulated. In addition, the LC3 and LAMP-1 positive areas were significantly increased. And co-localization of LC3 and LAMP-1 was found in pancreatic tumour sections. Moreover, the increased protein levels of ATG7, LC3, LAMP-1 and decreased P62 protein was observed in the pancreatic tumour tissues. *In vitro*, the protein level of LC3 in the lentiviruses-KTCC infected primary cells was increased by 6 times when compared with that in the control primary cells (P=0.0104).

Conclusion: An adult mouse model of pancreatic cancer can be generated by altering *Kras*, *Tp53*, *Cdkn2a* and *Cdkn2b* genes. Besides, increased autophagy was observed during the development of pancreatic cancer in our mouse model. These findings provide considerable insight into the role of autophagy in pancreatic cancer and autophagy inhibition might be a potential target in treating pancreatic cancer.

Introduction: Hyperthermia as a positive additive to chemotherapy is described in multiple studies. Despite controversial results hyperthermal intraperitoneal chemotherapy (HIPEC) is a standard treatment option for some types of gastrointestinal cancer that invades peritoneum. However, the results of clinical data and basic research are uneven. Moreover, there is a lack of fundamental knowledge on additive cytotoxic effect of hyperthermia on cancer cells of different origin.

Aims & Methods: Our aim was to analyse gastrointestinal cancer cell response to various hyperthermia levels, accompanied by chemotherapy, in a manner of cell cytotoxicity, apoptosis and intracellular cisplatin concentration. Cancer cell lines of gastric (AGS), pancreatic (T3M4) and colorectal (CACO-2) origin were exposed to cisplatin and different temperature regimens (37°C to 45°C) either in isolated manner, or in combination. Cells were treated for one hour, mimicking HIPEC timing in clinical setting. The intracellular concentration of cisplatin was measured immediately after experiment by mass spectrometry. 48 hours later changes of cell viability and apoptosis rates depending on temperature in addition to cisplatin treatment were evaluated by MTT and Annexin/7 AAD flow cytometry respectively.

Results: Response of AGS to hyperthermia was as implied. Viability of the cells was gradually decreasing by raising the temperature. CACO-2 cells had no significant response to temperature rise up to 42°C, but at 43°C viability dropped by 14% constantly remaining at higher temperatures. T3M4 cells acted in unpredictable manner, whereas decreasing viability by 30% in the interval between 37°C to 42°C and 20% increase at 43°C was observed. Following simultaneous exposure to hyperthermia and cisplatin we observed no additive temperature affect in interval between 37°C to 41°C. However, at particular temperature regimens, we observed temporary proliferation increase: AGS – at 42°C (33%); T3M4 – at 43°C (32%). Higher temperatures dramatically inhibited AGS – by 70%, T3M4 – by 76%. There was the linear pattern of slight decrease (up to 26% at 45°C) of viability in CACO-2 cells. Isobologram analysis of combined hyperthermia and cisplatin treatment revealed strong antagonism of hyperthermia and chemotherapy in all analyzed cell lines. Nevertheless, hyperthermia of 43°C in addition to cisplatin promoted apoptosis of AGS cells by 33%, CACO-2 by 26%, T3M4 by 19%. Moreover, application of hyperthermia (43°C) could contribute to increase of intracellular cisplatin concentration by 30%, 20% and 18% AGS, CACO-2 and T3M4 cells respectively.

Conclusion: Our results indicate that there is no linear contribution of hyperthermia to chemotherapy in all analyzed cell lines. Therefore, in clinical setting it should be applied individually, regarding cancer type. Moreover, particular temperatures can worsen the treatment and increase cancer cell growth.

Introduction: Cachexia is a multifactorial syndrome, characterized by the loss of skeletal muscle mass which is not fully reversible by nutritional support. Activin play a dominant role in the development and progression of cachexia and also in tumor cell growth in pancreatic adenocarcinoma via non-SMAD (MAPK, PI3K/Akt) pathways. Cachexia might be a keypoint in pancreatic ductal adenocarcinomas (PDAC) poor outcome.

Aims & Methods: Our goal was to assess the significance of activin protein expression in PDAC related to the clinical stage and survival. There were included patients with histological proven of adenocarcinoma (n=115) and a matched control group (n=124). The plasma levels of activin was analyzed using western blot. The t test was used to determine the difference between the two groups, Kaplan-Meier curve and log-rank tests were used to determine the differences in survival curves of studied patients.

Results: The activin was overexpressed more frequently in PDAC compared to controls (p=0.001). and has been closely related to advanced clinical stage (stage III-IV), tumor size, location and with the presence of metastasis (p<0.05). Activin expression was higher in patients with type 2 diabetes (p=0.04). No relationship between activin level and the patients age, sex or tumor size, was noted. Patients with activin high expression had a shorter survival time than PDAC patients with activin low expression (Log-rank = 4.35, p=0.03).

Conclusion: Activin pathway is related to cachexia and the local spread of PDAC, metastasis, the presence of diabetes and survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Intracellular cytoskeleton in pancreatic ductal adenocarcinoma (PDAC) might be a key point in its poor outcome. Reliable biomarkers estimating the cytoskeleton involvement are lacking and their relationship with the cachexia is not known. Ezrin is involved in intracellular signaling and adhesion, by linking in the PI3K/Akt pathways.

Aims & Methods: The goal is to assess the significance of ezrin protein expression in PDAC related to the clinical stage and survival. There were included patients with histological proven of adenocarcinoma (n=51) and a matched control group (n=51). The plasma levels of ezrin were analyzed using western blot. The t test was used to determine the difference between the two groups, Kaplan-Meier curve and log-rank tests were used to determine the differences in survival curves of studied patients.

Results: The ezrin was overexpressed more frequently in PDAC compared to controls (p=0.009 and p=0.05). Ezrin expression has been closely related to advanced clinical stage (p=0.03), but not with the presence of metastasis. No relationship between ezrin levels and the patients age, sex or tumor size and location of tumor was found. The survival of patients with high or low levels of ezrin expression was similar.

Conclusion: Ezrin pathway as a intracellular cytoskeleton biomarker is related to the local spread of PDAC, but not in metastasis or survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: kaoru_1238@yahoo.co.jp

Introduction: FOLFIRINOX (FFX) or nab-paclitaxel plus gemcitabine (GnP) are standard regimens in patients with advanced pancreatic cancer. However, chemotherapy can impair quality of life (QoL) due to adverse events. Because the life expectancy of this population is typically short, QoL is as important as the actual length of life.

Aims & Methods: The aim of this study was to assess QoL during chemotherapy in patients with advanced pancreatic cancer. Twenty-one Japanese patients with unresectable advanced pancreatic cancer and performance status 0–1 were included in this study. All patients were treated with FFX or GnP as first-line chemotherapy. QoL was assessed using the European Organization for Research and Treatment for Cancer Quality of Life Core Questionnaire (EORTC QLQ-C30), and anxiety and depression were measured using the Hospital Anxiety and Depression Scale (HADS) at baseline and 2 weeks and every month after initiation of chemotherapy. Changes between score at baseline and median score after chemotherapy were compared using Wilcoxon signed-rank test. Continuous variables are presented as median (range).

Results: Thirteen male and 8 female patients were included, with a median age of 65 (50–75) years and BMI of 21.2 (16.0–26.2) kg/m². The chemotherapy regimens were FFX in 5 men and 2 women, modified-FFX in 4 men and 4 women, and GnP in 4 men and 2 women. Eight patients took opioids for pain, and 4 received celiac plexus neurolysis. Regarding global health status (GHS) and functional scales in QLQ-C30, baseline scores were: GHS, 50 (17–92)%; physical, 87 (53–100)%; role, 83 (33–100)%; emotional, 67 (33–100)%; cognitive, 83 (33–100)%; and social, 67 (11–100)%. After chemotherapy, role function scale was decreased significantly (p=0.04), and nausea (p=0.02) and diarrhea (p=0.049) were more frequently observed, while pain was relieved (p=0.002). In analysis according to patients' background, a lot of evaluation in patients with BMI <21 kg/m² tended to be worse than in those with BMI ≥21 kg/m² after chemotherapy. Regarding HADS at baseline, 5 patients reported depression, 7 borderline depression, 5 anxiety requiring intervention, and 5 anxiety requiring follow-up. There were no significant changes in HADS after chemotherapy.

Conclusion: In patients with advanced pancreatic cancer, GHS and mental status had already deteriorated at baseline. Although pain scale might be improved due to analgesic treatment, role function scale, nausea and diarrhea became worse during chemotherapy. In particular, QoL tended to deteriorate in lean patients. These results indicate that pain as well as QoL factors should always be considered to manage chemotherapy properly in patients with advanced pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0783 C-REACTIVE PROTEIN (CRP) LEVEL IS AN INDICATOR OF THE THERAPEUTIC EFFECT OF TREATMENT RESPONSE TO ENDOSCOPIC ULTRASOUND-GUIDED CELIAC NEUROLYSIS (EUS-CPN) IN PATIENTS WITH PANCREATIC CANCER (PC) PAIN

G. Kimura, Y. Hashimoto, K. Umamoto, K. Watanabe, M. Sasaki, H. Takahashi, H. Imaoka, I. Oono, S. Mitsunaga, M. Ikeda
Hepato-biliary-pancreatic Internal Medicine, National Cancer Center Hospital East, Kashiwa/Japan

Contact E-mail Address: gengen_cocacola@yahoo.co.jp

Introduction: Pain devastates the quality of life and is often difficult to control in unresectable PC. Opioid analgesics are used to alleviate the pain. However, pharmacologic intervention sometimes fails and the side effects could become major problems. Recently, EUS-CPN has been shown to have a therapeutic effect against PC pain in the short term.

Aims & Methods: The objective of the study was to evaluate the efficacy and safety over the long term and to identify predictors of pain relief in patients

treated by EUS-CPN. Clinical information was obtained retrospectively from the medical charts and endoscopy reporting system. The follow-up period was until the patient died or was lost to follow-up. Between November 2014 and March 2017, 70 patients with PC pain were enrolled. We performed EUS-CPN by injection of 5 ml of bupivacaine mixed with 15 ml of pure ethanol on the celiac plexus and superior mesenteric plexus using a 22G endoscopic ultrasound-guided fine needle aspiration needle. Treatment response was assessed by self-reported pain relief and change in the daily dose requirement of morphine. Treatment response was defined as to decrease or stay of the same amount of morphine consumption after EUS-CPN, or achieve morphine dosage level within 4 weeks after EUS-CPN if morphine consumption temporarily elevated because of the delayed response of EUS-CPN. Pain evaluation was conducted at 1 week, 4 weeks, 12 weeks after EUS-CPN and tumor disease progression.

Results: The overall response rate was 81.4% (57/70). The median duration of pain relief was 4.0 months. 10 patients required a second EUS-CPN due to pain relapse, and 90% (9/10) showed response to the repeat procedure. Of the 44 patients who showed response to the initial EUS-CPN during chemotherapy, the pain relief persisted after the diagnosis of tumor progression in 16 patients (16/44: 36.3%). Between the response group and no-response groups, there were significant differences in the prevalences of liver metastasis (47 vs. 92%, $P=0.003$), lung metastasis (12 vs. 38%, $P=0.02$) and lymph node metastasis (56 vs. 92%, $P=0.015$), and in the serum levels of CEA (median: 6.7 vs. 17.1 ng/ml, $P=0.017$), CA19-9 (median: 617.2 vs. 3519 U/ml, $P=0.009$), CRP (median: 0.61 vs. 1.91 mg/dl, $P=0.029$) and albumin (median: 3.4 vs. 3.8 g/dl, $P=0.029$). Univariate analysis revealed a significantly smaller percentage of patients with CRP level elevation over 3.0 mg/dl from baseline within 4 weeks after EUS-CPN (11 vs. 38%, $P=0.01$). The overall survival after EUS-CPN was also significantly longer in the response group as compared to the no-response group (median: 5.8 vs. 3.1 months, $P=0.01$).

Conclusion: Our study demonstrated that EUS-CPN had therapeutic effect on intractable pain in unresectable PC in the long follow-up. Repeat EUS-CPN was also effective in patients who showed a treatment response to the first EUS-CPN. Patients who did not benefit from EUS-CPN had strong cancer inflammation and aggressiveness, indicative of higher CRP, CA19-9 and lower albumin levels, and the higher frequencies of liver metastasis.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) 5-year survival rate is only 6% as only 20% of patients are eligible for surgery at diagnosis, due to delayed diagnosis as symptoms are often unrecognized. Data on the association between presentation symptoms, diagnostic delay, disease stage and survival are however limited, with heterogeneous results. Furthermore, the association between risk factors for developing PDAC, such as smoking, obesity, alcohol intake, diabetes and PDAC family history and diagnostic delay has not been explored specifically.

Aims & Methods: We aimed to investigate the association between presentation symptoms, diagnostic delay, risk factors for PDAC, stage at diagnosis and survival. This was a retrospective analysis of a single-centre cohort of prospectively evaluated PDAC patients with the above mentioned data recorded in a dedicated database. Fisher test for comparison of proportions for categorical variables and Student's t-test for continuous variables were employed. Multiple logistic regression analysis was employed to investigate factors associated with metastatic stage at diagnosis or death. Survival probability was calculated with the Kaplan-Meier curve and Cox analysis was employed to calculate hazard ratios (HR). Tests of statistical significance and confidence intervals were two-sided; a $p < 0.05$ was considered to be statistically significant.

Results: In 434 PDAC patients the mean diagnostic delay was 4 months (95% CI 3.6–4.4). Jaundice was the leading presentation symptom in 74 (17%), weight loss in 164 (37.7%), pain in 105 (24%), new-onset diabetes in 43 (9.9%). Diagnosis was incidental in 24 cases (5.5%) or related with undetermined complaints in other 24 (5.5%). The diagnostic delay was significantly shorter for patients with jaundice (mean 1.1 months) compared to those with pain (3.6), new-onset diabetes (5.46) and weight loss (5.96). PDAC family history, smoking and previous diabetes were not associated with presentation symptoms or delay, but obese patients (4.3 vs 3.4 months; $p=0.03$) and those drinking alcohol (4.5 vs 3.6 months; $p=0.03$) had a longer delay. The mean diagnostic delay was of 4.5 months in patients with distant metastases, 4.1 in locally advanced and 3.4 in resectable disease ($p=0.02$). Patients presenting with jaundice had distant metastases at diagnosis in only 18% of cases compared to 45% of other presentations ($p=0.00001$). The mean survival was 11.8 months in the 395 patients with available follow-up. At Kaplan-Meier and Cox-proportional regression analysis age at diagnosis (HR = 1.02 per year) and metastatic stage at diagnosis (HR 2.5), but not the different presentation symptoms, or the diagnostic delay were associated with worse survival.

Conclusion: Different presentation symptoms, the presence of obesity and alcohol intake are associated with the diagnostic delay, which is in turn related with disease stage at diagnosis. However, symptoms and delay do not seem to affect prognosis. These results suggest that diagnosis at the preclinical stage is necessary to change disease prognosis.

Introduction: Cell-free DNA (cfDNA) shed from tumors into the general circulation offers opportunities to trace the genomic evolution of cancer. The level of cfDNA is generally higher in cancer patients than healthy individuals; however, detecting the rare fraction of circulating tumor-derived DNA (ctDNA) in patient plasma remains a technical challenge. Initial efforts have been made to quantify the ctDNA using conventional PCR, but the low sensitivity of this approach has limited its feasibility as a routine clinical test. New technologies for quantifying ctDNA are now sensitive enough for reliable application in the clinic (ref 1). Pancreatic ductal adenocarcinoma (PDA) is among the most lethal human malignancies. Intraductal papillary mucinous cystic neoplasias (IPMNs) are precursors of PDA and provide models of neoplastic progression from a benign intraductal tumor through increasing grades of dysplasia to PDA, and mutations in KRAS and/or GNAS mediate key signaling during early development of the tumors (ref 2). Better prediction of histological grades using non-invasive tools is urgently needed for IPMN patients to make appropriate management decisions.

Aims & Methods: In the current study, we sought to determine if quantification of major driver mutations such as KRAS and GNAS in the plasma cfDNA could serve as biomarkers for diagnosis of localized PDAs and risk stratification of IPMNs. We first established protocols for absolute quantification of very low concentrations of the target mutant alleles using a Bio-Rad QX200 droplet digital PCR platform (ddPCR). Using this novel protocol, feasibility of the assay was tested. At present, 92 PDA and 145 IPMN patients with either benign or malignant disease have been recruited (UMIN00012810).

Results: Although ddPCR-based assays have rather high precision and sensitivity (0.01%), limited plasma cfDNA yields in patients with resectable PDAs (Stage 0-II) resulted in significant intrinsic errors due to "subsampling". The issue associated with missing targets at very low abundance during compartmentalization could be effectively overcome by pre-amplification, and the sensitivity of mutant KRAS detection was greatly improved (80.3%) relative to a standard protocol (37.5%). Given the highly accurate assay, risk assessment of the IPMN cases was performed during follow-up. Although the concentration of plasma cfDNA in patient with IPMNs was not robustly higher than healthy subjects (15.1 +/- 5.8 ng/mL plasma vs 11.3 +/- 3.2 ng/mL plasma), mutant KRAS/GNAS alleles from patients, particularly in high-grade IPMNs, can be successfully quantified albeit at low levels. In the subset of patients who had no evidence of "high-risk stigmata" as well as "worrisome features" by imaging modalities (ref 3) and normal tumor markers (CA19-9 and CEA), oncogenic KRAS could be detected in plasma cfDNA earlier than the detection of invasive PDAs by imaging.

Conclusion: By setting an appropriate protocol for ddPCR-based cfDNA assay, serial blood sampling allows physicians to conduct real-time detection and monitoring of tumor genomic alterations (ref 4). Although larger validation studies are required before introduction into the clinic, early results of the study indicate that our approach allows the detection of localized early-stage disease and offers an alternative tool to monitor IPMN progression non-invasively.

Introduction: Pancreatic cancer is a lethal disease and the fifth most common cause of cancer-related death in Korea. Pancreatic cancer patients show dismal prognosis with a 5-year survival rate less than 10%, because the majority of patients are diagnosed in advanced stage. Since the late 1990s, gemcitabine-based chemotherapy has been used as a mainstay of metastatic pancreatic cancer (mPC) treatment and various combination therapies (such as combination with capecitabine or erlotinib) had been attempted to improve the patients' survival, so far. Recently, MPACT trial, a randomized phase III trial showed that combination of gemcitabine and nab-paclitaxel had statistically significant survival benefit compared with gemcitabine monotherapy. Based on the results of this trial, gemcitabine with nab-paclitaxel combination therapy is currently being used as a standard therapy for pancreatic cancer patients. However, only 2% of the MPACT trial study population was Asian, and other researches on Asian population group are also lacking. Therefore, we investigated treatment efficacy and safety of gemcitabine plus nab-paclitaxel combination therapy for mPC treatment in Korean population.

Aims & Methods: Total 66 metastatic pancreatic cancer patients treated with gemcitabine (1000mg/m²) and nab-paclitaxel (125 mg/m²) regimen (on day 1, 8, 15 of a 28-day cycle) as the first line chemotherapy from February 2016 were identified using the Severance Hospital Pancreatic Cancer Cohort Registry. Treatment efficacy (overall survival (OS), progression-free survival (PFS), objective response rate) and treatment-related adverse events (AE) of patients (occurrence rate, severity grade and dose-intensity) were analyzed.

Results: The median follow-up period was 7.4 months (range 1.5–14.9 months); during this period, 21 (31.8%) patients died. Median cumulative dose of gemcitabine and nab-paclitaxel were 13,000 mg/m² and 1487.5 mg/m². The median OS, PFS and objective response rate were 12.0 months (95% confidence interval [CI] 9.515–14.485), 7.8 months (95% CI 5.021–10.579) and 48.5%, respectively. The incidence of neurotoxicity was 54.5% and 12 (18.2%) patients experienced grade ≥ 3 neurotoxicity. 30 (45.5%) patients showed grade ≥ 3 neutropenia and 10 (15.2%) patients had febrile neutropenia. Grade ≥ 3 gastrointestinal AE was occurred in 11 (16.7%) patients and 28 (42.4%) patients experienced dermatologic AE such as alopecia and skin eruption. About 59% of patients experienced treatment delays due to adverse events. Dose reduction was performed in 39 (59.1%) patients and 14 patients experienced treatment cessation due to severe AE.

Table 1: Treatment efficacy and treatment-related adverse events of gemcitabine with nab-paclitaxel

Variables	
<i>Duration of chemotherapy</i>	
Cycles (28-day schedule)	5 (2–12)
Duration, days	141 (32–435)
<i>Efficacy of Chemotherapy</i>	
Overall survival - months (95%CI)	12.0 (9.515–14.485)
Progression-free survival - months (95%CI)	7.8 (5.021–10.579)
<i>Adverse events</i>	
Peripheral neuropathy	36 (54.5%)
Grade ≥ 3 neuropathy	12 (18.2%)
Grade ≥ 3 Neutropenia	30 (45.5%)
Febrile neutropenia	10 (15.2%)
Administration of G-CSF	14 (21.2%)
Grade ≥ 3 adverse event	11 (16.7%)
General weakness	32 (48.5%)
Dermatologic adverse event	28 (42.4%)
<i>Dose reduction due to AE</i>	
Gemcitabine	21 (31.8%)
nab-paclitaxel	39 (59.1%)
<i>Delay of administration due to AE</i>	
n (%)	39 (59.1%)
<i>Cessation of administration due to AE</i>	
n (%)	14 (21.2%)

Conclusion: These results suggest that gemcitabine and nab-paclitaxel combination therapy is effective for metastatic pancreatic cancer treatment in east-Asian population group. Similar to previous studies, this combination therapy showed remarkable neurotoxicity and myelosuppression. Careful monitoring and proper management during chemotherapy is required.

Introduction: Endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) is a useful and safe method for tissue confirmation of malignancy. This method has the risk of tumor cell dissemination along the needle track or within the peritoneum by preoperative EUS-FNA.

Aims & Methods: The aim of our study was to estimate the risk of peritoneal recurrence and the impact on long-term outcomes by preoperative EUS-FNA in resected pancreatic cancer. The records of patients diagnosed with pancreatic cancer who underwent curative resection between 2009 and 2013 were reviewed retrospectively. A total of 394 patients were included: 78 patients with preoperative EUS-FNA (EUS-FNA group) and 316 without preoperative EUS-FNA (Non-EUS-FNA group). Peritoneal recurrence was diagnosed based on image findings.

Results: Median length of follow-up was 23 months (range 1 ~ 94 months). A total of 82 patients had peritoneal recurrence; 34.6% (27/78) in EUS-FNA group vs. 28.2% (89/316) in Non-EUS-FNA group (P = 0.26). Cancer-free survival and overall survival were not different between the groups: median cancer-free survival in EUS-FNA group was 10.8 months compared with 10.6 months in Non-EUS-FNA group (P = 0.83), and median overall survival in EUS-FNA group was 56.4 months compared with or 56.7 months in Non-EUS-FNA group (P = 0.93).

Conclusion: Preoperative EUS-FNA for pancreatic cancer was not associated with an increased rate of peritoneal recurrence and mortality. Our study suggests that EUS-FNA is a safe method for obtaining tissues of pancreatic masses.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gemcitabine (Gem) therapy had been the standard treatment for advanced pancreatic ductal adenocarcinoma (PDAC) for long time. Even though FOLFIRINOX, a combination of fluorouracil, oxaliplatin and irinotecan, and gemcitabine/nab-paclitaxel (GnP) therapy are currently recommended as first-line drugs, Gem is still one of the important options. Efficient permeation of Gem into cells requires specialized integral membrane transporter proteins to cross plasma membranes. Among these transporters, the major mediators of Gem uptake into human cells are the human equilibrative nucleoside transporter 1 (hENT1). In the previous study started since 2005, we found hENT1 expression in endoscopic ultrasonography-guided fine-needle aspiration biopsy (EUS-FNAB) samples to be a useful prognostic marker of Gem-based chemoradiotherapy (Gem-CRT) for pancreatic ductal adenocarcinoma (PDAC) (Pancreas 2016). Since November 2011, our institution has replaced Gem + tegafur/gimeracil/oteracil (S-1) (GS)-CRT with Gem-CRT in an attempt to improve clinical response and prognosis. Aggregate median survival time (MST: months) of GS-CRT was compared with previous Gem-CRT result, and the superior efficacy of GS-CRT was observed (MST: 16 versus 20, respectively), particularly in hENT1-negative patients (MST: 9 versus 14, respectively). However, there were no differences in

hENT1-positive patients (MST: 25 versus 25, respectively). We suspect that genetic factors might play a role in this observed variability.

Aims & Methods: In the present study, we evaluated hENT1 and dihydropyrimidine dehydrogenase (DPD: enzyme involved in the degradation of tegafur) expression in EUS-FNAB samples for evaluating and predicting the clinical efficacy of GS-CRT. EUS-FNAB samples were obtained prior to GS-CRT administration. In total, 95 formalin-embedded PDAC specimens were obtained. In the samples determined to have sufficient material remaining following cytological/histological diagnosis (n=76), hENT1 expression was evaluated via immunohistochemical (IHC) examination. Following IHC analysis of hENT1, a further assessment of DPD expression was carried out in those samples determined to have sufficient material remaining (n=58).

Results: By reusing the EUS-FNAB specimens after diagnosis of PDAC, hENT1 and DPD expression could be successfully assessed in 79.2% (76/95) and 61.1% (58/95) of these cases, respectively. In those sufficient for hENT1 testing, 67.1% (51/76) were found to be positive. And in those sufficient for DPD testing, 27.6% (16/58) were found to be positive. MST was significantly longer in hENT1-positive patients (25 versus 14 negative; $P=0.015$). As for DPD, MST was significantly longer in DPD-negative patients (33 versus 14 positive; $P<0.001$). In the multivariate model including pretreatment clinical factors (age, sex, tumor location, tumor size, UICC-T classification, hENT1 expression, and DPD expression) and the clinical response after GS-CRT (response of GS-CRT, reduction rate in serum CA19-9 level, and distant metastasis after GS-CRT), only hENT1 expression (HR=3.511; 1.545-7.981, $P=0.003$) and DPD expression (HR=0.232; 0.108-0.496, $p<0.001$) were found to be significant independent prognosis factors.

Conclusion: hENT1 and DPD expression observed in EUS-FNAB samples can be useful clinical predictors in PDAC cases treated with GS-CRT.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Intraductal Papillary Mucinous Neoplasms (IPMN) require a close follow-up to early detect worrisome features, which imply a pejorative evolution towards dysplasia and surgery. However, some patients are symptomatic including post-prandial pancreas related abdominal pain (PPAP) or recurrent acute pancreatitis (RAP). We currently do not know if those symptoms are risk factor of cancer in IPMN, and there are no data about the efficacy of endoscopic sphincterotomy (ES) to manage them.

Aims & Methods: This was a retrospective multi-centered observational study in 4 tertiary expert centers. The files of 27 patients that underwent ES for symptomatic IPMN without worrisome features nor surgical indication were considered. Six were excluded (4=lack of data; 1=pseudocyst; 1=adenocarcinoma), thus 21 were analyzed. Age, sex, medical history, time of follow-up, characteristics of IPMN and ERCP procedures, clinical success, evolution and need for surgery were recorded. The primary endpoint was to assess the efficacy of ES for improving the symptoms of pain related to IPMN. The efficacy was defined as the resolution or the decreasing >50% of the symptoms' frequency. The secondary endpoints were to document, the need for a second ES, the occurrence of WF during follow-up, the need for surgery and its indications.

Results: There were 10 men and 11 women involved, with a mean age of 66 years old [45-87] and a mean total follow-up of 105 months [17-276]. Their symptoms were PPAP in 6 patients and RAP in the 15 others (5 being severe AP), with a mean of 3.6 episode/year [1-12]. The delay between diagnosis and ES was 41 months [1-192] and the patients were followed by MRI (81%), EUS (95%) CTscan (36%) or by alternating (MRI and EUS) for 45%. The IPMN were involving the accessory branch duct in 71%, or mixed type in 29%, with a wirsung duct always <7mm. The mean number of cysts was 3.5 [1-10], the larger measuring 12.7mm [5-25] mean. They were located for 59% in the head, 17% in the body or tail, and they were diffuse in 24%. None patient had worrisome features. Endoscopy: ERCP with pancreatic ES was performed in 100% of the cases (5 with pancreas divisum, 2 pre-cut required), associated with a biliary ES in 33% of the cases. A prophylaxis with NSAIDS was carried out in 38% of the cases and a plastic stent placement in 33%. There were 4 post-ERC benign pancreatitis, and the mean follow-up after ES was 54 months [13-167]. The clinical efficacy rate as defined after one session was 81% (17/21). Among them, one had a late recurrence (41 months) and underwent a second ES session with final success, whereas 4 have been operated (2 for initial pain, 2

for WF). Among the patients whom failed (4/21), one had a second ES with final success and 3 finally had surgery. The two groups were comparable in terms of age, sex, mean follow-up time, and characteristics of IPMN. The final efficacy of ES was 86% (19/21). In total seven patients were operated after a mean of 19 months of follow-up, 24% if success of ERCP and in 75% if failure. The indications were WF (n=4) or pain (n=3). The histopathology showed four low-grade dysplasia, one high-grade dysplasia, and two no dysplasia (=surgery for pain). No patients evolved towards adenocarcinoma in the follow-up.

Conclusion: ES for symptomatic IPMN without WF is effective in 81% of the cases. A symptomatic IPMN (pain) does not seem to be a valuable indication for surgery, since no patients developed with cancer after a follow-up greater than 5 years.

Contact E-mail Address: livia.archibugi@hotmail.it

Introduction: Statins are widely prescribed both for primary and secondary prevention of coronary artery disease and for the treatment of dyslipidemia. Several studies evaluated the association between statin use and the onset of pancreatic cancer (PDAC) in order to evaluate a possible chemopreventive effect, with heterogeneous results. Previous meta-analyses evaluating researches published up to 2012 did not find any association to the risk, but in the latest years new studies with interesting results have been published.

Aims & Methods: The aim of our study was to conduct a new systematic review and meta-analysis to clarify this association. A comprehensive literature search of PUBMED for articles published up to November 2016 and abstracts presented between 2012-2016 at the DDW and ASCO conventions was carried out. Eligible studies were case-control studies (CC), cohort studies (C) and randomized controlled trials (RCTs) assessing the effect of statin use on the risk of PDAC, compared with placebo or no treatment. Studies had to report Odds Ratio (OR), Relative Risk (RR), or Hazard Ratio (HR), estimates with 95% confidence interval (CI), or provide sufficient data for their calculation. Pooled adjusted ORs with corresponding 95% CIs were calculated using random effects model. Publication bias was assessed through Begg and Mazumdar test. Heterogeneity was assessed by means of the I^2 value.

Results: A total of 21 studies (12 CC, 6 C, 3 RCTs) contributed to the analysis. A total of 11383 PDAC patients and 2991004 controls were included. The pooled incidence of PDAC was 0.27% (3161/1167130) among statin users and 0.44% (8144/1835153) among the non-users. The overall pooled result for all studies demonstrated a reduced risk of PDAC among statin users (OR 0.82; 95% CI 0.69-0.96; $p=0.019$), compared to non-statin users. In a subgroup analysis the protective effect was limited to case-control studies (OR 0.72; 95% CI 0.56-0.93) and not to cohort (OR 0.93; 95% CI 0.73-1.19) nor RCTs (OR 1.04; 95% CI 0.56-1.94). No publication bias was found.

Conclusion: This is the first meta-analysis showing that statins exert a protective effect on the incidence of PDAC. Further studies taking into account statin dose, duration and subgroups of patients are needed in order to clarify the association.

Introduction: Genetic alterations responsible for the initiation of cancer may serve as immediate biomarkers for early diagnosis. Plasma levels of circulating cell-free DNA (cfDNA) in cancer patients are higher than those in healthy individuals; however, the major technical challenge for the widespread implementation of cfDNA genotyping as a diagnostic tool is the insufficient sensitivity and specificity of detecting early-stage tumors that shed low amounts of cfDNA. Droplet Digital PCR (ddPCR) has rather high precision and sensitivity for absolute quantification (0.01%). However, due to very low target concentrations of cfDNA in plasma, there may be an intrinsic error due to "subsampling" (Ref. 1). This is caused by limited cfDNA yield and missing targets at very low abundance during compartmentalization in ddPCR-based liquid biopsy assays. Such issues potentially result in large variations or errors in quantification, even when using highly accurate platform. Using ddPCR technology for early cancer diagnosis and risk stratification is still challenging.

Aims & Methods: In this study, we aimed to overcome the subsampling issue and to establish a more reliable framework for digital quantification of rare tumor cell-derived mutant alleles for non-invasive diagnosis of gastrointestinal cancer. To establish more reliable dd-PCR protocol for quantification of low-frequency alleles within a limited cfDNA pool, two-step multiplex ddPCR targeting eight clinically relevant mutant *KRAS* variants was examined using a Bio-Rad QX200 droplet digital PCR platform. Plasma samples from patients with colorectal (n = 10) and pancreatic cancer (n = 9) were evaluated, and cfDNA from healthy volunteers (n = 50) was utilized to calculate reference intervals.

Results: Limited cfDNA yields in patients with resectable colorectal and pancreatic cancers did not meet the requirement for efficient capture and quantification of rare mutant alleles by ddPCR. To overcome the subsampling issues and achieve better assay specificity, we attempted pre-amplification of plasma cfDNA using primers flanking *KRAS* exon 2 as the first-step PCR. Eight pre-amplification cycles followed by a second-run ddPCR were sufficient to obtain approximately 5000–10,000 target alleles/ng cfDNA, resolving the subsampling issue; furthermore, the signal-to-noise ratio for rare mutant alleles against the massive background presented by the wild-type allele was significantly enhanced. The cut-off limit of reference intervals for mutant *KRAS* was determined to be ~0.09% based on samples from healthy individuals.

Conclusion: The modification introduced in the ddPCR protocol facilitated the quantification of low-copy alleles carrying driver mutations, such as oncogenic *KRAS*, in localized and early-stage cancers using small blood volumes, thus offering a minimally invasive modality for timely diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

²Department Of Internal Medicine, Yonsei University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: chelle884@yuhs.ac

Introduction: Benefit of second line chemotherapy (SL) after failed first-line chemotherapy (FL) in advanced pancreatic cancer has not yet been established. We intend to identify prognostic factors and ultimately devise a model of clinical parameters for decision of SL versus basic supportive care (BSC) after failure of FL chemotherapy.

Aims & Methods: 408 patients who received gemcitabine based-first-line chemotherapy for advanced pancreatic adenocarcinoma at Yonsei University Hospital between January 2010 and December 2014 were retrospectively reviewed. Significant clinical parameters regarding second line related survival were reviewed for analyzing predictive factors.

Results: 161 of 408 (39.5%) received SL therapy. Median overall survival from the beginning of SL (OS2) was 20.0 weeks (14.0~34.0). Significantly more SL patients presented higher body mass index (BMI) (p=0.001) and ECOG 0-1 (p=0.003) at diagnosis, lower rate of lung metastasis (p<0.001) and longer duration of FL (p<0.001). More SL patients had received gemcitabine-based concurrent chemo-radiation therapy (CCRT) (p=0.029) compared to FL only patients. Prognostic factors significant to OS2 were BMI at diagnosis (p=0.019 HR=0.870), duration of FL therapy (median duration 16weeks (8.00-28.00) p=0.004, HR=0.986), presence of peritoneal metastasis (p=0.002, HR1.732) at diagnosis, malignant thrombotic event during firstline chemotherapy (p=0.001, HR=0.428). Experience of CCRT was also a significant prognostic factor (p=0.001, HR=2.245); initial staging of the CCRT group was TNM stage3, which might be the ultimate factor impacting OS2.

Conclusion: Study suggests that SL chemotherapy may be beneficial for patients with longer duration of FL chemotherapy, higher BMI at diagnosis, patients without peritoneal metastasis at diagnosis, no malignant thrombosis event during chemotherapy and patient initially TNM stage3, who received Gemcitabine based CCRT.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Rapid on site evaluation for endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) of the pancreas provides immediate information regarding cellular adequacy, avoiding repeated procedures.

Aims & Methods: The aim of this study was to evaluate the impact of ROSE in EUS-FNA of solid pancreatic lesions. Retrospective study of consecutive EUS-FNA of solid pancreatic lesions, in a tertiary center, between 2012 and 2016.

Results: A total of 259 EUS-FNA in 197 patients were included, 63.6% male, with mean age of 63.4 (+/-12.8) years. The anatomical distribution of the lesions was: 56.4% in the head, 17% in the body, 10% in the uncinate process and 5.8% in the tail. The mean number of passes were 3.3 (+/-1.4) and the needle size was 25G in 60.8% and 22G in 23.8%. ROSE was performed in 34.7% of the punctures (23.6% along with the initial EUS-FNA), with a mean number of passes 3.4 (+/-1.9). The diagnostic yield of initial EUS-FNA without ROSE was 44.8% vs 83.6% when ROSE was performed (p<0.001). When not conclusive, there was no significant differences in the diagnostic yield of the repeated EUS-FNA (with and without ROSE). Beyond ROSE in the first puncture, higher levels of Ca 19.9 (199 vs 10 ng/mL, p=0.001), size of the lesion (36.1 vs. 29.8 mm, p<0.001), invasion of adjacent structures (64.6% vs 47.9%, p=0.009) and malignancy (73.2% vs 25.4%, p<0.001) were associated with EUS-FNA diagnostic accuracy. In multivariate analysis, ROSE (p=0.001) and the size of the lesion (p=0.023) were independent predictors of adequate diagnostic samples. In this series, the definitive diagnosis was of malignancy in 64.9% (ductal adenocarcinoma 54.7%), benign in 25.8% and indeterminate in 9.3%.

Conclusion: In agreement with the reported evidence, ROSE along EUS-FNA improved the diagnostic yield in solid pancreatic lesions and should be considered whenever possible in the first procedure, until an overall adequate diagnostic yield (>80%) is achieved.

Introduction: Postoperative digestive fistula remain a challenging condition associated with a high morbi-mortality, unsatisfactory healing rates and high refractoriness. The limitation of current approaches highlights the need for a better therapeutic strategy in terms of both long-lasting efficacy and safety. Mesenchymal stem cell (MSCs) are strongly involved in tissue injury repair. MSCs feature an immune-privileged status while displaying pro-angiogenic,

and antifibrotic properties. Increasing evidences point out MSC action via sub-cellular entities known as extracellular vesicles (EVs). MSC EVs recapitulate the therapeutic properties of their cellular counterparts while offering remarkable advantages in terms of safety (no proliferation, no differentiation, no vascular occlusion following administration) and shelf life stability. Herein, we evaluated, in a porcine fistula model, the healing potential of allogenic MSC-EVs delivered through a thermoresponsive gel (Pluronic F127) allowing the administration in a sol state through a catheter and gelation *in situ* at body temperature to retain EVs at fistula site.

Aims & Methods: Seventeen esophageal fistulas were surgically created by placing two plastic stents during 30 days into the neck of 9 pigs and randomized into control group (n=6) and treated groups (gel alone n=6 and gel-EVs n=5). In the gel-EVs group, Pluronic F127 gel contained allogenic EVs collected from the swine adipose stem cell conditioned medium. Clinical, endoscopic and radiological evaluation of fistula healing was performed at day 30 and day 45, before histological assessment.

Results: All fistulas were successfully induced at day 30. At day 45, the control group featured open internal and external fistula orifices in all pigs. For this group, radiological evaluation showed open fistula tracts, which were confirmed by histology. In the gel group and gel-EVs groups, radiological examination showed a complete fistula closure in 67% (4/6) and 100% (5/5) of the animals, respectively. In the gel group, histological analysis confirmed a complete fistula for 3 from 6 cases while a partial closure was observed for 1 case from 6. In the gel-EVs group, histological complete fistula closure was reported for 4 from 5 cases while a partial closure was evidenced in 1 from 5 cases. In comparison with control group, treated fistulas showed a reduced inflammatory infiltrate and fibrosis and an enhanced angiogenesis, especially in the gel-EVs group.

Conclusion: This study provides the first evidence in the literature that MSC-EVs may provide a therapeutic effect in a pre-clinical fistula model. EVs were successfully administered via a thermoresponsive Pluronic F127 hydrogel, gelling *in situ* to enable EV retention in the fistula tract. Besides, the gel further provided a pro-angiogenic and an anti-inflammatory effect. The combined action of MSC EVs and the gel enhanced fistula healing associated with an anti-fibrotic effect in this esophageal fistula model. This investigation paves the way towards a future sub-cellular localized fistula therapy merging safety and efficacy.

P0795 REAL-TIME MULTIPHOTON MORPHOLOGICAL IMAGING FOR DIAGNOSING GASTRIC ATYPICAL HYPERPLASIA AND ADENOCARCINOMA

K. He¹, L. Zhao¹, M. Wang¹, X. Wang¹, L. Liu¹, Z. Fan¹

¹The First Affiliated Hospital with Nanjing Medical University, Nanjing/China

Contact E-mail Address: fannzhining@njmu.edu.cn

Introduction: Compared with histopathology, real-time histology or virtual biopsy is important for clinical diagnosis, especially for endoscopic examination. Based on two photon fluorescence (TPEF), multiphoton microscopy (MPM) imaging could demonstrate cell autofluorescence and second-harmonic generation (SHG) signal from collagen, which implied real-time information on tissue architecture and cellular morphology. More importantly, no contrast agent is needed for this live diagnosis. The aim of this study is to evaluate the feasibility of MPM to histologically diagnose gastric diseases, compared with other chromoendoscopy and H&E histopathology.

Aims & Methods: A pilot study was performed between March 2016 and August 2016. 30 gastric tissue slides (normal, low-grade dysplasia (LGD), high-grade dysplasia (HGD), and cancer) were examined under MPM. MPM and H&E images were compared by the experienced pathologist. Cellular-to-nuclei ratio was analyzed to compare morphological features, while the major/minor axis ratio was calculated to reveal cellular asymmetry.

Results: Near-infrared light (800 nm) was optimized and applied for multiphoton autofluorescence imaging in gastric tissue. Under MPM, gastric dysplasia tissue demonstrated enlarged, while cancer cells were characterized by irregular size and shape, enlarged nuclei, and increased nuclear-to-cytoplasmic ratio. All these were confirmed by H&E images. (Figure 1) The mean cellular/nuclei ratio for normal mucosa was 20.55 ± 4.84 , LGD 34.60 ± 3.90 , HGD 46.85 ± 3.22 , and cancer 56.80 ± 3.37 ($P < 0.05$). The mean major/minor axis ratio for normal mucosa was 1.31 ± 0.09 , LGD 2.02 ± 0.16 , HGD 1.70 ± 0.18 , and cancer 1.43 ± 0.18 ($P < 0.05$).

Conclusion: MPM-based optical biopsy was feasible and efficient to clinically diagnose gastric cancer. With miniaturization and integration of endoscopy, MPM will be applied to provide real-time histological diagnosis without invasive biopsy for gastric cancer in the future.

Introduction: Type 2 diabetes (T2D) and fatty liver disease are highly prevalent, often overlapping metabolic disorders where upstream insulin resistance is thought to be a common pathogenic driver. Simultaneous treatment of both conditions has been reported with insulin sensitizing interventions including weight loss, pharmacotherapy (GLP1 receptor agonists, TZDs), and bariatric surgery. Duodenal Mucosal Resurfacing (DMR) is a minimally invasive endoscopic procedure that has demonstrated glycemic efficacy in patients with T2D seemingly via an insulin sensitizing mechanism.¹ We report data supporting 12-month durability of improved metabolic indices in patients with T2D after a single DMR procedure in a single-arm, open-label, multicenter study.

Aims & Methods: In this endoscopic DMR procedure, the duodenal mucosa was treated with hydrothermal ablation using a patented balloon catheter. Efficacy was analyzed in a modified intent-to-treat cohort (mITT, patients who received ≥ 1 ablation) stratified into baseline alanine aminotransferase (ALT) level tertiles – lowest (ALT < 28 U/L), middle ($28 \leq \text{ALT} < 37$ U/L), and upper (ALT ≥ 37 U/L). Change from baseline in ALT, aspartate aminotransferase (AST), body weight, homeostasis model assessment index (HOMA-IR) and HbA1c were analyzed using repeated measures ANOVA. Data are reported as mean(SD).

Results: Baseline ALT and HbA1c in the mITT cohort (n=27; age, 55(9) y; diabetes duration, 6(2.5) y; BMI, 32.5(4.2) kg/m²) were 37.0(20.6) U/L, and 8.7(1.0)%, respectively. 12-month reductions in HbA1c, ALT, AST and weight were -1.0(1.2)% ($P=0.005$), -8(14) U/L ($P=0.18$), -6(7) U/L ($P=0.005$), -2.0(4.2) kg ($P=0.83$) and -3.6 ($P=0.037$). In the upper tertile, ALT reductions from baseline (59 (23) U/L) at 3 and 12-month were -22(15) ($P=0.024$), and -16(20) U/L ($P=0.72$); respective body weight changes were -3.8(2.9) ($P=0.24$), and -1.9(5.9) kg ($P=0.99$). 12-month reductions in AST, HbA1c and HOMA-IR were: -9(7) U/L ($P=0.13$), -1.1(0.5)% ($P=0.002$); and -4.7(5.2) ($P=0.94$). In the middle and lowest tertiles, 12-month ALT reductions were -4(11) and -2(3) U/L.

Conclusion: A single DMR procedure in patients with T2D produced significant reductions in HbA1c up to 12 months in the total cohort. In the highest baseline ALT subgroup, ALT was significantly lower at 3 months and remained lower than baseline at 12 months accompanied by significant lowering of hyperglycemia up to 12 months. Further studies are planned to quantify the efficacy, safety and durability of the hepatic and glycemic effects associated with DMR.

Introduction: Limited data are available with regard to the prevalence of upper gastrointestinal endoscopic findings in asymptomatic healthy individuals as an endoscopy is an invasive and costly procedure.

Aims & Methods: Individuals were recruited from general population in Latvia as part of the GISTAR pilot study. The study group has been referred for an upper endoscopy and was tested for serum pepsinogens and pepsinogen I/II ratio < 3

(Biohit, Plc., Helsinki, Finland) was considered decreased. Data were obtained from 1034 individuals (74% response rate). Upper gastrointestinal endoscopy procedures were performed between February 2014 and June 2016. The study was approved by local ethics committees and the Ethics Committee of the International Agency for Research on Cancer.

Results: Altogether 1034 (45% male) participants (average age 52; min-max 39–64) were enrolled and upper endoscopies performed in the study. Main endoscopic findings were not present only in 21% –219/1034 of asymptomatic individuals. The majority of the participants (n=815, 79%) showed abnormal endoscopic findings including the following: reflux esophagitis A- 18%, reflux esophagitis B- 6%, reflux esophagitis C-1, 3% and histologically confirmed Barrett's esophagus-1.3%. The most common main endoscopic finding was noted gastric erosions 232/1034 (22.4%). The prevalence of gastric peptic ulcer was 2.9% (30/1034) and gastric scar 0.9% (9/1034), but duodenal ulcer 2.3% (24/1034) and duodenal scar 5.9% (62/1034). In addition, three gastric adenocarcinoma cases (0.29%) have been identified during the upper endoscopy. The study showed statistically significant difference between the groups of individuals with normal and decreased pepsinogen tests with gastric polyps 3.6% vs 9.2%, $p=0.02$, gastric erosions 23.6% vs 11.2%, $p=0.04$, duodenal ulcer (scar) 6.5% vs 1%, $p=0.02$, duodenal lymphangiectasia 1.9% vs 6.1%, $p=0.02$ and reflux esophagitis A 18.7% vs 9.2%, $p=0.01$.

Conclusion: In this group of asymptomatic healthy individuals, only 20% showed normal endoscopic findings while the majority had clinically significant findings, some of which were related to the decreased pepsinogens levels. Further studies are needed to confirm our observations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0798 REBAMIPIDE SOLUTION AS A NOVEL SUBMUCOSAL INJECTION PROMOTES HEALING SPEED AND QUALITY OF ESD-INDUCED ULCER BY SUPPRESSING FIBROSIS

A. Fujimoto¹, T. Nishizawa², M. Shimoda³, O. Goto², Y. Ochiai⁴, T. Maehata², T. Akimoto², Y. Mitsunaga⁴, M. Kato², A. Nakayama², M. Sasaki², T. Uraoka², N. Yahagi²

Contact E-mail Address: ai-fujimoto@a8.keio.jp

Introduction: Peroral administration of rebamipide in addition to proton pump inhibitor (PPI) was reported to be effective to promote ulcer healing after endoscopic submucosal dissection (ESD). In this pilot study, we assessed the efficacy and safety of a novel rebamipide solution as a submucosal injection agent for ESD using in vivo porcine models.

Aims & Methods: The protocol was approved by the ethics review board of our animal experimental laboratory in advance (13055-(0)). ESDs of about 30 mm in diameter were performed at four sites in the stomachs of three pigs. An endoscopist blinded to the test agents performed the ESDs with a 2% rebamipide solution at two sites (rebamipide group) and with base solution alone at the other two sites (control group). The safety and the treatment results of rebamipide group were assessed. The gastric ulcer stages were evaluated by endoscopy once weekly up to week 4 after the ESD to determine a healing score based on ulcer staging using the classification of Sakita and Miwa. A1 stage was defined as score 1. A2, H1, H2, S1, S2 were defined as healing score 2, 3, 4, 5, 6, respectively. The average scores of each week were compared in the rebamipide group and the control group. One pig was sacrificed at 1 week after the ESD and the other two were sacrificed at 4 weeks, for pathological evaluation of ESD-induced ulceration and ulcer scarring by HE. The number of neutrophils and width of the fibrosis were also compared between the rebamipide group and control group at 1 week and 4 weeks. Neutrophils were counted in five fields around the ESD-induced ulcer in HE stained sections under $\times 400$ magnification and the average counts of the five fields. The width of the fibrosis was defined as the maximum diameter of α SMA-positive area in the depth direction from the submucosa to the muscle layer at a site of ESD-induced ulceration or ulcer scarring.

Results: There were no adverse events related with the use of the rebamipide solution. The average healing score was significantly higher in the rebamipide group than in the control group at 2 weeks ($p=0.027$). The folds into the centers of the ulcer scars were more regular in the rebamipide group than in the control group at 4 weeks after ESD. In the histopathological assessment of the ulcers at 4 weeks, mucosal healing was remarkably better in the rebamipide group than in the control group, with a thicker and more homogeneous mucosal layer. Fibrosis was significantly less extensive in the rebamipide group than in the control group at 4 weeks ($p=0.02$). In the evaluation of inflammation, the average number of neutrophils was lower in the rebamipide group than in the control group at both 1 week and 4 weeks, but not to a significant extent.

Conclusion: The rebamipide solution appeared to be safe and effective as an injection material for promoting the healing of ESD-induced ulcers. It also seemed to smoothen the folds of the ulcer circumference after ESD by suppressing fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0799 EFFECT OF ILAPRAZOLE ON THE HEALING OF ENDOSCOPIC SUBMUCOSAL DISSECTION-INDUCED GASTRIC ULCER: INTERIM ANALYSIS OF RANDOMIZED, MULTICENTER STUDY

Introduction: The optimal treatment regimen or duration of endoscopic submucosal dissection (ESD)-induced gastric ulcer has not been established. The aim of this study was to assess the efficacy of novel PPI, ilaprazole for the treatment of ESD-induced gastric ulcer.

Aims & Methods: This was a prospective, open-label, randomized multicenter study. Between June 2015 and April 2017, a total of 88 patients who underwent ESD for gastric neoplasm were randomly allocated with ilaprazole 20 mg or rabeprazole 20 mg daily for 8 weeks. The primary outcome was ulcer healing rate at 4 and 8 weeks.

Results: In the intention-to-treat analysis, the ulcer healing rate of each treatment group was not significantly different at 4 or 8 weeks (ilaprazole vs. pantoprazole; 96.7% vs. 96.4%, $P=0.80$ at 4 weeks, 99.7% vs. 99.0%, $P=0.19$ at 8 weeks). There was no independent predictive factors for a high ulcer healing rate in the multivariate analysis.

Conclusion: According to this interim analysis of trial, ilaprazole and rabeprazole showed no significant difference in the healing of artificial gastric ulcer. Most of the ulcers achieved complete healing within 4 to 8 weeks.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: ESD is the standard treatment for early gastric cancer and less invasive procedure compared with gastrectomy. Proton pump inhibitors (PPIs) have been widely used for the treatment of ESD-induced gastric ulcers. Many studies have reported that it is critical issues for ESD procedure to prevent post-operative bleeding. Vonoprazan, a potassium-competitive acid blocker (P-CAB), has a strong and continuous inhibition of gastric acid secretion, and is expected to improve effectively ESD-induced gastric ulcerations compared to the treatment with PPIs.

Aims & Methods: To determine whether vonoprazan can ameliorate more effectively ESD-induced gastric ulcerations and can reduce the incidence of post-operative bleeding than PPIs, we compared healing rate of ulcerations and bleeding incidence in the patients treated with vonoprazan with those treated with PPI. 139 patients who underwent gastric ESD between January 2015 and December 2016 were enrolled in Nippon Medical School Hospital. 11 patients who were injected triamcinolone into mucosa preventing stricture of the prepylorus were excluded. 59 patients were treated with P-CAB for 4 weeks (P-CAB group) and 69 patients were treated with PPI (4 omeprazole, 22 esomeprazole, 11 lansoprazole or 32 rabeprazole) for 4 weeks (PPI group), and subsequently underwent endoscopy for evaluation of ulcer size and intra gastric pH using gastric juice. The area of ulcerations was approximated by multiplying the length (mm) by the width (mm).

Results: The shrinking rate of ESD-induced ulcer at 4 weeks after ESD were not significantly ($95.4 \pm 8.1\%$ and $94.5 \pm 6.4\%$, $p=0.4852$) different between P-CAB and PPI groups. The post-ESD bleeding incidence (6.8%) in the P-CAB group were not significantly ($p=0.8189$) different from that (5.8%) in the PPI group. The intra gastric pH at 4weeks after ESD in the P-CAB group was significantly higher than that in the PPI group (6.9 ± 1.0 vs 6.1 ± 1.9 , respectively, $p=0.0028$).

Conclusion: Vonoprazan is superior to PPI in acid suppression, but there were no significant differences in ulcer healing and bleeding incidence between the two groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0801 INFLUENCE OF ANTITHROMBOTIC THERAPY ON DELAYED BLEEDING AFTER GASTRIC ESD: A RETROSPECTIVE ANALYSIS IN 665 CASES

H. Noda, N. Ueki, T. Akimoto, G. Ikeda, K. Higuchi, S. Agawa, Y. Maruki, H. Yamawaki, Y. Kodaka, T. Kawagoe, K. Miyake, S. Futagami, K. Iwakiri
Gastroenterology, Nippon Medical School Hospital, Bunkyo-ku, Tokyo/Japan

Introduction: Endoscopic submucosal dissection (ESD) for superficial gastric neoplasms is gaining an acceptance as one of curative treatment options. However, delayed bleeding still exists as a major complication of ESD. On the other hands, the number of patients taking antithrombotic agents are increasing because the evidence of antithrombotic therapy for prevention of thrombotic events has been established and population aging advances, which is thought to be a serious problem related to increasing delayed bleeding after ESD.

Aims & Methods: To assess the influence of antithrombotic therapy on delayed bleeding after ESD, we retrospectively investigated the delayed bleeding rate after ESD among the continuation of antithrombotic agents, the cessation of antithrombotic agents and heparin bridge therapy. 735 lesions in 665 patients were treated with ESD from January 2006 to December 2016. We compared the delayed bleeding rate in 153 patients receiving antithrombotic therapy with 512 patients without that. Furthermore, we compared the delayed bleeding rate in the patients continuing antithrombotic therapy with that in the patients with the cessation of antithrombotic therapy or with heparin bridge therapy. The patients who were taking two or more antithrombotic agents were treated with continuation aspirin or cilostazol. The cessation period of antithrombotic therapy before ESD followed the guidelines for therapeutic endoscopy in antithrombotic agents-users from Japan Gastrointestinal Endoscopy Society. We defined delayed bleeding as a hematemesis, a melena, or a decrease of Hb >2 g/dl.

Results: The delayed bleeding rate in the patients receiving antithrombotic therapy was 14.4% (22/153), which was significantly higher than that in the patients without antithrombotic therapy (5.7%; 29/512) ($p=0.0007$). The median timing of delayed bleeding in patients receiving antithrombotic therapy and that in patients without antithrombotic therapy were 5.7 ± 4.6 days and 7.0 ± 6.8 days, respectively, without significant difference ($p=0.48$). Of 153 patients taking antithrombotic therapy, 38 continued a single antithrombotic agent (all of them were antiplatelet drugs) during ESD (continuation group), 38 discontinued antithrombotic therapy and resumed it after ESD (cessation group), and 30 switched to heparin therapy before ESD (heparin bridge group). One patient was excluded because of uncertain about the period of cessation. The delayed bleeding rate of continuation group, cessation group and heparin bridge group were 13.2% (5/38), 13.1% (11/84) and 20.0% (6/30), respectively, without significant difference ($p=0.63$). The delayed bleeding rate of continuation group was equal to that of cessation group ($p=0.60$). The delayed bleeding rate of heparin bridge group seemed to be high (20.0%), but there was no significant difference compared to that of total number of continuation and cessation group (13.1% (16/122), $p=0.24$). Deep vein thrombosis was observed in one patient in the cessation group.

Conclusion: Antithrombotic therapy increased the delayed bleeding rate. However, the delayed bleeding rate in the patients continuing antithrombotic therapy during ESD was similar to that in the patients discontinuing antithrombotic therapy before ESD. Therefore, it is appropriate that the patients with high risk of thrombosis continue antithrombotic therapy on gastric ESD, but the heparin bridge therapy requires a further examination.

Introduction: Endoscopic submucosal dissection (ESD) permits en bloc resection for larger lesions. The number of the patients taking anti-thrombotic agents including low-dose aspirin (LDA) has increased. The Japanese guidelines recommended endoscopic procedures without interruption of LDA therapy in patients at high risk of thrombotic events who use LDA alone. And, bile acid reflux is known to cause gastric mucosal damage though the exact mechanisms are still unclear.

Aims & Methods: In this study, we aimed to clarify whether LDA treatment and gastric bile acid contents synergistically affect on postoperative bleeding and healing of ulceration after gastric ESD procedure. A total 224 patients with gastric neoplasms were treated with ESD at Nippon Medical Hospital, between January 2013 and June 2016. To investigate whether anti-thrombotic agents affect the ESD procedure-induced ulceration and ESD postoperative bleeding rate, we compared ulceration reduction rate (one month after ESD), postoperative bleeding rate and gastric bile acid contents among the patients treated with low dose aspirin, other anti-thrombotic agents and non-antithrombotic agents. On the day of ESD and one day after ESD, gastric juice was taken in endoscopy and total bile acids were measured spectrophotometrically after the enzyme reaction.

Results: Ulcer reduction rate in the patients treated with LDA was significantly ($p=0.0036$) higher compared to that in the patients with non-anti-thrombotic agents. ESD postoperative bleeding rate in the patients with LDA was significantly higher ($p=0.028$ and $p<0.0001$, respectively) compared to those in the patients with other anti-thrombotic agents and the patients with non anti-thrombotic agents. The difference of gastric bile acid contents between pre- and post-ESD procedure in the patients with low dose aspirin was significantly ($p=0.0426$) higher compared to that in the patients with non anti-thrombotic agents.

Conclusion: LDA increased gastric bile acid contents, which delayed the ulcer healing and increased the bleeding after ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0803 NARROW-BAND IMAGING (NBI) ENDOSCOPY WITH DUAL FOCUS MAGNIFICATION FOR CHARACTERIZATION OF GASTRIC NON-NEOPLASTIC AND NEOPLASTIC LESIONS

R. Kuvaev¹, S. Kashin¹, A. Aleshicheva¹, E. Kraynova², A. Nadezhin², E. Nikonov³

Introduction: Advanced endoscopic imaging has become an essential part of the diagnostic algorithm for characterization of gastric lesions. NBI endoscopy with magnification allows enhancing visualization of gastric mucosa and provides accurate pathology prediction. European Society of Gastrointestinal Endoscopy (ESGE) recommends the application of validated classification systems to support the use of optical diagnosis [1]. The improvement of current classifications and development of validated criteria or scales for diagnosis by advanced endoscopic imaging are a key areas of research for the endoscopic community.

Aims & Methods: The aim of this study was to evaluate the diagnostic accuracy of NBI features described in ESGE proposed NBI classification for gastric precancerous and neoplastic lesions [2]. 180 gastric lesions in 97 patients (mean age 59.7 years, SD=13.7, 48% male, 52% female) were observed with NBI endoscopy and dual focus magnification (GIF- HQ190, Exera III, Olympus, Japan). Mucosal and vascular patterns were classified into type A (regular circular mucosal pattern with regular vessels), type B (regular tubulo-villous mucosal pattern with regular vessels) and type C (irregular mucosal and vascular pattern), presence of "light blue crests" - LBC (blue-whitish areas) and demarcation line were assessed. Forceps biopsy or endoscopic mucosal resection/endoscopic submucosal dissection were performed for a histological evaluation of lesions.

Results: From 180 gastric lesions (62 lesions with chronic gastritis, 67 - intestinal metaplasia (IM), 20 - hyperplastic polyp, 5 - low-grade dysplasia, 10 - high-grade dysplasia, 16 - adenocarcinoma) 70 lesions had pattern A, 62 lesions - pattern B (36 lesions were LBC positive and 26 lesions were LBC negative) and 28 lesions - C pattern (table 1). 20 lesions of hyperplastic polyps had specific "coarse" pattern and were not classified due to the absence of appropriate category. Demarcation line was identified in 2%, 66% and 100% of lesions with pattern A, B, and C, respectively.

Conclusion: ESGE proposed NBI classification for gastric precancerous and neoplastic lesions demonstrated high diagnostic accuracy in detection intestinal metaplasia and neoplasia. Combination of pattern B, LBC and demarcation line was found to be the most accurate criterion for intestinal metaplasia. Benign hyperplastic polyps were characterized by specific pattern that need to be validated in further studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Esophageal endoscopic submucosal dissection (ESD) to remove superficial esophageal neoplasms is gradually becoming the standard treatment for superficial esophageal cancer, but is associated with esophageal stenosis, particularly when ESD involves the entire circumference of the luminal. Many methods to prevent post-ESD stricture, such as repeated Endoscopic balloon dilatation (EBD), temporary stent insertion, and oral steroid and intralesional steroid injection, have been used in different institutions. In recent years, new technologies such as autologous oral mucosal sheets or extracellular matrix scaffold material have also been suggested to manage esophageal strictures. There are no standard guidelines to prevent stricture in a patient with circumferential mucosal defect after ESD. In this study, we aimed to assess the effectiveness and safety of endoscopic transplantation of autologous esophagus mucosa in preventing formation of strictures after ESD.

Aims & Methods: We performed a single-arm, single-institute study. Nine patients who underwent wholly circumferential ESD for superficially extended

Abstract No: P0803**Table 1:** Results of the study

Pattern or endoscopic feature	Pattern A	Pattern B	LBC	Pattern B + LBC + demarcation line	Pattern C

esophageal squamous cell carcinoma at the endoscopic center of Xinqiao Hospital, Third Military Medical University (Chongqing, China) from January 2015 to February 2017, were enrolled in this study. We collected specimens of autologous esophageal mucosal tissue from these patients. After undergone ESD, these mucosal patches were first attached to the “ulcer surface” by hemoclips and then fixed by means of a covered metal mesh stent. The stent was removed on post-procedure day 7. All patients were monitored by endoscopy.

Results: En bloc ESD was safely achieved in all cases. The overall longitudinal diameter of resected specimens was 117.8 mm (range, 70 to 150 mm). Autologous esophagus mucosa were successfully transplanted to “ulcer surface” using an endoscope. The number of mucosal patches ranged from 8 to 28. Complete re-epithelialization occurred within a median time of 8.6 days with a graft survival rate at 93.06%. Postprocedural stricture accompanied by dysphagia occurred in seven patients on post-procedure day 24.7 (range, 18–34 days). The median sessions of EBD and intralesional steroid injection was 3.3 (range 1–6). No other serious complications occurred in these patients, such as immediate bleeding and perforation. Eight patients were still alive during the mean follow-up period of 11.6 months (range, 2.5 to 21 months). One patient developed lung metastasis and died of the disease 15 months after ESD.

Conclusion: Transplantation of autologous esophagus mucosa appears to be a safe means of relieving the severity of esophageal stenoses following Circumferential ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0805 ENDOSCOPIC CLOSURE OF POST-SURGICAL FISTULAS OR PERFORATIONS WITH OVER-THE-SCOPE-CLIP

P. Santos¹, D. Reis¹, C. Noronha Ferreira¹, J. Lopes¹, L. Carrilho Ribeiro¹, J. Velosa¹

¹Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, Lisbon/Portugal

Contact E-mail Address: patricia.sants@hotmail.com

Introduction: Gastrointestinal perforations and post-surgical fistulas are feared complications with high morbidity and mortality. The over-the-scope-clip (OTSC) has been successfully used for its resolution.

Aims & Methods: We aimed to evaluate the therapeutic efficacy of OTSC in the management of upper digestive tract post-surgical fistulas or perforations.

This was a retrospective review of consecutive patients at a single center from January 2011 to January 2017 who underwent upper endoscopy with attempt OTSC placement for the closure of post-surgical fistulas or perforations. Statistical analysis: IBM SPSS 23.0.

Results: A total of 18 patients (72% women), with a mean age of 48.9 ± 18.1 years were treated with an OTSC for the closure of post-surgical fistulas or perforations. Mean fistulas size was 5.8 ± 3.5 mm. Median follow-up time was 20.5 (5–84) months.

Etiology of fistulas: post-surgical (n = 16), perforation by foreign body (n = 1) and after endoscopic procedure (n = 1). Location of the fistulas: cardia (33%), esophagus (28%), gastric body (16%), antrum (11%), esophagus-jejunal anastomosis (6%) and duodenal bulb (6%).

Overall clinical success rate was achieved in 72.2% (n = 13). Fistulas were successfully closed in both non-surgical cases.

Regarding post-surgical fistulas (n = 16), 50% (n = 8) were after bariatric surgery. There was a clinical success rate of 68.8% (n = 11). The median time between surgery and the endoscopic intervention was 20.5 (2–550) days. There was no association between clinical success and the time between surgery and the endoscopic intervention (p = 0, 624) or the location of the fistula (p = 0, 334). In 1 case, endoscopic re-intervention with placement of OTSC was required due to persistence of fistula. In 5 (31%) cases the OTSC was not effective, requiring endoscopic re-intervention with stent placement (n = 2) or surgical intervention (n = 3). The overall recurrence rate was 11% (n = 2).

Conclusion: OTSCs can be safely and effectively used in patients presenting with post-surgical fistulas or perforations and, when feasible, may be more

advantageous and less costly than surgery. Further research is required to characterize the determinants of long-term success and risk factors for failure.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Early neoplastic lesions in Barrett's Esophagus (BE) can be effectively and safely removed by endoscopic resection (ER) using multi-band mucosectomy (MBM). Recently a new MBM device became available, designed for improved visualization, easier passage of accessories, and better suction power compared to other marketed MBM devices.

Aims & Methods: This study aims to document performance of the new MBM device for ER of early neoplastic lesions in BE.

This is a company sponsored, international, multicenter, single-arm, prospective registry study enrolling 300 subjects with early neoplasia in BE. Primary endpoint is successful ER defined as complete resection of the delineated target area in one procedure. Secondary outcomes: adverse events, procedure time.

Results: To date 259 subjects have been enrolled at 14 centers (Europe 10, US 3, Canada 1). Mean age was 67 ± 9 years, with 87% males. In these 259 subjects, a total of 301 lesions were removed using the new MBM device, with a mean of 2.5 ± 1.92 resections per procedure. Indication for ER was high-grade dysplasia (HGD) in 65%, early adenocarcinoma in 20%, visible lesion with low-grade dysplasia in 10%, and a visible lesion suspicious for neoplasia without pre-treatment histology in 5%. The primary endpoint of successful ER of a target lesion

was reached in 290/301 (96%) procedures. A perforation occurred in 3/301 ER procedures (1%, 95% CI 0.21%–2.88%). Two perforations were closed with clips, all three patients received intra-venous antibiotics and were admitted to hospital for 2, 3 and 9 days. Bleeding requiring intra-procedural hemostasis occurred during 15% of procedures. Significant post-procedural bleeding requiring an intervention occurred in 5 cases (2%). Dysphagia requiring endoscopic dilatation occurred in 7 patients (3%), after ER with a mean number of 4±2.9 resected pieces. Mean total procedure time for ER using the new MBM device was 33±17.1 minutes.

Conclusion: The new MBM device used in this study proved to be effective for resection of early neoplastic lesions in BE: successful ER was achieved in 96% of procedures. Perforations were seen in 1% and significant post-procedural bleeding in 2%, complications were effectively managed endoscopically.

P0807 COST-EFFECTIVE ANALYSIS COMPARING STANDARD BIOPSY VS. DIGITAL BIOPSY BY CONFOCAL ENDOMICROSCOPY

C. Robles-Medrand, M. Valero, J. Ospina, M. Puga-Tejada, H. Alvarado-Escobar, M. Soria, H. Pitanga-Lukashok

Introduction: Endoscopy has greatly influenced gastroenterological diagnosis. However, most lesions can be suspected but not certainly diagnosed only on the basis of endoscopic findings and therefore histology is needed. On the other hand the reliability of detecting lesions histologically depends on the site, number, and size of biopsy (Bx) specimens with a 20–30% probability of sampling mistakes. Probe based Confocal Laser Endomicroscopy (p-CLE) allows endoscopic in-vivo mucosal cellular evaluation of the gastrointestinal (GI) tract with a high (90%) diagnostic accuracy. It allows to perform target Bx. Moreover, the NPV is >98%. There is no information in the literature regarding the economic impact of performing digital biopsies (DBx) by p-CLE.

Aims & Methods: The aim of this study is to perform a cost-effectiveness analysis comparing the diagnosis of upper GI tract pathologies using only standard Bx following the literature recommendations (LR) vs. the diagnosis with DBx using p-CLE. This was a retrospective study with prospective collection data of patients included from Jan 2014 to Nov 2016. The pathologies included for p-CLE evaluation are summarized in Table 1. The diagnosis costs using standard Bx was calculated following the literature recommendations (Table 2). The standard Bx costs included the histological process and physician honoraria per Bx (USD 50.00), and one biopsy forceps per patient (USD 38.00). The DBx costs by p-CLE included the probe, the processor and the physician honoraria (USD 500.00). Baseline characteristics, p-CLE indications, the diagnostic accuracy of p-CLE and costs were described.

Results: 78 patients were included, 51.2% were female. The mean age was 50.18 years old. p-CLE indications distribution was: esophagus 29 (37.2%), stomach 46 (59%) and duodenum 3 (3.8%) subgroups. Biopsies were performed in 71/78 cases (91.0). Table 1 shows the procedure cost reached with the different pathologies, by following the Bx LR for initial diagnosis and follow-up. The efficacy of p-CLE in our study was 91.7% sensitivity, 89.8% specificity, 64.7% PPV, 98.2% NPV and 90.1% accuracy for the diagnosis of the malignant upper GI tract pathology, by Digital Biopsy with p-CLE. Finally, the cost-effective analysis showed that when applying p-CLE a diminishing cost in \$ 188 USD and \$138 USD is detected if more than 10 biopsies are attempted by procedure.

Table 1: Cost analysis following the Literature Recommendations (LR) for initial diagnosis and follow-up

Pathology	No. of Bx by LR	No. of Bx by Updated Sydney System	No. of total Bx	Total cost of Bx ^c (USD)
Esophageal Tumor ^a	8	–	8	438.00
Barrett's Esophagus 1 to 3.9 cm ^{a, b}	4	–	4	238.00
Barrett's Esophagus ≥4 cm ^{a, b}	8	–	8	438.00
Gastric Tumor ^a	8	5	13	688.00
Gastric Atrophy and/or Metaplasia ^{a, b}	12	–	12	638.00
Gastric Ulcer ^a	8	5	13	688.00

Bx: biopsies; LR: Literature Recommendations. a. For initial diagnosis. b. For follow-up. c. Cost includes histological process and physician honoraria per biopsy (USD 50.00), and the Bx forceps per patient (USD 38.00).

Conclusion: In our population, the digital biopsy by p-CLE proved to be more cost-effective, when ≥10 biopsies were indicated, like in cases of a Barrett's Esophagus ≥4 cm, a Gastric Tumor, or in the context of two or more suspected pathologies (e.g.: esophageal and gastric disease).

P0808 GASTRIC PER-ORAL ENDOSCOPIC PYLOROMYOTOMY (G-POEM) IN THE TREATMENT OF REFRACTORY GASTROPARSIS: EXPERIENCE OF THE FIRST 9 CASES IN A MEXICO

O. V. Hernandez Mondragon, R. Palos Cuellar, G. Blanco Velasco, J.M. Blancas-Valencia, M. L. Hernandez Reyes

Endoscopy, IMSS, Mexico city/Mexico

Contact E-mail Address: mondragonmd@yahoo.co.uk

Introduction: Gastroparesis is a syndrome characterized by a delayed gastric emptying in absence of a mechanic obstruction. Reduction in QOL scores have been observed. Etiologies include: idiopathic, diabetic, post-surgical. Diagnosis is based on the combination of symptoms and a delayed gastric emptying scintigraphy (GES) of >10% after 240 min. Multiple treatments have been used with temporary results or high morbidity, so new treatment options have been explored. G-POEM is a new endoscopic treatment which is based in the POEM treatment for achalasic patients and consist in a creation of a submucosal tunnel in order to perform an endoscopic pyloromyotomy. Initial results have been promising.

Aims & Methods: The aim of this study was to evaluate the safety and efficacy of G-POEM in a group of Mexican patients with refractory gastroparesis. This prospective study was carried out in a tertiary care center in Mexico city, between December 2016 and April 2017. We included patients with refractory gastroparesis defined as presence of symptoms such as: nausea, vomiting, early satiety with inability to finish a normal meal, bloating and upper gastrointestinal pain. These patients were on medical treatment and didn't respond and have a positive gastroparesis cardinal symptom index (GCSI) score combined with a >10% of retention at 240 min in the GES study. Exclusion criteria were malignancy, peptic ulcer disease, normal GES and coagulation disorders. Procedure steps were based in POEM procedure, beginning 5cms before the pyloric arch with an longitudinal incision, then submucosal tunnel creation, myotomy of the pyloric arch up to the serosa and 2cms before this point and finally closure with clips. Follow-up included GCSI, endoscopy and GES at 3 months after procedure. Characteristics of procedure, and patients were documented. Student paired t-test was used for comparisons between groups and p < 0.05 was considered as statistically significant.

Results: There were 9 patients included in this initial study, the mean age was 42.4±8.5 years. 6 patients were female and 3 male. The most common etiology was postsurgical 4/9 (44.4%), followed by diabetic 3/9 (33.3%) and idiopathic 2/9 (22.2%). The mean G-POEM time was 61.4±7.8 min, and complications were self-limited and presented in only 4 patients. The GCSI score decreased 68% between the pre-procedure levels as well as the GES which decreased 67% compared with levels at 3 months after G-POEM (34.3±5.8 vs 13.1±3.2 p=0.003/20.74±5.3 vs 6.83±1.78 p=0.001 respectively). 7/9 (77.7%) normalized the GES (<10% at 240 min). Endoscopy at 3 months after procedure didn't show any complication (Table 1).

Conclusion: G-POEM is a safe and effective procedure in Mexican patients with refractory gastroparesis with a normalization of the GES in up to 77% of these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

towards endoscopic management of FBs had been reported. No direct evidence has demonstrated the relationship between duration of FB impaction and outcomes of endoscopic management. Moreover, it remained unclear whether endoscopic management of FBs under general anaesthesia could improve endoscopic outcomes when compared with topical pharyngeal anaesthesia.

Aims & Methods: The aim of the present retrospective study is to analyze our endoscopic outcome and explores the best timing and anaesthesia methods of endoscopic intervention in population with FB ingestion. All consecutive patients suspected of FB ingestion were enrolled. The demographic, clinical and endoscopic data were collected and analyzed.

Results: Totally, 1294 cases were recruited in this retrospective research. The ages ranged from 7 months to 94 years, with a median age of 47.0 (31–63) years. The majority of patients (1191/1294 cases, 92.0%) presented with some symptoms after FB ingestion, in order of frequency odynophagia (415 cases, 32.1%), foreign body sensation (340 cases, 26.3%) and sore throat (267 cases, 20.1%). The duration of FB impaction ranged from 4 hours to more than 2 years with a median time of 1 (0.63–3) days. Bony FBs, jujube pit, food bolus and dental prosthesis were the most frequent FBs in population. Anatomically, FBs were mostly impacted in the oesophagus (n=1025, 86.9%), especially in the upper oesophagus (n=832, 70.5%), followed by stomach (n=95, 8.1%), duodenum (n=36, 3.0%) and pharynx (n=24, 2.0%). Nearly half of the patients (49.9%) developed FB-related complications, mainly including mucosal injuries (356 cases, 27.5%) and ulcers (210 cases, 16.2%). The most common underlying pathologies were oesophageal stricture (35 cases, 39.3%) and oesophageal cancer (11 cases, 15.5%). As the duration of FB impaction increased, positive finding and successful removal of FB by endoscopy significantly decreased ($p < 0.001$). Furthermore, complication rate significantly increased with time ($p < 0.001$). Age (OR=1.15, 95%CI: 1.20–1.91, $p < 0.001$), type and location of FBs (OR=4.51, 95%CI: 2.95–6.90, $p < 0.001$; OR=2.26, 95%CI: 1.48–3.46, $p < 0.001$), anaesthesia methods (OR=1.35, 95%CI: 1.05–1.75, $p = 0.02$) and duration of FB impaction (OR=1.74, 95%CI: 1.50–2.00, $p < 0.001$) were verified as risk factors for development of FB-related complication by logistic regression analysis. General anaesthesia could not improve positive FB detection ($p = 0.818$) or success rate of endoscopic management of FBs ($p = 0.135$), as well as decrease the complication rate when compared with topical pharyngeal anaesthesia (52.3% VS 47.5%, $p = 0.033$).

Conclusion: FB-related complication rate increased with time, endoscopic management under general anaesthesia could not improve therapeutic effects when compared with topical pharyngeal anaesthesia. Overall, Patients suspected of FB ingestion should receive endoscopic management as soon as possible.

P0810 CLINICAL OUTCOMES AFTER ENDOSCOPIC RESECTION FOR ESOPHAGEAL SQUAMOUS CELL CARCINOMA COMPARING THE CASES WITH MM AND SMI INVASION

S. Yoshimizu¹, T. Yoshio², K. Namikawa², A. Ishiyama², T. Tsuchida¹, J. Fujisaki²

¹Cancer Institute Hospital, Tokyo/Japan

²Gastroenterology, Cancer Institute Hospital, Tokyo/Japan

Contact E-mail Address: toshiyuki.yoshio@jfc.or.jp

Introduction: Recent advances in endoscopic resection (ER) provide us increasing chances for resecting esophageal squamous cell carcinoma (ESCC) with muscularis mucosae (MM) and SMI invasion. As MM/SMI invasive cancer is reported to have 8–20% of metastatic risks and is defined as relative indication for ER in guideline by Japan Esophageal Society. For them, we perform additional therapy such as chemo radiotherapy (CRT) or operation considering the risk of metastasis and patients' condition.

Aims & Methods: To know the difference of metastatic risk and long time outcomes, we retrospectively studied 121 cases of ESCC with pathological MM/SMI invasion (MM/SMI:97/24) resected by ER from 2003 to 2013 in Cancer Institute Hospital. After pathological diagnosis of resected lesions, we performed additional therapy such as CRT, radiation therapy (RT) or operation, to the cases with lymphovascular invasion (LVI) or droplet infiltration (DI). Median observation period was 48 months.

Results: Enrolled cases included 112 males and 9 females and their median age was 66 (39–86). We resected ESCC by ESD in 71 cases and by EMR-C in 50 cases

and their median size was 27 mm. Local recurrence was observed in 6 cases which were all after EMR (12%). As for local recurrence 5 cases were treated by re-EMR and 1 case by APC, resulted in no re-recurrence. Of 97 cases of MM, 15 cases (15.5%) had LVI, 10 cases (10.3%) had DI. We recommended additional therapy in 21 cases (21.6%). Additional therapy was performed in 15 cases (15.5%) (ope/CRT/RT:9/5/1). No case died of ESCC and 22 cases (22.7%) died of other diseases. Of 24 cases of SMI, 9 cases (37.5%) had LVI, 5 cases (20.8%) had DI. We recommended additional therapy in 12 cases (50.0%). Additional therapy was performed in 9 cases (37.5%) (ope/CRT/RT/chemotherapy: 3/4/1/1). Three cases died of ESCC and 5 cases (20.8%) died of other diseases. Comparing both groups, tumor size and local recurrence rate were not different each other. The frequency of LVI was significantly higher in SMI than in MM ($p < 0.05$) and the frequency of DI was higher in SMI, although not significant ($p = 0.161$). The metastatic recurrence was observed significantly frequent in SMI than MM (16.7% vs 2.1%; $p < 0.01$). The 5-year overall survival (OS)/disease specific survival (DSS)/relapse free survival (RFS) were 81.7%/100%/94.1% for MM and 62.9%/87.9%/91.7% for SMI. OS and RFS were not different each other, however, CSS was superior in MM than in SMI ($p < 0.01$).

Conclusion: ESCC with MM invasion was superior in metastatic recurrence and CSS than ESCC with SMI invasion, although we treat MM/SMI in the same way. Additional therapy should be considered more positively in cases of SMI than in cases of MM, considering metastatic risk and patients' conditions.

Introduction: ESD in generally is still under evaluation. The one-piece resection of lesions larger than 2 cm has many advantages against piece meal resection. One problem in ESD is to lift and prepare the specimen simultaneously. We used the ANUBIS-system for intragastric ESD.

Aims & Methods: The experimental study was conducted in a porcine model in general anesthesia. We started the study with 7 pigs in a survival model using the Anubisscope (Karl Storz, Germany). After insertion of the scope insufflations of the stomach was done using CO₂. After the opening of the valves at the tip of the scope, an area of 5 cm in diameter was selected for resection. Injection was done through the working channel with a hyperosmolar solution added with blue colour. After circle incision, preparation was done with the two arms of the scope using a grasper and a hook-knife. Also the grasper could use for coagulation. The specimen was removed with the scope after closing its valves.

Results: The procedure was successful in all animals with operation time ranging from 102 to 189 minutes with a learning curve. After weight gain in all cases, the animals were sacrificed after postoperative day 42 and the workup showed competent healing with a star-like scar.

Conclusion: The use of an operating platform like the Anubisscope has the advantage of flexible preparation in opposite position of the instruments in ESD. The disadvantages are the only two degrees of freedom of the flexible instruments and the rotation-like movements. Also, it is not possible to reach all regions of the stomach.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0812 USEFULNESS OF NARROW BAND IMAGING WITH MAGNIFYING ENDOSCOPY AS A SCREENING TEST FOR GASTRIC CANCER

T. Morinushi

Gastroenterology, Kameda Medical Center, Chiba/Japan

Contact E-mail Address: moristatu@yahoo.co.jp

Introduction: Narrow band imaging with magnifying endoscopy (NBI-ME) is useful for diagnosis of gastric cancer; however, whether NBI-ME is useful as a screening test for gastric cancers has not yet been determined. Additionally, it is important to consider the impact on the atrophy of the background gastric mucosa in gastric cancer screening because the incidence of gastric cancer depends largely on the degree of atrophy noted in the background gastric mucosa.

Aims & Methods: We aimed to determine the usefulness of NBI-ME as a screening tool for gastric cancer. We retrospectively studied 3515 patients who had undergone screening upper gastrointestinal endoscopy between April 2013 and March 2014. We excluded patients with advanced gastric cancer and those who had undergone gastrectomy. Thus, we studied 1080 patients who received NBI-ME and 2435 patients who had undergone conventional endoscopy. We classified the degree of atrophy of the background gastric mucosa using the Kimura-Takemoto classification. Severe atrophy was noted in 1620 patients (Group S), and mild atrophy in 1895 patients (Group M). We evaluated the biopsy rate, the detection rate of gastric neoplasms, and the accuracy of biopsy using NBI-ME compared to conventional endoscopy.

Results: The biopsy rate of NBI-ME and conventional endoscopy in Group M was 5.4 and 7.7%, respectively, while in Group S it was 14.9 and 14.8%, respectively. The biopsy rate did not differ significantly between those who received NBI-ME and those who had undergone conventional endoscopy. The detection rate of gastric neoplasms using NBI-ME and conventional endoscopy in Group M was 0 and 0.2%, respectively, while in Group S it was noted to be 4.2 and 1.8%, respectively. Thus, the detection rate of NBI-ME was significantly higher than that of conventional endoscopy in Group S ($p < 0.01$). The accuracy of biopsy with NBI-ME and conventional endoscopy in Group M was 0 and 3.2%, respectively, but in Group S was noted to be 36.4 and 14.1%, respectively. Thus, the accuracy of biopsy using NBI-ME is significantly superior to conventional endoscopy in Group S ($p < 0.01$).

Conclusion: NBI-ME as a screening test for gastric cancer is useful for patients with severe atrophy of the background gastric mucosa because this technique has shown a higher detection rate of gastric neoplasms and better accuracy of biopsy.

Introduction: ME-NBI is an important modality to diagnose early gastric cancer. A unified diagnostic system, the magnifying endoscopy simple diagnostic algorithm for early gastric cancer (MESDA-G), was proposed in 2016 by Muto et al. [1] and was thought to become a future mainstream system. Although the usefulness of ME-NBI has been often reported [2, 3], some cases are difficult to diagnose with ME-NBI.

Aims & Methods: We aimed to clarify endoscopic and histological features of difficult-to-diagnose cases using MESDA-G. We retrospectively analyzed 362 cases of early gastric cancer that underwent endoscopic resection at our hospital from January 2013 to December 2016. Lesions for which ME-NBI images were not taken at maximum magnification or difficult to evaluate because of mucus or erosions were excluded. After exclusion, a total of 350 lesions were enrolled in this study. Two expert endoscopists reviewed ME-NBI images of all lesions. Lesions diagnosed as non-cancer by both experts were defined as ME-NBI incorrect diagnosis lesions (ME-NBI-IDL). ME-NBI and histopathological findings of ME-NBI-IDL were analyzed. ME-NBI findings were defined according to the presence (+) or absence (-) of a demarcation line (DL) and regular (R), irregular (I) or absent (A) of micro vascular (MV) and micro surface (MS) patterns.

Results: Of 350 lesions, 32 (9.1%) were ME-NBI-IDL. Macroscopic types were I/IIa/IIa + IIc/IIb/IIc = 3/13/2/7/7, respectively. Twenty-seven of ME-NBI-IDL showed DL (-). Five of ME-NBI-IDL showed R or A of MS/MV patterns, despite of DL (+). The details were as follows; In the DL (-) group, MV/MS were R/R:25, I/R:1, and R/A:1. In the DL (+) group, MV/MS were R/R:4 and A/R:1. Histological types of ME-NBI-IDL were gastric adenocarcinoma of fundic gland type (GAFG)/well-differentiated carcinoma (well)/well-to-moderately differentiated carcinoma (well to mod)/papillary carcinoma (pap)/signet ring cell carcinoma (sig) = 20/4/1/1/6, respectively. Diagnostic difficulties were caused by two histological findings: 1) low-grade atypia type; surface structure of cancerous lesion was similar to surrounding mucosa due to very low-grade atypia (well/well to mod/pap = 4/1/1, respectively.), 2) covered type; cancer was unexposed to the superficial mucosal layer (GAFG/sig = 20/6, respectively).

Conclusion: Diagnostic limitations of ME-NBI (MESDA-G) were dependent on distinct histological characteristics. However, we suggest that the low-grade atypia type might be able to diagnose correctly by improving diagnostic accuracy of ME-NBI.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0814 BEST PRACTICE IN PLACEMENT OF PERCUTANEOUS ENDOSCOPIC GASTROSTOMY WITH JEJUNAL EXTENSION TUBE FOR CONTINUOUS INFUSION OF LEVODOPA CARBIDOPA INTESTINAL GEL IN THE TREATMENT OF ADVANCED PARKINSON'S DISEASE: THE ROLE OF GASTROENTEROLOGIST

A.G. Gravina, I. Apicella, V. M. Ormando, M.R. Amato, M. I. Russo, M. Romano, P. Esposito

Medical And Surgical Department Of Clinical And Experimental Internistic "J. Magrassi", Hepatogastroenterology and Digestive Endoscopy Unit, University of Studies "L. Vanvitelli", Napoli/Italy

Contact E-mail Address: antonietta.gravina@yahoo.it

Introduction: Levodopa is the gold standard in pharmacological treatment of the advanced Parkinson's disease (APD) and its oral administration in advanced disease is associated with development of symptoms and motor and non-motor complications. Due to its short plasma half-life, Levodopa requires repeated dosing (1, 2). Impaired gastric emptying is common in APD and reduces the absorption of Levodopa, requiring progressively higher doses and more frequent administrations. Continuous duodenal administration of modulated Levodopa/Carbidopa gel by Jejunal Extension Tube Placement through Percutaneous Endoscopic Gastrostomy (PEG-J), is a new therapeutic protocol in advanced APD (3).

Aims & Methods: Aim of this work is to verify efficacy and safety of intestinal gel (LCIG) delivered continuously through an Intrajejunal percutaneous tube (PEG-J). 24 adult (14 M, 10 F, median age 71 years) with APD and preserved sensitivity to L-Dopa were enrolled. 7 days before PEG-J placement, to evaluate the possible presence of mucosal or anatomical gastric anomalies, each patient underwent a diagnostic esophagogastroduodenoscopy (EGD). Treatment with LCIG consists in a water-based suspension containing micronized levodopa (20 mg/mL) and carbidopa (5 mg/mL) in methylcellulose, administered by continuous jejunal infusion for 12 h/day using a portable pump by PEG-J. Clinical evaluations were performed at baseline (T0), before LCIG initiation, and after 3 (T3) and 6 (T6) months of therapy. To evaluate efficacy and safety outcomes it has been used Unified Parkinson's Disease Rating Scale (UPDRS) parts II, III and IV. For the analysis of the differences between the clinical variables and to exclude biases due to the small number of the sample in question, the non-parametric Kruskal-Wallis H test was used for the comparison of three samples. A statistically significant value of p was less than 0.05. The analyzes were carried out using SPSS version 13 (SPSS Inc., Chicago, IL, USA).

Results: 1) Success rate for PEG-J placement was 100%; 2) Eight/24 patients (33%) dropped-out LCIG at T3; 3) Sixteen/16 patients (100%) showed statistically significant (p 0.05) higher performances in daily common activities and statistically significant (p 0.05) lower incidence and severity of motor fluctuations, as assessed by UPDRS part IV, compared to their best oral therapy; 4) During observational period, 6 patients experienced adverse events.

Conclusion: 1) This study demonstrates that continuous intrajejunal LCIG's infusion treatment is highly effective in decreasing motor fluctuations in advanced PD patients compared to oral administration of levodopa-carbidopa; 2) This therapeutic approach should be proposed in well selected APD patients with preserved sensitivity to L-dopa.

Disclosure of Interest: All authors have declared no conflicts of interest.

³Dept. Of Internal Medicine, Yonsei University, Seoul/Korea, Republic of

Contact E-mail Address: last_message@yuhs.ac

Introduction: Post-endoscopic submucosal dissection (ESD) bleeding is the most common complication of ESD. In previous studies, the post-ESD bleeding occurred from 1.8% to 15.6% of total procedures [1-4]. Recently, many patients who underwent ESD, have been prescribed antiplatelets or anticoagulants, because of various underlying diseases such as cerebrovascular accidents or

cardiovascular diseases [5]. Thus, the verified risk prediction model of post-ESD bleeding may enable to determine preventive therapeutic options and restarting date of antiplatelet agents.

Aims & Methods: The aim of this study is to develop the predictive risk model of post-ESD bleeding. A total of 5374 patients, who were taken ESD from January 2007 to November 2016, in a Korean tertiary hospital, were included in this retrospective study. To avoid overfitting of the prediction model, we divided the patients randomly into two groups, either a derivation group or a validation group. Preoperative and procedural-related variables were selected via univariate and multivariate analysis. A risk score was calculated to assess the bleeding prediction model of a patient in the derivation group and was discriminated in the validation group.

Results: Post-ESD bleeding occurred in 248 patients (4.84%). In the derivation group, multivariate logistic regression revealed renal diseases (odds ratio [OR], 3.90; 95% confidence interval [CI], 1.48–9.09; $P=0.0029$), anti-platelet agent (OR, 3.07; 95% CI, 1.44–6.05; $P=0.002$), and en-bloc resection (OR, 3.83; 95% CI, 1.34–9.34; $P=0.0059$) as significant risk factors (C-statistic=0.607; 95% CI, 0.552–0.661). In the validation set, the model also showed good discrimination power (C-statistic=0.580; 95% CI, 0.533–0.627). Based on the scoring system of odds ratio, bleeding risk was 4.1% in the low risk set (score ≤ 4), 7.0% in the high risk set (score > 4 , $P=0.003$) (validation set).

Conclusion: Our study investigated a prediction scoring system of estimating the bleeding risk, including the patient, endoscopist factors. A risk score can be calculated before the procedure and the endoscopists can predict bleeding potency before the gastric ESD. Based on the scoring system, endoscopists may alter therapeutic plans such as prolongation of admission dates or medication schedules.

P0816 USEFULNESS OF DUAL RED IMAGING IN ESOPHAGEAL AND GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION

T. Yamasaki¹, K. Yamamoto², Y. Yasui², Y. Sakata², M. Suo³, T. Ochiai¹, A. Kimura², A. Nakata², M. Yamamura², N. Hirata¹, T. Suekane², E. Sasaki², K. Sano², K. Watanabe², H. Nebiki¹

¹Gastroenterology, Osaka City General Hospital Dept. of Gastroenterology, Osaka/Japan

²Hepatology, Osaka City General Hospital, Osaka/Japan

Contact E-mail Address: tomorrow_aaa@yahoo.co.jp

Introduction: Endoscopic submucosal dissection (ESD) remains difficult procedure due to bleeding and perforation. One of the reasons that these complications are occurred is unclear visibility of submucosal layer. Dual red imaging (DRI) is a novel endoscopic image enhanced technology that is focus on slightly deeper layer by using narrow long wavelength light than white light imaging(WLI). Therefore, DRI improves the visibility of vessels and demarcation line between the submucosal and muscle layers for colorectal ESD¹. The aim of this study is to estimate efficacy of DRI for esophageal and gastric ESD.

Aims & Methods: A retrospective analysis was performed on patients who underwent ESD for esophageal or gastric cancer in our institution. ESD was performed by circumferential incision using WLI at first. Submucosal dissection was performed using DRI in principle, and Ulcer bed was observed with DRI after resection. Total resection time (from precut to complete resection), perforation rate, and hemostasis rate after procedure were recorded. These parameters were compared with our matched previous procedures using propensity score (1: 2). We recorded paired endoscopic images using DRI and WLI at the same point during the dissection, then estimated the visibility of vessels and submucosa by those images using visual analog scale (0–100) by 5 endoscopists. We compared the visibility of DRI with WLI followed by the estimation.

Results: Twenty lesions (esophagus: 3, stomach: 17) of 18 patients were enrolled for this study. Total resection time was 67.0 \pm 27.9 min, and was shorter than matched data (141.7 \pm 113.5 min) significantly ($p=0.0054$). Hemostasis rate after resection and perforation rate were not different significantly. The score of vessels visibility using DRI and WLI were 68.6 \pm 17.5 and 62.3 \pm 19.6, respectively. The score of submucosal visibility using DRI and WLI were 70.0 \pm 18.0 and 64.9 \pm 19.0, respectively. DRI was superior to WLI in both scores significantly ($p < 0.0001$).

Conclusion: Though our study is preliminary, DRI improves total resection time, visibility of vessels and demarcation line between the submucosal and muscle layers significantly as previous study showed on colorectal ESD. DRI uses narrow long wavelength light. The light reaches slightly deeper layer than WLI. Therefore, we can see not only clear vessels but intact submucosa with DRI, through submucosal surface is dirty and unclear by blood, fat, and fibrosis. We named this effect "noise cancelling effect" by DRI. This effect gets better the visibility better, therefore the esophageal and gastric ESD makes easier and safer.

Contact E-mail Address: osamu-d@koto.kpu-m.ac.jp

Introduction: Endoscopic diagnosis of early gastric cancer (EGC) is essential for ESD, which is a standard treatment for EGC. Magnifying endoscopy with blue laser imaging was useful for diagnosis of EGC prior to ESD [1]. A novel endoscopic system powered by unique four kinds of LED light sources sets a white-light imaging, blue light imaging and linked color imaging.

Aims & Methods: We prospectively evaluated whether blue light imaging with magnifying endoscopy (LED-BLI-ME) could be as efficient for diagnosis of EGC as blue laser imaging with magnifying endoscopy (BLI-ME). 43 patients with 45 tumorous lesions including 28 well-differentiated adenocarcinomas, two moderately differentiated adenocarcinoma, six poorly differentiated, and five adenomas that were diagnosed by biopsy specimens were enrolled in this study between December 2016 and May 2017. The patients with EGC underwent LED-BLI-ME observation, following BLI-ME observation in the same day. At first, an endoscopist evaluated a demarcation line and micromorphology in the part of EGC using LED-BLI-ME according to vessel and surface classification system. Then, the same endoscopist evaluated adenocarcinoma line in the same part of EGC using BLI-ME. All of the EGCs were immediately resected by ESD after the observation of two modalities. All of the EGCs could be evaluated one-to-one correspondence between the endoscopic image and pathological finding in detail. Primary end point was to analyze the diagnostic accuracy of LED-BLI-ME for EGC. Secondary end point was to compare the diagnostic accuracy and between LED-BLI-ME and BLI-ME. Our study was approved by the Ethical Review Committee of Kyoto Prefectural University of Medicine, and performed in accordance with the World Medical Association's Declaration of Helsinki. In addition, this study has been registered in the University Hospital Medical Information Network Clinical Trials Registry (UMIN-CTR; <http://www.umin.ac.jp/ctr/>) as trial UMIN 000025275.

Results: The clinicopathological features in the patients were as follows; mean age was 71.9 \pm 8.74, gender (male:female) was 31:14, location(U:M:L) was 9:15:21, macroscopic type (elevated: flat: depressed) was 18:1:26, median tumor size was 18.1 \pm 0.298 mm, and final pathological diagnosis (well-differentiated adenocarcinoma: moderately differentiated adenocarcinoma: poorly adenocarcinoma) was 37:1:7, respectively. Diagnostic accuracy of demarcation line of EGC using LED-BLI-ME and BLI-ME were 91.1% (41/45) and 91.1% (41/45), respectively. The rate of high confidence for diagnosis of a demarcation line of EGC using LED-BLI-ME and BLI-ME were 84.4% (38/45) and 91.1% (41/45), respectively. There was no significant difference of diagnostic accuracy between two modalities. The consistency rate in the demarcation line, microvascular pattern, and microsurface pattern of EGC between LED-BLI-ME and BLI-ME was 80.0% (41/45), 97.8% (44/45), and 97.8% (44/45), respectively.

Conclusion: LED-BLI-ME were demonstrated the high diagnostic performance for diagnosis of EGC demarcation, similar to BLI-ME.

Introduction: Foreign bodies (FBs) ingestion is a common medical emergency accounting for 4% of all emergency endoscopies, secondary only to the GI bleeding.^[1] 70~75% of FBs are located in the esophagus^[2]. The need of endoscopic management reached up to 63~76%^[3-5] with 3%~20% of incidence of complications^[6]. According to the latest guidelines from ESGE, emergent endoscopy is recommended for the impaction of sharp-pointed objects within 24 hours^[3]. However, there were still different opinions on the endoscopic methods with different FBs.

Aims & Methods: The study was performed from October 2015 to August 2016 among 595 patients with clinical suspicion of foreign body ingestion from 18 general hospitals in China. The patient data including age, gender, clinical features, and data about endoscopic management including types and locations of foreign bodies, retrieval devices, outcomes and complications were collected and analyzed.

Results: 1) The most common types of foreign bodies were fish bones (34.0%), chicken bones (22.1%), fruit nucleus (17.1%) and food bolus (14.6%). The majority of them were short objects (<2.5 cm, 74.0%), subsequently followed by middle objects (2.5~6.0 cm, 24.5%) and long objects (>6 cm, 1.5%). Most objects were lodged in the proximal esophagus (75.9%), followed by the middle segment (15.2%) and the distal segment (8.9%) of esophagus. 2) 96.3% of all cases had obvious clinical symptoms. Clinical symptoms occurred more often in the proximal segment of the esophagus (98.1%) than any other segments of the upper gastrointestinal tract (92.6%) ($P < 0.001$). 3) The successful removal rate through endoscopy was 94.5%. It was even higher with general anesthesia (99.3%) than without it (92.7%) ($P < 0.01$). 4) Complication rate was as high as 34.0%, which was increased with long retention time and sharp objects ($P < 0.001$). The rate was increased by 2.2- and 6.1- folds after impacted for over 24 hours or 48 hours as compared to 12 hours. Logistic regression analysis indicated that sharp objects had obviously more complications than non-sharp ones (OR 3.36, 95% CI: 1.97-5.74). In particular, the incidence of perforation was 5.6%, which was strongly related with long retention time and sharp objects ($P < 0.01$), but not with locations or lengths of the objects ($P > 0.05$).

Conclusion: General anesthesia could largely improve the retrieval rate through endoscopy. Foreign bodies, especially sharp ones, should be removed as soon as possible within 24 hours, to further decrease severe complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0819 BIOPSY STRATEGIES FOR ENDOSCOPIC SCREENING OF PRE-MALIGNANT GASTRIC LESIONS

Z. Meng

Department Of Gastroenterology, First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou/China

Contact E-mail Address: zm1990morphine@163.com

Introduction: GA and IM are detectable precursor lesions of most gastric carcinomas. Early endoscopy examination may potentially result in early detection and treatment of advanced precursor lesions and cancer. The annual incidence of GC is quite low in central Europe, for GA was 0.1% and for IM was 0.25%^[1-2]. The histological assessment and biopsy sampling protocol has been standardized in the updated Sydney system and the recommended five gastric biopsies were widely applied in the staging system for gastric cancer risk stratification^[3]. Some believe that the GA risk screening requires consideration of the cost, suffering of patients as well as rational utilization of medical resources, so adopt five biopsy may be presumably less appropriate in large-scale population gastric cancer risk screening. In this study, we evaluated the OLGA and OLGIM staging in a standardized five biopsy protocol through screening patients underwent endoscopy with abdominal pain and discomfort. In order to identify a more optimal biopsy strategy with quite high consistence with the standardized five biopsy protocol in OLGA and OLGIM staging and less number of biopsies during

cancer risk assessment, we re-evaluated OLGA and OLGIM staging adopting different biopsy combinations (evaluated the appropriate biopsy locations and number of biopsies).

Aims & Methods: Gastric atrophy (GA) and intestinal metaplastic (IM) are precursor lesions of gastric cancer (GC), the extent and severity of which was intimate correlated with the occurrence of GC. Operative Linkon Gastritis Assessment (OLGA) and Operative Linkon Gastric Intestinal Metaplasia Assessment (OLGIM) with five biopsy samples are superordinate stages system during Gastric risk stratification. We analysis the degree of GA and IM in these five locations and screen out an more representative, simple and convenient biopsy samples composition for gastric risk screening.

Methods: 368 patients with abdominal pain and other discomfort undergoing endoscopy were enrolled in the study. Five biopsy pieces (two from antrum, namely lesser and larger curvature, two from corpus, larger and lesser curvature and one from incisura angularis) were acquired and graded by senior gastroenterological pathologists according to the updated Sydney system. Gastric risk stratification was calculated by adopting OLGA and OLGIM staging system.

Results: GA and IM are more frequently acquired in the incisura angularis mucosa than the both lesser and larger curve of antrum and corpus respectively ($P < 0.05$), especially the moderate and severe degree. More GA and IM alternations happened in the lesser curve of the antrum and corpus than in the corpus ($P < 0.05$). The composition three biopsy pieces (lesser curvature of the antrum and corpus, angulus biopsy) with quite accurate consistence with five biopsy pieces protocol using OLGA and OLGIM staging (94.0% and 92.9%), together with a rather low omission diagnostic rate of OLGA and OLGIM III+IV (3.8% and 7.2%)

Conclusion: The incisura angularis with more moderate and severe GA and IM should be recommended as conventional biopsy site during endoscopy. The three biopsy pieces (lesser curvature of the antrum and corpus, angulus biopsy) with quite high consistence, more convenience and less cost comparing with five biopsy pieces protocol using OLGA and OLGIM staging system, and thus could be recommend in the further gastric risk screening applying OLGA and OLGIM staging.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: LCI is a novel color enhancement feature available for LASEREO endoscopy systems (FUJIFILM CO., Tokyo, Japan), which can enhance the slight color difference on gastrointestinal mucosa. Recently we reported that color enhancement of the diffuse redness by LCI was useful for the diagnosis of *H. pylori* infection. Therefore, we expected that LCI facilitate the endoscopic recognition of early gastric cancer and gastric adenoma by enhancing its color difference between normal and atypical mucosa.

Aims & Methods: The aim of this study was to evaluate the usefulness of LCI for recognition of early gastric cancer and gastric adenoma compared to conventional white light imaging (WLI), WLI with Indigo Carmine contrast staining (IC) and Blue Laser Imaging-bright (BLI-brt) imaging. We retrospectively analyzed 39 lesions in 33 patients who had endoscopic submucosal dissection (ESD) at Murakami Memorial Hospital from June 2014 to May 2016. All lesions were scanned with four imaging mode, WLI, IC, BLI-brt and LCI (LASEREO with EG-L590ZW scope), and assigned a recognition score from 3 (excellent visibility) to 0 (poor visibility) by three endoscopists.

Results: The overall mean recognition score of LCI was significantly higher than that of WLI/IC/BLI-brt (2.18 ± 0.073 vs. $1.56 \pm 0.080/1.86 \pm 0.099/1.91 \pm 0.073$). For type 0-IIa lesions (18 lesions), the mean recognition score of LCI was significantly higher than WLI and BLI-brt (2.26 ± 0.12 vs. $1.83 \pm 0.12/2.14 \pm 0.097$), whereas no significant difference was seen between LCI and IC (2.26 ± 0.12 vs. 2.35 ± 0.12). For type 0-IIb or 0-IIc lesions (21 lesions), the mean recognition score of LCI was significantly higher than WLI/IC/BLI-brt (2.11 ± 0.11 vs. $1.33 \pm 0.10/1.44 \pm 0.13/1.73 \pm 0.10$). And the mean recognition score of BLI-brt was also significantly higher than WLI/IC, but no significant difference was seen between WLI and IC. Regarding WLI, IC, and BLI-brt, the mean recognition score of type 0-IIa lesions in each mode was significantly higher than that of type 0-IIb or 0-IIc lesions. However, regarding LCI, there was no significant difference in the mean recognition score between type 0-IIa lesions and type 0-IIb or 0-IIc lesions. These results indicated that the detection of type 0-IIb or 0-IIc lesion was difficult compared to 0-IIa in WLI, IC and BLI-brt mode. However, LCI mode enable us to detect these type 0-IIb or 0-IIc lesion as easily as type 0-IIa.

Conclusion: LCI mode was useful for recognition of early gastric cancer and gastric adenoma, especially for type 0-IIc and 0-IIb lesions that are frequently found in post-*H. pylori* eradication gastric mucosa.

Introduction: In gastrointestinal stromal tumors (GISTs) without a risk of metastasis to other organs, local resection is acceptable. In small GISTs, however, it is controversial whether surgical resection is necessary because a risk of recurrence/metastasis in these tumors are considered to be quite low. Laparoscopic endoscopic cooperative surgery (LECS) is a promising surgical technique as one of minimally-invasive, function-preserving surgeries. By using this technique, we are aggressively resecting gastric SMTs including relatively small ones.

Aims & Methods: To investigate necessity of surgical resection for small GISTs, we retrospectively assessed a malignant potential of these tumors which were resected nonexposed endoscopic wall-inversion surgery (NEWS) (nonexposure LECS technique) as well as feasibility and safety of this technique. Between August 2013 and October 2016, NEWS was conducted in 33 consecutive SMTs which met all of following conditions: possible GIST which was preoperatively diagnosed by histology or imaging modalities, less than 3 cm in size and intraluminally/intramurally-growing type. In the NEWS procedure, a lesion was resected in a following manner: endoscopic mucosal markings, laparoscopic serosal markings just behind the mucosal markings, endoscopic submucosal injection, laparoscopic sero-muscular incision and suturing with the lesion inverted toward the inside of the stomach, endoscopic muco-submucosal incision and peroral retrieval. Short-term outcomes of NEWS and a potential risk of recurrence/metastasis in each tumor according to the Fletcher's classification were assessed.

Results: Mean age and size of the lesion were 59.9±13.7 years-old and 23.3±8.4 mm, respectively. The procedure was successfully completed in all cases in a mean procedure duration of 206±43 min. The patients were discharged without severe adverse events 7.3±1.5 days after the procedure. The first endoscopy after the procedure was performed 5.8 months after discharge in 22 cases, which showed no residual food in the remnant stomach in all cases. Neither apparent impairment of food intake nor disease-related death occurred and a body weight loss was 0.9±2.3 kg during the mean observational period of 16 months. GIST was histologically diagnosed in 20 cases. A risk of recurrence/metastasis in these GISTs was classified into high (2), intermediate (1), low (12) and very-low (5), respectively. In a comparison of two groups (high/intermediate and low/very-low), a mean tumor size and existence of nodule formation were 31.7 mm and 21.6 mm ($p=0.036$), and 67% and 12% ($p=0.028$), respectively.

Conclusion: Some small GISTs which could be retrieved transorally had a high malignant potential. NEWS was feasible, safe and therefore recommended for these tumors including ulcerated GISTs as a minimally-invasive surgical option to avoid an additional surgical scar for the retrieval of the specimen and a risk of iatrogenic tumor cell seeding into the peritoneum during the procedure.

P0822 LONG-TERM OUTCOMES OF PERORAL ENDOSCOPIC MYOTOMY FOR ACHALASIA IN PATIENTS OLDER THAN 70 YEARS

J. Zhu, Q. Li, P. Zhou

Endoscopy Center, Zhongshan Hospital, Fudan University, Shanghai/China

Contact E-mail Address: zjysjtu@yahoo.com

Introduction: Achalasia is a rare esophageal motor disorder characterized by esophageal aperistalsis and incomplete relaxation of lower esophageal sphincter (LES). The Elderly patients have longer courses of disease, less perception of symptoms and similar manometric findings compared with younger patients. Peroral endoscopic myotomy (POEM) is a novel endoscopic therapy which recently has been described as an incisionless and less invasive scarless myotomy alternative for treating achalasia. However, very few studies concentrated on the long-term outcomes of POEM for achalasia patients, especially for elderly patients.

Aims & Methods: Peroral endoscopic myotomy (POEM) is a minimally invasive endoscopic myotomy for achalasia. But the long-term outcomes of POEM for achalasia in elderly patients are unclear. We therefore aim to evaluate the efficacy and safety of POEM for achalasia in patients older than 70 years. A total of 33 consecutive patients aged ≥70 years were enrolled in this study, who had undergone POEM for achalasia from May 2011 to March 2016 in the Endoscopy

Center of Zhongshan Hospital. We retrospectively assessed the short and long term outcomes of these patients including Eckardt score, lower esophageal sphincter pressure, adverse events and recurrence.

Results: All patients underwent POEM successfully. Mean procedure time was 50.7±22.0 min and postoperative hospital stay was 2.8±1.5 days. No severe complications related to POEM were encountered. During a mean follow-up period of 40.5±19.1 months (range from 12.2 to 70.9 months), the therapeutic success rate was 90.9% (30/33). Mean Eckardt score was 7.6±2.0 and 1.4±1.3 before and after POEM, respectively ($P<0.001$). Mean LES pressure decreased from a mean of 20.3±5.8 mmHg to 3.9±2.9 mmHg after POEM ($P<0.001$). Clinical gastroesophageal reflux occurred in 11 cases (33.3%) after the procedure which was successfully resolved by proton pump inhibitors.

Conclusion: POEM can be a safe and effective treatment option for achalasia in elderly patients older than 70 years with significant improvement in symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0823 POST-POEM ESOPHAGITIS – REAL REFLUX ESOPHAGITIS OR JUST A HEALING PROCESS?

D. Erhartova¹, J. Krajcova¹, Z. Vackova¹, Z. Rabekova¹, P. Stirand¹, T. Hucl¹, J. Spicak¹, J. Martinek¹

¹Department Of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: denisaerhartova@gmail.com

Introduction: POEM has become a standard treatment of achalasia based on its excellent efficacy and safety. However, unlike in laparoscopic myotomy, POEM is not accompanied by an antireflux procedure and thus the rates of both clinically relevant post-POEM reflux (measured by symptoms and/or 24 h pH monitoring) and post-POEM esophagitis are key questions of long-term POEM safety. Several studies have reported the rates of post-POEM reflux and post-POEM esophagitis being as high as 30–40%. The aim of this retrospective analysis was to analyze whether esophageal erosions, detected endoscopically early after POEM, represent real reflux esophagitis or rather signs of still ongoing healing process after POEM.

Aims & Methods: A single-center retrospective analysis of 192 patients who underwent POEM in our institution. Three months after POEM, 162 patients underwent both pH monitoring and endoscopy and treatment with PPIs was assessed. At 24–36 months, a control endoscopy was performed in 41 patients to screen for esophagitis. We reviewed all available video recordings of POEM procedures and subsequent control endoscopies to analyze whether the localization of erosions was limited to the site of submucosal tunneling (e.g. between 2–4 o'clock in patients after anterior POEM) or also outside this area (real reflux esophagitis). We also analyzed evolution of esophagitis in time and correlated it with pH monitoring and intake of PPIs.

Results: At 3 months, esophagitis was present in 64 out of 162 patients (39.6%). Of those, 21 (33%) were on PPIs by the time of endoscopy and 43 (67%) were not. Among 43 patients with esophagitis and available video recording, 29 (67.4%) had erosion(s) only on the site of submucosal tunnel and 14 (32.6%) had erosions also elsewhere. Among patients with erosion(s) only on site of the tunnel, 13 (44.8%) had normal acid exposure time (assessed by pH monitoring

performed off PPIs). At 24–36 months, esophagitis was present in 9 out of 41 examined patients (21.9%), $p=0.04$ vs. 3 months. In 6 out of 10 patients with esophagitis present at 3 months, who underwent control endoscopy at 24–36 months, esophagitis resolved completely even though only 2 patients had been treated by a PPI.

Conclusion: After POEM, the majority of patients with esophagitis had erosions on site of submucosal tunnel and early esophagitis often occurred in patients without an abnormal acid exposure. These findings suggest that an ongoing healing process after POEM might interfere in findings of presumed post-POEM reflux esophagitis. Thus, the rate of real post-POEM reflux esophagitis may be lower than previously thought.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0824 ENDOSCOPIC SUBMUCOSAL TUNNEL DISSECTION FOR LESSER GASTRIC CURVATURE SUPERFICIAL NEOPLASMS

D. Shi, R. Li, W. Chen, X. Wang, C. Ma, D. Zhang

Gastroenterology, the First Affiliated Hospital of Soochow University, Suzhou/China

Contact E-mail Address: lrhcsz@163.com

Introduction: Endoscopic submucosal dissection (ESD) has been widely used for resection of gastrointestinal neoplastic lesions, but there are still technical challenges in treating large ones especially located in lesser gastric curvature. In the tunnel technique, incisions at the lower and upper lesion edges are joined by a submucosal tunnel and then lateral incisions are made. The mucosa is thereby easily separated from the muscular layer. We report our experience of endoscopic submucosal tunnel dissection (ESTD) in lesser gastric curvature.

Aims & Methods: To estimate the safety and efficiency of endoscopic submucosal tunnel dissection (ESTD) for lesser curvature superficial neoplasms. 47 patients with lesser curvature superficial neoplasms undergoing endoscopic resection were analyzed retrospectively. 26 patients underwent ESTD and 21 received endoscopic submucosal dissection (ESD). Operation time, security, En bloc resection rate and complications were compared between the two groups. The major difference between ESTD and ESD is that, instead of pre-cutting circumferential mucosal, a submucosal tunnel was created by submucosal dissection from the oral incision to the anal incision. Bilateral resection was then performed to remove the lesion completely.

Results: The differences between the two groups in the age of the patients and the diameter of the lesions had no statistically significant ($P > 0.05$). En bloc resection rate was 100% in the study group and 90.5% in the control group (19/21), and the difference was statistically significant ($P < 0.05$). The average operation time was 46 minutes (36–59 minutes), the control group was 67 minutes (48–110 minutes), the difference was statistically significant ($P < 0.05$). The intraoperative bleeding rate of the study group was 57.7% (15/26), the control group was 100%, the difference was statistically significant ($P < 0.05$). The incidence of perforation was 0% in the study group and 9.5% in the control group (2/21), and the difference was statistically significant ($P < 0.05$). There was 1 case of delayed bleeding after operation in the two groups, there were no postoperative perforation, and the difference was not statistically significant ($P > 0.05$). There were no recurrence and metastasis in the two groups after the operation.

Conclusion: ESTD for lesser curvature superficial neoplasms can obviously shorten the operation time and have a higher security, compared with the traditional ESD operation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Propofol is recommended for sedation in gastrointestinal endoscopy (GE) [1], but preliminary data suggests addictive potentials in animal models [2, 3] and healthy volunteers [4]. There is an increasing number of reports of propofol addiction in physicians and nurses associated with high mortality up to 30% within the first year of abuse [5–7]. Some patients and medical laymen developed propofol addiction and feigned an indication for endoscopy to receive propofol [8, 9]. Survivors after propofol abuse reported that the abiding memory of the intense relaxation many years ago was a major reason to abuse propofol years thereafter [10]. However, it is unknown how many patients develop a euphoric drug reaction after endoscopy.

Aims & Methods: The primary objectives were to define the frequency of a euphoric reaction pattern under propofol sedation, to evaluate the reminiscence one week later and to investigate the superposition of negative feelings by that respective propofol-induced euphoria. Eighty-two patients undergoing elective GE under propofol-sedation in an ambulatory setting were enrolled in a prospective observational study. The grade of anxiety, expectation or relief about the examination's result and affective state in terms of cheerfulness, relaxation, activation, sedation and anxiety were surveyed using a numeric rating scale (1 to 10) immediately before (t1), after GE (t2) and seven days (t3) later. Statistics: hierarchical cluster analysis, heat map, χ^2 test and paired t-test.

Results: Mean propofol dosage was 264 ± 120 mg. The average indices of cheerfulness, relaxation and activation increased significantly (t1 to t2 to t3), whereas sedation and anxiety decreased. Two clusters of mood changes emerged (t1 vs. t2). One ($n=46.56.1\%$) was characterized by an unease reaction pattern with equal values regarding cheerfulness, relaxation and anxiety, while relaxation decreased; the other cluster showed a euphoric reaction pattern ($n=36, 43.9\%$) with markedly increased cheerfulness, relaxation and decreased anxiety. These effects intensified at recall (t3). Despite similar endoscopy results, euphoric cluster patients rated these more positively. No association between cluster and personal traits, prior use of psychotropic drugs, alcohol consumption or smoking habits were found.

Conclusion: Propofol induces euphoria in nearly half the patients undergoing elective GE with persisting, even enhanced reminiscence. Consequently, endoscopists should be aware of a potential risk of addiction in vulnerable subjects.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0826 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR UPPER GI SUBMUCOSAL TUMOURS

H. Awadie, D. J. Tate, A. Klein, L. Desomer, M. Ma, S. Heitman, N. J. Burgess, E. Y. t. Lee, V. Kwan, M. J. Bourke

Gastroenterology And Hepatology, Westmead Hospital, Sydney/Australia

Contact E-mail Address: halimawadie@gmail.com

Introduction: Submucosal tumours (SMT) in the upper gastrointestinal tract (UGI) impose diagnostic and therapeutic challenges. They may have malignant potential and endoscopic ultrasound (EUS) guided diagnosis is often inaccurate. A substantial proportion may not involve the muscularis propria (MP) and thus may be amenable to endoscopic excision. Snare-based techniques are usually unable to completely excise such lesions, though without complete excision ongoing endoscopic surveillance may be necessary. Endoscopic submucosal dissection (ESD) offers the possibility of complete resection and definitive

histological diagnosis to guide management decisions. Western data on ESD for SMT is absent. Our aim was to analyse the data from our referral centre.

Aims & Methods: A prospectively collected ESD database was analysed to identify patients with SMT of the UGI. All lesions underwent EUS assessment with the aim to exclude MP involvement prior to resection, and in the case of neuroendocrine tumours (NET) blood tests and Octreotate PET scan were performed.

Results: Over 42 months, 30 ESDs for SMT lesions were performed. The mean age was 62 years with 19 male patients (63%). Mean lesion size was 18mm. Twenty five patients (83.3%) had completely resected tumours. Four patients (13%) had involvement of the MP which was identified during the resection, and one patient (3%) had MP injury which precluded complete resection. Three of five lesions of the incompletely ESD procedures were in the proximal body of the stomach, however only two lesions of the completely resected lesions were in the proximal body (P=0.004). Otherwise, there were no significant differences between the patients and lesions characteristics. The histology of the SMT lesions were 9 NET, 6 leiomyoma, 5 Granular cell tumours, 4 inflammatory fibroid polyp, 2 GIST, 2 dysplastic Lipoma, one myofibroblastic tumour and one Warthin's like tumour. Nineteen patients had completed surveillance endoscopy (SE) without an endoscopic and histological recurrence (Median follow up 18 months). Six patients are pending SE. The four patients with deep MP involvement were referred for surgery.

Conclusion: ESD for selected UGI SMT is an effective treatment. Long-term endoscopic follow-up confirmed the absence of recurrence endoscopically and histologically. MP involvement cannot be reliably excluded by prior EUS. This technique should be considered for UGI SMT lesions without MP involvement in experienced centres.

Introduction: The incidence of oesophageal cancer has increased significantly over the past two decades. The majority of these cancers are incurable at diagnosis. Therefore, the management is aimed at maintaining quality of life by ensuring adequate nutrition and palliation of symptoms, mainly dysphagia. Self-expanding metallic stents (SEMS) have a well-recognised role in the palliative management of patients with oesophageal cancer. These stents are inserted endoscopically, under direct vision (EC) or with fluoroscopic assistance to endoscopy (FAE). There is little evidence to compare outcomes between these approaches.

Aims & Methods: The objective of this study was to compare the outcomes, using various performance indicators, in patients who underwent SEMS for palliation in oesophageal cancer via different approaches (EC or FAE) at the Royal Infirmary of Edinburgh (RIE). A retrospective observational study was conducted between May 2014 to April 2016; a total of 62 SEMS. The approach to stent insertion was subject to operator choice and availability of fluoroscopic assistance, and as such can be akin to randomized study. We compared early and late complications associated with two techniques. Early complications included pain, vomiting, bleeding, perforation and tachyarrhythmia. Late complications included tumour overgrowth, oesophagitis, stricture and stent migration. We also compared morbidity, the need for repeat procedures and the number of additional stents required following each approach.

Results: Forty-seven stents were inserted by EC and fifteen by FAE. The median age among the two groups were comparable at 75 and 69 years respectively. There was male predominance in both the groups (70% and 67%). Adenocarcinoma was the most common malignancy (56%), followed by squamous cell carcinoma (35%) among the study subjects. We observed a higher frequency of technical difficulties with EC placement (13%) to FAE (0%), however no malposition was observed in the EC group. Early complications were comparable in both groups, however chest pain (21%) was more frequently associated with the EC group. Late complications such as tumour overgrowth, oesophagitis, oesophageal stricture and stent migration were comparable in both groups. Food bolus obstruction and dysphagia was more common in EC placement (28%) to FAE (0%) necessitating a higher number of endoscopies. However, a relatively higher number of re-stent procedures were performed in the FAE group. Median survival was comparable in both of the groups.

Variable	EC (47)	FAE (15)
Male (%)	33 (70)	10 (67)
Location of tumour Upper	32 (9)	40 (6)
Limit (IQR) Lower	37 (5.1)	38 (7)
Limit (IQR)		
Sedation and analgesia use- median dose (IQR)	2 (1.8)	3 (2.5)
Midazolam dose (mg)	50 (50) 100 (0)	75 (50)
		100 (0)

(continued)

Continued

Variable	EC (47)	FAE (15)
Fentanyl (mcg) Local		
Throat Spray (mg)		
Commonest Stent	7/10 ultraflex (38)	7/10 ultraflex (33)
Placement difficulties	6 (13)	0 (0)
Previous failed attempts	1 (2)	0 (0)
Early complications:	3 (5) 2 (4) 3 (6) 10 (21)	1 (7) 0 (0) 1 (7) 1 (7)
Vomiting		
Tachyarrhythmia		
Aspiration pneumonia		
Chest pain		
Late complications Tumour overgrowth	9 (19) 2 (4)	5 (33) 0 (0)
Oesophagitis Stricture	1 (2) 9 (20) 32	1 (7) 3 (15) 29
Stent migration: Mean days		
Malposition	0 (0)	1 (7)
Food bolus obstruction	10 (21)	0 (0)
Second stent: Mean days	8 (17) 96.1days	5 (33) 171days
Third stent: Mean days	2 (4) 188.5days	2 (7) 286.5days
Fourth Stent: Mean days	0 (0)	2 (7) 377.5days
Median Survival days (IQR)	102 (73)	126 (161)

Conclusion: Our results are comparable to findings of other authors (1, 2), in that neither approach is superior. Both FAE and EC techniques have similar early and late complications and comparable median survival. EC offers the advantage of stent placement with direct visualization, however a learning curve must be acknowledged. FAE insertion is a time-consuming procedure and exposes both patients and endoscopy staff to radiation. In conclusion, the approach used should be based on individual characteristics including operator experience, tumour characteristics and previous endoscopic interventions.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Ingestion of caustic substances is relatively frequent and can cause serious lesions in the upper gastrointestinal tract, carrying important morbidity and even mortality.

Aims & Methods: We aimed to characterize the population assisted for caustic ingestion, the therapeutic approach, complications and risk factors for severe oesophageal lesions.

Retrospective cohort of adults presenting due to caustic ingestion between 2000 and 2015. Demographic and clinical data were collected. The endoscopic Zargar classification was applied. We analysed risk factors for severe oesophageal lesions, defined as Zargar 2b-3. Statistical tests: Mann-Whitney; Spearman (significance level 5%).

Results: Overall 72 patients were included, with a mean age 53 ± 17 years, 65.3% female. Ingestion was voluntary in 49.3% of the cases, 33.3% had previous suicide attempts. Alkaline substance in 90.4%. Most common symptoms at admission: 60.3% odynophagia, 41.1% epigastric pain, 32.9% vomiting. Oropharyngeal lesions in 41.1%. In 79.5% endoscopy was performed in the first 12 hours. Oesophageal lesions were present in 46.6% of patients (Zargar classification: I-2.7%, IIa-23.3%, IIb-5.5%, IIIa-6.8%, IIIb-8.2%); gastric lesions in 58.9% and duodenal lesions in 13.7%. 53.4% were hospitalized, 51.3% in intensive/intermediate care units. The mean length of hospital stay was 14.9 days. Medical treatment prescribed: 76.7% proton pump inhibitors, 15.1% corticoids, 15.1% prophylactic antibiotics. Parenteral feeding was initiated in 28.8% of patients. Eight patients required invasive ventilation and two were tracheotomised. Early complications: infections in 12 patients (16.4%), perforations in 2 (2.7%); late complications: stenosis in 7 (9.6%); dilation in 6, surgery in 3. One patient died from gastric perforation after voluntary ingestion of acid. Severe oesophageal lesions were associated with increased inflammatory parameters, tachycardia and/or hypotension at admission and motivated longer hospital stays, requirement of intensive care and further complications ($p \leq 0.002$). The ingestion of acidic substances (100% of voluntary intake) was associated with severe oesophageal damage in 3/7 (42.9%) patients, severe gastric lesion in 5/7 (71.4%), acidemia in 5/7 (71.4%), complications in 5/7 (71.4%) and 100% hospitalization.

Conclusion: Early changes in blood tests were seen in severe oesophageal lesions. Severe oesophageal lesions were associated with longer hospitalization and complications (infection/stenosis/perforation). Ingestion of acidic substances was a risk factor for severe digestive lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A value of the combination of magnifying endoscopy of and image enhancement endoscopy (IEE) technology (e.g. NBI, BLI) is reported in a diagnosis for the early gastric neoplasm. That method is useful, but in order to master it is necessary to learn and familiarize complex classifications. Therefore, this diagnostic method is still more difficult for general endoscopists. Linked Color Imaging (LCI) was recently developed using a laser endoscopic system (Fujifilm Co., Tokyo, Japan). LCI acquires images by simultaneously using narrow-band short wavelength light and white light in an appropriate balance. This combination of light provides more information about the vasculature and architecture on the mucosal surface than that obtained with typical white-light imaging. When we use acetic acid indigocarmine mixture (AIM) with LCI mode, we reported that the magnifying images of early gastric cancer are very clear, three-dimensional and near to real histology. So, we examined the utility of this method.

Aims & Methods: This was a prospective observational study performed at a single tertiary referral center. The subjects are 120 lesions of 115 patients with gastric neoplasm. We are indicated of the endoscopic submucosal dissection (ESD), and were given preoperative endoscopy in our hospital from September 2014 to February 2017. Firstly we observed the lesions by magnifying endoscopy with the BLI mode and diagnosed using VS classification system. Secondly we observed the lesions by magnifying endoscopy with LCI+AIM method and diagnosed using VS classification system. Furthermore, we classified tumor differentiation into high differentiation, moderately differentiated, and poorly differentiated by its surface pattern. Finally, we classified the visualization ability of the surface fine structure in Clear, Visible, and Invisible and evaluated it. We carried out ESD and compared the image with the histopathology.

Results: By the pathology results, 92 lesions were gastric cancer and 28 lesions were gastric adenoma. The differentiation ability of a cancer and the non-cancer (adenoma) did not have the significant difference between the BLI mode and the LCI+AIM methods. Diagnosis of differentiation of gastric cancer was correct in 87 of 92 cases (94.6%). In the classification of visualization ability, 32 lesions were Clear, 44 lesions were Visible, 44 lesions were Invisible by BLI mode. On the other hand, 45 lesions were Clear, 64 lesions were Visible, 11 lesions were Invisible by LCI+AIM method. In the visualization ability of the surface fine structure, LCI+AIM method is significantly clearer than BLI mode ($p < 0.001$).

Conclusion: When we use AIM, indigocarmine accumulates in pit of the duct, and duct structures become clear by the acetic acid. By LCI mode, we can observe the vascular pattern of the lesion clearly. So by the combination of AIM and LCI, we can observe the endoscopic images closer to actual histological images. By this method, we can compare histopathology with an endoscopic image intuitively, so we believe that a magnifying endoscopy diagnosis of the gastric cancer is enabled even if we do not use various confusing classifications.

Introduction: Endoscopic submucosal dissection (ESD) is one of the most useful methods for treating early gastric neoplasms. The advantages of ESD include the ability to control the size and shape of the resection, permitting *en bloc* resection

of large and ulcerated lesions. The frequency of gastric ESD for patients aged 85 years or older has increased along with increases in the average population age. However, few studies have reported the short-term and long-term outcomes of gastric ESD in elderly patients.

Aims & Methods: The aims of our study were to evaluate and compare the efficacy, safety, and clinical outcomes of gastric ESD in patients aged 85 years or older and in younger patients. The subjects were 705 patients who collectively presented with 876 gastric tumors (288 adenomas and 588 early gastric cancers). All patients underwent ESD at our hospital between June 2007 and December 2016. The patients were divided into two groups: elderly (Group A: aged ≥ 85 years, consisting of 59 patients with a collective 71 lesions) and non-elderly (Group B: aged < 85 years, consisting of 646 patients with a collective 805 lesions). We evaluated the clinical and pathological findings, resection rates, complications, and long-term outcomes, including the survival rate. The local and distant recurrence rates were analyzed in the cohort with curative resection and observationally managed with non-curative resection. The 3- and 5-year overall survival and tumor-specific survival rates were analyzed in the entire study cohort.

Results: The patients' mean ages were 87 (Group A) and 71 years (Group B), and the male-to-female ratios were 30/29 (Group A) and 646/805 (Group B). No significant differences were found in the mean tumor size for Group A (15 mm) and Group B (20 mm). Regarding histopathological findings, the prevalence rates of tubular adenoma were 28.3% (21/71; Group A) and 33.8% (267/805; Group B); intramucosal carcinomas, 52.1% (37/71; Group A) and 53.8% (433/805; Group B); shallow submucosal invasive carcinomas ($< 500 \mu\text{m}$), 7.0% (5/71; Group A) and 6.5% (52/805; Group B); and deep submucosal invasive carcinomas ($> 500 \mu\text{m}$), 11.3% (8/71; Group A) and 6.6% (53/805; Group B). Once again, the groups showed no significant differences. The *en bloc* resection rates were 100% (71/71 lesions; Group A) and 97.1% (782/805 lesions; Group B), histological complete resection rates were 94.4% (67/71; Group A) and 92.9% (748/805; Group B), and the curative resection rates were 78.8% (56/71; Group A) and 86.3% (695/805; Group B). Among the non-curative cases, 13 (86.6%) of the 15 patients in Group A and 41 (46.3%) of the 110 patients in Group B received no additional treatment. These results were significantly higher for Group A than for Group B. Concerning complications, the postoperative hemorrhage rates were 2.8% (2/71 patients; Group A) and 2.6% (12/479 patients; Group B), and the perforation rates were 0% (0/71; Group A) and 0.5% (4/805; Group B). Regarding long-term outcomes, analysis of recurrence revealed the local and distant recurrence rates to be 0% for Group A and 0.9% (7/746; local) and 0.1% (1/746; distant) for Group B. Regarding survival analysis, the mean follow-up period in Group A and Group B was 839 and 1156 days, respectively. The 3- and 5-year overall survival rates were 95.5% (3 year) and 74.7% (5 year) for Group A and 92.8% (3 year) and 87.7% (5 year) for Group B. The 3- and 5-year tumor-specific survival rates were 100% for Group A and 99.2% (3 year) and 98.3% (5 year) for Group B (using the Kaplan-Meier method and long-rank test). There were no significant differences observed in the survival rates. 6 (10.0%) of 59 patients in Group A and 54 (9.3%) of 646 patients in Group B died, and disease-specific mortality rates in Groups A and B were 0% (0/59) and 0.8% (5/646), respectively.

Conclusion: Gastric ESD in patients aged 85 years or older can be effectively and safely performed. According to the long-term outcomes, gastric ESD performed as a local resection (total biopsy) in elderly patients may be acceptable, even in non-curative cases.

P0831 RESULTS FROM THE FIRST UK VIRTUAL COMPLEX POLYP MDM

A. Chatree, M. Rutter

Gastroenterology, University Hospital of North Tees, Stockton on Tees/United Kingdom

Contact E-mail Address: amitchattree@nhs.net

Introduction: Data from the UK Bowel Cancer Screening Programme (BCSP) has established that the assessment and management of large non pedunculated colorectal polyps (LNPCPs) varies markedly, leading to variable and often sub-optimal outcomes, especially for the most complex lesions¹. A multicentre complex polyp multidisciplinary team meeting was created within the North East of England BCSP with the aim of ensuring more robust decision making and management of complex LNPCPs.

Aims & Methods: A virtual multicentre MDM was conducted via audioteleconferencing within the North East of England between 2014-6 to discuss complex LNPCPs (LNPCPs with increased risk of malignancy or complexity associated with endotherapy, as defined in BSG/ACPGBI guidelines²). Non-complex LNPCPs were not discussed. Patient data was distributed securely via NHSmail. Outcomes were assessed prospectively using key performance indicators (KPIs) from the BSG/ACPGBI guidelines.²

Results: 61 complex LNPCP cases were managed via the MDM with 8 excluded from analysis (7: managed prior to MDM referral, 1: MDM advice not followed), 27 lesions were managed with primary endotherapy, 23 with primary surgery and 3 cases conservatively. Of the endoscopic cases, 2 required surgery due to failed endotherapy and 2 due to a finding of malignancy. 12-month recurrence was 8.7% with no reported complications. The rate of surgical management using the BSG/ACPGBI KPI (including only surgically managed benign lesions or lesions subject to failed endotherapy) was 39.5%. The *en-bloc* resection

rate of complex LNCPs with features suggestive of increased malignancy risk was 71.4%. **Breakdown of Outcomes (n=53)** *Primary endoscopic therapy (n=27) -23 excised with curative intent -21 cases with no recurrence at 1y -2 cases with recurrence (8.7%) both <1cm and managed endoscopically -4 required secondary surgery -2 failed endotherapy -2 proved to be malignant *Primary Surgical Management (n=23) -10/23 malignant lesions (43.5%) -9/23 subject to transanal surgery (39.1%) *Conservative management (n=3) **Breakdown via High risk features of malignancy/SMSA4/SMSA3 (n=53)** *High risk features of malignancy (any SMSA score) (n=21) -7 endoscopically managed -5 pEMR, 2 ESD -2/7 (28.6%) cases (both managed with pEMR) malignant -13 managed surgically (4/13 (30.8%); transanal surgery) -9/13 malignant (69.2%) -1 managed conservatively *SMSA 4 (n=25) -12 managed endoscopically -12 managed surgically (due to technical considerations) -3/12 malignant (25%) -1 managed conservatively *SMSA3 (n=7) -4 managed endoscopically -2 management surgically (both lesions originating from within appendix) -1 managed conservatively.

Conclusion: 61 complex LNCP cases were managed via the MDM with 8 excluded from analysis (7: managed prior to MDM referral, 1: MDM advice not followed), 27 lesions were managed with primary endotherapy, 23 with primary surgery and 3 cases conservatively. Of the endoscopic cases, 2 required surgery due to failed endotherapy and 2 due to a finding of malignancy. 12 month recurrence was 8.7% with no reported complications. The rate of surgical management using the BSG/ACPGBI KPI (including only surgically managed benign lesions or lesions subject to failed endotherapy) was 39.5%. The en-bloc resection rate of complex LNCPs with features suggestive of increased malignancy risk was 71.4%.

Introduction: Patients of endoscopists with high (≥20%) adenoma detection rate (ADR) have less risk for interval cancer than of those with an low ADR (<20%). Lesion-related-factors, such as size, shape and histology influence these quality measure, as physicians with high ADR tend to detect more flat and serrated adenomas than those with low ADR.

Aims & Methods: Our study aim is to investigate the differences of size, shape and serrated histology of adenomas between low- and high-ADR group in our screening cohort. We analyzed 221.534 screening colonoscopies performed by 261 endoscopists between 2007 and March 2017 within the austrian certificate of screening colonoscopy. T-Test was used to assess differences.

Results: 39.1% of endoscopists were categorized in the ADR low- and 60.9% in the high-ADR group. Overall, mean ADR was 23.06% (SD 0.55) with a minimum of 0.39% and a maximum of 48.72%. In the low-ADR-group mean ADR was 14.56 (SD 0.42) and 28.51 (SD 0.50) in the high-ADR group. Relating to size, there was a significant difference (p=0.029) in detection of adenomas of 1–2 cm with a mean of 8.44% (SD 6.02) in low- vs. 10.22% (SD 6.64) of all adenomas in high-ADR group but no differences between adenomas <0.5 cm, 0.5–1 cm and those bigger than 2 cm. Regarding shape, proportion of pedunculated adenomas in low-group-ADR differ significantly higher (p=0.002), with a mean of 19.36% (SD 14.69) vs. 14.70% (SD 9.55) but there were no differences between flat and sessile adenomas. With a mean proportion of 4.43% (SD 5.61) vs. 6.64% (SD 5.97), the proportion of sessile serrated adenomas (SSA) differ significantly between low-ADR vs. high-ADR-group (p<0.01). There was no significant difference regarding traditional serrated adenomas (p=0.800).

size	ADR-Group	Mean	SD	p-value
<0.5 cm	<20%	53.49	20.58	p = 0.384
	≥20%	51.31	19.14

SSA	<20% ≥20%	4.43	6.64	p < 0.01
TSA	<20% ≥20%	0.88	0.94	p = 0.800

Conclusion: Endoscopists with higher ADR tend to detect significant more SSA and adenomas with 1–2 cm in size, but have lower proportions of pedunculated adenomas than those with a low ADR. In our study cohort no significant differences in flat shape or diminutive size was measurable.

Introduction: ESD is a complex procedure, mainly in non-Asian countries where the learning process is not well established. Results may be improved in Western countries with a careful selection of lesions for ESD and avoiding those with a greater chance of technical difficulty. Factors predicting technically difficult ESD when it is performed by non-Asian endoscopists should be clarified.

Aims & Methods: We aimed to identify the potential risk factors that are associated with a higher technical difficulty during ESD in a Western European setting where there are no available Asian experts. We prospectively recorded consecutive ESD cases performed by members of the ESD Working Group of the Spanish Society of Digestive Endoscopy. Demographic and clinical characteristics of the patients, location and morphology of the lesions, and technical factors were collected. We defined difficult ESD as those aborted procedures, time-consuming (duration > 180 min.) or when changing the technique to piecemeal resection was needed to remove the tumor. Analyses were carried out using IBM SPSS software for Windows (IBM Corp., Armonk, NY, USA). Parametric continuous variables are reported as the mean ± standard deviation (SD). A Kolmogorov-Smirnov test was used to evaluate normal distribution. Categorical variables are reported as either frequencies or percentages. Statistical differences between the groups were analyzed using a chi-squared method for categorical data. The meaningful variables with a p value < 0.1 in the univariate analysis were included in the logistic regression model. Multivariate analysis was performed using binary logistic regression methods. Odds ratios (ORs) and 95% confidence intervals (CIs) were calculated to assess the strength of the influence of each individual variable.

Results: We included 265 lesions in 265 patients [mean age ± SD: 69 ± 10 y; 150 males (56.6%)]. They were recruited in 15 Spanish University Hospitals between January 2016 and March 2017. Location of the lesions were: esophagus (n=7; 2.6%), cardia (n=5; 1.8%); stomach (n=48; 18.1%); duodenal bulb (n=1; 0.3%); colon (n=144; 54.3%) and rectum (n=60; 22.6%). Mean lesion size was 38.6 ± 18.5 mm. Median duration of the procedure was 105 min. (8–375). In 73 cases (27.5%) criteria for difficult ESD were fulfilled. Endoscopic resection was aborted in 7 cases (2.6%). When endoscopic resection was achieved (n=258; 97.3%) both situations, duration > 3 h and a piecemeal resection, were noted in 21 (8.1%) patients. Duration > 3 h in 25 cases (9.7%) and unsuccessful *en bloc*

resection in 20 (7.7%) were observed in isolation, respectively. Table 1 shows the univariate and multivariate analysis of factors regarding technically difficult ESD.

Table 1: Univariate and multivariate analysis of possible factors related to technically difficult ESD.

Variables	UNIVARIATE ANALYSIS		MULTIVARIATE ANALYSIS	
	OR (C.I. 95%)	p	OR (C.I. 95%)	p
Procedure				
Case load ≤ 10	0.8 (0.4–1.6)	0.5		
2 endoscopists (vs. 1 operator)	20.6(5.9–72.6)	<0.0001	9.7 (0.9–94.9)	0.06
Location				
Colorectal	2.6 (1.2–5.7)	0.01	2.2 (0.6–8.3)	0.2
Stomach	0.5 (0.2–1.0)	0.06		
Lesion				
Size > 30 mm	2.4 (1.3–4.4)	0.004	5.0 (1.7–14.4)	0.003
Recurrent tumor	3.2 (1.3–8.1)	0.008	8.1 (1.4–45.9)	0.02
Protruded morphology	0.9 (0.5–1.9)	0.9		
Depressed component	0.6 (0.2–1.7)	0.4		
Poor manoeuvrability	3.5 (1.7–7.5)	0.001	3.5 (1.4–8.7)	0.006
Previous biopsy	1.0 (0.6–1.8)	0.9		
Submucosal invasion	1.3 (0.5–3.7)	0.6		
Severe submucosal fibrosis (F2 vs. F0/F1)	3.3 (1.7–6.4)	0.0002	1.3 (0.4–4.4)	0.6
Complications				
Intraprocedural bleeding	4.1 (1.9–8.7)	0.0003	5.1 (1.3–19.9)	0.02

Conclusion: The factors independently associated with technically difficult ESD (aborted procedures, time-consuming or finished with a piecemeal resection) were: lesion size > 30 mm, poor manoeuvrability, recurrent lesions and intraprocedural bleeding. Except for the last one, the remaining factors can be identified during the first diagnostic endoscopy. Endoscopists who will start performing ESD should try to avoid these difficult procedures in the early part of their learning curves.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0834 EPOCH-MAKING TECHNIQUE OF FULL-THICKNESS RESECTION FOR THE COLORECTAL TUMOR BY USING LAPAROSCOPY ENDOSCOPY COOPERATIVE SURGERY (LECS)

Contact E-mail Address: yoshiro.tamegai@jfc.or.jp

Introduction: We established the Laparoscopy Endoscopy Cooperative Surgery (LECS) procedure to overcome the limitation of colorectal endoscopic submucosal dissection (ESD). This procedure is a local full-thickness resection of the combined procedure of laparoscopy assisted colectomy (LAC) and ESD procedure. Also, it is the method that is epoch-making for minimal invasive treatment that kept an intestinal function.

Aims & Methods: The aim of this study was to investigate the feasibility and safety of LECS procedure applied with endoscopic submucosal dissection (ESD) technique obtained adequate surgical margin. We performed ESD on 1376 colorectal tumors in 1341 patients (male: female = 777:564; mean age, 66.1years). Among these cases, six cases had perforation (0.4%), and three of six cases required emergent surgery. We examined the cause of perforation and the limit of ESD from the view point of safety. We performed one-piece resection for 11 cases (male: female = 7:4; mean age, 63.5years) of colorectal tumors using LECS procedure. In the first, the indication of LECS is at high risk of the perforation by the treatment of ESD and EMR and is the lesion that safety cannot secure. In addition, the indication is the lesion which is curable by the local excision without lymph node dissection. Therefore, submucosal invasive (T1) cancer with the risk of lymph node metastases does not become the indication for this full-thickness resection technique. From the above-mentioned basic concept, indications of the LECS procedure for colorectal tumors were thought to be as follows: 1) Intramucosal carcinoma (Tis) and adenoma with high-grade atypia (Vienna Classification; Category 3, 4) accompanied by wide and severe degree fibrosis in the submucosal layer (tumor recurrence after endoscopic and surgical resection); 2) submucosal tumors; 3) Intramucosal carcinoma (Tis) and adenoma

with high-grade atypia involved appendix or diverticle. We examined the clinicopathological outcomes of the above-mentioned 11 cases.

Results: Four of six cases that caused perforation in ESD were cases with fibrosis in the submucosal layer. Three cases of those were moderate to severe degree fibrosis cases, and a limit of ESD seemed to exist in these lesions from the viewpoint of safety and curability. We accomplished full-thickness resection successfully for 11 cases using LECS procedure as follows: 5 cases of Tis cancer, 4 cases of adenoma, 1 case of schwannoma, and 1 case of GIST. The reasons that we judged as the indication of LECS procedure were as follows: three cases accompanied by severe degree fibrosis, 2 cases involved diverticle, 3 cases involved appendix, 2 cases of submucosal tumor, and 1 case of poor endoscopic operability. These cases were considered a limitation of ESD due to the high risk of perforation. An operative time was an average of 195.8 minutes (127 to 332), and the perioperative bleeding was an average of 8.9 g/dl (3 to 20). We experienced no complications, and average post-operative hospital stay was 7.7(6 to 12) days. Histological examination of the resected specimens revealed negative lateral and deep margins. The postoperative follow-up was carried out first a half year later, and it was every one year subsequently. In the above-mentioned follow-up schedule, blood examination, colonoscopy, CT scan were performed for clinical evaluation. The residual/local recurrence case was absent for 31.6 months (range 10–60 months) for the mean follow-up period. Also, without complications such as postoperative anastomotic stricture or adhesive ileus, we followed favorable course.

Conclusion: We developed a LECS procedure to overcome the limit of ESD, and completed full-thickness one-piece resection of the tumors considered as high risk of perforation in the endoscopic treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic mucosal resection (EMR) and submucosal dissection (ESD) are effective procedures for reducing the need for colorectal surgery. Many studies have focused on major adverse events related to EMR and ESD such as bleeding and perforation. However, data on structured assessment of minor post-procedural adverse events remain scarce. We therefore evaluated the incidence of major and minor adverse events within 30 days of EMR or ESD.

Aims & Methods: We prospectively performed a single-center study on consecutive patients who underwent colonoscopic EMR or ESD between April 2014 and April 2016. We asked for permission to interview the patients 1 day, 14 days, and 28 days after their procedure. Four gastroenterologists performed all procedures. The assigned nurse prospectively recorded the data and interviewed the patients in person on 1 day and 14 \pm 2 days, and via phone on 28 \pm 2 days after their respective EMR/ESD procedure. A standardized interview form was developed to assess the occurrence of (i) major adverse events (hospital visit required), (ii) minor adverse events, and (iii) working days lost due to adverse events. The primary outcome was the occurrence of all adverse events, which were classified as either “major” or “minor”.

Results: We enrolled 630 patients who underwent EMR or ESD. 615 (97.6%) patients (499 EMR, 116 ESD) were contacted. Male comprised 68.5% (n = 415), and the mean age was 57.9 years (\pm 11.3). Major adverse events occurred in 31 (5%), 16 (2.5%), and 1 (0.2%) patients on days 1, 14, and 28, respectively. Minor adverse events occurred in 284 (46.1%), 344 (55.9%), and 25 (4.1%) patients on days 1, 14, and 28, respectively. Bleeding was the most common major event on days 1 and 14; abdominal bloating and bowel habit change were the most common minor events on days 1 and day 14, respectively. 11 (1.8%) and 2(0.3%) patients took leaves of absence due to adverse events on day 14 and 28, respectively. The detailed events are listed in Table 1.

Conclusion: Although the number of major adverse events was small, nearly half of the patients reported minor adverse events on 14 days following colon EMR/ESD. Most minor adverse events subsided by the day 28.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Patient experience is increasingly recognised as a key measure of quality of care. Ensuring positive experience is important to patients and fundamental in maximising participation in screening programmes and re-attendance for surveillance procedures. Current measures of patient experience of gastrointestinal (GI) endoscopy are clinician derived.(1) Patient Reported Experience Measures (PREMs) should be patient derived and incorporate pre-and post-procedure experience. We aimed to identify themes considered as important to patients undergoing GI procedures as a basis for developing PREMs.

Aims & Methods: We aimed to identify themes important to patients undergoing GI investigations, to enable questionnaire development. Patients who had undergone upper or lower GI investigations (gastroscopy, colonoscopy and CT pneumocolon) were invited to attend for a semi-structured interview. 32 interviewees were purposefully sampled to ensure diversity. Interviews were conducted by a research fellow trained in qualitative methods and were audio recorded and transcribed verbatim. Recruitment continued until saturation was achieved. Analysis used qualitative thematic methods focusing on anticipated and emergent themes, using constant comparison to ensure that all perspectives were included in the explanation of the data.

Results: 168 patients were approached. 32 interviews were completed (12 gastroscopy, 10 colonoscopy and 10 CT pneumocolon), with a male:female ratio of 18:14. The time interval from examination to procedure ranged from 5 to 44 days. Mean age was 63.1 years (SD 11.5)

The interviews provided an in-depth understanding of patient experience of GI procedures. 6 over-arching and inter-linking themes emerged across all procedures; anxiety, expectations, choice/control, communication/information, comfort and embarrassment/dignity. Relation of themes was seen e.g. if the

procedure appointment was sooner than expected, patients were anxious about the potential outcome. Choice was important in terms of appointment, endoscopist and choice of pre-medication, however it was highly individualised. Communication prepared patients and managed expectations, with one patient describing poor endoscopist communication affecting the whole experience. Patients described embarrassment related to changing and waiting areas; sensitive nature of the test; exposure and physical reaction. Discomfort during the procedure was attributed to instrument and air insertion.

Conclusion: Despite heterogeneity between procedures consistent themes related to patient experience emerged. This work will be used to develop PREMs for Gastrointestinal Endoscopy.

P0838 RANDOMIZED CONTROLLED TRIAL OF ABDOMINAL VIBRATION STIMULATION AND WALKING EXERCISE FOR BOWEL CLEANSING PRIOR TO COLONOSCOPY

C. Noh, J.K. Kang, K.M. Lee, S.J. Shin, S.G. Lim, K.J. Lee
 Gastroenterology, Ajuu university School of Medicine, Suwon/Korea, Republic of

Contact E-mail Address: cknoh23@gmail.com

Introduction: Adequate bowel preparation is important to perform colonoscopy for accurate mucosa examination, lesion detection and treatment. Walking exercise is known to be effective for colon cleansing. However, it is difficult for patients with uncomfortable walking to improve the status of bowel cleansing.

Aims & Methods: Therefore, we prospectively evaluated the clinical feasibility and clinical validity of the abdominal vibration stimulation for bowel

preparation. In this randomized, prospective, investigator-blind study and single center study, 141 inpatients for elective colonoscopy were randomized to two groups. PEG solution was used for bowel cleaning in all patients. The one is walking over 3000 steps and the other is having abdominal vibrator more than 30 minutes before colonoscopy. After examination we recorded procedure results, sedation information, patient's satisfaction and adequacy of bowel preparation by using the Boston Bowel Preparations Scale (BBPS).

Results: There were no significant differences between vibrator group (n=75) and walking group (n=66) in bowel preparation quality (Total BBPS 7.40 vs 7.23, p=0.519), withdrawal time (30.40 vs 30.05 mins, p=0.829), number of polyps (4.09 vs 3.17, p=0.085), patient satisfaction (4.39 vs 4.12, p=0.249) and number of diarrhea after taking PEG (11.49 vs 11.42, p=0.503). Vibrator group was superior than walking group in time of first defecation after taking PEG (112.89 vs 123.42 mins, p=0.005) and cecal intubation time (6.23 vs 8.52 mins, p=0.011).

Conclusion: Bowel preparation accompanied with abdominal vibration stimulation showed almost similar results to a walking group which was conventional methods for adequate bowel preparation. The patients with the conditions which cause uncomfortable gait such as old age, CVA, Parkinsons, or joint disease, bowel preparation with abdominal vibrator is expected to help in proper bowel cleansing for therapeutic colonoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Electrical and rheological properties of the submucosal cushioning solutions are crucial to avoid complications secondary to endoscopic resections. Electrical resistance (R) of a substance is a measure of the difficulty to pass an electric current through that solution. The higher the R, the resection will be quicker, easier and safer, with less temperature increase. Our group has developed a new solution to perform submucosal injection (TriBio).

Aims & Methods: To analyze the electrical (R) and rheological (temperature, viscosity, height and lasting of the cushioning) properties of different submucosal solutions in an ex vivo model of porcine stomach. Tested solutions were: Saline (S), Gliceol® (GC), Hyaluronic acid (HA), Distilled water (DW), Platelet-rich plasma (PRP), Glucosated serum 10% (GS), Gelaspan (GP), TriBio (TB) and PRP+TB. Measurements were done at time 0 and 30 minutes.

Results: The solutions that showed the best basal R were: PL, HA, GS, TB and TB+PRP. At 60 minutes, the best R were: PRP, TB, PRP+TB, HA and GS. The best durability at 60 minutes was for TB, PRP, TB+PRP and PL that maintained the height at around 80% of its original in comparison to the other substances which were at around 60%. During the resection the solutions that underwent a lower temperature increase were: TB+PRP, PL, and TB.

	Viscosity (pa)	% diminution cushion (60 min)	Trans-epithelial R (MΩ)	Increase in T° during endoscopic resection (°C)
Basal	n.a.	n.a.	10	83.5
Saline	0.0043	39.6	9	49.1
Gelaspan	0.009	45.5	9	116.6
Glyceol	0.009	26.3	10	44.9

(continued)

Continued

	Viscosity (pa)	% diminution cushion (60 min)	Trans-epithelial R (MΩ)	Increase in T° during endoscopic resection (°C)
Glucosated saline 10%	0.008	29	12	29.9
Pluronic 20%	0.9*	0.52	14	12
Hyaluronic acid 5%	0.04	24.4	13	12.5
TriBio (TB)	0.9*	2.8	15	36.5
Platelet-rich Plasma (PRP)	0.01**	17	13	20.8
TB+PRP	0.45*	11.5	15	5.6

n.a.: not applicable * gelification at 37°C ** viscoelastic solid when activated

Conclusion: Based on electrical and rheological properties, the best submucosal solutions to perform safer endoscopic resections are: TB+PRP, TB, PL and PRP.

³Institute Of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg/Sweden

Contact E-mail Address: sara.sjoblom@vgregion.se

Introduction: Patients with chronic diseases, such as inflammatory bowel disease, experience a lower degree of being involved in health care than others. Compared with other countries Swedish patients report lower possibility to be involved in their care and receive less information about care (1).

Aims & Methods: To investigate the perception of written and oral information given before and after a colonoscopy, the perceived knowledge of planned follow-up and preference to be more involved in decisions/participate in their care in different patient groups. Outpatients (>18 y) undergoing colonoscopy (all indications) were consecutively included (n=862). Before the procedure patients completed questionnaires regarding sociodemographic data and the written information about bowel preparation and examination. After the procedure patients reported their perceptions about the information provided regarding the colonoscopy and the follow-up.

Results: Data from 862 patients were analyzed (447 females) (mean age 52; 18-90 y) A large number of patients (n=740, 87%) rated the written information sent home before the colonoscopy as distinct, while a subset (n=110, 13%) rated it as indistinct/very indistinct. When questions of importance were asked to the medical staff during the colonoscopy most patients were content with the answers from the physician or nurse. A small proportion of patients (n=57, 7%) stated that they received too little information or that they did not understand the information about the colonoscopy results; these patients were mainly younger (<50 y) (p<0.001). The majority of the patients (n=602, 74%) reported thorough knowledge about the follow-up, while 26% (n=207) lacked this knowledge. More than 1/3 (n=275) of the patients wished to be more involved in decisions regarding their care and treatment. Desire for a higher degree of involvement were more pronounced in patients <40 y (p<0.05) and in patients with IBD (p<0.05) compared to patients with other indications for colonoscopy. Patients referred from outpatient clinics in the hospital desires a higher degree of involvement than patients referred from primary care (p<0.01).

Conclusion: The majority of the patients undergoing colonoscopy reported that they received satisfactory information about the procedure and preparation. However, there is room for improvement regarding follow-up information and patients' involvement in their care and treatment. Specifically, improvements seem warranted for younger patients and patients with chronic diseases, such as IBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A "skirt" is a slightly elevated flat lesion with wide pits occasionally observed at the margin of laterally spreading tumors (LSTs), and rectal LSTs had significantly more skirt lesion in comparison to colonic LSTs. Although the clinicopathological, endoscopic, and molecular characteristics of LSTs with a skirt have been reported [1], there are no reports concerning the incidence of synchronous neoplastic lesions of rectal LSTs with a skirt.

Aims & Methods: The aim of this retrospective study was to clarify the incidence of synchronous advanced neoplasia (AN) of rectal LSTs with a skirt. A total of 13,116 cases underwent colonoscopy in our hospital between January 2012 and June 2016. Of these, 101 consecutive rectal LSTs were examined to assess the incidence of synchronous AN detection rate and the number of AN according to the location of AN lesion; divided into the right colon, left colon and rectum. A skirt was defined on the basis of the following endoscopic findings: spreading across the margins of the LST, consisting of a slightly elevated flat lesion, and containing wide pits. AN was defined as the presence of any of the following features: adenomas larger than 10 mm, adenomas with villous histology or high-grade dysplasia including intra-mucosal carcinoma and invasive cancer.

Synchronous advanced neoplasias of rectal LSTs with and without skirts

	Rectal LSTs with skirts (n=25)	Rectal LSTs without skirts (n=76)	p value
Patients with advanced neoplasia			
Total	5 (20.0%)	36 (47.4%)	0.02
Right colon	2 (8.0%)	23 (30.3%)	0.03
Left colon	1 (4.0%)	21 (27.6%)	0.01
Rectum	3 (6.0%)	5 (6.6%)	0.41
Number of advanced neoplasia			
Total	7	74	0.02
Right colon	2	35	0.03
Left colon	2	34	0.04
Rectum	3	5	0.44

Results: A skirt was observed in 25 of 101 rectal LSTs (24.8%). Rectal LSTs with a skirt (median age 69 years, 52% female, mean size 51.7 ± 27.1 mm) had 22 high-grade dysplasia and 3 submucosal carcinomas, and rectal LSTs without a skirt (median age 72 years, 34% female, mean size 24.7 ± 16.0 mm) had 8 low-grade dysplasia, 45 high-grade dysplasia, and 23 submucosal carcinomas, respectively. The overall AN detection rate in rectal LSTs with a skirt (20.0%) was significantly lower compared with rectal LSTs without a skirt (46.8%, $p=0.02$). As for the analysis of AN detection rate according to the location, there were significant differences in the right colon (8.0% vs 29.9%, $p=0.03$) and the left colon (4.0% vs 27.3%, $p=0.01$) between LSTs with and without a skirt. In contrast, there was no significant difference with respect to the rectum (6.0% vs 6.5%, $p=0.41$). The total number of AN in rectal LSTs with a skirt ($n=7$; right colon: 2, left colon: 2 and rectum: 3) was significantly lower than in rectal LSTs without a skirt ($n=74$; right colon: 35, left colon: 34 and rectum: 5). There were significant differences in the right colon ($p=0.03$) and the left colon ($p=0.04$), while, there was no significant difference between these groups with respect to the rectum.

Conclusion: The rectal LSTs with a skirt had significantly lower synchronous advanced neoplasia than rectal LSTs without a skirt, especially in the right and left colon. Our results may suggest that rectal LSTs with a skirt have different characteristics compared with rectal LSTs without a skirt in terms of the incidence of synchronous neoplastic lesion.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic resection of large lesions leads to extensive mucosal defects and submucosal exposure, with a substantial risk of adverse events. The prevention of these complications is inefficient with current methods. Endoscopic shielding, as a simple and safe technique, has been proposed to improve mucosal restoration, and therefore, the incidence of these events. Previous reports have confirmed the efficacy of the placement of hydrogels based on platelet-rich plasma (PRP) (1) or hyaluronic acid with other substances (TriBio) (2), but never the combination of both hydrogels, in the prevention of delayed complications after mucosal damage.

Aims & Methods: To assess the efficacy of endoscopic shielding with the combination of PRP and TriBio in a rat model of thermal injury. Thermal injury was obtained according to our rat model (3). Lesions were performed in male Sprague-Dawley rats (400-450 g) under general anesthesia. Animals were randomized to receive one of the following shields onto the lesions: PRP + TriBio, PRP and TriBio. Rats underwent endoscopic follow-up at 7 days and 2 weeks. Afterwards, animals were sacrificed and ulcers sites were macroscopically and histopathologically evaluated.

Results: Animals treated with PRP + TriBio obtained the best results in comparison with other hydrogels (PRP and TriBio). Mucosal healing rate (percentage of mucosal restoration) at 14 days was significantly higher with PRP + TriBio (100% vs 82% and 90%; $p < 0.05$). Histological study confirmed these data, showing total restoration of mucosal layer with PRP + TriBio

Conclusion: The use of a combination of two covering agents (TriBio and PRP) is the best approach to obtain mucosal healing in a rodent model of endoscopic thermal injury in colon

Introduction: Colonoscopic procedures have become massive in the last years since colorectal cancer (CRC) is becoming a prevalent disorder. The next frontier of this technique will be to provide an active substance in a precise site of the colon (targeted therapy). This has many advantages (targeted therapy, dose adjustment, limiting side effects, assessment of mucosal healing, etc.); however, this selective and direct administration of drugs is not possible nowadays, but it is a true challenge. Following these evidences we have developed drug eluting platform to locally treat CRC lesions

Aims & Methods: To evaluate the efficacy of intratumoral injection of our drug-eluting platform with different combinations of these antitumoral drugs (afibercept 2 mg/mL, cetuximab 16 mg/mL, panitumumab 6 mg/mL, irinotecan 3.5 mg/mL and bevacizumab 5 mg/mL) in a rat model of azoxymethane-induced colorectal cancer. Rats underwent endoscopic follow-up at 1 and 2 weeks after endoscopic therapy. Afterwards, animals were sacrificed and tumors were excised and macroscopically and histopathologically evaluated.

Results: Intratumoral injection was feasible in all animals with no adverse events. Basal mean size of tumors ranged from 6 to 8 mm. Anti-VEGF in comparison with Anti-EGF obtained the best results (significant reduction in size and cell necrosis). However, only aflibercept showed total acute tumoral necrosis.

Conclusion: Intratumoral injection of anti-VEGF in a drug-eluting platform is able to produce tumoral necrosis in an experimental model of CRC. This technique could open a new way to manage CRC.

P0844 A THREE-DIMENSIONAL IMAGING SYSTEM IMPROVES THE ENDOSCOPIC VISIBILITY OF NON-POLYPOID COLORECTAL NEOPLASMS

T. Matsumura, D. Maruoka, K. Okimoto, N. Akizue, T. Nakagawa,

Introduction: Three-dimensional (3D) imaging techniques have been developed in the medical field. Previous research reports that simulated 3D colonoscopy improves the detection of colonic lesions [1]. A novel 3D imaging system has been recently developed, which can create 3D virtual video images from conventional two-dimensional (2D) endoscopic images [2]. However, actual cases have not been studied.

Aims & Methods: This study aimed to investigate whether the 3D system can improve the visibility of colorectal neoplasms compared with conventional 2D endoscopy. We studied two non-polypoid colorectal neoplasms and recorded their videos using conventional 2D endoscopy and the 3D system. The movies were evaluated by 8 endoscopists (4 experts and 4 non-experts) and 4 medical students. Each neoplasm was assigned a visibility score between 4 (excellent visibility) and 1 (poor visibility).

Results: The mean visibility scores were 3.35 ± 0.58 for 2D endoscopy and 3.75 ± 0.44 for the 3D system. The score was significantly higher for the 3D system than for 2D endoscopy ($p < 0.01$). When comparing the evaluations by the experts, non-experts, and medical students, the differences in the scores by the non-experts and medical students were noted to be higher ($p < 0.05$). In contrast, the scores by the experts were also higher for the 3D system, but no statistical difference was observed (3.50 ± 0.53 for 2D endoscopy and 3.87 ± 0.35 for the 3D system, $p = 0.08$). As a result, 10 out of 12 observers noted that the 3D system had better visibility than conventional 2D colonoscopy, and none of the observers noted deterioration in visibility with the 3D system.

Conclusion: The present findings suggest that the 3D imaging system improves the visibility of non-polypoid colorectal neoplasms, and this is more effective for non-experts. Our findings would contribute to improvement in the detection of these neoplasms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pain is a subjective perception, which contributes to difficulties to provide adequate pain relief according to every patient's needs. Colonoscopy is by many patients considered as a painful and strenuous procedure.

Aims & Methods: To investigate congruence and differences between patients' and caregivers' report of pain during colonoscopy. Patients (≥ 18 years) undergoing an outpatient colonoscopy (all indications) have consecutively been included ($n = 862$). Before the procedure the patients completed questionnaires regarding sociodemographic information and anxiety. After the colonoscopy the patients registered their pain experience on a six-grade scale, ranging from "no pain" to "extremely severe pain". Caregivers (physicians and endoscopy nurses) estimated patient's pain using the same scale.

Results: Data from 785 patients has been collected, mean age 52 (18–90) years; 413 women. Approximately half of the patient's reported no or mild pain, 21% moderate pain and a subgroup of 14% were not adequately relieved. These subgroup reported severe, very severe or extremely severe pain. 90% of the patients were given analgesics and sedation during the investigation. For patients who reported, "severe, very severe or extremely severe pain" ($n = 111$), pain was underestimated by physicians and nurses in 58% of all assessments. This was most commonly seen among the youngest patients, 18–29 years ($n = 99$), where pain was underestimated in 25.5% among the group. There was also a difference according to gender; physicians underestimated pain in 60% of men who reported "moderate pain" ($n = 66$) while the nurses underestimated pain in 27% among the same group of men. Women's pain was overestimated by caregivers in 26% ($n = 188$) of all cases with mild pain. Patients undergoing colonoscopy for the first time ($n = 331$), and reporting "moderate pain", were underestimated by physicians in 58% and by nurses in 25%. 58% of the patient reports that they were anxious before the procedure. This group reported more pain than the group without anxiety ($p < 0.001$). Presence of anxiety and a high level of pain among the group enhanced the agreement between the caregiver's and the patient's pain report. The agreement between pain reports from patients and caregivers were poor to fair, with slight differences between nurses ($\text{Kappa} = 0.37$; $p < 0.000$) and physicians ($\text{Kappa} = 0.29$; $p < 0.000$). In total, congruent pain reports between patients and caregivers were seen in 36% of all assessments.

Conclusion: Agreement between caregivers' and patients' pain reports is far from perfect, and the agreement is influenced by several factors such as the profession of the caregiver, as well as patient factors including pain severity, anxiety, age, gender and previous experience of colonoscopy. The goal for the future should be to individualize the use of analgesics based on every patient's needs, which seems to be of special importance in specific groups of patients.

Introduction: The SCENIC consensus proposed recommendations for optimal detection and management of dysplasia during colonoscopic surveillance for IBD¹. Characterization of colonic lesions in IBD remains challenging even by using advanced endoscopic imaging modalities (high definition [HD], virtual chromoendoscopy [VCE] dye chromoendoscopy [DCE]).

Aims & Methods: We aimed to develop a unified endoscopic classification of advanced imaging to predict histology of colonic lesions, and to validate by international experts (Frankfurt Advanced Chromoendoscopic Ibd LESions-FACILE Group). We developed an endoscopic classification of IBD lesions, based on morphology, colour, demarcation, surface pattern, vessel pattern, signs of inflammation (table). A library of 60 colonic lesions, including dysplasia, sessile serrated adenomas/polyps, invasive cancer and pseudopolyps collected at surveillance colonoscopy by using HD, DCE and VCE with i-scan or NBI were assessed. The diagnostic performance of the score was tested based on the final histopathology and the inter-observer variability of the eight examiners. The examiners have had to perform a pre-test (45 minutes) before analyzing the colonic lesions. Multivariate analysis with bootstrapping, of characteristics of the classification was performed to determine the strength of endoscopic predictors of dysplasia.

Results: Of the 60 IBD lesions, 33 (55%) were dysplasia, 6 (10%) cancer, 9 (15%) SSA/PS and 12 (20%) pseudopolyps. Across the experienced academic raters sensitivity, specificity, PPV, NPV and accuracy in predicting histology, were 72%, 72%, 91%, 40%, 72%. Individual rater accuracy ranged from 66% to 77%. Sensitivity, specificity, PPV, NPV, accuracy, for predictions made with high confidence were 72%, 90%, 97%, 46%, 76%, which were significantly more accurate compared with a low confidence of diagnosis (76% vs 65%; $P < 0.001$). Univariate analysis showed that the non polypoid lesions, irregular and vessel architecture and signs of inflammation within the lesion were predictive of dysplasia. Subsequent multivariate analysis confirmed that of these endoscopic findings non polypoid lesion OR 11.6 (95% CI:6.71–20.2), surface pattern

OR 0.31 (95% CI:0.17–0.54), vessel architecture OR 5.1 (95% CI: 2.7–10.2), sign of inflammation within the lesion OR 0.39 (95% CI: 0.18–0.85) were independent predictors of dysplasia, with vessel architecture and morphology being the best predictors. The sensitivity, specificity, PPV, NPV and accuracy at the multivariate analysis stage were 94% (95% CI: 90–96%), 51%(95% CI: 43–58%), 88% (95% CI: 82–92%), 69% (95% CI:62–75%), 85% (95% CI: 79–90%). Inter-observer agreement of the raters improved from the pre-test (Kappa = 0.27.95% CI: 0.19–0.38) to post test (Kappa = 0.34.95% CI: 0.23–0.45;P = 0.02) but was moderate.

Conclusion: We developed and validated the first endoscopic classification using all imaging modalities (HD, VCE, DCE) to characterize and differentiate dysplastic from non-dysplastic lesions in IBD. Non polypoid lesions, irregular surface and vascular pattern as well as inflammation within the lesions were predictive of dysplasia. The inter-observer variability of the score was moderate. The classification will be further refined based on the multivariate analysis and a prospective study is ongoing.

Table 1: Advanced endoscopic classification of IBD lesion

Morphology (mm):

Introduction: Participants' experience with a screening test can influence adherence, and therefore the efficacy of a screening programme. We compared the satisfaction with decision and willingness to repeat colorectal cancer screening with flexible sigmoidoscopy (FS) and faecal immunochemical test (FIT).

Aims & Methods: In a prospective, randomised trial 3257 individuals (50–74 years) were invited to either FS or FIT (1:1) of whom 1650 (52.6%) attended. In total, 1497 screening participants completed at least one questionnaire measuring willingness to repeat screening, recommend screening and satisfaction with decision to attend, either before screening, and/or three times in the following year. There were 769 and 728 responders in the FS and FIT group respectively. Of these FS participants, 581 participants also completed a pain-questionnaire.

Results: One year after screening, 10% of the FS participants were not willing to repeat screening, compared to 5% of FIT participants, adjusted OR 0.47 (95% CI: 0.31–0.72). In the FS group, there was a higher percentage of women who would not repeat screening, compared to men, adjusted OR 2.52 (95%CI: 1.48–4.28). Notably, 22% of women reported pain during the FS, compared to 5% of the men. Both men and women who self-reported pain were statistically significantly less willing to attend FS screening again compared to participants who reported no pain. When we added pain to the model, pain was significantly associated with the unwillingness to repeat FS OR 3.15 (95%CI: 1.68–5.87), while gender was no longer OR 1.53 (95%CI: 0.82–2.88).

Conclusion: Acceptance for FS and FIT were high among Norwegian screening participants, though FIT participants were more willing to repeat screening. Women were less willing to repeat screening with FS compared to men. This gender difference seemed partly due to pain, and therefore preventable.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0848 THE ROLE OF PROBE CONFOCAL LASER ENDOMICROSCOPY WITH IMAGE ENHANCED ENDOSCOPY IN CHARACTERISATION AND ENDOSCOPIC RESECTION OF DYSPLASTIC LESIONS IN INFLAMMATORY BOWEL DISEASE PATIENTS

M. Iacucci¹, X. Gui², S. Ghosh¹

Introduction: Detection, characterization and therapeutic management of flat dysplastic lesions during surveillance colonoscopy in inflammatory bowel disease (IBD) can be a challenge. The recent SCENIC consensus has introduced a new terminology and concept “endoscopically resectable” when the distinct margins of a detected lesion could be identified. New endoscopic techniques and skills are required to recognize the margins reliably and assess the surrounding mucosa to plan endoscopic removal successfully and organ sparing. We report our experience of the use of probe confocal endomicroscopy (pCLE) combined with selective electronic virtual (VCE) and dye chromoendoscopy (DCE) for management of challenging dysplastic lesions during surveillance in IBD.

Aims & Methods: IBD patients underwent surveillance colonoscopy using high-definition (HD)-iSCAN (Pentax EC-3940Fi; Japan) VCE and DCE in combination with pCLE (Cellvizio, Paris, France). pCLE was applied following IV injection of fluorescein 5% 10 ml to assess the histological features of the lesion, the margins and the mucosa surrounding the visible colonic lesion. Biopsies eventually proved dysplasia or SSA of the colonic lesions. The study was approved by the Calgary Conjoint Health Services Research Ethics Board of the University of Calgary. All patients gave informed consent.

Results: Seven patients with IBD and disease duration of ≥8 years and in clinical remission {Eaden, 2001 #2} (mean age 55 years; 6 male, UC = 4 CD = 3) were prospectively included. They underwent surveillance colonoscopy using HD-iSCAN (Pentax EC-3940Fi; Japan). When a colonic lesion was detected, selective iSCAN -VCE was performed with or without DCE (five out of seven had DCE)

with methylene blue 1% to characterize the surface, vascular pit pattern and the margins of the lesion. Each of the 7 patients had non polypoid colonic lesions, 4 were sessile (Paris Is) and 3 flat (IIa/IIb). Four of them were amenable to endoscopic therapy and were successfully removed using endoscopic mucosal resection (EMR) en-block or piecemeal technique. Interestingly, one patient with multiple scattered 'pseudopolyps' had a 8mm sessile pseudopolypoid lesion with a suspicious areas of SSA in the midst that was confirmed by real pCLE.

The endoscopic, endomicroscopic and histological findings of all the lesions were described in Table 1.

Conclusion: This case series highlights the first successful use of pCLE in combination with VCE and DCE to predict, characterise and treat colonic neoplasia in IBD. pCLE may be an additional tool to aid the endoscopist in therapeutic management by deciding endoscopic resectability versus colectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0849 THE SAFETY AND EFFECTIVENESS OF COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION USING A SCISSORS-TYPE KNIFE IN ELDERLY PATIENTS

T. Kuwai¹, T. Yamaguchi¹, H. Imagawa¹, S. Funaki¹, K. Tao¹, R. Miura¹, T. Takasago¹, Y. Sumida¹, Y. Miyasako¹, A. Yamaguchi¹, H. Kouno¹, H. Kohno¹, S. Ishaq²

Introduction: Endoscopic submucosal dissection (ESD) is one of the most useful methods for treating early colorectal neoplasms and conventionally utilizes an IT, hook, or needle knife. However, because these devices are used without fixation to target, it confers a potential risk of complications due to unexpected incision. To reduce the risk of complications from ESD performed using a conventional knife, we used a scissors-type knife (SB Knife Jr: Akita Sumitomo Bakelite, Japan) that allows keeping an adequate dissection layer and preventing unexpected muscular layer injury. In the previous study, we reported that ESD performed using SB Knife Jr is a technically efficient and safe method for treating early colorectal neoplasms. However, the efficacy and safety of colorectal ESD using SB Knife Jr in elderly patients remain unclear.

Aims & Methods: The aims of our study were to evaluate the efficacy, safety, and clinical outcomes of colorectal ESD using SB Knife Jr in patients aged ≥ 75 years in comparison with those in younger patients. We evaluated 291 colorectal lesions in 271 patients (male-to-female ratio, 148:123; median age, 70 years) treated with ESD using SB Knife Jr between October 2010 to March 2017 at Kure Medical Center and Chugoku Cancer Center. The patients were divided into two groups, an elderly group (group A: age, ≥ 75 years; 95 patients, 97 lesions) and a non-elderly group (group B: age, < 75 years; 176 patients, 194 lesions). We evaluated the en bloc resection rate, complete resection rate, curative resection rate, resected tumor size, procedural time, complications, and long-term outcomes, including survival rate. The 3-year overall survival and tumor-specific survival rates were analyzed in the entire study cohort, and the local and distant recurrence rates were analyzed in the cohort with curative resection and observationally managed with non-curative resection.

Results: The mean age was 80.0 years in group A and 64.3 years in group B. The male-to-female ratios were 45:50 and 103:73 in groups A and B, respectively. Regarding histopathological findings, the prevalence rates of tubular adenoma were 37.1% (36/97) and 36.1% (70/194); Tis, 39.2% (38/97) and 44.8% (87/194); T1a, 10.3% (10/97) and 10.3% (20/194); and T1b, 13.4% (13/97) and 8.8% (17/194) in groups A and B, respectively, showing no significant difference. The mean resected tumor size was 33.9 \pm 16.6 mm in group A and 34.7 \pm 15.2 mm in group B, and the median procedure time was 75.6 min (range, 10–420 min) in group A and 75 min (range, 10–533 min) in group B, showing no significant difference. The en bloc resection rates were 96.9% (94/97) and 99.0% (192/194); the complete resection rates, 94.8% (92/97) and 94.8% (184/194); and the curative resection rates, 83.5% (81/97) and 88.1% (171/194) in groups A and B, respectively, showing no significant difference. Regarding complications, no perforation during the procedure occurred in any of the cases. The delayed bleeding rate was 1.0% (1/97) in group A and 2.6% (5/194) in group B. Delayed perforation and rectal stricture occurred in one patient each in group A and were treated conservatively. Regarding long-term outcomes, the local recurrence rate was 1.0% (1/97) in group A and 0.5% (1/194) in group B, and no distant recurrence was observed in the recurrence analysis cohort. Regarding survival analysis (mean follow-up period: group A, 523 \pm 469 days; group B, 628 \pm 582 days), the 3-year overall and disease-specific survival rates were respectively 98.8% and 100% in group A, and 93.3% and 98.3% in group B. One patient (0.5%, 1/194) died of colorectal cancer and 5 patients (2.6%, 5/194) died of other diseases in group B, while one patient (1.1%, 1/95) died of other diseases in group A.

Conclusion: ESD performed with SB Knife Jr. is a technically efficient and safe method associated with favorable long-term outcomes in cases of early colorectal neoplasms both in elderly and non-elderly patients.

P0850 QUALITY IN COLONOSCOPY; HAVE YOU REALLY GOT TO THE CAECUM?

S. Budihal

Department Of Endoscopy, Nottingham University Hospitals, Nottingham/United Kingdom

Contact E-mail Address: shivbudihal@yahoo.co.uk

Introduction: Poor quality and incomplete colonoscopy is associated with missed diagnosis and failure to prevent interval cancers.¹ Caecal intubation rate is the most frequently used Quality Indicator of colonoscopy. British Society of Gastroenterology guidelines recommend obtaining “clear images of caecal

landmarks or terminal ileum” while the European and American guidelines suggest “auditable photo documentation of completion preferably a panoramic view of the ileocecal valve and caecum”. In this retrospective study we aimed to assess colonoscopists’ practice in photo documentation of colonoscopy completion.

Aims & Methods: Colonoscopy reports for colonoscopies performed at an endoscopy site in a University Hospital over a period of three months from 01/01/2014 to 31/03/2014 were retrieved from the Trust’s Endoscopy database. Photo documentation from the reports were then analysed for caecal landmarks and terminal ileum images.

Results: A total of 292 colonoscopies were performed by 21 endoscopists (5 Colorectal Surgeons (24%), 3 Nurse Endoscopists (14%), 3 Specialist Registrar Gastroenterology (14%) and 10 Consultant Gastroenterologist (48%)). Caecal intubation was achieved in 248 cases (85%). In 8(3%) cases the anastomosis was reached. The ileo-caecal valve was photographed in 172(70%) cases, the appendix in 102(41%) cases, the caecum in 83(33%) cases and a panoramic view was achieved only in 43(17%) patients. Terminal Ileum was intubated in 53 cases (21%) and images were recorded in 25 cases (40%). In the case of anastomosis, 7 images (88%) of the anastomosis were obtained. In some of the reports images were labelled and in a number of reports no photos were recorded at all.

Conclusion: This study shows that photo documentation is poor and needs to be improved in order to adhere to national and international guidelines. Evidence of caecal intubation is imperative as it can protect against medicolegal implications². Obtaining clear images of caecal landmarks will ensure definite caecal intubation and efforts towards recording them will prompt the endoscopist to attain adequate mucosal views. In order to achieve excellence we suggest colonoscopists obtain images of all caecal landmarks including the ileum (when intubated), label photographs and where possible record video clips of caecal intubation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: iacuccim@yahoo.it

Introduction: Sessile Serrated polyps (SSA/PS) are pre-malignant lesions that may lead to colorectal cancer in accelerated manner. These lesions are easily missed by endoscopists as these are difficult to detect in IBD patients. We aimed to assess the prevalence, detection rate and endoscopic findings of SSA/PS in long standing IBD patients prospectively undergoing surveillance colonoscopy using dye (DCE) or virtual electronic chromoendoscopy (VCE) or high definition white light (HD-WLE) colonoscopy alone.

Aims & Methods: A total of 270 randomized patients (55% men; age range 20–77 years, median age 49 years) with long-standing IBD (median duration of the disease 14 years) undergoing surveillance colonoscopy were assessed by HD-WLE (n=90), VCE (n=90) or DCE (n=90). Surveillance colonoscopy with High Definition (HD) alone, or with iSCAN VCE or DCE was performed. Endoscopic features were recorded in each group with regard to location, morphology (polypoid/non polypoid), size and mucosal pit pattern, and these were characterised using the Kudo modified classification and Paris classification. The histology was reported by modified Vienna classification.

Results: Thirty -three SSA/PS were detected in 20 (11UC; 9 CD; 11 female, age range 34–72 y, median age 61 years) patients out of the 270 patients with IBD enrolled (12.2%). The endoscopic features of SSA/P lesions were: non-polypoid appearance (51.5%), predominant localization in the proximal colon (vs distal) (87%), ≥ 5 mm in size (48.4%), Kudo pit pattern modified type IIO (79%). Kudo pit pattern modified type IIO had a sensitivity of 79% and specificity of 82% for diagnosing SSA/PS at surveillance colonoscopy in IBD patients. There was no difference in detection rates of SSA/P using HD-WLE, DCE or VCE.

Conclusion: SSA/PS are not an infrequent finding at surveillance colonoscopy in IBD. There are prevalent in the right colon location and these generally have Kudo pit pattern of IIO. SSA/PS can be recognized endoscopically by Kudo pit

Abstract: P0851

	F	Age mean	UC/CD	Localization&Size				Paris classification		Kudo pit pattern	
				Right	Left	<5mm	≥ 5 mm	Is/p	IIb/IIa	I/II	IIO III-IV
Serrated adenoma n=33	11	61	11/9	29	4	16	17	16	17	1	26 6

pattern even in IBD patients. Further studies are needed to evaluate the natural history and outcome of the SSA/Ps pathway lesions in IBD patients.

Introduction: The histological characterization of colorectal polyps using FICE (Fujinon Intelligent Color Enhancement) technology presents high diagnostic acuity. However, the excellent results in histological prediction are a reflection of the clinical practice by trained endoscopists, and their application remains to be confirmed outside this context.

Aims & Methods: To evaluate the *in vivo* histological prediction acuity of colorectal polyps <10 mm (hyperplastic polyps vs adenomas) in WLE (White light endoscopy) and using FICE technology, comparing both modalities. Prospective evaluation, using WLE and FICE, of colorectal polyps <10 mm in patients submitted to colonoscopy between 12/2016 and 02/2017 by four inexperienced endoscopists in FICE, except for a previous 20-minutes interactive session. Polyps were evaluated using the FICE classification [tubular or oval crypts (adenoma), round crypts or featureless appearance (hyperplastic polyps), indicating their confidence level (low <90% vs high >90%). Statistics: SPSS v23

Results: 25 polyps were included, with a mean size of 4.5 mm, 14 adenomas, 10 hyperplastic and 1 serrated adenoma. From the global assessment of all polyps and observations, the use of the FICE classification for prediction of adenomatous histology obtained values of sensitivity, specificity, positive and negative predictive value identical to WLE (100%, 62.5%, 60% and 100%, respectively). Overall, diagnostic acuity in histological prediction was identical in both modalities (76%). The individual acuity of the endoscopists ranged from 66% to 100%. Higher confidence scores were not associated with a higher probability of correct classification, both in WLE (77% vs. 75%) and FICE (75% vs. 80%), $p > 0.05$.

Conclusion: The use of FICE technology by inexperienced endoscopists in the histological prediction of colorectal polyps has no advantage over WLE, having both suboptimal acuities. The lack of recourse to magnification may have contributed to these results.

P0853 POLYP DETECTION RATES IN COLONOSCOPIES PERFORMED UNDER GENERAL ANAESTHETIC COMPARED TO CONVENTIONAL SEDATION

B. Perren, A. S. Bancel, A.G. Lim, P. Youd, S. J. Moodie, P. Patel
Medicine, Epsom and St Helier University Hospitals, London/United Kingdom

Contact E-mail Address: ben.perren@doctors.org.uk

Introduction: Colonoscopies are performed under general anaesthesia (GA) for various reasons, but mainly due to previous procedures being poorly tolerated with normal sedation. During the procedure, the endoscopist must be aware of the patient's comfort levels and reactions to endoscopic manoeuvres. Polyp detection rate is a recognised indicator of quality of colonoscopy. It has been demonstrated that use of sedation increases the quality of colonoscopy^[1]. We hypothesised that complete removal of the patient factor may increase the detection rate of polyps further.

Aims & Methods: The study was undertaken retrospectively at a district general hospital. Results were analysed for all colonoscopies performed under GA between February 2016 and February 2017 to identify whether polyps had been detected, the number of polyps detected, and the site of polyp detection. Studies performed for surveillance of previously diagnosed Inflammatory Bowel Diseases (IBD) were excluded. The age and gender of each group was also analysed to identify possible confounding factors.

Results: 40 colonoscopies were performed under propofol sedation within the defined criteria; 40 colonoscopies performed using conventional sedation were randomly selected to use for comparison. A significant increase in rate of polyp detection was found in GA studies (45% vs non-GA studies 30%, $p = 0.0384$). GA studies identified a mean of 1.275 polyps per study, compared to a mean of 0.325 polyps where conventional sedation was used ($p < 0.0001$). There was an insignificant ($p = 0.175$) difference in age between the GA (59.7 ± 18.2) and non-GA (64.7 ± 14.2). There was a significant ($p = 0.0005$) difference in gender between groups; there was an even distribution of gender in the conventional pool, while the GA pool of patients was 77% (31:9) female.

Conclusion: Use of propofol sedation during colonoscopy provides a statistically significant increase to both the rate of detection of polyps, and the number of polyps identified when compared to procedures performed for similar indications using conventional sedation. This may be due to elimination of the patient factor. The implications of this are unclear and thus further larger comparison studies are needed. It is not practical for all colonoscopies to be performed under GA due to capacity issues, anaesthetic requirements and time allocated to lists. However, it may be a clinically effective tool for high-risk patients, such as those being screened for hereditary colonic malignancies or IBD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Adenoma and polyp detection rates are correlated to the risk of interval colorectal cancer and is consequently considered as a quality benchmark for colonoscopy. We prospectively evaluated this variable in our daily practice, involving all the endoscopists of our endoscopy unit.

Aims & Methods: 6027 colonoscopies were performed between 01/01/2016 and 31/12/2016 by 30 physicians. Regarding patients, the following data were prospectively collected: age, gender, indication for colonoscopy, preparation procedure and quality of the preparation (assessed by the Boston Scale), number and size of polyps and polyp histopathology. Regarding physicians, age, gender, number of colonoscopies and mean withdrawal time (calculated from the normal colonoscopies) were studied. Neoplasia was defined as grade 4 or 5 of the Vienna classification (4: non-invasive high grade neoplasia (high grade adenoma/dysplasia, non-invasive carcinoma and suspicion of invasive carcinoma; 5: invasive neoplasia (intramucosal carcinoma, submucosal carcinoma or beyond). Links between these data and polyp detection rate (PDR) were assessed by uni- and multivariate analysis (stepwise logistic regression).

Results: We enrolled 2719 Male patients (45.1%) and 3308 Female patients (54.9%), 73.6% of them of 50 year-old or more. A sub-optimal preparation (defined by Boston scale score <6 or at least one sub-sore <2) was observed in 6.1% of the patients. Caecal intubation rate was 99%. 21 endoscopists were Male and 10 were under 50 year-old. The median number of colonoscopy per physician was 140 (range: 10–720). 2054 colonoscopies detected 3914 lesions or polyps: 2914 tubular/villous adenomas, 496 serrated adenomas, 242 hyperplastic polyps (hyperplastic polyps located in the rectum and sigmoid colon were not considered as at risk for cancer and were excluded), 212 other histology leading to a Mean Number of Polyps (MNP) of 0.65 and a Polyp Detection Rate (PDR) of 34.1%. 1935 colonoscopies detected at least one adenoma (adenoma detection rate, 32.1%). Large Polyp Detection Rate was 7.9% with detection of 538 polyps >1 (13.7% of polyps), in 477 patients. Neoplasia Detection Rate was 3.6% (300 neoplasias in 220 patients). Among the endoscopists, the median PDR was 32.5% (range 14–62%). Among them, 4 had a PDR <20%, 17 had a PDR between 20 and 39% and 9 had a PDR >40%. Mean withdrawal time was 490 seconds (range 228–831). 10 physicians had a mean withdrawal time <420 seconds with a mean ADR of 31% compared to 34.5% for physicians with a withdrawal time of more than 420 seconds ($p > 0.05$). In the univariate analysis, a high PDR was significantly associated with patient-dependant factors: age, Male gender, a familial history of polyp/cancer, screening or positive faecal immunochemical test (FIT+) and quality of preparation. Regarding physician-dependant factors, a high PDR was significantly associated with Male gender, high volume (>140 colonoscopy per year) and withdrawal time. In the multivariate analysis, the only factors associated with a high PDR were: familial history of polyp/cancer, FIT+ and patient age.

Conclusion: In this large series of routine colonoscopies, we found medically-relevant polyps in more than one third of the patients, irrespectively of age and indications. In multivariate analysis, a high PDR was significantly associated with familial history of polyp/cancer, FIT+ and age of the patient. This may suggest that the Male gender is no longer a risk factor for polyps. In addition, even if there are still discrepancies regarding PDR among physicians, we found no physician-dependant factor associated with a high PDR in the multivariate analysis.

Acknowledgment to all the endoscopists and nurses of the Clinique de Bercy.

P0855 EFFICIENCY OF COLONOSCOPY IN CASE OF POSITIVE FECAL IMMUNOCHEMICAL TEST: ONE-YEAR EXPERIENCE AND RESULTS ON 391 PATIENTS IN ROUTINE PRACTICE IN FRANCE

M. Cavicchi¹, G. Tharsis¹, P. Burtin², P. Cattan¹, F. Venezia¹, G. Tordjman¹, A. Gillet¹, J. Samama¹, K. Nahon-Uzan¹, D. Karsenti¹

¹Pôle Digestif Paris Bercy, Clinique de Bercy, Charenton-le-Pont/France

²IGR, Villejuif/France

Contact E-mail Address: m.cavicchi@wanadoo.fr

Introduction: Fecal immunochemical test (FIT) has progressively replaced the guaiac test for colorectal screening in average risk population in France since May 2015. With a high sensitivity and a good specificity, it is supposed to increase colonic cancer detection. However, its efficiency has not been described in routine colonoscopy.

Aims & Methods: Among 6027 colonoscopies performed between 01/01/2016 and 31/12/2016 in our endoscopy unit, 391 were performed for a positive FIT (FIT

+-). The following variables were prospectively collected: patient age and gender, quality of preparation (Boston scale), number, size and histopathology of polyps. Neoplasia was defined as categories 4 and 5 of the Vienna classification (high-grade dysplasia, in-situ carcinoma, intra-mucosal carcinoma, submucosal carcinoma or beyond). Comparison was made with the whole population of 3876 patients aged of 50 to 75, referred for other reasons. Statistical analysis was performed in uni- and multivariate analysis using a stepwise logistic regression study.

Results: 391 patients with FIT + were included (6.4% of the patients). 201 were Males and 190 were Female with a median age of 58 (range: 50–75). The preparation was considered as sub-optimal in 6.4% of cases (Boston scale score <6 or at least one sub-score <2). 498 lesions were detected in 230 patients. These lesions corresponded to 423 adenomas and adenocarcinomas, 41 serrated adenomas, 14 hyperplastic polyps (hyperplastic polyps located in the rectum and the sigmoid colon were not considered as lesions at risk and were therefore excluded from the analysis), 20 other pathology, leading to a mean number of polyps (MNP) of 1.27. Polyp detection rate (PDR) and adenoma detection rate (ADR) were 58.8% and 58%, respectively. By comparison, PDR and ADR in the whole population were 39.1% and 37.0%, respectively. From the 498 detected lesions, 122 (24.5%) were ≥ 1 cm in 109 patients, resulting in a large polyp detection rate (LPDR) of 27.9% as compared to 9.4% in the whole population; 66 neoplastic lesions (13.2% of the polyps) were detected in 57 patients, resulting in a neoplasia detection rate (NDR) of 14.6% as compared to 4.9% in the whole population. In Males, MNP, ADR and NDR were 1.52, 67% and 18.9% respectively compared to 1, 49.5% and 10% respectively in female patients. The multivariate analysis showed that FIT + was significantly associated with a high PDR (OR 2.8; 95%CI 2.2–3.6), a high LPDR (OR 8.1; 95%CI 5.4–12.3) and a high NDR (OR 12.8; 95%CI 6.2–26.4).

Conclusion: In case of positive FIT, colonoscopy detects medically-relevant polyps in 59% of patients. Furthermore, the detection rates of large polyps and neoplastic lesions were very high, especially in Male patients, confirming the high predictive positive value of FIT compared to guaiac test. Our results are in agreement with the highest quality benchmarks recently proposed in case of positive FIT (et al., *Am J Gastroenterol*, 2016 Oct 11). **Acknowledgment to all the endoscopists and nurses of the Clinique de Bercy.**

Disclosure of Interest: All authors have declared no conflicts of interest.

P0857 TWO LITERS OF POLYETHYLENE GLYCOL (PEG) WITH 15 MG OF BISACODYL VERSUS 4 LITERS OF PEG FOR BOWEL PREPARATION TO COLONOSCOPY. PROSPECTIVE RANDOMIZED STUDY. PRELIMINARY RESULTS

E.M. Amine¹, Z. Abdelkrim¹, E.M. Aziz¹, W. Khannoussi¹, G. Kharrasse², Z. Ismaili¹

Introduction: Adequate bowel preparation is one of the most important quality factors of colonoscopy. Several formulations of bowel preparation have been evaluated for their ability to have a clean colon and be well tolerated by patients. Currently, PEG 4L solution is the preferred method of bowel preparation to colonoscopy. This preparation has the disadvantage of being poorly tolerated by patients. Furthermore, recent studies have shown that a low-volume PEG solution (2L) associated with Bisacodyl for bowel cleansing is as effective and better tolerated as a large volume PEG (4L).

Aims & Methods: This study aims to assess the efficacy and tolerance of the new regimen (2L of PEG + Bisacodyl) compared to the classical regimen (4L of PEG). **Materials and methods:** A prospective comparative randomized study comparing the tolerance, acceptability and efficacy of a protocol A based on 4L of PEG and a protocol B corresponding to 2L of PEG + 15mg of Bisacodyl. Using the Boston Bowel Preparation Scale (BBPS) by endoscopists, who did not know bowel preparation type, to evaluate the quality of preparation.

Results: Sixty-six patients were included (35 in group A and 31 in group B), with a sex ratio = 1. The average age of patients was 52 \pm 15 years [17–86 years] with a median of 51.5 years. Eight patients in the first group found the preparation difficult or moderately difficult vs 3 in group B (p = NS) with mild to severe side effects 54% of group A and 29% of group B (p = 0.03) and A mean side effect per patient was 2.26 vs. 1.89 (p = NS). Nausea and vomiting were respectively (34% and 26% vs 19% and 13%) (p = NS). However, 5 patients in group A had sleep disorders vs only one case in group B. Four patients who received 4 L of PEG had expressed their refusal to resume the same preparation if necessary while 2 patients in group B had refused. A score greater than or equal to 7 was recorded 60% versus 84% respectively (p = 0.03). On average; the overall score obtained was 6.49 versus 7.32, respectively. This score (BBPS) tended to be better in protocol B than in protocol A in the right segment (2.55 vs 2.17), transverse colon (2.58 vs 2.43) and left colon (2.19 vs 1.94). This same trend was recorded in relation to the number of patients with a maximal score of (9/9), with 4 patients in group B and no patient in group A. Seven patients refused to repeat the test even if indicated. This refusal was secondary to the preparation in 4 cases (2 cases of each group). Abdominal pain and post-endoscopic distension in both groups A and B were respectively (62.8% and 65.7% vs 32% and 22.5%) (p = 0.016 and p < 0.001).

Conclusion: Preliminary results from our study suggest that the low-volume 2 L PEG with bisacodyl does improve patient tolerability with a tendency to be better for good Bowel preparation as compared to the traditional 4 L PEG. We

continue our study to have a more significant number of patients view these encouraging results.

Introduction: Colonoscopy is a cumbersome technique to train, with high variability of time spent to reach the cecum, depending on endoscopist experience, patient characteristics and type of colonoscopy used. Recently, the ROLCOL study demonstrated an advantage in time and patient comfort during progression in right lateral position (RLP) when compared with traditional left lateral position (LLP).

Aims & Methods: To compare time to reach cecum, patient and endoscopist comfort (using a visual analogue scale (VAS) in colonoscopies with progression on RLP and LLP. Prospective study, between January and April 2017, of colonoscopies under conscious sedation, randomly assigned to RLP and LLP. Olympus 190 series and Fuji EC-530 WI3 colonoscopes were used. Inclusion criteria: routine colonoscopies, patients > 18 years of age, abdominal surgeries other than colonic, examinations done by residents in second and fifth year of training and specialists. Exclusion criteria: incomplete colonoscopies or prior history of colonic surgery.

Results: One hundred and eighty-eight colonoscopies (94 on each side) were included. There was no statistical difference in mean age (RLP:LLP = 61 Vs. 64 years; p > 0.05), gender (49 Vs. 52 males; p > 0.05), body mass index (27.4 Vs. 26.4; p > 0.05), previous history of abdominal surgery (44 Vs. 34; p > 0.05), endoscopists experience (residents: 53 Vs. 41, specialists: 41 Vs. 53; p > 0.05), sedation dosage (midazolam 1.04 Vs. 1.09 mg, petidine 25 Vs. 25 mg; p > 0.05) or colonic preparation (BBPS 6 Vs. 6, 01; p > 0.05). Globally, there was no difference in "time to cecum" between the two positions (612 Vs. 633 seconds; p > 0.05), nor the patients comfort (VAS 3.92 Vs. 3.94; p > 0.05). This did not change after exclusion of less experienced endoscopists colonoscopies (581 Vs. 579 seconds, VAS 3, 71 Vs. 3.76; p > 0.05). Surgical and overweight patients did not benefit from any of the positions (time to cecum: 650 Vs. 702 and 570 vs 657; p > 0.05, comfort: 4.2 Vs. 4.12 and 3.83 Vs. 3.96; p > 0.05, respectively). However, endoscopists comfort was higher in LLP (4.62 Vs. 3.78; p < 0.05). Both groups required position change during progression or loop palpation by the nurse in equal percentage (54% Vs. 46%; p > 0.05 and 49.5% Vs. 50.5%; p > 0.05). Additionally, there was no difference in time to do cecum, patients or endoscopists comfort between the colonoscopies performed with Fuji or Olympus colonoscopes.

Conclusion: In our experience, progression in right lateral position did not show additional advantage over standard LLP in time to reach the cecum or patients comfort. We did not find any difference in time to progression or comfort between Olympus and Fuji colonoscopes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0859 NON-GRANULAR LATERALLY SPREADING COLONIC LESIONS ≥ 20 MM (LSL) ARE SMALLER AND MORE COMMONLY MULTIPLE THAN GRANULAR LSL; IMPLICATIONS OF A 'COLONIC MUCOSAL PHENOTYPE' FOR PRACTITIONERS OF ENDOSCOPIC RESECTION

Introduction: The surface morphology of laterally spreading colonic lesions ≥ 20 mm (LSL) can be described as granular (G) or non-granular (NG). NG lesions are more difficult to detect, harder to resect endoscopically and harbour a higher risk of submucosal invasive cancer (SMIC) than G lesions.

Aims & Methods: We aimed to characterise the population of LSL in patients presenting for endoscopic mucosal resection (EMR). From 9/2008 until 03/2017 LSL were identified within a prospective observational cohort of patients undergoing endoscopic mucosal resection at a single academic tertiary centre. LSL were interrogated using high-definition white light (HDWL) at the time of EMR and the morphology of LSL were described along with patient, lesion and procedural factors. All LSL detected during the study period were eligible. LSL with mixed or indeterminate morphology were excluded. Serrated LSL were excluded. Lesions not attempted for EMR were excluded. Patients with multiple LSL were categorised according to the largest (dominant).

Results: 1382 LSL in 1243 patients were analysed. 1155/1243 (92.9%) patients had a solitary LSL. The majority of patients with multiple LSL had two (77.3%) or three (15.9%) lesions. 889/1382 (64.3%) of LSL were G. G LSL were more likely to be solitary (87.0%) than NG LSL (77.5%, $p < .001$). G LSL were more commonly large (≥ 40 mm in size) (49.3%) than NG LSL (26.0%, $p < .001$) and were more commonly found in the right colon (proximal to transverse colon) (54.2% versus 48.3%, $p = .034$). In 88 patients with multiple LSL the dominant LSL was G (49/88 [55.7%]). A dominant G LSL was associated with fewer other LSL than a dominant NG LSL, $p = .029$.

Table 1; The morphology of the dominant (largest) laterally spreading lesion (LSL) predicts the presence and number of synchronous LSL. Morphology of the dominant lesion did not predict the others would be of the same morphology ($p = .697$). The dominant LSL was large in 43.2% of cases. Size of the dominant LSL predicted size of the other LSL ($p < .001$). 58.0% of dominant LSL were located in the right colon. In 65.9% patients all LSL were in the same colonic segment; this was not predicted either by the location of the dominant LSL ($p = .860$) or its morphology ($p = .228$).

Dominant LSL Morphology	Solitary (n = 1155)	Multiple (n = 227)	<i>P</i>		
Granular (n = 889)	773 (87.0)	116 (13.0)	< .001		
Non-granular (n = 493)	382 (77.5)	111 (22.5)			
Dominant LSL Morphology	Number of synchronous LSL				
	2	3	4	5	<i>P</i>
Granular (n = 49)	41 (83.7)	4 (8.2)	3 (6.1)	1 (2.0)	.029
Non-granular (n = 29)	27 (69.2)	10 (25.6)	0	2 (5.1)	

Conclusion: 7% of patients will have more than one LSL. In these patients the dominant lesion morphology predicts the presence and number of additional LSL (the Colonic Mucosal Phenotype). More than 20% of NG LSL are associated with an additional LSL whereas G LSL are predominantly large and solitary. Practitioners of endoscopic resection should be aware that NG LSL may be multiple and ensure full examination of the colonic mucosal surface, particularly since they are higher risk for SMIC than G LSL.

P0860 WIDE-FIELD PIECEMEAL COLD SNARE POLYPECTOMY OF LARGE SESSILE SERRATED POLYPS WITHOUT A SUBMUCOSAL INJECTION IS SAFE

D. J. Tate, H. Awadie, F. Bahin, L. Desomer, R. Lee, S. Heitman, K. Goodrick, M.J. Bourke

Contact E-mail Address: djtate@gmail.com

Introduction: Large series suggest endoscopic mucosal resection is safe and effective for the removal of large sessile serrated polyps ≥ 10 mm (large SSP) but it exposes the patient to the risks of electrocautery, principally delayed bleeding.

Aims & Methods: We aimed to examine the feasibility and safety of piecemeal cold snare polypectomy (pCSP) for the resection of large SSP. Over 12 months sequential large SSP without endoscopic evidence of dysplasia referred to a tertiary endoscopy centre were considered for pCSP. The technique for pCSP was standardised. The lesion and its margins were assessed using high definition endoscopic imaging. Snare resection commenced at one margin including a 2–3 mm rim of normal tissue. A thin-wire snare was used in all cases. Firm downward pressure and suction of luminal gas aided tissue capture. Subsequently the assistant closed the snare until resistance was felt, and then completely once the endoscopist was satisfied with the amount of captured tissue. If transection did not occur within five seconds gentle traction was exerted on the snare catheter against the tip of the colonoscope. If transection still did not occur, the snare placement was revised. The mucosal defect was then expanded with a flushing pump containing 0.9% saline. Further resections were then performed aligning the snare with the cut edge of the expanding mucosal defect. Once the resection was completed the mucosal defect was inspected for residual serrated tissue. If residual was detected further generous snare resection was performed. Oozing of blood from the resection site was common and was not actively treated. Submucosal injection was not performed. High-definition imaging of the defect margin was used to ensure the absence of residual serrated tissue. Adverse events were assessed at 2 weeks and surveillance was planned between 6 and 12 months.

Results: 41 SSP were completely removed by pCSP in 34 patients. 7 patients had two lesions removed. The median size of SSP was 15 mm (IQR 14.5–20), range 10–35 mm. The median duration of procedures was 4.5 minutes (IQR 1.4–6.3). There was no evidence of perforation or significant intra-procedural bleeding. There were no significant adverse events at 2 week follow up including delayed bleeding and post polypectomy syndrome. 8/41 lesions underwent first follow-up at median 6 months with no evidence of recurrence.

Table 1: Baseline characteristics and outcomes of the 34 patients and 41 SSP that underwent piecemeal cold snare polypectomy (pCSP). IQR – interquartile range, SC1 - first surveillance colonoscopy.

	pCSP (n = 41)
Patient	
Age, mean (standard deviation)	68.58 (10.12)
Sex, female (%)	27 (79.4)
Lesion	
Size, median (IQR)	15 (14.5–20)
Location, proximal to transverse colon (%)	26 (63.4)
Paris classification (%)	
0-IIa	40 (97.6)
0-IIb	1 (2.4)
Endoscopic evidence of dysplasia (%)	0 (0)
Kudo, highest (%)	
II-O	41 (100)
Procedure	
Duration, median minutes (IQR)	4.5 (1.4 to 6.3)
Pieces, median (IQR)	3.0 (3–5)
Protrusion within defect (%)	9 (22.0)
Intra-procedural bleeding requiring intervention (%)	0 (0)
Histopathology, serrated adenoma (%)	41 (100)
Low grade cytological dysplasia (%)	3 (7.3)
Outcomes	pCSP (n = 41)
Adverse events	
Clinically significant post endoscopic bleeding (%)	0 (0)
Delayed perforation (%)	0 (0)
Post procedural pain (%)	0 (0)
Admission to hospital for related complication within 2 weeks	0 (0)
Follow up	
Months to SC1, IQR	6 (5–7)
Recurrence at SC1, (%), n = 8	0 (0)
Histologic recurrence at SC1, (%), n = 5	0 (0)

Conclusion: There is potential for pCSP to become the standard of care for non-dysplastic large SSP. This may reduce the burden on patients and healthcare systems of removing SSP, particularly by avoidance of delayed bleeding.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0861 THE PROSPECTIVE OBSERVATION STUDY FOR OVER 10MM COLORECTAL LESIONS ENDOSCOPICALLY RESECTED USING BIPOLAR SNARE

Introduction: Polypectomy of adenomas reduces death due to colorectal cancer; therefore colonoscopy is the gold standard to detect and treat adenomatous lesions. Most adenomatous lesions are less than 20 mm in size. Therefore, these are not indication for endoscopic submucosal dissection (ESD). Recently, there are some reports about cold snare polypectomy (CSP). CSP is effective and easy to remove lesions of less than 5–10 mm in size. On the other hand, in over 10 mm lesions, many endoscopists would remove it by endoscopic mucosal resection (EMR) with monopolar snare. It is expected that the bipolar snare would decrease the incidence of perforation because of electric current flow peculiar to bipolar snare that does not flow through the wall of colon. So, by using bipolar snare, hot snare polypectomy (HSP) that can be easily resected in a short time may be safely performed for over 10 mm colorectal lesions. However, there is no report about them.

Aims & Methods: We aimed to clarify removal method, procedure time and complications for over 10 mm colorectal lesions endoscopically resected using bipolar snare. Consecutive patients with over 10 mm colorectal lesions endoscopically resected using bipolar snare in National Cancer Center Hospital East between September 2016 and March 2017 were enrolled in this study, prospectively. The removal method rate of these lesions, each procedure time, complete resection rate, bleeding rate and perforation rate, and pathological finding were assessed.

Results: A total 92 lesions in 67 patients were analyzed. 47 patients (70%) were male, and the median age was 67 years (range: 44–88). The median lesion size was 13 mm (range: 10–30). The macroscopic type was 33 (36%) polypoid lesions and 59 (64%) flat lesions. The location was 55 (60%) lesions in right colon, 31 (34%)

in left colon and 6 (6%) in rectum. Pathological diagnosis was 22 (24%) hyperplastic polyp or SSA/P, 42 (46%) low grade dysplasia (LGD), 23 (26%) high grade dysplasia (HGD), and 1(1%) submucosal invasive cancer. In the removal methods, HSP was 71 (77%) lesions and EMR was 21 (23%). The median procedure time of HSP and EMR was 37 seconds (range: 7–430) and 167 (range: 60–450) ($p < 0.001$). The median lesion size of was HSP and EMR was 12 mm (range: 10–30) and 20 (range: 10–28) ($p < 0.001$). The immediate bleeding of HSP and EMR occurred in 7 (10%) lesions and 6 (33%) ($p = 0.009$). The delayed bleeding of HSP and EMR occurred in 2 (3%) lesions and 0 ($p = 0.437$). Perforation was not occurred. No tumors were horizontal and vertical margin positive. In the pathological diagnosis, 86% of hyperplastic polyp or SSA/P, 86% of LGD, and 57% of HGD was resected by HSP, and submucosal invasive cancer was resected by EMR.

Conclusion: Of over 10 mm colorectal lesions was resected by using bipolar snare, 77% were resected by HSP. The procedure time of HSP was significant shorter than EMR.

Introduction: The 'SMSA' polyp scoring system is a method of risk stratifying the difficulty of polypectomy based on expert consensus opinion. The score is simple, intuitive and has previously not been evaluated in a large multicentre setting.

Aims & Methods: We aimed to determine the ability of the SMSA polyp score to predict robust endpoints after endoscopic mucosal resection (EMR) of colonic laterally spreading lesions (LSL). The SMSA polyp score was applied to a prospectively collected multicentre database of LSL resected by EMR over eight years. This score describes the complexity of polypectomy with respect to four major domains (table 2) and is subsequently divided into four levels. Standard inject and resect EMR procedures were performed with detailed patient, procedural and outcome data recorded prospectively over the study period including all features of the SMSA. In patients who had multiple lesions resected the largest lesion was retained for analysis. The primary endpoints were correlation of SMSA score with completion rate, adverse event rate and adenoma recurrence. **Results:** 2305 lesions in 2305 patients (47.4% M, 45, 2% right colon) underwent EMR. The majority of lesions were SMSA 4 (50.2%) with a median lesion size of 30 mm (range 20–160 mm). Failed single session EMR occurred in 97 (4.2%) and this was predicted by increasing SMSA ($p < .001$). Intra-procedural bleeding was significantly more common with increasing SMSA (SMSA 2, 19/229 (8.3%) versus SMSA 4 291/1158 (25.1%), $p < .001$). Clinically significant post EMR bleeding (CSPEB) was more common as SMSA increased with 4 (1.7%) in the SMSA 2 group and 90 (7.8%) in the SMSA 4 group, $p = 0.001$. Intra-procedural perforation and delayed perforation were no different between the groups. After EMR surgery at two weeks was more common in the SMSA 4 group ($p < .001$). Of those patients that underwent their first surveillance colonoscopy (SC1), endoscopic recurrence (EDR) was more common in the SMSA 4 group than the SMSA 2 group, 206 (23.7) as compared to 9 (5.4%), $p < .001$. This was also the case for histologic recurrence ($p < .001$). The difference in EDR persisted to the second surveillance colonoscopy (SC2) with no recurrences in the SMSA 2 group versus 9.1% in the SMSA 4 group.

Table 1: Outcomes after endoscopic mucosal resection at the initial procedure, 2 weeks and subsequent surveillance procedures.

	SMSA 2	SMSA 3	SMSA 4	p value
Total	229 (9.9)	918 (39.8)	1158 (50.2)	
Successful EMR (%)	226 (98.7)	894 (97.4)	1088 (94.0)	<.001
Duration - min (median IQR)	10 (5–15)	15 (10–20)	30 (20–45)	<.001
IPB (%)	19 (8.3)	115 (12.5)	291 (25.1)	<.001
Deep injury * (%)	11 (4.8)	33 (3.6)	54 (4.7)	.448
CSPEB (%)	4 (1.7)	46 (5.0)	90 (7.8)	.001
Delayed Perforation (%)	0 (0)	2 (0.2)	5 (0.4)	.640
Surgery at 2w (%)	20 (8.7)	50 (5.4)	117 (10.1)	.001
Underwent SC1 (n)	166	685	871	
EDR SC1 (%)	9 (5.4)	71 (10.4)	206 (23.7)	<.001
HDR SC1 (%)	3 (6.4)	36 (13.4)	120 (28.7)	<.001
Surgery SC1 (%)	1 (0.6)	7 (1.0)	12 (1.4)	.747
Underwent SC2 (n)	88	326	462	
EDR SC2 (%)	0 (0)	21 (6.4)	42 (9.1)	.008
Surgery SC2 (%)	0 (0)	1 (0.3)	3 (0.6)	.766

EMR – endoscopic mucosal resection, IPB – intra-procedural bleeding, IPP – intraprocedural perforation, CSPEB – clinically significant post endoscopic bleeding (bleeding after EMR requiring admission to hospital or re-intervention), 2w – two weeks, SC1/2 – surveillance colonoscopy 1/2. * target sign or actual hole corresponding to DMI type III/IV - Sydney Classification (1)

SMSA score (2)

Size	Points	Morphology	Points	Access	Points	Site	Points
<1 cm	1	Pedunculated	1	Easy	1	Left	1
1–1.9 cm	3	Sessile	2	Difficult	3	Right	2
2–2.9 cm	5	Flat	3				
3–3.9 cm	7						
>4 cm	9						
SMSA Level	Points						
1	4–5						
2	6–9						
3	9–12						
4	>12						

Conclusion: SMSA is a simple readily applicable clinical score that identifies a subgroup of patients who are at increased risk of EMR related complications including CSPEB and recurrence. This information is useful for planning EMR lists with respect to time and resource allocation. Moreover SMSA could have a major impact on training, both in identifying appropriate training cases and providing an objective benchmark against which to assess the progress of trainees in EMR.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0863 USE OF ACETIC ACID FOR EVALUATING SESSILE SERRATED ADENOMA/POLYP: A PILOT STUDY

S. Yamamoto, M. Shafazand

Gastroenterology, Sahlgrenska University Hospital Östra, Göteborg/Sweden

Contact E-mail Address: shun0515suke@gmail.com

Introduction: Sessile serrated adenoma/polyp (SSA/P) has been accumulated increasing attention since its risk for developing to cancer had been clarified. These polyps are difficult not only to detect but also to determine their precise margin after detection especially in right side colon. Such a difficulty leads high recurrence rate after endoscopic resection. Magnifying function and narrow band imaging (NBI) is reported to be useful for evaluation of SSA/P but it needs special equipment, extra time, and expertise. Easier, uncomplicated, and non time consuming method is desired. The use of acetic acid or acetic acid-indigo carmine mixture have been introduced into endoscopic diagnosis in Barrett's esophagus, early gastric cancer, and colorectal early cancer. However, there have been no reports on using this agent as aid for the optimal diagnosis of the margin of SSA/P. If this rather cheap agent were helpful for realizing the precise margin of SSA/P, it could decrease insufficient removal of the polyp and recurrence after that.

Aims & Methods: The aim of this pilot study is to assess whether the acetic acid could facilitate the recognition of the margin of SSA/P. We used acetic acid as a mixture with indigo carmine and compared it to conventional evaluating methods; narrow band imaging (NBI) and indigo carmine. From December 2016 to February 2017, patients in whom SSA/P more than 10 mm were found in right side colon in daily practical colonoscopy by single endoscopist in our institute were included. We used the standard scope without magnifying function. First we observed lesions with conventional white light and NBI. Second, we recorded pictures with indigo carmine (IC) spray alone on it. Finally, we sprayed the mixture of acetic acid and indigo carmine mixture (AIC) directly through the endoscopic working channel without using catheter onto lesion. Using recorded pictures during these procedures, ability for recognizing the margin of polyps were compared between IC and AIC, or NBI and AIC by 3 endoscopists, and the concordance rate of diagnosis among these three were assessed as Kappa statistics.

Results: 9 SSA/P lesions in 7 patients were investigated. In all cases, AIC was helpful to recognize the margin of polyps without causing any obstructive effect. We also observed disappearance of mucous on the surface, dilated crypts caused by acid contact, and aceto-whitish reaction on the surficial glands in all lesions. In comparing the ability for recognizing the margin of the lesions, 6.3 in 9 lesions (mean among 3 practitioners) were thought to be as AIC better than IC, and

similarly 7.3 in 9 were better than NBI. Kappa value among participants was 4.8; moderate agreement ($p=0.0016$). All polyps were removed endoscopically after evaluation. All lesions were histologically diagnosed as SSA/P without dysplasia. **Conclusion:** Acetic acid was useful and promising to facilitate the endoscopic recognition of the precise margin of SSA/P in right side colon. Strength of this method is that it is very simple and needs no special equipment nor skill. **Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Preoperative localization or tattooing is essential for minimally invasive surgery. Although preoperative endoscopic tattooing using India ink or indocyanine green is widely used, clinical evidence and safety profile supporting the use of these agents is lacking.

Aims & Methods: We assessed the efficacy and safety of preoperative endoscopic tattooing using autologous blood. A total of 80 patients who underwent endoscopic tattooing using either India ink or autologous blood were included in this study. From February 2016, all patients who required localization of a target lesion before colorectal surgery underwent endoscopic tattooing using autologous blood at a single tertiary medical center, and the outcomes were collected prospectively. As a comparison, we retrospectively reviewed the medical records of a further 40 consecutive patients who underwent endoscopic tattooing using India ink before February 2016. The primary outcomes were the visibility of the tattooing in the peritoneal cavity and related adverse events.

Results: Endoscopic tattoos produced using India ink were visible in 38 (95%) patients, and tattoos created using autologous blood were visible in 36 (90%) patients. In the autologous blood group, the tattoo could not be identified in four patients due to excessive peritoneal fat, bleeding tendency, congenital anomaly, and tattooing to an inadequate depth. Eight (20%) patients in the India ink group and four patients (10%) in the autologous blood group experienced endoscopic tattooing-related adverse events.

Conclusion: Preoperative endoscopic tattooing using autologous blood is a feasible and safe modality for the preoperative localization of colorectal lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0865 SUBMUCOSAL INVASION IN COLORECTAL LATEROALLY SPREADING TUMORS (LST) AND ABILITY OF THE ENDOSCOPIST FOR CANCER DETECTION

Introduction: Laterally spreading tumors (LSTs) are defined as lesions >10 mm with a low vertical axis and lateral extension. They are separated in 2 groups with 2 subclasses for each of them: granular LST (LST-G) with, or without large nodule; and non-granular LST (LST-NG), separated into flat lesions (IIa) and depressed lesions (IIa+IIc). Every subclass have been associated with a proper risk of cancer and submucosal invasion (T1sm)^{1, 2}. Knowing this aspect could help for the decision of the resection technique (endoscopic mucosectomy EMR, endoscopic submucosal dissection ESD, or surgery). The aim of our study was to determine the rate of cancer (submucosal and mucosal adenocarcinoma) in a western series of LST treated by endoscopic resection, and to evaluate the ability of the endoscopist to predict the depth of cancer invasion.

Aims & Methods: The entire patients with a LST ≥ 20 mm treated between January 2012 and December 2016 in our single center were included. Endoscopic data were collected (size, location, LST classification, analysis of pit pattern, endoscopic suspicion of cancer). We also reported the resection technique, histological results, and the follow-up at 1 year.

Results: 377 LST were included in our study. The average age was 67.7 years old. The mean size of lesion was 40.6 mm. LST were located in the right colon, the rectum, the left colon and the transverse colon in 44.5%, 32.6%, 14.0% and 8.8%, respectively. The resection technique used was a monobloc EMR in

15.4%, piecemeal EMR (pEMR) in 42.9%, ESD in 27.3% and assisted ESD in 14.5%. ESD was associated with a significant lower risk of recurrence after 1 year (4.9% against 18.1%). Considering the LST classification, there were 27.0% LST-G without large nodule, 28.4% LST-G with large nodule, 35.5% flat LST-NG IIa, and 9.0% LST-NG with depression IIa+IIc. The overall rate of adenocarcinoma was 19.7%, and 9.0% with submucosal invasion. The rates of adenocarcinoma and the rates of submucosal invasion in every subtype of LST are reported in table 1. They were higher for LST-G with large nodule (34.5% and 15.9% respectively) and for LST-NG with depression (35.3% and 20.6%). Regarding the prediction of submucosal cancer by the endoscopist, we report a low sensitivity, and positive predictive value (respectively 64.7% and 32.8%). However, we had a good specificity and negative predictive value (86.0% and 96.0%). Endoscopic predictors of submucosal cancer were invasive pit pattern (HR 33.0; $p=5.78e-07$) and depression (HR = 11.86; $p=0.049$).

Rate of adenocarcinoma and submucosal invasion for each type of LST

	LST G	LST-G with large nodule	LST-NG type IIa	LST-NG IIa+IIc
Number (n/%)	102/27, 0	107/28, 4	134/35, 5	34/9, 0
Cancer (n/%)	12/11, 8	37/34, 5	11/8, 2	12/35, 3
T1sm (n/%)	5/4, 9	17/15, 9	4/3, 0	8/20, 6

Conclusion: Our western series confirm similar rates of submucosal adenocarcinoma according to the type of LST as compared to Asian series. LST-G with large nodule, and LST-NG with depression were associated with a higher risk of submucosal invasion and invasive pit pattern was the stronger predictor of malignancy. Endoscopic submucosal dissection should be systematically performed in these cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0866 ETHNIC VARIATION OF COLONIC POLYPS: FINDINGS FROM AN INTERNATIONAL HOSPITAL FOR MEDICAL TOURISM IN THAILAND

S. Techapaitoon¹, V. Permpoon¹, K. Pongpirul²

¹Digestive Disease Center, Bumrungrad International Hospital, Bangkok/Thailand

²Department Of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore/United States of America/MD

Contact E-mail Address: kpongpi1@jh.edu

Introduction: Evidence on an international variation of pathological types and anatomical distribution of colonic polyps is beneficial for early detection and management but limited.

Aims & Methods: To characterize differences in colonoscopy findings by ethnicity, a random sample of patients aged at least 50 years without colonic symptoms or history of colonic diseases who underwent colonoscopy were reviewed. Of 26,508 subjects, 2651 were randomly selected. Of 1300 subjects who met the inclusion criteria, abnormal findings were identified in 878 cases (67.54%), of which 452 cases had 940 polyps and 7 cancer lesions were found in 6 cases. Of 452 patients with polyps, half had only one polyp (53.76%) and were Asian (54.65%), followed by Caucasian (26.99%), Middle Eastern (15.71%), and other ethnic origins (2.65%) (Figure). Ethnicity-specific polyp prevalence were 36.26%, 38.05%, 27.24%, and 34.15%, respectively. Polyps of Caucasian subjects tended to be smaller (4.52 mm) and locate on the left side of the colon (65.63%) than that of other ethnicities (44.44%–60.53%). The majority of the polyps (84.04%) were small (≤ 5 mm) whereas 8.19% were large (> 10 mm); hyperplastic polyp, tubular adenoma (TA), and tubulovillous (TVA) adenoma were identified in 43.19%, 53.83%, and 2.34%, respectively. Premalignant (TA+TVA) polyps were found in 56.08%, 50.19%, and 64.23% of the polyps of Asian, Caucasian, and Middle Eastern patients, respectively. Premalignant lesions were found in 52.91% of small polyps.

Conclusion: The findings suggested that number, size, distribution, and pathological type of colonic polyps vary across ethnic groups. As more than half of small polyps were a tubular adenoma, we propose that polyps of all sizes should be removed when feasible.

P0867 ARE WE READY FOR COLONIC ESD IN FRANCE?J. Jacques¹, J. Albouys¹, A. Charissoux², J. Rivory³, D. Sautereau¹, T. Ponchon⁴, R. Legros¹, M. Pioche⁵¹Hepato-gastro-enterology, CHU Limoges - Hepato-Gastro-Enterology, CHU Limoges; Limoges/FR, Limoges/France²Pathology, CHU Limoges, Limoges/France³Hepatogastroenterology, Hôpital Edouard Herriot, Lyon/France⁴Dept. Of Digestive Diseases, Edouard Herriot University Hospital, Lyon/France⁵Hepatogastroenterology, Hôpital Edouard Herriot, Lyon/France**Contact E-mail Address:** jeremiejacques@gmail.com

Introduction: Endoscopic submucosal dissection represents the standard of care for large superficial colo-rectal neoplasms in Japan. In Europe, only few studies reported promising results, essentially in the rectal location. Colonic ESD is more technically challenging because of the colonic loops, intestinal motility, the folded anatomy, problems caused by inconstant gravity, and submucosal fibrosis. Colonic ESD is although more risky because perforations are most often non clinically significant in the rectal location (under peritoneal reflection) contrary to the colonic location. Here we reported our results of two years of colonic ESD performed by two French expert teams that began colonic ESD after a strong animal training and a strong experience in rectal and upper-digestive tract ESD.

Aims & Methods: Retrospective bicentre study of all cases of colonic ESD performed between 01/2016 and 03/2017 for superficial pre-cancerous or cancerous neoplasms. Primary Endpoint was to evaluate the En bloc, R0, curative resection rate and extended curative resection rate (Curative resection + non-curative due to positive horizontal margins and without recurrent disease on endoscopic control). Secondary endpoints were to compare these results with results of rectal ESDs performed during the same period.

Results: 87 colonic ESD were performed in two French centers between 01/2015 and 03/2017 for superficial pre-cancerous or cancerous neoplasms. During the same period 93 rectal ESDs were performed for superficial pre-cancerous or cancerous neoplasms. **Descriptive results:** male 54 (61%), mean size of the specimen: 49 mm, mean duration of procedure 125.1 min, mean speed of ESD: 18.9 mm²/min, perforation rate: 9 (10.3%), post procedural bleeding rate: 2.3%, secondary surgery 13 (15.3%) (3 (23%) for a perforation; 10 (77%) for a failure or pathological risk factor or lymph node metastasis) Colonic location: 26 (30%) sigmoid, 8 (9.2%) left colon, 6 (6.9%) splenic flexure, 9 (10.3%) transverse colon, 10 (11.5%) hepatic flexure, 14 (16.1%) right colon, 14 (16.1%) caecum Pathological analysis: low grade dysplasia in 24.7%, high grade dysplasia in 35.8%, intra-mucosal carcinoma in 19.8%, superficial submucosal carcinoma in 7.5%, deep submucosal carcinoma in 8.6% and T2 adenocarcinoma in 3.7%. Only 2 patients (3.1%) had a recurrent disease during endoscopic follow up. **Primary Endpoint:** En bloc resection: 87.4%, R0 resection: 73.5%, curative resection: 63.8%, extended curative resection: 85.7% **Secondary Endpoint:** No statistically significant parameters have been found between rectal and colonic ESD (Table 1).

	RECTUM n=87	COLON n=93	p
Age (Y)	66.9	66.9	0.99
Duration (min)	124	125	0.93
Large diameter (mm)	54.6	49	0.03
Small diameter (mm)	41.6	38	0.17
Surface (mm2)	1948	1937.5	0.95
Speed (mm2/min)	20.1	18.9	0.6
Exclusive ESD	96%	92%	0.09
Monobloc resection	94.40%	87.40%	0.09
R0 resection	74.10%	73.50%	0.73
Curative resection	68.50%	63.90%	0.87
Extended curative resection	91.40%	85.80%	0.3
Perforation	7.70%	10.30%	0.6
Post ESD bleeding	6.60%	2.30%	0.28
Pathological analysis			0.76
DBG	24.80%	24.70%	
DHG	33.70%	35.80%	
Intramucosal ADK	27%	19.80%	
sm < 1000 ADK	3.40%	7.50%	
sm > 1000 ADK	9%	8.60%	
T2 ADK	2.20%	3.70%	
secondary surgery	8 (8.8%)	13 (15.3%)	0.16
Perforation	0 (0%)	3 (23%)	
failure	2 (25%)	6 (46.1%)	
Pathological reason	6 (75%)	4 (30.8%)	
Recurrence	0 (0%)	2 (3.1%)	0.7

Conclusion: Colonic ESD could be performed with similar results than rectal ESD in French expert teams with prior strong experience in animal ESDs and rectal ESDs. It allows en bloc resection of large superficial colorectal neoplasms with a very low risk of recurrence. RCTs comparing colonic ESD to piece-meal EMR are needed to determinate the appropriate place of each technique in Europe.

P0868 RISK OF COLORECTAL NEOPLASM IN PATIENTS WITH ACROMEGALY -A CASE-CONTROL STUDYY. Ochiai¹, T. Iizuka¹, N. Inoshita¹, S. Yamada², S. Hoteya¹¹Dept. Of Gastroenterology, Toranomon Hospital Dept. of Gastroenterology, Tokyo/Japan²Dept. Of Hypothalamic And Pituitary Surgery, Toranomon Hospital Dept. of Gastroenterology, Tokyo/Japan**Contact E-mail Address:** y.ochiai.1987@gmail.com

Introduction: It is well known that acromegals have been at an increased risk of colorectal neoplasm. However, there has been few reports of them in Japanese patients with acromegaly. In this study, we attempted to elucidate the risk of colorectal neoplasm in Japanese patients with acromegaly comparing with healthy controlled patients.

Aims & Methods: Between April 2008 and September 2016, a total of 745 patients were underwent Hardy operation in our institute. Among them, a total of 178 patients were performed colonoscopy in our hospital during perioperative period and were enrolled in the case group. In contrast, a total of 356 patients were selected randomly from those who were performed colonoscopy in our medical check-up in the same period by means of being matched to cases of the age and gender. The incidence, size, location and histology of colorectal neoplasm were investigated.

Results: As background, 84 patients (47.2%) were men and 94 patients were women, and the median age was 47.5 years old (18 to 75) in the case group. The median height/weight was 165.5 cm/65.1 kg in the case group and it was significantly larger than the control group (163.4 cm/60.1 kg) ($p=0.038$, $p<0.001$ respectively). The median Body Mass Index (BMI) were 23.4 in the case group and 22.5 in the control group. There was a significant difference between two groups ($p<0.001$). The frequency of colorectal neoplasm was 66.8% (119/178 patients) in the case group and was significantly higher than control group of 24.2% (86/356 patients) ($p<0.001$). The average number and size of neoplasm were 2.44 and 4.74 mm in the case group and 1.77 and 3.89 mm in the control group. There was a significant difference between two groups ($p=0.001$). The distribution of neoplasm in the case group vs in the control group was shown 12.6% vs 12.8% in cecum, 30.3% vs 36% in ascending colon, 23.5% vs 30.2% in transverse colon, 15.1% vs 10.5% in descending colon, 66.4% vs 40.7% in sigmoid colon, and 31.9% vs 19.8% in rectum. The incidence of neoplasm in sigmoid region had a significant difference in two groups (the case group 80.7% vs the control group 53.5%) ($p<0.001$). In terms of neoplasm larger than 5 mm, the frequency was 34.3% (61/178 patients) in the case group and 7.6% (27/356 patients) in the control group ($p<0.001$). In addition, as for neoplasm larger than 10 mm, that was 15.2% (27/178 patients) and 2.2% (8/356 patients) respectively ($p<0.001$). The number of neoplasm resected by endoscopy was 71 lesions (24.5% of all) in the case group and 25 lesions (16.4%) in the control group. The pathological examination in the case and control group showed eight and one had hyperplastic polyps, 2 and zero had sessile serrated adenoma/polyp, 3 and zero had inflammatory polyp, 48 and 19 had low to moderate grade adenomas, 4 and 3 had High grade adenomas, one and zero had carcinoid, and 5 and 2 had carcinoma respectively. There were no significant differences between two groups in the limited cases of high grade adenoma and carcinoma.

Conclusion: This study showed the acromegalic patients had an increased risk of colorectal neoplasm especially, in the sigmoid region. It is important to be performed colonoscopy at the diagnosis of acromegaly.

Introduction: Colonoscopy in ulcerative colitis (UC) is performed as first diagnosis and during screening for dysplasia and disease flares. It is an invasive procedure with a burden of discomfort and possible complications. To overcome discomfort and complications due to colonoscopy an Italian high-tech start-up (Endotics, Peccioli, Italy) developed a soft, self-propelled, disposable robotic colonoscope (R), approved with CE mark.

Aims & Methods: We wanted to compare diagnostic performance and tolerability of R with those of standard white light colonoscopy (S) in patients with ulcerative colitis. Consecutive patients referred for colonoscopy to our endoscopy departments with clinically mild to moderate ulcerative colitis that signed the informed consent for both procedures were studied first with R and then with S (Olympus CF-145), by two different operators, blinded to previous observations. R had the following technical specifications: 17 mm outer diameter, rest position length probe 30 cm; maximum length of probe 54 cm; working length 210 cm; NTSC CMOS analog camera. Conscious sedation with midazolam was administered as

needed. We recorded endoscopic activity according to Baron criteria, time to reach the caecum, sedation, patient's pain/discomfort and operator's difficulty.

Results: We studied 12 patients (7M/5F), mean age 41 yrs and disease duration 5.33 yrs. 53 colonic segments out of the 54 evaluated had the same assessment of disease activity (absent=0 points, mild=1 pt, moderate=2 pts and severe=3 pts) with R and S. Mean activity score with R was 0.35 pts (SD 0.60) and 0.33 pts (SD 0.60) with S, without significant difference. The caecum was reached in 11/12 cases by S in an average of 29.42 min (SD 28.94), and in 10/12 cases by R, in an average of 46.67 min (SD 24.98 min), with a mean difference of 17, 25 min., not statistically significant. Incomplete colon explorations with R clustered in Milan, probably because of smaller experience. An average of 1.45 (SD 0.79) mg of midazolam were used during S while 0.41 (SD 0.38) mg during R. Mean pain/discomfort on a 0–10 scale was 2.08 (SD 1.67) for R and 4.17 (SD 1.74) for S, with a statistically significant difference ($p=0.066$) favouring R. Mean perceived operator's difficulty on a 0–10 scale was 4.44 (SD 1.78) for R, and 4.08 (SD 1.44) for S, with a mean difference of 0.42 pts favouring S, not statistically significant.

Conclusion: R appears to be a promising method for disease staging in patients with ulcerative colitis, because of comparable accuracy and reduction in pain and discomfort. A tool channel to obtain biopsies and perform therapeutic endoscopy, together with images of higher definition (CMOS digital Camera HD ready) and virtual chromo-endoscopy, useful for follow-up and screening for dysplasia in patients with long duration of disease are now available in the latest version of R. The "column" connected to the latest version of the robot is the size of a portable suitcase, and suitable for remote operation. Further studies with newer versions of R are needed to assess the role of this technology from an economic point of view and in special settings like failed screening colonoscopies, dysplastic lesions in UC, bed-side colonoscopy, colonoscopy in rural areas.

Introduction: The LST classification and Paris classification systems are internationally used to describe polyp morphology. Differences between Japanese and Western endoscopists in the use of classification systems, have been observed. We aimed to evaluate the inter-observer agreement of LST classification amongst Western & Japanese experts.

Aims & Methods: A total of 40 endoscopic video clips depicting LSTs (10% malignant) were by 6 expert endoscopists; 3 from Japan and 3 from the West. Assessments included LST classification (LST-G homogeneous, LST-G mixed, LST-NG flat, LST-NG pseudodepressed), Paris classification, invasiveness, treatment suggestion and mean size of lesion. We calculated the interobserver agreement with weighted kappa and Chi square.

Results: Japanese endoscopists diagnosed more lesions as LST-G than Western (62.7 vs. 45.4%). Western diagnosed more LST-NG than Japanese (54.6 vs. 37.3%; $p=0.007$). The interobserver agreement of the LST classification among the six experts was good with a weighted Kappa of 0.61 (IC 95% 0.43–0.78) for Japanese, and moderate at 0.45 (IC95% 0.27–0.64) for Western. Difference in concordance between the two cohorts was not statistically significant ($p=0.22$). When only two categories were considered (LST-G vs NG), agreement was very good for Japanese (weighted Kappa of 0.81; 95% CI 0.65–0.97) and good for Western endoscopists (0.65; 95% CI 0.46–0.85). Again, difference in concordance was not statistically significant ($p=0.22$). Piecemeal Endoscopic Resection was suggested in 34, 7% cases by Western, but never by Japanese endoscopists, whereas Endoscopic Submucosal Dissection was recommended in 50.4% and 16.1% cases by Japanese and Western experts respectively ($p < 0.001$).

Conclusion: This study is the first to validate the LST classification system comparing East and West. There were significant differences in the types of LST diagnosed, and concordance was good in the Japanese cohort and moderate in the Western, but not significantly different. The recommendations for treatment were also different. We suggest a modification of the classification system to enable a more unanimous diagnosis and therapeutic strategy.

Introduction: A scoring system based on size, morphology, site and access (SMSA score) was established for determining the complexity of polypectomy or endoscopic mucosal resection (EMR) and it could predict outcomes.

Aims & Methods: The aim of this study was to assess the usefulness of the SMSA scoring system relating the difficulty level with outcomes and complications of EMR and to compare it with a subjective classification of difficulty. We conducted a prospective multi-center study with 1997 consecutive patients with large (≥ 20 mm) non-pedunculated colorectal lesions (LNPL) treated by EMR (n=2198) at 23 hospitals belonging to the Spanish Endoscopy Society Endoscopic Resection Group, from January 2013 to October 2016. We

calculated the SMSA score of difficulty and assessed the ability of SMSA to identify 5 outcomes: 3-months recurrence, 1-year recurrence, global recurrence (endoscopy not effective after 2 or more treatments), delayed bleeding and perforation. We compared results with those obtained using a subjective classification of difficulty: easy or medium vs difficult. Comparisons were conducted using chi-squared tests and complemented with logistic regression models.

Results: The SMSA scoring system classified 690 polyps (39%) as level 4 and 1098 (61%) as level 3, whereas the subjective classification system classified 399 (22%) as difficult and 1389 (78%) as easy or medium. The agreement between measures of difficulty was weak ($k = 0.33$). 255 patients (19.9%) had recurrence 3 months after EMR, 84 (11.6%) had recurrence at 1 year, 78 (3.5%) suffered delayed bleeding and 35 (1.8%) perforation. The level 4 polyps had significantly higher rates of recurrence at 3 months and 1 year ($p < 0.001$ in both cases) and delayed bleeding ($p = 0.012$). We did not find differences for global recurrence and perforation. Using the subjective indicator of difficulty, recurrence was also more frequent in the higher difficulty category at 3-months, 1-year and the global recurrence ($p < 0.001$ in all three cases) and for delayed bleeding too ($p = 0.006$), but not for perforation.

Conclusion: The SMSA grading tool is a predictor of outcomes or recurrences and bleeding following resection of LNPCL. However, in our multi-center sample, it does not appear to overcome the ability of a subjective indicator of difficulty made by the endoscopist during the EMR. It seems that this score can be used to facilitate planning, training or competency assessment, but efforts should be focused on validating the scoring system in a real situation, adjusting the score of variables or including new ones.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0872 NARROW BAND IMAGING GUIDED BIOPSY IMPROVES THE YIELD OF HISTOLOGY FOR THE DIAGNOSIS OF GASTROINTESTINAL TUBERCULOSIS (GITB)

N. Berry, S. K. Sinha, S. Malik, R. Kochhar, K. Vaiphei, K. Sharma, N. Dhaka, A. Koshi

Gastroenterology, Postgraduate Institute of Medical Education and Research, Chandigarh/India

Contact E-mail Address: sarojksinha@hotmail.com

Introduction: Accurate diagnosis of gastrointestinal tuberculosis (GITB) is challenging due to pauci-bacillary nature of disease and poor sensitivity of histopathology. Role of tissue acquisition using narrow band imaging magnification (NBI-M) to improve yield of histopathology over high-definition white light endoscopy (HD-WLE) has not been assessed.

Aims & Methods: To compare the utility of narrow band imaging with magnification versus high-definition white light imaging guided endoscopic biopsy for diagnosis of gastrointestinal tuberculosis. In this prospective study from July 2015 to November 2016, adult cases of clinically suspected GITB were recruited. All patients underwent mantoux test, contrast enhanced computed tomography of abdomen, esophagogastroduodenoscopy and/or colonoscopy using both HD-WLE and NBI-M and guided biopsies using both were taken. Histopathological examination was done by two independent pathologists. A final diagnosis of GITB was made if acid-fast bacilli were seen in tissue or grown in culture, histopathology showed caseous necrosis with granulomatous inflammation or clinical/radiological and endoscopic features were suggestive of tuberculosis and a good clinical response to antitubercular therapy.

Results: A total of 55 cases of clinically suspected GITB were recruited. A final diagnosis of tuberculosis was made in 32 cases (duodenal $n = 4$, ileocolic $n = 28$). Concomitant evidence of active or healed pulmonary tuberculosis was seen 21% of cases. The mean age, haemoglobin and erythrocyte sedimentation rate of patients with tuberculosis were 36.41 ± 14.6 years, 10.2 ± 2.4 g/dL, 37.8 ± 15.3 mm/hour respectively. The mean duration of symptoms was 10.9 months. The most common symptoms were pain abdomen (78%), weight loss (62.5%), and loss of appetite (40.6%), fever (37.5%), vomiting (34%) and diarrhoea (22%). Mantoux test was positive in 40.6% cases. The most common endoscopic findings were ulcerations (75%), nodularity (46.8), distorted ileocecal valve (28%) and strictures (21.8%) (Table 1). The most common radiological

findings were mural wall thickening (65.6%), mesenteric lymphadenopathy (56%) and strictures (40%) (Table 1). NBI-M guided biopsy confirmed the diagnosis of GITB in 46.88%, while HD WLE guided biopsy confirmed diagnosis of GITB in 28.12% ($P, 0.04$). The two sets of biopsies together confirmed diagnosis of GITB in 53.1%. The area under curve for NBI-M plus HDWLE, NBI-M alone and HDWLE alone were 0.77(0.63–0.87) 0.73 (0.60–0.85) and 0.64 (0.50–0.77) respectively. Patients were started on anti-tubercular therapy for nine months. Four patients underwent surgery for intestinal obstruction while on antitubercular therapy. Twenty eight completed full therapy and improved.

Conclusion: NBI-M guided biopsy improved the yield of histology for diagnosis of GITB.

Endoscopic findings		Radiological findings	
Parameter	N (%)	Parameter	N (%)
Ulcerations	24 (75)	Mesenteric lymphadenopathy	18 (56)
Nodularity	15 (46.8)	Mural thickening	21 (65.6)
Stricture	7 (21.8)	Stricture	13 (40)

Introduction: Colorectal cancer is a leading cause for cancer related mortality. Adenomatous polyp, the precursor, can usually be endoscopically resected to prevent cancer. Currently, there are no criteria for surgical vs. endoscopic resection and decision is individually made by the treating physician.

Aims & Methods: We aimed to evaluate factors associated with short-term efficacy and safety of endoscopic resection of large (≥ 20 mm) and giant (≥ 40 mm) adenomas. Consecutive cases that underwent endoscopic resection of adenomas larger than 20 mm were included. Endoscopic, clinical and histological details of polyps and of the endoscopic procedure were recorded as well as the need for surgical resection.

Results: Total of 351 resections were included. Average diameter was 30.34 ± 10.66 mm. Surgery was indicated in 21 (5.98%) cases. In a multivariate analysis for efficacy, two variables were independent risk factors for surgery: adenoma size (OR 95%CI 1.08 (1.04–1.12)) and cecal location (OR 95%CI 5.97 (1.60–22.33)). Post-polypectomy complications were documented in 85 cases (24.2%); bleeding - 69 (19.7%), 54/69 managed during procedure), perforations - 8 (2.3%) and significant discomfort up to early termination of procedure - 15 (4.3%). Only 21 (6.0%) developed serious complications requiring further hospitalization. In multivariate analysis for safety, independent risk factors for post-polypectomy complications were: adenoma size (OR 95%CI 1.04 (1.01–1.06), polyp morphology (sessile OR 95%CI 2.55 (1.45–4.51), flat OR 95%CI 2.40 (1.04–5.52)) and submucosal adrenaline injection (OR 95%CI 1.87 (1.11–3.20)). Every increment of 1 mm in adenoma diameter above 20 mm, increased the need for surgery by 8% and the risk for complications by 4%.

Conclusion: Resection of large or giant adenomas is generally a safe procedure when performed by an experienced endoscopist. Although adenoma size is the most significantly related to efficacy and safety, each case of giant adenoma should be evaluated in a referral center for feasibility of endoscopic resection.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0874 COLORECTAL MUCOSAL DEFECT CLOSURE FOLLOWING ENDOSCOPIC MUCOSAL RESECTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

C. Palmela¹, P. Marques Da Costa², A. O. Ferreira¹

¹Gastroenterology Department, Hospital Beatriz Ângelo, Loures/Portugal

²Gastroenterology And Hepatology Department, Hospital de Santa Maria, Lisboa/Portugal

Contact E-mail Address: palmela.carolina@gmail.com

Introduction: Clinically meaningful delayed bleeding is the most frequent adverse event following endoscopic colorectal mucosal resection. Observational and interventional studies on the efficacy of prophylactic closure (PC) following endoscopic mucosal resection (EMR) showed conflicting results.

Aims & Methods: The primary objective of this review is to evaluate the effectiveness in preventing bleeding and post-polypectomy syndrome (PPS) or perforation of PC of colonic mucosal defects following endoscopic resection. We performed a systematic review and meta-analysis of randomized controlled trials (RCTs) from MEDLINE. We included studies with humans submitted to colonoscopy and in whom mucosal flat or sessile (Paris classification 0-II or Is) lesions with an estimated size ≥ 10 mm were found and removed.

Results: 269 articles were initially screened: 5 were RCTs, 4 of them were pooled in the quantitative analysis. A total of 555 patients and 557 resected lesions (proximal colon: 220; distal: 337) were included. Endoscopic procedures: 459 loop polypectomies and 98 submucosal dissections. A total of 298 lesions were randomized to PC versus 259 to non-closure (NC). Number of events on PC group: delayed bleeding (n=3), PPS and perforation (n=6). Number of events on NC group: delayed bleeding (n=13), PPS and perforation (n=14). Prophylactic mucosal defect closure was effective in reducing delayed bleeding risk (OR 0.206, 95%CI 0.054–0.779; $p=0.020$; $I^2=0$, 0%; 2 RCT and 452 lesions included). There was a non-significant trend for PPS/perforation risk reduction after PC (OR 0.349, 95%CI 0.114–1.070, $p=0.066$; $I^2=0$, 0%; 2 RCT and 374 lesions included).

Conclusion: Prophylactic closure of mucosal defects after EMR of flat or sessile colorectal lesions ≥ 10 mm reduces the risk of delayed bleeding. Further studies are needed to evaluate the effect on PPS/perforation prevention.

Introduction: Endoscopic Submucosal Dissection has become the standard of care for large superficial rectal precancerous and cancerous lesions. It allows an en-bloc resection of large superficial lesions that increase the quality of pathological analysis and considerably decrease the risk of recurrence. Risk of having large superficial lesions increase with age and no study have focused specifically on ESD in very old people (>80 years). Indeed in this population alternative surgery had a high morbidity and is often refused or contraindicated for these patients

Aims & Methods: Retrospective bicentre study of all cases of rectal ESDs performed between 06/2010 and 12/2016 for superficial pre-cancerous or cancerous neoplasms in patients older than 80 years four French teams that performed more than 150 ESDs in the last 5 years. Primary Endpoint was to evaluate the En bloc, R0, curative resection rate and complications in patients older than 80 years. Secondary endpoints were to compare these results with results of rectal ESDs performed during the same period for patients younger than 80 years.

Results: 58 rectal ESDs were performed in four French centers between 06/2010 and 12/2016 for superficial pre-cancerous or cancerous neoplasms in patients older than 80 years. **Descriptive results:** male 28 (48%), mean size of the specimen: 56.4 mm, mean duration of procedure 143.7 min, mean speed of ESD: 19.8 mm²/min, perforation rate: 3 (5.2%), post procedural bleeding: 7 (12%), secondary surgery 2 (3.4%) (All for pathological reason) Pathological analysis: low-grade dysplasia in 19%, high-grade dysplasia in 28%, intra-mucosal carcinoma in 5%, superficial submucosal carcinoma in 5%, deep submucosal carcinoma in 5%, T2 adenocarcinoma in 3.4% and anal SCC in 6.9%. Only 1 patients (1.7%) had a recurrent disease during endoscopic follow up. **Primary Endpoint:** En bloc resection: 86.2%, R0 resection: 62.5%, curative resection: 62.5%. **Secondary Endpoint:** Duration of procedure was longer in older people. Speed of ESD was lower. En bloc and R0 resection were lower in very old patients. Cancer was more frequent in very old patients. All comparative data between very old patients (>80 years) and younger patients (<80 years) are resumed in table 1.

	>80 (n = 58)	<80 (n = 275)	p
Duration	143.69	113.78	0.053
Large diameter (mm)	56.43	56.36	0.98

(continued)

: Continued

	>80 (n = 58)	<80 (n = 275)	p
small diameter (mm)	43.31	41.42	0.54
Surface (mm2)	2289.67	2154.64	0.68
Speed (mm2/min)	19.76	24.72	0.01
Perforation	5.20%	6.30%	1
post ESD bleeding	12%	5.50%	0.07
Exclusive ESD	86.20%	95.50%	0.007
En bloc	86.20%	95.50%	0.007
R0	62.50%	74.20%	0.08
Curative	62.50%	69.30%	0.31
Pathological analysis			0.009
LGD	19%	23.6%	
HGD	28%	34%	
im ADK	31%	29%	
sm < 1000 ADK	5%	6.9%	
sm > 1000 ADK	5%	3.6%	
T2 ADK	3.4%	2.1%	
anal SCC	6.9%	0.3%	
Secondary surgery	3.40%	7.30%	0.39
Recurrence	1.70%	1.40%	0.84

Conclusion: ESD is feasible and efficient in very old patients. However, En bloc resection and R0 resection are less frequent than in younger patients probably due to more challenging lesions (more frequent cancer on the pathological analysis). ESD should be the treatment of choice for large rectal superficial neoplasms of the rectum in very old patients in view of its oncological efficiency and its safety in comparison to the surgical alternative.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0876 COLONOSCOPY SPLIT-DOSE PROTOCOL IMPLEMENTATION: A SINGLE-CENTRE EXPERIENCE

C. Palmela, C. Gomes, M.P. Costa Santos, M. Rocha, S. Pereira, D. Tavares, R. Ribeiro, A. O. Ferreira, E. Barjas, M. Cravo

Gastroenterology Department, Hospital Beatriz Ângelo, Loures/Portugal

Contact E-mail Address: palmela.carolina@gmail.com

Introduction: Split-dose bowel preparation (SD) is more effective in bowel cleansing than previous day preparation (PD).

Aims & Methods: The main objective of the study was to explore the impact of a SD protocol in bowel cleansing quality in patients from a district hospital. This was an exploratory observational study of patients who underwent total colonoscopy between jun/2016-mar/2017 with polyethyleneglycol bowel preparation before and after SD protocol implementation. Bowel cleansing quality was assessed prospectively (using Boston Bowel Preparation Score) and compared between SD and PD groups. Tolerance was assessed using a patient questionnaire.

Results: A total of 344 patients were included, 53% were male, mean age of 61.8 \pm 13.6 years. Bowel preparation: 66% SD and 34% PD. Overall, 72% of colonoscopies occurred in morning shifts. Mean interval between finishing bowel preparation and colonoscopy was 4h50 (SD) and 8h09 (PD). Adequate bowel cleansing was found in 81% of patients (SD 83% vs. PD 79%; $p=0.34$). There was an association between adequate bowel cleansing and a shorter interval between finishing preparation and colonoscopy (5h40 vs. 7h15; $p=0.010$). Split-dose preparation was associated with a better cleansing in the right colon (2.17 \pm 0.69 vs. 2.03 \pm 0.65; $p=0.047$) and a trend for better overall cleansing (6.70 \pm 1.87 vs. 6.32 \pm 1.90; $p=0.067$). On morning shifts, there was a significant association between SD prep and better overall cleansing ($p=0.030$) and also right colon cleansing ($p=0.034$). After adjusting for morning shifts, we found an association between SD preparation and better bowel cleansing (risk difference 0.406; 95%CI -0.023–0.834; $p=0.063$). There was no difference between groups on bowel urgency (SD 2.6% vs. PD 1.7%; $p=0.718$). SD preparation was associated with worse sleep quality (SD 25% vs. DA 7%; $p=0.004$).

Conclusion: The implementation of a split-dose bowel preparation protocol in our hospital was associated with better bowel cleansing, especially on the right colon. Split-dose preparation was not associated with higher bowel urgency, although there was a worse sleep quality.

P0877 EQUAL ADENOMA DETECTION RATE IN COLONOSCOPIES OF PATIENTS WITH SPINAL CORD INJURY AND CONTROLS – A CASE-CONTROL STUDY

A. Blanco Belyer¹, M. Aach², W. Schmiegell¹, T. A. Schildhauer², R. Meindl², T. Brechmann¹

¹Department Of Gastroenterology And Hepatology, Berufsgenossenschaftliches University Hospital Bergmannsheil GmbH, Bochum/Germany

²Department Of General And Trauma Surgery, Spinal Cord Injury Unit, Berufsgenossenschaftliches Universitätsklinikum Bergmannsheil gGmbH, Bochum/Germany

Contact E-mail Address: thorsten.brechmann@rub.de

Introduction: Spinal cord injury (SCI) is a devastating event that occurs with a discharge incidence of 109 per million, which results in an estimated prevalence of up to 2525 per one million [1]. Cancer is a major cause of death in patients with spinal cord injury (SCI) [2]. Preventive strategies claim increasing attention, but must deal with special problems. Most SCI patients suffer from neurogenic bowel alterations, characterized by loss of bowel control, diarrhea, reduced bowel motility, constipation or evacuation difficulties. Therefore, bowel preparation requires modified and intensified regimens and more intensive care to prevent pressure ulcers and optimum skin management [3, 4, 5]. Colonoscopy itself might be associated with reduced efficacy in SCI patients, since a poorer quality of bowel cleansing or failure to reach the caecum could diminish adenoma detection rates (ADR) [6, 7], while complication rates could increase due to severe morbidity.

Aims & Methods: The primary objective was to determine the adenoma detection rate (ADR) in general, right and left hemicolon. Secondary objectives were polyp, advanced adenoma and carcinoma detection rates, size of adenomas and polyps in either localization, intensity and effect of bowel preparation, rate of complete colonoscopies, need for re-endoscopy, duration of colonoscopic procedures, deepest point of insertion and complication rates. We reviewed retrospectively consecutive SCI patients who underwent colonoscopy from 2003 to 2014 and assigned an age-, gender- and year of performance-matched control group.

Results: In 236 SCI, compared to 414 control patients, bowel preparation lasted longer (3.57 ± 1.5 vs. 1.15 ± 0.6 days, $p = 0.001$), achieved insufficient cleansing results more often (23.7 vs. 3.6%) and caused more adverse events. Colonoscopy needed longer time (36.9 vs. 25.0 min, $p = 0.001$), remained incomplete more often (24.6 vs. 4.6%), resulting in more re-colonoscopies (14.8 vs. 4.3%). Endoscopy- and sedation-related adverse events were equal. However, neither overall nor size-dependent polyp (30.9 vs. 34.8%), adenoma (21.2 vs. 21.0%), advanced adenoma (6.8% vs. 7.2%) or cancer (1.7 vs. 2.0%) detection rate differed.

Conclusion: Despite intensified protocols, bowel preparation shows inferior results in SCI patients and colonoscopy needs more efforts to succeed, but achieves a comparable quality.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0878 RISK FACTORS AND PRACTICAL CONSEQUENCES OF COLORECTAL ESD CONVERSION TO EMR AT A WESTERN REFERRAL CENTER IN DAILY PRACTICE

E. Perez-Cuadrado-Robles, H. Piessevaux, T. Moreels, P.H. Deprez
Gastroenterology Department, Cliniques Universitaires Saint-Luc, Brussels/Belgium

Contact E-mail Address: kikemurcia@gmail.com

Introduction: There are limited data concerning risk factors and consequences of colorectal endoscopic submucosal dissection (ESD) conversion to mucosal resection (EMR) in western centers.

Aims & Methods: Hospital-based frequency-matched case-control retrospective study. All patients were identified from a database of 225 consecutive dissections between 2013 and 2017. The cases were those with ESD conversion to EMR for a >20 mm colonic lateral spreading tumor (LST). The controls were randomly selected by frequency 1:2 matching for tumor size (± 50 mm) and location

(rectum/non-rectum). The presences of different factors were evaluated to determine whether they predicted ESD conversion.

Results: One-hundred and seventeen patients (39 cases, 78 controls) were included (mean age: 68 ± 10.9 years, 52.1% male). Mean tumor size was 38.5 ± 14.4 mm and the most common location was the right colon/transverse ($n = 71$, 60.7%). By multivariable analysis using backward stepwise method, non-lifting [OR: 0.324 (CI95%: 0.117–0.896), $p = 0.03$], duration > 120 min [OR: 3.127 (CI95%: 1.305–7.493, $p = 0.011$) and LST-G type [OR: 2.881 (CI95%: 1.074–7.727), $p = 0.036$] were independent factors associated to ESD conversion. Duration was also significant when adjusted by fibrosis (OR²: 21.212, $p = 0.028$) and related to en-bloc resection (62.8% vs. 91.9%, $p < 0.001$). Fibrosis ($p = 0.032$) and non-retroview ($p = 0.025$) were significant factors only in univariate analysis. Previous biopsy/polypectomy, referral status, presence of a fellow, circumferential (> 75%) tumor, intra-procedure complications (14.5%) and start time were not associated to ESD conversion. R0 was achieved in 64.7% ($n = 11/17$) cases with en-bloc EMR resection and in 91% controls ($p < 0.001$). There were two recurrences (13.3%) at 3-months within the 15 cases with piecemeal resection, treated endoscopically. No recurrences were noted in en-bloc (ESD or EMR) resection patients ($p = 0.044$). Three (7.7%) and one (1.3%) patients had an indication for surgery in case-control groups ($p = 0.107$).

Conclusion: The presence of certain factors should be assessed during the procedure to identify patients who are high-risk for ESD conversion regardless of size or location, particularly the duration of the dissection.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0879 CONTRIBUTION OF COLONOSCOPY IN ELDERLY PATIENTS OLDER THAN 70 YEARS

A. El Mekkaoui¹, A. Taiymi¹, A. Zazour¹, W. Khannoussi², G. Kharrasse³, Z. Ismaili⁴

Introduction: The elderly patients are considered as a particular population. Colonoscopy has an important place at this population because of the limited number of normal paraclinical examinations and the high incidence of tumor disease, specially the colo rectal cancer.

Aims & Methods: The aim of this study was to determine the indications and results of colonoscopy in people older than 70 years We performed a retrospective descriptive study over a period of 2 years from the beginning of the endoscopic unit until February 2017, conducted in the department of hepato-gastroenterology of our university hospital. All patients over the age of 70 years who have underwent colonoscopy have been included.

Results: A total of 1059 colonoscopies were performed, 10.3% were indicated for people older than 70 years. The mean age was 74.15 years with a median age of 75 years and a maximum age of 91 years. The prevalence of males was 51%. 10.5% of cases ($n = 10$) were diabetic, 12.6% ($n = 12$) hypertensive, 12.6% ($n = 12$) with ischemic heart disease. 8.4% ($n = 8$) had cirrhosis and 9% ($n = 9$) had a digestive neoplasia. Colonoscopy was indicated for hematochezia in 40% ($n = 38$), transit disorders in 33.6% ($n = 32$), abdominal pain in 14.7% ($n = 14$), IBD in 3.1% ($N = 3$), radiographic abnormalities in 13.6% ($n = 13$), iron deficiency anemia in 4.2%, and for patients with a family history of colorectal cancer in 1% of cases. Colonoscopy was abnormal in 83% ($n = 93$), with polyps in 48.3% ($n = 45$), suspected lesions of malignancy in 16.1% ($n = 15$), Diarrhea in 19.3% ($n = 18$), IBD in 3.2% ($n = 3$), arteriovenous malformations in 12% ($n = 11$) and rectal erosions in 2.1% ($n = 2$). The rate of malignant lesions diagnosed by colonoscopy was 53.3% of females ($n = 8$) versus 46.7% of males ($n = 7$) ($p = 0.26$), 13.3% ($N = 2$) with hematochezia versus 86.7% ($n = 13$) without hematochezia ($p = 0.07$), and 26.7% with altered general status ($n = 4$) versus 73.3% with conserved general status ($n = 11$) ($p = 0.07$). The evolution of 46.6% of patients diagnosed with malignant tumor pathology showed that 33.3% of patients underwent surgery and 13.3% of patients had died.

Conclusion: In our study, suspected lesions of malignancy were diagnosed in 16.1% of cases. Colonoscopy in this age group is intended not only to detect possible polyps which could degenerate in the future but rather to diagnose the cancer already installed, especially with the presence of clinical signs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0880 ENDOSCOPIC CLOSURE OF ACUTE IATROGENIC PERFORATIONS OF THE GASTROINTESTINAL TRACT AND PREDICTORS OF NEED FOR EARLY SURGERY: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Gabr¹, N. Ammar², M. El Houssine², M. Rutter³

¹East Kent University Hospitals NHS, FD/United Kingdom

²Public Health Department, Ain Shams University, Cairo/Egypt

³Gastroenterology, University Hospital of North Tees, Stockton on Tees/United Kingdom

Contact E-mail Address: ahmedgabr@hotmail.co.uk

Introduction: Acute iatrogenic perforations are one of the recognized complications of both diagnostic and therapeutic gastrointestinal endoscopy. For decades, surgical treatment has been the standard of care, but endoscopic closure has become a more popular approach, due to feasibility and the reduction of the

burden of surgery, combined with the availability of various endoscopic closure devices.

Aims & Methods: To assess the technical and clinical success and safety of endoscopic closure, in total, and for each endoscopic device used. Also, to identify factors predicting surgery as a first line treatment, and failure of endoscopic treatment. Medical literature (Cochrane library, EMBASE, MEDLINE) from 1966 till September 2016 was searched. A systematic review and meta-analysis were performed on studies reporting technical and clinical success of endoscopic closure of acute iatrogenic perforations, according to PRISMA (Preferred Reporting Items for Systematic Reviews and Metaanalyses) guidelines.

Results: 764 studies were identified. 28 studies, in human, met our inclusion criteria and were analysed. A total of 474 endoscopic closures were attempted in these studies. The overall technical success rate was 93.1% (n=451/474, 95% CI: 89.8%–96.4%), clinical success was 89.7% (n=431/474, 95% CI: 85.5%–93.9%), and complication rate was 1.3% (n=7/474, 95% CI: 0.3%–2.3%). Technical success for endoclip closure was 96.6% (95% CI: 94.2%–98.2%), and clinical success was 93% (95% CI: 87.1%–97.2%), and complication rate was 1.5% (95% CI: 93.75%–96.25%). For OTSC (Over the scope clip device), technical success was 83.8% (95% CI: 63.9%–96.6%), clinical success was 77.9% (95% CI: 56.8%–93.3%), and complication rate was 4.1% (95% CI: 90.3%–99.1%). The technical success rate for Self-expanding metal stent (SEMS) is 100% (95% CI: 71.5%–100%), clinical success is 91% (95% CI: 74.1%–108%), and complication rate of 9.1% (95% CI: 78%–112%). Only one study for endosuturing met our criteria, with technical and clinical success rate of 100%, and without any complication. Factors predicting failure of endoscopic treatment and need for early surgical intervention included large perforation size, leucocytosis, fever, severe abdominal pain, large amount of peritoneal free air, necrotic or soft inflammatory margins, unfavourable anatomical site, stool contamination, diffuse peritonitis and failure of endoscopic closure.

Conclusion: Our study suggests that endoscopic closure is a suitable treatment option for acute iatrogenic gastrointestinal perforations. Several factors have been suggested as predictors of need for surgery as a first line treatment. The study is limited by the low methodological quality of most studies included, indicating the need for further research.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0881 REAL-TIME HISTOLOGICAL CHARACTERIZATION OF COLORECTAL POLYPS - THE IMPACT OF TRAINING

J. Castela, J. Cortez-Pinto, S. Mão De Ferro, I. Rosa, S. Ferreira, J. Pereira Da Silva, I. Claro, S. Faías, P. Lage, A. Dias Pereira
Núcleo Regional do Sul da Liga Portuguesa Contra o Cancro, Lisboa/Portugal

Contact E-mail Address: joanarocastela@gmail.com

Introduction: Narrow-band imaging (NBI) allows, after training, "in-vivo" classification of colorectal polyps. Recent guidelines propose a "do not resect" strategy for rectosigmoid hyperplastic polyps ≤5mm, characterized with a high degree of confidence, with ≥90% negative predictive value (NPV) for adenomatous histology.

Aims & Methods: We aimed to evaluate the impact of training for the simultaneous application of NICE (International Colorectal Endoscopic Classification) and WASP (Workgroup Serrated Polyps and Polyposis) classifications. Prospective, single-center study of patients undergoing elective colonoscopy (colonoscopy-CF-H190®, Olympus), in two periods: P1: January-February/2016 and P2: January-February/2017. Endoscopists had no prior experience in NBI in P1, except for an interactive session of 20 minutes, and after P1 applied the technique during 2016 at their discretion. Polyps were assessed for its location, size and morphology (Paris classification); NICE/WASP: 1p (hyperplastic), 1s (sessile serrated), 2 (adenoma), 3 (deep submucosal invasive cancer); confidence level (low: <90% vs high: >90%) of the predictions. NICE/WASP classifications were compared with histology. Learning impact evaluated by P1 and P2 comparison. Statistics: Software-R (version 3.1.2I).

Results: 290 polyps of 135 patients were analysed (P1: n=192; P2: n=98), average size 6.4mm (2–35mm), 60% located in the left colon, 71.0% 0-Is. No difference in size, location, morphology and histology between P1 and P2 groups. An improvement of global acuity in the application of NICE/WASP classification in P2 was observed: 74.5% (95% CI: 67.7%–80.5%) vs 81.6% (95% CI: 72.5%–88.7 (p=0.222), statistically significant for high confidence level predictions (P1: 77.6%, P2: 75.5% of the predictions); 78.5% (95% CI: 71.1%–84.8%) vs 90.5% (95% CI: 81.5%–96.1%) (p=0.044). In the P2 data subanalysis, NICE/WASP classification for adenoma showed sensitivity, specificity, positive predictive value and NPV of 82% (70–99%), 94% (80–99%), 96% (87–100%) and 72% (56–85%), respectively; for rectosigmoid polyps ≤5mm, with high confidence level (n=35), NPV for adenoma was 80% (59–93%).

Conclusion: The overall performance of endoscopists significantly improved with one year of training, but did not meet the standards for the implementation of the "do not resect" strategy. However, the results may have been affected by the addition of an additional category (1s) to the NICE classification.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0882 "O-RING SIGN" AS A NOVEL COLONOSCOPIC FINDING WITH NARROW-BAND IMAGING FOR DETECTING DEPRESSED-TYPE COLORECTAL LESIONS

T. Fujii

Dept. Of Gastroenterology, TF Clinic Dept. of Gastroenterology, Tokyo/Japan

Contact E-mail Address: tfclinic@khaki.plala.or.jp

Introduction: In recent years, post-colonoscopy colorectal cancer (PCCRC) has become a focus of attention as likely representing "missed" or "rapidly-growing" lesions in colonoscopic screening for colorectal cancer (CRC). Currently, lesions thought responsible for PCCRC include sessile serrated adenomas/polyps or flat and depressed-type lesions occurring on the right side of the colon, and there is an increasing need for endoscopic modalities to prevent overlooking these lesions. Colorectal screening using narrow-band imaging (NBI) during colonoscopy withdrawal from the cecum, which was started at our clinic since November 2008, suggested that NBI colonoscopy was superior to white-light imaging (WLI) colonoscopy in detecting flat and depressed-type lesions (1). With NBI, the depressed area of a lesion is recognized as "whitish" and the surrounding ring-like mucosa as "brownish", which constitutes the "O-ring sign".

Aims & Methods: We aimed to evaluate the incidence and characteristics of the "O-ring sign" in depressed-type colorectal lesions. A total of 227 endoscopically resected and histologically confirmed depressed lesions (IIa+IIc, 156; IIc, 71) were included for analysis. The colonoscopic images of these lesions were retrospectively examined for "O-ring sign" positivity and intensity (grade 0, negative; grade 1, mildly to moderately positive; and grade 2, highly positive). Of these, 16 were excluded as unevaluable and a total of 211 evaluable lesions were analyzed.

Results: Of the 211 lesions (IIa+IIc, 141; IIc, 70) analyzed, 84 (IIa+IIc, 60; IIc, 24), 105 (IIa+IIc, 69; IIc, 36), and 22 (IIa+IIc, 12; IIc, 10) were found to be in grades 0, 1, and 2, respectively, with 60.2% of these shown to be "O-ring sign"-positive (127/211), with IIa+IIc and IIc accounting for 57.4% (81/141) and 65.7% (46/70), respectively, of these lesions. While an examination by tumor size and location revealed no clear tendency in "O-ring sign" positivity, an examination by grade revealed a higher "O-ring sign" positivity rate among those with high-grade dysplasia (84.6%; 11/13) than those with low-grade dysplasia (59.2%; 116/196).

Conclusion: NBI colonoscopy screening for the "O-ring sign" as an index appears to improve the detection of depressed-type colorectal lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

²Gastroenterology, Machida Icho Hospital, Tokyo/Japan

Contact E-mail Address: naohiko.akimoto07@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) has been acceptable as a minimally invasive therapy and providing en-bloc resection for early malignant and pre-malignant lesions of gastrointestinal cancer. Colorectal ESD has some difficulties such as a risk of perforation and its severity compare to gastric ESD. Hence, Colorectal ESD is more challenging than gastric ESD in endoscopic technique. In Japan, where has high incidence of gastric cancer, endoscopists

could have many experiences of gastric ESD that may be beneficial for the introduction of colorectal ESD. However there is little knowledge about the learning curves of the young endoscopists who perform the colorectal ESD first.

Aims & Methods: We conducted multi-center retrospective observational study to elucidate the safety and learning curve of the trainee who perform the colorectal ESD first. The study subjects were consecutive 261 cases of colorectal ESD performed by three endoscopists in Nippon Medical School Hospital and Machida Ichu Hospital from 2010 to August 2016. The ESD devices were Flush knife BT (Fujifilm), Dual knife (Olympus), Hook knife (Olympus) or a combination of these selected by operators demand. The endoscopist A and B, who had over 10000 examinations of colonoscopy and experiences of gastric ESD (as expert group), and endoscopist C had about 1000 colonoscopy and started colorectal ESD first (as trainee group). The completion rate of operation, which is defined as en-block resection rate without changing operator, operation time, speed (time/mm²) and complications were analyzed in each endoscopist. Furthermore, we divided these procedures in three periods equally such as early, middle and late.

Results: The median age was 70 (range 26–91) years old, and genders were 158 males and 103 females. Tumor locations were proximal colon, distal colon and rectum in 143(54.8%), 59(22.6%), and 59(22.6%), respectively. The histological types were well and moderately differentiated tubular adenocarcinoma, adenoma, hyperplastic polyp, SSA/P, and neuroendocrine tumor in 139(60.4%), 68(29.6%), 5(2.1%), 10(4.3%) and 8(3.8%), respectively. There is no statistical significance in age, gender, tumor location, tumor size and histological type. The average operation time was 68.0 minutes, the median 80.1 (range 13–353) minutes. The completion rates of endoscopist A and B reached 100% in all three time periods and endoscopist C showed an increase: 41%, 67%, and 100% in the initial, middle, late period, respectively. In the operation time, there was a significant difference between endoscopist A (73.1±38.9, median 67.5) and C (100±60.8, median 85), B (62.9±45.1, median 55.5) and C (P < 0.001). In addition, there was difference in the operation speed of endoscopist C among each periods. The complications were perforation and delayed bleeding in 8 cases (3.1%) and 2 cases (0.8%). All cases recovered with medical and/or endoscopic treatment alone.

Conclusion: Trainee endoscopist may have a good learning curve in completion rate and increasing experience reflects in a remarkable success in colorectal ESD. We concluded that the training of colorectal ESD first was acceptable by the trainee endoscopist who had no experience of gastric ESD.

Introduction: Removal of large common bile duct (CBD) stones is one of the challenges during ERCP and it seems more difficult in cirrhotic patients due to suspected higher rates of adverse events especially bleeding diathesis. Patients with liver cirrhosis can tolerate ERCP to treat their biliary tract or pancreatic diseases. Patients with liver cirrhosis are three times more susceptible to cholelithiasis, than the non-cirrhotic population plus the biliary and pancreatic cancer and other diseases and that is why ERCP is increasingly performed for patients with cirrhosis. Endoscopic sphincterotomy (EST) has become a standard step in management of CBD stones and introduction of both mechanical lithotripsy (ML) and large balloon dilation (LBD) facilitated extraction of the large stones. Despite the increasing use of both techniques, a head-to-head comparison between EST followed by LBD and EST followed by ML is lacking in the literature, and to the best of our knowledge none were done on cirrhotic patients

Aims & Methods: This study aimed at comparing the therapeutic benefits and complications between mechanical lithotripsy and large balloon dilation after sphincterotomy in patients with liver cirrhosis. Ninety eight cirrhotic patients with calculi obstructive jaundice were included and randomly divided into 2 groups: Group A; 49 patients treated by large balloon dilation (LBD), Group B; 49 patients treated by mechanical lithotripsy. All patients underwent sphincterotomy initially. Inclusion criteria for this study included: Age of 18–60 years, any sex, liver cirrhosis patients Child A or B with clinical and laboratory proved obstructive jaundice, presence of large bile duct stones and deep selective cannulation of the bile duct. Exclusion criteria included: Known allergy to the used contrast material, Child C cirrhosis, the Need for needle knife precutting in order to achieve bile duct cannulation, Selective bile duct cannulation achieved after more than five accidental pancreatograms and severe Coagulopathy All patients were subjected to thorough history taking, complete clinical examination. Pancreatic enzymes concentrations were measured 4 hours before and 24 hours after the procedure, complete blood cell count and liver function tests were performed before and the morning after the procedure. Before and during ERCP, stone size and number were verified. Diagnosis of common bile duct stones was confirmed either by pre-ERCP investigations including abdominal ultrasonography (US), CT, MRCP or at the time of ERCP Large CBD stone: Is defined before ERCP by a bile duct stone 12 mm or more (transverse diameter of the largest stone) by US, CT or MRCP and during cholangiography showed large filling defect more than 12 mm that could not be extracted using a standard balloon catheter

Results: There were no dropouts and all subjects remained in the study till the end. The demographic and biochemical data of both groups at base line were comparable. At base line, there was no significant difference between both groups regarding CBD diameter (18.96±2.5 vs 18.8±1.5, p value 0.8), stones size (17.1±2.2 vs 17.2±1.53, p value 0.71) and stone number (1.49±0.65 vs 1.41±0.49, p value 0.61) The overall success rate for stone extraction in this study is 95.6% (94/98). The success rate of ERCP was also comparable between the two groups. The success rate for CBD clearance was 98% and 93.8% for large balloon dilation and mechanical lithotripsy respectively. Although, patients in balloon dilation group showed more success in stone retrieval rate, the difference was not statistically significant (P value 0.61). The rate of adverse events in this study was 10.2% (10/98) and bleeding was the commonest reported complication 50% (5/10); group B that was treated by ML developed more (16.3%) adverse events than group A treated by LBD (4.1%) and the difference was statistically significant (P value 0.04)

The reported complications in both groups

Complications	Group A	Group B	P value
No	47 (95.9%)	41 (83.7%)	0.04
Bleeding	1 (2%)	4 (8%)	
Pancreatitis	1 (2%)	2 (4%)	
Cholangitis	0 (0%)	2 (4%)	

Conclusion: In conclusion endoscopic sphincterotomy plus LBD is a safe and effective treatment for endoscopic removal of large common bile duct stones in cirrhotic patients when compared with endoscopic sphincterotomy plus ML. Bleeding is the most common adverse event reported in cirrhotic patients undergoing these procedures

Disclosure of Interest: All authors have declared no conflicts of interest.

P0885 SAFETY AND EFFICACY OF ENDOSCOPIST-DIRECTED BALANCED PROPOFOL SEDATION (BPS) DURING ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY (ERCP)

Introduction: Endoscopist-directed balanced Propofol sedation (BPS), defined as a fixed dose of an opioid and benzodiazepine combined with incremental doses of Propofol, has been shown to be a safe and effective moderate sedation regimen for gastroscopy and colonoscopy. However, there are very limited data on the safety and efficacy of endoscopist-directed BPS in ERCP.

Aims & Methods: We aimed to evaluate the safety and efficacy of endoscopist-directed BPS, as well as to compare patient outcomes with anesthesiologist-administered BPS, for both in-patients and out-patients undergoing ERCP. We performed a retrospective cohort study using prospectively collected endoscopy data from a tertiary care, university-affiliated medical center where endoscopist-directed BPS during ERCP is routine practice amongst the ERCPists, all of whom have up-to-date advanced cardiac life support (ACLS) certification. ERCP nurses also maintain up-to-date certification in ACLS and cardiopulmonary resuscitation equipment and medications are available within the advanced endoscopy suite. During ERCP, the endoscopist and the endoscopy nurse as a team were responsible for monitoring patient vital signs (e.g., pulse, blood pressure, oxygen saturation levels). Each endoscopist was responsible for directing the provision and dosing of the BPS. Patient-level demographics and pre/post procedure vital signs were collected along with BPS drug dosages, American Society of Anesthesiologists score (ASA) and measured "hard endpoint" patient outcomes, including: need for bag-mask ventilation or endotracheal intubation, aborted ERCP due to sedation effects, need for hospital admission post-ERCP (out-patients only) or need for change in level of hospital care (in-patients only), and mortality within 24 hours of ERCP.

Results: Over the course of 17 months (October 2015 – March 2017), 501 patients underwent ERCP and received endoscopist-directed BPS (Cohort 1: 380 (76%) inpatient, mean age 64.1 years, 46% males, 24% ASA I, 65% ASA II, 11% ASA III). During this same time period, 24 patients received anesthesiologist-administered BPS (Cohort 2: 19 (79%) inpatient, mean age 65.0 years, 67% males, 12% ASA I, 25% ASA II, 38% ASA III, 25% ASA IV). In Cohort 1, the indications for ERCP were: 231 (46%) suspected choledocholithiasis, 68 (13%) stent replacement, 62 (12%) evaluation of known/suspected malignancy, 48 (10%) jaundice, 40 (8%) post-hepatobiliary intervention complications, 8 (2%) abdominal pain, and 44 (9%) other/unspecified. BPS dosages (mean±SD: range) were: Fentanyl 0.06 mg±0.02 mg: 0.05–0.10 mg; Midazolam 1.7 mg±0.7 mg: 1.0–2.5 mg; and Propofol 178 mg±103 mg: 10–640 mg. Propofol dose inversely correlated with patient age (r = -0.42, p < 0.001), ASA score (r = -0.19, p < 0.001) and Mallampati score (r = -0.24, p < 0.001). No clinically meaningful differences were found in patient vital signs pre and post ERCP. Moreover, no patient required bag-mask ventilation, endotracheal intubation nor hospital admission/change in level of in-hospital care following ERCP. One patient in Cohort 2 who

received anesthesiologist-directed BPS, required bag-mask ventilation and the ERCP was aborted due to sedation effects. There was no mortality from any cause within 24 hours of ERCP. All patients were discharged from the advanced endoscopy suite without adverse events.

Conclusion: Endoscopist-directed BPS appears feasible, safe and efficacious for ASA I-III patients undergoing inpatient or outpatient ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0886 A NOVEL METHOD OF PREVENTING DUODENOBILIARY REFLUX BY MEANS OF SUSPENDED OVERLENGTH BILIARY STENTS IN PATIENTS WITH BILIARY STRICTURE

Y. Huang, X. Yan, H. Chang, Y. Zhang, W. Yao, K. Li

Gastroenterology And Hepatology, Peking University Third Hospital, Beijing/China

Contact E-mail Address: 13911765322@163.com

Introduction: Endoscopic insertion of plastic or metal stents is a well-established treatment for malignant or part of benign biliary obstruction. The major limitation of this technique is stent occlusion. Duodenobiliary reflux has been considered as a key contributor to stent occlusion. No appropriate method can so far prevent duodenobiliary reflux. Different strategies to prolong the patency of plastic stents included changing stent size, stent design, but stent sludge due to duodenal biliary reflux remains an unsolved problem. We have been using a novel suspended overlength biliary stents (reformed with nasobiliary tube) as substitution for ordinary biliary plastic stent to prevent the reflux from January 1, 2016 to December 31, 2016.

Aims & Methods: The aim of the study is to evaluate the efficacy and patency of the suspended overlength biliary stents. The suspended overlength biliary stents (SOBS) were placed in intrahepatic bile duct in 61 patients with extrahepatic bile ducts stricture who were followed up at least three months from January 1, 2016 to December 31, 2016. Nasobiliary tube of 7.5Fr or 8.5Fr with multiple side holes were cut 30 cm with operation knife from the top on sterile operating table. The purpose of the set of 30 cm length is to ensure the tail reaches the duodenal horizontal part. The SOBS were placed in the intrahepatic biliary duct by using conveyer under the fluoroscopic guidance at the end of ERCP. Radiography of the Meglumine Diatrizoate was performed in each patient of SOBS group to evaluate the existence of duodenal biliary reflux. 74 patients who were performed at least two or more ERCP with extrahepatic bile ducts stricture treated with ordinary plastic stents (OBS group) from last ten years were compared with SOBS group.

Results: (1) The mean age of SOBS and OBS were 68.8 ± 15.8 yrs and 60.4 ± 14.7 yrs ($P=0.002$), respectively. (2) 35 (57.4%) and 34 (45.9%) patients were malignant biliary obstruction in SOBS and OBS group, respectively ($P=0.227$). Malignant obstruction included bile duct cancer and biliary duct invasion of pancreatic cancer. Benign obstruction included autoimmune pancreatitis, chronic pancreatitis, post operation stenosis, inflammatory stenosis due to cholelithiasis. (3) The mean first and second patency was 4.5 months and 5.6 months in SOBS groups. All the patients in OBS group experienced at least three ERCP to exchange plastic stents. The mean first and second patency were 3.9 months and 4.4 months in OBS patients with malignant biliary obstruction. Yet the mean patency was 5.1 and 6.5 months in OBS patients with benign biliary obstruction. (4) The occlusion rates of SOBS and OBS group after 3, 4, 5, 6 months of first ERCP were 13.1% and 36.5%, 27.1% and 55.4%, 42.4% and 67.6%, 55.9% and 77.0%, respectively ($P=0.003, 0.001, 0.005, 0.015$). Multiple factors with logistic regression analysis showed that gender, age, location of biliary stricture were not related with the patency except the character of stricture. (5) SOBS were occluded in only 11 patients (11/61, 18%) with the patency from 80 days to 12 months (mean patency was 5.2 months). The mean follow-up period of the other 50 patients in SOBS groups was 6.5 months. (range from 3 months to 15 months). No evidence of duodenal biliary reflux were detected in SOBS group.

Conclusion: Suspended overlength biliary stents can prolong the patency and reduce the occlusion rate effectively due to duodenobiliary reflux in both malignant and benign biliary stricture.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Recent studies describe multiple outbreaks of multi-drug resistant organisms caused by contaminated duodenoscopes, used for endoscopic retrograde cholangiopancreatography (ERCP) procedures. Contamination of duodenoscopes is attributed to their complex design, which includes a side viewing tip, forceps elevator and elevator wire channel. Linear echoendoscopes (LEs), used for endoscopic ultrasound (EUS) procedures, have a similar design with an additional balloon channel. Previously, we found that contamination of duodenoscopes was widespread in the Netherlands. It is unclear if the increased awareness of contamination and associated outbreaks has improved reprocessing outcomes of duodenoscopes and linear echoendoscopes (DLEs).

Aims & Methods: This cross-sectional study was conducted to determine the prevalence of bacterial contamination of all reprocessed DLEs in The Netherlands. All 75 Dutch ERCP/EUS centres were invited to sample all DLEs using centrally distributed kits, according to uniform sampling methods explained by video instructions. Local staff sampled four to six sites per DLE depending on endoscope type, including swabs (protection cap, forceps elevator), flushes (biopsy, suction, air/water and forceps elevator channel) and brushes (biopsy, air/water and balloon channel). Samples were centrally cultured. Sampling procedure, culture processing and culture interpretation were consistent with Dutch guidelines. Contamination was defined as AM20: any microorganism with ≥ 20 colony forming units (CFU)/20 mL, and MGO: presence of microorganisms with gastrointestinal or oral origin, independent of CFU count.

Results: Between October 2016 and April 2017, 62 (85%) Dutch ERCP/EUS centres responded with 1130 samples of 215 DLEs (158 duodenoscopes and 57 LEs). Fifteen different DLE types from three distinct manufacturers were sampled. In total 29/62 (47%) centres had at least one AM20 or MGO contaminated DLE, similar to the prevalence (31/66 centres; 47%) in our previous study ($p=0.98$). Twenty-eight (13%) DLEs from 19 (31%) centres were AM20 contaminated. Thirty-two (15%) DLEs from 23 (37%) centres were contaminated with MGO, including *Enterobacteriaceae*, *Pseudomonas aeruginosa* and *Candida* spp. AM20 contamination was identified in eight different DLE types, MGO contamination in all nine duodenoscope types and three LE types. For both definitions, contamination was not duodenoscope or LE dependent (P -values > 0.72), nor type (P -values > 0.14) or microbial surveillance dependent (P -values > 0.45).

Conclusion: Similar to our previous findings, in 47% of all Dutch ERCP/EUS centres at least one patient-ready DLE was AM20 or MGO contaminated. Of all DLEs, 15% was contaminated with digestive tract bacteria, indicating inadequate reprocessing. These results suggest that any additional awareness of contamination has had no lasting effect or that the current reprocessing technique is not suitable for current DLE designs. This highlights the need for new preventive measures to minimize the risk of interpatient microbial transmission by DLE.

Introduction: Although a newly digital cholangio/pancreato-scipy (SpyDS) has been reported to be useful for therapeutic purpose in patients with biliary diseases, clinical application for diagnostic purpose of pancreatobiliary neoplasm remains unclear.

Aims & Methods: To evaluate the usefulness and safety of cholangio/pancreato-scipy using a SpyDS for preoperative evaluation of pancreatobiliary neoplasm. Patients and methods: Between Oct/2015 and Feb/2017, consecutive 26 patients (19, cholangiocarcinoma; 7, IPMN) who underwent cholangio/pancreato-scipy using a SpyDS for preoperative evaluation were included in this study. Diagnostic accuracy of malignancy and tumor extent evaluation by cholangio/pancreato-scipy guided biopsy/cytology and adverse event after the procedure were retrospectively investigated.

Results: Of 19 patients with cholangiocarcinoma, success rate of SpyDS guided mapping biopsy was 83% (103/124 sites). Diagnostic accuracy of longitude

Overall Technical Success				
Overall Cognitive Success	20	2268	12 (60)	5 (25)

* Primary analysis: success defined as score of 1 or 2 (no assistance/minimal verbal cues), Acceptable failure rate -p0=0.1 and unacceptable failure rate - p1=0.3 ** Sensitivity analysis: success defined as score of 1 (stringent definition of success)

tumor extent using SpyDS plus mapping biopsy was 92%. One patient developed mild cholangitis after the procedure. As for IPMN, pancreatoscopy using a SpyDS could visualize intraductal papillary tumors in all patients, and SpyDS guided biopsy/cytology was successfully performed. Diagnostic accuracy of malignancy was 100% without any adverse event after the procedure.

Conclusion: Preoperative evaluation using a SpyDS plus histological evaluation for pancreatobiliary neoplasm was found to be useful and safety. Further study is needed to establish evidence about the usefulness of this technique.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is one of the most technically complex procedures performed by gastroenterologists. After a significant increase in the indications for implementing ERCP, gastroenterologists began to pay greater attention to complications identification and prevention. Despite the widespread improvement of endoscopic techniques and increased experience of endoscopists, the rate of complications has not declined significantly.

Aims & Methods: To analyze the frequency of probable causes of asymptomatic hyperamylasaemy and acute pancreatitis after ERCP and their prevention. Two groups of patients were covered: a retrospective (340) and prospective (154) group. Patients had evidence of bile ducts impaired passability of varying etiology. In these cases ERCP is the final stage in the diagnostic and therapeutic algorithm. All ERCPs were carried out by one expert endoscopist. Patients from the prospective group were administered intramuscularly with Diclofenac (75 mg) before and after the manipulation. The methods used in the study were: demographic data; history and physical examination; laboratory data; imaging methods; ERCP; clinical course and statistical methods for processing data received.

Results: The most common indication for ERCP in all patients was cholestasis constellation (88.1%). In a minority of patients ERCP was purely diagnostic (6.1%), while at 93.9% it was also therapeutic. Of all patients at 47 of cases (9.5%) hyperamylasaemy was observed, and at 12 or 2.4% - acute pancreatitis was observed. Patients who developed acute pancreatitis often have acute calculous cholecystitis. Due to the small number of patients with acute pancreatitis, however, these results should be carefully commented. Patients who developed acute pancreatitis were found to have a lower level of alkaline phosphatase and ESR and higher values of leukocytes on the 72nd hour. The univariate logistic regression analysis identified the following risk factors for developing hyperamylasaemy: cholelithiasis; sclerosing papilloiditis of ERCP; normal values of serum total bilirubin and elevated CRP levels in receiving. In order to establish a

predictive model a multiple logistic regression analysis was performed. The model includes: average total bilirubin at entry and cannulation of the pancreatic duct more than 3 times. The estimated true percentage for predicting lack of hyperamylasaemy with this predictive model is very good - 97%. Univariate logistic regression analysis identified the following risk factors for the development of acute pancreatitis: cannulation of the pancreatic duct and the presence of calculous cholecystitis when entering.

Conclusion: We detected a low incidence of asymptomatic hyperamylasaemy (9.5%) and acute pancreatitis (2.4%) in the group of patients which were subjected to ERCP. Clinical and laboratory parameters characterizing the patients who developed these complications, and risk factors for acute pancreatitis and asymptomatic hyperamylasaemy were determined. The effect of intramuscular Diclofenac administered before and after ERCP has no effect.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0890 MOST ADVANCED ENDOSCOPY TRAINEES DO NOT MEET COMPETENCE FOR NATIVE PAPILLAE CANNULATION IN ERCP: RESULTS FROM A PROSPECTIVE MULTICENTER STUDY

S. Wani¹, M. Hall¹, V. Simon¹, S. Han¹, D. Early², R. Keswani³

Introduction: Advanced endoscopy trainees (AETs) achieve ERCP competency at variable rates and specific case volumes do not ensure competence. However, training and credentialing guidelines continue to utilize an absolute procedure volume to determine competence. There are limited data on whether current training composition and volumes ensure ERCP competence in the US.

Aims & Methods: (i) To define ERCP learning curves, utilizing a centralized database, with a focus on cannulation rates using a large national sample of AET programs (AETPs). (ii) To critically examine the composition of current ERCP training in AETPs. ASGE-recognized AETPs were invited to participate and AETs were graded on every ERCP after completion of 25 hands-on ERCP exams. Grading was performed using our previously developed and validated tool [The EUS and ERCP Skills Assessment Tool (TEESAT)] which assesses technical and cognitive competence in a continuous fashion. Grading for each skill was done using a 4-point scoring system: 1-no assistance, 2-minimal verbal cues, 3-multiple verbal cues or hands-on assistance and 4-unable to complete. A comprehensive data collection and reporting system was built using REDCap, a web-based data collection software, and SAS to create learning curves using cumulative sum (CUSUM) analysis for overall and individual technical and cognitive components of ERCP. Individual results and comparison to peers were sent to AETs and trainers quarterly. Acceptable and unacceptable failure rates were set a priori. AETs with <20 evaluations were excluded and success was defined as a skill score of 1 or 2. Individual and combined graphs to assess change in cannulation success rates were constructed and the Cochran-Armitage trend test was used to assess improvement in success rates.

Abstract: P0891. Table 1.

	E1	Notes	A1	Notes
Procedure numbers	132		118	
Complications				
Pancreatitis (PERCPP)	3; 2.3%	One death within 30 days	2; 1.7%	
Perforation	1; 0.8%	Retroduodenal	0	
Hyperamylasaemia	1; 0.8%	Metal stent for cholangiocarcinoma	1; 0.8%	Plastic stent for bile leak
Immediate bleeding	1; 0.8%	Controlled with metal stent	2; 1.7%	Haemostasis with adrenaline injection
Delayed bleeding	0		0	
Intramural duodenal haematoma	0		1; 0.8%	On CT
Post-ERCP cholangitis	0		0	
Patient & procedural characteristics				
Female	71; 53.8%		79; 66.9%	
Median age	63.5		63	
History of Sphincter of Oddi dysfunction	0		0	
History of PERCPP	0		0	
History of chronic pancreatitis	1; 0.8%		1; 0.8%	
Trainee involvement	0		0	
Normal LFTs	21; 16.5%	No data for 5 patients	11; 10%	No data for 8 patients
Non-dilated bile ducts	39; 29.5%		18; 15.3%	
Pancreatic duct wire/contrast	19; 15%	Excludes 5 unsuccessful cannulations	30; 25.9%	Excludes 2 unsuccessful cannulations
Precut sphincterotomy	4; 3%		9; 7.6%	

Results: Of the 62 programs invited, 20 AETPs participated and 20 AETs were included in the final analysis. At the end of training, median number of ERCPs performed/AET was 350 (15–500). Overall, 2649 ERCP exams were graded; the majority were ASGE biliary grade 1 (77%) and only 14% for pancreatic indication. Among biliary ERCP cases, AETs attempted native papilla cannulation and sphincterotomy in 1199 (53%) and 901 (40%) cases, respectively. The mean time allowed for cannulation was: overall - 4.0 min (SD 4.3), native papilla - 5.7 min (SD 4.8), and AET failed cannulation cases - 6.2 min (SD 5). There was no change in the time allowed for native papilla cannulation during the 1-year period ($p=0.28$). AETs were involved in a small proportion of cases requiring advanced cannulation techniques such as double-wire technique, placement of pancreatic duct stent and precut sphincterotomy (6%). Learning curves for individual endpoints, overall technical and cognitive aspects noted substantial variability. Majority of AETs achieved overall technical (60%) and cognitive (100%) competence at the end of training. While there was a statistically significant improvement in overall and native papilla cannulation rates (both $p < 0.001$), only 18% of AETs achieved competence for native papilla cannulation (Table 1). **Conclusion:** The results of this study confirm the substantial variability in learning curves and competence among AETs in ERCP validating the shift away from threshold numbers to determine competence. We report the feasibility of establishing a centralized national database to report individualized ERCP learning curves using a novel web-based comprehensive data collection and reporting system. Using strict definitions, a minority of AETs achieved competency in native papilla cannulation which may, in part, be due to limited cannulation time provided to AETs. Selective native papilla deep cannulation needs to be an important benchmark for assessing competence. Methods to improve native papilla cannulation rates and strategies to increase AET exposure to advanced ERCP techniques are required.

P0891 SIMILAR POST-ERCP PANCREATITIS RATES IN ENDOSCOPIST- VS ASSISTANT-CONTROLLED WIRE-GUIDED BILE DUCT CANNULATION: A SINGLE CENTRE OBSERVATIONAL STUDY

M. Hu, A. Bhagwat, M. Hayat

Dept Of Gastroenterology, Northumbria Healthcare NHS Foundation Trust, North Shields/United Kingdom

Contact E-mail Address: maxworth.hu@gmail.com

Introduction: A recent randomised study by Buxbaum et al¹ demonstrated a significantly lower rate of post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PERCPP) in endoscopist- versus assistant-controlled bile duct cannulation. We set out to audit the rates of PERCPP at our centre based on this finding.

Aims & Methods: All ERCPs performed by two endoscopists between April 2015 and March 2016 were audited retrospectively. The two endoscopists practiced endoscopist- (E1) and assistant-controlled (A1) wire-guided cannulation exclusively. Both E1 & A1 had access to the same medications, sphincterotomes, equipment, and teams. Data was obtained and anonymised from electronic patient records and endoscopy reporting software. PERCPP was defined as abdominal pain with hyperamylasaemia at least three times the upper limit of normal (ULN) 24–48 hours after ERCP with or without corresponding imaging findings within 7 days; or abdominal pain with a further rise in pre-existing hyperamylasaemia to at least three times ULN 24–48 hours after ERCP with or without corresponding imaging findings within 7 days. Additional data was

collected for CT evidence of post-ERCP complications, hyperamylasaemia without pancreatitis, bleeding, and post-ERCP cholangitis. Patient and procedural characteristics predisposing to pancreatitis were also recorded.

Results: A total of 250 procedures were audited. E1 performed 132 procedures (54% female; median age 63.5) and A1 performed 118 procedures (67% female; median age 63). The rates of PERCPP in E1 and A1 were 2.3% (3 patients) and 1.7% (2 patients) respectively. One 84-year-old patient of E1 with a presumed malignant common bile duct (CBD) stricture had PERCPP and died 17 days after ERCP, having opted for palliation. The remaining 4 patients had uneventful conservative management of PERCPP. E1 had one patient with immediate bleeding post-sphincterotomy controlled with a CBD stent whilst A1 had 2 patients requiring adrenaline injection for haemostasis. In addition, E1 had one patient with retroduodenal perforation managed conservatively and A1 had one patient with CT evidence of intramural duodenal haematoma which was uneventful. Both E1 and A1 had one case each of uncomplicated hyperamylasaemia. A summary of complications, with patient and procedural characteristics, is listed in Table 1.

Conclusion: In our observational study, which was not intended or powered for statistical analysis, there was no overt difference in the rates of PERCPP when comparing between endoscopist- or assistant-controlled wire-guided CBD cannulation. The overall complication rate was similar and although there were some differences in procedural characteristics between the two endoscopists, there were no characteristics predisposing to PERCPP overtly skewed towards either endoscopist's case load. Further randomised trials, or a crossover study; provided the endoscopists and assistants are equally competent in both methods of wire cannulation, are needed to clarify the safety profile of either technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Most endoscopic retrograde cholangiopancreatography (ERCP) - related procedures are performed under "conscious sedation", a drug-induced depression of consciousness during which patients are comfortable and able to maintain purposeful responses to verbal or tactile stimulation, and cardiorespiratory function generally remains intact¹. Meanwhile, we sometimes observe adverse events related to conscious sedation after ERCP such as aspiration pneumonia². So far, it is unknown whether immediate recovery from conscious sedation with antagonists is necessary or not.

Aims & Methods: We aimed to reveal the efficacy of flumazenil, an antagonist to benzodiazepines, on the prevention of adverse events, especially, aspiration pneumonia related to conscious sedation which is most frequent after ERCP. One hundred ninety patients who underwent ERCP between January to December

2014 in a general hospital in Japan were included. The patients were divided to two groups: the group with flumazenil (F group) and the group without flumazenil (non-F group) just after ERCP and they were compared and analyzed. Examination items were 1) patient characteristics, 2) procedure characteristics, and 3) occurrence rates of post-ERCP aspiration pneumonia. Pearson's Chi-squared test and Fisher's exact test were used for statistical analysis of categorical data.

Results: 1) One hundred fifteen patients (60.5%) were administered flumazenil just after ERCP (F group) and 75 patients (39.5%) were not (non-F group). The median age, 76 (47–94) in the F group and 78 (46–94) in the non-F group; male/female ratio, 57/58 in the F group and 34/41 in the non-F group. The distributions of the basic disease (CBD stone/malignant biliary disease/malignant pancreatic disease/others) were 64/8/17/26 in the F group and 30/11/16/18 in the non-F group. The distributions of used benzodiazepines (midazolam/diazepam/none) and the patient number who got aspiration pneumonia were 102/13/0 and 1 in the F group and 59/13/2 and 1 in the non-F group, respectively (Fisher's test: p -value = 0.074). There were no significant differences of patient characteristics between both groups. 2) The mean procedure times were 36.7 minutes in the F group and 30.3 minutes in the non-F group, respectively. The details of procedures for the major papilla (endoscopic sphincterotomy/endoscopic papillary balloon dilation/others/none) were 40/13/5/56 in the F group and 25/5/3/41 in the non-F group. The distributions of endoscopic biliary drainage or stenting/none were 94/21 in the F group and 59/16 in the non-F group. (Fisher's test: p -value = 0.85) There were no significant differences of procedure characteristics between both groups. 3) Two patients (1.05%) developed aspiration pneumonia after ERCP. One (94 years old, male) was in the F group and the other (81 years old, female) was in the non-F group (Pearson's Chi-squared test p -value = 1). Both of them were over 80-year old. The patients who were given oxygen during ERCP were 86 (45.2%). Of them, one patient developed pneumonia (Pearson's Chi-squared test p -value = 1).

Conclusion: Flumazenil did not have no preventive effect on the occurrence of aspiration pneumonia related to conscious sedation after ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO893 PREVENTION OF POST-ERCP PANCREATITIS: RESULTS OF AN AGGRESSIVE HYDRATION PROTOCOL

P. Marcos, C. Atalaia-Martins, S. Barbeiro, I. Cotrim, C. Gonçalves, L. Eliseu, H. Vasconcelos

Gastroenterology, Centro Hospitalar de Leiria ("Leiria Hospital Center"), Leiria/Portugal

Contact E-mail Address: pedromarcos1ster@gmail.com

Introduction: Pancreatitis is the leading complication of endoscopic retrograde cholangiopancreatography (ERCP). Some studies have shown that aggressive intravenous hydration may reduce the incidence of this serious adverse event, the post-endoscopic retrograde cholangiopancreatography pancreatitis (PEP). In our department we implemented an aggressive hydration protocol (AHP) for patients undergoing ERCP in order to prevent PEP.

Aims & Methods: The aim of this study was to evaluate the impact of this protocol on the incidence and severity of PEP. Patients and methods Retrospective analysis of all patients submitted to ERCP in one center during 16 months, including patients hospitalized in the gastroenterology department who were managed according to the AHP and patients hospitalized in other departments who underwent standard hydration (SH). Patients who underwent AHP received intravenous sodium lactate solution (RL) at 200 mL/hour starting 1 hour before, during the procedure and the anesthetic recovery; in those who remained asymptomatic after the ERCP, the RL was maintained at 100 mL/hour for 8 hours and after it was changed to a balanced salt solution with glucose (PG) at 80 mL/hour; in those patients who had abdominal pain or amylase >3 times normal limit after ERCP, the RL was maintained at 200 mL/hour during 8 hours and after it was changed to PG at 120 mL/h. We evaluated the incidence and severity of PEP, the established patient and procedure-related risk factors for PEP (except the difficulty of cannulation) and the occurrence of complications. Data were analyzed with SPSS statistical software.

Results: We analyzed 192 patients, 290 ERCP (AHP n = 168, SH n = 122). The incidence of PEP was 3.8% (11/290), slightly lower in the SH group (4/11 versus 7/11; p = 0.766). In the SH subset, only 1 PEP was moderate and the remaining 3 were mild. In the AHP group, 3 PEP were moderate and 4 were mild. There were no complications related to AHP. We didn't find any patient or procedure-related variable significantly associated with the development of PEP.

Conclusion: Our AHP didn't reduce the incidence of PEP or its severity. Indeed, the AHP group presented more PEPs than the SH group, although the difference between both PEP incidences was not significant. Despite our study didn't show any advantage related to the use of an AHP, intravenous aggressive hydration

may have a role in PEP prophylaxis. Further studies are needed to establish its true value.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO894 ERCP CYTOLOGY YIELD – DOES THE BRUSH MATTER?

I. Mocanu, A. Laranjo, S. Pires, N. Veloso, L. Gonçalves, R. Godinho, I. Medeiros

Gastroenterology, Hospital Espirito Santo de Évora, Évora/Portugal

Contact E-mail Address: irina.mocanu.24@gmail.com

Introduction: Extra-hepatic biliary tree strictures are caused by a variety of malignant and benign diseases. The brushing of such stenosis during ERCP is safe and easy to perform, however, it has a low sensibility, ranging from 30 to 60%. Efforts to improve cytology yield include dilation of the stricture prior to brushing and multiple brush passages, both without significant success. In 2011, US Endoscopy introduced the Infinity® cytology brush - a 14Fr (4, 75 mm) device that combines soft and stiff bristles in order to improve acquisition of cytology samples.

Aims & Methods: We aimed to determine if a new-design brush can improve the diagnostic yield of biliary cytology. From February 2015 until December 2016, the new Infinity® brush was used in all cases of ERCP cytology. These were compared with historical controls, where a classical 8Fr biliary cytology brush was used. In both groups, at least two passages were made, with transfer to a thin prep solution, as per prior protocol. Follow-up data, namely clinical course, radiological data or other histological results were collected for a definitive diagnosis.

Results: Thirty-five new brush cases were compared with 52 historical controls. There was no significant difference between gender (57% Vs. 52% male; p > 0.05), age (mean 70.5 Vs. 74 years; p > 0.05), location of stricture (common bile duct 77% Vs. 84%; p > 0.05), length of stricture (between 1–3 cm in 80% Vs. 84%; p > 0.05) or dilation prior to sampling (71% Vs. 57.7%; p > 0.05) between the two groups. Physicians' impression of malignant stricture during ERCP was more frequent in new brush cases, with near statistical significance (91% Vs. 75%; p = 0.052). Sufficient sample size for cytological analysis was more frequently obtained in cases when compared to controls (86% vs. 100%, p < 0.05). Definitive diagnosis were as follows (cases Vs. controls): pancreatic neoplasia 57% Vs. 48%, cholangiocarcinoma 25.7% Vs. 23%, ampuloma 0 Vs. 1.9%, benign conditions 17.3% Vs. 21%, no definitive diagnosis 0 Vs. 6.1%. In malignant cases, there was no difference between sensibilities of the cases (31%) and controls (27%), either for pancreatic cancer (20% Vs. 24%; p > 0.05) nor cholangiocarcinoma (55.6% Vs. 50%; p > 0.05). Specificity, positive predictive value and negative predictive value of Infinity® brush and classical 8Fr brush were as follows: 100% Vs. 100%; 100% Vs. 100%, 23% vs. 35.7%. Of the 16 strictures with benign features on ERCP (3 cases Vs. 13 controls), 14 had negative cytology and 2 were inconclusive (both controls).

Conclusion: There were significantly more samples with adequate cellularity for cytological analysis with the new Infinity® brush, however, the global sensibility of the new brush was not superior to the standard devices. With both brushes, the yield is twice as better for cholangiocarcinoma than for pancreatic cancer. One disadvantage we noted with the Infinity® brush is the increased difficulty in passing very tight, fibrotic strictures, even after dilation, due to its width and rigidity. Further ways to improve results would be the routine production of a smear sample, cell block analysis or intra-ductal biopsies. The future era of cholangioscopy could dramatically increase our ability to sample biliary strictures.

P0895 PROSPECTIVE STUDY OF EARLY PRECUT VS. UTMOST PRECUT WITH PANCREATIC STENT IN INITIAL PANCREATIC DUCT CANNULATION

E.T. Park, B.C. Yun, S.U. Lee, B.H. Han

Internal Medicine, Kosin University, Gospel Hospital, Busan/Korea, Republic of

Contact E-mail Address: euntpark@hanmail.net

Introduction: In biliary access, repeated biliary cannulation attempts are a risk factor for post ERCP pancreatitis (PEP). Early precut is an effective technique for successful biliary cannulation and can significantly reduce the incidence of PEP. The aim of this study was prospectively to evaluate clinical efficacy the performance of utmost early precut with pancreatic stent in the patients in whom pancreatic duct cannulation was performed initially.

Aims & Methods: When guidewire was placed in the pancreatic duct initially by chance, the patients were randomized into early precut (Group A) or utmost early precut sphincterotomy with pancreatic stent (Group B). In Group A, pancreatic duct cannulation within 5 times and attempted precut papillotomy without pancreatic stent. In Group B, from the first, pancreatic stent was inserted and then precut with an incision over a pancreatic stent was done. Main outcome measurements were frequency of successful CBD cannulation and post-procedure related complications.

Results: From January 2015 to August 2016, the two groups were similar with regard to patient demographics. A total of 50 patients were enrolled. 26 patients were assigned to the Group A and 24 to the Group B. Successful CBD cannulation was achieved in 23 of 26 (88.5%) patients in the Group A and 23 of 24 (95.8%) patients in the Group B. The mean cannulation time was 16.9 minutes in the Group A and 14.8 minutes in the Group B. Post-procedure hyperamylasemia was significantly higher in Group A. The overall incidence of post-procedure pancreatitis was 11.5% (3/26) in the Group A and 4.2% (1/24) in the Group B ($P < 0.001$).

Conclusion: In patients with pancreatic duct cannulation initially by chance, compare to early precut group, utmost early precut with pancreatic stent over the guidewire group not only facilitate biliary cannulation and the success rates but also promise low incidence of post-ERCP pancreatitis. In experienced hands, utmost early precut technique can dramatically reduce the trauma of ampulla and risk of PEP compared with conventionally persistent cannulation attempts.

Disclosure of Interest: All authors have declared no conflicts of interest.

⁴Anesthesiology, Chung-Ang University, Seoul/Korea, Republic of

Contact E-mail Address: ohcgi@cau.ac.kr

Introduction: Antithrombotic therapy with antiplatelet agents (APA) has been increasingly utilized during the last few decades. This study aimed to determine the risk of post-ERCP bleeding among those patients who are taking APAs, especially in the era of multiple agents.

Aims & Methods: From July 2012 to May 2016, the patients who underwent 1st therapeutic ERCP were identified from the ERCP database of 3 institutions in USA and Korea. The primary outcomes were the frequency, type, and severity of ERCP-related bleeding according to the use of APA.

Results: The frequencies of post-ERCP bleeding among the four different groups were 16 of 2083 (0.8%) in No drug group, 12 of 256 (4.7%) in Aspirin group, 3 of 48 (6.3%) in Single APA group, and 4 of 48 (8.3%) in Multiple APA group ($p < 0.001$). Most cases of post-ERCP bleeding were mild (29/35, 88%). In the univariate analysis, post-ERCP bleeding was associated with age, pull-type sphincterotomy, and APA, and inversely associated with balloon dilation of the biliary orifice. In the multivariate analysis, pull-type sphincterotomy (odds ratio [OR] 7.829, 95% confidence interval [CI] 1.411-43.453, $p=0.019$) and country (Korea; OR 0.124, 95% CI 0.042-0.361, $p < 0.001$) were associated with post-ERCP bleeding.

Conclusion: The frequency of post-ERCP bleeding was statistically higher in patients on any APAs within 6 days prior to ERCP. However, in the multivariate

analysis, APA use was not associated with post-ERCP bleeding. Until a large study adequately powered to detect differences in bleeding rates, caution is recommended when considering invasive procedures during ERCP in patients on APAs.

Contact E-mail Address: yunnah@schmc.ac.kr

Introduction: In a recent, a digital version of single-operator cholangioscope (SpyGlass DS) and direct POC (DPOC) using a multibending ultraslim endoscope were introduced as improved forms of each POC, especially in image quality and technical difficulty, respectively.

Aims & Methods: In this study, we prospectively compared the procedure success rate of SpyGlass DS and DPOC for diagnosis and treatment of BD lesions. A total of 15 patients with BD lesions (diameter of CBD ≥ 8 mm) requiring evaluation or treatment using POC were enrolled prospectively. All patients received POCs using SpyGlass DS and multibending ultraslim endoscope for DPOC. According to the presence of obstructive lesion, all patients were classified as obstructive type or non-obstructive type, respectively. Procedural success defined as an ability to advance the cholangioscope to the desired target and get adequate cholangioscopic visualization for the targeted lesion.

Results: The overall technical success rates of SpyGlass DS and DPOC were 100% and 93.3%, respectively ($P=0.5$). In DPOC, 1 patient was failed to insert the endoscope into the CBD. In SpyGlass DS, 2 patients were failed to visualize the targeted lesion. The procedural success rates of SpyGlass DS and DPOC according to the type of lesion were not different in 9 obstructive type (100% vs. 88.9%, $P=0.5$) and 6 non-obstructive type (66.7% vs. 100%, $P=0.227$). The successful diagnostic and therapeutic procedures by DPOC and SpyGlass DS were observed in 8 of 8 patients (100%) and 7 of 9 patients (77.8%) ($P=0.265$), respectively.

Conclusion: Both advanced image quality of SpyGlass DS and improved technical difficulty of DPOC by a multibending ultraslim endoscope showed comparable and high procedure success rates in patients with dilated BD. Future prospective studies focused on overall cost savings and long-term clinical outcomes are seems to be required for deciding adequate indications of each POC systems.

P0899 THE DILEMMA OF MANAGMENT BORDERLINE COMMON BILE DUCT STONE. DOES STONE SIZE MATTER?: A PROSPECTIVE RANDOMIZED STUDY

E. Abdellatif, E. Elhanafy, A. Elnakeeb

Surgery, Gastroenterology Surgical Center, Mansoura/Egypt

Contact E-mail Address: dr.ehab.atif@icloud.com

Introduction: Management of common bile duct stones (CBDS) in patients with borderline CBD presents a surgical challenge. The aim of this study was to compare conservative treatment with endoscopic stone extraction for the treatment of borderline CBD with stones.

Aims & Methods: This prospective randomized controlled trial includes patients with CBDS in borderline CBD (CBD < 10 mm) associated with gallbladder stones who were treated with conservative treatment or endoscopic stone extraction followed by laparoscopic cholecystectomy (LC) and intraoperative cholangiogram (IOC). The primary outcome was successful CBD clearance. The secondary outcomes were the overall complications, cost, and hospital stay.

Results: LC and IOC revealed complete clearance of CBDS in 48 (96%) cases in the endoscopic retrograde cholangiopancreatography (ERCP) group (52% of patients by ERCP, and 44% of patient passed the stone spontaneously), and in the remaining two patients, the CBDS was removed by transscystic exploration. In the conservative group, LC and IOC revealed complete clearance of CBDS in 90% of cases, and in the remaining 10% of patients, the CBDS was removed by transscystic exploration. Post-ERCP pancreatitis (PEP) is noticed significantly in the ERCP group (2 [4%] versus 8 [16%]; $P=.04$). The average net cost was significantly higher in the ERCP group. Recurrent biliary symptoms developed significantly in the ERCP group after 1 year (10% versus 0%; $P=.02$) in the form of recurrent cholangitis and recurrent CBDS.

Conclusion: Management of CBDS in patients with borderline CBD represents a surgical challenge. Borderline CBD increases the technical difficulty of ERCP and increases the risk of PEP. Conservative management of CBDS in borderline CBD not only avoids the risks inherent in ERCP and unnecessary preoperative ERCP, but it is also effective in clearing CBDS. The hepatobiliary surgeon

should consider a conservative line of treatment in CBDS in borderline CBD in order to decrease the cost and avoid unnecessary ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0900 PROSPECTIVE STUDY ON METHODS AND SUCCESS OF BILIARY CANNULATION OF 458 VIRGIN PAPILLAS - QUALITY ASSURANCE OF ERCP AT OUR DEPARTMENT

Á. Orbán-Szilágyi, K. Lorinczy, K. Rábai, M. Horváth, F. Zsigmond, T. Gyökere

Gastroenterology, Medical Centre, Hungarian Defence Forces, Budapest/Hungary

Contact E-mail Address: tiborgyokeres@freemail.hu

Introduction: The cannulation of a virgin papilla is the most difficult and high-risk step in ERCP and it requires significant experience to maximize the success and to minimize poor outcomes. Cannulation rate is one of the accepted quality indicators of ERCP. It is mandatory to regularly assess quality indicators of endoscopic procedures to maintain and improve endoscopic service.

Aims & Methods: We prospectively collected data about cannulation details of all patients with virgine papillas and post-ERCP complications from April 2016 to April 2017.

Results: During this 12-months period we have performed 1102 ERCPs, in 458 of them we had virgin papilla. All ERCPs had therapeutic intentions and all of the patients were followed up. In 13 patients papillas were not accessible due to duodenal stenosis (10/13) or postoperative situations (3/10). In two of them the indication was ceased (because the biliary obstruction resolved spontaneously), 11 patients got percutaneous transhepatic drainage (PTD). The primary cannulation success rate of accessible papillas was 88.5% (394/445) while the overall cannulation success was 96.6% (430/445). 56.1% of primary successful cannulations were achieved by conventional method, in 14.2% we used pancreatic guidewire assisted technique, in 20.1% we used early precut sphincterotomy, and in the rest cases we used combined techniques. In 51 primary unsuccessful cases we repeated ERCP attempt in 4 days on average and successfully cannulated 70.5% (36/51) of them at the second or third attempts. 27 of them were achieved by conventional method, 7 of them after extending the precut, one case was cannulated using pancreatic guidewire technique, and we used profilactic pancreatic stent in one patient, as well. Out of the 15 patients with finally unsuccessful cannulation, we performed precut without deep cannulation in 10 cases. 7 of them resolved after precut, 2 of the 10 patients got PTD and one patient refused further investigation. In 4 patients out of the 15 unsuccessful cannulations the obstruction resolved without any further intervention and one patient got PTD. We had in sum 3.4% (15/445) post-ERCP pancreatitis, 7 of them were mild, and 8 moderate, we had no severe one. We observed endoscopic signs of bleeding during ERCP in 34 cases that needed some endoscopic interventions (infiltration/coagulation/stenting), 7 of them (1.6%) required blood transfusion. Three patients suffered perforation during ERCP. One of them got biliary stent and was discharged uneventfully on the 8th day. We had 2 sphincterotomy related perforations, 1 had early surgery – he died on the 14th day, another patient had delayed surgery, he recovered.

Conclusion: Quality assessment of ERCP performance is essential. Our overall cannulation rate was acceptable. We used pancreatic guidewire technique just after first guidewire passage of pancreatic duct and switched on to precut at early phase of process to avoid long lasting traumatization of the papilla. Our complication rate of post-ERCP pancreatitis was good while the post-sphincterotomy bleeding rate should be considered higher than in the literature, therefore we changed the settings of electrosurgical current.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0901 RISK FACTORS FOR POST-ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY PANCREATITIS: A PROSPECTIVE MULTICENTER STUDY

A. Suzuki¹, B. Endoh², K. Chikugo³, T. Kawakami⁴, T. Suzuki⁴, N. Yoshitaka⁵, K. Kusumoto⁵, Y. Itokawa⁵, O. Inatomi⁶, S. Bamba⁶, K. Uno¹, Y. Mizumoto², K. Tanaka¹

Introduction: The procedures related to endoscopic retrograde cholangiopancreatography (ERCP) play a major role in the diagnosis and treatment of pancreatobiliary disease. However, post-ERCP pancreatitis (PEP) remains the most common and severe complication of ERCP. The incidence rates of and risk factors for PEP have mainly been reported from retrospective studies.

Aims & Methods: This study aimed to identify the incidence rate of and risk factors for PEP in a prospective large cohort study. This is a prospective cohort study of all patients who underwent ERCP-related procedures at 5 high-volume centers between February 2015 and May 2016. Patients who presented with acute pancreatitis, post biliary reconstruction, and failure to reach the papilla were excluded. The incidence rates of PEP and its severity were

examined. Multivariate analysis was used to identify the risk factors for the disease. Patients who presented with at least two of the following three manifestations were diagnosed with PEP: 1) elevated levels of serum amylase, 2) abdominal pain lasting more than 24 hours, and 3) abnormal findings of acute pancreatitis on computed tomography. An increase in serum amylase level of at least three times greater than the normal upper limit at approximately 18 h after the procedure (the next morning) was regarded as significant. The severity of PEP was graded according to the severity assessment of the Japanese Ministry of Health, Labour, and Welfare.

Results: A total of 1932 patients were finally analyzed. PEP occurred in 142 patients (7.3%); it was mild in 117 patients (6.0%) and severe in 25 patients (1.3%). Univariate analysis showed that female gender, naïve papilla, surgically altered gastrointestinal anatomy, no coexistence of acute cholangitis, diagnostic ERCP, elective ERCP, procedure time after reaching the papilla, number of cannulation attempts, precut sphincterotomy, intraductal ultrasonography, pancreatic duct injection, insertion of guidewire into the pancreatic duct, and placement of prophylactic pancreatic stent were significant risk factors. In the multivariate analysis, female gender (OR 2.273; 95%CI 1.570–3.291), naïve papilla (OR 3.024; 95%CI 1.805–5.066), surgically altered gastrointestinal anatomy (OR 2.607; 95%CI 1.378–4.931), procedure time after reaching the papilla (OR 1.009; 95%CI 1.001–1.017), pancreatic duct injection (OR 2.297; 95%CI 1.493–3.534), and intraductal ultrasonography (OR 1.620; 95%CI 1.015–2.585) were independent risk factors.

Conclusion: The incidence of PEP was similar to those reported in previous studies. These risk factors are important as predictors of PEP. A shorter procedure time and avoidance of unnecessary pancreatic duct injection are important for prevention of PEP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0902 USEFULNESS OF AMY MEASUREMENTS AT 2 HOURS AFTER ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PREDICTING THE SEVERITY OF POST-ERCP PANCREATITIS, : MULTICENTER PROSPECTIVE STUDY, SOSUI

K. Takumi¹, T. Suzuki¹, H. Sato¹, N. Yoshida¹, Y. Nakai², K. Kusumoto², Y. Itokawa², A. Suzuki¹, B. Endoh³, K. Chikugo³, O. Inatomi⁴, S. Bamba⁴, Y. Mizumoto³, K. Tanaka¹

³Department Of Gastroenterology, Kyoto Medical Center, Kyoto/Japan

⁴Division Of Gastroenterology, Shiga University of Medical Science, Shiga/Japan

Contact E-mail Address: mbyqm671@yahoo.co.jp

Introduction: The severity of post-ERCP pancreatitis (PEP) is a major problem because of occasional lethality. However, no predictor of the severity has been identified. In the present multicenter prospective study, SOSUI, we investigated the potential predictors of severity.

Aims & Methods: Of 2078 subjects who underwent ERCP between February 2015 and May 2016 at five high-volume centers, 1932, excluding those who had been complicated by pancreatitis, undergone biliary tract reconstruction, or had papilla not reached, were included. Of the 1932 patients, 163 who developed PEP were compared between the mild and severe cases to examine potential predictors of severity. PEP was diagnosed based on two or more of the following three conditions: (1) serum amylase elevation (above the upper limits of each center) on the following day, (2) abdominal pain lasting for longer than 24 hours, and (3) pancreatitis on CT. Severity was assessed based on the severity criteria of the Ministry of Health, Labour and Welfare. For continuous variables, the Mann-Whitney U test was employed. For binomial comparison, univariate analysis was conducted using a chi-square test.

Results: Twenty-five severe (1.3%) and 138 mild (7.1%) PEP patients were included. Patient and procedural factors were examined, demonstrating that the AMY values at 2 hours after ERCP were significantly higher in the severe cases than in the mild ones ($P=0.005$). ROC analysis was conducted on the AMY values at 2 hours as a predictor of severe PEP, demonstrating that the cutoff value was 3.7 times higher than the upper limits of each center (sensitivity: 64%; specificity: 70%; and AUC: 0.65). In multivariate analysis using logistic regression by dividing the AMY values at 2 hours after ERCP into higher or lower than 3.7 times the reference values of each center, abdominal pain immediately after ERCP and AMY values at 2 hours after ERCP were identified as independent factors.

Conclusion: Severe PEP should be diagnosed as early as possible for intervention. However, it may take a long time to assess clinical courses or examine images after examination. In the present study, abdominal pain immediately after ERCP and AMY values at 2 hours were identified as predictors of severity, being useful for facilitating early therapeutic intervention.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0903 ENDOSCOPIC ULTRASOUND-BASED TRANSDUODENAL CHOLECYSTOLITHOTOMY VIA DOUBLE-FLANGED FULLY COVERED METAL STENT WITH HOT STENT DELIVERY

S. Sun

Endoscopy Center, Shengjing Hospital of China Medical University, Shenyang/China

Contact E-mail Address: sunsiyucmu@aliyun.com

Introduction: Laparoscopic cholecystectomy (LC) has become the 'gold standard' for the treatment of symptomatic gallstones. However, before clinical implementation, instruments still need modification, and a more convenient treatment is still needed.

Aims & Methods: The aim of this study was to evaluate the transduodenal tractcholecystoscopy technique in the treatment of gallbladder disease without cholecystectomy. The patient with cholesterol gallstones and high surgical risks were enrolled between January 2015 and March 2017. Endoscopic ultrasound (EUS)-guided cholecystoduodenostomy by deploying a double-flanged fully covered metal stent with hot stent delivery was performed and endoscopic sphincterotomy (EST) was also performed during this procedure for those patients with accompanying common bile duct stones. One or two weeks later an forward-viewing endoscope was advanced into the gallbladder via the stent, and cholecystolithotomy or polypectomy was performed. After the stents were removed, a pigtail-type naso-cholelithotomy catheter was inserted into the gallbladder over the guide wire and removed 2 days later. Four weeks later gallbladder was assessed by abdominal ultrasound.

Results: EUS-guided cholecystoduodenostomy with double flanged metal stent deployment was successfully performed in all of 26 patients (Male/Female, 11/15; mean age, 61 ± 16.19yrs). After the procedure, fistulas had formed in each of the hepatopituitary and the stones of 7 patients expelled themselves completely. Endoscopic cholecystolithotomy (19) and polyps resection (2) were successfully performed through the stents, and then the stents were removed. Common bile duct stones were also successfully removed in 6 patients. EGD showed all the fistula closed completely after 3 days. The ultrasound examination of the gallbladder 4 weeks later showed no stones remaining and also showed satisfactory functioning of the gallbladder. The mean follow-up period was 11 months (range: 1–27months). Cholesterol gallstones recurrence were not detected in any patient during follow-up.

Conclusion: The EUS-guided placement of a novel metal stent with hot stent delivery is a safe and simple approach for performing an endoscopic cholecystoduodenostomy, which can subsequently allow procedures to be performed for treating biliary disease, including cholecystolithotomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: helena.brito@brb.pt

Introduction: Quantitative second generation endoscopic ultrasound (EUS) elastography allows the quantitative analysis of tissue stiffness and can be a useful auxiliary tool in the differential diagnosis of pancreatic solid tumors (1)(2).

Aims & Methods: The aim of this study was to evaluate the accuracy of the quantitative EUS elastography in the differential diagnosis of pancreatic solid masses, discriminating malignant from benign masses, using strain ratio (SR) analysis. A prospective study was performed for 15 months and included 29 consecutive patients who underwent EUS for the evaluation of solid pancreatic

masses. EUS elastography was performed by 2 operators, using a linear echoendoscope. The mean of 3 measures was considered as the SR final result for each lesion. EUS-fine-needle aspiration of the lesions was performed after SR assessment and the final diagnosis was based on the cytology or histology results. Accuracy of the elastography was obtained by the analysis of ROC curves.

Results: Included 29 patients in a total of 30 lesions with conclusive histological/cytologic diagnosis (8 inflammatory masses, 19 adenocarcinomas, 2 neuroendocrine tumors and 1 undifferentiated carcinoma). The mean SR value was significantly higher in the malignant tumors comparing with the benign tumors (55.56 vs 23.93, p=0.001). The sensitivity and specificity of SR for detection of pancreatic malignancy for a cut of 15.89 were, respectively, 95.45% and 87.5% (area under the curve of 0.89, 95% CI). The overall accuracy of the EUS elastography using the SR for the detection of pancreatic malignancy was 93%.

Conclusion: Quantitative EUS elastography presents good accuracy in the differentiation between malignant and benign pancreatic masses. It is a promising EUS technique in the diagnostic approach of solid pancreatic lesions, which may complement the study and characterization of the tumors, aiding in the diagnostic and follow-up of these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0905 IS ENDOSCOPIC ULTRASONOGRAPHY EXAMINATION USEFUL BEFORE ENDOSCOPIC SUBMUCOSAL DISSECTION IN PATIENTS OF SUPERFICIAL ESOPHAGEAL SQUAMOUS CELL CARCINOMA?

Y.Y. Chu¹, S.C. Ng², J.M. Lien¹, C.T. Chiu¹

¹Gastroenterology And Hepatology, Chang Gung Memorial Hospital, Taoyuan/Taiwan

²Internal Medicine, Chang Gung Memorial Hospital, Keelung/Taiwan

Contact E-mail Address: chu2235@yahoo.com

Introduction: Esophageal squamous cell carcinoma (ESCC) ranked the seventh most frequent cancers, and is the fifth leading cause of cancer death in Taiwan. The overall 5-year survival rate of ESCC is 12–15%. It is important to diagnose ESCC in early stage and receive curative treatment. Endoscopic submucosal dissection (ESD) is a well-developed skill to complete resect gastrointestinal (GI) tract early cancer. The limitation of ESD is cancer invasion to submucosal layer and increasing the risk of lymph node metastasis (10–45%) of ESCC. Endoscopic ultrasonography (EUS) is an examination for detecting the invasion depth (T stage) of GI tract cancer, the reported accuracy of T1 stage is around 85% of ESCC, however, the result of detail discrimination of EUS among each subdivision of mucosa (T1a or m) or submucosa (T1b or sm) is unsatisfied.

Aims & Methods: The aim of this study is to evaluate the accuracy of T1 stage subdivision of ESCC by higher frequency EUS probe prior to ESD treatment. From 2013 to 2016, there are 825 patients diagnosed with ESCC, further stage with EUS, computerized tomography and PET-CT. The EUS examination is performed with miniprobe (UM-2R, 12 MHz, UM-3R, 20 MHz; Olympus Optical Co. Ltd., Tokyo, Japan) and water immersion method.

The enrolled criteria of this study: 1. ESCC was proved by biopsy result. 2. T1a or T1b stage diagnosed by EUS. 3. No lymph nodes or distant metastasis. 4. Treatment with ESD. All EUS-T stage results were correlated with final pathological T stage, including T1a/T1b.

Results: Total 90 patients enrolled in this study and there were 83 patients with T1a and 7 were T1b stage of ESCC by EUS. After ESD treatment, all specimens were confirmed as T1 on pathology. EUS stage of T1a in 83 patients and 66 (80%) were confirmed as T1a, 17 (20%) were T1b on pathology; of 7 T1b (patients refuse surgery) on EUS, 2 (29%) were confirmed as T1a and 5 (71%) were T1b on pathology, further subdivision of pathological T1a: 68 (m1: 33, m2: 15, m3: 20), and T1b: 22 (<sm1: 6, >sm2: 16). The sensitivity, specificity, positive predictive value and negative predictive value of EUS T1a is 97%, 23%, 80% and 71%, respectively. All the patients with pathological T1b stage received further esophagectomy or concurrent chemoradiotherapy if surgery unfit.

Conclusion: EUS demonstrates excellent accuracy for T1a diagnosis, but low accuracy of distinguishing between stages T1a and T1b of ESCC. Even with high-frequency miniprobe (20 MHz), the main cause of understage of T1b is difficult to detect the cancer micro-infiltration into submucosal layers, and peritumoral inflammation or submucosal fibrosis causes some difficulties in differentiating mucosal from submucosal lesions is the reason of overstage of T1a. To improve the diagnostic accuracy, developing advanced EUS device and more experienced endoscopist are needed. Comparing with other locoregional staging method, EUS remains a valuable tool of detecting ESCC T1a stage when ESD treatment is considered.

³Department Of Pathology, Kyungpook National University School of Medicine, Daegu/Korea, Republic of

Contact E-mail Address: sekj319@hanmail.net

Introduction: Determining the cause of suspected biliary strictures is always challenging in clinical practice. Although EUS-guided tissue sampling (EUS-TS) revealed a better diagnostic yield in suspected malignant biliary obstructive lesions comparing to ERCP-guided tissue sampling (ERCP-TS), there was few studies for which techniques are better dependent on primary tumor.

Aims & Methods: The aim of our study is to compare the diagnostic yields between EUS-TS and ERCP-TS in patients with suspected malignant biliary obstructive lesion according to primary tumor sites. By reviewing medical records, we enrolled patients who underwent same-session examination of EUS and ERCP for the evaluation of suspected pancreatobiliary obstructive lesion. For cytopathologic diagnosis, endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) or biopsy (EUS-FNB) and ERCP-TS using brush cytology and/or forceps biopsy were performed. The diagnostic performances were compared between two techniques according to primary tumor sites.

Results: From January 2011 to September 2016, we enrolled 125 patients and 32 patients were excluded due to the following reasons: loss of follow up in 8, ERCP-TS from pancreatic duct in 23, and ERCP-TS from periampullary biopsy in 4. Among the enrolled patients (93 patients; 62 males, mean age 65.8 years), 86 (92.5%) had malignant tumor such as cholangiocarcinoma in 39, pancreatic cancer in 37, and other malignant tumors in 10 patients. And 7 (7.5%) patients had benign lesions. EUS-TS revealed higher rate of overall diagnostic accuracy comparing to ERCP-TS (82.8% vs. 60.2%, $p=0.001$). Depending on primary lesions, the diagnostic accuracy for pancreatic lesions was statistically higher in EUS-TS than ERCP-TS (84.4% vs. 51.1%, $p=0.003$).

Conclusion: EUS-TS is superior to ERCP-TS for the evaluation of suspected malignant pancreatobiliary obstructive lesions. Especially, if the biliary obstruction was caused by pancreatic lesions, EUS-TS would need to be a priority for cytopathologic diagnosis

P0907 PREVALENCE OF POSTERIOR MEDIASTINAL LYMPHADENOPATHIES IN PATIENTS UNDERGOING ENDOSCOPIC ULTRASONOGRAPHY FOR NON-MALIGNANT INDICATIONS: A PORTUGUESE SINGLE-CENTRE PROSPECTIVE STUDY

J. Veloso Do Carmo, S. C. Marques, M. Bispo, C. Chagas

Gastroenterology, Hospital Egas Moniz - Centro Hospitalar de Lisboa Ocidental, Lisboa/Portugal

Contact E-mail Address: joanavcarmo@gmail.com

Introduction: Significant heterogeneity in geographic distribution in the prevalence and features of mediastinal lymphadenopathies have been documented in CT studies. Awareness of the geographic prevalence and characteristics of lymphadenopathies will be relevant when performing endoscopic ultrasonography (EUS) for nodal staging of malignant neoplasia.

Aims & Methods: 1. To document the prevalence and characteristics of mediastinal lymphadenopathies in patients submitted to EUS for non-malignant extra-thoracic disease. 2. To identify predictive factors for the presence of mediastinal lymphadenopathies. A prospective, unicentric study was performed between July and December 2016. Mediastinal stations 9, 8, 7, 6, 5, 4L and 2 were systematically evaluated using a linear echoendoscope in all patients undergoing EUS due to benign extra-thoracic pathology, without history of oncologic disease. Demographic, clinical and EUS features were analysed, including location, number, shape, dimensions and echogenicity of the lymphadenopathies.

Results: We analysed 75 patients: M/F, 32/43; Mean age, 63 years. The majority (72%) of the patients presented lymphadenopathies in at least one mediastinal station and 88% of these were found in stations 7 or 4L. Only 6% of these had short axis diameter >10mm, most were oval (59%) or triangular (37%) and 40% had a hyperechogenic center. The prevalence of lymphadenopathies was higher in smoker patients (83% vs 64%, $p=0.024$), with a higher average number of lymphadenopathies per patient in this group (2.1 vs 1.6; $p=0.017$). Similar findings were documented in patients with relevant occupational or environmental respiratory exposure (prevalence 83% vs 71%; average number 3 vs 1.7). By logistic regression analysis, none of the variables analysed was independently associated with the presence of mediastinal lymphadenopathies.

Conclusion: This prospective Portuguese study documented a higher prevalence of mediastinal lymphadenopathies than previously reported in northern Europe¹, in patients with no evidence of oncologic disease. This higher prevalence, mostly in smokers or patients with relevant occupational exposure, may negatively influence the specificity and positive predictive value for malignancy of mediastinal lymph node (N) staging by EUS, with particular relevance in esophageal and pulmonary cancer staging.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Recent studies demonstrated the positive impact of neoadjuvant treatment for gastric adenocarcinoma $T \geq 2$ and/or N+.

Aims & Methods: We aimed to assess the accuracy of endoscopic ultrasound in the selection of patient with gastric adenocarcinoma for neoadjuvant therapy. A unicentric retrospective analysis of patients with the anatomopathological diagnosis of gastric adenocarcinoma between 2011 and 2016, who performed endoscopic ultrasound for staging and underwent surgery without prior neoadjuvant treatment. The concordance (kappa) and accuracy [sensitivity (S) and specificity (E)] of the endoscopic ultrasound for $T \geq 2$ and/or N+ (criteria for neoadjuvant treatment) were assessed using the anatomopathological staging of the resected surgical specimen.

Results: The final sample included 144 patients (64.6% male) with a median age of 68.5 ± 12.2 years. In most cases (80.6%), the neoplasia was distal (antrum, incisura angularis and body). The neoplasia was of the intestinal type, diffuse and mixed in 65.3%, 18.8% and 16% of the cases, respectively. After examination of the resected surgical specimen, 53.5% of patients had criteria for neoadjuvant treatment ($T \geq 2$ and/or N+). The overall kappa, sensitivity and specificity of the endoscopic ultrasound for $T \geq 2$ and/or N+ were 0.720 ($p < 0.001$), 85.2% (95% CI: 75.6-92.1%) and 87.3% (95% CI: 76.5-94.4%), respectively. The overall kappa, sensitivity and specificity of the endoscopic ultrasound for $T \geq 2$ and/or N+ were higher in proximal lesions (cardia and JEG) ($k=0.924$, S-94.4% and E-100%) compared with distal lesions ($k=0.671$, S-82.5% and E-84.9%) and in intestinal type lesions ($k=0.765$, S-84.9% and E-92.7%) compared with diffuse type lesions ($k=0.682$, S-88.4% and E-80%) or mixed ($k=0.566$, S-81.8% and E-75%).

Conclusion: In one of the largest series of patients, we showed that endoscopic ultrasound has an overall high agreement and accuracy in the selection of gastric adenocarcinoma patients for neoadjuvant therapy, although they higher for proximal and intestinal lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0909 IS IT USEFULL TO REPEAT ENDOSCOPIC ULTRASOUND WITH FINE NEEDLE ASPIRATION OF PANCREATIC CYSTIC LESIONS? A RETROSPECTIVE STUDY

S. Faia¹, J. Pereira Silva¹, I. Marques², R. Fonseca³, A. Dias Pereira²

Introduction: Pancreatic cystic neoplasms (PCNs) require initial imaging characterization and frequently follow-up. Endoscopic ultrasound with fine-needle aspiration (EUS-FNA) for CEA measurement and cytology of cystic fluid is the most accurate diagnostic method in these lesions. The role of repeated EUS-FNA with cystic fluid analysis in follow-up of PCNs is not clear.

Aims & Methods: To determine if patients with pancreatic cysts with a second repeated EUS-FNA for cystic fluid analysis for CEA and cytology had a change in cyst classification or on clinical decision. Retrospective analysis of a EUS database, with 284 patients who had EUS-FNA for pancreatic cyst evaluation from 2007-16, of which 35 had 2 EUS procedures, and of these, 22 had 2 consecutive EUS-FNA procedures.

Results: In our series: 16/22 females (73%), mean age = 58 ± 13 years old (29–77). Mean follow-up time = 60 ± 34 months (6–116). Cyst location: head/body/tail: 11/8/3. Mean size in 1st EUS-FNA: 3 ± 1, 5 cm (1, 2–7 cm) vs 2nd EUS-FNA: 3, 1 ± 1, 9 cm (1, 2–10 cm); with both EUS-FNAs with 36% cysts > 3 cm. Mass/mural nodule present: 7/22 vs 4/22 on 2nd EUS-FNA. Repetition of EUS-FNA due to: nodule, imagiologic change or increasing size. Mean interval between the two subsequent EUS-FNAs: 35 months (3–117). Cysts with CEA level > 192 g/mL (7 vs 10 patients) and acellular cystic fluid samples (62% vs 59%), between the 1st and the 2nd EUS-FNA, not statistical significant. There were 4 patients operated that had previously a repeated EUS-FNA (2nd EUS-FNA 3, 4, 7 and 10 months after the 1st EUS-FNA). Surgical pathology (respectively): Intraductal papillary mucinous neoplasm, mucinous cystic neoplasm, solid pseudopapillary neoplasm and a neuroendocrine tumour. Comparing the group of patients who had pancreatic cyst surgery with patients on imagiologic follow up, there was a statistical difference in cystic size > 3 cm and the presence of a mural nodule or mass in the surgery group, but no significant differences in age, CEA value or a diagnostic cytology between the two groups. The mean time between the two EUS-FNA procedures was significantly shorter in the surgical patients group.

Conclusion: Clinical follow-up of pancreatic cysts with successive EUS-FNAs can be useful in larger cysts and if worrisome features (mural nodule or mass) are present, and should be performed early on follow-up. If these features are absent, most cysts have an identical CEA (increase to > 192 mg/mL in only 14% of patients, without statistical significance) and the EUS-FNA doesn't change clinical decision making.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0910 DETERMINATION OF INTRACYSTIC GLUCOSE CONCENTRATIONS IN THE DIFFERENTIAL DIAGNOSIS OF PANCREATIC CYSTS: A PROSPECTIVE STUDY

A. Cantamessa, M. Bruno, S. Gaia, G. Saracco, C. De Angelis
Gastroenterology Unit, A.O. Città della Salute e della Scienza di Torino - Università di Turin, Turin/Italy

Contact E-mail Address: eusdeang@hotmail.com

Introduction: Despite advances in imaging techniques, differential diagnosis of pancreatic cysts still remains challenging. There has been an increasing interest in new pancreatic cyst biomarkers as a way to differentiate different cyst subtypes and avoid unnecessary surgery. Recently intracystic fluid glucose has been proposed as a promising marker. The aim of this prospective study was to verify this early finding.

Aims & Methods: We enrolled in the study all the patients who underwent Endoscopic Ultrasound (EUS) guided Fine Needle Aspiration of a pancreatic cyst at our Institution from October 2015 to February 2017. The cyst fluid was sent for cytology, mucin staining and determination of amylase, Carbohydrate Antigen 19-9 (CA 19-9), Carcinoembryonic Antigen (CEA) and glucose. When deemed necessary by the endoscopist, needle-based confocal laser endomicroscopy (nCLE) of the cyst wall and/or contrast-enhanced EUS was performed. A definitive diagnosis of the nature of the cyst was reached relying on surgery, cytology or mucin staining, a typical pattern of nCLE or by consensus (on EUS and radiological features) by three expert endosonographers, blinded to cyst markers concentrations.

Results: Twenty-nine patients (13 males, median age 72 years, range: 30–83) entered the study. Nineteen (66%) pancreatic cysts were unilocular while 10 (34%) were multilocular, the median largest diameter was 45 mm (range: 20–70 mm). Sixteen (55%) cysts were located in the pancreatic head, 10 (35%) in the body and 3 (10%) in the tail. CE-EUS was performed in 14 (48.3%) patients, nCLE in 12 (42.8%) subjects. Eighteen (62.1%) cysts were finally classified as mucinous (6 mucinous cystadenomas; 12 intraductal papillary mucinous neoplasm) and 11 (37.9%) as non-mucinous (6 serous cystadenomas; 5 pseudocysts). The final diagnosis was reached relying on surgery in 9 patients (31%), on cytology in 4 (13.8%), on nCLE in 8 (27.6%) and on consensus in 8 (27.6%). Mean glucose concentrations in mucinous cyst were significantly lower than in non-mucinous cysts (7.7 mg/dl vs 95.7 mg/dl, $p < 0.0001$). In the diagnosis of mucinous cysts, sensitivity of CA 19-9 (cutoff more than 5000 U/ml), CEA (cutoff more than 192 mg/ml) and glucose (cutoff less than 50 mg/dl) was respectively 22.2%, 66.7% and 94.4%. Specificity was respectively 72.7%, 100% and 100%. Accuracy was respectively 41.4%, 79.3% and 96.6%. Only two subjects in this cohort were affected by diabetes, this condition did not impact on intracystic glucose concentration.

Conclusion: Although limited by the small sample size, this study confirms the utility of intracystic glucose levels in differentiating mucinous from non-mucinous pancreatic cysts. This cheap, new marker outperformed CA 19-9 and CEA in sensitivity, specificity and accuracy.

Introduction: Liquid-based cytology (LBC) preparation method is one of the preparation methods of cytology samples, which is being increasingly used in gynecological and non-gynecological cytology samples, due to its ability to decrease screening time, insufficient sample rate, and air-drying artifacts compared to a conventional smear method. Additionally, immunocytochemistry (ICC) can be performed after LBC.

Aims & Methods: The aim of this study is to show the actual method of LBC and to evaluate the utility of LBC in EUS-FNA samples of the pancreatic lesions. 292 specimens obtained by EUS-FNA from patients with pancreatic disease were enrolled in this study. Clinical diagnosis was pancreatic cancer (PC) in 210 cases, acinar cell carcinoma in three cases, adenosquamous cell carcinoma in one case, invasive ductal carcinoma derived from IPMN in three cases, metastatic pancreatic tumor in eight cases, pancreatic neuroendocrine tumor (PNET) in 20 cases, solid pseudopapillary neoplasm in one case, serous cystic neoplasm (SCN) in five cases, mass-forming pancreatitis in four cases, and autoimmune pancreatitis (AIP) in 40 cases. Just after EUS-FNA, tissue sample in the FNA needle was flushed out into petri dish with saline. The specimen was carefully examined to divide visual tissue core from liquid specimen. Divided visual tissue core was formalin-fixed and processed for pathological evaluation. All residual liquid specimen in whole was immediately immersed in liquid-based fixation medium (CytoRich™Red) at the bedside. The liquid was centrifugalized and processed for cytological evaluation in the laboratory. Sufficient material rate of cytology was retrospectively evaluated in all cases, and diagnostic yield between cytology and histology in patients with malignant diseases was compared. In addition, availability of immunohistochemistry (IHC) and ICC was assessed retrospectively.

Results: Sufficient material rate in cytological evaluation was 96.6% in all enrolled specimens (282/292). 10 insufficient materials were obtained from PC in two, SCN in four, PNET in one, and AIP in three. In seven of the 10 cases with insufficient materials, sampling error occurred because sufficient material was not confirmed using rapid onsite evaluation. Accuracy of cytology, histology, and combination of cytology and histology were 84.4%, 72.9%, and 90.0%, respectively. In the study of 255 specimens with malignant diseases, sufficient material rate of cytology and histology are 99.1% (223/225) and 89.3% (201/225). Positive predictive values of cytology and histology are 81.7% (184/225) and 67.6% (152/225). 65.8% (48/73) of pathologically non-diagnosed cases could be diagnosed as malignancy owing to cytology. In 26 specimens where immunocytochemistry was needed, IHC was available in 23 of the 26 specimens (88.5%) and ICC was available in all specimens. In the three specimens, IHC was not available owing to pathological insufficiency.

Conclusion: LBC in pancreatic cell samples obtained by EUS-FNA may be useful for reducing insufficient material rate and conducting ICC as well as in samples in other medical fields.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0913 ANTIBIOTIC PROPHYLAXIS AFTER PANCREATIC CYST PUNCTURE – LESS IS MORE? ONE-TIME VERSUS EXTENDED CIPROFLOXACIN PROTOCOL

Introduction: Echoendoscopy with fine needle aspiration (EUS-FNA) is a useful tool for the characterization of pancreatic cystic lesions (PCL) due to its ability to provide samples for biochemical and cytological examination. This is a safe procedure, with low complications rate (0–2, 5%). Nevertheless, peri-procedural and even several days after EUS-FNA antibiotic prophylaxis has been the standard practice due to the possible risk of pancreatic infection.

Aims & Methods: We aimed to compare adverse outcomes after EUS FNA of PCL with two protocols: group 1: Ciprofloxacin 200 mg iv, one-dose, immediately before FNA, and group 2: Ciprofloxacin 200 mg iv, one-dose, immediately before FNA plus three days of oral Ciprofloxacin, 500 mg, bid. Retrospective study of single-operator EUS-FNA of CLP in two centers with different antibiotic prophylaxis protocols, between January 2014 and December 2016. A telephonic questionnaire regarding post-procedural complications was applied to all patients that agreed to enter the study.

Results: Two hundred and four EUS-FNA were analyzed: 51.5% (n = 105) in group 2.60% (n = 123) women, mean age 63.4 ± 12.8 years. We were able to contact 86.9% (n = 86) patients in group 1 and 94.3% (n = 99) in group 2 ($p > 0.05$). The mean time between EUS-FNA and questionnaire application was 14, 7 months for group 1 and 17 months for group 2 ($p > 0.05$). There was no statistical difference between the two protocol groups regarding the morphological features of the PCLs (size, morphology, location) or procedure (needle size, location of puncture, number of passages or percentage of cysts with complete collapse after aspiration). Five patients had intra-cystic limited bleeding after puncture (two in group 1 and three in group 2). In group 1, 6.2% (n = 6) reported complications: 1 major (mild acute pancreatitis) and 5 minor (epigastric pain, vomiting). In group 2, 9.1% (n = 9) reported 1 major (mild acute pancreatitis) and 8 minor (epigastric pain, transient fever, nausea) complications, with no difference between the two groups ($p > 0.05$). The patients with intra-cystic bleeding did not have a worse outcome. Additionally, five patients (1.9%) reported any type of adverse reaction related to antibiotic use (75% in group 2).

Conclusion: EUS-FNA is a safe procedure, with 1% rate for major complications in our series and none of them with evidence of infection. We did not find any additional benefit from extension of antibiotic prophylaxis beyond the one-time administration during EUS-FNA. It has even been questioned whether antibiotic

prophylaxis is mandatory during EUS-FNA of PCLs, since it does not seem to have a protective effect. Moreover, the raise in antibiotic resistance and possible adverse effects related to their use should be balanced against the very low infectious complication rate of EUS-FNA. One limitation of our study is its retrospective nature, with a significant delay between the EUS-FNA and the time to inquiry, which could have biased the patients' answers.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The endoscopic ultrasound (EUS) has proven useful in the study and evaluation of the adrenal gland (AG) by endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA), in both the left and right glands.

Aims & Methods: To analyze the diagnostic performance, safety, impact on clinical management, predictors of malignancy and cyto-pathological correlation of the EUS-FNA with adrenal gland.

National multicenter retrospective study. Mailing-SEED (Spanish Society of Digestive Endoscopy) partners. Participation: 17 Spanish centers. Inclusion period: April/2003 to April/2016. Inclusion criteria: All adrenal gland (Left/Right) punctured by endoscopic ultrasound. Variables reviewed: demographic characteristics, clinical, extension studies, EUS and pathological data. Comparison between variables; and estimation of multivariate logistic model for cytology, mortality and therapeutic change.

Results: A review of 205 EUS-FNA of adrenal gland in 200 patients (154 males). Average age: 65.3 (DE 9.6). Primary tumor: lung 69%, unknown 10%, another 20%. Adrenal gland left (191); adrenal gland right (14). Main features: CT scan-pathological (71.2%), PET scan-high uptake (82%), hypoechoic (88%) and suspected by endoscopist (69%). Puncture technique most commonly used: cytological needle (75%), 22-G (64%), suction-syringe (66.3%), passes 2.17 (DE 1.38). 92% of samples allowed a cytological diagnosis, 60% malignant. Variables associated with malignancy: CT scan pathological morphology (OR: 2.99 IC 95% 1.41–6.44), heterogeneous pattern EUS (OR: 2.11 CI 95% 1.13–3.97), morphology EUS 'Variegated' (OR: 2.46 CI 95% 1.00–6.24) and suspected by endoscopist (OR 17.46 CI 95% 6.2 to 58.5). A size <30mm was associated with lower mortality (OR: 2.27 CI 95% 1.17 to 4.48). Pathological suspicion of the endoscopist was associated with a greater therapeutic change (OR: 4.48 CI 95% 2.38 to 8.62). No description of adverse events.

Conclusion: Adrenal gland by endoscopic ultrasound-guided fine-needle aspiration is a safe and high diagnostic yield method. The variables most associated with malignancy are the suspicious echo endoscopic images objectified by expert endoscopists, a heterogeneous pattern and variegated morphology. The results suggest the possibility of developing a predictive malignancy model pre-procedure.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0915 RELIABILITY OF GIST'S PRE-TREATMENT RISK ASSESSMENT CLASSIFICATION WITH EUS-FNB BY USING DESIGNED CORE NEEDLES

R. Grassia, P. Capone, F. Cereatti, E. Iiritano, Vjero K., M. Martinotti, G. Tanzi, F. Buffoli

Gastroenterology, ASST Cremona, Cremona/Italy

Contact E-mail Address: robertograssia@yahoo.it

Introduction: The current classifications of non-metastatic GIST are based on post-operative pathologic criteria and are usefully employed to estimate the potential risk of postoperative recurrence and determine the value of adjuvant Imatinib. The proposed pre-treatment classification currently recognized risk factors as tumor diameter, mitotic rate and site (gastric vs non-gastric). EUS-guided tissue samples remains mainstay for pathological diagnosis of GIST, but previous studies showed that EUS-FNA with standard 19 or 22 gauge needles does not reliably reflect GIST's proliferation and size.

Aims & Methods: We aimed to investigate the EUS-FNB diagnostic yield for GIST and to evaluate whether EUS-FNB samples reflect prognostic criteria obtained from resected GISTs.

A prospectively maintained database was retrospectively reviewed to identify consecutive patients with surgically resected subepithelial lesions who received a diagnosis of GIST at a previous EUS-FNB with a 19 or 22 gauge core-needle (EchoTip®ProCore™, Cook Medical). Size from EUS examination and mitotic/proliferative indexes obtained from EUS-FNB samples were compared with surgical specimens.

Results: Between November 2012 and December 2016 18 patients were studied (11 males; mean age 71.6 years, range 44–88 yo). The tumour site was the stomach in 15 out of 18 patients and the duodenum in 3 out of 18 patients. Agreement between EUS-FNB and surgical pathology was 100% with respect to the diagnosis of GIST (18/18). Proliferative indexes (Ki67/MIB1) were determinable in 14/18 (77.7%) of biopsies versus all cases (as expected) in resected specimens. In our series Ki67/MIB1 were generally underestimated. We found only 2 patients with the required number of 50 HPFs for mitotic count examination. They showed a mitotic index <5/50 HPFs comparable to surgical specimens. No mitotic figures were seen in core biopsy specimen from any of the remaining 16 patients. In these patients the number of HPFs for mitotic count examination ranged from 1 to 22. In their corresponding surgical specimen we found mitoses in 16/16 patients, ranging from 1 to 5 per 50 consecutive HPFs. Tumour size of the surgical specimen exceeded (>5 mm) tumor EUS-size in 12 out of the 18 investigated cases (66.6%) and was equal (±5 mm) in 6 cases (33.3%).

Conclusion: In our experience, EUS-guided tissue core biopsy have an extremely high diagnostic accuracy for GIST diagnosis, but underestimates the proliferation indexes and rarely allows for a reliable mitotic count. The main reason responsible for these results is the uneven distribution of the mitotic figures throughout the lesion, which can cause the biopsy to miss the most mitotically active areas. Furthermore, EUS examination generally underestimates the size of the lesions; this limit is fundamentally linked to the "bidimensional" evaluation of lesions obtained by ultrasound. In addition, the underestimation of the size is greater for large lesions because of the low depth of field evaluated by high frequencies used in EUS. Our data obtained with EUS-FNB are similar to previous studies with FNA and constitute a major limitation for developing a possible pre-treatment and biopsy-based risk classification of GIST. Alternative parameters (genotype profiling) must be validated on pre-surgical biopsy samples from GISTs for prognostication purposes.

Contact E-mail Address: eshin3@jhmi.edu

Introduction: Pancreatic cancer (PC) remains a disease with overall poor prognosis, despite significant advances over the past decade. Stereotactic body radiation therapy (SBRT) is able to deliver higher biological effective dose to the tumor over a shorter period of time with reduced local toxicity compared to conventional external beam radiation therapy. EUS-guided fiducial placement has been shown to improve the accuracy and localization during SBRT.

Conventional EUS-guided fiducial placement requires back-loading each fiducial through the tip of the FNA needle. Thus, delivery of multiple fiducials can be cumbersome and time-consuming.

Aims & Methods: We aimed to evaluate the feasibility, safety, and performance characteristics of fiducial deployment in PC patients using a novel exchangeable FNA system with pre-loaded 22-gauge EUS fiducial needles. This was a single-center pilot study of 10 consecutive PC patients undergoing EUS-guided fiducial placement for SBRT. The fiducial delivery system contains a 22-gauge EUS needle pre-loaded with 2 gold markers with knurled design. After the 2 markers were deployed, the EUS fiducial needle insert was exchanged out for a second pre-loaded EUS fiducial needle insert through the exchangeable FNA system for total deployment of 4 markers in each patient. All patients underwent CT after fiducial placement as part of SBRT to evaluate successful deployment and complications. The primary endpoint was procedure success, defined as deployment of at least 3 fiducials into the desired target area. Secondary endpoints were total procedure time, fiducial delivery time, and safety.

Results: Fiducial placement was attempted in 10 consecutive patients with PC (mean age 61.7 years, males 60%). The tumor was located in the head (n=6), neck (n=2), and the body (n=2) of the pancreas. Mean size of the tumor was 2.7 cm (range 1.6–5.3). Procedure success was achieved in all 10 (100%) patients. All 10 patients successfully received 4 fiducials. Mean total procedure time was 12.2 minutes (range 5–18). By comparison, using historic controls of the first 10 patients who underwent conventional EUS-guided fiducial placement, the mean total procedure time was 26 minutes (range 16–44, $p=0.002$). Mean fiducial delivery time was 4.2 minutes (range 1–8). There were no immediate or delayed (7 days) complications.

Conclusion: EUS-guided fiducial placement with a novel exchangeable FNA system with pre-loaded 22-gauge EUS fiducial needle is quick, technically feasible and safe. This system may theoretically decrease the risk to the clinical staff by eliminating the need for back-loading fiducials through exposed needle tip and handling of potentially dirty needles. Given the potential safety and time advantages, further prospective studies are warranted for validation.

Introduction: Bubbles can impair the visualization of the small bowel (SB) mucosa during capsule endoscopy (CE).

Aims & Methods: Our aim was to develop and to validate a computed algorithm, which would evaluate the abundance of bubbles in SB-CE. Two sets of 200 SB-CE normal still frames were extracted from 45 complete third-generation SB-CE videos. Two experienced SB-CE readers analyzed both sets of images twice, in a random order. Each still frame was categorized as "scarce in" or "abundant in" bubbles (<10% or ≥10% of bubbles covering the frame, respectively). Reproducibility (κ coefficient), sensitivity (Se), specificity (Sp), Receiver Operating Characteristic [ROC] curve, and calculation times were measured for different algorithms (Grey-level of co-occurrence matrix [GLCM], fractal dimension, Hough transform, and Speeded-Up Robust Features [SURF]) using the experts' reading as reference. Algorithms with highest reproducibility,

Se and Sp were then selected for a validation step on the second set of frames. Criteria for validation were $\kappa=1$, Se ≥ 90%, Sp ≥ 85%, and a low calculation time.

Results: Both SURF and GLCM algorithms had high operating points (Se and Sp over 90%) and a perfect reproducibility ($\kappa=1$). At the validation step, the GLCM detector strategy had the best diagnostic capabilities, with Se = 95.79%, Sp = 95.19%, and a mean calculation time of 0.037s per frame. Table 1: Sensitivity (Se), specificity (Sp), negative predictive value (NPV), positive predictive value (PPV) and area under receiver operating characteristic curve (AUROC) of four algorithms for evaluation of bubble abundance in small bowel capsule endoscopy still frames (development step).

Conclusion: A GLCM detector strategy has high diagnostic performances to categorize "scarce in" or "abundant in bubbles" SB-CE frames. This algorithm is of interest for clinical use (i.e. quality in CE reporting) and for research (providing an objective comparison tool of different preparations, including anti-bubble agents).

Introduction: Capsule endoscopy has been demonstrated to be a first-line tool for small bowel visualization. However, it has some limitations such as incomplete examinations - i.e: the capsule does not reach the cecum - leading to missing lesions.

Aims & Methods: To evaluate those factors that can predict incomplete examinations, to identify those patients at risk for incomplete procedures and to define those approaches that may improve the efficiency of the examination reducing the time of the diagnostic process as well as the need to repeat procedures. A total of 1918 patients who underwent capsule enteroscopy at our center between 2008 and 2015 were retrospectively analyzed. We evaluated variables such as age, sex, anthropometric parameters, comorbidity, drugs, outpatient care, analytical parameters, indication of the test and transit times. Initially, a univariate analysis and then, a multivariate analysis using a logistic regression model were carried out.

Results: In the univariate analysis, the following variables showed a statistically significant association with the rate of incomplete examinations: age, gender, indication of procedure, outpatient care, history of abdominal surgery, heart disease, capsule ingestion posture, hemoglobin levels, renal failure and both gastric and small bowel transit times. These variables were included in the multivariate analysis were age > 65 years (OR = 1.99, 95% CI: 1.34–2.95), gastric transit time > 41 minutes (OR = 2.60, 95% CI: 1.72–3.93) and small bowel transit time > 286 minutes (OR = 3.52 95% CI: 2.26–5.48) showed a statistically significant association with the risk of incomplete examination.

Conclusion: Incomplete capsule endoscopy is predictable. Patients older than 65 years and/or a gastric emptying time greater than 42 minutes are independent predictive factors for incomplete procedures. In these clinical scenarios, pharmacological preventive measures or endoscopic introduction should be taken into account to avoid incomplete examinations.

Introduction: A many variety of pharmaceuticals for the treatment of colon disease can be more effective and have less side effects if targeted for precise delivery in the colon. Over the years, many types of delivery vehicles have been developed with the aim of targeting the colon, such as Ph based delivery technologies, time dependent drug release mechanisms, pressure based mechanisms, flora sensitive mechanisms and others. These technologies have performed with variable degrees of success due to the wide distribution of motility and other physiological variability between patients. We describe a novel capsule technology which incorporates a diffused gas sensor that allows for an accurate sensing of colon entrance; as well as a 3D real time positioning system that allows for an accurate, programmable, localized, and in colon drug delivery system.

Aims & Methods: Data was collected from 14 patients that swallowed capsules in a multi-center clinical trial using an x-ray imaging capsule (GUT 2016). The patients were sent home to continue their normal life routine while the capsule naturally traveled in the gastrointestinal tract until excretion. (Subjects signed informed consent forms and the study was performed after local IRB approval). The capsules contained electronics and software that allowed for live communication between the capsule and a recording device that is placed directly on the patient's back. This device tracks the position of the capsule and communicates with it, receiving diffused gas pressure from the capsule sensor and fusing this information with 3D position information from the capsule. The capsule system exhibited position accuracy of ± 1 cm and the ability to detect movements in real time, as well as potential of ~ 1 ml of payload for drug containment.

Results: The average total transit time of the capsule was 43 hours (range: 15–68 hours). The average transit time to cecum was 13.8 hours, and the average time across the colon was 12.8 hours (range 6–25). The position tracking and the RF communication between the capsule and the recorder showed >90% coverage in all cases, even in obese patients. No adverse events were reported. Figure 1 illustrates the recorder placement on the patient back. Figure 2 is a typical averaged capsule position trace in the colon.

Conclusion: A capsule with accurate position tracking, 2-way communication, and on line algorithms can determine colonic entrance and identify exact locations in the colon. A wide variety of drugs can accurately be delivered to their exact target in the colon. It enables for a more effective (high dose) and less toxic (no systemic delivery) therapy for IBD and cancer.

P0920 COLON CAPSULE ENDOSCOPY: HOW DOES INADEQUATE PROCEDURE CLEANSING CORRELATE WITH PROCEDURE ACCURACY?

S. Perek¹, S. Farkash², N. Schwartz³¹Medicine A, Rambam Health Care Campus, Haifa/Israel²Pathology, HaEmek Medical Center, Afula/Israel³HaEmek Medical Center, Afula/Israel**Contact E-mail Address:** shayperek@gmail.com

Introduction: Colon Capsule Endoscopy (CCE) procedure requires a preparation regimen, which provides a clean colon, clear capsule images and promotes capsule propulsion through the entire colon. A four-point cleansing grading scale system (poor, fair, good and excellent) has been used to describe the quality of colon preparation. "Poor" and "fair" are considered inadequate cleansing, while "good" and "excellent" – adequate for polyp detection. Adequate cleansing has been associated with significantly higher diagnostic accuracy, when compared with inadequate cleansing (72% vs. 28% respectively).[1]

Aims & Methods: Evaluate the relation between CCE procedure cleansing and accuracy – with an emphasis on inadequate cleansing. This is an additional post study analysis[2], including 767 screening population participants, from 17 sites in the United States and Israel, who underwent CCE procedure followed by a blinded colonoscopy. Capsule preparation included 12 mg Senna, 4 liters split dose of sulfate-free polyethylene glycol (PEG), with 6 and 3 oz of oral sulfate solution - for capsule propulsion. The CCE video was reviewed by 1 of 5 highly experienced CCE gastroenterologists. These physicians assessed colon cleansing

on a "poor" to "excellent" scale. Incomplete studies were included in the analysis. Polyps were considered a match, if the size measured by the capsule ($\pm 50\%$) range overlapped the size measured by the colonoscopy ($\pm 50\%$) range, and polyp location estimates by the 2 methods were in the same or adjacent segments[2].

Results: The mean age of the analyzed cohort was 57.1 (SD 5.8) with 342 males (44.6%).

Conclusion: This analysis indicates, that when utilizing 4 liter PEG and oral sulfate solutions for CCE procedure preparation, current cleansing assessment scale and methodology may need to be re-evaluated - to better correlate with polyp detection. Currently, "fair" cleansing may not indicate inadequate cleansing for polyp detection.

P0921 COLON CAPSULE ENDOSCOPY MAY REDUCE COLONOSCOPY MISS RATE – A MULTICENTER STUDY

S. Perek¹, N. Schwartz²¹Medicine A, Rambam Health Care Campus, Haifa/Israel²HaEmek Medical Center, Afula/Israel**Contact E-mail Address:** shayperek@gmail.com

Introduction: Colonoscopy miss rate is an area of intense focus, as it directly correlates with colorectal cancer incidence rate. Previous studies reported a colonoscopy miss rate of 2%–22%, depending on polyp size and histology [1]. Colon Capsule Endoscopy (CCE) is a visualization diagnostic modality of the colon mucosa, which has demonstrated high sensitivity for polyps and adenomas [2]. Determining the nature of polyps detected by CCE but missed by the imperfect gold standard (colonoscopy), may facilitate both optimization of CCE application (potential CCE additive value) and increase colonoscopy polyp detection.

Aims & Methods: Characterize polyps detected by CCE, which were missed by colonoscopy. 695 screening population participants, from 17 sites in the United States and Israel, underwent CCE procedure followed by a blinded colonoscopy. The overall colonoscopy adenoma detection rate in this study was very high – 39% [2]. Following the blinded colonoscopy, the patient's CCE report was assessed. Based on the findings in this report, the colonoscopy performing physician decided whether or not to immediately follow up with a second colonoscopy. 70 of the CCE findings were detected by the second colonoscopy. These 70 polyps were compared with 683 polyps detected by blinded colonoscopy, using logistic regression model. Adjusted Odds Ratios (Adj.OR) and corresponding Confidence Intervals (CI) were estimated.

Results: Of the 70 polyps missed by first colonoscopy and detected by second colonoscopy, 20 (29%) were 6 mm or larger (based on colonoscopy size estimation), 19 (27%) were either adenomatous or sessile serrated lesions and 16 (23%) were described as either flat or sessile-flat by colonoscopy performing physician. Stratification of polyps based on location:

	Detected by blinded colonoscopy (n = 683)	Detected after CCE and unblinding (n = 70)
Cecum	64 (84%)	12 (16%)
Ascending	181 (94%)	11 (6%)
Transverse	98 (96%)	4 (4%)
Descending-Sigma	243 (90%)	26 (10%)
Rectum	97 (85%)	17 (15%)

Abstract: P0920

Colon cleansing	Sensitivity (≥ 6 mm); n = 272	Specificity (≥ 6 mm); n = 495
Adequate cleansing	153/195 = 78.5% (72.2%–83.7%)	308/350 = 88.0% (84.2%–91.0%)
Inadequate cleansing	54/77 = 70.1% (59.1%–79.2%)	130/145 = 89.7% (83.5%–93.7%)
P-value	0.147	0.600
Poor cleansing	3/9 = 33.3% (11.7%–64.9%)	15/16 = 93.8% (69.7%–100%)
Fair, good and excellent cleansing	204/263 = 77.6% (72.1%–82.2%)	423/479 = 88.3% (85.1%–90.9%)
P-value	0.007	1

Poor cases had significantly lower CCE sensitivity compared with fair, good and excellent cases, for 6 mm polyps (P-value = 0.007). When stratifying cases based on the current adequacy cutoff, sensitivity for 6mm polyps is similar in inadequate ("poor" + "fair") cases compared to adequate ("good" + "excellent") cases (70.1%, 78.5% respectively; P-value = 0.147).

Multivariate logistic regression revealed that after adjusting to polyp's size, cecal and rectal segments were associated with increased chance of CCE additive value to colonoscopy (cecum vs. ascending or transverse colon: Adj.OR = 3.2 [95%CI: 1.3–7.6] and Adj.OR = 4.5 [95%CI: 1.4–14.6] respectively; rectum vs. ascending or transverse colon: Adj.OR = 2.6 [1.1–5.8] and Adj.OR = 3.6 [95%CI: 1.2–11.4] respectively). There were 59 patients (8.49% of study population), with at least one CCE additive value to colonoscopy event.

Conclusion: CCE has the ability to detect polyps missed by traditional colonoscopy, especially lesions in the cecum and rectum.

Disclosure of Interest: S. Perek: Employee of Medtronic
N. Schwartz: Employee of Medtronic

Introduction: Only small series (<10 patients) have described endoscopic management of postoperative pancreatic fistulas (POPF). The purpose of this retrospective study was to describe the indications, technique and results of endoscopic treatment of POPF.

Aims & Methods: From a prospective database of an endoscopic unit of a tertiary center, patients with POPF who underwent pancreatic endoscopic treatment during a retrograde endoscopic cholangiopancreatography (ERCP) were identified between January 2010 and June 2016. POPF was classified according to the definition of the International Study Group of Pancreatic Fistula Working Group. The indications, the techniques and results of endoscopic drainage and the patients' outcomes were registered.

Results: Among 6473 ERCPs performed during the inclusion period, 31 patients had POPF treated endoscopically (14 men, 7 women, mean age \pm standard deviation [SD]: 63 years [\pm 15]). Surgeries at the origin of the fistula were: distal pancreatectomy with spleen resection (n=19); spleen preserving distal pancreatectomy (n=3); central pancreatectomy (n=2); enucleation (n=4); partial pancreatectomy (n=1); left nephrectomy (n=2), for the following indications: IPMN (n=7), pancreatic adenocarcinoma (n=5), neuroendocrine tumors (n=4), insulinoma (n=3), adrenocortical carcinoma (n=6), metastasis (n=2), pheochromocytoma (n=1), cystadenomas (n=2), spleen artery aneurysm (n=1). The mean time between surgery and first ERCP (\pm SD, [range]) was 70 days (\pm 145, [6–806]). POPF was grade B in 19 patients and grade C in 12 patients. All patients had somatostatin analogs and 13 (41.9%) had an external radiological drainage prior to endoscopic drainage. In 9 patients (29%) a pancreatic cystogastrostomy was performed during follow-up (FU) in addition to the transpapillary drainage. The pancreatic cannulation rate was 96.8% at the first ERCP and 100% after 2 ERCPs: 90.3% by the major papilla, 9.7% by the minor papilla. All patients had a pancreatic sphincterotomy and the placement of a pancreatic plastic stent. 3 early complications (<72h) occurred: 2 post-sphincterotomy bleeding and 1 perforation, all medically treated. The mean FU (\pm SD, [range]) was 378 days (\pm 497 [2–2227]) after the first ERCP. During FU, there were 3 stent migrations and 2 stent obstructions requiring a subsequent ERCP for stent replacement. Eight patients (25.8%) died after surgery complications. Among the 23 remaining patients, the closure rate of POPF was 100% within an average (\pm SD [range]) of 153 days (\pm 81 [16–326]) after the first ERCP, after a mean number of ERCP performed per patient (\pm SD) 2.5 (\pm 1.0). No late reopening fistula occurred after removal of the pancreatic stent.

Conclusion: This retrospective study, the most important one reported to date, shows that the endoscopic treatment of POPF resistant to medical therapy is an effective option.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0923 EFFICIENCY OF PANCREATIC STENTS IN DIFFICULT CANNULATION – A RETROSPECTIVE SINGLE - CENTER STUDY

V. Sandru¹, M. Ilie¹, O.M. Plotogea¹, E. Rinja¹, I. Moroi¹, B. Ungureanu², G. Constantinescu¹

Introduction: Difficult biliary cannulation is defined by the presence of one or more of the following: more than 5 contacts with the papilla while attempting to cannulate; more than 5 minutes spent attempting to cannulate following visualization of the papilla; more than one unintended, pancreatic duct cannulation or opacification. In these situations, pancreatic stent insertion might prove to be very useful for prophylactic and tactical purposes.

Aims & Methods: We are proposing in this paper to present the experience of Clinical Emergency Hospital Bucharest regarding difficult biliary cannulation and how pancreatic stent insertion proves to be efficient in these situations. This paper is a retrospective study of the patients who presented difficult cannulation and to whom pancreatic stents were inserted for prophylactic and tactical purpose. The study included patients with ERCP (Endoscopic Retrograde Cholangiopancreatography) performed in Clinical Emergency Hospital Bucharest between December 2014 and December 2016. The patients were evaluated in terms of pancreatic stents efficiency regarding successful cannulation and post ERCP pancreatitis rate. The stents used were 5 Fr, 3 cm and 5 cm.

Results: We introduced in the study 158 patients with ERCP and difficult biliary cannulation, who required pancreatic stent insertion for prophylactic and tactical purpose. Patients' mean age was 60 years, while the sex ratio was 2:1 in favor of the female gender. Pancreatic stents proved their efficiency in 98% cases, in only 3 patients deep cannulation being unsuccessful. On average, patients required 1, 15 ERCP procedures in order to obtain biliary access. ERCP indication for benign pathology was predominant (60%). The stents used were 5 Fr, 5 cm (102 patients) and 5 Fr, 3 cm (56 patients). Precut sphincterotomy was performed in 82 cases (37 before stent insertion and 45 after stent insertion). From all patients included, only 19 patients (12%) presented post procedure elevation of serum amylase 3 times higher than normal value associated with abdominal pain. **Conclusion:** Pancreatic stents proved to be efficient in obtaining biliary cannulation in difficult situations. Regardless of their length, 5 Fr (3 cm, 5 cm) stents ensure the same success rate for cannulation and offers protection against post ERCP pancreatitis, as long as they are correctly inserted.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic ultrasonography (EUS)-guided biliary drainage (EUS-BD) is increasingly used in the treatment of malignant biliary obstruction after failed ERCP. However, Multi-step process for EUS-BD is closely related to adverse events.

Aims & Methods: The present study was designed to determine feasibility and safety of stent placement using a thin delivery-system stent without dilation step during EUS-BD. Three types of the new designed partially covered laser-cut metal stents (6-mm-wide and 60-mm-long) with 7Fr delivery catheter with hard tip (7Fr hard tip), 7.5Fr delivery catheter with hard tip (7.5Fr hard tip) and 7Fr delivery catheter with soft tip (7Fr soft tip) were prepared respectively. A phantom model with a silicon plate was created. The plate was punctured with s 19-G needle and a guidewire was passed the plate. The delivery system was advanced over the guidewire to pass the plate and the resistance force was measured. A biliary obstruction model was created by clipping the papilla in 10pigs, EUS-BD (choledochoduodenostomy) using the thin delivery system stents was attempted following 19-G needle puncture without the use of dilation devices. The technical success and adverse events within 2 weeks after EUS-BD were analyzed for three types of stents.

Results: Among the three types of stents, 7Fr soft tip had the least resistance in the phantom model. In the animal model, the median common bile duct diameter before puncture measured on EUS and the median procedure time was 7.66 mm (4.05–9.5) and 29.3 minutes (16–47) respectively. In all pigs, EUS-BD using the three types of stents were technically successful. Dilation was unnecessary in 25% (1/4), 0% (0/2) and 100% (4/4) for the 7Fr hard tip, 7.5Fr hard tip and 7Fr soft tip, respectively. Even in the cases requiring dilation, stent placement was successful, immediately after dilation only with a thin catheter (5.5Fr). Neither cautery dilation nor balloon dilation was needed. There were no procedure-related complications occurring during and 2 week after EUS-BD. All stents remained in place without migration. At necropsy, fistulas were created between the bile duct and duodenum in all pigs and the growth of fibrous tissue was observed in the microscopic findings.

Conclusion: Among the three types of stents, the 7Fr soft tip was suitable for EUS-BD without dilation in the phantom and animal models. The thin delivery-system stent may be technically feasible and safety for EUS-BD and possibly reduce adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0925 TREATMENT WITH FULLY-COVERED METAL STENTS OF POST-SPHINCTEROTOMY EARLY AND LATE BLEEDING

P. Gambitta¹, S. Pallotta², A. D'Alessandro³, F. Iannuzzi², E. Bareggi², A. Ballerini¹

Introduction: Post-endoscopic sphincterotomy bleeding is treated endoscopically with pharmacologic injection, electrosurgical coagulation, balloon tamponade or clipping, but severe cases may require angiographic or surgical approach. An alternative long-acting tamponade treatment with fully-covered metal stents (FCMS) has been advocated.

Aims & Methods: We report here on the use of FCMS in post-sphincterotomy early and late bleeding. Patients referred for in- and out-patient ERCP were informed of the potential off-label treatment with FCMS of post-sphincterotomy bleeding, and of treatment approval by the local ethical committee. We treated post-sphincterotomy bleeding first with adrenaline and/or sclerosing agent injection. When this first line hemostasis failed, we placed short FCMS in the distal choledochus. Endoscopy was rescheduled after 1 month to remove the FCMS. During the early post-procedural period the patients were treated with blood transfusions if needed, and antiplatelet drugs as well as oral anticoagulants were avoided.

Results: 17 Patients (10M/7F), aged on an average 70 years (range 38–90) received 18 FCMS (10mm×40mm, Boston Scientific) for failed hemostasis since 2015. Technical success was 100%. Hemostasis was obtained in 16 patients, with an average loss of 1 g/dl of Hb and 9 packed red cells units transfused. In our cases we had 1 outlayer, a patient that had received needle-knife sphincterotomy without early bleeding but developed delayed bleeding with hypovolemic shock. He received a second ERCP and a FCMS after 3 days. After further 3 days the patient was in the intensive care unit because of persistent bleeding and we performed a third ERCP. The FCMS was in place, but we removed it, retreated the bleeding by injective therapy and placed a second FCMS, obtaining a stable hemostasis. This single patient received 8/9 of the packed red cells unit used in the study. The FCMS spontaneously migrated in 4/18 cases, one had been removed for incomplete bleeding control and substituted after 3 days, and 13 were easily removed as per protocol. In two cases FCMS were removed and a plastic double pig-tail stent was put in place, for persistent choledochal distal stenosis.

Conclusion: These cases represent a large collection of evidence showing that treating post-sphincterotomy early bleeding with FCMS is feasible, safe and effective. Late bleeding associated with needle-knife pre-cut was much harder to control and required endoscopic revision, intensive care unit support and re-stenting. Our results are consistent with and support previous research in the field.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0926 EFFICACY OF SELF-EXPANDABLE METALLIC STENT PLACEMENT IN THE MANAGEMENT OF ANASTOMOTIC STRICTURE AFTER ORTHOTOPIC LIVER TRANSPLANTATION

S. Jang, M. Parsi, R. Lopez, A. Bhatt, J. J. Vargo

Gastroenterology, Cleveland Clinic, Cleveland/United States of America/OH

Contact E-mail Address: jangs@ccf.org

Introduction: Anastomotic bile duct stricture (ABS) remains as one of the most common complications after orthotopic liver transplantation (OLT). Current standard of practice of endoscopic retrograde cholangiopancreatography (ERCP) with insertion of multiple plastic stents (PS) often requires multiple procedures before achieving satisfactory stricture resolution. In recent years, studies utilizing covered self-expandable metallic stent (cSEMS) in refractory ABS management reported varying degree of success.

Aims & Methods: The aim of this study was to analyze efficacy of SEMS in resolution of anastomotic stricture in patients with orthotopic liver transplantation. In addition, we sought to identify factor(s) influencing the likelihood of stricture resolution, the rate of adverse outcome(s). A retrospective cohort study was conducted using a registry of consecutive patients who underwent ERCP with biliary SEMS placement from January of 2010 to November of 2016 for the management of refractory ABS. Demographic variables including age, gender, and clinical variables including body mass index (BMI), number or prior ERCP with PS insertion, stent brand and dimensions and duration of SEMS insertion period were collected. The rates of stricture resolution, adverse outcomes

including post ERCP pancreatitis, cholangitis and stent dysfunctions (occlusion, and) migration) were calculated. This study was approved by the Institutional Review Board of the Cleveland Clinic.

Results: There were 47 OLT patients who underwent ERCP-cSEMS insertion for refractory ABS during the study period. Of 47 patients, 37 patients (78.8%) achieved stricture resolution after single SEMS treatment. Longer duration of SEMS insertion was the only variable associated with increasing probability of stricture resolution as there was 20% increase in odds of stricture resolution for every additional week SEMS was in place. Among those who achieved initial stricture resolution, 27 patients (73%) maintained bile duct patency throughout the follow up period. The most common adverse outcome was internal migration of cSEMS which occurred in 11 patients (23.4%). Post-ERCP pancreatitis was observed in 3 (6.4%) patients.

Conclusion: The efficacy rate observed in resolving refractory ABS with cSEMS placement appears to be comparable to that of multiple ERCPs with PS placement method. Furthermore, durability of ABS resolution with cSEMS use further supports its potential long-term efficacy. Hence, cSEMS should be considered as a viable alternative treatment of refractory ABS. Longer stent insertion period is associated with higher likelihood of ABS resolution. The high rate of internal migration observed with SEMS warrants further endeavor in stent design improvements.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Disconnected pancreatic duct (DPD) can occur in patients after drainage of pancreatic fluid collections (PFC). Concerns have been raised about clinical relevance of DPDs.

Aims & Methods: To assess the frequency of DPD and its clinical significance after EUS guided drainage of PFC. Patients of acute or chronic pancreatitis with symptomatic PFC, who underwent Endoscopic Ultrasound (EUS) guided drainage between January 2011 to December 2016 were included, after an informed consent. Stents used for drainage procedure were either bi-flanged metal stent (BFMS) or double pigtail plastic stent. All these patients underwent MRCP between 4 to 8 weeks after drainage to evaluate pancreatic duct (PD) anatomy and confirm resolution of PFC. Subsequently, they had Endoscopic Retrograde Pancreatography (ERP) and, if required, stent removal. BFMS was removed in all patients. Plastic stents were retained indefinitely, if DPD was confirmed. All patients were systematically followed at 3–6 monthly intervals for any recurrence of PFC or new onset clinical event.

Results: A total of 407 patients (346 males, mean age 33.5 years, range 5–69 years) were followed up after EUS guided drainage for PFC. Of these 260 underwent BFMS and 147 underwent plastic stents placement. 319 patients had pancreatogram (ERP and MRCP) after resolution of PFC. The pancreatic duct abnormalities observed were as follows: DPD in 197 (61.7%), PD leak in 36 (11.3%), PD stricture in 20 (6.3%) patients. Normal PD was seen in 43 (13.5%) patients. Calcific pancreatitis was noted in 23 (7.2%). Among the patients with DPD, the location of PD “cut off” was in head (32, 16.2%), genu (59, 29.9%), body (90, 45.6%) and tail (16, 8.1%). Overall, the follow-up after stent removal ranged from 3–72 months, with a median follow up of 12 months. Pseudocyst recurred in 29 patients (8.5%) at a mean follow up of 3.5 months (range 1–30 months), which included DPDS 27, PD stricture 1, and CCP 1. 20/29 had pain (symptomatic) and rest 9 were asymptomatic. 15/20 underwent intervention (EUS drainage with plastic stent in 12, surgery in 3) and 5 resolved spontaneously.

Conclusion: Disconnected Pancreatic Duct is observed in 60% patients following EUS guided drainage of PFC. However, only a small proportion (<10%) of DPD had symptomatic recurrent fluid collection.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0928 FULLY COVERED SELF-EXPANDABLE METAL STENT IN THE MANAGEMENT OF DUODENAL RETROPERITONEAL PERFORATIONS DURING ERCP: A SINGLE CENTER EXPERIENCE

M. Pizzicannella¹, G. Andrisani¹, M. Martino¹, R. Rea¹, M. Pandolfi¹, F.M. Di Matteo¹

¹Digestive Endoscopy Unit, Campus Bio Medico, Rome/Italy

Contact E-mail Address: f.dimatteo@unicampus.it

Introduction: ERCP-related perforation is rare (0.39%), but it is associated with an overall mortality of 7.8%. Duodenal retroperitoneal perforation (Type II) is the most frequent, among the ERCP-related perforations. The management of this complication has not been standardized yet: traditionally surgery was considered the only rescue therapy, but in the last years the majority of cases has been managed conservatively. The endoscopic treatment included biliary stent and/or nasobiliary drainage. In our institution, from 2010 we have been using fully covered self-expandable metallic stent (FCSEMS) with nasobiliary drainage always after resolution of the initial indication for ERCP. These stents have the advantage of covering the laceration and allowing free flow of bile into the duodenum instead of into the retroperitoneal space. The aim of this study was to evaluate in our cohort of patients, the benefits of FCSEMS in type II perforations

Aims & Methods: We experienced six type II perforations associated with ERCP. We retrospectively evaluated the clinical findings, the length of hospital stay, the need for surgery and death.

Results: Of the 3250 ERCP procedures performed from March 2010 to November 2016, only six (0.18%) resulted in perforations (male/female, 2/4; median age: 69 years; age range: 54–80 years). ERCP procedures were performed with carbon dioxide insufflation. Five patients underwent ERCP for biliary stones. In all cases standard sphincterotomy was performed and perforation was immediately detected. Successful closure of persistent sphincterotomy-related duodenal perforation using FCSEMS was obtained in all patients. One patient developed ERCP-related pancreatitis, successfully treated with medical therapy. Three FCSEMS were successfully removed after a median of 18 days, the remaining three fell out spontaneously. The median length of hospital stay was 8.5 days (range 4–20 days). There were no deaths or need for surgery.

Conclusion: The placement of FCSEMS is easy, safe and quick. In our cohort of patients, FCSEMS is the effective endoscopic approach for management of type II perforations recognized during ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Duodenal obstruction is often seen in patients with advanced pancreatic cancer (APC). Endoscopic duodenal stenting (DS) has become increasingly popular due to its less invasiveness compared with surgical gastrojejunostomy. With recent new advances in chemotherapy and radiation therapy, conversion surgery after neoadjuvant therapy are performed in some cases with APC.

Aims & Methods: To evaluate the efficacy and safety of DS as palliative treatment and bridge to surgery in patients with APC. We retrospectively analyzed patients who received DS placement between March 2012 and March 2017. Twenty-three patients (11 men/12 women median age, 65.9; 46–82 years) with APC. GOO scoring system (GOOSS) was used as an index of clinical success.

Results: A total of 23 Patients consisting of 6 patients treated with chemotherapy and 11 patients treated with neoadjuvant chemoradiotherapy were included in

this study. Obstructed parts of the duodenum were D1 in 2, D2 in 5, D3 in 12, and D4 in 4. Technically success of DS was achieved in 100% of patients. The mean GOOSS before DS and after DS were 0.5 and 2.6 respectively ($p < 0.001$). The median time to restart soft solid meal after DS was 2.9 days. Biliary obstruction was seen in 13 patients and managed with endoscopic biliary stenting. Adverse events occurred in 6 patients, including 1 with cholangitis, 1 with bleeding and 3 with stent occlusion. The reintervention technical and clinical success rates were 100% (5/5) and 80% (4/5), respectively. The median survival time after DS was 159 days. In neoadjuvant chemoradiotherapy patients, 4 patients were performed surgery for APC.

Conclusion: DS in patients with APC was effective and safe. The findings of this study suggest that DS is worth considering as the bridge to surgery in patients receiving neoadjuvant therapy.

³Dept. Of Gastroenterology, University of Tokyo, Tokyo/Japan

Contact E-mail Address: rei1484@gmail.com

Introduction: Endoscopic stenting with self-expandable metallic stents (SEMS) has become widely accepted for an alternative to emergency surgery in the management of malignant large bowel obstruction (LBO) after the initial introduction of SEMS in 1991. Recent years, advance in procedural equipment and accumulation of experience have improved technical success rate in colonic stenting for malignant LBO. However, there is still a divergence in the success rate of technical and clinical.

Aims & Methods: The aim of this study is to clarify the factors that reduce clinical success rate of stent placement. This study was conducted by a retrospective chart review at a single center. The endoscopy database and clinical records from the University of Tokyo Hospital, Tokyo, Japan, were reviewed retrospectively between May 2007 and February 2017. Patient's symptoms, characteristics, clinical data were obtained from electric medical record. The obstructions were diagnosed clinically and radiologically and were evaluated by the Colorectal Obstruction Scoring System (CROSS). Technical success was defined as deployment of a stent across the entire length of the stricture on the first attempt. Clinical success was defined as resolution of symptoms and radiological relief of the obstruction within 24 hours, as confirmed by radiographic observations.

Results: A total of 172 patients (91 males, 81 females; mean age 66.9 years) underwent colonic stenting for malignant LBO. This procedure was performed to 80 colorectal cancer (CRC) patients (48%) and to 92 patients (52%) with cancer of other etiology. Stenting was performed as a bridge to surgery (BTS) therapy in 33 patients (19.2%), whereas stenting was planned palliative procedure in 139 patients (80.8%). Sixty-seven patients (39%) had a tumor causing obstruction in the proximal colon, and 105 patients (61.0%) in the distal colon or rectum. The mean length of obstruction was 6 cm, and obstruction of 60 patients (34.9%) longer than 6 cm. The technical and clinical success rate was 98.8% and 89.5%, respectively. Clinical success rate dropped from 98.9% (91/92) to 78.8% (63/80) when the obstruction caused by extra-colonic malignancy (ECM) ($p < 0.05$). There was also reduction of clinical success rate from 99.1% (111/112) to 71.7% (43/60) in all patients ($p < 0.05$) when attempting to stent lesions of longer than 6 cm. Clinical success rate was 85.7% (90/105) and 95.5% (64/67) ($p < 0.05$) when the patient had obstruction of distal colon or rectum vs in proximal colon. In multivariate analysis, placement in distal colon or rectum, obstruction by ECM, and obstruction longer than 6 cm were independent risk factors associated with lower clinical success rate (odds ratio [OR] 3.19; 95%CI 0.96–10.6, [OR] 24.5; 95%CI 3.19–189.3, [OR] 31.7; 95%CI 4.32–232.7).

Conclusion: The placement of SEMS for malignant LBO is safe and effective, but clinical success rate drops in the cases with obstructions of distal colon or rectum, longer than 6 cm, or caused by ECM. Considering the indication of colonic stenting for malignant LBO, these factors should be evaluated before procedure.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0931 THE CLINICAL EFFICACY OF MITOMYCIN-C INJECTION THERAPY IN REFRACTORY BENIGN ESOPHAGEAL STENOSIS: A PRELIMINARY STUDY

S.G. Lim¹, J. Kim¹, K.M. Lee¹

¹Gastroenterology, Ajou University School of Medicine, Suwon/Korea, Republic of

Contact E-mail Address: mdlsk75@gmail.com

Introduction: Refractory Esophageal Stenosis (RES) definition differs among studies. Unresolved benign esophageal stenosis even after 5 or more sessions of endoscopic dilation therapy in most studies. Until now, there have been no treatment showing the satisfactory results. Mitomycin C (MMC) inhibits DNA synthesis/reduces fibroblastic collagen formation. Tried in RES in several studies. The meta-analysis about treatment of refractory gastrointestinal stenosis with MMC in total 24 studies. The most commonly reported site esophagus (79%). Only 9 recruited adult patients (n=38). Of these, 23 patients were RES.

Complete/partial response of MMC for RES patients: 59.5%/40.5%, respectively.

Aims & Methods: The aim of this study was to evaluate the clinical efficacy of MMC injection therapy in patients who had refractory benign esophageal stenosis. Between October 2013 and February 2016 Enrollment criteria: Patients with refractory benign esophageal stenosis who did not respond even after five or more endoscopic dilation therapy. The patients should be more than eighteen year old. Exclusion criteria: Malignant esophageal stenosis, Pregnant or breast feeding women, Deteriorated patients who could not tolerate endoscopic procedures. The method of MMC application –Via 23 gauge injection needle (Optimos injector, Taewoong Medical, Korea) –4 mL of saline-diluted MMC was prepared, with concentration of 0.5 mg/mL –Injection of 0.5 mL MMC at eight points of the stenotic site immediately after bougienage. Follow-up –Interview After 1 week and every four weeks after MMC injection upto 52 weeks. Endoscopy Four weeks after MMC injection and when the obstructive symptoms appeared. Primary end-point –The rate of clinical success. Secondary end-points –The mean score of GOOSS before and after MMC injection therapy, Complication rates. Definition –Clinical success: Improvement of GOOSS score more than one point after MMC injection therapy, compared before MMC injection

Results: Ten patients with refractory benign esophageal stenosis were initially enrolled. Two patients were excluded due to death from hypovolemic shock due to persistent bleeding and esophagectomy as patient's wish. Finally, Eight patients were analyzed. The rate of clinical success of MMC injection therapy in patients with refractory benign esophageal stenosis was 87.5%. Mean scores of GOOSS were significantly reduced after MMC injection therapy, from 2.5 to 0.29. In all patients, MMC injection therapy below two sessions was needed to improve the symptoms of enrolled patients. Major complications did not occur in any patients.

Table 1: Outcomes of MMC injection therapy

Variables	values
Number of Bougie dilation before MMC injection 5/6/7/8/9	5/1/0/1/1
The number of session of MMC injection 1/2	3/5
Mean GOO score before MMC injection	2.5
Mean score of GOOSS after final MMC injection	0.29
Mean diameter of stenosis before MMC injection, mm	5.2
Mean diameter of stenosis 3 month after final MMC injection, mm	8.9
Clinical success rate (%)	87.5
Complications (N,%) perforation bleeding requiring transfusion of other interventions others	0(0) 0(0) 0(0)

Conclusion: In our study, the mitomycin injection therapy was effective in patients who had retractable benign esophageal stenosis. The mitomycin injection therapy could be considered as an alternative for retractable benign esophageal stenosis. A large-scale prospective studies are required in future.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0932 TREATMENT WITH MULTIPLE REABSORBABLE STENTS OF COMPLETE AND PARTIAL LOWER GI ANASTOMOSIS DEHISCENCE AND STENOSIS

P. Gambitta¹, S. Pallotta¹, F. Iannuzzi¹, E. Bareggi¹, A. Ballerini¹, A. D'Alessandro²

¹Digestive Endoscopy, ASST Fatebenefratelli- Sacco, Milan/Italy

²Clinical Medicine And Surgery, University of Naples Federico II Clinical and Experimental Medicine, Naples/Italy

Contact E-mail Address: rasmusklump1974@gmail.com

Introduction: Anastomotic stenosis or dehiscence are serious complications of colorectal surgery. Colostomy or ileostomy and later redo anastomosis or

Hartmann's procedure are the mainstay of therapy, but edema and inflammation due to abdominal sepsis or later adhesions can prevent the use of standard management, and therefore alternative salvage repair methods may be required. Reabsorbable polydioxanone stents are a proposed method but with still debatable results in terms of correct placement, clinical success, early and late stenosis, stent migration, perforation, bleeding, fecal incontinence and local pain.

Aims & Methods: We report here on the use of reabsorbable polydioxanone stents (RPS) in colorectal anastomotic stenosis or dehiscence. We treated with RPS placement, endoscopic dilation and daily mesalazine enemas and/or suppositories 5 complex cases since 2015. Endoscopy was repeated 1 month after and then every two months or earlier if needed. Endoscopic dilation and progressive apposition of partially overlapping stents were repeated until a stable lumen was observed. During follow-up the patients were treated with local mesalazine.

Results: 5 Patients (3 M/2F), age (49 years mean; range 23–70) were informed of the off-label use of stents and treatment approval by the local ethical committee. See table 1. Technical initial success was 100%. We did not dilate patients with dehiscence prior to stent placement. After the first RPS we could deploy a 2nd (100%, average 3.5 – range 1.5–6 months) and a 3rd stent (40%, average 11, range 7.5–14.5 months). Later, after 2.5–15.5 months, lumen was stable and restored. Granulation tissue in-between stent fibers produced early stenosis, treated by re-stenting. 1 stent prolapsed partially from the anus and was shortened with scissors. Bleeding was not present. Pelvic pain in all the patients needed NSAIDs and reduced over time.

Conclusion: These cases show that stenting with RPS of anastomotic dehiscences is feasible, safe and effective. Due to restenosis associated with dehiscence multiple stents were needed. Distal migration was easily managed. Distal anastomoses might explain the presence of pelvic pain. 3 patients have been subjected to recanalization without complaints.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0933 EVALUATION OF FACTORS ASSOCIATED TO A SUCCESSFUL DILATION IN POST-ESD STRICTURES

E. Perez-Cuadrado-Robles¹, H. Piessevaux¹, T. Moreels¹, R.C.P. Yeung¹, E. Danse², P.H. Deprez¹

¹Department Of Gastroenterology, Cliniques Universitaires Saint-Luc, Brussels/ Belgium

²Radiology, Cliniques Universitaires Saint-Luc; Université Catholique de Louvain, Brussels/ Belgium

Contact E-mail Address: kikemurcia@gmail.com

Introduction: The prevalence of post-ESD esophageal strictures is non-negligible, with a critical impact on the patients' quality of life. Balloon-dilation may be the first-line therapy. However, factors associated to a successful dilation in post-ESD strictures remain unclear.

Aims & Methods: This is an observational and analytical retrospective study. Sixty-eight consecutive patients (mean age: 65 ± 11y, 76.5% men) who underwent endoscopic dilation because of post-ESD symptomatic esophageal strictures between 2006 and 2016 were included. They had Barrett's esophagus (n=46, 67.6%), epidermoid carcinoma (n=21, 30.9%) and other (n=1). Patients with previous endoscopic dilations or resections, esophageal surgery, radiotherapy or motor disorders were excluded. Clinical, morphological and technical features were collected and analysed to determine the factors associated with a positive outcome, defined as the absence of dysphagia during at least twelve months following last dilation. The need of surgery, gastrostomy or prosthesis was considered as negative.

Results: Resected lesions (95.6% en-bloc) presented a median size of 52.5 mm (range: 22–110) and achieved ≥75% of the circumference in 50% of cases (p=0.435). They were mostly located in inferior esophagus (70.6%, p=0.231) and required two endoscopic sessions in 8 patients (11.8%). Oral and injected corticoids were used in 11 (16.2%) and 12 (17.6%) cases, with no effect in outcome (p=0.181/0.282). No specific factor could be associated to a better outcome (median follow-up: 23 months): early dilation (≤15days after ESD), number of dilations (p=0.345), short (≤2cm) stenosis (p=0.319), balloon diameter (p=0.475) and Barrett's vs. squamous cell carcinoma (p=0.458). The overall positive outcome rate was 92.6% after a median of 3 (range: 1–27) dilations and 5 months of treatment (1 dilation/6.7weeks). A prosthesis was placed in 4 patients with clinical improvement in two of them. There were 3 complications (4.4%, all perforations).

Conclusion: Most of patients presenting with post-ESD strictures and dysphagia improve at long-term but they need a median of 3 sessions. No specific factor was associated to a better outcome.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0934 EFFECTIVENESS OF REPEATED DILATIONS IN THE MANAGEMENT OF ESOPHAGEAL BENIGN STRICTURES

A. Benezech, A. Debourdeau, J. Gonzalez, M. Barthet

Service De Gastroentérologie, Assistance Publique - Hôpitaux de Marseille, CHU Nord, Marseille/France

Contact E-mail Address: alban.benezech@ap-hm.fr

Introduction: Refractory or recurrent esophageal benign strictures (REBS) are frequent, and defined as the impossibility to reach or maintain a diameter of 14 mm after 5 sessions of endoscopic dilation (ED). Because of a lack of guidelines, their management remains challenging, sometimes leading to radical surgical procedure.

Aims & Methods: The aim of this study was to define the efficacy of long-term and repeated ED in the management of REBS. This was a monocentric retrospective study involving patients managed in our tertiary center between January 2002 and April 2017 for REBS. All the endoscopic dilations were performed using Savary bougies or hydraulic balloons, depending on the operator's choice. Demographical and clinical data were recorded for each patient. The endoscopic management was detailed with the number of procedures, the endoscopic device used, the diameter of dilation, and potential concomitant treatment (as self-expanding metal stent, steroid injection or incisional therapy). The primary endpoint was the efficacy of sustained and recurrent ED, defined as the absence of further dilation within 3 months of the last procedure or an interval between the 2 last ED greater than 3 months. A failure was considered in case of death, need for surgery, permanent enteral feeding tube or an interval between the last 2 procedures lower than 3 months. The secondary endpoints were to document the characteristics of dilation procedures and concomitant treatments, the decreasing of the number of dilations per trimester, and to elucidate potential predictive factors for success of ED.

Results: A total of 39 patients (23 men) with a mean age of 47.5 ± 20.7 years were included. The etiologies of strictures were anastomotic (46.1%), caustic (28.2%), peptic (10.3%) or other etiologies (radiation injuries, esophageal diverticulectomy, severe viral esophagitis, 15.4%). A clinical success of repeated ED was achieved in 27 patients (69.2%). Twelve patients (30.8%) experienced failure, among them seven (17.9%) required frequent dilatations, two (5.1%) underwent surgery, two (5.1%) maintained an enteral feeding tube, and one patient (2.6%) died consecutively to inhalation pneumonia. A mean of 9.8 ± 4 ED sessions were performed per patient, with a mean treatment duration of 22.6 ± 20.1 months. Regarding concomitant treatments, 16 patients (41%) had at least one fully-covered metallic stent placement, incisional therapy was performed in 11 patients (28.2%), and 3 patients (7.7%) received corticosteroid injections. The number of dilations per trimester gradually decreased over time. No significant predictive factor of success was found, such as etiology of stricture or the use of concomitant treatment, particularly. Nevertheless, a greater number of dilations during the first trimester could promote the success of the management (3.2 ± 2.2 dilations in the success group vs 2.2 ± 0.8 in failure group, $p=0.056$).

Conclusion: Repeated and maintained endoscopic dilations are effective (70%) in the management of REBS, regardless of the etiology of stricture. A prolonged management up to 2 years, and the initial rhythm of endoscopic procedures may

favor the final success. A systematic schedule for ED would improve the efficacy of this management.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0935 EFFICACY AND SAFETY OF NEWLY DEVELOPED ENDOSCOPIC COLONIC STENTS WITH AN INCREASED EXPANDABLE FORCE: A RETROSPECTIVE COMPARISON WITH CONVENTIONAL COLONIC STENTS

Introduction: Endoscopic stenting with self-expandable metallic stents (SEMSs) is a widely accepted procedure for treating malignant colonic obstruction. This procedure was covered by the National Health Insurance of Japan in January 2012, and the WallFlex colonic stent and Niti-S colonic stent can currently be used in Japan. In the previous study, we reported that the WallFlex colonic stent has more expanded force than the Niti-S colonic stent. On the other hand, the risk of stent-related perforation was lower when using the Niti-S stent due to its structure. Currently, we newly developed an SEMS (Niti-S structure, with 18-mm diameter with increased expanded force compared with the conventional type), which comprised the benefits of both WallFlex and Niti-S. In this study, we compared the efficacy and safety of the newly developed colonic stent with the conventional colonic stents.

Aims & Methods: This study aimed to compare the efficacy and safety of the newly developed colonic stent with the conventional colonic stents (the WallFlex colonic stent and the Niti-S colonic stent). Overall, 91 patients (96 lesions, male/female: 48/43, average age: 73.2 years) underwent endoscopic SEMS placement between November 2011 and March 2017 at Kure Medical Center and Chugoku Cancer Center. The WallFlex colonic stent was used in 36 patients (38 lesions: Group W), the Niti-S colonic stent in 51 patients (53 lesions: Group N), and the newly developed colonic stent in 5 patients (5 lesions: Group D). Stratified analysis of the clinical background, technical success rate, procedure time, clinical success rate, and complications was performed to compare Group W, Group N, and Group D.

Results: Endoscopic SEMS placement was attempted in 96 lesions as a bridge to surgery (BTS) in 52 lesions (54%) and as palliative therapy (PAL) in 44 lesions (46%). In Group W, SEMS was placed in 19 lesions (50%) as BTS and in 19 lesions (50%) as PAL; in Group N, SEMS was placed in 32 lesions (60%) as BTS and in 21 lesions (40%) as PAL; and in Group D, SEMS was placed in 1 lesion (20%) as BTS and in 4 lesions (80%) as PAL. The technical success rate was 100% in all groups. The overall clinical success rate was 93.7% (90/96): 89.5% (34/38) in Group W, 96.2% (51/53) in Group N, and 100% (5/5) in Group D. Complications within 7 days included abdominal pain (3/38, 8%), poor

expansion (1/38, 3%), and fever (1/38, 3%) in Group W and perforation due to obstructive colitis (2/53, 4%) in Group N. Complications after 8 days included stent-related perforations (4/38, 11%) and stent occlusion (1/38, 3%) in Group W and stent occlusion (2/53, 4%) in Group N. All 4 patients with stent-related perforations had undergone palliative stenting with the WallFlex colonic stent, and the stent-related perforation rate in Group W was significantly higher than that in Group N ($P < 0.05$). In Group D, there were no complications and no stent occlusion.

Conclusion: The technical and clinical success rates were extremely high in all groups. The risk of stent-related perforation was higher when using the WallFlex stent, while there was also perforation due to obstructive colitis when using the Niti-S stent. On the other hand, there were no complications when using the newly developed endoscopic colonic stent with an increased expanded force. Although these results were obtained for a limited sample size, this new stent is expected to exhibit more efficacy and safety than conventional colonic stents.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Heller-Dor operation is a radical treatment for cases of esophageal achalasia. However, postoperative recurrence of symptoms is observed in some cases. Conventionally, repeat surgery or endoscopic balloon dilatation is additionally performed on such cases. Repeat surgery is associated with issues related to adhesion, whereas endoscopic balloon dilatation is associated with issues related to effect reliability and constancy. Peroral endoscopic myotomy (POEM) is a new endoscopic treatment that was first reported by Inoue et al. in 2008. POEM can be accomplished normally without being affected by the previous Heller Dor operation, if POEM is performed at the contralateral site of the previous myotomy. Moreover, POEM enables making a long myotomy that cannot be made in laparotomy. At our hospital, we have performed POEM on 12 cases that previously underwent the Heller-Dor operation. Herein, we report on the treatment outcomes.

Aims & Methods: We performed POEM on 210 cases between September 2011 and April 2017. Of those cases, 12 cases (5.7%) had previously undergone Heller-Dor operation. The treatment outcomes were retrospectively investigated. The reasons for the relapse of the symptoms were investigated based on the results of medical interview, endoscopy, esophagography, esophageal manometry, and 24-hour PH monitoring test.

Results: The POEM cases that previously underwent Heller-Dor operation included 8 men and 4 women with the mean age of 54.8 ± 15.4 years. As regards the cause for the recurrence of symptoms, the lower esophageal sphincter was the responsible lesion in 10 patients, the esophageal body in 1 patient, and another reason in 1 patient. POEM was performed by incising the posterior wall in all cases, and the treatment was not prematurely discontinued for any cases. The mean length of the muscular layer incision was 14.3 ± 6.1 cm on the esophageal side and 2.8 ± 1.0 cm on the gastric side. The mean surgical duration was 136.5 ± 35.6 minutes. No accidental symptom associated with POEM was observed. The integrated relaxation pressure was preoperatively 22.1 ± 8.6 mmHg and 13.6 ± 5.4 mmHg. The Eckardt score was 4.1 ± 2.5 preoperatively, 0.67 ± 1.1 at 3 months after the surgery, and 1.0 ± 1.2 at 12 months after the surgery ($P < 0.05$). The symptoms improved in all cases.

Conclusion: The treatment outcomes of the POEM performed on cases that previously underwent Heller-Dor operation were favorable. POEM differs from repeat surgery by laparotomy as it can be used to perform a long muscular layer incision without adhesion if an appropriate route is used. The major advantages of POEM are the reliability and constancy of the effectiveness compared to endoscopic balloon dilatation. POEM is a very effective treatment method for cases for which Heller-Dor operation has not been sufficiently effective.

Introduction: Postoperative immunosuppression in transthoracic esophagectomy for patients with esophageal cancer is a common finding [1]. In fact, both transhiatal and transthoracic esophagectomy induce severely depressed monocyte and

T-lymphocyte cytokine production [2]. Remarkably, lymphopenia is an independent predictive factor for long-term survival in patients with esophageal cancer [3].

Aims & Methods: The aim of this study was to assess the predictors of postoperative immune suppression in esophageal or esophago-gastric junction cancer. One hundred ninety three consecutive patients with esophageal or esophago-gastric junction cancer were enrolled in this retrospective study. White blood cells count, polymorph nucleate cells and lymphocytes counts were observed at preoperative time, post-operative day (POD) 1, 3 and 7. Post-operative outcome details were also retrieved. Multiple regression models were fitted to the data to test the association between potential predictors and preoperative lymphopaenia and lymphopenia on POD1 as parameters of immune suppression. **Results:** The preoperative lymphocyte count was 1, 240/ml (IQR: 0.895–1.700) while the lymphocyte count on POD1 was 0.670/ml (IQR: 0.500–0.982), $p < 0.001$; on POD3, it was 0.800/ml (IQR: 0.580–1.070), $p < 0.001$; and on POD7, it was 0.825/ml (IQR: 0.550–1.180), $p < 0.001$. In a model that also included the interval between the end of neoadjuvant therapy and the esophagectomy and the preoperative whiteblood cells count, only the final dose of radiotherapy resulted to be an independent predictor of preoperative lymphocyte count. Similarly, in a model that also included the interval between the end of the neoadjuvant therapy and the esophagectomy, the number of surgical accesses (laparotomy, thoracotomy and cervicotomy) and the number of nodal metastasis, only the final dose of radiotherapy resulted to be an independent predictor of lymphocytes count on POD1.

Conclusion: Patients with esophageal and esophago-gastric junction cancer present a significant post operative immunosuppression that lasts at least for the first postoperative week. The total amount of radiation received by the mediastinum is the only predictor of the preoperative and postoperative lymphocyte count.

Introduction: Surgery and endoscopic stapling have been the mainstay of treatment modalities for Zenker's diverticulum. The need for general anesthesia (GA) is however a limiting factor in high-risk patients, as patients with ZD are often elderly with cardiorespiratory co-morbidities. In recent years, flexible endoscopic septum division (FESD) has gained popularity as a less invasive treatment modality for ZD, that can be performed under deep sedation, and has the potential to be performed safely in patients otherwise deemed unfit for full GA.

Aims & Methods: The aim of this pilot study was to assess the efficacy and safety of FESD for patients deemed unfit for GA. Patients had been referred to our tertiary centre for FESD. Data on 14 consecutive day case patients (median age 81, range 67–95, 7 females) with an ASA score of 3 that underwent FESD between August 2015 and November 2016 were collected retrospectively. All patients underwent FESD under deep sedation with propofol and remifentanyl, and did not require ventilatory support. The amount of propofol used was recorded. Demographic data as well as information of the nature of symptoms and recurrences was retrieved. The severity of dysphagia was measured with the Dakkak scale. Data on procedural and 30-day post-procedural complications, including sedation-related side effects, were collected

Results: All patients complained of dysphagia (median Dakkak score 2, range 1–3) and regurgitation before the procedure. There were no procedure-related nor sedation related adverse events in any of the patients. There were no 30-day post-procedural adverse events. All patients but one experienced complete symptom relief after one treatment session. Median propofol used was 173 mg (range 59–

330 mg). One patient required an additional treatment session due to persisting dysphagia (score 1) to achieve symptom remission. This was carried out without complications.

Conclusion: Our results suggest that FESD is a safe, feasible and effective treatment in high risk patient who are otherwise not suitable for GA, and can be performed as a day case in an endoscopy unit. It is less invasive hence should be considered as a preferred option over endoscopic stapling. Close interaction and team working with anesthesiologist is important to ensure a safe outcome

Disclosure of Interest: All authors have declared no conflicts of interest.

P0939 INCREASING LYMPH NODE RETRIEVAL IN ESOPHAGECTOMY, OUTCOMES OF THE DUTCH UPPER GASTROINTESTINAL CANCER AUDIT

Introduction: To improve the quality of esophageal cancer surgery in the Netherlands, the number of retrieved lymph nodes (LNs) is evaluated in one of the quality indicators in the Dutch Upper gastrointestinal Cancer Audit (DUCA). (1) All hospitals in the Netherlands can use the outcomes of the DUCA indicators to monitor their own results in relation to the national average. The aim of this study was to analyze the outcomes of the quality indicator: 'a minimal number of 15 retrieved LNs' in the past years and to determine factors associated with this outcome.

Aims & Methods: Patients with an esophageal carcinoma who underwent an esophagectomy with curative intention and who were registered in the Dutch Upper gastrointestinal Cancer Audit between 2011–2016 were included in this retrospective national cohort study. The primary outcome: 'percentage of patients with ≥ 15 LNs' was analyzed by year and hospital. Factors tested with univariable and multivariable analysis for the association with ≥ 15 LNs were: age, Charlson score, weight loss, BMI, cT-, cN-, cM-stage, tumor location, neo-adjuvant therapy, type of procedure, intraoperative complications, hospital volume and year of resection. The postoperative outcomes: radicality, intraoperative complications, morbidity, and mortality were tested on association with ≥ 15 LNs.

Results: The overall percentage of patients in the Netherlands with ≥ 15 LNs increased between 2011 and 2016 from 51% to 81%. The variation between hospitals decreased. Multivariable analysis showed an independent association with ≥ 15 LNs for the factors: cN2-stage (OR [95% confidence interval]: 1.37[1.05–1.79]), resection in a hospital with 26–50 or > 50 resections/year (reference: 0–25 resections, 2.03[1.57–2.63] and 3, 21[2.43–4.23]) and resection between 2012–2016 (reference: 2011, ORs: 1.55, 1.81, 2.43, 2.20, 2.64). Factors independent associated with < 15 LNs are: neo-adjuvant chemo-radiation-therapy (reference: no neoadjuvant therapy, 0.66[0.47–0.93]), intraoperative complications (0.55[0.39–0.80]) and open and minimally invasive transhiatal resections (reference: open transthoracic, 0.24[0.18–0.32]) and 0.38[0.26–0.55]). Postoperative morbidity and mortality were not associated with ≥ 15 LNs.

Conclusion: The outcomes of the quality indicator 'a minimal number of 15 retrieved LNs' is increased between 2011 and 2016. The variation between hospitals is decreased. The cN-stage, neoadjuvant therapy, type of procedure, intraoperative complications, year of resection and hospital volume seem to be associated with the outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0940 COLONIC INTERPOSITION AFTER OESOPHAGECTOMY IN ADULTS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE INFLUENCE OF CONDUIT CHOICE AND ROUTE ON OUTCOME

J. Brown¹, D. Chan², W. Lewis², G. Clark², G. Blackshaw², A. Foliaki²

¹Cardiff Medical School, Cardiff/United Kingdom

²General Surgery, University Hospital of Wales, Cardiff/United Kingdom

Contact E-mail Address: HawkinsJ12@cardiff.ac.uk

Introduction: Colonic interposition was first described as a method to create a neo-oesophagus in 1911 by Kelling and Vuillet, and in contemporary practice is usually only considered if the stomach is not a viable neo-conduit because of the associated high morbidity and mortality. There is no consensus on the optimum choice of colonic conduit (right vs. left) or the route of placement (posterior mediastinal, retrosternal or subcutaneous).

Aims & Methods: The aim of this review was to determine the optimum choice and route of conduit following colonic interposition after oesophagectomy in adults. PubMed, MEDLINE and the Cochrane Library (January 1985 to January 2017) were systematically searched for studies which reported outcomes of colonic interposition after oesophagectomy in adults. The primary outcome measure was overall morbidity and secondary outcome measure was operative mortality.

Results: Twenty-seven studies, involving 1849 patients (median age 60 years, 1177 males, 697 malignant disease) who underwent colonic interposition were analysed. The overall pooled morbidity rate of left vs. right colonic conduit was 9.6% [95% CI (6.24–12.87), $p < 0.00001$] vs. 16.5% [95% CI (11.07–22.02), $p < 0.00001$] respectively. The overall pooled mortality rate of left vs. right colonic conduit was 5.6% [95% CI (3.50–7.60), $p < 0.0001$] vs. 10.3% [95% CI (7.23–13.27), $p < 0.0001$] respectively. Retrosternal route placement was associated with the lowest overall pooled morbidity of 9.2% [95% CI (6.48–11.99), $p < 0.00001$], and lowest overall pooled mortality of 4.8% [95% CI (3.74–5.89), $p < 0.0001$].

Conclusion: Left colon is the conduit of choice for colonic interposition after oesophagectomy in adults and the retrosternal route should be favoured.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0941 THE ROLE OF LIVER RESECTION AFTER CHEMOTHERAPY FOR SYNCHRONOUS COLORECTAL LIVER METASTASIS

A. Ouchi, Y. Shimizu, K. Komori, Y. Senda, T. Kinoshita, S. Natsume, T. Ooshiro

Department Of Gastroenterological Surgery, Aichi Cancer Center Hospital, Aichi/Japan

Contact E-mail Address: akira.ouc@gmail.com

Introduction: The combination of chemotherapy and molecular targeted therapy has improved the outcome of patients with colorectal liver metastasis (CRLM); however, treatment outcomes of liver resection after preceding chemotherapy for CRLM, especially synchronous CRLM (sCRLM), remain unclear. For patients with technically resectable and oncologically suitable sCRLM, we conduct hepatic resection for the metastases at an interval of 3 months after colorectal resection, whereas for those with technically unresectable or oncologically unsuitable sCRLM, we perform preceding chemotherapy. The aim of this study was to retrospectively evaluate treatment outcomes of our strategy for sCRLM and explore prognostic factors for determining the indication for liver resection, particularly in patients receiving chemotherapy for sCRLM.

Aims & Methods: Between April 2006 and March 2016, 157 consecutive patients underwent primary tumor resection for sCRLM at our department; of them, 35 patients (S group) underwent subsequent staged liver resection, 109 patients received preceding chemotherapy, and remaining 13 patients received other treatments. Among those who received preceding chemotherapy, 25 patients (CS group) underwent liver resection after chemotherapy, but 84 patients (C group) could not undergo liver resection and continued ongoing chemotherapy. In the

CS group, 16 patients had unresectable disease (due to lack of remnant liver volume, invasion to hepatic hilar area, or invasion to three hepatic veins) and 9 initially had unsuitable disease (progressive primary disease or suspicion of other distant metastasis); therefore, upfront chemotherapy was selected.

Results: The frequency of adverse prognostic factors tended to be higher in the CS group than in the S group, e.g., tumor number (mean \pm SD: 6.0 ± 3.5 vs 2.7 ± 1.7) and number of metastatic lymph nodes (4.2 ± 6.3 vs 2.7 ± 2.3). Nevertheless, overall survival (OS) in the CS and S groups since primary tumor resection was equivalent (3-year survival rate: 86.9% vs 93.4%, Log-rank $P=0.34$) and much better than that in the C group (3-year survival rate: 40.2%). Although liver-limited relapse-free survival (RFS) since hepatectomy tended to be worse in the CS group than in the S group (3-year survival rate: 45.0% vs 62.7%, Log-rank $P=0.14$), RFS after hepatectomy was equivalent in the CS and S groups (3-year survival rate: 33.3% vs 21.6%, Log-rank $P=0.97$). Early tumor shrinkage (ETS) was found to be a stronger poor prognostic factor for liver resection after chemotherapy than existing prognostic factors in univariate and multivariate analyses, and RFS was much better in patients with ETS than in those with non-ETS (3-year survival rate: 62.5% vs 7.7%, Log-rank $P=0.05$).

Conclusion: OS and RFS in the CS group compared favorably with those in the S group despite the high frequency of poor prognostic factors; patients with ETS had a better prognosis after liver resection. Liver resection after chemotherapy revealed comparatively favorable prognosis in well-selected patients with sCRLM, and early responsiveness to chemotherapy was useful in determining the indication for liver resection in patients receiving chemotherapy for sCRLM.

Introduction: Hepatopancreatoduodenectomy associated with hemihepatectomy or more extended liver resection (HPD) is occasionally indicated in patients with advanced gallbladder or bile duct cancers, and is still a highly invasive surgical procedure. Feasibility of this invasive procedure for biliary cancers has not fully investigated.

Aims & Methods: The aim of this study is to review surgical outcome of HPD in terms of case series of a single surgeon at three Japanese tertiary referral centers. Consecutive one hundred one hepatobiliary resections with caudate lobectomy were carried out by a single surgeon (TS) at National Cancer Center, Tokyo, Aichi Cancer Center, Nagoya, and Aichi Medical University, Nagakute since 2002 and 2016. Of these 14 included 13 patients with bile duct cancer and one with gallbladder cancer underwent HPD were analyzed. Essentially, liver transection was performed in terms of Pean clamp crushing method under intermittent inflow occlusion and pancreatojunostomy was carried out in terms of duct to mucosa anastomosis.

Results: There were 9 men and 5 women. The median age was 66 years old (34–81). All patients underwent preoperative biliary drainage and 12 patients underwent preoperative portal vein embolization. As to the extent of liver resection, left hemihepatectomy was performed in 2, right hemihepatectomy in 11, and right trisectionectomy in 1 patient, respectively. Combined portal vein resection and reconstruction was carried out in 6 (42.9%), and hepatic arterial resection and reconstruction in one patients (7.1%). The median operation time was 822 minutes (518–992), and the median intraoperative blood loss was 1716 ml (730–2930), respectively. Although one patient underwent left trisectionectomy with segmental portal vein resection and reconstruction of 101 hepatobiliary resections resulted in the postoperative mortality (mortality rate 1.0%), HPD was accomplished with zero mortality in this studied period. Histologically, the proximal bile duct margins were confirmed positive for cancer cells in two patients with bile duct cancer (R1 resection). Four patients with bile duct cancer survived more than 5 years without evidence of tumor recurrence, on the other hand one patient with gallbladder cancer died from recurrence 7 months after the surgery. **Conclusion:** HPD may become a safe and potentially feasible surgical procedure for bile duct cancer, the indication of HPD for gallbladder cancer should be elucidated for further investigations in terms of large case series.

Introduction: Pancreatoduodenectomy (PD) is one of the operations associated with high rate of surgical site infection (SSI). The one of the reasons is said that SSI is associated with the preoperative biliary infection caused by preoperative examinations or drainage of biliary tract. In our clinical trial [1], SSI after pancreatobiliary surgery could be decreased by using the perioperative selective antibiotics based on preoperative bile culture. The bacteria cultured from SSI were Enterobacteriaceae such as *Enterococcus* and *Enterobacter* species with high frequency.

Recently, however, most of the patients who had planned to undergo PD received internal biliary drainage preoperatively. It means preoperative collection of the bile juice is hard for the patient with internal biliary drainage. In order to solve this problem, we compared the conventional perioperative prophylactic antibiotics (Cefmetazole: CMZ) and the broad-spectrum antibiotics covering the Enterobacteriaceae (Piperacillin/Tazobactam + Vancomycin: PIPC/TAZ + VCM), retrospectively. The aim of this study is to assess the impact of two types of perioperative antibiotics usage in patients undergoing PD.

Aims & Methods: Sixty-nine patients underwent PD at Hokkaido University Hospital (Japan) between April 2015 and March 2016, when prospective surgical site infection surveillance was performed. Thirty-eight patients were administered CMZ as perioperative prophylactic antibiotics from April 2015 to March 2016, and 31 were PIPC/TAZ + VCM from April 2016 to March 2017. CMZ was injected intravenously every three hours from the start of operation, and once after the operation. PIPC/TAZ was injected intravenously every three hours from the start of operation and three times on the next day of the operation, whereas VCM was injected intravenously in the morning of operation (20 mg/kg) and just after the operation (15 mg/kg).

Comparison between CMZ group and PIPC/TAZ + VCM group was performed to variables from clinical features (gender, age, body mass index, performance of neoadjuvant chemotherapy and preoperative biliary stent), operative outcomes (operation time and blood loss) and postoperative course (the incidence of SSI, the duration of postoperative antibiotics and postoperative stay). The side effects of VCM or PIPC/TAZ, and the occurrence of multidrug resistant bacteria were investigated, as well.

Results: There were no significant differences in clinical features and operative outcomes between the two groups. The patients with PIPC/TAZ + VCM received significantly shorter duration of postoperative antibiotics administration than the patients with CMZ (5.9 ± 8.5 vs. 13.0 ± 18.2 days; $p=0.048$). Significantly lower incidence of SSI was revealed in patients with PIPC/TAZ + VCM (9/31(29.0%)) than in those with CMZ (20/38(52.6%)) ($p=0.048$). Especially, significantly lower incidence of incisional SSI was revealed in patients with PIPC/TAZ + VCM (2/31(6.5%)) than in those with CMZ (14/38(36.8%)) ($p=0.004$). The redneck syndrome as one of the side effects of VCM was observed in 5/31 patients (16.1%). No multidrug resistant bacteria were identified.

Conclusion: The broad-spectrum perioperative antibiotics covering Enterobacteriaceae such as *Enterococcus* and *Enterobacter* species could decrease the incidence of SSI and duration of postoperative antibiotics administration compared to CMZ. More strict indication to select the patients who should be administered VCM, because the occurrence of side effects of VCM was relatively high.

Introduction: Gallbladder cancer is the fifth most common gastrointestinal malignancy and the most common of all biliary tract cancers. Overall, it is associated with a poor prognosis. Consensus guidelines suggest that patients with T1a cancers can be observed with cholecystectomy alone while patients with T1b or greater lesions should undergo lymphadenectomy in the hepatoduodenal ligament. Extent of surgery is especially important for those patients given efficient systemic therapy is lacking.

Aims & Methods: The aim of this study was to critically explore whether those suggestions hold true on a population-based level given that current evidence is mainly based on small patient series. Especially we assessed the rate of T-stage specific lymph node positivity and the impact of lymphadenectomy on long-term outcomes. The National Cancer Data Base of the United States was reviewed from 2004 to 2012 to identify non-metastatic gallbladder cancer patients with T1a, T1b, or T2 stage primary tumors. Patients were grouped by whether a dedicated lymphadenectomy was performed or not while those with missing information were excluded. Groups were compared for baseline characteristics. Predictors of dedicated lymphadenectomy were assessed by univariate and multivariable adjusted logistic regression with adjustment for important patient- and tumor characteristics. Overall survival was assessed using Cox proportional hazard regression analyses before and after full bipartite pairwise propensity score matching.

Results: Of the 3879 patients included, 287 (7.4%) had T1a, 661 (17.0%) T1b, and 2931 (75.6%) T2 gallbladder cancer. Most patients were female (n = 2751, 70.9%), median age was 72 years (range 21–90). Among patients with T1a, T1b, and T2 disease, 102 (35.5%), 278 (42.1%), and 1526, (52.1%) underwent a dedicated lymphadenectomy, respectively. Over the study period, the rate of lymph node excision increased from 43% to 58% (p for trend = 0.005). The rates of positive lymph nodes were 11.8%, 16.2%, and 42.5% for T1a, T1b, and T2-stage, respectively. 5-year overall survival rate was 31.6% for patients without and 44.6% for patients with a dedicated lymphadenectomy and 58.6%, 43.9%, and 34.5% for T1a, T1b, and T2-stage, respectively. After multivariable adjustment, the odds of undergoing a lymphadenectomy increased with tumor stage compared to T1a disease (vs. T1b: OR: 1.37; CI: 1.01–1.86, vs. T2: OR: 1.95; CI: 1.48–2.57). Compared to their counterparts, patients who underwent lymphadenectomy for gallbladder cancer were more likely to have had an R0 resection status, underwent chemo- or radiation therapy, were diagnosed in later years, were younger, had a lower Charlson-Deyo-comorbidity score, were operated in high volume centers and traveled a longer distance to the treatment facility. In univariate analysis, no survival benefit of lymphadenectomy was found for T1a disease (HR 1.04, 95%CI 0.70–1.54) while lymphadenectomy improved overall survival in T1b (HR 0.72, 95%CI 0.58–0.90) and T2 stage (HR 0.59, 95%CI 0.53–0.65). Given significant bias of undergoing lymphadenectomy, full bipartite, pairwise propensity-score matching was performed. A trend towards overall survival improvement was then also found for T1a disease (HR 0.65, 95%CI 0.39–1.09). Overall survival benefit remained for T1b (HR 0.68, 95%CI 0.51–0.91) and T2-stage (HR 0.63, 95%CI 0.55–0.71).

Conclusion: Our results support current consensus guidelines that T1b and T2 gallbladder cancer patients should undergo LA. However, based on the high rate of nodal positivity among patients with T1a disease and the trend towards overall survival improvement among T1a patients who underwent lymphadenectomy, we suggest to rethink this dogma and advocate to perform lymphadenectomy also in surgically fit patients with T1a disease.

P0945 RECTAL SWAB CULTURE CAN DIRECT ANTIMICROBIAL PROPHYLAXIS AND PREDICT THE RISK OF INFECTIOUS COMPLICATIONS AFTER PANCREATICOUDENECTOMY

M. De Pastena¹, S. Paiella¹, D. Ciprani¹, G. Marchegiani¹, A.M. Azzini², E. Concia², R. Salvia¹, C. Bassi¹

Contact E-mail Address: salvatore.paiella@univr.it

Introduction: Despite improvements in the perioperative care, the morbidity rate after Pancreaticoduodenectomy (PD) is still higher than 50%. In particular, infectious complications (ICs) occur in about one-third of cases. This study aims to examine the correlation between preoperative rectal swab (RS) and intraoperative bile cultures, and its impact on postoperative course of patients submitted to PD.

Aims & Methods: The institutional electronic database was queried for all consecutive PD performed from January 2015 to July 2016. Data were retrospectively analyzed. Based on the positivity/negativity of preoperative surveillance RS for multi-antibiotic resistant Gram-negative and Gram-positive enteric rods, the population was divided into two groups consequently compared (RS+ vs. RS-).

Results: Three hundred thirty-eight patients were considered for the analysis. Overall 50 patients (14.8%) showed a RS+. Preoperative biliary drain (PBD) was the only independent risk factor associated to RS+ (p = 0.021, OR 2.6). The groups statistically differed in the overall morbidity, ICs, sepsis, pulmonary complications, reoperation and mortality (p < 0.05). At multivariate analysis, ICs and mortality remained independently associated to RS+ (p = 0.013 OR 2.9, p = 0.009 OR 3.4, respectively). Bile-culture showed a perfect correlation (species and antibiotic susceptibility) with RS culture in 157 patients (86.7%). The most common microorganisms found were *E. Coli* ESB (6.6%) and *Klebsiella pneumoniae* carbapenemase-resistant (2.2%).

Conclusion: Preoperative RS-culture's positivity strictly correlates to biliary colonization with enteric rods that occurs after PBD. Infectious complications and mortality after PD are independently associated with a positive RS culture. Our study suggests that preoperative RS can direct antibiotic prophylaxis in order to reduce the burden of ICs and deadly events after PD.

P0946 EFFECT OF TRICLOSAN-COATED SUTURE USE ON THE INCIDENCE OF SUPERFICIAL INCISIONAL SURGICAL SITE INFECTIONS AFTER GASTROENTEROLOGIC SURGERY: A PROPENSITY SCORE MATCHING RETROSPECTIVE STUDY

K. Yamashita, S. Takeno, S. Hoshino, H. Shiwa, S. Hasegawa

Department Of Gastroenterological Surgery, Fukuoka University Faculty of Medicine, Fukuoka/Japan

Contact E-mail Address: kanefumi0519@yahoo.co.jp

Introduction: Surgical site infections (SSIs) after gastroenterological surgery cause significant morbidity, prolong hospitalisation and increase health care costs. Thus, SSI prevention is critical. To prevent bacterial colonisation in suture material, which disables local mechanisms of wound decontamination, triclosan-coated sutures were developed. We retrospectively analysed the efficacy of triclosan-coated polydioxanone sutures in abdominal fascia and skin closure using a propensity score matching analysis. We further analysed the surgery types for which these sutures are best suited.

Aims & Methods: The study protocol followed the principles of the Declaration of Helsinki and received ethical approval from the Ethics Committee of the Fukuoka University (approval no. 12-7-06). At our department, we used conventional abdominal closure methods during gastroenterological surgery before August 2012. Thus, we retrospectively collected surveillance data over a 1.5-year period for the control group. From September 2012, we began using triclosan-coated sutures for closure. Hence, we collected data for the study group from September 2012 to September 2013. In total, we included 1768 patients (control group, n = 640; study group, n = 1128) who underwent gastroenterological surgery. Baseline differences and selection bias were adjusted using propensity score matching.

Results: Before matching, the SSI incidence differed significantly between the control and study groups for all gastroenterological surgeries [12.4% (140/1128) vs. 5.5% (35/640); p < 0.001]. The SSI incidence according to the surgery type was as follows in the control and study groups: 12.7% (26/204) vs. 10.5% (12/114) (p = 0.347) for upper gastrointestinal (GI) surgery, 14.6% (43/294) vs. 5.3% (10/190) (p = 0.001) for lower GI surgery, 8.8% (24/274) vs. 4.1% (7/169) (p = 0.045) for hepato-biliary-pancreatic surgery, 18.2% (40/220) vs. 7.8% (5/64) (p = 0.030) for emergency surgery and 5.1% (7/136) vs. 1.0% (1/103) (p = 0.074) for others. Of 1768 cases, 483 pairs were matched using propensity score matching. No parameter used for the propensity score differed between the groups. After matching, we found a significant difference in the SSI incidence between the control and study groups for all gastroenterological surgeries [9.7% (47/436) vs. 5.7% (28/455); p < 0.001]. We found a significant difference in the SSI incidence between the control and study groups for lower GI [17.0% (16/78) vs. 4.3% (4/90); p = 0.008] and hepato-biliary-pancreatic [16.4% (11/56) vs. 4.3% (4/63); p = 0.049] surgeries. No significant difference was found between the groups for upper GI surgery, emergency surgery and others. Multivariable logistic regression analysis showed that triclosan-coated suture use for lower GI surgery was the independent factor affecting the SSI incidence (p = 0.017). The sutures demonstrated a significant efficacy in lower GI surgery.

Conclusion: Few studies have focussed on the types of surgery best suited for triclosan-coated sutures. Our findings suggest that abdominal fascia and skin closure using these sutures reduces the SSI risk, particularly after lower GI surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0947 COMPARISON OF POSTOPERATIVE CONDITIONS BETWEEN ESOPHAGOGASTROSTOMY WITH THE DOUBLE-FLAP TECHNIQUE AND THAT WITH A CIRCULAR STAPLER IN LAPAROSCOPIC PROXIMAL GASTRECTOMY

M. Hayashi, H. Kawakubo, S. Mayanagi, K. Fukuda, R. Nakamura, K. Suda, N. Wada, Y. Kitagawa

Department Of Surgery, Keio University School of Medicine, Tokyo/Japan

Contact E-mail Address: sas.jtf@gmail.com

Introduction: In recent years, laparoscopic proximal gastrectomy (LPG) has been actively performed in our institution to reduce invasiveness. However, proximal gastrectomy is sometimes followed by reflux. Until February 2015, we performed esophagogastrostomy with a circular stapler (CS) accompanied by fundoplication in LPG. Since March 2015, to avoid the postoperative complication, we have been using esophagogastrostomy with the double-flap technique (DFT) in LPG for gastric cancer.

Aims & Methods: We conducted this study to examine whether DFT can reduce the incidence of reflux and influence postoperative conditions. From January 2012 to February 2017, 47 LPGs were performed at Keio University Hospital. First, surgical time, bleeding, incidence of postoperative complication, post-operative hospital stay, and incidence of anastomotic stenosis were examined as surgical factors and compared between the DFT and CS groups. Second, gastroesophageal reflux finding on endoscopy, condition of the remnant stomach according to residue, gastritis, bile (RGB) classification at postoperative 6 months and 1 year, and proton pump inhibitor (PPI) intake were examined as postoperative factors. Finally, albumin and hemoglobin levels at postoperative 6 months and 1 year were examined as nutrient factors. Gastroesophageal reflux was assessed with scores of 0–5 in accordance with the Los Angeles (LA) classification.

Results: Twenty-three LPGs with DFT and 24 LPGs with CS were performed during the period. Compared with the CS group, the DFT group had a significantly longer surgical time (272.3 ± 35.5 vs 241.1 ± 26.7 min, $p < 0.01$). Other surgical factors showed no statistically significant differences between the two groups. As for postoperative factors, although no significant differences in PPI intake, LA classification, and RGB classification were found, the DFT group showed a significantly lower score than the CS group ($p < 0.01$). Postoperative nutrient factors did not show any significant difference between the groups.

Conclusion: Although LPG with DFT required a longer surgical time than LPG with CS, DFT is thought to be a safe reconstruction method in LPG. In addition to its safety, DFT can reduce postoperative reflux in patients who undergo LPG.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0948 NOVEL ENDOSCOPIC REPAIR TECHNIQUE FOR GASTROINTESTINAL LEAKS AND PERFORATIONS USING NEGATIVE PRESSURE THERAPY WITH OPEN-PORE POLYURETHANE-FOAM AND FILM DRAINAGE

G. Loske¹, F. Rucktaesche², T. Schorsch¹, C. T. Mueller¹

¹Department For General, Abdominal, Thoracic And Vascular Surgery, katholisches Marienkrankenhaus gGmbH, Hamburg/Germany

²Medical Clinic, Westküstenkliniken, Heide/Germany

Contact E-mail Address: loske.chir@marienkrankenhaus.org

Introduction: Gastrointestinal (GI) leaks and perforations are difficult to manage and often mandate laparotomy and extensive surgical interventions for their repair. Endoscopic Negative Pressure Therapy (ENPT) has been developed to treat GI defects such as leaks, fistulae and perforations. However, ENPT has only been utilized in the management of rectal and esophageal leakages. By modifying the delivery catheter we were able to adapt ENPT to treat duodenal defects, that otherwise would have required surgery or more invasive methods to be repaired.

Aims & Methods: Herein, we report ENPT using open-pore Polyurethane-foam and Film Drainage in a series of 10 patients with duodenal leakages. This is an open-label, retrospective, single-center study. Open-pore polyurethane-foam drainage (OPD) devices were constructed out of a piece ($1.5\text{ cm} \times 1.5\text{ cm} \times 3\text{ cm}$) of open-pore polyurethane-foam which was fixed surrounding the tip of a naso-gastric drainage tube. Small bore open-pore film drainage (OFD) device was constructed with a strip of a very thin fragment open-pore double layered film ($2 \times 2^{10}\text{ cm}$) which was wrapped surround the tip of a nasogastric drainage tube. The open- film consists out of two permeable membranes with a small interspace. Fluids are drained along the interspace and through the membranes. Diameter of small-bore OFD is 4–6 mm, depending on the diameter of the drainage tube. OPD is inserted transorally. The foam is grasped with endoscopic forceps and guided to the duodenal lumen. After correct placement into the duodenal lumen for intraluminal ENPT, the tube is transferred out nasally, to become a naso-duodenal tube. Due to its smaller outer diameter OFD insertion is similar to placing a naso-gastric or naso-intestinal feeding tube (i.e. through the nose). After nasal insertion into the esophagus OFD is grasped with a forceps and advanced into the stomach, and guided into the duodenal lumen for intraluminal ENPT. In case of a duodeno- cutaneous fistula the pull-through technique has

been used for duodenal placement. In one case rendezvous technique was used in combination with operative procedure. OPD and OFD are connected to an electronic vacuum device and negative pressure is applied. We use standard negative pressure of 125 mmHg, continuous suction, and high intensity, which results in collapse of the duodenal lumen around the open-pore foam or film with subsequent closure of the defect zone. Furthermore, duodenal secretions are actively removed through the tubes.

Results: We treated 10 patients with ENPT because of a duodenal leakage. Reason of duodenal defects were: rupture of operative suture ($n = 8$), iatrogenic perforation during ERCP ($n = 1$), perforation due to an operative drain ($n = 1$). Nine patients were treated with intraluminal and one patient with intracavitary variant of ENPT. In 7 patients we used the OPD device, in one patient OFD, and in two patients OPD and OFD. All leakages (100%) were successfully closed after a treatment period of 11 days in median (range 7–19 days).

Conclusion: ENPT using small diameter tube with open-pore film was effective to treat duodenal leakages. Advantage of OFD is the small diameter which allows easy endoscopic placement through small openings and nasally insertion. OPD and OFD devices can be positioned accurately at the site of duodenal leaks and perforations using common endoscopic techniques and thus represent a potential addition to the armamentarium to treat these difficult lesions.

P0949 INFLUENCE OF THE HYBRID METHOD OF DETOXICATION ON BLOOD CLARIFICATION EFFECTIVENESS AT PATIENTS WITH THE MULTIORGAN FAILURE

K. G. Khalikulov, B. A. Saidkhanov, D. B. Saidkhanova

Extracorporeal Detoxication, National Center of Surgery named after acad. V. Vakhidov, Tashkent City/Uzbekistan

Contact E-mail Address: drhgh@hotmail.com

Introduction: The main releaser for development of multiorgan failure syndrome (MOFS) in most cases are aggressive mediators of inflammation which are very often occur after surgical complications and more than in 70% of cases leads to lethal outcomes. Increase of an endotoxemia leads to development of the expressed pathological processes and to a fast decompensation of bodies of natural detoxication with the subsequent development of a multiorgan failure. Increase in detoxication ability of sorbents can happen due to change of chemical composition, or due to collimating of padding properties to them by their modification by various agents by means of an immobilization on their surface of organic and inorganic compounds. In this plan especially important role is got by the researches directed to development of sorbents with oxidizing activity.

Aims & Methods: Aim of study is to estimate effectiveness of the modified haemosorbent application for patients about the MOFS. The experimental part of work was conducted on 14 not purebred dogs with the acute liver failure modelled by bandaging of distal department of the CBD. After development of pathological process animals were divided into 2 groups. To the first group of animals the procedure of a haemosorbition was carried out by a reference technique with use of a haemosorbent of SKN-2K. To the second group of animals the haemosorbition was carried out by the developed technique with the same sorbent, but the solution of a neutral anolyte subjected to oxidizing modification. For this purpose, in the flowing mode carried out a half-hour incubation of a sorbent from 2 l of solution of a neutral anolyte.

Results: Results showed that at animals of the 2nd group in comparison with group of comparison improvement of a condition of an organism was expressed in much larger degree. After performing detoxication therapy by the developed technique a normalization of all studied parameters is registered. The same tendency is revealed also concerning nontoxic components. It is necessary to pay special attention to dynamics of a ratio of the common protein and an index average molecules/the common protein, pointing to synthesis process activation. The carried-out all-clinical blood test revealed the considerable improvement of indexes of white blood. In group of comparison it was not succeeded to achieve the complete normalization of the studied indexes. On the basis of what the conclusion was drawn on high effectiveness of the developed technique, and expediency of its introduction in clinical practice. Under our observation there were 45 patients needing carrying out getter detoxicating in the postoperative period. The control group (25) was created by a random sample of case histories from set of the patients with a similar syndrome who were earlier on treatment in our clinic and receiving a course of haemo perfused therapy by a reference technique. The analysis of results of treatment of patients of a basic group showed that the positive dynamics of clinical indexes expressed in decrease of manifestations of an intoxication syndrome, improvement of health and laboratory indexes is noted in earlier terms, and degree of expressiveness of positive changes at them was much higher. Dynamics of decrease in endogenic intoxication is reflected by data of laboratory researches.

Conclusion: Thus, the received results showed that it is possible to increase quality of detoxicating by a pretreatment of a haemo sorbent solution of a neutral anolyte. As a result of it the sorbent gains padding, oxidizing properties. At such modification there is an inclusion of oxygen-containing and acid groups in structure of a haemo sorbent. Besides, on a surface of a sorbent protogenic groups of carboxylic and phenolic types thanks to which the oxidized coals gain the expressed cation-exchange ability are formed. Therefore, besides actually getter, such sorbent follow-up gains oxidizing properties. Modification of a sorbent solution of a neutral anolyte incidentally allows to solve also other problem connected about need of use of anticoagulants for prevention of a thrombogenesis in a column. Use it in this quality provides decrease in risk of postoperative violations from system of a hemostasis.

Introduction: Gastric leaks are severe complications of Bariatric Surgery (BS). Surgical re-intervention may be indicated but is associated with high morbidity and mortality. The use of self-expanding esophageal metallic stents (SEMS) has become an effective alternative. Over the scope clips (OTSC) have also been used. Nevertheless some patients develop a refractory fistulae after stent removal or other failed endoscopic treatments. Cardiac Septal Defect Closure Devices (CSDCD), used in interventional cardiology have been described to treat post-surgical digestive fistulae in non-bariatric cases.

Aims & Methods: We aim to present the experience using CSDCD for gastric leaks secondary to BS. In this retrospective study, patients with leaks secondary to gastric bypass (GBP) or sleeve gastrectomy (SG) from 4 centers were included. Data collected from november 2012 to january 2016 included sex, age, type of surgery, previous treatment, tract path, size of the leak opening and defect closure. Leaks were grouped according to the International Sleeve Gastrectomy Expert Panel Consensus in acute (post-operative days 1–7), early (1–6 weeks), late (after 6 weeks) and chronic (> 12 weeks). Biliary catheters were adapted to introduce the CSDCD through the gastroscopes working channels. Clinical success was defined as complete and permanent resolution of abdominal or thoracic drainage with imaging documentation of closure (CT with contrast or upper GI contrast study) after 2 months.

Results: 42 patients with leaks were included (31 SG, 11 GBP). Three acute leaks, 5 early, 22 late and 12 chronic. Prior failed therapies included: SEMS and enteral tube feeding (ETF), SEMS alone, SEMS and gastrostomy of excluded stomach, OTSC, ETF alone, jejunostomy and none (3 acute leaks had CSDCD as the primary treatment). Tract path was grouped as gastric-cutaneous (37), gastric-pleural (3) and gastric-bronchial (2). Median follow-up was 34, 8 weeks. All 3 patients with acute leak failed to close the defect. The CSDCD were removed within 7 days and SEMS were placed instead leading to defect closure. The 5 patients with early leaks had initial good response but within 30 days drainage recurred. The CSDCD were removed and replaced for a larger diameter device leading to permanent defect closure. Clinical success was achieved on 38 patients (90, 5%). In one patient with late leak the tract path was connected to an undrained cavity. Evolution was unsatisfactory and total gastrectomy accomplished.

Conclusion: CSDCD are effective to treat post bariatric surgery late and chronic leaks despite of the failed previous endoscopic treatment. Although early leaks finally healed it seems advisable to maintain conservative treatment and wait for the leak to become late or chronic before CSDCD placement. Acute leaks must be managed with a combination of SEMS, ETF, OTSC as first step.

P0951 COMPARATIVE EVALUATION OF LAPAROSCOPIC SINGLE-PORT (SILS) CHOLECYSTECTOMY AND LAPAROSCOPIC FOUR-PORT CHOLECYSTECTOMY

A. Alekberzade, N. Krylov, E. Lipnitsky
 Surgery, Sechenov First Moscow State Medical University, Ministry of Health of the Russian Federation, Moscow/Russian Federation

Contact E-mail Address: aftandil.v.alekberzade@gmail.com

Introduction: Laparoscopic cholecystectomy is the gold-standard for the treatment of gallbladder stone disease. Single-incision laparoscopic (SILS) cholecystectomy was introduced with the aim of reducing the invasiveness of classic laparoscopic surgery. Despite satisfactory cosmetic results of SILS cholecystectomy and its reputed a painless procedure, there are few published studies comparing early and long-term postoperative period of laparoscopic SILS cholecystectomy versus laparoscopic four-port cholecystectomy.

Aims & Methods: The aim of this study is the comparative evaluation of SILS cholecystectomy and laparoscopic four-port cholecystectomy. Early and long-term postoperative period has been analyzed in 240 patients who underwent laparoscopic cholecystectomy including 120 cases of single-port technique and 120 cases of four-port technique. Both groups were compared in surgical time, pain syndrome severity (visual analog scale), need for analgesics, postoperative complications, hospital-stay, daily activity recovery and return to physical work, patients' satisfaction of surgical results and their aesthetic effect.

Results: It was revealed that SILS cholecystectomy is associated with lower severity of postoperative pain, quick recovery of daily activity and return to physical work, high satisfaction of surgical results and their aesthetic effect compared with four-port cholecystectomy. Disadvantages of SILS cholecystectomy include longer duration of surgery, high incidence of postoperative umbilical hernia. However, hernia was predominantly observed during the period of surgical technique development.

Conclusion: Further studies to standardize, evaluate the safety and benefits of SILS cholecystectomy are necessary.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Bibliometric analysis highlights key topics and publications, which have shaped the development of laparoscopic surgery (LS). Here the 100 most cited manuscripts in the field of LS are analyzed.

Aims & Methods: The Thomson Reuters Web of Science database was used to identify all English language full manuscripts for the study with the search term 'laparoscop*' and 'surg*'. The 100 most cited papers were further analyzed by topic, journal, author, year and institution.

Results: 71,524 eligible papers were returned and the median (range) citation number was 585.76 (range 1635 to 368). The two most cited papers received 1635 citations each. The first (Nelson¹) compared laparoscopic and open colectomy for malignancy, and the second (Clavien²) described the classification of post-operative morbidity. *Annals of Surgery* published the highest number of papers (n = 22) and received most citations (n = 12,356). The country with the highest number of publications was the USA (n = 55), and the year with the greatest number of publications was 2004 (n = 13). The most ubiquitous topic was the treatment of cancer (n = 35), followed by surgical technique (n = 24), and comparison of laparoscopic with open surgery (n = 22).

Conclusion: The most cited manuscripts highlighted laparoscopic surgical technique and compared laparoscopic with open surgery, and this review provides the most influential references in this arena, serving as a guide as to a citable paper.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Laparoscopic technique is the first choice for multiple surgical procedures today. Laparoscopic surgery differs from traditional open surgery in several aspects, for example two-dimensional view of a three-dimensional interior, higher demands on eye-hand coordination and lack of tactile feedback. Laparoscopic surgical skills can be substantially improved by simulator training. Learning via simulators are under constant development and it is important to understand the value of baseline characteristics and abilities to further optimize simulators and training curricula within surgical education. In this study, focus will be on the impact of PC-gaming experience and visuospatial skill.

Aims & Methods: The aim of the study is to further analyse different factors to laparoscopic simulator training. 48 medical students completed three tasks in a laparoscopic virtual reality simulator, a validated Minimally Invasive Surgical Trainer (MIST, Mentice, Gothenburg, Sweden). Prior to the task, they performed a visuospatial test and answered questions regarding baseline characteristics (e.g. PC-gaming experience, age, gender, previous simulator experience). The data were analysed regarding different parts of the simulation (time, economy of movement, error and total score).

Results: The group with high PC-gaming experience performed significantly better in total time (Mean difference = 85.49, $p = 0.021$) and economy of movement ($M = 25.30$, $p = 0.018$) in task 1 and 2. There were no differences between either of the groups in task number 3. A high visuospatial score correlated with a better result in time to completion ($M = 68.89$, $p = 0.026$) and total score ($M = 80.16$, $p = 0.036$). The group with both low PC-gaming experience and low visuospatial score performed worst in the simulator exercises.

Conclusion: Both PC-gaming experience and visuospatial abilities have an impact on laparoscopic simulator performance. No remaining significant differences by the third simulation exercise indicates a learning effect that could be more important than baseline skills. It could be valuable to identify individuals with both low PC-gaming experience and low visuospatial score to offer them additional simulator training.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0954 PERITONEAL TUBERCULOSIS: EPIDEMIOLOGICAL DATA, CLINICAL AND EVOLUTIVE ASPECTS ACCORDING TO THE EXPERIENCE OF A TUNISIAN CENTER

W. Ben Ameur, J. Hanen, E. Hammami, E. Nour, M. Kssia, B. Ahlem, A. Salem, A. Ben Slama, J. Ali

Gastroenterology Service, Sahloul, Sousse/Tunisia

Contact E-mail Address: wafabenameur1@hotmail.fr

Introduction: Tuberculosis is a major cause of morbidity and mortality worldwide. Its incidence is continually increasing. Peritoneal localization is a particular entity, even less well known, because of its atypical and confusing symptomatology, which in most cases imposes a malignant condition.

Aims & Methods: We collected all patients hospitalized for peritoneal tuberculosis between 2005 and 2015. The aim of this retrospective study was to study the epidemiological, clinical, paraclinical, diagnostic, therapeutic and evolutionary specificities of peritoneal tuberculosis in its various presentations.

Results: The total number of patients was 65. It was 15 men (23.1%) and 50 women (76.9%). The sex ratio was 0.3. The mean age at diagnosis was 40 years (15–79 years). No personal history of tuberculosis has been found in our series. A personal history of tuberculosis was found in 3 patients (4.6%). The general signs of tuberculin impregnation were frequently found (91%). The digestive functional signs that brought the patients to consult are: abdominal pain (87.7%), abdominal distension (87.5%), diarrhea (16.9%) and sub occlusive syndromes (4.6%). An abdominal mass was observed in only 4 patients (6.1%). Hepatomegaly and splenomegaly were noted in 2 cases for each. The intradermal reaction was positive in only 24% of patients. The research of BK in the ascites fluid was systematically performed in all patients but returned negative in all cases. The quantiferon-TB Gold was performed in 3 patients only and returned positive. The mean level of CA 125 was 250.3 IU/ml. Confirmation of diagnosis was obtained on the histological analysis of peritoneal biopsies or adnectomy pieces. The main operative findings (in patients with coelioscopy or exploratory laparotomy) were: Whitish granulations (98%), adhesions (43.1%) and agglutinated loops (1.5%). The presence of tuberculous granuloma was observed in 52 patients (81%). The course of treatment was as follows: cure in 50 patients (80.6%), recurrence in 6 patients (9.6%), relapse in 2 patients and 3 patients were lost to follow-up. The mortality in our series was 0%.

Conclusion: Peritoneal tuberculosis raises diagnostic problems in the first place, because of its polymorphic and non-evocative clinical expression; Hence the value of carrying out radiological, endoscopic and histo-bacteriological investigations to confirm the diagnosis before the evolution towards serious or even fatal forms.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0955 ABDOMINAL TUBERCULOSIS: A RETROSPECTIVE SERIES OF 150 CASES

S. Jarak, H. Kchir, N. Maamouri, H. Chaabouni, N. Ben Mami
Tunis, Rabta b, Tunis/Tunisia

Contact E-mail Address: sondajarak1@gmail.com

Introduction: Tuberculosis is still a problem of public health in Tunisia, which is a country of endemicity. The epidemiological situation of the disease is marked by the rise of the extrapulmonary forms especially abdominal tuberculosis.

Aims & Methods: The aim of this study was to analyze the epidemiologic, clinical, diagnostic, therapeutic and evolutive features of abdominal tuberculosis in a series of 150 patients. This was a retrospective and descriptive monocentric study of 150 cases of abdominal tuberculosis conducted from 2004 to 2014 in a tunisian center. Diagnosis of tuberculosis was based on histological evidence or otherwise on a beam of arguments.

Results: There were 150 patients enrolled. The mean age was 37.2 (17–72 years). Ninety seven (64.6%) were females. Symptoms were ascites 107 (71.3%), abdominal pain 28 (18.6%), weight loss and reduced appetite 80 (53.3%). Un tableau pseudo-chirurgical a révéla la maladie dans 9.3% des cas (14 cas). Sub-acute and acute intestinal obstruction was seen in 10 (6.6%) and 4 (2.6%) respectively. 105 patients (70%) had peritoneal tuberculosis, 34 (22.6%) had intestinal tuberculosis. The association of the two forms was found in one case. 10 patients (6.6%) had a Lymph node involvement. Basis of diagnosis of abdominal tuberculosis were histo-pathology (tissue obtained during surgery, colonoscopy, CT or ultrasound guided biopsy, laparoscopy and upper gastro intestinal endoscopy) in 122 (81.3%) patients. Response to medical treatment was found in 141 (94%) patients.

Conclusion: Abdominal tuberculosis is one of the most common site of extrapulmonary tuberculosis. No single test is adequate for diagnosis of abdominal tuberculosis in all patients. Abdominal TB remains an ongoing diagnostic dilemma requiring a high index of clinical suspicion.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0956 PATHOBIONT-FREE MICROBIOTA PROTECTS AGAINST GUT INFLAMMATION INDUCED BY AN INNATE IMMUNE DEFICIENCY OR DIETARY PERTURBANT OF THE MICROBIOTA

B. Chassaing¹, A. T. Gewirtz²

¹Institute For Biomedical Sciences, Georgia State University, Atlanta/United States of America

²Institute For Biomedical Sciences, Georgia State University, Atlanta/United States of America/GA

Contact E-mail Address: bchassaing@gsu.edu

Introduction: Inability to maintain a stable and beneficial microbiota is associated with chronic gut inflammation, which classically manifests as colitis but may more commonly exist as low-grade inflammation that promotes metabolic syndrome. Alterations in microbiota and associated inflammation can originate from dysfunction in host proteins that manage microbiota, such as the flagellin receptor TLR5, and/or be promoted by exogenous factors that disturb host-microbiota interactions, such as the detergent-like dietary emulsifiers carboxymethylcellulose (CMC) and polysorbate 80 [1, 2, 3]. That the complete absence of a microbiota (i.e. germ-free conditions) eliminates all evidence of inflammation in

TLR5-deficient and emulsifier-treated mice demonstrates that these models of gut inflammation are microbiota dependent. We hypothesize that such microbiota dependency of inflammation reflects an inability to manage pathobiont bacteria, such as Adherent-Invasive *E. coli* (AIEC).

Aims & Methods: Our goal was to examine extent to which microbiota mismanagement and associated inflammation in TLR5-deficient and emulsifier-treated mice would manifest in a limited pathobiont-free microbiota. WT and TLR5-deficient mice were maintained in gnotobiotic isolators containing altered Schaedler flora (ASF), a community of eight bacterial species. Mice were treated with either CMC or P80, or inoculated with AIEC reference strain LF82 [4]. Feces were assayed for bacterial loads, microbiota composition, and inflammatory marker lipocalin-2. Fecal LPS and flagellin bioactivity were measured via a cell-based reporter assay, and morphologic and metabolic parameters were determined.

Results: Neither CMC nor P80 induced evidence of intestinal inflammation nor metabolic syndrome in WT ASF animals. Analogously, relative to similarly maintained WT mice, loss of TLR5 did not result in low-grade intestinal inflammation nor metabolic syndrome under ASF conditions. Concomitantly, the ASF microbial community was not disturbed by CMC nor P80 and, moreover, was similar between WT and TSKO animals. Inoculation with AIEC strain LF82 resulted in profound alteration of the ASF community in TSKO mice compared to WT control animals. AIEC LF82 inoculation in ASF TSKO mice correlated with microbiota exhibiting elevated levels of bioactive LPS and flagellin, and was associated with modest level of low-grade inflammation and increased adiposity.

Conclusion: In a limited-complexity pathobiont-free microbiota, loss of the flagellin receptor TLR5 or emulsifier consumption does not impact microbiota composition nor its ability to promote inflammation. Addition of AIEC to this ecosystem perturbs microbiota composition, increases levels of lipopolysaccharide and flagellin, but only modestly promotes gut inflammation and adiposity, suggesting that the phenotypes previously observed require disruption of complex microbiota.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Lamina propria represents a thin layer of connective tissue rich in lymphoid cells and macrophages, underlying the epithelium of mucous membranes. Lamina propria mononuclear cells (LPMCs) are immune system's first line of defense in the intestine characterized by the ability of differentiating invading pathogens from beneficial intestinal flora and swiftly removing them. Disrupted regulation of LPMCs is implicated in pathology of a group of disorders causing chronic intestinal inflammation, termed Inflammatory bowel disease (IBD). Two major types of IBD are ulcerative colitis, limited to the colon and Chron's disease affecting any segment of the gastrointestinal tract. Chron's disease and ulcerative colitis were shown to be mediated by Th1-polarized helper (CD4+) T-cells and Th2-polarized CD4+ and NKT cells, respectively, while Th17-polarized cells are involved in pathogenesis of both diseases¹. Therefore, research into biology and regulation of LPMCs is of essential importance for development of treatments for IBD symptoms.

Aims & Methods: The aim of this study was development of a robust method for isolation and characterization of LPMCs from human colonic mucosa, compatible with further *ex vivo* cell culturing and research. Mucosal tissue samples contained the tissue not affected by tumor, removed during tumor surgery of patients that consented to donation of tumor and the surrounding resected tissue. The tissue may be considered as healthy in terms of IBD. We have employed an isolation method consisting of disruption of epithelial cells by incubation of mucosa in a DTT and EDTA containing solution, followed by enzymatic and mechanical digestion of tissue and purification of mononuclear cells by density gradient centrifugation. Isolated cells were characterized by flow cytometry (FACS) detection of cell-type specific surface antigens and cytological analysis. To examine the plasticity of isolated cells in terms of polarization towards IBD-associated phenotypes, the cells were seeded at conditions mediating Th1, Th2 and Th17 differentiation of CD4+ T-cells and analyzed for activation of differentiation-specific gene expression and cytokine production by qPCR and ELISA

assays. Aliquots of cells were cryopreserved and further analyzed for the effect of cryopreservation on distribution of surface antigens and CD4+ T-cell responses.

Results: Approximately 95% cell viability and 90% leukocyte (CD45+) cell purity was determined by FACS analysis of isolated LPMCs. According to cytological analysis, CD45-negative cells may represent CD45-negative population of plasma cells; no contamination with epithelial cells was detected. Within CD45+ cell population, 26–47% T-lymphocytes, 17–24% B-lymphocytes, 8–17% macrophages and 21–46% monocytes were detected by FACS and cytological analyses (N=3). Cryopreservation did not significantly affect cell viability and surface-antigen distribution. Isolated cells were successfully polarized towards Th1, Th2 and Th17 CD4+ T-cell phenotypes, as confirmed by IFN γ gene expression and cytokine production for Th1, IL13 gene expression and IL5 cytokine production for Th2 and IL17 cytokine production for Th17 differentiated cells. Differentiation was confirmed also in cryopreserved cells, with lower level of phenotype-specific cytokine production.

Conclusion: Method for LPMC isolation from human colonic mucosa tissue samples was successfully established with approximately 95% viability of isolated cells, 90% purity of CD45+ cells and no detectable epithelial cell contamination. Within CD45+ cells, 26–47% of T-lymphocytes, 17–24% B-lymphocytes, 8–17% macrophages and 21–46% of monocytes were detected. Isolated cells were successfully polarized towards IBD-associated Th1, Th2 and Th17 CD4+ T-cell phenotypes, as confirmed by activation of phenotype-specific gene expression and cytokine production. Cryopreservation of isolated LPMCs did not significantly affect cell viability, distribution of cell-type specific surface antigens or polarization towards Th1, Th2 and Th17 CD4+ T-cell phenotypes.

Introduction: The Inflammatory Bowel Disease-Disability Index (IBD-DI) has recently been validated to measure disability in IBD.

Aims & Methods: We aimed to assess disability in IBD outpatients using IBD-DI and to determine the sociodemographic, clinical and psychological factors that are associated with greater disability. Between August and October of 2016, patients with an established diagnosis of Crohn's Disease (CD) or Ulcerative Colitis (UC) for at least 3 months and followed up at our outpatient clinic were invited to participate. Socio-demographic and clinical data were collected from electronic health record and interview. Optimism and disability were evaluated by applying, personally or by phone, the validated Portuguese versions of the Revised Life Orientation Test (LOT-R) and IBD-DI, respectively. The association between sociodemographic, clinical and psychological variables (optimism) and IBD-DI (scale 0–100, proportional to the reported disability) was determined by univariate and multivariate analysis.

Results: A total of 143 patients (70 DC and 73 UC; 50.3% females) with a mean age of 38 ± 13 years were included. Most (85.3%) was in clinical remission. The median IBD-DI-PT score was 17.9 ± 10.7, with no significant difference between DC and CU (p=0.944). In univariate analysis, female gender, high level education, number of days off from work, articular manifestations, number of comorbidities, use of psychotropic drugs and pessimism (low LOT-R score) were significantly associated with higher disability (IBD-DI-PT score). In multivariate analysis, only female gender (B=0.150), number of comorbidities (B=0.186) and pessimism (B=0.370) were significantly associated with higher disability. Clinical activity was associated with higher disability only for CD patients (B=0.321).

Conclusion: IBD outpatients reported low levels disability associated with their disease, which can be explained by the high percentage of patients in clinical remission. Comorbidities and psychological factors (optimism) emerged as the main predictive factors of greater disability, reinforcing the importance of multi-disciplinary approach to these patients. Clinical activity seems more important to CD than UC patients in terms of disability.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Imbalance of immune bowel environment is associated with development of many diseases, such as Crohn's disease (CD). Although the pathogenesis of CD remains unclear, a key feature of CD is dysregulation of immune system (Zhang and Li, 2014). Human immune cells are the front line of inflammatory responses and include, in addition to other cells, CD4+ and CD8+ T cells, which comprises adaptive phase and require proper inflammatory cues for their effector function. After activation, CD4+ and CD8+ T cells express several markers that give them powerful functional abilities (Abbas et al., 1996). CD38 and HLA-DR besides being classically markers of cellular activation, are also known as markers of diseases progression (Lovelace et al., 2017). Some studies shows that CD4+ T cells play a key role in the immune inflammatory response leading to CD but this cells are poorly characterized in the blood of the patients.

Aims & Methods: This study aimed to characterized CD4+ and CD8+ T cells in the blood of patients with CD. The study was performed in individuals with CD (n = 46) and healthy controls (n = 38). Blood of healthy donors and patients with CD was collected in clinical laboratory from Hospital Albert Einstein. CD4+ and CD8+ T cells was quantified by multiparametric flow cytometry. Dosage of calprotectin and ASCA was performed by commercial Elisa kit. The groups were compared for numerical measures using Student's t-tests, ANOVA, Mann-Whitney or Kruskal-Wallis, depending on the suitability of the data and the number of groups to be compared. The computational package used for the analyzes was R 3.0.3 and GraphPad Prism 6.

Results: The highest prevalence in both group was female, aged between 19 and 66 years with a median of 37.5 years. Among clinical exams, 61% of cases present a value greater than 200 in the dosage of Calprotectin, whereas in the control group the rate was only 18.4% (p < 0.001). ASCA IgG (p = 0.001) and IgA (p < 0.001) measures were also higher in group of cases when compared to control group. The population of CD3+ cells in peripheral blood of healthy controls and patients with CD was evaluated both in biological and corticoid treatment. A significant increase in this population was observed in patients receiving corticosteroids (p = 0.02) compared to healthy controls. In the population of CD4+ a significant increase was observed in patients undergoing treatment with corticosteroids in relation to patients undergoing biological treatment (p = 0.0027). In CD8+ population, no statistical difference was observed between the groups. The markers CD38, CD62L and HLADR were also evaluated. In relation to CD38 (p = 0.0022) and CD62L (p = 0.015) in subpopulation of CD4+ T cells, a significant increase in the expressions was observed in the group of patients receiving corticosteroids in relation to the group receiving biological therapy. Regarding HLADR, statistical difference (p = 0.01) was observed between the group undergoing biological treatment and the group of healthy controls. In the subpopulation of CD8+ T cells, a significant increase (p = 0.02) was observed in the CD38 marker when compared patients on corticoid treatment with patients undergoing biological treatment. Regarding the CD62L marker, only a statistical difference (p = 0.04) was observed when compared patients on corticosteroid treatment with healthy controls. Finally, a statistical difference (p = 0.02) was also observed in relation to the HLADR marker when comparing the group of patients receiving corticoid with the group of patients in use of biological therapy.

Conclusion: We conclude that the use of biological therapy suppresses activated state of CD4+ and CD8+ T cells by regulation of CD38, CD62L and HLADR in relation to the use of corticosteroids.

Introduction: Advancing of sequencing technologies in the first decade of the XXI century gives the opportunity to realization of large scale projects such as the 1000 human genomes project. This project provides enormous amount of the data for *H.sapiens* population genetics studies and different GWAS studies aimed

to investigate connection of the human genetics variations with different diseases. It is especially interested to study the connection between the human genetics, the microbiome metagenomics of mucosa and different pathological conditions. Previously revealed, the size of the summary gut microbiome metagenome is on order more than the size of a human genome. The most of works devoted to the study of the connection of metagenome changes with different pathological conditions based on the investigation of fecal samples. On our opinion, in the case of ulcerative colitis it is more effective to study the mucosal microbiome of the affected regions.

Aims & Methods: The aim of our work was to study the composition of mucosal microbiomes in the colon mucosa biopsies from patients with ulcerative colitis by using the target high throughput sequencing of bacterial 16S rRNA genes. Biopsies from four caucasoid race patients with left-sided ulcerative colitis in the abating relapse phase (Meyo endoscopic index - 3, Rachmelevich clinical index - 4) and two patients from control group with irritable bowel syndrome were collected. The DNA was extracted from mucosal biopsies and 16S rRNA genes from it's were target sequenced by using Illumina Miseq sequencer. Sequencing reads were quality checked by the FastQC software and trimmed by using the trimmomatic software. To characterize the composition of the microbiota, trimmed reads were analyzed by the QIIME software. The obtained results were compared with the earlier published data: SRA Project - ERP001780 (96 samples from patients of control group, 44 samples from patients with ulcerative colitis)[1] and SRA Project - SRP056002 (703 samples from patients with ulcerative colitis).

Results: More than 124 bacterial genres were founded in biopsies of four patients with ulcerative colitis. The analyzed samples of patients with ulcerative colitis were split in two groups by using the PCoA analysis. The first group was characterized by decreasing the concentration of the *Firmicutes* type bacteria (p-value < 0.005) and increasing the concentration of *Bacteroidetes* type bacterias (p-value < 0.05). For the second group, it was founded decreasing of the concentration of the *Actinobacteria* type bacterias (p-value < 0.05), 70-fold excess of *Bacteroides vulgatus* species bacterias concentration was revealed for one sample of the first group (normalized number of reads in control samples was less than 0.003 and reached 0.21 in samples of patients with ulcerative colitis). Additionally, the concentration of *Escherichia coli* species bacterias was increased in the 40 times for that sample (normalized number of reads in control samples was less than 0.0008 and reached 0.03 in samples of patients with ulcerative colitis). Although, the predominance of *Proteobacteria* genus bacteria was not founded. The concentration of *Faecalibacterium prausnitzii* species bacteria was decreased by three orders of the magnitude for samples from the first group (normalized number of reads in control samples reached 0, 2 and was less than 0, 06 in samples of patients with ulcerative colitis).

Conclusion: The concentration increase of the conditional-pathogenic mucosal microflora (a mostly *Bacteroidetes* type bacteria) was discovered, which playing the important role in the development of ulcerative colitis and lead to a mucosa damage. Also, the deficiency of *Faecalibacterium prausnitzii* species bacteria was discovered, which decrease resistance of mucosa to the conditional-pathogenic microflora.

P0962 COLONIC INFLAMMATION DELAYS DEVELOPMENT OF STREPTOZOTOCIN-INDUCED DIABETES IN MICE THROUGH MODULATION OF ENDOGENOUS INCRETIN SYSTEM

H. Zatorski, M. Salaga, M. Zielińska, J. Fichna
Department Of Biochemistry, Medical University of Lodz, Lodz/Poland

Introduction: The role of incretin hormone, GLP-1, in inflammatory bowel diseases (IBD) development and exacerbations is still poorly understood. GLP-1 decreases blood glucose level and is co-secreted by intestinal L cells with GLP-2, which may be responsible for intestinal growth and enhancement of intestinal function. The prevalence of type 2 diabetes among IBD patients is low, even though IBD sufferers may be at a greater risk of development of T2D due to overproduction of pro-inflammatory cytokines and excessive administration of diabetogenic drugs. We hypothesize that the possible mechanism underlying this phenomenon is related to changes in the levels of incretin hormones.

Aims & Methods: The primary aim of this study was to investigate, in the mouse model, whether coexisting colitis postpones development of experimental diabetes. The secondary goal was to investigate the potential involvement of incretin hormones as an underlying factor. Experimental diabetes was induced by administration of streptozotocin for 5 consecutive days (50 mg/kg, i.p.). Mice with blood glucose levels above 200 mg/dL were considered as diabetic. To develop a chronic and relapsing colonic inflammation, mouse model of colitis induced by intracolonic administration of TNBS (first dose: 150 mg/kg at day 1, booster dose: 75 mg/kg at days 12, 23, 34, 45, 56) was used. On day 60 mice were sacrificed and macroscopic score, ulcer score, colon length and bowel thickness were recorded. In all experiments the levels of inflammation markers: myeloperoxidase (MPO) activity, TNF- α and IL-1 β expression were determined. The

effect of colitis on T2D development was studied by assessing fasting glucose levels, as well as the incretin hormone levels, GLP-1 and GLP-2 in the blood.

Results: The development of hyperglycemia in mice treated with TNBS was delayed compared to a non-inflamed group, what was associated with significantly higher level of GLP-1 in blood. Surprisingly, the levels of GLP-2 were significantly reduced in diabetic mice with colitis, suggesting that two distinct mechanisms are involved in the regulation of the incretin hormones in response to intestinal inflammation. There were no significant differences in macroscopic score, colon length, and bowel thickness in diabetic mice with or without colitis. Notably, ulcer score was significantly increased in diabetic mice with colitis compared to diabetic mice with no inflammation. No changes in MPO, TNF- α , IL-1 β were observed between these groups.

Conclusion: We propose that GLP-1 production may be stimulated in response to colonic inflammation and thus postpone development of diabetes. This observation is the first to reveal possible connections between T2D and IBD and may lead to better understanding of the pathophysiology of these two diseases. Furthermore, our data suggest that the incretin hormones may become a potential new therapeutic option in treatment of IBD.

Introduction: Pathogenesis of inflammatory bowel disease (IBD) is multifactorial and establishing diagnosis requires a performance of series of variable tests. The alternative, non-invasive, markers of IBD are intensively searched for. Eosinophils are acidophilic multifunctional granulocytes that remain outside the mainstream research on IBD. However, they are a rich source of cytotoxic proteins, pro- and anti-inflammatory cytokines, chemokines and growth factors and are likely to contribute to both inflammatory and regenerative phases of the disease. Accordingly, peripheral eosinophils of IBD patients are primed and pre-activated. They display increased responsiveness, adhesiveness, migration, and degranulation and are characterized by up-regulated secretion of their mediators. Locally, increased number and activation of eosinophils have been repeatedly observed in areas of active inflammation. Despite the acknowledged contribution of eosinophils to the disease pathogenesis, available data on cytokines closely related to the development and activity of peripheral eosinophils in IBD patients are either scattered or non-existent.

Aims & Methods: Aim of the study was assessment of the circulating eosinophil-associated cytokines and growth factors as differential markers and indicators of mucosal healing in inflammatory bowel disease.

Study population consisted of 277 individuals: 101 patients with Crohn's disease (CD), 77 with ulcerative colitis, 16 with irritable bowel syndrome (IBS) and 83 healthy controls. The disease severity was assessed using the Crohn's Disease Activity Index (CDAI) for CD and the Mayo Disease activity index (MDAI) for UC. Additionally, Mayo endoscopic score was applied to evaluate the severity of bowel inflammation in UC patients. The concentrations of eosinophil-associated cytokines and growth factors: eotaxin, GM-CSF, IFN γ , IL4, IL5, IL8, IL12(p70), IL13, RANTES and TNF α were measured simultaneously in patient's sera using Luminex xMAP® technology and referred to IBD activity and the levels of hsCRP. The suitability of eosinophil-associated cytokines and growth factors as differential markers and potential indicators of mucosal healing, individually and in multi-marker panels, was evaluated using ROC analysis.

Results: As compared to IBS patients or healthy controls, patients with CD had significantly higher levels of IL5, IL8, IL12(p70), GM-CSF, and TNF α and patients with UC the levels of eotaxin, IL4, IL5, IL8, IL12(p70), IL13, GM-CSF, and TNF α . As compared to CD patients, patients with UC had significantly higher levels of eotaxin, IL4, IL5, IL8, and IL1. In turn, the concentrations of hsCRP were significantly higher in CD than UC. Except for IL13, all cytokines and hsCRP positively correlated with CDAI but solely IL12(p70) and hsCRP were significantly higher in patients with active than inactive CD. In UC, a positive correlation with MDAI was observed for hsCRP, GM-CSF, IL12(p70), and IFN γ and a negative one for IL8. The concentrations of hsCRP, GM-CSF, IFN γ , IL12(p70) and RANTES were higher in UC patients with active than inactive disease whereas those of IL8 and TNF α were significantly lower. As differential individual markers, eotaxin displayed superior accuracy as an indicator of active UC (71%), followed by hsCRP as an indicator of active CD (66%). The combined assessment of eotaxin, hsCRP and IFN γ had slightly higher accuracy (78%) and allowed for a correct classification of 72% patients. The concentrations of hsCRP, GM-CSF, IFN γ , and IL12(p70) were significantly and positively correlated with the degree of bowel inflammation, expressed as Mayo endoscopic subscore. Of these, a drop in GM-CSF had superior accuracy as an indicator of mucosal healing (91%), allowing for a correct classification of 87% of patients. IL5, IL8, IL12(p70), TNF α , and GM-CSF were significantly higher in both CD and UC than in IBS. Of these, IL8 had superior accuracy in differentiating IBS and IBD (91%), allowing for a correct classification of 93% of patients.

Conclusion: Eosinophil-associated cytokines are elevated in IBD, more pronouncedly in UC, and may support the differential diagnosis of IBD and aid in monitoring of mucosal healing.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0964 MACROPHAGE IL10 SIGNALING IS REQUIRED FOR THE THERAPEUTIC EFFECT OF ANTI-TNF THERAPY IN INFLAMMATORY BOWEL DISEASE

Introduction: Interleukin(IL)10 is an important anti-inflammatory cytokine for the maintenance of gut homeostasis. Defects in the IL10 signalling pathway in macrophages leads to dysregulation of regulatory (M2) type macrophages and subsequent inflammatory bowel disease (IBD). IBD patients are frequently successfully treated with anti-TNF α antibody therapy, although not all patients are responsive.

Aims & Methods: We determined the effect of anti-TNF α therapy in both IL10 knock-out (KO) mice and in the CD4+CD45Rb high T-cell transfer model of colitis. Macrophage populations were quantified using qPCR analysis for CD206 and iNOS and flow cytometry for CD206. IL10 mRNA and protein levels were analysed with qPCR and ELISA.

Results: Colitis in the IL10 KO mice was completely resistant to anti-TNF α therapy, in sharp contrast to the colitis in SCID or Rag1 KO mice upon transfer of CD4+CD45Rb high T-cells, which was significantly reduced by anti-TNF α therapy. Successful anti-TNF α therapy was accompanied by an increase of IL10 levels and an increase of regulatory (M2) type macrophages in the intestine. Blocking IL10 signaling, with an IL10 Receptor blocking antibody, diminished the therapeutic efficacy of anti-TNF α therapy. Anti-TNF α therapy was also effective in Rag1 KO mice that received a transfer with IL10 Receptor KO CD4+CD45Rb high T-cells, indicating that IL10 signaling in T-cells was not important for the therapeutic efficacy of anti-TNF α . In contrast, LysMCre IL10Ra flox/flox Rag1 KO mice defective in macrophage IL10 signaling, were unresponsive to anti-TNF α therapy upon receiving CD4+CD45Rb high T-cells. In these mice there was also no increase of intestinal M2 macrophages.

Conclusion: IL10 signaling in macrophages is pivotal for the therapeutic efficacy of anti-TNF α therapy in animal models for IBD. Defects in the IL10 pathway may also play a role in anti-TNF α non-responders which is subject of further investigation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0965 LONG-TERM CONSEQUENCES OF ANTIBIOTIC THERAPY: ROLE OF SCFAS AND INTESTINAL BARRIER INTEGRITY

Introduction: Epidemiological studies revealed that antibiotics exposure increases the risk of inflammatory bowel diseases (IBD) development (Hviid, 2011, Shaw, 2011, Kronman, 2012). However, mechanisms of this association are not fully understood. Recent studies revealed sustained alterations in gut microbiota after antibiotic treatment (Rashid, 2015, Dethlefsen, 2011), the full consequences of which remain unknown.

Aims & Methods: Here we investigated long-term effects of antibiotic treatment on gut microbiota, short-chain fatty acids (SCFAs) production, transport & sensing, colon mucosa functional state, surface mucus layer and epithelial barrier integrity. Male Wistar rats (n=178, 140-160 g) were treated for 14 days with broad-spectrum antibiotic ceftriaxone (Cf) (300 mg/kg, i.m.) or vehicle; euthanized in 1, 14 or 56 days after Cf withdrawal. The fecal microbiota was analyzed by bacteriological culture methods; fecal SCFAs – by gas chromatography; colonic localization and levels of FFA2 & FFA3 receptors and MCT1, MCT4 & SMCT1 transporters of SCFAs – by immunohistochemistry; levels of FFA2, FFA3, ERK1/2, p38, HIF1 α proteins in colon mucosa – by Western blot analysis; superoxide dismutase (SOD) and matrix metalloproteinases (MMP) activity – by zymography method; catalase activity, level of thiobarbituric acid (TBA) reactive substances, mucus glycoproteins and its carbohydrate composition – colorimetrically; epithelial permeability was evaluated by Evans blue permeation and bacterial translocation.

Results: Cf injection leads to compositional changes of fecal microbiota which progress over time. In 56 days, we found increased level of *Clostridium spp.*, *E. coli*, conditionally pathogenic and hemolytic bacteria. Levels of *Bifidobacterium*

& *Lactobacillus* were unchanged during the study. Moreover, the concentrations of acetic, propionic, butyric acids and total SCFAs were decreased 2.9-, 13.8-, 8.5-, 4.8-fold ($P < 0.05$), respectively, the first day after Cf withdrawal. These changes were accompanied by decreased immunoreactivity for the FFA2, FFA3 receptors, SMCT1 and increase MCT1 & MCT4 transporters of SCFAs in colon mucosa. In 56 days, concentration of SCFAs and level of FFA3 was still below control values. These changes evoked a significant shift in colonic mucosal homeostasis. We revealed increased level of TBA-active substances, decreased the activity of SOD and catalase antioxidant enzymes with increased HIF1 α , activation ERK1/2 and decreased p38 MAP kinases activity after Cf injection. Hypoxia and oxidative stress development were associated with increased permeability of colon epithelium and bacterial translocation to blood in 56 days after Cf withdrawal. Moreover, the levels of mucus glycoproteins, hexoses and fucose decreased while sialation of mucus glycoproteins increased which is typical for IBD development. These changes were accompanied by increased activity of MMP-9 and decrease – MMP-2 in rats colon mucosa.

Conclusion: We showed for the first time that antibiotic treatment induced long-term changes in SCFAs composition, levels of their receptors and transporters in colonic mucosa. It was associated with alterations in mucus composition, increased epithelial permeability that might increase susceptibility to IBD development.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: According to our previous report, the imbalance of Treg/Th17 cells in the DSS induced UC mice is related with the reduction of CD45RA⁺FoxP3^{high} activated Treg(FrII) cells, which has the real function of immunosuppression, and with the elevation of CD45RA⁺FoxP3^{low} Treg(FrIII) cells, which provide FoxP3⁺IL17a⁺ trait but lack of immunosuppressive capacity. Activation of Toll-like receptor 2 (TLR2) leads to elevation of FrIII, which show FoxP3⁺IL17a⁺ trait by secreting IL-17a.

Aims & Methods: To investigate the influence of TLR2 on imbalanced Treg/Th17 in DSS induced ulcerative mice. 18 mice were divided into three groups, including healthy control mice (group A), ulcerative colitis mice (group B) and TLR2mAb intervened-UC mice (group C). Weight and DAI (disease activity index) of every mice were recorded once a day. After being sacrificed, pathological examination of the rectum of all the mice were carried out. Treg cells with their subsets, Th17 cells and CD3⁺CD8⁺CD25⁺FoxP3⁺IL-17a⁺ cells from the lamina propria of colon (LPC) and other tissues of mice were evaluated by flow cytometry.

Results: (1) Declined vitality, anorexia, weight lost and bloody purulent stool were the major symptoms of UC mice. The symptoms of TLR2mAb intervened-UC mice were alleviated, and the DAIs of these mice showed difference from UC mice ($P < 0.05$). The inflammation of colonic mucosa in TLR2mAb intervened-UC mice were also attenuated compared with UC mice. (2) Compared with group A, the Treg cells of group B were increased in PBMC, MLN and LPC (1.275 \pm 0.063 vs 1.168 \pm 0.028, 6.067 \pm 0.152 vs 3.652 \pm 0.639, 5.657 \pm 0.211 vs 1.173 \pm 0.150, $P < 0.05$ respectively). The level of Treg cells in PBMC of group C was declined compared with group B (1.153 \pm 0.028 vs 1.275 \pm 0.063, $P < 0.05$). (3) The levels of Th17 cells were elevated in PBMC and LPC of group B compared with group A (0.488 \pm 0.015 vs 0.328 \pm 0.023, 4.300 \pm 0.137 vs 1.333 \pm 0.126, $P < 0.05$), but Th17 cells were decreased in PBMC of group C compared with group B (0.273 \pm 0.061 vs 0.488 \pm 0.015, $P < 0.05$). (4) Descended FrII cells were detected in PBMC, MLN and LPC of group B compared with group A (0.016 \pm 0.005 vs 0.030 \pm 0.009, 0.123 \pm 0.012 vs 0.465 \pm 0.024, 0.233 \pm 0.022 vs 0.367 \pm 0.018, $P < 0.05$ respectively). Otherwise, increased FrII cells were in spleen, PBMC, MLN and LPC of group C compared with group B (0.577 \pm 0.016 vs 0.220 \pm 0.309, 0.030 \pm 0.009 vs 0.016 \pm 0.005, 0.467 \pm 0.016 vs 0.123 \pm 0.012, 0.365 \pm 0.019 vs 0.233 \pm 0.022, $P < 0.05$ respectively). FrIII cells were elevated in PBMC, MLN and LPC of group B compared with group A (4.215 \pm 0.490 vs 3.128 \pm 0.171, 14.463 \pm 0.463 vs 8.740 \pm 1.140, 9.487 \pm 0.604 vs 3.760 \pm 0.104, $P < 0.05$ respectively). Moreover, declined FrIII cells were observed in spleen and PBMC of group C compared with group B (8.967 \pm 0.354 vs 14.122 \pm 0.438, 3.070 \pm 0.763 vs 4.215 \pm 0.490, $P < 0.05$). (5) Compared with group A, CD3⁺CD8⁺CD25⁺FoxP3⁺IL17a⁺ cells were increased

in PBMC, MLN and LPC in group B (3.915 \pm 0.264 vs 2.533 \pm 0.076, 1.672 \pm 0.158 vs 0.898 \pm 0.044, 5.967 \pm 0.100 vs 2.308 \pm 0.252, $P < 0.05$ respectively). But the level of CD3⁺CD8⁺CD25⁺FoxP3⁺IL17a⁺ cells were decreased in spleen, PBMC, MLN and LPC compared with group B (0.538 \pm 0.021 vs 1.238 \pm 0.017, 2.523 \pm 0.066 vs 3.915 \pm 0.264, 0.897 \pm 0.040 vs 1.672 \pm 0.158, 2.443 \pm 0.052 vs 5.967 \pm 0.100, $P < 0.05$ respectively).

Conclusion: By blocking TLR2, TLR2mAb could improve the level of FrII cells in PBMC, MLN and LPC, but reduce the levels of FrIII and FoxP3⁺IL17a⁺ cells in DSS induced UC mice. Furthermore, TLR2mAb could alleviate the DAI index as well as the inflammation of colitis in DSS induced UC mice.

Introduction: Previous studies have shown that the gut microbiota plays an important role in IBD, however there is not a consensus on which bacteria are responsible for the disease. 16S gene profiling studies generate large amounts of information, however they can be confounded by genetic and environmental factors. Twin studies are instrumental in controlling for some of these variabilities, and in this study we investigated the microbiota of twin pairs discordant for Crohn's disease (CD) and Ulcerative colitis (UC) using 16S rRNA gene sequencing, with the aim of identifying taxa associated with disease.

Aims & Methods: Participants were recruited via the UK IBD Twin Registry. Stool samples were collected and frozen using standard methods. Participants who had received antibiotics within 3 months were excluded. Harvey Bradshaw Index and Simple Clinical Colitis Activity Index were recorded. Full medical history was available from the UK IBD Twin Registry. Samples underwent 16S rRNA sequencing using the Illumina MiSeq platform and analysed using our data analysis pipeline. PERMANOVA was used to evaluate associations with clinical metadata, which included matching of twin pairs for analysis, and STAMP was used to identify taxonomic differences between groups.

Results: 20 twin pairs discordant for CD (5MZ:15DZ mean age 52 years) and 17 discordant for UC (6MZ:11DZ mean age 59.7 years) were recruited. 7 subjects with CD had active disease as did 4 with UC.

Gut microbiota from active CD patients had lower bacterial diversity compared to remission CD patients and healthy twins (Shannon diversity index, $p < 0.001$ healthy vs active CD, active vs remission CD, 1-way ANOVA post-hoc = Tukey). Active UC patients also had lower bacterial diversity compared to remission UC patients and healthy twins (Shannon diversity index, $p < 0.01$ healthy vs active UC, $p < 0.05$ active vs remission).

We found that active CD patients had a higher proportion of *Clostridium hylemonae* and *Lactobacillus delbrueckii* compared to healthy twins, and a lower proportion of *Bacteroides uniformis*, *Bacteroides vulgatus*, and *Faecalibacterium prausnitzii* ($p < 0.05$). We found that active UC patients had a lower proportion of *Alistipes* spp. compared to their healthy twins and UC patients in remission ($p < 0.05$).

Conclusion: This study confirms previous findings showing decreased diversity in IBD patients and changes in some bacterial taxa, however our study is the first to show decreases in *Alistipes* spp. in active UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0968 CD4⁺ T CELLS OF IBD PATIENTS ARE CHARACTERIZED BY AN INCREASED EXPRESSION OF THE NUCLEOTIDE RECEPTOR P2Y2, WHICH IMPACTS RELEVANTLY ON PRO-INFLAMMATORY SIGNALING CASCADES

J. Panteleev-Ivlev¹, S. Zundler¹, R. Atreya¹, M. F. Neurath¹, I. Atreya¹

Introduction: Chronic and acute inflammation is often associated with an upregulation of extracellular UTP and ATP nucleotides, which are able to interact with various cell types via purinergic G protein-coupled P2 receptors. Interestingly, former studies already described an increased expression of the ATP/UTP receptor subtype P2Y2 (P2Y2R) in the colonic tissue of IBD patients [1]. However, it remained unknown in how far immune cells of IBD patients are also characterized by an altered P2Y2R expression and whether this might impact on their pro-inflammatory capacity.

Aims & Methods: P2Y2R mRNA and protein expression on primary CD4⁺ T cells from the blood of IBD patients or healthy donors was analyzed via qPCR or western blot, respectively. Furthermore, primary human CD4⁺ T cells were stimulated in the presence of UTP or the selective P2Y2R agonist 2-thio-UTP and

subsequently analyzed for STAT3 signaling (western blot), NFkB signaling (NFkB Transcription Factor Assay, western blot) and cytokine secretion (ELISA).

Results: Peripheral blood CD4⁺ T cells from IBD patients could be characterized by a significantly increased P2Y2R expression compared to healthy controls, while expression levels of the P2Y4 receptor subtype turned out to be comparable between both groups. Further subdividing the group of included IBD patients into Crohn's disease and ulcerative colitis patients, we could not observe a significant difference in the P2Y2R levels between both disease entities. Interestingly, the increased P2Y2R expression in the lymphocyte compartment of IBD patients seemed to be limited to CD4⁺ T cells, as CD8⁺ T cells of those patients even showed decreased P2Y2R levels. Regarding potential regulators of P2Y2R expression in the context of IBD, our data identified IL-6 and TGF- β as potent inducers of P2Y2R expression in human CD4⁺ T cells. Interestingly high extracellular UTP levels resulted in a decreased expression of the TGF- β 1 receptor on CD4⁺ T cells, implicating a potential negative feedback loop in which P2Y2R signaling might inhibit TGF- β induced P2Y2R expression over time. Regarding the impact of P2Y2R signaling on the pro-inflammatory capacity of human lymphocytes, our data indicate that the selective P2Y2R agonist 2-Thio-UTP is able to mediate NFkB as well as STAT3 activation and to induce secretion of the pro-inflammatory cytokines IL-6 and IL-17 in stimulated human CD4⁺ T cells.

Conclusion: The observed increased expression of P2Y2R in CD4⁺ T cells of IBD patients together with the demonstrated pro-inflammatory effects of P2Y2R signaling in human T cells markedly strengthen the role of P2Y2R as a promising molecular target in IBD.

Introduction: Environmental hypoxia has been increasingly recognized as an important environmental factor associated with Inflammatory Bowel Disease (IBD). Hypoxia allows the stabilization of hypoxia inducible factor (HIF) complexes and has been linked to the activation of autophagy. HIF1 α is induced in the inflamed mucosa from IBD patients and mouse models of colitis, but its role in intestinal inflammation is still controversial since both, positive and negative effects have been reported.

Aims & Methods: We aim to elucidate the effects of HIF1 α stabilization in autophagy and the development of intestinal inflammation in a murine model of colitis. Female C57BL/6J mice between 8–10 weeks of age were exposed to 2% DSS in drinking water for 7 days, and received 8 mg of the hydroxylase inhibitor dimethylxaloylglycine (DMOG) intraperitoneally every second day. Mice were killed at day 9, mucosal damage was assessed by colonoscopy and murine endoscopic score of colitis severity (MEICS) was calculated. H&E staining was performed to analyze the histological damage. Expression of TNF, IL-6, IL-1 β and Nlrp3 was analyzed by qPCR and protein expression of p-NFkB, NFkB, p-mTOR, mTOR, Nlrp3, p62, LC3 was assessed by Western Blot. HT-29 cells were subjected to normoxia (21% O₂) or hypoxia (0.2% O₂) for 24 h in the presence or absence of 40 μ M chloroquine. Cells were stained with DAPI and LysoTracker Yellow-HCK-123 to monitor lysosomal accumulation. Chromatin immunoprecipitation (ChIP) analysis was performed using an antibody against HIF1 α and PCR was performed using the promoter-specific primers for the p62 promoter binding sites of HIF1 α .

Results: DMOG administration induced a significant lower reduction of body weight in DSS-treated mice compared to DSS-treated mice administered with vehicle. Furthermore, mice administered with DMOG presented less reduction in the colon length, a significant reduction in the MEICS and histological scores showing intact crypts in large areas without extensive infiltration or thickening of the mucosa. The mRNA expression of the pro-inflammatory factors TNF, IL-6, IL-1 β and Nlrp3 was significantly reduced in mice treated with DMOG compared to vehicle-treated mice. At a protein level, DMOG administration reduced p-NFkB and NLRP3 expression. DMOG-treated mice also showed activation of autophagy, as evidenced by a decrease in p-mTOR and p62 expression and increase of LC3II. *In vitro*, hypoxia induced a significant accumulation of lysosomes in HT-29 cells and a reduction of p-NFkB. The late-stage autophagy inhibitor chloroquine reverted this effect indicating that was autophagy-mediated. Finally, ChIP analysis revealed that hypoxia induced the binding of HIF1 α to the promoter of p62.

Conclusion: Our results indicate that DMOG-mediated HIF1 α stabilization ameliorates DSS-induced colitis, activates autophagy and significantly reduces inflammatory gene expression and signaling. In cultured intestinal epithelial

cells hypoxia triggers lysosomal formation and HIF1 α binds to the promoter of p62, thereby promoting autophagy.

Introduction: There are several medical treatment options for inflammatory bowel disease (IBD), but all have drawback due to their significant adverse effects. Many new drugs are being developed for more safe and effective treatment. Apocynin is a chemical 4-hydroxy-3-methoxyacetophenone which is an inhibitor of NADPH oxidase and has showed promising effect in various chronic inflammatory diseases such as asthma and atherosclerosis. Due to its anti-inflammatory effect and safety profile, apocynin can be new candidate for the treatment of IBD.

Aims & Methods: In this study, we aimed to investigate effect of apocynin on colonic inflammation and the action mechanism using chemically-induced colitis mouse model. We used dextran sulfate sodium (DSS)-induced colitis model. 8 weeks old male BALB/c mice were divided into four groups (each group, n=6): control, DSS only, DSS with apocynin, and DSS with sulfasalazine. Water (control and DSS group), apocynin (400 mg/kg) and sulfasalazine (150 mg/kg) were administered by oral route using sonde during 7 days. For western blot analysis, mouse colon was lysed and protein was extracted. The following antibodies were used: iNOS (BD Biosciences), COX-2, Nrf2 (Santa Cruz Biotechnology Inc), MCP-1, TNF- α , p-Nrf2, HO-1 (Abcam), and β -actin (Sigma).

Results: Protective effect of apocynin was evident by weight change and colon length. Histologic analysis also showed improved erosion and decreased neutrophilic infiltration in apocynin group compared to DSS group. In colon tissue, several pro-inflammatory enzymes and cytokines are decreased by apocynin. Apocynin also activated anti-inflammatory pathway by inducing activation of Nrf2 and production of heme oxygenase-1 (HO-1).

Conclusion: Apocynin, a NADPH-oxidase inhibitor, showed significant anti-inflammatory effect in DSS induced colitis model. Considering its good safety profile, this molecule can be a new candidate for the treatment of IBD.

Introduction: Faecal metabolic profiling has been shown to distinguish Inflammatory Bowel Disease (IBD) from healthy controls (HC), specifically with depletion of gut-associated short chained fatty acids (SCFA) as the predominant feature separating these groups (1). Previous and current studies have used proton nuclear magnetic resonance (1H NMR) spectroscopy or mass spectrometry (MS) to measure faecal metabolites to examine the metabolic, microbiomic and clinical response of IBD patients to different treatments. Both techniques require a significant amount of sample pre-processing.

Rapid Evaporative Ionization Mass Spectrometry (REIMS) is a relatively new technology which applies a laser to a biological sample, and the resulting vapour, containing gas phase ions of metabolites and structural lipids, is analysed by a mass spectrometer (2). Unprocessed faecal samples can be rapidly assessed using this technique to obtain lipidomic spectral profiles (2). To our knowledge this is the first study that has used REIMS to investigate whether IBD patients can be distinguished from healthy controls using faecal samples.

Aims & Methods: Unprocessed faecal samples from 109 IBD patients and 46 healthy controls were analysed using Rapid Evaporative Ionization Mass Spectrometry. Clinical and dietary data were collected, and patients with significant other co-morbidities were excluded. Partial least squares discriminative analysis (PLSDA) was performed to examine whether there was differences in the metabolic data between patients with Inflammatory Bowel Disease and healthy controls. Further subgroup analysis was then carried out including examining whether ulcerative colitis could be distinguished from Crohn's disease.

Participant characteristics

	IBD	Healthy Control
Number (%)	109	46
Age (mean)	48	55
Male	51 (47%)	19 (41%)
Caucasian	63 (58%)	21 (46%)
Crohn's disease	62 (57%)	–
High IBD (> 30 kg/m ²)	14 (13%)	10 (21%)

Results: Supervised multivariate analysis (PLSDA) was able to separate faecal samples of IBD patients from healthy controls, and sub-analysis showed a stronger separation of Crohn's disease patients from healthy controls (Q2 quality assurance of 0.2) compared to UC from healthy controls. A model comparing Crohn's disease from UC was able to separate the two groups.

Conclusion: This early preliminary analysis shows that there is a degree of separation between samples of IBD patients compared to healthy control. This suggests that REIMS analysis has good potential as a research tool in IBD metabonomic studies, and importantly in the current ongoing longitudinal IBD research. Further analysis will include identifying the principal metabolites that separate these groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0972 THE PATHOGENIC MECHANISM OF ARYL HYDROCARBON RECEPTOR MEDIATED ABNORMAL DIFFERENTIATION OF INTESTINAL ILC3/ILC1 IN CROHN'S DISEASE

X. Zhao, H. Zhang

Department Of Gastroenterology, Jiangsu Province Hospital and Nanjing Medical University, Nanjing/China

Contact E-mail Address: zhaoxj91718@163.com

Introduction: The abnormal differentiation of intestinal innate lymphoid cells ILC3 and ILC1 exist in autoimmune disease. ILC3 decreased and ILC1 increased in Crohn's disease (CD) patients, suggesting that CD patients have abnormal intestinal ILC3/ILC1 alteration.

Aims & Methods: The present study investigated the aberrant colonic mucosal ILC3/ILC1 in active CD patients and 2, 4, 6-trinitrobenzene sulphonic acid (TNBS)-induced colitis mice. The expressions of aryl hydrocarbon receptor (AhR) in colon of active and quiescent CD patients were detected by western blot and immunofluorescence. The ILC3/ILC1 were investigated in CD patients and 2, 4, 6-trinitrobenzene sulphonic acid (TNBS)-induced colitis mice (AhR^{-/-}, AhR^{+/-}).

Results: Compared to quiescent CD patients, the expression of aryl hydrocarbon receptor (AhR) in the intestinal tissue in active CD patients was decreased. Meanwhile, the number of ILC3 in active CD patients and AhR knockout mice was decreased while ILC1 increased. The intestinal inflammation in AhR knockout mice given TNBS was more severe than wild-type mice.

Conclusion: These findings suggest that AhR may mediate abnormal differentiation of ILC3/ILC1, and the production of inflammatory cytokines, finally, promotes the pathogenesis of CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Long polar fimbriae (LpfA), FimH adhesin and ChiA chitinase have been related with adherent-invasive *E. coli* (AIEC) pathogenesis. Controversial results have been found regarding the prevalence of LpfA in AIEC vs non-AIEC (1, 2). Some FimH amino acid variants were reported to be specific for AIEC (3) whereas other variants were associated with phylogroup and disease origin of the strains (4). Differences in the ChiA sequence were reported between LF82 and K-12 strains but this gene has not been studied in other AIEC yet (5).

Aims & Methods: The prevalence of lpfA and the distribution of fimH and chiA variants in a collection of AIEC and non-AIEC from different disease origins - Crohn's disease (CD), ulcerative colitis (UC) and colorectal cancer (CRC) - were studied with the purpose to determine if these genes could be used as molecular markers for AIEC identification and disease diagnostics. In a collection of 37 AIEC and 29 non-AIEC isolated from CD, UC, CRC patients and controls, lpfA gene was PCR-amplified to assess its presence and fimH and chiA genes were sequenced to identify point mutations. For comparison of FimH and ChiA protein sequences, UPGMA phylogenetic tree and allele identification was performed using MEGA5. The genetic differences were annotated using as reference the K-12 strain. Then, they were analysed statistically according to AIEC pathotype, phylogroup, and disease origin by the χ² test and non-parametric tests were used to evaluate amino acid variability regarding the adhesion and invasion indices.

Results: Low gene frequency for lpfA141 and lpfA154 was reported (11.7% and 16.7% respectively). LpfA154 was only found in strains from A (22%) and B1 phylogroup (86%) and no relation with AIEC phenotype or disease was observed. Two main clusters of FimH were obtained by phylogenetic analysis, classifying the strains according to the presence of S78N mutation. N70S and S78N variants were characteristic from strains of B2 and D phylogroups as none of the A or B1 strains presented it. Despite statistical significance was not reached, the strains with N70S, S78N, V163A, R166H mutations showed the highest adhesiveness. Regarding ChiA, two main clusters defined by the presence or absence of an insertion in 312–314 residues were obtained. None of the five previously mutations found in LF82 strain were associated with AIEC strains, whereas the V415A variant was found specifically in AIEC (20%) (p=0.049). Of note, among the strains harbouring the 312–314 insertion, a subcluster that shared identical amino acid sequence included the LF82 strain and the 44% of AIEC strains but only the 10% of the non-AIEC (p=0.019). No differences between FimH/ChiA variants and origin of isolation was observed.

Conclusion: In contrast with other studies, no relation of lpfA presence nor in FimH mutations with AIEC pathotype or disease was observed. Nonetheless, a variant in ChiA sequence more frequently found in AIEC isolates was reported, being an interesting signature sequence for the detection of at least a subgroup of AIEC strains. Further confirmation in a wider strain collection would be required.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Primary sclerosing cholangitis (PSC) is a progressive disorder of biliary tree which can lead to end-stage liver disease, liver transplantation or even death^{1, 2}. Colitis accompanying PSC is considered to be a phenotype of IBD (inflammatory bowel disease) distinct from ulcerative colitis (UC) and is often referred to as "PSC-IBD"³.

Aims & Methods: Our aim was to compare the gut bacterial microbiota of patients with PSC and UC. Stool samples were prospectively collected and relevant clinical data obtained from 106 study participants, 43 PSC patients with (n=32) or without (n=11) concomitant IBD, 32 UC patients, and 31 healthy controls (HC). Sequencing of the 16S rRNA gene including the V3 and V4 regions was performed on Illumina MiSeq platform to cover low taxonomic

levels. Data were further processed in QIIME employing MaAsLin and LEfSe tools for analysis of the output data.

Results: Microbial profiles in both PSC and UC were characterized by low bacterial diversity and significant change in global microbial composition. *Rothia*, *Enterococcus*, *Streptococcus*, *Veillonella*, and three other genera were markedly overrepresented in PSC regardless of concomitant IBD. *Rothia*, *Veillonella* and *Streptococcus* were tracked to the species level to identify *Rothia mucilaginosa*, *Streptococcus infantus*, *S. alactolyticus*, and *S. equi* along with *Veillonella parvula* and *V. dispar*. PSC was further characterized by decreased abundance of *Adlercreutzia equolifaciens* and *Prevotella copri*. Decrease in genus *Phascolarctobacterium* was linked to presence of colonic inflammation regardless of IBD phenotype. *Akkermansia muciniphila*, *Butyrivibrio pullicaecorum* and *Clostridium colinum* were decreased in UC along with genus *Roseburia*. Unclassified *Actinomyces* species were markedly increased in overlap syndrome of autoimmune hepatitis (AIH) and PSC. Low levels of serum albumin were significantly correlated with enrichment of order Actinomycetales.

Conclusion: PSC was characterized by microbial features independent of concomitant IBD. Several bacterial taxa clearly distinguished IBD phenotypes (PSC–IBD and UC) as well as PSC from PSC/AIH.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The characteristic inflammation associated with IBD contributes to repeated cycles of epithelial wounding and repair in the intestine. The epithelium functions as a selective barrier, critical for mucosal protection. During intestinal inflammation, damage to the vasculature leads to reduced oxygen availability (hypoxia) at the mucosa. Epithelial wound healing processes occur in this hypoxic environment and are critical to restore barrier integrity and gut homeostasis. A key factor in the co-ordination of mucosal wound healing is the transcription factor Hypoxia inducible factor (HIF)-1. HIF-1 mediates an array of protective mechanisms for cell survival and repair. Previous work has shown that pharmacological stabilisation of HIF-1 α by prolyl hydroxylase inhibitors (PHDi) is protective in murine models of colitis. Importantly, our work has identified HIF-1-mediated induction of integrin- β 1 at the mucosa as critical to this process.

Aims & Methods: We aimed to examine the functional role and post-translational activity of epithelial α -integrin subunits dimerizing with integrin- β 1 to promote HIF-1-mediated wound healing by PHDi. Cell migration and inhibition scratch assays were performed on T84 monolayers (~1% O₂ and/or PHDi (AKB-4924), wound closure was monitored over 24 hours. Monolayers were stained by immunofluorescence for α -integrin subunits at 12 hours post-wound. Novel biopsy-wound models were used to extend the study of PHDi-mediated wound healing *in vivo*.

Results: PHDi treatment significantly accelerated wound closure in T84 monolayers, which was inhibited by antibodies functionally targeting integrin- α 3. Immunofluorescent imaging of cell monolayers showed both hypoxia and PHDi treatments increased expression of integrin- α 3, localized at the leading edge of the wound. PHDi treatment also significantly accelerated mucosal wound closure in the colons of mice following biopsy wounds with elevated expression of integrin- α 3 associated with the wound epithelium.

Conclusion: These data suggest that PHDi-mediated HIF-1 stabilisation promotes mucosal healing through regulation of epithelial integrins, in particular α 3 β 1. Integrin- α 3 β 1 is a key regulator of epithelial cytoskeletal organization therefore PHDi compounds may enhance wound closure through integrin- α 3 β 1-mediated re-organisation of the cytoskeleton.

P0977 EFFECTS OF TIME ON URINARY METABOLIC SIGNATURES IN INFLAMMATORY BOWEL DISEASE

Introduction: Metabolic profiling (metabonomics) has been proposed as a novel clinical tool in IBD to predict development of complex disease, or for longitudinal non-invasive monitoring of activity and/or response to drug treatment. Urinary metabonomics can distinguish IBD from healthy controls(1) but no studies to date have assessed the stability of these discriminatory profiles over time. Studies in healthy adults show metabolic signatures are largely unchanged over periods of up to 3 years(2), but signals are influenced by multiple external factors including medication and surgery, so how these change in IBD is unknown. The aim of this study was to compare baseline urinary metabolic profiles of IBD patients with a repeated sample several years later to assess similarity, and also to test if any clinical outcomes could be retrospectively predicted from the baseline sample.

Aims & Methods: Two urine samples from 39 IBD patients (22 Crohn's disease (CD) and 17 ulcerative colitis (UC)) were collected - one at baseline and one several years later (range 7–9 yrs). These were analysed by 1H NMR spectroscopy. Disease progression was defined as initiation of immunosuppression or biologics, progression of disease location or phenotype, or surgery. Principal components analysis was used to visualise the variance between the two time-points within the cohort. Orthogonal partial least squares discriminant analysis (OPLSDA) was used to establish if the metabolic signatures could be used to predict adverse clinical outcomes in the patients studied.

Results: 57% of CD patients and 17% of UC patients had clinical progression at follow-up sampling. PCA showed clustering of sample pairs from the baseline and several years later in most individuals, suggesting intra-individual similarity across time. OPLSDA showed no statistical models could be built to predict combined poor outcome based on the initial urinary metabolic profile ($p=0.26$). However, the small subgroup who went on to require surgical intervention could be separated from the cohort in a model ($Q^2=0.015$; $p=0.03$) constructed on their baseline profiles.

Conclusion: The metabolic profile of IBD in an individual appears relatively stable over a significant time period despite a variety of clinical outcomes and interventions. Variations in longitudinal measurements appear to be subtle, and therefore application of this technique for disease monitoring and risk stratification could prove difficult. These results may suggest that metabolic profiling could be exploited to predict a higher risk of requiring future surgery.

P0978 BACTERIAL TRANSLOCATION CONTINUES IN ULCERATIVE COLITIS DESPITE MUCOSAL HEALING AND CONTINUED CLINICAL REMISSION

A. Steel

Gastroenterology, Royal Liverpool & Broadgreen University Hospital, Liverpool/United Kingdom

Contact E-mail Address: alan.steel@rlbuht.nhs.uk

Introduction: Mucosal healing is considered to be the hallmark of successful therapy in Ulcerative Colitis, and has become increasingly used as a target of therapeutic interventions. Loss of mucosal integrity and associated translocation of bacterial components across the mucosal epithelial barrier occurs in Ulcerative Colitis and persistence of a structural mucosal defect is a characteristic of chronic inflammatory bowel disease. Mucosal healing can be defined by clinical, endoscopic and histological means but no clear definition of the required extent of mucosal healing exists, nor is there agreement on how functional mucosal healing is defined.

Aims & Methods: To define the extent and associations of mucosal healing in patients with Ulcerative Colitis and the relationship with bacterial translocation and clinical remission. Patients with established diagnosis of Ulcerative Colitis undergoing endoscopic evaluation were recruited to the study (Ethics: South West London REC2 10/H0706/26). Clinical history and long-term follow-up data were recorded. Blood and mucosal samples were prepared as mononuclear cells. Healthy controls recruited from cohort undergoing routine lower gastrointestinal investigations without positive findings. Flow cytometry characterisation of cells by cell surface CD45RO, CD27, CD3, CD14, CD8 and CD161 and cytokine expression after staphylococcal enterotoxin B stimulation by IL-2, IL-17a, IL-22, TNF, IL-17f and IFN γ . Immunohistochemistry to define tight junction apical epithelial expression (Claudin 1, Claudin 4 and Occludin) and lipopolysaccharide within the lamina propria. Peripheral blood markers of bacterial translocation: bacterial DNA (16srDNA), lipopolysaccharide Binding protein (LBP), soluble CD14 and plasma lipopolysaccharide. Statistical analysis by Mann Whitney or Kruskal Wallis analysis with Dunn's post test correction, or by Spearman rho correlation.

Results: 28 patients with Ulcerative Colitis, duration of disease 4 months to 31 years (median 6.3 years) and 22 Healthy Controls were recruited to the study. Half of the patients had active disease as assessed by Ulcerative Colitis Severity Score. Disease severity positively correlated with frequency of mucosal Th17 (CD4+IL-17a+) and IL-17f. Breaches in tight junction protein expression were greater in UC than controls: Claudin 1 ($p < 0.0001$), Claudin 4 ($p = 0.0016$) and occludin ($p = 0.03$). The serum marker of bacterial translocation, lipopolysaccharide binding protein (LBP) was elevated in UC compared to controls ($p = 0.0078$) and was positively correlated with breaches of Claudin 1 and Occludin ($p = 0.018$ and $p = 0.012$ respectively). Staining colon biopsies for the presence of lipopolysaccharide in the lamina propria demonstrated positive findings in healthy controls, supported by data from 16s rDNA analysis of blood from healthy controls. In the Ulcerative Colitis cohort in clinical remission the absence of lipopolysaccharide in the lamina propria was associated with elevated levels of LBP and increased breaches of Occludin ($p = 0.0022$).

Conclusion: Breaches of tight junction proteins in the colon of patients with stable clinical remission can be detected and are associated with perturbations of mucosal immunological function and markers of bacterial translocation. Lipopolysaccharide presence in the lamina propria of patients in remission appears to be associated with less tight junction breaches and reduced local and systemic evidence of bacterial translocation. These findings require further study, specifically to examine the role of mucosal immune tolerance to lipopolysaccharide and other bacterial cell products that may be present in the healed mucosa of ulcerative colitis.

P0979 EFFECT OF FIBER AND FAT CONSUMPTION ON DISEASE ACTIVITY AND QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

I. Pefkianaki, I. Mouzas, I. Koutroubakis

Contact E-mail Address: medp2011775@med.uoc.gr

Introduction: Diet may influence intestinal inflammation via various pathways but the evidence regarding the role of fiber or fat intake in patients with inflammatory bowel disease (IBD) is controversial.

Aims & Methods: The aim of this study was to investigate the association between dietary fiber or total fat intake and disease activity or quality of life in Greek IBD patients. We prospectively collected food frequency questionnaires (FFQ) from consecutive IBD patients at outpatient visits. The European Prospective Investigation into Cancer and Nutrition (EPIC) Study FFQ for Greek population with the MAFF photographic food atlas were used in order to collect information for dietary habits of IBD patients. Moreover, disease activity using the simple colitis activity index (SCCAI) (for ulcerative colitis (UC)) and Harvey-Bradshaw index (HBI) for Crohn's disease (CD)) as well as quality of life using the short inflammatory bowel disease questionnaire (SIBDQ) were evaluated. Patients' demographic, clinical characteristics, nutritional status, laboratory data [C reactive protein (CRP), haemoglobin, erythrocyte sedimentation rate (ESR), platelets and albumin] and treatment data were recorded and analysed for all participants.

Results: A total of 141 consecutive IBD patients (53 UC, 88 CD, mean age 47.2 ± 16.1 years, 84 males 57 females, mean BMI 26.7 ± 5.3) were included. Patients' mean daily fiber intake was 21.8 gr (IQR 13.8–34.6) and mean daily total fat was 161.4 gr (121.2–237) with 43.5% percent energy from fat. Regarding disease activity 34 (24.1%) patients had active disease with HBI or SCCAI score ≥ 5 whereas 45 (31.9%) patients had poor quality of life with SIBDQ score ≤ 50 . There was no difference in daily fiber or fat consumption between patients with UC and CD [median daily fiber intake 23.5 (IQR 10.8–36.5) gr vs 21.7 (14.6–34.2) gr ($p = 0.86$), median fat intake 148.7 (112.4–242.8) gr vs 169.4 (127.1–236.7) gr ($p = 0.30$)]. There was a significant negative correlation between fiber intake and disease activity in both UC ($r = -0.37$ $p = 0.007$) and CD ($r = -0.32$, $p = 0.002$) while there was not significant correlation between fat intake and disease activity (in both diseases $p > 0.05$). No association of fiber or fat consumption with abnormal CRP, increased ESR, presence of anemia, thrombocytosis or low albumin was found (all with $p > 0.05$). SIBDQ score had a significant correlation only with fiber intake ($r = 0.31$ $p = 0.0002$) but not with fat intake ($r = 0.07$ $p = 0.40$).

Conclusion: Higher dietary fiber intake is associated with lower disease activity and better quality of life in patients with IBD. Fat consumption does not seem to influence the disease activity and patients' quality of life. Based on these results it could be suggested that the amount of fiber consumption by IBD patients may play an important role in the disease course.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Crohn's disease (CD) is a progressive disease that over time can lead to the development of complications such as strictures or internal penetrating disease that will ultimately lead to surgery. Only few population-based studies from the biological era and widespread use of immunomodulators have investigated the change in disease behaviour and subsequent risk of surgery in CD.

Aims & Methods: The EpiCom-cohort is a population-based cohort of unselected patients with inflammatory bowel disease diagnosed in 2010 in Eastern and Western European centres. Patients were followed prospectively for five years and clinical data were captured throughout the follow-up period. Disease behaviour was defined according to the Montreal classification as B1: non-stricturing, non-penetrating; B2: stricturing; B3: penetrating based on endoscopy, cross-sectional imaging or surgery. The risk of progressing from B1 to B2/B3 as well as the risk of surgical resection was analysed by Cox regression analyses using the proportional hazard assumption including multiple covariates (age, gender, disease location, diagnostic delay, smoking status, change in behaviour, geographic region and treatment with biologics within 6 months from diagnosis).

Results: A total of 488 incident CD patients were included in the study, of which 347 (71%) had B1. A total of 141 (29%) patients had complicated CD at diagnosis. After 5 years' follow-up, this number increased to 190 (39%) (Table 1). Of patients diagnosed with B1, 35 (10%) progressed to B2 while 14 (4%) progressed to B3 after a median of 21 months (range: 0–62). The proportion of B1 patients changing behaviour was highest during the 1st year of disease (5%) but stable during the remaining follow-up period (approx. 2%/year). Colonic location (L2 vs L4 HR: 0.3 CI95%: 0.1–0.8), extra-intestinal manifestations at diagnosis (HR: 0.2 CI95%: 0.1–0.8), and the need for early biologics (HR: 2.5 CI95%: 1.2–5.1) were associated with progression in behaviour. During follow-up, a total of 107 (22%) patients had a resection. Of patients with B1 as initial behaviour a total of 37 (11%) patients had a resection. A change in behaviour from B1 to B2/B3 (HR 6.8 CI95%: 3.0–15.6) and early biologics (HR 0.5 CI95%: 0.2–0.5) was

associated with the risk for resection. No difference in the results was found between Eastern and Western European patients.

Table 1: Disease behaviour in Crohn's disease at diagnosis and follow-up

At diagnosis	At follow-up			Total (diagnosis)
	B1	B2	B3	
B1, non-stricturing, non-penetrating	298 (61%)	35 (7%)	14 (3%)	347 (71%)
B2, stricturing	–	89 (18%)	11 (3%)	100 (21%)
B3, penetrating	–	–	41 (8%)	41 (8%)
Total (follow-up)	298 (61%)	124 (25%)	66 (14%)	488 (100%)

Conclusion: In this European population-based inception cohort of unselected CD patients 14% of patients with B1 progressed to B2 or B3 after five years of follow-up. The risk of surgery was increased in patients with B1 who progressed to B2/B3. No clinical predictors for progression in behaviour including smoking and treatment with biological therapy could be identified.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0981 CHANGES IN GUT MICROBIOTA COMPOSITION CORRELATE WITH SHORT TERM CHANGES IN FACIAL CALPROTECTIN AND CRP IN PATIENTS WITH CROHN'S DISEASE

D. Chan¹, D. Kumar¹, M. Mendall²

¹Department Of Gastroenterology And Colorectal Surgery, St. George's Hospital, London/United Kingdom

²Department Of Gastroenterology, Croydon University Hospital, Croydon/United Kingdom

Contact E-mail Address: derekchan65@hotmail.com

Introduction: Faecal microbiota are believed to play an important role in the pathogenesis of Crohn's disease (CD). It is not known for certain whether gut microbiota composition (GMC) changes in response to inflammation or whether inflammation in the gut wall is a response to changes in GMC. Dynamic changes in bowel wall inflammation and short term changes in GMC have not previously been studied, but would give a clue as to the aetiological importance of GMC.

Aims & Methods: We aimed to assess the correlation between short changes in GMC and a faecal marker of gut inflammation faecal calprotectin (FC) and CRP a marker of systemic inflammation.

We conducted a blinded sham controlled cross-over study of 32 subjects assigned to IgG4 guided exclusion diets. Each subject was randomised to one month of true or sham diet followed by a one month washout period followed by a further cross-over trial diet. Stool and blood specimens were obtained at time 0, 1 month (completion of first trial diet), 2 months (completion of washout) and 3 months (end of cross-over trial diet). Taxonomic profiling was performed using 16s RNA next generation sequencing. Copy counts were made for firmicutes and bacteroidetes as a phylum; *Roseburia* and *Bifidobacterium* as a genus and *Faecalibacterium prausnitzii* as a species. Shannon diversity was calculated.

Results: 26 people fully completed the study. For each participant this provided six timepoints for comparison: timepoint 1–2, 2–3, 3–4, 1–3, 1–4 and 2–4. The relative abundance of bacteria groups were calculated. Kendall Tau correlation coefficient was used to assess correlation between change in FC and CRP to change in relative abundance of various bacteria. We found significant negative correlation with change in FC and CRP with *Bifidobacterium* genus and change in CRP with *Roseburia* genus. There were poor correlation and inconsistent changes in other species and firmicutes and bacteroidetes and Shannon diversity.

Conclusion: *Bifidobacterium* relative abundance correlate closely with short term changes in FC suggesting a possible causal association. Other genera and species had poor and inconsistent correlations with short term changes in FC suggesting that they may not be causally related to short term changes in gut inflammatory activity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Risk factors for colorectal cancer (CRC) in Inflammatory Bowel Disease (IBD) are still debated (1).

Aims & Methods: In a prospective multicenter, nested case-control IG-IBD study at 4 years, we aimed to assess the frequency and risk factors for incident CRC in IBD. The role of IBD phenotype vs thiopurines (IS) and/or anti-TNFs as risk factors for CRC was also evaluated. From Jan. 2012 to March 2017, all incident cases of CRC in IBD pts referring to 16 IG-IBD Units were recorded. Each IBD pt with CRC (IBD-CRC) was matched with 2 IBD pts with no cancer (IBD-C) for: IBD type (Crohn's Disease, CD vs Ulcerative Colitis, UC), gender, age (± 5 yrs). Cases of CRC derive from a larger cohort of IBD pts referring to the same Units, with incidence of any cancer separately reported at 4 years (follow up at 3 yrs reported for cancer overall)(2). Statistical analysis: data expressed as median (range), Wilcoxon test, Chi-squared test, Fisher exact test; multivariate logistic regression analysis.

Results: Incident cases of CRC occurred in 66 IBD pts: 41 UC (UC-CRC), 25 CD (CD-CRC). IBD group therefore included 198 pts (66 IBD-CRC, 132 IBD-C). UC group included 123 pts (41 UC-CRC, 82 UC-C) and CD group included 75 CD pts (25 CD-CRC, 50 CD-C). The frequency of incident CRC was higher in the tested UC versus CD population (62.1% vs 37.9%; $p=0.009$). Gender was equally distributed in IBD groups (UC: 14 F [34%]; CD: 12 F [48%]; $p=1$). The median age was comparable between IBD-CRC and IBD-C (UC-CRC vs UC-C 62 [37–86] vs 59 [35–86]; CD-CRC vs CD-C: 51 [23–76] vs 55 [22–76]; $p=1$). UC duration was longer in pts with vs without CRC (20 [0–37] vs 10 [0–35]; <10 yrs: 6 [15%] vs 35 [43%]; ≥ 10 yrs: 35 [85%] vs 47 [57%]; $p=0.001$). Conversely, CD duration was comparable between pts with vs without CRC (20 [1–47] vs 13 [0–35]; <10 yrs: 6 [24%] vs 15 [30%]; ≥ 10 yrs: 19 [76%] vs 35 [70%]; $p=0.58$). IBD

CRP	2–4	–0.103	0.465	0.126	0.369	–0.158	0.260	0.080	0.573	0.089	0.531	0.215	0.122

pts with CRC were younger at diagnosis of IBD than their IBD-C (UC-CRC vs UC-C: median yrs:39 [15–76] vs 46 [20–81]; <40 yrs, n=: 21 [51%] vs 27 [33%]; ≥40 yrs: 20 [49%] vs 55 [67%]; p=0.04; CD-CRC vs CD-C: median yrs 27 [6–67] vs 37 [10–67]; <40 yrs, n=19 [76%] vs 26 [52%]; ≥40 yrs: 6 [24%] vs 24 [48%]; p=0.04). The median age at diagnosis of CRC was comparable in UC vs CD (60 [35–83] vs 51 [20–76]; p=0.19). The frequency of CRC was comparable between UC pts using or not IS and/or anti-TNFs (CRC-UC vs CRC-UC: IS monotherapy 6 [15%] vs 17 [21%]; Anti-TNFs monotherapy: no CRC; Combination: 5 [12%] vs 6 [7%]; no IS/no anti-TNFs: 11 [27%] vs 23 [28%]; p=0.88). No differences were also observed between CD pts treated or not with IS and/or anti-TNFs (CRC-CD vs CRC-C: IS monotherapy: 4 [16%] vs 9 [18%]; Anti-TNFs monotherapy: 2 [8%] vs 3 [6%]; Combination: 10 [40%] vs 23 [46%]; no IS/no anti-TNFs: 16 [64%] vs 35 [70%]; p=0.59). CD pts with CRC showed a higher frequency of pattern B1 (B1 vs B2 vs B3 (n [%]): 14 [56%] vs 3 [12%] vs 8 [32%]; p=0.019). Risk factors for CRC considered in multivariate analysis included: age (<40 vs ≥40 yrs), IBD duration (<10 vs ≥10 yrs), smoking habits (Yes/No; Y/N), ISS-anti-TNFs (Y/N), IBD-related surgery, UC extent (extensive vs distal; subtotal vs distal), CD pattern (B3 vs B1, B2 vs B1), perianal CD. In UC, the only significant risk factor was UC duration (OR [95% CI]: OR 3.33 [1.44–9.11], as the other risk factors were not significant: OR 0.94 [0.36–2.98]; 1.28 [0.48–3.04]; 0.96 [0.36–3.08]; 1.78 [0.60–4.66]; 1.36 [0.66–2.89]; 0.38 [0.08–1.23], respectively). In CD, perianal disease was the only significant risk factor for CRC (OR 3.11 [1.16–8.33], as no other significant risk factors were identified (OR 2.21 [0.70–9.87]; 1.66 [0.62–4.96]; 0.56 [0.19–1.41]; 0.99 [0.41–2.52], 0.54 [0.2–1.43], 0.83 [0.26–2.55], 0.23 [0.04–0.83], respectively).

Conclusion: In a prospective, multicenter, nested-case control IG-IBD study, incident cases of CRC were more frequent in UC than in CD. In our cohort, UC duration and perianal CD, but not immunomodulators use, were identified as risk factors for incident cases of CRC in IBD.

Aims & Methods: **Aims:** Primary: to evaluate the incidence of inflammatory bowel disease (IBD) in Spain. Secondary: to describe the characteristics of patients at diagnosis; to evaluate the need for immunomodulators (IMM), biologics, surgery and hospital admissions in the first year of diagnosis and to assess the time from the onset of symptoms to the diagnosis of the disease.

Methods: Prospective and population-based nationwide study. Adult patients diagnosed with IBD %Crohn's disease (CD), ulcerative colitis (UC) or indeterminate colitis (IC)% during 2017 in the 17 Spanish regions are being included. Each case is also being followed-up for 12 months after diagnosis to describe changes in phenotype or location, to evaluate the requirement of IMM and biologics and to determine the need for hospitalization or surgery during the first year from the diagnosis. Data was captured in a web-based database (AEG-REDCap).

Results: An updated interim analysis of the incidence of IBD is planned 6 months after the beginning of the study (June 2017). Up to April 1st 2017, 557 patients from 156 centres have been included: 53% males, mean age 40 years, 27% smokers. 51% had UC, 44% CD, and 5% IC. 13% of patients had a family history of IBD. The mean time to IBD diagnosis from symptoms onset was 3 months (range 0–198). At the time of diagnosis, 10% of the patients had extra-intestinal manifestations (the most frequent being rheumatologic manifestations, in 6% of the cases). In CD patients, 53% had ileal location, 20% colonic, 26% ileocolonic, 2.4% upper gastrointestinal tract involvement, and 13% perianal disease; 8% of patients had stenosing and 7% fistulising behaviour at the time of diagnosis. In UC patients, 30% had extensive colitis and 36% left-sided colitis at diagnosis. The therapeutic requirements were: 28% oral steroids, 13% intravenous steroids, 9% thiopurines, 0.9% methotrexate, 0.4% cyclosporin, and 3.2% anti-TNFs. Twelve patients (2.2%) were operated (5 abdominal and 7 perianal surgery), and 133 patients (24%) required hospital admission within the first 3 months following diagnosis.

Conclusion: In this large nationwide epidemiologic study we describe how the treatment requirement and the consumption of health resources was already high from the time of diagnosis as, indeed, a relevant proportion of IBD patients required surgery or hospital admission within the first 3 months after the diagnosis.

P0984 IMPACT OF ANORECTAL COMPLAINTS ON QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE - A SURVEY OF THE DUTCH NATIONAL CROHN'S AND COLITIS ORGANISATION

P. F. Vollebregt¹, A. A. Van Bodegraven¹, M.I. Markus-De Kwaadsteniet², D. Van Der Horst², R. J. Felt-Bersma¹

¹Gastroenterology And Hepatology, VU University Medical Centre Amsterdam, Amsterdam/Netherlands

²Dutch Crohn's and Colitis organisation, Woerden/Netherlands

Contact E-mail Address: p.vollebregt@vumc.nl

Introduction: Anorectal complaints occur in a considerable group of patients with IBD. There is a dearth of evidence relating to the impact of these complaints on IBD patients' lives. We aimed to survey the effect of anorectal complaints on quality of life in a large cohort of patients who engaged in the Dutch Crohn's and Colitis organisation (CCUVN).

Aims & Methods: In October 2016, the CCUVN had a membership database of 10,047 patients. A comprehensive study questionnaire was sent out online by the CCUVN in January 2015 and October 2016 to a voluntary panel, which consisted of 1710 CCUVN patients. The panel is represented by patients who voluntarily participate in online surveys with regard to disease related subjects. Inclusion criteria were age over 18 years old and a self-reported diagnosis of Crohn's disease (CD), ulcerative colitis (UC) or IBD-unclassified (IBD-U). The survey included the St. Marks incontinence score, perianal disease activity index, faecal incontinence quality of life (FI-QOL) questionnaire and the SF-36 questionnaire. Multiple imputation was used for covariates with missing data. Multivariate regression analysis was performed.

Results: A total of 1094 patients (64%) responded the online survey. Mean age was 47 years (range 18–87), CD diagnosis was predominant (621 CD patients (57%), 431 UC patients (39%) and 42 IBD-U patients (4%)) and diagnosis was established for a mean period of 13 years (interquartile range 3–19 years). Active perianal disease was present in 243 CD patients (39%) and perianal surgery (abscess- or fistula-related) was previously performed in 153 (25%). Faecal incontinence (≥ 1 episode per month) was reported in 305 CD (58%), 230 UC (56%) and 20 IBD-U (51%) patients. Weekly episodes occurred in 41 CD (8%), 22 UC (5%) and 3 IBD-U (8%) patients (mean St. Marks incontinence score 14). FI-QOL scores were not different between the different diagnoses. Multivariate regression analysis (adjusted for gender, diagnosis and previously performed abdominal operations) showed a reduced total SF-36 score in patients with faecal incontinence (β -8.57 [-11.33; -5.81]; $p < 0.0001$) and active perianal disease (β -4.13 [-7.35; -0.91]; $p = 0.01$). A better score was reported in UC patients compared to CD patients (β 3.53 [0.48–6.58]; $p = 0.02$). Previously performed perianal surgery was not associated with SF-36 score in the multivariate analysis.

Conclusion: Anorectal complaints have a substantial impact on the quality of life in patients with IBD, with a (usually unmet and) clear need to treat. More awareness for this highly distressing and most commonly cumbersome treatable disease manifestation is needed.

Introduction: The human gut microbiome is made up predominately of four major bacterial phyla, Firmicutes, Bacteroidetes, Proteobacteria and Actinobacteria. Changes or imbalance of these phyla is termed dysbiosis. Specifically, in inflammatory bowel disease (IBD), key changes have been identified such as a reduction in beneficial bacterial species including *Faecalibacterium prausnitzii* and increases in more pathogenic species including members of the *Enterobacteriaceae*. Currently it is not understood if dysbiosis is

the cause of, or the effect of, intestinal inflammation. It is difficult to chronologically assess the microbiota changes prior to developing IBD as currently we are unable to predict those individuals who will develop the disease. The pouch is a potential model to study pathogenesis of inflammation as 40% of those that develop pouchitis do so within 12 months. The relative short time from pouch formation to inflammation allows the longitudinal study of the microbiota which gives insight into potential microbiota patterns occurring both in disease and non-diseased states. Interestingly, inflammation within the pouch is rarely seen in patients who have this operation for Familial Adenomatous Polyposis (FAP), thus raising the possibility that pouchitis shares a similar pathogenesis to the inflammation that is seen in ulcerative colitis.

Aims & Methods: 1. To understand changes in pouch microbiota over time. 2. To understand pouch microbiota that is associated with pouch inflammation. A computer assisted search of the on-line bibliographic databases MEDLINE and EMBASE was carried between 1966 and February 2016. Randomised controlled trials, cohort studies and observational studies were included. Inclusion criteria: Studies which reported microbiota analysis on either faecal samples or tissue from the ileo-pouch anal anastomosis. Studies that provided information on specific bacterial taxa. Exclusion criteria: Studies which did not report on patterns of individual bacterial taxa differences in the pouch. Studies on the microbiota of Crohn's disease or UC in isolation without any data on pouch patients. Studies with less than ten patients.

Results: The search strategy found 844. There were a total of 27 papers included in the analysis. Microbiota in pouchitis: *Bacteroidetes*, *Enterococcaceae*, *Lachnospiraceae*, *Faecalibacterium*, *Ruminococcaceae*, *Streptococci* *Alcaligenaceae* and *Bifidobacterium* were reduced in patients with pouchitis. Whereas *Enterobacteriaceae*, including *E. coli* *Fusobacterium* and *Clostridia* were increased in patients with pouchitis. One study highlighted bacteria that were exclusively found in pouchitis which included *Leptospira*, *Pseudoalteromonas*, *Desulfohalobium*, *Microcystis*, *Methylobacter*. Chronic pouchitis was associated with a significant increase in *Staphylococcus aureus* and it has been suggested that this may be a responsible pathogen for chronic pouchitis. Furthermore, *Enterococcus*, *F. prausnitzii*, *Lachnospiraceae* and *Insertae Sedis XIV* and have been shown to be significantly reduced in chronic pouchitis patients. These differences were largely due to a decrease in sequences from members of the genera *Ruminococcus*, *Dorea*, *Clostridium*, and *Eubacterium*.

Conclusion: The microbiota undoubtedly plays an important role in both the inflamed and the healthy pouch. However, a direct causal relationship has not yet been established between individual microbiota changes and inflammation. There are many studies that highlight changes in bacterial composition, but studies are limited by heterogeneity of and in particular, analysis techniques and sampling strategies. Studies used a variety of methods to define microbial diversity which can be broadly split into culture vs culture-independent approaches. Culture-based studies are likely to have a bias towards culturing more aerobically friendly microbes than exist in a true pouch environment, thus over-representing aerobic bacteria whilst possibly under-representing anaerobic bacteria. The use of 16 S rRNA analysis methods will negate this effect and represents the future in accurately determining the microbiota.

Introduction: Anti TNF cross placenta during pregnancy and are detectable in the newborn in the first 6 months at least. Along this, European consensus recommends to avoid live vaccines within 6 months of live in newborn exposed in utero to anti TNF treatments. Moreover, anti-TNF treatments are of low risk for breastfed infants but data are scarce. The aim of our study was to evaluate the rate and tolerance 1) of live-vaccines before and after 6 months of life in newborn exposed in utero to anti TNF and 2) of breastfeeding under anti TNF.

Aims & Methods: We performed an observational and retrospective study in 22 French departments of gastroenterology from February 2016 to April 2017. Included patients were inflammatory bowel disease (IBD) women, pregnant under anti TNF, giving birth to alive newborn and agree to answer a questionnaire concerning 1) live-vaccines (BCG, rotavirus, MMR) in their child during first year, 2) breastfeeding and complication and 3) information given during pregnancy.

Results: 124 pregnant women treated with antiTNF were included. The mean age of women was 31 year (IQR 5). 96 (77%) women received anti TNF for Crohn's disease and 28 (23%) for ulcerative colitis or undetermined colitis. AntiTNF used were Infliximab in 76 (61%) patients, Adalimumab in 46 (37%) patients, Golimumab in one patient (1%) and Certolizumab in one (1%) patient. Thiopurine was associated in 29 (23%) patients. 31 (25%) patients experienced flare of IBD during pregnancy, 18 (15%) women were treated with steroids. AntiTNF was discontinued before 26 gestational weeks in 66 (53%) women and resumed after delivery in 112 (90%) patients. 55 women (45%) breastfed their infant and no complication was noted. Among 69 women who did not perform lactation, 42 (63%) did not for personal choice and 25 (37%) because not recommended by the gastroenterologist. Concerning vaccination questionnaires, 96 responses were obtained. BCG was performed in 29 children (30%) and was administered before 6 months in 15 children (14%). One local abscess was reported with favorable evolution. Rotavirus vaccination was performed in 7 children (7%) and before 6 months in 5 (%) cases. One case of fever was reported. MMR vaccination (Measles, Mumps and Rubella) was performed in 62 children (65%); before 6 months in 5 cases. Information concerning fetal exposure to antiTNF and vaccination recommendation was given to 111 (91%) IBD women during pregnancy, by at least the gastroenterologist in 89% of cases, the obstetrician in 25% of cases and the pediatrician in 16% of cases. Information was at least oral in 105 (86%) cases and written in 39 (32%) cases.

Conclusion: Half of women breastfed their child with no reported complication. BCG was administered in 30% of the newborn and performed before 6 months in 50% of cases, with only one case of local abscess. Rotavirus vaccination is rare but often performed before 6 months. Information to pregnant IBD women is only given by gastroenterologist in the majority of cases. Information in maternity by obstetrician and pediatrician should be improved.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0987 OUTCOME OF ENDOSCOPIC ALLY RESECTED DYSPLASIC LESIONS IN ULCERATIVE COLITIS

H. Saoula, A. F. Boutaleb, H. Mahiou, M. Aissaoui, Y. Zmiri, N. Hamidouche, R. Osmane, Y. Aissat, A. Mitiche, A. Gamar, K. Belhocine, N. Bounab, T. Boucekine, L. Kecili, S. Berkane, Z. Amir, M. Nakmouche
Gastroenterology, CHU Bab El Oued, Algiers/Algeria

Contact E-mail Address: houriasaoula@yahoo.fr

Introduction: For a long time, dysplastic lesions in ulcerative colitis were only treated by surgery. Recent guidelines recommend the complete endoscopic resection of dysplastic lesions in ulcerative colitis.

Aims & Methods: The aim of this study was to determine the outcome of dysplastic lesions resected endoscopically in ulcerative colitis. In this prospective study between January 2008 and January 2015, dysplastic lesions detected in patients with longstanding ulcerative colitis were assessed for their resectability, then when it was possible were resected. The patients were followed, and an endoscopic control was done at 6 month than every one year.

Results: 36 dysplastic lesions were identified in 25 patients; 5 lesions were judged not resectable and referred to surgery. 31 lesions were resected in 21 patients: 22 low-grade dysplasia, 7 lesions indefinite for dysplasia, and 2 high-grade dysplasia. 18 patients (85.7%) had endoscopic control: mean 2.8 (maximum: 5 minimum: 1). 2 patients refused next colonoscopy, one patient was not controlled because of a bad bowel preparation for 4 times. In 13 patients (72.2%) no

dysplasia was detected after a mean follow up of 30.16 months (range: 7.56–62.5). Neoplastic lesions were found in 5 patients (27.7%): one adenocarcinoma of the sigmoid detected in a woman that have had a high-grade dysplasia resected in the sigmoid; in 3 patients new dysplastic lesions localized in other segments of the colon than those initially resected. In one patient a serrated rectal adenoma was found in the same place where was resected a serrated adenoma, reflecting an incomplete resection.

Conclusion: Our results confirm that a complete endoscopic resection may be sufficient in dysplastic lesions occurred in ulcerative colitis. Nevertheless a closer follow-up is necessary because these patients may develop newer neoplastic lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0988 CYTOMEGALOVIRUS INFECTION IS ASSOCIATED WITH A POOR OUTCOME IN PATIENTS WITH ULCERATIVE COLITIS TREATED BY VEDOLIZUMAB

X. Roblin¹, L. Bricchet¹, S. Pillet², E. Del Tedesco¹, J.M. Phelip¹, B. Pozzetto², N. Williet¹

¹University of St. Etienne Dept. de Gastroenterologie, Saint Etienne/France²Virology, Saint Etienne university, Saint Etienne/France**Contact E-mail Address:** xavier.robilin@chu-st-etienne.fr

Introduction: Cytomegalovirus (CMV) infection has been associated to resistance to several immunomodulatory therapies in Ulcerative Colitis (UC) patients. The impact of CMV infection in UC patients treated with Vedolizumab is unknown. The aim of this study was to analyze the outcome of UC patients treated with Vedolizumab and to analyze the risk factors for CMV disease associated to Vedolizumab therapy.

Aims & Methods: We performed a retrospective case-control study of all patients with UC treated with Vedolizumab from June 2014 through November 2016 at our IBD center. All eligible patients had presented latent CMV infection with presence of IgG against CMV and undetectable CMV DNA load determined by real time PCR (qPCR) in colonic biopsies before treatment. During the follow-up, a colonoscopy or rectoscopy with sampling of 2 biopsies in inflamed tissue was performed for each patient in case of loss of clinical response under Vedolizumab. Patients with primary non response to Vedolizumab were excluded. All patients with high mucosal CMV DNA load (>250 copies/mg of tissue) were treated with valganciclovir. Patients with undetectable CMV DNA load disease were considered as control group.

Results: Thirty two patients were eligible (sex ratio M/F: 3/1, mean age: 43.6 years, mean disease duration: 7.5 years, E3 phenotype according to the Montreal classification: 90%). Six patients (19%) exhibited high colonic CMV DNA load (median load: 734 copies/mg of tissue) during the first year of the follow-up and were treated with valganciclovir for 6 weeks in association with continued Vedolizumab treatment; the 26 others patients with a undetectable CMV DNA load were included in the control group. After antiviral treatment, the CMV DNA load was found undetectable for all 6 patients. Treatment change was more frequent in the CMV disease group (HR = 3.15 [1.02–9.7], p = 0.03507) with only 16.7% patients who continued Vedolizumab treatment versus 65.4% in the control group (p = 0.052). Colectomy was also more frequent in the CMV group (33.3% versus 7.7% p = 0.064). By multivariate analysis, the only factor associated with the occurrence of CMV disease was a fecal calprotectin less than 600 mcg/g stools at the beginning of the vedolizumab treatment. A previous CMV colic infection also was more frequent but not statistically significant. There was no association between CMV infection and Vedolizumab levels in the sera.

Conclusion: The occurrence of CMV disease, documented with high CMV DNA load on colonic biopsy samples, in UC treated with Vedolizumab is responsible for a negative impact on the natural evolution of UC, with more therapeutic failure and surgical treatment, even after an efficient antiviral treatment.

P0989 F-CALPROTECTIN USE IN INFLAMMATORY BOWEL DISEASE IS CHARACTERISED BY IMPROVED DIAGNOSTIC ACCURACY, LESS PATIENT HARM AND DECREASED COSTS, COMPARED WITH CONVENTIONAL SEROLOGICAL MARKERS AND COLONOSCOPY. THE SPANISH SCENARIO

B. Mascialino¹, A. A. Vora²

¹Immunodiagnosics, Thermo Fisher Scientific, Uppsala/Sweden²Immunodiagnosics, Thermo Fisher Scientific, Portage/United States of America/ MN**Contact E-mail Address:** barbara.mascialino2@thermofisher.com

Introduction: Gastrointestinal disorders may exhibit overlapping symptoms making diagnosis difficult in the primary and specialty care settings. Inflammatory bowel disease (IBD), with a prevalence of <0.5% in the general population[1], is characterized by chronic inflammation of the gastrointestinal tract, non-specific elevation of conventional inflammatory markers such as ESR and CRP and may present with extra-intestinal manifestations. Irritable bowel syndrome (IBS), in contrast, is a functional disorder without gastrointestinal inflammation and with an estimated prevalence of 10–20% [2]. Endoscopy is the gold standard for detecting and quantifying IBD vs. IBS, but due to the low prevalence of IBD, is negative in the majority of cases. Furthermore, it is invasive, expensive, and uncomfortable for the patient and not without risks. Moreover, inadequate bowel preparation prior to colonoscopy is known to

increase the burden of disease from both the clinical and the economic perspective: shorter intervals between repeated procedures, higher missed rates, patient inconvenience, and increased risk of complications are reported in the scientific literature. F-Calprotectin (FC) is a fecal marker of intestinal inflammation; IBD patients exhibit FC levels significantly higher than the general population; IBS patients have FC levels higher than healthy controls, but significantly lower than IBD patients [3]. Therefore, FC can be used as a pre-endoscopic test to differentiate between IBD and IBS. The present study aims at evaluating the cost-effectiveness of FC compared to the combined usage of CRP and ESR, and the gold standard to distinguish IBD from IBS in Spain.

Aims & Methods: An 18-week Markov model was developed for each diagnostic strategy, simulating 1000 patients presenting to a primary care physician with non-specific gastrointestinal symptoms. In the model, 1.6% of the colonoscopies brought about complications [4], which may result in Emergency Room visits and surgery. Inadequate colon preparation (23%)[5] and consequent repeated colonoscopies (30.3%)[6] were also included in the calculations. Outcomes include cost savings, cost per corrected IBD diagnosed, and colonoscopy reduction. Uncertainty was addressed with sensitivity analysis.

Results: FC is cost-effective when compared to CRP + ESR, and to colonoscopy (Table 1): It results in more correctly IBD diagnoses at a lower price; It reduces the number of unnecessary endoscopies, increasing the number of correctly diagnosed IBD (N = 63) and IBS (N = 26) patients.

Clinical and health economics results

	F-Calprotectin	CRP + ESR	Colonoscopy
N correctly diagnosed IBS	683	657	900
N correctly diagnosed IBD	98	35	100
Total costs (EUR)	290 527	477 787	582 106
Average cost/patient (EUR)	290.5	477.8	582.1
Colonoscopy complication costs (EUR)	1 978	2 269	6 313
N colonoscopies avoided	706.3	640.6	0
Savings ascribable to the avoided colonoscopies	336 338	305 051	0

Conclusion: Results show that the usage of FC as pre-endoscopic diagnostic tool is associated with fewer colonoscopies and correctly identifies more disease while decreasing costs compared to the alternatives. Consequently, FC demonstrates superior value both from patient and payer perspective, while simultaneously increasing diagnostic efficacy.

Introduction: The increased use of immunomodulators and biological agents for the treatment of patients with inflammatory bowel disease (IBD) is associated with a key safety concern considering potential serious infection. Healthcare workers were thought to be at substantial risk for acquiring such infection due to daily and close interactions with infected patients and asymptomatic carriers of pathogens.

Aims & Methods: We performed a retrospective observational study, collecting data from the Groupe d'Etude Thérapeutique des Affections Inflammatoires du tube Digestif (GETAID) from January 2015 to June 2016, on all 482 consecutive patients with IBD (68.5% with rohn's disease, 28.4% with ulcerative colitis and 3.1% with IBD undetermined) who work as healthcare workers (27.2% of physicians, 33.0% of nurses; 13.1% of nurses' aides and 26.7% of other healthcare personnel working in interaction with in-hospital patients), in 17 tertiary centers in France and Belgium. We selected a control group of patients with IBD who do not work as healthcare personnel from the monocentric MICISTA database. Controls were matched on age (± 2.5 years), sex, IBD type and date of IBD diagnosis (± 2.5 years). Serious infection was defined as (1) *Clostridium difficile* infection (2) community-acquired pneumonia (3) *Mycobacterium tuberculosis* infection (4) any community-acquired infection that required hospitalization. Serious infection-free survival was studied with Kaplan-Meier method, log-rank test and Cox regression model. In each patient, the duration of IBD was divided into semesters which were independently analyzed regarding the occurrence of serious infection too take into account the influence of various treatments.

Results: 482 patients (126 male; median age: 24.0 [IQR 19.9–32.1] years) were included in the present study. The median follow-up period was 9.3 [4.6–16.2] years. A total of 74 serious infection was recorded in healthcare workers including 14 *Clostridium difficile* infection, 19 EBV or CMV-related serious viral infection, 8 tuberculosis infection including 4 tuberculosis and 4 tuberculous primo-infection, 8 community-acquired pneumonia and 25 miscellaneous serious infection. The probabilities of serious infection-free survival were 1.0%, 6.1%, 10.8% and 14.1% at 1, 5, 10 and 15 years. No difference was found between healthcare workers and control patients regarding the occurrence of serious infection in time-dependent analysis and in independent semester analysis. However, a increased risk of tuberculosis infection was found in healthcare workers (0.07 infections for 100 patient-years vs. 0.009, $p = 0.02$). In multivariate analysis, serious infection was decreased in patients with Crohn's disease (OR = 0.63, IC95%[0.43–0.91], $p = 0.01$) and increased in patients treated with corticosteroids (OR = 3.05, IC95%[2.06–4.52], $p < 0.001$), immunosuppressant (OR = 1.98, IC95%[1.38–2.84], $p < 0.001$) and anti-TNF agents (OR = 2.93, IC95%[2.02–4.27], $p < 0.001$).

Conclusion: Although there is an higher exposure to potential pathogens in healthcare workers, this is not associated with an higher risk of serious infection as compared with controls with the exception of tuberculosis infection. Prospective studies are needed to confirm that the level of occupational exposure to potential pathogens should not be taken into account when discussing the introduction of immunomodulator or biological agents with the exception of the risk of tuberculosis infection.

Introduction: Several endoscopic scores have been used to assess the severity of inflammatory activity in Ulcerative Colitis (UC), however, few consider the extension of the disease. Scores such as the Dublin Score (DS) and the Modified Mayo Endoscopic Score (MMES) combine the severity of inflammation with the extent of the disease.

Aims & Methods: We aimed to calculate the correlation between the endoscopic scores -Mayo Endoscopic Score (MES), DUBLIN, MMES and the biomarkers of inflammation - erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and Calprotectin - and to compare the ability of these scores to predict Calprotectin > 100 µg/g. This was a retrospective study, including patients with diagnosis of left or extensive UC who underwent colonoscopy between 2015 and 2016. The biomarkers were obtained with a maximum interval of one week in relation to colonoscopy and without introduction of new therapy. The Spearman test calculated the correlation between scores and biomarkers. ROC curves (AUC) were obtained for each score to predict Calprotectin > 100 µg/g.

Results: 60 patients were included, 46.7% female patients with mean age 45.3 ± 12.8 years with mean values of ESR 4.4 ± 12.8 mm, CRP 5.12 ± 6.00 mg/l and Calprotectin 354 ± 430 µg/g. The correlation between Calprotectin and MES was $r_s = 0.623$ $p < 0.001$, for DS $r_s = 0.548$ $p < 0.001$ and for MMES $r_s = 0.588$ $p < 0.001$. Regarding CRP, a correlation with the MES was $r_s = 0.415$ $p = 0.001$ and with the MMES was $r_s = 0.404$ $p = 0.001$, but no correlation was found with the DS. There was no significant correlation between ESR and endoscopic scores. To predict values of Calprotectin > 100 µg/g the AUC for the MES was 0.848, for the DS 0.801 and for the MMES 0.815, and there was no statistically difference between the curves.

Conclusion: Although there is a good correlation between endoscopic scores and Calprotectin, the correlation between scores that take into account the extension were not superior to Mayo Endoscopic Score.

P0992 IBD – IS IT A RISK FACTOR FOR THE DIAGNOSIS OF HEPATIC STEATOSIS?

C. Arieira¹, S. Monteiro¹, S. Xavier¹, F. Dias De Castro¹, J. Magalhães¹, M.J. Moreira², J. Cotter²

¹Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães, Guimarães/Portugal

²Pt Government Associate Laboratory

⁴ ICVS/3B's, Braga/Guimarães/Portugal

Contact E-mail Address: catia_arieira@hotmail.com

Introduction: Although is not yet established, recent studies suggest an increase prevalence of hepatic steatosis (HS) in patients with inflammatory bowel disease (IBD). Factors such as chronic inflammation, previous surgeries, drug-induced hepatotoxicity, malnutrition and intestinal dysbiosis seem to be involved in the pathogenesis of this disease.

Aims & Methods: We aimed to assess the frequency of HS in IBD patients quantified by CAP (controlled attenuation parameter) and by clinical-analytical methods: Hepatic Steatosis Index (HSI) and Fatty Liver Index (FLI). A secondary aim is to investigate risk factors associated with HS in IBD patients. This was a cross-sectional study that included consecutive outpatients that were observed in our department between January and March 2017. Patients with known liver disease or alcohol habits were excluded. HS was defined as $HSI \geq 36$ or $FLI \geq 60$ or $CAP > 248$.

Results: 149 patients included with mean age 40.7 ± 13 years, 83 female (55.7%), 59.7% with Crohn's disease (CD). 62 patients (41.7%) had $CAP > 248.20$ (13.4%) $FLI > 60$ and 40 (26.8%) $HSI > 36$. There were no differences in the mean CAP value (244 ± 54.2), HSI (33.3 ± 5.18), and FLI (31.5 ± 25.3) among patients with CD and Ulcerative Colitis. We found that patients with $CAP > 248$ were more frequently obese (27.4% vs 0% $p < 0.001$), males (54.8% vs. 36.8% $p = 0.029$) and presented more frequently metabolic syndrome (25% vs 4.6% $p < 0.001$). Regarding the IBD factors, patients with HS had a higher frequency of previous surgeries (30.6% vs 16.1% $p = 0.035$). There were no differences between hospitalization, duration of the disease, use of corticosteroids or other IBD treatments.

Conclusion: In our cohort the frequency of HS varied between 13.4% and 41.7% defined by non-invasive methods. We found that the presence of metabolic syndrome and obesity were more frequent in patients with HS. Regarding factors related to IBD, patients with previous history of surgery were more frequently diagnosed with HS.

P0993 BONE HEALTH IN CROHN'S DISEASE IN THE ERA OF TNF-ALPHA INHIBITORS

S. Hakimian¹, J. Kheder², D. Cave², B. Hyatt²

¹Internal Medicine, University of Massachusetts, Worcester/United States of America/MA

²Gastroenterology, UMass Medical Center, Worcester/United States of America

Contact E-mail Address: shahrad.hakimian@umassmemorial.org

Introduction: Osteoporosis and fractures are common in Crohn's disease (CD). Recently, several inflammatory cytokines, including tumor necrosis factor (TNF)-alpha have been linked to increased bone resorption. Therefore, it is hypothesized that anti-TNF therapy may influence osteoporosis and fracture risk. However, few studies have evaluated osteoporosis and fracture risk in the CD population.

Aims & Methods: The aim of this study is to gain a better understanding of the epidemiologic risk factors for osteoporosis and vitamin D deficiency in the era of TNF-alpha inhibitors. We conducted a retrospective review of 714 consecutive patients with CD in our GI clinic between 2008 and 2015 to identify 464 patients who met the inclusion criteria for the study comprising of all adults older than 18 years with confirmed CD based on labs and endoscopic findings. Data extracted for analysis included demographics data, disease phenotype, duration of disease, measures of disease activity, imaging and endoscopic data. Statistical analysis was performed using student t-test and chi-square test.

Results: We reviewed the charts of 290 patients with CD treated with TNF-alpha inhibitors (TNF) and 174 patients who are anti-TNF naïve (NB). There were 207 (45%) males and 257 (55%) females in this cohort. TNF patients tended to be younger (average age of 43 ± 15 and 54 ± 18 years in TNF and NB groups respectively). Mean duration of disease was 14.9 ± 10.2 for TNF and 18.6 ± 19.2 for NB group. Approximately half of the patients had a smoking history. Average BMI was 27.6 ± 6.6. Rates of vitamin D deficiency, insufficiency and normal vitamin D-25-OH levels were not significantly different between TNF and NB groups. Vitamin D level was not associated with age, duration of disease, or inflammatory markers (ESR). However, there was a weak positive correlation between nutritional status (lowest albumin) and vitamin D level (Pearson's $R = 0.19$). DXA scans were available for 168 patients which included 100 patients in the TNF group and 68 patients in the NB group. There was similar rate of osteoporosis (16% vs 18%), osteopenia (53% vs 57%) and normal bone density (31% vs 25%) between the TNF and NB groups respectively. Furthermore, there was no statistically significant difference in T-scores at the hip (-1.2 vs -1.3), the spine (-1.0 vs -0.95), or the lowest T-scores (-1.5 vs -1.4) between TNF and NB patients. However, Z-scores at the spine (-0.47 vs -0.05), the hip (-0.55 vs -0.40) and the lowest Z-scores (-0.91 vs -0.67) were lower in the TNF group, but only reached significance at the spine ($P = 0.03$). Interestingly, a significantly higher proportion of TNF patients under 60 years of age met the criteria for osteoporosis (T-score < -2.5 below the mean) as compared to NB patients (15% vs 3.6%). Additionally, rates of osteoporosis in the NB group were very different before and after age 60 (3.6% vs 30%) [table 1]. There was no correlation with bone density and vitamin D level, nutritional status (based on lowest albumin level), or degree of inflammation (highest ESR or CRP levels). However, there was a moderate positive correlation with BMI and bone density (Pearson $R = 0.39$) and a negative correlation with age ($R = -0.25$).

Table 1: Osteoporosis rates in patients on anti-TNF therapy (TNF) and those naïve to biologic medications (NB) before and after age 60.

Group	Age < 60	Age > 60
TNF	15.4%	18.2%
NB	3.6%	30.0%

Conclusion: Rates of vitamin D deficiency, and osteoporosis were similar among patients on anti-TNF medications to those on no biologics. TNF group patients were diagnosed with osteoporosis at an earlier age compared to NB group. Patients on anti-TNFs also had statistically lower Z-scores at the spine. Prospective studies are necessary to further determine the role of anti-TNF medications in osteoporosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0994 THE AVAILABILITY OF INFLIXIMAB TROUGH LEVELS IN IBD PATIENTS ON MAINTENANCE THERAPY DEEPLY IMPACTS THERAPEUTIC DECISION-MAKING

T. Lobaton¹, F. Cañete¹, A. Teniente², E. Cabré¹, M. Mañosa¹, E. Martínez², E. Domènech¹

¹Gastroenterology, Hospital Universitari Germans Trias i Pujol, Badalona/Spain

²Immunology, Hospital Universitari Germans Trias i Pujol, Badalona/Spain

Contact E-mail Address: trianany2010@gmail.com

Introduction: Infliximab (IFX) trough levels (ITLs) have emerged as a promising tool for the management of inflammatory bowel disease (IBD) patients and they correlate with clinical response and endoscopic remission. However, its use in clinical practice is still under debate, particularly in clinically stable patients.

Aims & Methods: 1) to describe real-life ITLs in clinically stable IBD patients; 2) to identify factors associated with infratherapeutic ITLs; and 3) to evaluate the impact of ITLs availability by comparing the CCD with TLGD. The decisions between experts were also compared. Both comparisons were calculated by the linear Cohen's Kappa (κ) index. IBD patients on maintenance IFX therapy were prospectively included from June 2015 to June 2016. Demographic, clinical and biological data including C-reactive protein (CRP) levels from the same infusion day were collected. At each IFX infusion, patients were visited by their physician; a "current clinical decision" (CCD) was taken regarding clinical data and CRP. ITLs were measured just before the IFX infusion and were considered as infratherapeutic if $<2\mu\text{g/ml}$. Once ITLs were known, 3 experts took a hypothetical decision on treatment based on the same clinical and biological data plus ITLs (ITL-guided decision -TLGD-).

Results: A total of 224 IFX infusions from 74 patients (76% Crohn's disease) were analyzed. Median (IQR) disease and IFX therapy duration was 10 years (5–18) and 23 months (7–61), respectively; 87% received concomitant immunosuppressant therapy; 70% were on standard dosing, whereas 10% were scheduled every 4–6 weeks and 20% every 10–12 weeks. 60% of the patients were in clinical and biological remission. Median (IQR) CRP levels were 3.1 mg/ml (1.5–6.1). Median (IQR) ITLs were $1.79\mu\text{g/ml}$ (0.35–3.74), with 52% of patients having infratherapeutic ITLs. In the multivariate analysis, the only risk factor for infratherapeutic ITLs was the presence of biological activity. Concordance between CCD and TLGD was poor ($\kappa=0.10$ [95%CI:0.01–0.20]/ $\kappa=0.11$ [95%CI:0.01–0.21]/ $\kappa=0.10$ [95%CI:0–0.21]) for experts A/B/C, respectively. This "disagreement" was mainly due to a higher proportion of dose-escalations according to the TLGD as compared to the CCD. Among the 203 infusions in which no action was taken according to the CCD, 93 (40%), 48 (20%) and 65 (30%) would have been dose-escalated according to the TLGD for experts A, B and C, respectively. Moreover, concordance between experts was moderate ($\kappa=0.55$ [95%CI:0.41–0.71]/ $\kappa=0.40$ [95%CI:0.26–0.55]/ $\kappa=0.30$ [95%CI:0.21–0.40]) for experts A-B/B-C/A-C respectively.

Conclusion: Our results highlight the impact of the inflammatory burden on ITLs and the need of re-defining their therapeutic range in patients clinically stable. Both the clinical and economical impact of ITL-assisted decision-making in IBD patients should be evaluated in prospective cohorts.

Disclosure of Interest: E. Domènech: Fees for advisory, lectures and research grants from MSD, AbbVie, Takeda, Kern and Pfizer. All other authors have declared no conflicts of interest.

P0995 THE DIAGNOSTIC UTILITY OF LINKED-COLOR IMAGING IN THE EVALUATION OF MUCOSAL INFLAMMATION IN PATIENTS WITH ULCERATIVE COLITIS

H. Hamamoto, S. Kanmura, S. Arima, Y. Nasu, S. Tanoue, F. Sasaki, S. Hashimoto, A. Ido
Digestive And Lifestyle Diseases, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima/Japan

Contact E-mail Address: h-hitomi@m3.kufm.kagoshima-u.ac.jp

Introduction: Recent studies recommend the histological mucosal healing of the intestinal tissue as a treatment goal in ulcerative colitis (UC). The intestinal activity in UC is usually evaluated based on conventional endoscopic findings by white-light imaging (WLI). However, these findings are not always correlated with the histological findings, and often tend to underestimate the inflammatory activity in comparison to the histological findings. Linked-color imaging (LCI) is a new endoscopy system that enhances the color differences of the gastrointestinal mucosa. We investigated the efficiency of LCI in the evaluation of the intestinal activity, including the histological activity, in patients with UC.

Aims & Methods: Thirty-one UC patients underwent colonoscopy from August to December 2016. Twenty-one UC patients, who were evaluated using an EC-L600ZP endoscope with the LASEREO system (FUJIFILM Co., Tokyo, Japan), were enrolled. All of the target lesions were observed by WLI and LCI, and biopsy specimens were obtained from the lesions with the reddest tones in each view. A total of 96 lesions were biopsied. We quantified the color tones on LCI based on the $L^*a^*b^*$ color values (LCI-L, LCI-a, LCI-b), where L^* , a^* and b^* represent lightness, red color, and yellow color, respectively. We also quantified the color tones on WLI and LCI (WLI-L, WLI-a, WLI-b) based on the $L^*a^*b^*$ color values. The endoscopic images were classified according to the Mayo endoscopic score (MES), and biopsied specimens were classified according to the Geboes score. The endpoint of this study was to measure the correlation between the $L^*a^*b^*$ color values and the (1) MES, (2) Geboes score, (3) mucosal healing, and (4) histological healing. Furthermore, we defined MES 0 as inactive endoscopic disease, mucosal healing, and a Geboes score of ≤ 2 as inactive histological disease, histological healing.

Results: (1) A moderate correlation was observed between the LCI-a and MES values ($r=0.56$, $p<0.001$). (2) The Geboes score was moderately correlated with the LCI-a value ($r=0.45$, $p<0.001$) and weakly correlated with WLI-a ($r=0.24$, $p<0.001$), and WLI-b values ($r=0.28$, $p=0.006$). (3) The LCI-a and WLI-a values were significantly higher in patients with active endoscopic disease than they were in those with mucosal healing ($p<0.001$). The area under the curve (AUC) of the receiver operating characteristic (ROC) curve of LCI-a for mucosal healing was 0.82, while the ROC-AUC of WLI-a was 0.71. (4) The LCI-a values of patients with active histological disease were significantly higher, in comparison to those with histological healing ($p=0.001$). The ROC-AUC of LCI-a for histological healing was 0.69. Moreover, WLI was not correlated with histological activity.

Conclusion: LCI was superior to WLI for predicting mucosal healing and histological healing. The findings suggest the utility of LCI in evaluating mucosal inflammation in patients with UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0996 WHAT SITUATIONS PRODUCE PSYCHOLOGICAL MALAISE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE? PERCEPTIONS FROM PHYSICIANS AND PATIENTS. THE ENMENTE PROJECT

Introduction: Inflammatory Bowel Disease (IBD) patients live situations that may trigger negative feelings and psychological malaise. ENMENTE Project aims globally to improve identification and early management of psychological impact in IBD patients followed in Spanish hospital gastroenterology clinics. The aim of the study was to describe possible differences among perceptions from physicians and patients about the clinical situations triggering anxiety in patients with IBD.

Aims & Methods: During April 2016 two surveys were available on-line, one for IBD patients, in the ACCU Spain website (Confederation of IBD Spanish Patients' Associations) and another one for physicians members of GETECCU (Spanish Group for IBD treatment). Both invited their members to participate by email and the patients' survey was announced in social networks. The scientific committee (3 gastroenterologists, 2 psychologists, 1 nurse and 1 patient) decided which potentially stressful clinical situations were considered. Physicians and patients rated these situations on a scale from 1 to 10 as potential triggers of anxiety for the patient. A Mann-Whitney test was used to compare perceptions from patients and physicians taking 151 valid questionnaires from physicians and a randomized sample of 155 patients' questionnaires.

Results: The survey was completed by 912 patients (mean age 39 (± 10) years, 67% women) and 170 physicians (mean age 44 (± 10) years, 58% women). Having an ostomy, fecal incontinence in public or surgery are important triggers of anxiety agreed between physicians and patients (table). Patients, however experience anxiety from a possible new flare or from being fatigued, whereas physicians are more concerned about anxiety due to telling about a new IBD diagnosis and about pregnancy in IBD patients (table).

Mean scores from physicians and patients about clinical situations triggers anxiety or depression

To what extent these clinical situations may trigger anxiety or depression?	Physicians (n = 151)	Patients (n = 155)	p-value
The lack of diagnosis	6.3	6.0	ns
The diagnosis of IBD	6.2	5.6	$p < 0.05$
The performance of an endoscopy	5.6	5.7	ns
The explanation of an ostomy	6.6	5.9	ns
A new oral treatment	4.8	4.8	ns
A new auto-injectable treatment	5.6	5.3	ns
A new intra-venous treatment	5.9	5.3	ns
A surgery	6.7	6.5	ns
Having an ostomy	6.9	6.6	$p < 0.05$
A pregnancy	5.9	4.0	$p < 0.05$
The pain	6.3	6.1	ns
An episode of public incontinence	6.8	6.6	ns
A new flare	6.2	6.5	$p < 0.05$
Changes in the body image	6.3	5.9	ns
Tiredness, fatigue, reduction in performance	6.0	6.3	$p < 0.05$

Conclusion: The main anxiety triggers in patients were having an ostomy, fecal incontinence in public, a surgery, a new flare and the feeling of fatigue. These last

two situations were scored higher by patients than by physicians. Teaching the patient to identify and early manage a new flare and the treatment of fatigue are aspects that would help to reduce the anxiety feeling and should be taken into account in clinical practice. Introduction: Flixabi, an infliximab biosimilar referencing Remicade®, was developed by Samsung Bioepis, the joint venture between Samsung BioLogics and Biogen. SB2 received approval in EU for all approved indications of the reference infliximab. Many decision algorithms based on the measure of Infliximab (IFX) trough levels and antibodies to infliximab (ATI) have been increasingly used to optimize infliximab in Crohn's disease and ulcerative colitis. The aim of our study was to appreciate if the biosimilar SB2 could be efficiently monitored using the Lisa-Tracker infliximab and anti-infliximab immunoassays developed by Theradiag (France).

Aims & Methods: During this evaluation, standard curves of Infliximab and two different batches of SB2 were compared and then accuracy of the Lisa-Tracker IFX kit in detecting the spiked concentration of SB2 was measured using the Lisa-tracker assay. Levels of infliximab (from 5 spiked samples with known amount of SB2 and 10 clinical samples from patients treated with infliximab) were calculated according to each of the 3 standard curves (infliximab, SB2 batch1 and SB2 batch2). All samples and standards were tested in duplicate. R^2 must be >0.95 and the slope must be comprised between 0.9 and 1.1. Intra-run and inter-run precision were also measured with spiked samples of different known SB2 (from 2 to 12 µg/ml) amounts. Capacity of polyclonal antibodies directed against infliximab to block the detection of SB2 using the Lisa-Tracker infliximab assay and the capacity of SB2 to block the detection of anti-infliximab antibodies using the Lisa-Tracker anti-infliximab assay were tested.

Results: We demonstrated the perfect equivalence of infliximab standard curve to the SB2 standard curve and that the Lisa-Tracker assay is suitable for the quantification of SB2 in human serum samples ($R^2 = 0.99$; the levels of infliximab of the 20 samples were calculated according to the 3 standard curves infliximab, SB2 batch 1 and SB2 batch 2 with CV ranged from 2.1 to 12.6%). Quantification of SB2 is not affected by serum matrix and the % of recovery were comprised between 82% and 113%. High intra-run and inter-run precision were obtained with the Lisa-Tracker infliximab assay for the quantification of SB2 (CV ranged from 3.3 to 17.9%). Finally, the capacity of polyclonal antibodies to infliximab to block the detection of SB2 in 5 spiked samples was demonstrated with percentages of inhibition comprised between 80% and 97%. The capacity of SB2 to block the detection of anti-infliximab antibodies in 5 positive clinical samples was also confirmed with high percentages of inhibition between 84% and 95%.

Conclusion: In conclusion, Lisa-Tracker Infliximab and anti-Infliximab assays are suitable for the monitoring of patients treated with SB2. Acknowledgements: Biogen provided the SB2 drug for this study. Biogen reviewed the abstract and provided feedback to the authors.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0998 THE MEASURE OF TROUGH LEVELS OF INFLIXIMAB IS LINKED TO THERAPEUTIC RESPONSE IN IBD PATIENTS

X. Roblin¹, A. Berger², G. Boschetti³, B. Flourie³, S. Nancey⁴, S. Paul²

Introduction: If the association between trough levels of infliximab (TLI) and clinical remission or mucosal healing is demonstrated, we don't really know the cause and effect between TLI and target value to obtain this association. So, the aim of our study was to evaluate the causality or the association between TLI and clinical remission.

Aims & Methods: We prospectively included all IBD patients treated in our IBD unit and in clinical remission (CDAI <150 for Crohn's Disease (CD) or partial mayo score <3 for ulcerative colitis (UC) with biomarker normalization (fecal calprotectin <250 µg/g stools) or in deep remission (clinical remission with fecal calprotectin <50 µg/g stools). We analyzed median of TLI and fecal calprotectin at the inclusion (M0) and 6 months before eligibility (M-6). We excluded patients with deep remission at M-6.

Results: 111 patients were included (60 CD, sex ratio M/F: 0.8, 51 patients in deep remission at M0). All these 111 patients were in clinical remission at M-6. Median fecal calprotectin at M-6 were similar in the two groups of patients (210 µg/g in the group of patients who achieved deep remission at M0 vs

220 µg/g in the group of patients who achieved only biomarker remission respectively; $p=0.40$). Conversely, median TLI at M-6 was significantly lower in patients who did not achieved deep remission at M0 (2.8 vs 4.1 µg/L respectively; $p=0.01$). A ROC curve analysis was not able to isolate a cut-off value associated to deep remission achievement. (AUROC = 0.61). Next, we analyzed separately median of TLI and fecal calprotectin levels 6 months before eligibility (M-6) of patients in deep remission at M0 (51 patients). The median TLI was significantly lower at M-6 than at M0 (4.1 µg/mL vs 5.9 µg/mL respectively; $p=0.03$). Conversely, median fecal calprotectin was significantly higher at M-6 in comparison to M0 (190 vs 35 µg/g stool; $p=0.01$). A negative and weak significant correlation between fecal calprotectin and TLI was observed (Spearman's rank correlation coefficient (q) = -0.25; $p=0.045$).

Conclusion: Although TLIs may increase with decreased drug clearance due to deep remission, we show for the first time that the residual rate is the causal element for achieving clinical remission.

Introduction: Fecal volatile organic compounds (VOCs) are gaseous carbon-bound metabolic products considered to reflect intestinal microbiota composition. There is increasing evidence that VOCs may serve as non-invasive biomarkers for a broad range of gastrointestinal diseases. As smoking leads to a substantial shift in intestinal microbial composition in healthy and diseased persons, the aim of this study was to assess the effect of smoking status on fecal VOC pattern.

Aims & Methods: In this cross-sectional pilot-study adult smokers, non-smokers and former smokers scheduled for colonoscopy at the VU University medical center were instructed to collect a fecal sample prior to bowel cleansing. Patients were included if no abnormalities were found during colonoscopy. Exclusion criterium was use of antibiotics three months prior to participation. All participants completed a questionnaire on standard demographics, BMI, diet and smoking habits. Fecal VOC profiles were measured using an electronic nose device (Cyranose 320®).

Results: Fecal samples from 56 subjects (11 smokers, 21 non-smokers, 24 former smokers) were analyzed. Median age was 62 years (27–82 years). Furthermore, there were no significant differences between groups for the variables age, sex, BMI, diet, sample weight, chronic diseases and medication and supplement use. Fecal VOC profiles differed between smokers and non-smokers (PC1: p -value = 0.003). Smokers could be distinguished from non-smokers based on fecal VOC profiles was possible with an overall accuracy of 75% and corresponding sensitivity and specificity values of 72.7% and 76.2%. No significant differences between the fecal VOC profiles from smokers and former smokers (PC1: p -value = 0.083) and between profiles from non-smokers and former smokers (PC1: p -value = 0.081) were observed.

Conclusion: This study showed that smoking status has a significant influence on fecal VOC profiles. This implicates that the smoking status should be taken in account when performing (fecal) VOC analysis. The finding that VOC profiles did not differ between smokers and former-smokers could be due to the wide divergence (6 month – 43 years) in smoke-free time in former smokers group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1000 CLOSTRIDIUM DIFFICILE INFECTION AND IBD PATIENTS IN ONE CLINICAL CENTER

A. Atanassova¹, A. Georgieva²

¹Gastroenterology, Medical University of Varna, Varna/Bulgaria

²Clinic Of Gastroenterology, Medical University, Varna, UMHAT "S. Marina" Varna, Varna/Bulgaria

Contact E-mail Address: aniatanassova@abv.bg

Introduction: The prevalence of *Clostridium difficile* infection (CDI) in patients suffering from inflammatory bowel disease (IBD) has increased rapidly over the past several decades. However, the exact global epidemiology remains unclear because of insufficient data from developing countries.

Aims & Methods: The goal of our study is to examine the incidence of CDI in patients with IBD. A retrospective, observational study evaluating IBD patients in a referral center was performed to evaluate the incidence of *Clostridium difficile*. Diagnosis was confirmed with stool toxin analysis. Demographic information, diagnosis, anatomic location, IBD therapy, antibiotic exposure, hospitalizations, and surgeries were recorded. For a period of 3 years 202 IBD patients were studied, 105 of which have UC and 97 - Chron's disease (CD). We used the *Clostridium difficile* Glutamat Dehydrogenase + Toxin A + B based on the principle of quantitative immunochromatographic assay for the determination of *Clostridium difficile* Glutamat Dehydrogenase, Toxin A and Toxin B in stool samples.

Results: The results show that all patients with a positive CDI test have a clinical picture, which resembles a relapse of the disease ($p < 0.05$). There's a tendency towards growth in the incidence of IBD patients who are CDI positive. Their number in 2016 is significantly higher than that in 2014. In 2014 it was -5.90% with CD and 12.50% with UC, whereas in 2016- 12.20% with CD and 27.80% with UC ($p < 0.05$). The results show that the incidence of CDI patients with UC is significantly higher than in patients with CD, respectively 18.1% to 9.30% ($p < 0.05$). There is a strong correlation between CDI incidence in patients with IBD and the severity of their disease. Patients positive for CDI have a much more severe course of the disease, UC (46.40%) and CD (24.20%) ($p < 0, 05$).

Conclusion: There is an increase in incidence of CDI, and patients with UC are more affected by it. The results of our study are confirmed by other authors as well. A significant part of patients with CDI have a severe disease that needs extra prospective researches to determine the incidence and influence of the infection amongst patients with IBD, who receive different therapy regimes and also to understand how the CDI affects the evolution of the disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1001 DEVELOPMENT OF A NEW SCORE PREDICTIVE OF SUSTAINED CLINICAL REMISSION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE UNDER INFLIXIMAB-AZATHIOPRINE COMBOTHERAPY

B. Sivarid¹, N. Williet¹, J. Phelip¹, E. Del Tedesco¹, S. Paul¹, X. Roblin¹

¹Hepato-gastroenterology, university hospital of Saint-Etienne, Saint-Priest en Jarez/France

Contact E-mail Address: xavier.robilin@chu-st-etienne.fr

Introduction: There is no blood test predictive of sustained clinical remission in patients with Crohn's Disease (CD) or Ulcerative colitis (UC) under Infliximab (IFX) - azathioprine (AZA) combotherapy.

Aims & Methods: All patients with CD or UC, consecutively treated by the combination of IFX-AZA between August 2015 and March 2017, were included in this monocentric study. Clinical, biological (blood cells count, liver function enzymes, C-reactive protein (PCR)) were retrospectively collected at baseline, at week 14 (W14) and at 6 months (W24) from the start of combination therapy.

Trough level of IFX (TLI) at W14 was also recorded. Sustained clinical remission was defined as clinical remission for 6 months under combotherapy with no need of AZA dose modification, nor therapeutic switch or need for surgery. A predictive score before combotherapy was developed basing on receiver operating characteristic (ROC) curves and logistic regression analyses.

Results: Of 71 patients enrolled (median age: 36.3 yrs; women: 52.5%; CD: 61.3%; current tobacco: 28.7%), 58 (81.7%) experienced sustained clinical remission. The clinical biological score was calculated at baseline by adding attributed points for these variables as follows: alkaline phosphatase ≤ 58 UI/L (11 pts), lymphocytes $\leq 1.2 \times 10^9$ /L (6 pts), red blood cell count $< 4.4 \times 10^{12}$ /L (5 pts), mean corpuscular volume > 87 fl (4 pts), white blood cell count $< 9.3 \times 10^9$ /L (4.5 pts), neutrophils $< 5.0 \times 10^9$ /L (4 pts), body mass index > 22 kg/m² (3 pts), platelets count $< 330 \times 10^9$ /L (3 pts), PCR > 3.7 mg/L (3 pts) and Gamma-glutamyl transpeptidase < 30 UI/L (3 points). A total score ≥ 17 was predictive of sustained clinical remission with good performance (Area under the curve (AUC): 90.1% [95%CI: 81.8%–98.5%]; sensitivity (Se): 81.3%, specificity (Sp): 90.9%; Positive predictive value (PPV): 97.7%; Negative predictive value (NPV): 50%); especially in UC patients (AUC: 98.2% [95%CI: 93.9%–100%], Se: 90.5%, Sp and PPV: 100%; NPV: 66.7%). Corresponding outcomes for CD were also satisfying (AUC: 83.9% [95%CI: 70%–97.8%], Se: 75%, Sp: 85.7%, PPV: 96%; NPV: 42.9%). In contrast, performance of TLI at W14 (> 2.87 µg/mL) for the prediction of sustained clinical remission were moderately interesting (AUC: 60.9% [95%CI: 38.7%–83.1%]; Se: 79.3%, Sp: 61.3%; PPV: 90.2%; NPV: 40%). These results were not significantly different between patients who had received an AZA monotherapy before combotherapy compared to those who did not.

Conclusion: This new score is a promising tool for the prediction at baseline of sustained clinical remission in inflammatory bowel disease patients who start combotherapy. It may help to identify easily patients who should benefit optimization of IFX rather than early switch treatment in this setting. However, a prospective validation is needed before recommending its use in clinical practice.

P1002 LOWER GI SYMPTOMS IN YOUNG PATIENTS: CAN SYMPTOMS AND NON-INVASIVE TESTS BE USED SYSTEMATICALLY TO AVOID UNNECESSARY COLONOSCOPIES?

A. Alakkari, B. Ryan

Gastroenterology Department, Adelaide and Meath Hospital, Dublin/Ireland

Contact E-mail Address: alakkar@yahoo.com

Introduction: Young patients commonly present with lower gastrointestinal symptoms to gastroenterology clinics nationwide. Most colonoscopies in such patients are normal, but risk potentially serious complications. There is an over reliance on endoscopy in clinical practice leading to increasing demand on limited resources. As a result, some patients with potentially life-threatening conditions (e.g. colon cancer) may have a significant delay in diagnosis that may result in a worsened prognosis. Many endoscopic procedures are absolutely necessary, but many might be avoided if other, non-invasive forms of investigations were available which could reliably exclude significant pathology. This in turn could lead to reduced waiting times and improved access for those who really need them.

Aims & Methods: We aimed to assess colonoscopies, relevant faecal and blood tests in young patients with lower gastrointestinal symptoms. Colonoscopies performed over a 1-year period were retrospectively identified from the Endoscopy Reporting System. Patient charts, faecal calprotectin (FC), C Reactive Protein (CRP), and Coeliac serology were reviewed. A raised CRP > 5 mg/L or FC of ≥ 50 µg/g was considered abnormal. A Colonoscopy with mucosal inflammation confirmed on histology was considered abnormal. Inclusion and exclusion criteria are in table 1.

Table 1: Study criteria

Inclusion criteria	Exclusion criteria
Age ≤ 45 years	Known Iron deficiency anaemia
Presenting complaint: diarrhoea, constipation and abdominal pain/bloating	Overt or obscure GI bleeding
	Known Inflammatory Bowel Disease

Results: 2155 medical GI outpatient colonoscopies performed over 12 months were identified. 242 met inclusion criteria for the study. Median age of the patient cohort was 34 years (range 16–45), with 141 (58%) females. The cohort was stratified according to indications; Group A: 132 (55%) patients with diarrhoea predominant symptoms, and Group B: 110 (45%) patients with constipation, abdominal pain and bloating. Colonoscopy was normal in 104 (79%) of Group A and 102 (93%) of Group B ($p=0.002$). 36 (15%) Colonoscopies were abnormal; 7 patients had active ileitis, 22 had colonic inflammation (12 IBD, 2 lymphocytic colitis, 8 non-specific inflammation), and 7 had ileocolonic inflammation (all diagnosed with IBD). 28 of 36 (78%) patients with mucosal inflammation confirmed on histology had diarrhoea ($p=0.0001$). FC was available in 36 patients, and CRP in 171 patients. In group A the negative predictive value, positive predictive value and specificity of CRP/FC were 88%, 43% and

86% respectively. In group B these figures were 95%, 38% and 95% respectively. 21 patients had incidental early adenomatous polyps. 180 (74%) patients were investigated for Coeliac Disease. 4 had positive findings: 3 in Group A and 1 in Group B. One patient in Group A had both coeliac disease and lymphocytic colitis.

Conclusion: Colonoscopy has low yield in young symptomatic patients, especially those with non-diarrhoeal symptoms. Non-invasive tests should be used systematically to better identify patients requiring colonoscopy. We are conducting a prospective study to explore non-invasive diagnostic paradigms. Implementation of these strategies will help reduce colonoscopy waiting times.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1003 FAECAL CALPROTECTIN AND MAGNETIC RESONANCE IMAGING ARE RELIABLE TOOL TO DETECT ENDOSCOPIC POSTOPERATIVE RECURRENCE IN CROHN'S DISEASE

Introduction: As surgical resection is not curative in Crohn's disease (CD), post-operative recurrence (POR) remains a crucial issue. The POCER trial (1) has recently confirmed that the therapeutic management has to be adapted according to endoscopic findings within the first year following surgery to prevent POR. However, as colonoscopy is a burdensome procedure, alternative tools have been developed such as faecal biomarkers and magnetic resonance imaging (MRI).

Aims & Methods: We aimed to assess the performances of MRI and faecal calprotectin to detect endoscopic POR in CD patients. Adult CD patients from two tertiary centers who underwent ileal or ileocolonic resection were consecutively included in this prospective study. All the patients underwent magnetic resonance enterography including diffusion-weighted sequences with apparent diffusion coefficient (ADC) calculation (mm²/s) and evaluation of Clermont score (2), MaRIA (3) and MR score (4) within the first year after surgery or restoration of intestinal continuity (median = 6 months IQR [5.0-9.3]). Colonoscopy and MRI were performed within a median time of 14 days IQR [6.5-31] and stools were collected for faecal calprotectin measurement the day before the colonoscopy.

Results: Overall, 30 CD patients were enrolled in the study. Among them, 15 (50.0%) were female and 7 (23.3%) were active smokers. Disease location was ileal, colonic or ileocolonic in 15 (50.0%), 1 (3.3%) and 14 patients (46.7%), respectively. The patients included in this study were treated with no medication (20.0%), 5-ASA (6.7%), thiopurines (56.7%) or anti-TNF agents (20.0%) in preventing endoscopic POR. Within the first year after surgery, endoscopic findings according to Rutgeerts index were i0 for 8 patients (26.7%), i1 for 5 patients (16.7%), i2a for 4 patients (13.3%), i2b for 6 patients (20.0%), i3 for 5 patients (16.7%) and i4 for 2 patients (6.7%). In defining endoscopic POR as Rutgeerts index \geq i2, ADC value (2.22 vs 2.12; $p=0.35$), related contrast enhancement (RCE) (77% vs 119%, 0.056), Clermont score (9.3 vs 7.9; $p=0.11$), MRI score ($p=0.57$) and MaRIA (5.3 vs 6.4; $p=0.21$) were not significantly different in patients with endoscopic POR. Using Rutgeerts index \geq i2b as cut-off value to define endoscopic POR, ADC mean value was lower in patients with endoscopic POR (\geq i2b) (2.03 vs 2.27, $p=0.032$). Clermont score (7.4 vs 10.4, $p=0.038$) and related contrast enhancement (RCE) (75% vs 132%, 0.01) were higher in patients with endoscopic POR (\geq i2b). In contrast, MaRIA (5.0 vs 7.3; $p=0.15$) and MRI scores ($p=0.17$) were not significantly higher in patients with endoscopic POR (\geq i2b). In case of severe endoscopic POR (\geq i3), RCE (87% vs 135%; $p=0.046$) was increased while none of the following MRI parameters was significantly different: ADC (2.05 vs 2.20; $p=0.18$), Clermont score (8.0 vs 11.0; $p=0.14$), MaRIA (5.3 vs 7.8; $p=0.25$) and MRI score ($p=0.11$). Faecal calprotectin values were significantly higher in patients with endoscopic POR defined as \geq i2 (87.8 vs 314.9 μ g/g; $p=0.0064$), \geq i2b (92.6 vs 366.1 μ g/g; $p=0.0075$) or in patients presented with severe endoscopic POR \geq i3 (98.8 vs 544.4 μ g/g; $p=0.0003$). CRP value was not significantly higher in patients with endoscopic POR defined as \geq i2 (2.5 vs 5.9; $p=0.10$) and \geq i2b (3.2 vs 6.2; $p=0.43$), but was increased in patients with severe endoscopic POR (3.0 vs 9.8; $p=0.02$). Using ROC curves, we determined the best thresholds and their performances to detect endoscopic POR (Table 1).

Table 1: Performances of MRI parameters and faecal calprotectin to detect endoscopic postoperative recurrence in Crohn's disease

	AUC	Se	Spe	NPV	PPV
Detection of Rutgeerts \geq i2					
Clermont score $>$ 8.4	0.70	36%	77%	47.6%	66.7%
MaRIA $>$ 7	0.67	29%	77%	45.5%	62.5%
Faecal calprotectin $>$ 100 μ g/g	0.84	60%	100%	64.7%	100%
Detection of Rutgeerts \geq i2b					
Clermont score $>$ 8.4	0.73	47%	82.4%	66.7%	66.7%
MaRIA $>$ 7	0.70	38.5%	82.4%	62.5%	63.6%
Faecal calprotectin $>$ 100 μ g/g	0.79	66.7%	92.9%	76.5%	88.9%
Detection of Rutgeerts \geq i3					
Clermont score $>$ 8.4	0.67	42.9%	73.9%	81%	33.3%
MaRIA $>$ 7	0.63	42.9%	78.3%	81.8%	37.5%
Faecal calprotectin $>$ 100 μ g/g	0.96	100%	89.5%	100%	77.8%

Conclusion: Faecal calprotectin and MRI are reliable tools to detect endoscopic POR in CD patients and could be used as non-invasive alternative options to colonoscopy.

Introduction: PEG preparations reduce the acceptability of endoscopic explorations but remains recommended before performing a small bowel videocapsule (SBVC). No study has evaluated its impact on the small bowel cleanliness compared to other modalities in patients with Crohn's disease (CD). The objective of this study was to compare three methods of preparation, one using polyethylene-glycol and two simplified methods in adult patients with CD.

Aims & Methods: Three methods of preparation i.e. low-residue diet the evening before more 1 L PEG before the capsule (PEG), liquid diet the evening before the capsule (LD) and 1.5 L of water at the time of the capsule (Water) were compared. All patients were prospectively included and had an SB3 (Medtronic) capsule after the ingestion of a Patency Agile™ capsule. The small bowel was identified between the 1st duodenal and the 1st cecal images or the last recorded image and was separated into 3 equal segments. A standardized quantitative cleanliness score was calculated rating the luminosity, the presence of bubbles, turbid liquids, food residues and the percentage of visible mucosal surface in the entire small bowel and in each tertiles. The quantitative score ranged from 0 (worse) to 10 (best) and a qualitative score was obtained rating the cleanliness in excellent, good, fair and poor. After anonymization of the films, the recordings were randomized and re-read by 4 investigators blinded to the mode of preparation. The demographic and clinical characteristics of the patients were collected at the time of the capsule. The cleanliness scores were compared on the whole small bowel and on each segment.

Results: Between January 2015 and August 2016, 97 patients (38 men, mean age 40.8yrs) were included and performed 105 capsules with 35 capsules in each group of preparations. The groups were comparable concerning the clinical and demographic characteristics (sex ratio, disease duration, history of intestinal resection, phenotype, treatment, indication of the capsule). The mean duration of the small bowel transit time was comparable between the three groups (198 min (PEG), 245 min (LD), 226 min (Water) ($P=0.102$). The endoscopic activity of the disease was comparable between the 3 groups ($P=0.358$). The cecal intubation rate was significantly lower in the PEG group 66% versus 91% (LD) and 94% (Water) ($P=0.04$). No capsule impaction was observed. The mean quantitative cleanliness score for the whole small bowel was not significantly better for the PEG group (5.7) compared to the other modalities LD (6.3) and Water (6.5) ($P=0.262$). In the first tertile, the quantitative score was significantly better in the LD (7.9) and Water (7.6) groups compared to the PEG group (6.8) ($P=0.043$). The preparation by water was considered qualitatively better compared to the two other modalities ($P=0.04$).

Conclusion: This is the first study evaluating the relevance of PEG preparation in a large population of adult patients with CD. Our study has demonstrated that there is no benefit in using PEG for the preparation of the small bowel before the capsule in patients with CD. Quantitatively, the two simplified preparation methods were more efficient than the preparation with PEG and qualitatively, the preparation using water was considered as the most efficient.

Introduction: Bile acid malabsorption (BAM) is a well-known disorder associated to inflammatory bowel disease patients, however, it is underdiagnosed in clinical practice. ⁷⁵SeHCAT test is the current clinical gold standard for diagnosing bile acid diarrhoea widely used in Europe.

Aims & Methods: We aimed to analyze the incidence of BAM in Crohn's disease (CD) patients with chronic diarrhoea through ⁷⁵SeHCAT and to assess whether there is a relationship between the malabsorption degree and the presence of ileal resection. We analyzed, retrospectively, 30 patients with CD and chronic diarrhoea with and without ileal resection during the period between August 2015-April 2016. In all patients, an inflammatory activity was previously discarded through biomarkers and endoscopy/MRI. No patients had received treatment with bile acid sequestrants (Cholestyramine) before the study. We perform the test after the ingestion of a ⁷⁵SeHCAT capsule (0, 37 MBq) prior fasting the night before. Seven-day measurements were compared with 3 hours activity to calculate the abdominal retention percentage. The interpretation of the retention results was made considering $\geq 10\%$ BA is consistent with a normal result. Mild BAM is considered 7–10%, moderate 4–7% and severe $< 4\%$ retention at seventh day measurements. Epidemiological and clinical data were collected from the local database ENEIDA.

Results: We studied 15 women and 15 men with mean age of 46.5 years old (26–58). The median duration of the disease was 13 years (2–27). At diagnosis, ileal location was present in 50% of the patients, ileocolonic 40% and colonic in 10%. According to the behavior of the disease, 50% presented non-stricturing non-penetrating, 23% stricturing and 27% penetrating pattern, and 43% patients had perianal disease. In relation with smoking status, 34% were active smokers. Regarding actual treatment, 40% of the patients are controlled with only immunosuppressive drugs, 10% with biologics, while 20% used combotherapy. 83.3% of the patients had undergone ileal resection. Median length of intestinal resection was 24 cm (2–80). Six of them needed more than one intestinal resection during the evolution of the disease. Median time from CD diagnosis to surgery was 24 months (0–192 months). In the total number of patients, the median of depositions was 6 per day (2–10). After performing ⁷⁵SeHCAT scan, 96.8% of patients demonstrated abnormal values defined as $< 10\%$ abdominal retention of ⁷⁵SeHCAT after seven days. All patients with ileal resection had BAM but also the majority of patients without resection (86%). 92% of patients with ileal resection had severe malabsorption and 8% moderate malabsorption. 72% of patients without resection had severe malabsorption, 14% moderate malabsorption and 14% had normal retention. There was no statistical association ($p = 0.253$) between ⁷⁵SeHCAT retention and intestinal resection.

Conclusion: ⁷⁵SeHCAT is an useful procedure for diagnosing BAM in patients with CD and chronic diarrhea. High incidence of BAM is present in CD patients and there was no significant association between ⁷⁵SeHCAT retention and performing surgery.

Introduction: Linked Color Imaging (LCI) is a novel image-enhanced endoscopy technique which increases distinctiveness of the mucosal color of endoscopic images. The aim of this study is to investigate the usefulness of LCI to evaluate the activity of mucosal inflammation in ulcerative colitis (UC) patients

Aims & Methods: Totally, 10 consecutive patients with inactive or mildly active UC were enrolled, and fifty-three areas were assessed by LCI. All examinations were conducted with a LASEREO endoscopic system (FUJIFILM CO., Tokyo, Japan). During the colonoscopy, each region of interest (ROI) of terminal ileum, cecum, ascending colon, transverse colon, descending colon, sigmoid colon, and rectum was observed by both white light imaging (WLI), and LCI. The Commission internationale de l'éclairage (CIE) LAB color differences (ΔC^*) were calculated among WLI and LCI in each ROI. After ROI was observed by colonoscopy, the biopsy specimen was taken in each ROI. Inflammatory cell infiltration, erosion, crypt abscesses, and goblet cell depletion were assessed as the histologic findings of acute inflammation. For evaluation of chronic inflammation, crypt atrophy, crypt distortion, and basal plasmacytosis were assessed. The correlation between ΔC and Mayo endoscopic sub-score was assessed, indicating that the higher ΔC mean easier color difference for recognition.

Results: The mean age of patients who were enrolled in the present study was 41.6 ± 17.7 years. The sex ratio (men/women) was 4: 6. The type of extent of UC (ulcerative proctitis/left-sided UC/extensive UC) was 0:3:7. 1. Correlation between CIELAB color differences and histology. The mean ΔC of ROI without inflammatory cell infiltration was significantly higher than that of ROI with inflammatory cell infiltration (15.9 ± 4.9 vs. 12.5 ± 6.7 , $p = 0.046$). The mean ΔC was not affected by histological findings of erosions, crypt abscesses, goblet cell depletion, crypt atrophy, crypt distortion, and basal plasmacytosis. LCI distinguished colon mucosal white color compared to WLI with use of three-dimensional color space, indicating the remission-colon mucosa of UC with no inflammatory cell infiltration in ROI was easily detected by LCI. 2. Correlation between CIELAB color differences and Mayo endoscopic subscore. Low Mayo endoscopic sub-scores tended to be inversely proportional to high ΔC (ΔC : 15.5 ± 4.9 , 11.8 ± 5.1 , $13.0 \pm 9.1 \pm 5.3$), but not significant in the present evaluation. The colon mucosa with the low Mayo endoscopic sub-scores were relatively easily detected by LCI compared to WLI.

Conclusion: The present pilot trial indicated that the inactive UC mucosa could be easily detected as the white area by the LCI mode compared to WLI, suggesting that LCI might be one of novel approaches for evaluation of disease activity of UC.

PI007 THE ROLE OF SENSE OF COHERENCE IN DETERMINING HEALTH RELATED QUALITY OF LIFE AND DISABILITY IN INFLAMMATORY BOWEL DISEASE

G. Wild, M. Vitagliano, I. Albanese, K. Shirlow

Gastroenterology, McGill University Health Centre, Montreal/Canada

Contact E-mail Address: gary.wild@mcgill.ca

Introduction: There is an ever growing body of evidence that indicates that Health Related Quality of Life (HRQoL) is significantly impaired in IBD. While clinical variables and disease activity status influence HRQoL, a host of psychosocial and personality variables also play an important role. This contention is supported by evidence of impaired HRQoL and disability in IBD patients in the absence of demonstrable disease activity. Moreover, individual differences may play a key role in the psychological adaptation to living with IBD and coping with the psychological distress associated with the disorder. Sense of coherence (SOC) is an emerging theoretical and dynamic construct that seeks to explain why some individuals in the face of adversity experience illness while others do not. Antonovsky's theory of SOC suggests that individuals with strong SOC exhibit effective and flexible coping strategies when faced with stressors (e.g. chronic medical condition) whereas those with weak SOC are less likely to adapt to health stressors and have less motivation when confronted with challenges to their health. While a number of studies have shown that SOC appears to have an impact on HRQoL, data regarding this association in IBD are limited.

Aims & Methods: The goal of the current study was to examine the associations between an individual's sense of coherence, and their overall health-related quality of life. The first part of this analysis looked at whether sense of coherence accounted for more of the variance in disability level, and an individual's illness perception, as compared to other reported psychosocial factors. The second part of this study evaluated whether sense of coherence, as well as illness perception, were associated with an individual's self-reported quality of life, and if this interaction was moderated by the individual's level of anxiety. Additionally, the correlations between sense of coherence, and self-efficacy, as well as self-reported emotional intelligence were also further evaluated. This is a cross-sectional observational cohort of IBD patients attending MUHC (McGill University Health Center) IBD outpatient clinics. The patient population (N = 95) demographics are as follows: mean age (42.4 ± 12.44), gender (40.6% male), disease type (58.4% CD, 33.7% UC), disease activity (27.7% active, 65.3% inactive). Patients completed multiple validated questionnaires pertaining to a variety of psychosocial parameters. Data was analyzed by multiple linear regression using statistics software (SPSS version 17.0).

Results: Preliminary analyses of this patient population reveal that 40.2% of the variance in level of disability is explained by sense of coherence. This model suggests a significant negative correlation between sense of coherence and level of disability ($\beta = -0.64$, $p < 0.05$). A smaller, albeit significant contribution of sense of coherence with illness perception was additionally found (14.1% of the variance, and $\beta = -0.39$, $p < 0.05$). Furthermore, 32.3% of the variance in self-

reported quality of life was explained by sense of coherence ($\beta = 0.43$, $p < 0.05$) and illness perception ($\beta = -0.28$, $p < 0.05$). However, the individual's report of anxiety did not moderate this relationship. Significant positive correlations between sense of coherence and self-efficacy were also seen in this patient population ($r = 0.61$, $p < 0.01$), as well as with self-reported emotional intelligence ($r = 0.52$, $p < 0.01$).

Conclusion: These data indicate that Sense of Coherence is an important psychological construct that is associated with HRQoL and disability in IBD. Screening for these factors, in addition to the physiological markers, should be considered in order to provide the most holistic treatment strategies.

Introduction: Inflammatory bowel disease (IBD) is primarily assessed by endoscopy, which is a costly and invasive procedure with serious risk of complication, underlining the need for novel non-invasive diagnostic biomarkers. In previous studies, plasma amino acid analysis has revealed significant differences between IBD subjects and controls. This 'aminogram' has not yet been studied in faecal samples of IBD patients. The aim of this explorative study was to compare faecal amino acid composition between paediatric de novo IBD patients and healthy controls, and between the phenotypes ulcerative colitis (UC) and Crohn's disease (CD).

Aims & Methods: In this cross-sectional case-control study, paediatric treatment naïve IBD patients from a tertiary centre were included, before bowel cleansing and colonoscopy. Control patients were recruited from schools in the province North Holland, the Netherlands. All participants collected a faecal sample on which amino acid analysis was performed by means of high performance liquid chromatography (HPLC, Biochrom 30). To correct for the influence of faecal consistency, the samples were freeze dried for 24 hours before the analysis was performed. To prevent bias by peak overlap of different amino acids, outcomes of 5 nmol/mg or lower were excluded from further analysis.

Results: Faecal samples from 15 subjects (5 healthy, 5 UC, 5 CD) were analysed. Median age was 14 (8–17) years. Subjects and controls were matched on age and sex. A total of 42 different amino acids were analysed, of which 30 were excluded due to quantities of ≤ 5 nmol/mg. In particular, alanine, glycine, phenylalanine, leucine, isoleucine, valine and lysine differed between IBD patients and healthy controls with ratios up to 5:1 (table 1). In addition, UC and CD patients differed remarkably based on levels of glycine, phenylalanine and serine with ratios up to 4:1 (table 1).

Table 1: Levels of amino acids in patients with Crohn's disease, ulcerative colitis and healthy controls

Amino acid	healthy controls median	ulcerative colitis median	Crohn's disease median
Alanine	2.07 (1.88–4.39)	5.28 (3.31–10.38)	8.21 (4.59–13.05)
Phenylalanine	0.48 (0.48–1.46)	1.37 (1.07–3.09)	2.62 (1.74–3.91)
Glycine	1.06 (0.91–2.65)	1.91 (1.10–3.58)	5.28 (2.17–5.97)
Leucine	1.00 (0.86–2.88)	3.04 (2.34–5.32)	4.13 (3.80–7.45)
Isoleucine	0.76 (0.09–2.15)	1.69 (0.88–2.01)	3.07 (1.68–4.56)
Valine	0.96 (0.76–2.61)	2.43 (2.35–5.19)	4.41 (3.29–6.64)
Lysine	1.72 (1.21–4.03)	2.63 (1.27–5.64)	4.62 (2.27–8.04)
Serine	0.81 (0.52–1.69)	1.08 (0.97–1.96)	2.57 (1.48–4.57)

^all levels are displayed in nmol/mg

Conclusion: This was the first pilot study to assess the potential of the faecal aminogram as non-invasive biomarker for disease activity of paediatric IBD. We observed remarkable differences in faecal amino acid composition between IBD patients and healthy controls, and between the IBD phenotypes. Whether these differences reflect decreased absorption or increased loss by inflamed intestines needs to be elucidated. Currently, we are awaiting the results of a larger proof-of-concept study on these faecal amino acid profiles.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Measurement of infliximab trough levels (IFX-TLs) and antibodies to infliximab (ATIs) has been suggested as an important parameter for the optimization of IFX treatment of patients with inflammatory bowel disease (IBD). **Aims & Methods:** We aimed to cross-sectionally investigate the correlation between IFX-TLs or ATIs and clinical, biochemical as well as endoscopic activity in Greek IBD patients. Consecutive IBD patients on maintenance treatment with IFX, were included. IFX-TLs and ATIs were measured using ELISA (Eagle BioSciences, Nashua, NH, USA) on serum samples drawn before infusion. At the same time quality of life using short IBD questionnaire (SIBDQ) and clinical disease activity using Harvey-Bradshaw Index (HBI) for Crohn's disease (CD) or simple colitis activity index (SCAI) for ulcerative colitis (UC) were assessed. Moreover, biomarkers (hemoglobin, ESR, CRP, platelets, albumin) were measured and latest colonoscopies (within 6 months) were reviewed and evaluated for presence or not of mucosal healing.

Results: A total of 74 patients receiving IFX maintenance therapy [55 CD, 19 UC, 49 males, mean age 42.3 years, 45 on combination therapy with immunomodulators (IMMs), 10 under intensified dose (either 10 mg/kg/8w or 5 mg/kg/4–6w)] were studied. Median time since IFX initiation was 26 (13–71) months and median value of serum IFX-TL was 4.83 µg/ml (0.03–30.7). Seven out of 74 (9.5%) were positive for ATIs (>10 tAU/ml). Patients on combination treatment had significantly higher IFX-TLs (6.98 µg/ml, 0.34–30.7) compared to those on IFX monotherapy (1.85 µg/ml, 0.09–25.8) ($p = 0.01$). Patients with positive ATIs had median IFX-TLs 0.99 µg/ml (0.09–1.40) statistically lower compared to those with negative ATIs (6.01 µg/ml, 0.03–30.69) ($p = 0.0005$). The correlations of IFX-TLs and ATIs with clinical, biochemical and endoscopic indices of disease activity in IBD patients are presented in Table 1. No other significant correlations of IFX-TL or ATIs with other disease characteristics were observed. In the logistic regression analysis only IFX-TLs (OR 0.86, 95% CI 0.76–0.97 $p = 0.017$) and duration of IFX treatment (OR 0.97, 95% CI 0.95–0.99 $p = 0.04$) were independently correlated with the presence of mucosa healing.

Table 1: Correlations of infliximab trough levels and antibodies to infliximab with clinical, biochemical and endoscopic indices of disease activity in patients with inflammatory bowel disease

N = 74	Infliximab trough levels (IFX-TLs)		Antibodies to Infliximab (ATIs)	
	r	p	r	p
HBI (CD)	0.11	0.41	−0.31	0.02
SCAI (UC)	0.18	0.48	0.17	0.47
SIBDQ	0.09	0.44	−0.06	0.63
CRP (mg/dl)	−0.27	0.02	0.24	0.04
Hgb (mg/dl)	0.08	0.48	−0.19	0.10
ESR 1st hour (mm)	0.09	0.42	−0.05	0.65
PLT ($\times 10^9/\mu\text{L}$)	0.19	0.09	−0.17	0.88
Alb (mg/dl)	0.003	0.77	0.009	0.94
ATIs	−0.34	0.01	–	–
Combined with IMMs	0.25	0.03	−0.26	0.02
Mucosal healing (N = 53)	0.38	0.006	−0.34	0.01

Conclusion: Therapeutic drug monitoring is valuable in IBD-patients on maintenance IFX-treatment. Combination treatment with IFX and IMMs is associated with higher IFX-TLs compared to IFX monotherapy. Higher IFX-TLs are independently associated with the presence of mucosal healing.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1010 COMPARATIVE INVESTIGATION OF ENTEROBACTERIA BUSH IN ULCERATIVE COLITIS PATIENTS, AND THEIR CONSANGUINEOUS, AND NON-CONSANGUINEOUS RELATIVES

K. Fukuda

St Luke's International Hospital, Tokyo/Japan

Contact E-mail Address: fukukats@luke.ac.jp

Introduction: In recent years, the gut microbiota has been recognized as a relevant fingerprint to predict the development of inflammatory bowel disease (IBD) like ulcerative colitis (UC). Accordingly, inter-individual variation in the gut microbial community may reflect inter-individual variation in the risk of developing IBD or other diseases. Further recently, the Next-Generation Sequencing (NGS) has been validated for determining bacterial species in faecal samples. Essentially, NGS is a molecular biology sequencing technique for the precise identification and assessment of bacterial species.

Aims & Methods: With the major focus of our study being to establish a relevant biomarker of disease activity in UC patients based on the intestinal microbiota, 82 UC patients together with 61 healthy relatives as controls were included for investigations of gut microbiota in faecal samples. Twenty-five patients had active UC (group I) and 57 had quiescent UC; 29 with mild inflammation in the large intestine (group II), and 28 without inflammation (group III). The patients' relatives were consanguineous (group IV, n=33), and non-consanguineous (group V, n=28). The subjects' age ranged from 15 to 69 years. Faecal bacteria between groups I to V were compared by the t-test. The Discriminant analysis in all five groups was done for each Phylum, Class, Order, Family, Genus and Species. The Canonical Discriminant Function Coefficient (Df) for each bacterial community was calculated. The quantity of each bacteria was multiplied by the Df value, and the sum was termed the Discriminant Score (Ds). Next, we tried to analyze the quantity and the diversity of the bacteria which had significant difference.

Results: We obtained 1011 varieties of bacteria as Phyla, Class, Order, Family, Genera and Species. Any individual bacterial quantity with 0 value $\geq 95\%$ of group I and group V, the mean of the individual quantity of bacteria $\leq 0.05\%$ cases (648) were excluded. The t-statistics was done on 363 bacteria between groups I to V. Significant difference was calculated in 18 Species, 10 Genera, and 4 Families. The Discriminant analysis was done on these 18 Species from all groups. The Ds value showed an increasing tendency in this order: group I < group II < group III < group IV < group V. Significant difference was calculated for group I vs group II, vs group III, vs group IV, and vs group V ($P < 0.05$). Likewise, group V vs group I, vs group II, vs group III ($P < 0.05$), indicating a relevant association between gut microbial species and the development of UC. In bacteria having significant difference, especially Bacteroidaceae Family and Bacteroides Genus were numerous clearly, and both were higher in group I, active UC. It's odd that the diversity of Bacteroides Genus was higher in Group V, non-consanguineous relatives, but the quantity of Bacteroides Genus was higher in group I. And *Bacteroides fragilis* was increased in group I, and the others of Bacteroides were increased in group V, it depends on the amount of *Bacteroides fragilis*. In active UC, the amount of *Bacteroides fragilis* was increased, but the diversity of Bacteroides Genus was decreased. It's very interesting, and the balance can be key point between *Bacteroides fragilis* and the diversity of Bacteroides in UC activity. And about Genus Anaerococcus, Finegoldia and Peptoniphilus, about Species *Anaerococcus vaginalis*, *Finegoldia magna* and *Peptoniphilus gorbachii* were increased in group I significantly. All these bacteria belong to Peptoniphilaceae Family.

Conclusion: In this study, we compared 363 bacteria between active UC patient to control, significant difference was calculated in 18 Species, 10 Genera, and 4 Families. To our knowledge, this is the first report on so many bacteria being related to UC activity. Additionally, the Ds related to UC, or otherwise absence of UC in the five groups. Potentially, Ds might be a clinically relevant biomarker of disease activity in UC. This is the first application of the Ds to the study of microbiota in UC patients, consanguineous and non-consanguineous relatives by using NGS. Moreover we could obtain a lot of interesting results about the quantity and the diversity of the bacteria, especially Bacteroides and Peptoniphilaceae. Clinical trial No: UMIN000017103

Introduction: Endoscopy is the gold standard diagnostic tool in ulcerative colitis (UC). However noninvasive methods like cross-sectional imaging and fecal biomarkers are needed for interval clinical assessments and assessing response to medical treatment. The combination of positron emission tomography (PET) with 18F-fluorodeoxyglucose (18F-FDG) with magnetic resonance imaging (MRI) as integrated PET/MRI in one examination is a new cutting-edge technology for the non-invasive assessment of the inflammatory activity in UC. In addition a panel of noninvasive biomarkers like Lactoferrin and Calprotectin are increasingly popular and used in all-day patient care.

Aims & Methods: To compare the performance of non-invasive biomarkers to PET/MRI and colonoscopy in patient with UC. In every patient a PET/MRI including the maximum standardized uptake value ratio gut/liver (SUVQuot) and a colonoscopy including an endoscopy index (EI) was performed within 48 hours and the Disease Activity Index Mayo score (DAI) was calculated. Fecal Lactoferrin (LF), CalprotectinIMUN (CalI), CalprotectinCALPREST (CalP), PMN-elastase (PMN-E), S100A12, Eosinophil-derived Neurotoxin (EDN) as well as CRP were correlated to the SUVQuot, the DAI and the EI using correlation analyses. Sensitivity, specificity and diagnostic accuracy were calculated using optimized cut-offs. All analyses were performed using SPSS (IBM SPSS Statistics for Windows, release 22.0).

Results: 32 patients (21 female), mean age 44.4 ± 10.63 years (range 23–67) with diagnosed UC were included in the study. Mean time since diagnosis was 11.41 years (SD=6.42). EI and SUVQuot ($r(32)=.45$; $p=.009$), EI and DAI ($r(32)=.87$; $p=.000$) as well as DAI and SUVQuot correlated significantly ($r(32)=.40$; $p=.022$). SUVQuot was correlated significantly with LF ($r(32)=.36$; $p=.046$), EDN ($r(32)=.49$; $p=.005$), and CRP ($r(32)=.36$; $p=.043$), but not with PMN-e, CalP, S100A12, and CalI (all $p > .05$). DAI was correlated significantly with PMN-e ($r(32)=.55$; $p=.001$), LF ($r(32)=.55$; $p=.001$), EDN ($r(32)=.70$; $p=.000$), CalP ($r(32)=.46$; $p=.008$), and CRP ($r(32)=.56$; $p=.001$), but not with S100A12 and CalI (all $p > .05$). EI was correlated significantly with LF ($r(32)=.61$; $p=.000$), EDN ($r(32)=.68$; $p=.000$), PMN-e ($r(32)=.51$; $p=.003$), S100A12 ($r(32)=.41$; $p=.021$), CalP ($r(32)=.52$; $p=.002$), CRP ($r(32)=.44$; $p=.012$), but not with CalI ($p > .05$). The median levels (inactive/active) were: LF: 1.75/20.13 µg/g, CalI: 60.25/105.60 µg/g, CalP: 167.25/370.65 µg/g, PMN-E: 0.07/0.19 µg/g, S100A12: 18.82/88.96, EDN: 0.39/2.35 µg/g, CRP: 0.15/0.75 mg/dl. Sensitivity, specificity, diagnostic accuracy (confidence interval) and optimized cut-off for LF was 87.5%/87.5%/87.5% (CI 72.1%–100%); 4, 27 µg/g; CALP: 62.5%/62.5%/62.5% (CI 38.9%–97.5%); 361 µg/g; CALI: 62.5%/62.5%/62.5% (CI 36.7%–86.2%); 68, 43 µg/g; PMN-e: 83.3%/75.0%/81.25% (CI 60.5%–99.9%); 0.085 µg/g; S100A12: 75.0%/75.0%/75% (CI 56.9%–94.1%); 60.40; EDN: 75.5%/75.0%/75% (CI 80.5%–100%); 1, 30 µg/g; CRP: 70.8%/75.0%/71.9% (CI 53.5%–94.9%); 0, 35 mg/dl.

Conclusion: Using EI as gold standard reference we found that fecal biomarkers LF, EDN, PMN-E and S100A12 can reliably distinguish between active and inactive UC. However, Calprotectin did not perform well. LF, EDN and CRP were significantly correlated to the SUVQuot which was significantly correlated with EI and DAI. In conclusion, Lactoferrin and Eosinophil-derived Neurotoxin performed best using endoscopy and PET/MRI as reference.

P1012 MMP3 (METALLOPROTEINASE 3): A NEW MARKER FOR ASSESSING LOSS OF RESPONSE TO INFLIXIMAB IN IBD

B. Barberio, R. D'Inca, L. Digiglio, S. Facchin, M. Picocchi, R. Cardin, M.G. Vettorato, M. Dalla Gasperina, A. Rigo, G.C. Sturniolo

Introduction: At present, drug response to infliximab is monitored by trough levels (TL) and anti-drug antibody levels (ATI). Recently, another pathway of drug degradation has been hypothesized since MMP3 and MMP9 were found to be able to cleave IgG, like infliximab, in both animal and human experimental studies (1).

Aims & Methods: We collected serum samples in 102 patients (27 Crohn's Disease and 75 Ulcerative Colitis) treated with stable doses of infliximab for at least 6 months (t_0) and 6 months thereafter (t_1). In each patient TL, ATI values and MMP3 levels were assessed at t_0 and t_1 by ELISA. In addition, MMP3 levels were also determined in 28 healthy subjects as controls. Clinical (HBI or Mayo score) and biochemical (CRP, fecal calprotectin) markers were assessed to define disease remission/activity. TL were considered therapeutic if >3.8 mcg/ml, ATI were considered positive if >10 mcg/ml. Data are presented as mean \pm Standard Error Mean (SEM). Comparison among groups was performed by non-parametric tests.

Results: MMP3 levels were similar at t_0 and t_1 in patients which maintained therapeutic TL (14.5 ± 1.7 pg/ml and 15.0 ± 1.6 pg/ml, respectively) and in healthy controls (13.1 ± 0.8 pg/ml). Patients with low TL but ATI negative had significantly higher MMP3 levels compared to the group with low TL and ATI positive (33.2 ± 3.0 and 20.0 ± 2.7 respectively, $p=0.0003$), showing another pathway of drug degradation. 21 patients lost response between t_0 and t_1 : 15 out of 21 patients demonstrated high levels of MMP3 (22.0 ± 2.1 pg/ml) already at t_0 ; in addition, 17 of these 21 patients were in clinical remission at t_0 , while at t_1 all patients had disease activity.

Conclusion: Serum MMP3 levels are useful in predicting loss of response to anti TNF α in patients with low TL but without ATI. High MMP3 levels predict with 90.5% accuracy loss of response over the next 6 months.

Introduction: More than one third of inflammatory bowel disease patients (IBD) present extraintestinal manifestations, with articular manifestations being the more common, clearly the more incapacitating and which more alter the quality of life of IBD patients. These patients could benefit from a multidisciplinary approach for quicker diagnosis and for optimizing treatments.

Aims & Methods: The aim of the study was to evaluate the impact of a multidisciplinary approach carried out by both a rheumatologist and a gastroenterologist in the management of these patients. Therapeutic changes after the combined assessment were also evaluated. Methods From April 2015 to April 2017, all IBD patients reporting articular pain to the IBD-dedicated gastroenterologist were referred to an experienced rheumatologist. The day of the consultation a multidisciplinary committee with a rheumatologist and a gastroenterologist evaluated and discussed in all patients their possible diagnosis and potential changes in their treatment. Assessment was made according to current guidelines and data recorded in a common database regarding the reasons why patients were remitted from IBD, their rheumatologic diagnosis and all changes implemented in their treatments. Results are shown in percentages.

Results: 112 consecutive IBD patients were remitted from the IBD Unit and analyzed by the committee. Mean age 38 years (ranging from 18 to 73). Most patients were women (67%), 19% were smokers and 23% former smokers. 51% of patients analyzed had Crohn's disease and 49% ulcerative colitis. The main causes for derivation from IBD were a suspicion of inflammatory arthropathies in 43% and of arthralgias in 40%. The more frequent diagnosis after the rheumatology consultation and the committee meeting were inflammatory arthropathies associated with IBD in 41% (51.5% presented axial arthropathies and 48.5% presented peripheral arthropathies) and fibromyalgia in 15%. Regarding treatment changes, after the multidisciplinary committee with a rheumatologist and a gastroenterologist, changes were made in 28% of patients. Of those, in 35% of patients methotrexate was added in patients with biologic treatment (in some of them patients were in monotherapy, but in others the drug was introduced for replacing thiopurines). In 24% of patients sulfasalazine was introduced instead of mesalazine. In the other patients either other biologics like ustekinumab were introduced or the doses of anti-TNF were optimized in accordance with rheumatologic schedules.

Conclusion: A multidisciplinary consultation combining inflammatory bowel disease and rheumatology allows both an earlier detection of inflammatory arthropathies associated with IBD and earlier changes in treatment, thereby helping to optimize the hospital resources. Fibromyalgia is common among IBD

patients, though it is important that it is detected it should not be confused with inflammatory arthropathies.

P1014 PERFORMANCE OF THE BÜHLMANN QUANTUM BLUE® ADALIMUMAB RAPID TEST DEDICATED FOR THERAPEUTIC DRUG MONITORING OF SERUM ADALIMUMAB TROUGH LEVELS

T. Schuster¹, M. Wieser¹, S. Kräuchi¹, R. Sokoll¹, F. Bantleon¹, J. Weber¹, M. Schneider¹, A.P. Abel²

Introduction: Adalimumab is a human monoclonal antibody used for the treatment of inflammatory diseases like Crohn's Disease (CD) and Ulcerative Colitis (UC). For efficient treatment trough levels of adalimumab need to be adjusted within a therapeutic window between 5 to 10 μ g/mL¹. A rapid test allows a much faster analysis of trough levels, providing a great advantage over test formats that need samples to be sent to a central laboratory. Here, we present the analytical performance characteristics as part of the validation of the Quantum Blue® Adalimumab test from BÜHLMANN.

Aims & Methods: The sandwich lateral flow immunoassay uses a tumor necrosis factor alpha coated label and a highly specific monoclonal antibody to detect adalimumab in a diluted human serum sample. Evaluation was performed according to CLSI guidelines. The linearity study included multiple concentration levels covering and exceeding the expected measuring interval, obtained by blending two sample pools, low and high. The within laboratory precision was performed with five (5) samples within the measuring range (20 days - two runs per day in two replicates). Method comparison was performed with a commercial available ELISA (RIDASCREEN® ADM Monitoring, Art. No. G09043, R-Biopharm, Darmstadt, Germany) and is based on 106 serum samples. For recovery analysis six clinical samples over the measuring interval of the test were spiked with 6 μ g/mL adalimumab in negative serum and compared with the expected values. The high dose hook effect was evaluated with spiked pooled human serum in two runs, the second run with an additional dilution of the samples into the measuring interval of the test.

Results: The BÜHLMANN Quantum Blue® Adalimumab test exhibits a linear range from 0.93 to 34.61 μ g/mL. The recovery of clinical samples ranged from 80% to 89%. No high dose hook effect was observed up to 1002 μ g/mL of adalimumab. The applied additional dilution into the measuring interval yielded a linear relationship. The mean total within-laboratory precision of the device was 23.9% (20.7 to 28.9%) with a repeatability of 21.2% (16.4 to 27.8%). The method comparison revealed a slope of 1.18 and a regression coefficient (r) of 0.92 (Passing Bablok) suggesting that the new Quantum Blue® Adalimumab test showed an excellent correlation compared to the ELISA method.

Conclusion: The BÜHLMANN Quantum Blue® Adalimumab lateral flow test enables the quantitative determination of adalimumab trough level in serum with time to result of only 15 minutes. The developed test allows to measure adalimumab over a wide range, well beyond the therapeutic window. Hence, it represents a valuable tool for the clinician to assess the adalimumab trough level.

Introduction: Adalimumab (ADA) is an anti-TNF α drug approved for patients with refractory luminal Crohn's disease (CD). Recently, mucosal healing (MH) emerged as a major therapeutic goal in inflammatory bowel disease. Few data are available on ADA trough levels (TL), anti-ADA antibodies (AAA) during long term follow-up of CD patients, and their potential association with MH and disease outcome.

Aims & Methods: The aim of our prospective study was to evaluate a possible association between achievement of MH, ADA TL, and AAA in CD patients. Moreover, we assessed the presence of a possible association between clinical outcome and MH. We prospectively enrolled moderate to severe CD patients who were primary responders to ADA treatment. Blood samples were withdrawn at standardized time points during treatment (0-, 2-, 6-week and every 8 weeks thereafter), before ADA administration. ADA TL were measured using an homogenous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States). Disease activity was assessed by means of Harvey-Bradshaw Index (HBI, remission defined by HBI <5). As to endoscopic activity, we defined MH in case

of a value of Crohn's Disease Endoscopic Index of Severity below 8, so far we included patients with complete MH and those with a minimal residual endoscopic activity. Endoscopic evaluation was performed within two weeks of blood sampling, and at least after 6 months of ADA treatment.

Results: In our prospective study we enrolled 22 CD patients primary responders to ADA therapy (13 males, median age = 43 years, range 23–67 years) who had a median treatment duration of 52 weeks (range 24–121 weeks). ADA TL were significantly higher ($P=0.0002$) in patients who achieved MH (12.1 mcg/mL, range 6.8–17.2 mcg/mL) as compared to patients without MH (4.50 mcg/mL, range 0.0–9.9 mcg/mL). Receiver Operating Characteristic curve identified an ADA TL cut-off of 6.43 mcg/mL as the threshold with the highest accuracy for identification of patients who achieve MH (AUROC 0.934, sensitivity 100%, specificity 81.8%, PPV 84.6, PNV 100). Moreover, achievement of MH was associated with absence of AAA ($P=0.012$). Lastly, HBI was significantly lower ($P=0.0002$) in patients with MH (4, range 3–8) than in patients without (11, range 4–17).

Conclusion: In our cohort of CD patients, we observed a clear association between ADA TL, AAA development, and MH. In particular, an ADA TL of 6.43 mcg/mL has been identified as the best cut-off to obtain endoscopic remission or at least a minimal residual endoscopic activity. Moreover, we observed that CD patients on ADA therapy who achieved MH had a lower disease clinical activity. Thus, our data support the use of therapeutic ADA monitoring for the management of CD patients in order to obtain clinical and endoscopic remission of the disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI016 ULTRASONOGRAPHIC RESPONSE TO ANTI-TNFS IS ASSOCIATED WITH BETTER OUTCOMES IN CROHN'S DISEASE

E. Calabrese¹, F. Zorzi¹, E. Lolli¹, S. Onali¹, M. C. Fantini¹, L. Biancone¹, G. Monteleone¹

¹Gastroenterology, Department Of Systems Medicine, University of Rome Tor Vergata, Rome/Italy

Contact E-mail Address: emma.calabrese@uniroma2.it

Introduction: Crohn's disease (CD) management targets mucosal healing on ileo-colonoscopy as a treatment goal.

Aims & Methods: We hypothesized that ultrasonographic response to anti-TNFs is also associated with better long-term outcomes. Patients with CD treated with anti-TNFs who had serial small intestine contrast ultrasonography (SICUS) between January 2011 and April 2017 were identified. Disease site (based on bowel wall thickness), extent of lesions, and presence of complications (stenosis, prestenotic dilation, abscess, or fistulas) were evaluated using SICUS. Inclusion required pre-therapy SICUS with follow-up SICUS after 12 months, or 2 SICUS ≥ 12 months apart while on maintenance therapy. At second SICUS, complete responders had improved lesions, non-responders had worsening or new lesions, and partial responders had other scenarios. CD-related outcomes of corticosteroid need, hospitalization, and surgery were assessed at one year from the second SICUS.

Results: Seventy-nine CD patients treated with anti-TNFs (37% with Infliximab, 63% with Adalimumab) were identified. Most patients had ileal disease (67%) and stricturing phenotype (52%). Based on SICUS, thirty-six patients (46%) were complete sonographic responders, 30 partial (38%), and 13 non-responders (16%). Complete and partial responders at SICUS had a reduced risk for surgery in comparison with non responders [$p=0.003$ (OR:34.6, CI:1.7–700), $p=0.003$ (OR 12, CI:0.6–2.40)]. Complete responders at SICUS had a reduced number of hospitalizations in comparison with non responders [$p=0.04$ (OR 4.2, CI:1–17.3)]. Complete and partial responders at SICUS had a reduced risk for need for rescue corticosteroids in comparison with non responders [$p=0.005$ (OR:7.8, CI:1.9–32.4), $p=0.002$ (OR 5.2, CI:1.7–15.3)].

Conclusion: Ultrasonographic response to medical therapy is associated with significant reductions in long-term risk of surgery, hospitalizations and steroid usage among CD patients. These findings suggest the significance of response assessed by ultrasonography as a treatment target.

Introduction: Inflammatory bowel disease (IBD) is characterized by recurrent flares of disease activity, which may lead to hospitalisations, surgery, and eventually disease progression. The exact role of psychosocial factors as triggers remains controversial and current literature focuses on the global presence of psychosocial symptoms preceding a flare instead of distinguishing pre-existing from novel symptoms. In this prospective study, we aim to explore the impact of newly developed symptoms of anxiety, depression, fatigue, psychological stress, and life events on IBD flares.

Aims & Methods: IBD patients were recruited from the MyIBDCoach study cohort (de Jong et al., *Lancet* 2017, in Press). MyIBDCoach is a telemedicine tool to monitor IBD patients at home. During the 12-month study period, participants reported on disease activity and psychosocial parameters (including psychological stress, anxiety, depression, fatigue, and life events) through MyIBDCoach every 1–3 months. Flares were defined as clinical disease activity in combination with one of the following: faecal calprotectin $>250 \mu\text{g/g}$, disease activity on endoscopy or other imaging techniques, or dose escalation or initiation of a new drug to induce remission. For all psychosocial parameters, a binary variable was created to indicate whether symptoms were newly developed or pre-existing with reference to the previous measurement, thereby correcting for invariability. A generalized estimating equation model was used to separately determine which psychosocial parameters were associated with flares in the three preceding months, correcting for immortal time bias after a flare and adjusting for gender, disease phenotype, smoking status and disease duration.

Results: In total, 2748 measurements from 381 IBD patients were included. Fifty-one patients (13%) flared after clinical remission was achieved. Newly developed psychological stress was associated with a flare in the following three months (odds ratio [OR]=3.01; 95% CI=1.48, 6.12). Newly reported symptoms of depression (OR=1.29; 95% CI=0.53, 3.14), anxiety (OR=1.06; 95% CI=0.46, 2.43), fatigue (OR=1.59; 95% CI=0.79, 3.22), or the occurrence of a life event (OR=2.07; 95% CI=0.94, 4.55) were not significantly associated, although the latter did occur more frequently before flares.

Conclusion: Newly developed psychological stress is associated with disease flares in IBD patients. Therefore continuous monitoring of patients' stress levels and interventions such as mindfulness and coaching might be interesting to prevent flares and eventually improve disease course.

Introduction: Strain elastography has become a new emerging technique in ultrasonic diagnostics of gastrointestinal pathology. Currently there is few published data on the use of elastography for making the diagnosis and following the course of inflammatory bowel diseases.

Aims & Methods: Objective. To assess the accuracy of strain elastography concerning stricture detection in Crohn's disease (CD).

Materials and Methods. 24 patients aged from 18 to 43y were included into the study, 1 of them having a colonic stricture, 1 patient having a stricture of ileo-transverse anastomosis and 22 patients having a stricture in the small intestine. Surgical treatment was carried out in 22 patients, in each case histopathological evaluation of surgery specimens was conducted. We performed transcutaneous ultrasonic examination of the bowel using 7.5 MHz linear and 3.5 MHz convex probes with power Doppler mode and colonoscopy in all 24 patients. Strain elastography was used during each US-examination to differentiate inflammatory and fibrotic strictures.

Results: Ultrasonic examination invariably showed local narrowing of the intestinal lumen in stricture sites. Inflammatory stricture length was 29 mm (21.1–55.5), (median (2.5th - 97.5th percentile)) with intestinal wall thickening of 6 mm (4.23–9.00) and the presence of ulcers. The lesion length in fibrotic strictures was 30 mm (20–60), wall thickness –6 mm (4.16–8.27), ulcers were visualized either. In 22.7% of cases we observed the signs of partial bowel obstruction. Strain ratio (SR) values for inflammatory strictures were 1.53 (0.43–3.17), for fibrotic strictures – 4.19 (1.57–6.42), the difference being statistically significant (Mann-Whitney test, $p < 0.05$). According to morphologic studies inflammatory strictures were characterized by transmural inflammatory infiltration. In fibrotic strictures we found fibrosis in submucosal layer with loci of muscularis propria involvement. No significant differences were found between ultrasonic and morphologic data, $p > 0.05$.

Conclusion: The proposed ultrasonic and elastographic signs of stricturizing CD facilitate preoperative detection and differential diagnosis of fibrotic and inflammatory strictures, helping to choose appropriate surgical treatment.

Introduction: IBDs are disabling conditions that negatively affect physical, psychological, familial and social dimensions of life. The concept of quantifying disability has become established for the evaluation of many other chronic diseases. Thus, specific tools have been used to assess the impact of disease and its treatment options on relevant end-points such as health-related quality of life (HRQL), measured by the IBD-Questionnaire (IBD-Q). Recently, the IBD-Disability Index (IBD-DI) has been developed to evaluate the entire spectrum of limitations in functioning in patients with IBD. This index is inspired to the International Classification of Functioning, Disability and Health (ICF). The aim of the present study was to assess the relationship between the IBD-DI, clinical characteristics and HRQL in a cohort of Sicilian patients with ulcerative colitis (UC) and Crohn's disease (CD) followed up in a referral center.

Aims & Methods: IBD-Q and IBD-DI questionnaires were administered to consecutive UC and CD adults outpatients from July 2016 to April 2017. The IBD-DI consists of 28 items that evaluate the 4 domains of body functions, activity and participation, body structures and environmental factors. IBD-Q consists of 32 questions grouped into 4 dimensions: bowel, systemic, social, emotional. Scores range from 1 (poorest QoL) to 7 (best QoL) with higher scores indicating better QoL. Disease activity was assessed by partial Mayo score for UC and by Harvey-Brandshaw Index for CD. The mean differences of DI score in relation to dichotomic clinical variables were performed by Student's t test. By linear regression analysis we assessed also the relationship between DI and IBD-Q. Differences were reported as statistically significant if the p value was <0.05.

Results: Data from UC and CD patients were analysed separately. **100 UC patients** (59% males, median age 49 years) were enrolled; 17% were smokers. 83% had inactive or mild disease, 17% moderate disease. None of the recruited patients had severe disease. Concomitant medications at the time of the interview were conventional therapy (5-aminosalicylic acid, oral steroids) in 72 patients (72%) or immunosuppressive therapy (immunosuppressant or anti-TNF-α) in 28 patients (28%). The mean IBD-DI score was 23.15 ± 17.492; 62% of patients had low DI ≤ 25 (62/100) while 7% had high DI (>50). No correlations were found between IBD-DI and gender, disease duration, disease extension (Montreal Classification) and immunosuppressive therapy. IBD-DI was related to clinical disease activity (p < 0.001) and extraintestinal manifestations (P = 0.005). By linear regression analysis, IBD-DI was significantly associated with IBD-Q (R² 0.573; p < 0.001). Interestingly, 5% (n = 5) of patients with inactive or mild disease had severe disability (≥50) and 5% (n = 5) with active disease had low disability (≤25). **54 CD patients** (59% males, median age 41 years) were enrolled; 22% were smokers. 94% had mild disease, 17 (6%) severe disease. Concomitant medications at the time of the interview were conventional therapy (5-aminosalicylic acid, oral steroids) in 22 patients (40%) or immunosuppressive therapy (immunosuppressant or anti-TNF-α) in 32 patients (60%). The mean IBD-DI score was 20.17 ± 16.24; 72% of patients had low DI ≤ 25 (39/54) while only 2 patients had high DI (>50). No correlations were found between IBD-DI and disease characteristic (gender, disease duration, disease extension, extraintestinal manifestations). By linear regression analysis, IBD-DI was significantly associated with IBD-Q (R² 0.604; p < 0.001).

Conclusion: Our preliminary results show that the IBD-DI is significantly related to HR-QoL both in UC and CD. In UC IBD-DI is also related to disease activity and presence of extraintestinal manifestations. However, most of our patients were in clinical remission. A larger sample with different grades of disease activity could provide a more accurate evaluation of the reliability of this tool in measuring functional status and disability in IBD. IBD-DI could become a major end-point in RCTs targeting the course of IBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: DPP-4 is a membrane-bound glycoprotein expressed on the cell surface of enterocytes and lymphocytes. It is released in plasma, maintaining its proteolytic activity and inactivating cytokines, chemokines and neuropeptides.

Aims & Methods: We aimed to investigate the diagnostic and prognostic value of DPP-4 in patients with inflammatory bowel disease (IBD). A total of 203 adult patients [n = 149 IBD patients; n = 42 healthy controls; n = 12 immune controls - systemic lupus erythematosus (SLE) in remission] were prospectively recruited. Plasma DPP-4 was analysed in all groups; faecal samples from IBD patients were collected for DPP-4 and calprotectin analysis. Disease activity was assessed using the Harvey-Bradshaw Index (HBI) for Crohn's disease (CD), the partial Mayo Score (pMS) for Ulcerative colitis (UC) and the Systemic Lupus Erythematosus Disease Activity Index for SLE. A multi-biomarker model was derived using logistic regression to evaluate predictors of disease activity and Cox regression to evaluate predictors of treatment escalation (disease outcome). Treatment escalation was defined as the need for escalation to immunomodulatory/biologic therapies or intestinal resection surgery, as a consequence of a disease flare.

Results: Median plasma DPP-4 values were lower in active CD vs CD in remission [1043ng/mL, interquartile range (IQR): 824–1345 vs 1685 ng/mL, IQR: 1519–2237; P < 0.001]; as well as in active UC vs UC in remission (1323 ng/mL, IQR: 1064–1766 vs 2149 ng/mL, IQR: 1616–2478; P < 0.001). IBD patients in remission showed plasma DPP-4 values significantly lower than healthy subjects; no differences were found between immune and healthy controls. Median faecal DPP-4 values were much lower in active UC vs UC in remission [1213ng/mL, IQR: 559–1682 vs 7814 ng/mL, IQR: 2555–7985; P < 0.001], but no differences were found between active CD and CD in remission. In CD, plasma DPP-4 correlated strongly with faecal calprotectin (FC) (r = −0.61, P < 0.001), C-reactive protein (CRP) (r = −0.60, P < 0.001) and HBI (r = −0.56, P < 0.001), while no statistically significant correlation was found with faecal DPP-4. In UC, plasma DPP-4 correlated moderately with FC (r = −0.31, P < 0.05) and CRP (r = −0.32, P < 0.05), strongly with pMS (r = −0.52, P < 0.001) and with faecal DPP-4 (r = 0.52, P < 0.001). The multivariable logistic regression model showed that plasma DPP-4 and CRP are independent predictors of CD activity [odds ratio (OR): 26.95; 95% confidence interval (CI): 3.01–240.96; P = 0.003 and OR: 38.02; 95% CI: 4.25–340.48; P = 0.001, respectively]. In UC patients, plasma DPP-4, FC and CRP showed to be independent predictors of disease activity (OR: 62.10; 95% CI: 2.93–1315.62; P = 0.008 and OR: 65.90; 95% CI: 4.96–875.53; P = 0.002 and OR: 48.19; 95% CI: 3.35–692.76; P = 0.004, respectively). At follow-up (median 578 days; IQR: 426–688), plasma DPP-4 and CRP independently predicted treatment escalation in CD [hazard ratio (HR) 9.09; 95% CI: 1.77–46.57; P = 0.008 and HR 5.90; 95% CI: 1.53–22.78; P = 0.010; respectively], as well as in UC (HR 7.80; 95% CI: 1.60–38.04; P = 0.011 and HR 12.23; 95% CI: 2.30–64.98; P = 0.003; respectively). At 1 year, the proportion of patients who needed treatment escalation was 66% in CD and 41% in UC, if ≥2 biomarkers criteria were met.

Conclusion: An activity assessment model and a prognostic model that combines plasma DPP-4 and other biomarkers accurately predicts IBD activity and an aggressive disease course. Faecal DPP-4 correlates well with plasma DPP-4 in Ulcerative colitis, but not in Crohn's disease.

P1021 ROLE OF PET-CT TO ASSESS DISEASE ACTIVITY IN ULCERATIVE COLITIS AND ITS CORRELATION WITH CLINICAL CRITERIA, ENDOSCOPY AND FECAL BIOMARKERS

N. Berry, S. K. Sinha, A. Bhattacharya, K. Prasad, C. Vaishnavi, K. Vaiphei, J. Samanta, R. Prasad, N. Dhaka, R. Kochhar

Gastroenterology, Postgraduate Institute of Medical Education and Research, Chandigarh/India

Contact E-mail Address: nehaberry86@hotmail.com

Introduction: Disease activity in ulcerative colitis (UC) is best assessed clinically by Mayo score and endoscopy. Positron emission tomography - computerized tomography (PET-CT) is a non-invasive imaging technique to assess disease activity, extent, treatment response in UC, specially in pediatric population, sick patients and those unwilling for endoscopy.

Aims & Methods: We conducted a prospective observational study at our tertiary care centre with the aim of assessing and correlating UC disease activity by clinical criteria, endoscopy, histology, serum and fecal biomarkers and PET-CT. 60 eligible patients of UC were enrolled into 3 groups (26 remission, 24 moderate and 10 severe activity) as per Mayo score and ^{18}F FDG PET-CT was performed within 72 hours of endoscopy. ESR, CRP and fecal calprotectin levels were determined for all patients.

Results: Of 60 enrolled patients, 10% patients had proctitis, 43.3% had left-sided colitis and 46.7% had extensive colitis. ESR, CRP, fecal calprotectin levels and rectal PET activity were significantly higher in patients with moderate and severe disease activity as compared to those in remission. Rectal PET activity showed a significant correlation with the Mayo score ($k=0.465$, $p<0.001$), endoscopic sub-score ($k=0.526$, $p<0.001$), histological score ($k=0.496$, $p<0.001$), and fecal calprotectin levels ($k=0.279$, $p=0.031$). Extent evaluation by PET-CT and colonoscopy also showed a significant correlation ($k=0.582$, $p<0.001$) with each other. We found that CRP at a cut-off level of $<12\text{ mg/L}$ had a sensitivity of 70.59% and specificity of 92.3%, and fecal calprotectin at a cut-off of $<143\text{ ug/g}$ had a sensitivity of 82.35% and specificity of 88.46% to predict remission. Besides, PET-CT identified sacroilitis in 1, mesenteric lymphadenopathy in 5, mesenteric stranding in 4, and adenocarcinoma in 1 patient.

Conclusion: PET-CT is a reliable non-invasive tool for assessing disease activity in UC with good correlation with the Mayo score, endoscopic score, histology and fecal calprotectin. It is an accurate measure to determine disease extent, and a good predictor of remission. Thus, with a better patient compliance, it holds promise in replacing colonoscopy where it is refused or difficult to perform.

Biomarkers and rectal PET activity of patients

Variables	Remission (n = 26)	Moderate activity (n = 24)	Severe activity (n = 10)	Total (n = 60)	P* value between groups
ESR (mm) (mean \pm SD)	23.3 \pm 18.7	35.1 \pm 22.3	48.9 \pm 9.7	32.3 \pm 21.0	0.002
CRP mg/L (mean \pm SE)	5.6 \pm 1.2	25.3 \pm 4.3	93.3 \pm 23.4	28.1 \pm 5.7	0.000
Fecal calprotectin ($\mu\text{g/g}$) (mean \pm SE)	72.27 \pm 13.65	276.29 \pm 30.43	426.6 \pm 64.95	212.93 \pm 24.23	0.001
Rectal PET-CT activity (SUV _{max}) (Mean \pm SD)	6.04 \pm 5.50	10.79 \pm 3.88	12.70 \pm 10.50	9.05 \pm 6.56	0.004

Introduction: The importance of therapeutic drug monitoring (TDM)-based algorithms to guide infliximab (IFX) adjustments in inflammatory bowel disease (IBD) patients is unquestionable. Currently, most of the methods commercially available for the quantification of IFX are ELISA-based delaying the target dosage adjustment to the following infusion. A new rapid assay is now available in the market.

Aims & Methods: This study aimed to explore a recently-launched IFX quantification rapid test from a clinical perspective. A prospective cohort involving 110 ulcerative colitis (UC) patients under IFX maintenance therapy was study. IFX trough levels were quantified using a rapid quantification assay and a commonly used reference kit.

Results: IFX values were statistically different when comparing patients with or without endoscopic remission (Mayo endoscopic score = 0) and stratified by their faecal calprotectin (FC) levels, regardless the methodology used. Though the two

methods correlated well with each other (Spearman correlation coefficient = 0.843, $p<0.001$; intraclass correlation coefficients = 0.857, 95% CI: 0.791–0.903), values obtained with the reference kit were on average 2.62 units higher than those obtained with the rapid system. Nevertheless, 3 ug/ml was shown to be an appropriate cut-off to assess endoscopic remission and inflammatory burden levels with both assays. In fact, eighty eight percent of patients that had a positive outcome showed IFX values, with the rapid assay, above 3ug/mL, Mayo endoscopic score ≤ 1 and for an FC concentration $<250\text{ ug/g}$.

Conclusion: Our results show that the rapid IFX assessment system is a reliable alternative to the time-consuming ELISAs in patients on the maintenance phase of IFX operating a threshold of 3 ug/ml.

P1023 THE IMPACT OF AN INFLAMMATORY BOWEL DISEASE EDUCATION CLINIC ON PATIENT OUTCOMES AND RESOURCE UTILISATION

W. On, B. Collins, H. Stanley, A. Westhoff, S. Tynan, D. McClements, V. Theis, J. McLindon, R. Chandy, A. Bassi

Gastroenterology, St Helens & Knowsley Teaching Hospitals NHS Trust, Liverpool/United Kingdom

Contact E-mail Address: weiheng.on@gmail.com

Introduction: Patient education and awareness in those who have inflammatory bowel disease (IBD) and is regarded by the United Kingdom (UK) IBD standards group as a key standard in the provision of care towards patients with IBD.¹ Our district general hospital implemented an IBD education clinic in 2015 which is run quarterly per annum by a multidisciplinary panel of doctors, specialist nurses, pharmacists and dietitians. Patients who have been newly diagnosed with IBD are invited to attend this clinic. Clinic attendees are given an overview of their disease, treatment modalities, options of non-medical support (e.g. psychology) and are made aware of our telephone helpline open access service. To date, there has not been any published data on the impact of an IBD education clinic on resource use or patient outcomes.

Aims & Methods: We aimed to evaluate the impact of the education clinic on resource use in patients who attended the clinic compared to patients who did not. A retrospective analysis was done of patients who were diagnosed with IBD between January 2013 and May 2015. 40 patients were identified and divided equally (20 patients each) into clinic attenders (CA) and non-attenders (NA). Resource use was determined at 12 months from diagnosis in the NA group and 12 months from attendance in the CA group. The median time from diagnosis to clinic attendance in the CA group was 7 months. Data was obtained from our hospital's electronic database system. Statistical analysis was carried out with the student's t-test.

Results: The median age was 37 in the CA group and 33 in the NA group. In the CA group, 10 patients had ulcerative colitis (UC), 9 patients had Crohn's Disease (CD) and 1 patient had unclassified IBD. In the NA group, 13 patients had UC and 7 patients had CD. The median of resource use and patient outcomes over a 12 month period (from diagnosis in the NA group and from clinic attendance in the CA group) is detailed in the table below.

Resource use and patient outcomes	NA	CA	p-value
Steroid courses	0.47	0.51	1
Unplanned hospital admissions	0.19	0.21	1
IBD telephone helpline consultations	0.24	2.58	0.001
Clinic appointments	3.71	2.84	0.08
Blood tests (excluding essential monitoring blood tests)	5.81	3.68	0.14
Endoscopies	0.33	0.26	0.77
Radiological imaging	0.24	0.16	0.5
Therapy escalation	1.4	1.15	0.62

Conclusion: In our cohort of patients, patients who attended the IBD education clinic were more likely to utilise our open access IBD telephone helpline service. There was a trend towards increased frequency of outpatient clinic appointments and blood tests in patients who did not attend the IBD education clinic although this was not statistically significant. There were no differences in the rates of hospital admissions or steroid courses in either group. The limitations of our data include the small sample size and short follow-up period.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1024 EMERGING ROLE OF IL-33/ST2 LEVELS IN PREDICTING MUCOSAL RESPONSE TO ANTI-TNF THERAPY IN ULCERATIVE COLITIS

L.R. Lopetuso¹, V. Petito¹, C. Graziani¹, T. T. Pizarro², F. Scaldaferri¹, A. Gasbarrini¹

Contact E-mail Address: lopetusolioris@libero.it

Introduction: Tumor necrosis factor (TNF) inhibitors (anti-TNF) are considered to be effective in inducing mucosal healing in patients with moderate-to-severe Ulcerative Colitis (UC). The role of IL-33 and its receptor, ST2, in intestinal inflammation is incompletely understood, with both pro-inflammatory and regulatory properties described. Recent evidence has shown that anti-TNF is able to modulate the IL-33/ST2 axis in inflammatory conditions.

Aims & Methods: The aim of our study was to explore the potential role of the IL-33/ST2 axis in the mucosal healing process mediated by anti-TNF therapy in UC. Endoscopic MAYO score was calculated before the first anti-TNF infusion (T0) and after 6 weeks (T2). 24 UC patients (MAYO score at T0 ≥ 2), grouped into 12 responders with mucosal healing (MAYO score ≤ 1) and 12 non-responders to anti-TNF at T2 (MAYO score ≥ 2) were enrolled. 10 healthy controls undergoing routine colonoscopy for tumor screening were also enrolled. At each time point, serum samples were collected and ELISA performed to assess IL-33/ST2 protein levels. Intestinal biopsies were also taken from the rectum and IHC was done to evaluate mucosal IL-33/ST2 expression and localization.

Results: IL-33 protein levels were significantly increased in responders vs. non-responders, both at T0 and T2. Among responders, IL-33 protein was slightly reduced at T2 vs. T0, while unchanged in non-responders. Interestingly, significantly higher levels of ST2 were found in responders vs. not responders at T0, while no differences between groups were found at T2. Among responders, ST2 levels were dramatically reduced at T2 vs. T0. No significant differences were found in non-responders at both time points. Healthy controls showed significantly lower levels of both IL-33 and ST2 compared with other groups. IHC confirmed these observations. In particular, IL-33 and ST2 staining was more intense within the inflamed and ulcerated mucosa of responders compared to non-responders at T0. After 6 weeks, ST2 staining was even more evident in responders, notably localized to the healed mucosa and in close proximity to areas of re-epithelialization. Little to no staining for both IL-33 and ST2 was present in healthy controls.

Conclusion: Our results suggest a possible role for IL-33/ST2 in predicting gut mucosal wound healing in patients with moderate-to-severe UC treated with anti-TNF. Further studies are underway to determine mechanisms of action that support these findings.

Introduction: Higher infliximab (IFX) serum concentrations have been associated with higher rates of clinical remission in inflammatory bowel disease patients^{1,2}. However, the correlation between IFX trough levels (TL) during the induction phase and in medium or long-term remission in Crohn's disease (CD) patients is less clear³.

Aims & Methods: We aimed to analyse whether the IFX-TL were able to predict medium (22 weeks) and long-term (54 weeks) remission in CD patients. Consecutive CD patients receiving IFX (5mg/kg at weeks 0, 2, 6 and every eight weeks at least until 22 week) were included retrospectively. IFX-TL were measured by capture ELISA and anti-Infliximab antibodies (ATI) by a bridging ELISA before each infusion⁴. Clinical response and biological parameters were also measured. The investigator defined remission based on clinical (Harvey-Bradshaw score), biological and endoscopic or imaging techniques; partial or no response, as well as intensification decided by investigators were considered as non-remission patients. U-Mann Whitney test was used to assess association between IFX-TL and remission. ROC curves were included to obtain cut points for clinical use.

Results: 32 CD patients were screened, but finally 29 analysed, because 3 patients had IFX discontinued at week 14. Baseline characteristics included: 16 female: 55.2%, 31% smoker, 31% ex-smoker, 79.3% ileal or ileocolonic involvement, 44.8% inflammatory behavior, with 6.9% previous abdominal surgery and 86.2% on concomitant immunosuppressant, 34.5% non-naïve to biological therapy. On week 22, 44.8% patients were in remission; on week 54, 40% were in remission.

	Week	REMISSION Median (IQR) IFX-TL(µg/mL)	NO REMISSION Median (IQR) IFX-TL(µg/mL)	Z	p
Week 6	22	24.6 (18.4–41.3)	12.7 (5.2–22.2)	–2.982	0.002
	54	28.2 (18.3–40)	15.1 (5.6–21.3)	–2.441	0.014
Week 14	22	9.5 (6.8–14)	1.8 (0.9–9.2)	–2.647	0.007
	54	8.4(5.2–13.3)	3.8 (1.3–9.5)	–1.580	0.123

On week 6, IFX-TL > 24 µg/mL was associated with remission at week 22 (ROC 0.83; S: 61.5%, Sp: 81.3%) and at week 54 (ROC 0.79; S 60%, E 80%). On week 14, IFX-TL > 11 µg/mL was associated with remission at week 22 (ROC 0.80; S: 41.7%, Sp: 93.8%) and at week 54 (ROC 0.70; S: 44.4%, Sp: 86.7%).

Conclusion: IFX-TL during the induction period are associated with remission at 6 and 12 months. Optimal TL ranges associated to remission can be calculated to guide clinical decisions. can be calculated to guide clinical decisions.

Introduction: Several histological scores of activity have been developed in Inflammatory Bowel Disease (IBD). However, their usefulness in clinical practice and the correlation between clinical, endoscopic and histological scores is undefined.

Aims & Methods: To assess, in a prospective study, the correlation between clinical, endoscopic and histological activity scores in a cohort of IBD patients (pts) undergoing colonoscopy. Secondary end-point was to assess the role of histological scores in clinical practice. From Feb. to Dec. 2016, IBD pts undergoing colonoscopy according to clinical indication were enrolled. Inclusion criteria: 1. Diagnosis of IBD; 2. Age > 18 and <80 yrs; 3. Regular follow up; 4. Indication for colonoscopy; 5. No severe comorbidities. During colonoscopy, ≥ 2 biopsies were taken from ≥ 1 macroscopically involved area and, possibly, from ≥ 1 uninvolved area. Clinical activity was assessed by the Mayo score (activity ≥ 3)(2) for Ulcerative Colitis (UC) and the CDAI (activity ≥ 150)(1) for Crohn's Disease (CD) pts. All colonoscopies were performed by one IBD-dedicated gastroenterologist. Endoscopic activity was assessed in UC pts by the Mayo score (activity ≥ 2)(2), and in CD by the Rutgeerts' score (recurrence ≥ 2)(3) or the SES-CD (activity ≥ 3)(4), according to previous surgery. Histological activity was assessed by one pathologist using the Global Histologic Activity Score (GHAS) for CD (5) or the Geboes simplified score for UC (activity ≥ 3)(6). Each of the 3 investigators was blind regarding the other activity scores. *Statistical analysis.* Data expressed as median [range], correlations assessed by the Spearman correlation test.

Results: IBD group included 107 pts: 67 (62.6%) UC (M 36 [53.7%], age 50 [24–80], UC duration 14 yrs [1–48]), 40 (37.4%) CD (M 24 [60%], age 46 [19–75], CD duration 14 yrs [1–36]). UC extent included: pancolitis in 34 (51%), left sided in 17 (25%), proctitis in 16 (24%) pts. CD involved (n = [%]): the ileum (21 [52%]), colon (6 [15%]), ileum-colon (12 [30%]), upper GI (1 [3%]), previous surgery in 18 (45%). CD behavior was fibrostricturing (n = 15; 37%), penetrating (n = 11; 28%), non-stricturing non-penetrating (n = 14; 35%). No complications occurred. *Clinical Activity:* UC. The day of colonoscopy, UC was clinically active in 14 (21%), in remission in 53 (79%) pts. *Endoscopic activity:* UC. Endoscopic activity was observed in 31 (46%), remission in 36 (54%) pts. (Mayo score: 0 [n = 14]; 1 [n = 22]; 2 [n = 13], 3 [n = 18]). *Histologic activity:* UC. Microscopic activity was observed in 24/67 (36%) pts: 4/24 pts showed endoscopic remission. *Correlations:* UC. In UC, a significant correlation was observed between: clinical and endoscopic scores (r = 0.52; p < 0.0001); clinical and histologic scores (r = 0.28; p = 0.02); endoscopic and histologic scores (r = 0.56; p < 0.0001). *Clinical Activity:* CD. At colonoscopy, CD was clinically

active in 5 (12%), in remission in 35 (88%) pts. **Endoscopic activity:** CD. Colonoscopy was incomplete in 2/40 pts. In the 24 pts with no previous surgery, SES-CD was: 0 (n=4); 3 (n=1); 4 (n=3); 6 (n=2); 8 (n=3); 9 (n=2); 10 (n=1); 11 (n=1); 12 (n=1); 13 (n=1); 14 (n=1); 17 (n=1); 19 (n=1) pts (median 4 [0–19]; activity: 20/24 [80%], remission: 4/24 [20%]). In the 16 pts with previous surgery, the Rutgeerts' score was: 0 (n=3); 1 (n=1); 2 (n=6); 3 (n=2); 4 (n=4) (recurrence: 12/16 [75%]). **Histologic activity:** CD. The GHAS was: 0 (n=5); 1 (n=11); 2 (n=3); 4 (n=1); 6 (n=2); 7 (n=1); 9 (n=1) in pts without previous surgery, and 0 (n=3); 1 (n=9); 3 (n=1); 10 (n=1) in pts with previous surgery. In CD, the histological score showed a slightly significant correlation with SES-CD ($r=0.41$; $p=0.046$) and no correlation with the Rutgeerts' score ($r=0.31$; $p=0.247$).

Conclusion: In a prospective study, a significant correlation was observed between clinical, endoscopic and histological activity in UC. Histological activity may be observed in UC patients in endoscopic remission, thus suggesting that this finding may represent a predictive marker of clinical relapse.

P1027 THE RELATIONSHIP BETWEEN SERUM INFlixIMAB AND ADALIMUMAB CONCENTRATIONS AND THEIR CORRESPONDING ANTI-DRUG ANTIBODY LEVELS: ANALYSIS OF OVER 50, 000 PATIENT RESULTS USING LAB-DEVELOPED CHEMILUMINESCENT IMMUNOASSAYS

K. Y. Chun¹, J. Yang²

Introduction: Assays to measure TNF inhibitors and anti-drug antibodies (ADAb) in patient serum are being utilized to manage failure to respond and loss of response. These monitoring assays may also be used to proactively titrate doses and dosing intervals. Here, 36,477 infliximab (IFX) and 21,284 adalimumab patient results from the past 4 years were analyzed.

Aims & Methods: Measurements of drug and ADAb levels were performed by lab-developed chemiluminescent immunoassays.[1] Lower limits of quantitation are 0.4 ug/mL for IFX and 0.6 ug/mL for adalimumab. ADAb assays are drug tolerant in the presence of up to 100 ug/mL of drug. Clinical histories and blood collection timing are unknown.

Results: Of 36,477 measured IFX samples, 56% (20,353) were ADAb-free and 44% (16,224) had measureable ADAb ranging from 22 to 3.5 million ng/mL. In the absence of ADAb, IFX concentrations were from 0.4 to > 100 ug/mL, with the majority (>60%) between 3.0 to 20 ug/mL. In the presence of ADAb, an inverse relationship between IFX concentrations and anti-IFX antibodies is clearly evident (Table 1). As a reference, an ADAb-free mean drug level was determined from samples with IFX between 0.4–30 ug/mL. Decreasing mean IFX concentrations (column 3) with increasing ADAb (column 1) are demonstrated where low ADAb (<200 ng/mL) appears to have minimal impact on mean drug levels while high ADAb (>1000 ng/mL) is invariably associated with severely diminished IFX (10% or less than the mean). A similar drug - ADAb relationship was observed with adalimumab (Table 2). Interestingly, even low titer anti-adalimumab antibodies are associated with a diminished mean adalimumab (3.4–5.6 ug/mL) where the baseline mean adalimumab (6.1 ug/mL) was calculated from 10,784 ADAb-free samples with adalimumab from 0.6–15 ug/mL. Anti-adalimumab antibody levels >300 ng/mL are associated with free adalimumab concentrations <30% of the mean. Of all adalimumab patient samples, 60% (12,873) were free of ADAb, and 40% (8411) were ADAb positive, ranging from 25 to 2.8 million ng/mL. For adalimumab in Table 2, as ADAb levels increase (column 1), their corresponding mean drug concentrations diminish (column 3), similar to IFX results in Table 1.

Table 1: Anti-Infliximab Antibody Distribution and Corresponding Mean Free Drug Levels

Anti-Infliximab Antibody Ranges (ng/mL)	n	Mean Drug Concentration (ug/mL)	% with Undetectable Drug (<0.4 ug/mL)
undetectable	15692	10	0%
22–100	6785	9.5	11%
101–200	2684	8.6	19%
201–300	1344	6.3	27%
301–500	1427	5.2	38%
501–700	789	3.7	53%

(continued)

Table 1: Continued

Anti-Infliximab Antibody Ranges (ng/mL)	n	Mean Drug Concentration (ug/mL)	% with Undetectable Drug (<0.4 ug/mL)
701–1000	802	3.0	63%
1001–2000	1246	1.0	79%
2001–4000	575	<0.4	86%
4001–3.5 million	572	<0.4	100%

Table 2: Anti-Adalimumab Antibody Distribution and Corresponding Mean Free Drug Levels

Anti-Adalimumab Antibody Ranges (ng/mL)	n	Mean Drug Concentration (ug/mL)	% with Undetectable Drug (<0.6 ug/mL)
undetectable	10784	6.1	0%
25–100	3904	5.6	5%
101–200	1144	3.4	12%
201–300	570	2.4	24%
301–500	655	1.8	39%
501–700	330	1.1	57%
701–1000	303	0.7	75%
1001–2000	496	<0.6	93%
2001–4000	394	<0.6	97%
4001–2.8 million	610	<0.6	99%

Conclusion: Upon analysis of 57,861 infliximab and adalimumab patient samples from 2012–2016, 43% exhibited anti-drug antibodies. We found that low-titer antibodies do not appear to impact drug levels. Our findings are consistent with American Gastroenterological Association Critical Care Pathways for Crohn's Disease and Ulcerative Colitis where low and high antibody scenarios are managed very differently (increase drug/consider immunomodulator vs. switch drug within class). High resolution antibody assays may be helpful in dosing TNF inhibitors and in other treatment and management decisions.

P1028 REAL-WORLD USE OF IMMUNOSUPPRESSIVES AMONG PATIENTS WITH INFLAMMATORY BOWEL DISEASE TREATED WITH VEDOLIZUMAB

M. Raluy Callado¹, R. Carroll¹, R. Curtis², M. J. Khalid², H. Patel²

¹Evidera, London/United Kingdom

Contact E-mail Address: hari.patel@takeda.com

Introduction: Immunosuppressives (IM) are often used as maintenance therapy to reduce the risk of relapse among patients with inflammatory bowel disease (IBD). Vedolizumab (VDZ), a humanized monoclonal antibody that targets the $\alpha 4\beta 7$ integrin, has been approved for the treatment of moderately-to-severely active Crohn's disease (CD) and ulcerative colitis (UC).

Aims & Methods: The aim was to assess the real-world use of IM therapy and compare outcomes in IBD patients with, versus without a history of IM use, who initiated treatment on VDZ in the United States. The Explorys Universe database was used to identify all IBD patients >18 years of age who: (1) initiated VDZ therapy between May 20, 2014, and February 22, 2016 (the date of VDZ initiation was the assigned index date); and (2) had 365 days of available data pre- and post-index date (follow-up). Patients were stratified based on the use of IM at any point in their treatment history before the index date. Key outcomes in the follow-up period included the use of IM; and the incidence of IBD-related surgeries, hospitalizations, and flares (defined as the use of intravenous corticosteroids, IBD-related surgeries, or hospitalizations).

Results: A total of 567 patients were included, of which 68.4% had CD, and 31.6% had UC. Mean (standard deviation [SD]) age at index was 44 (15.0) years; 58.6% were female. Overall, 54.6% had a history of prior IM use, and 64.6% received anti-TNFs before starting VDZ therapy. On average, patients initiated VDZ 4.5 (3.6) years following their initial diagnosis. Of the 54.6% of patients with a history of IM therapy, 61.0% did not use IM during maintenance treatment with VDZ during follow-up. Of the 45.4% of patients without a history of IM use, 87.0% did not initiate IM therapy during follow-up. Amongst VDZ patients with a history of IM vs. without history of IM use, there was a trend of increased flares (38.7% vs. 30.0%, $p=0.034$), hospitalizations (21.9% vs. 19.8%, $p=0.605$), and surgeries (10.6% vs. 6.6%, $p=0.103$). Findings for UC and CD patients are presented in Table 1.

Conclusion: The majority of patients with a history of IM use did not use IM therapy after initiating VDZ in a real-world clinical practice. The use of IM after initiating VDZ was also low amongst patients without a history of IM use. Lower rates of healthcare resource utilization were observed among patients without a history of IM use. Further research is needed to better understand the degree to

which IM therapy is used concomitantly with VDZ and potential impact on outcomes in real-world clinical practice.

P1029 MOLECULAR SURROGATES OF HISTOLOGIC ACTIVITY IN CROHN'S DISEASE

C. Monast¹, K. Li¹, E. Myshkin², C. Brodmerkel¹, J. Friedman¹, F. Baribaud¹

¹Janssen Research & Development, LLC, Spring House/United States of America/PA

Contact E-mail Address: cmonast1@ITS.JNJ.com

Introduction: Biomarkers of inflammatory bowel disease activity have been researched for decades but objective markers of disease severity that support clinical decision-making are still needed. Well-established markers include serum C-reactive protein and fecal calprotectin, but their use as a standalone surrogate for disease activity has been controversial. We hypothesize that novel objective markers of tissue inflammation are best identified at the site of disease with a tissue-level assessment of disease activity.

Aims & Methods: Biopsy samples were obtained from participants in the UNITI trials of ustekinumab in moderate-to-severe Crohn's disease. The UNITI induction trials included two cohorts, patients who failed ≥ 1 TNF antagonists (UNITI-1) or patients who failed conventional therapies (UNITI-2). Pairs of adjacent biopsies were taken from the rectum, splenic flexure, and ileum. One biopsy from each pair was assessed by Global Histology Disease Activity Score (GHAS) while the other was submitted to microarray analysis. Partial least squares regression and random forest were used to identify biomarkers associated with histological severity in the UNITI-1 cohort. Robustness of the resulting models was assessed using cross-validation within the training set and multiple external validation sets (defined within the UNITI-1 and UNITI-2 cohorts).

Results: In UNITI-1, a single multivariate model comprising 16 genes was identified that predicted histological activities in rectum or splenic flexure biopsies. This model was characterized by $R^2=0.78$ for the training set, and $R^2=0.59$, 0.54, and 0.32 on external validation sets also from UNITI-1. A separate 14-gene model capturing histological activity in ileal biopsies was characterized by $R^2=0.5$ for the training set and $R^2=0.45$ in the external validation set. In general, both models contained genes related to tissue degradation, barrier function, and immune regulation, including CXCL11 (I-TAC). Both models retained performance in external validation datasets from UNITI-2 but exhibited lower performance. De novo models generated from UNITI-2 also exhibited lower performance. Indeed, weighted gene co-expression network analysis indicated weaker associations between gene expression and histology scores for UNITI-2 compared to UNITI-1 subjects.

Conclusion: Our analysis supports the ability of biopsy transcriptomics combined with machine learning approaches to capture disease-relevant variability in Crohn's disease and, more importantly, supports the use of similar approaches to identify additional surrogate markers. Interestingly, this approach was more

successful in the TNF antagonist failure cohort compared to the conventional therapy failure cohort. We hypothesize that this is related to increased strength of the transcriptional signal in the TNF antagonist failure cohort. We identified specific genes that could be used together as surrogates for histologic measurement, which may not be susceptible to the subjectivity inherent in GHAS scoring. Finally, the specific genes identified by our analysis provide insight into the molecular processes driving histological disease activity in Crohn's disease.

Introduction: Indirect evidence is needed to inform the clinical efficacy of ustekinumab in Crohn's disease (CD). Indirect treatment comparisons in CD are challenged by withdrawal trial designs limiting placebo arm transitivity. This treatment sequence analysis builds on previous work¹ proposing a solution to challenges inherent to CD datato compare one year efficacy of biologics in CD patients having failed anti-TNF therapy. Analyses accounted for delayed responders (induction non-responders attaining response after additional doses) to generate more comprehensive estimates of biologics' relative efficacies.

Aims & Methods: A systematic literature review identified randomized controlled trials in CD patients having failed anti-TNF therapy for induction and maintenance of ustekinumab (UST), adalimumab (ADA), or vedolizumab (VDZ). Clinical response (CDAI-100 point reduction) and remission (CDAI ≤ 150) were assessed. The probability of achieving response after induction was multiplied by the conditional probability of maintaining response/achieving remission at one year. Separate calculations were conducted for early and delayed responders. Their respective treatment sequence rates were summed to obtain overall response and remission rates. Placebo rates were imputed using data from patients induced and maintained on placebo from the IM-UNITI study, adjusted for responder and remitter induction rates. Bayesian analyses generated relative

Abstract: P1028. Table 1: Characteristics and outcomes among patients newly started on vedolizumab stratified by IBD type and history of immunosuppressive therapy

	CD (N = 388)			UC (N = 179)		
	With history of IM use (N = 225)	Without history of IM use (N = 163)	P-value	With history of IM use (N = 85)	Without history of IM use (N = 94)	P-value

Surgeries	12.4%	7.4%	0.128	5.9%	5.3%	>0.999
Flares	43.6%	32.5%	0.035	25.9%	25.5%	>0.999

Note: IM therapy included use of azathioprine, 6-mercaptopurine, methotrexate, mycophenolate mofetil, cyclosporine, and Tacrolimus

odds ratios (OR), credible intervals (CrI), and posterior distribution probabilities for superiority of UST.

Results: Accounting for delayed responders, the absolute proportions of patients having maintained response and being in remission at one year were 30% of patients receiving UST every 8 weeks, 19% of those receiving VDZ every 4 weeks, and 23% of patients receiving ADA every other week or weekly. Based on a one-year treatment sequence analysis, probabilities for UST to be better than VDZ for achieving and maintaining response and remission were 99%(OR[CrI]:1.94[1.07;3.48]) and 98%(OR[CrI]:1.82[1.00;3.28]), respectively. UST had higher likelihoods of remission than ADA given weekly(83%, OR[CrI]:1.36[0.72;2.58]) or every other week(85%, OR[CrI]:1.41[0.74;2.68]).

Conclusion: This approach deals with methodological issues inherent to CD trial data. In CD patients having failed anti-TNF therapy, ustekinumab had higher likelihoods of response or remission than adalimumab and vedolizumab over a one-year treatment sequence. Additional induction doses and continued maintenance therapy with ustekinumab have demonstrated benefits in delayed responders compared to other biologics. Previous research¹ is limited to indirect treatment comparisons in early responders only. Including delayed responders provides a more accurate picture of CD patients' response to biologics and better informs clinical practice.

Introduction: Indirect evidence is needed to inform the clinical efficacy of ustekinumab in Crohn's disease (CD). Indirect treatment comparisons in CD are challenged by withdrawal trial designs limiting placebo arm transitivity. This treatment sequence analysis builds on previous work¹ proposing a solution to challenges inherent to CD data to compare one year efficacy of biologics in CD patients having failed conventional therapy. Analyses accounted for delayed responders (induction non-responders attaining response after additional dosing) to generate more comprehensive estimates of biologics' relative efficacies.

Aims & Methods: A systematic literature review identified randomized controlled trials in CD patients having failed conventional therapy for induction and maintenance of ustekinumab (UST), adalimumab (ADA), or vedolizumab (VDZ). Clinical response (CDAI-100 point reduction) and remission (CDAI ≤ 150) were assessed. The probability of achieving response after induction was multiplied by the conditional probability of maintaining response/achieving remission at one year. Separate calculations were conducted for early and delayed responders. Their respective treatment sequence rates were then summed to obtain overall response and remission proportions. Placebo rates were imputed using data from patients induced and maintained on placebo from the IM-UNITI study and adjusted for responder and remitter induction rates. Bayesian analyses generated relative odds ratios (OR), credible intervals (CrI), and posterior distribution probabilities for superiority of ustekinumab.

Results: When accounting for delayed responders, the absolute proportions of patients having maintained response and being in remission at one year were of 50% in patients receiving UST, 39% in those receiving VDZ, and 33 or 36% in patients receiving ADA every other week or weekly, respectively. Based on a one-year treatment sequence analysis, probabilities for UST to be better than VDZ for achieving and maintaining response and remission were 84%(OR[CrI]:1.39[0.73;2.62]) and 69%(OR[CrI]:1.19[0.59;2.38]), respectively. UST had higher likelihoods of remission than ADA given weekly (75%, OR[CrI]:1.33[0.58;3.02]) or every other week (82%, OR[CrI]:1.47[0.64;3.33]).

Conclusion: This approach deals with methodological issues inherent to CD trial data. In CD patients having failed conventional therapy, higher likelihoods of response or remission were observed for ustekinumab versus adalimumab and vedolizumab over a one-year treatment sequence. Additional induction doses and continued maintenance therapy with ustekinumab in delayed responders have demonstrated benefits compared to other biologics. Previous research¹ is limited to indirect treatment comparisons in early responders only. Including delayed responders provides a more accurate picture of CD patients' response to biologics and better informs clinical practice.

Introduction: Anti-TNF therapies have revolutionised the management of IBD. Recently, the infliximab (IFX) biosimilar (CT-P13) received market authorisation for IBD allowing cost benefits with switches to CT-P13 with annual savings of £5400/patient (70 kg patient receiving 5mg/kg 8 weekly). We present our experience of switching patients from the originator IFX to CT-P13 for new and existing patients.

Aims & Methods: Recorded baseline characteristics included indication, age, sex, disease duration, treatment duration, concomitant immunomodulators, baseline CRP and HBI/Mayo scores. Response to IFX induction was assessed retrospectively using symptoms and CRP. Treatment response and remission rates, primary and secondary loss of response rates, and adverse events in patients who initiated IFX in the 12 months pre-Feb 2016 were compared with those who initiated CT-P13 in the 12 months post-Feb 2016. Sustained response was compared for existing IFX patients who switched to CT-P13 in Feb 2016 against those who continued with the original IFX. Drug and antibody levels were measured before switch and at 3, 6, and 12 months post.

Results: 53 patients commenced IFX in the 12 months pre-Feb 2016 (26 Crohn's Disease (CD), 13 fistulating CD, 13 Ulcerative Colitis (UC), 1 IBD-Unclassified (IBD-U)) compared with 69 patients who commenced CT-P13 in the subsequent 12 months (22CD, 9 fistulating CD, 35UC, 3IBD-U). Baseline characteristics did differ, with a greater proportion of UC patients in the CT-P13 cohort (51% v 24.5% ($p=0.003$)). This group had a higher mean CRP (20.2 v 10.6 ($p=0.008$)) although a lower median Mayo score (5 v 11 ($p=0.007$)). There was no difference in response (12(23%) v 15 (21.74%) ($p=0.905$)), remission (14(26%) v 29(42%) ($p=0.074$)), primary non-response (8(15%) v 4(5.8%) ($p=0.087$)), secondary loss of response (12(23%) v 15(21.74%) ($p=0.905$)), or adverse events (6(11%) v 6(8.7%) ($p=0.629$)) in those who initiated originator IFX compared with CT-P13. 191 patients switched to CT-P13 post-Feb 2016, while 19 patients continued on originator IFX. There was no difference in the response (2(11%) v 24(12.6%) ($p=0.797$)), remission (9(47%) v 11(58.1%) ($p=0.367$)), secondary loss of response (8(42%) v 47(24.6%) ($p=0.098$)), or adverse events (0% v 9(4.7%) ($p=1$)) between the originator IFX and CT-P13 respectively. Drug and antibody levels were available pre-switch to CT-P13 for 134 patients. Therapeutic drug levels with no significant antibodies were associated with clinical remission 12 months post-switch compared with low/undetectable drug levels and significant antibodies (60(67%) v 0% ($p=0.0008$)). Loss of response or discontinuation of therapy at 12 months post-switch was significantly lower in those with therapeutic drug levels and no significant drug antibodies compared with patients low/undetectable drug levels and significant antibodies (18(20%) v 7(100%) ($p<0.0001$) and 6(7%) v 6 (86%) ($p<0.0001$) respectively).

Conclusion: There was no significant difference in response and remission rates, primary and secondary loss of response, or adverse events between originator IFX and CT-P13 during the first 12 months after switching. The presence of low/undetectable drug levels and significant antibodies pre-switch was associated with loss of response and discontinuation of treatment. Switching to CT-P13 in 191 patients in our unit lead to >£1million in savings.

Introduction: Low prevalence of *Helicobacter pylori* (HP) infection has been reported in patients with inflammatory bowel disease (IBD), however, it is unclear whether the eradication therapy for HP can exacerbate disease activity of IBD. We then aimed to clarify the safety and efficacy of HP eradication in patients with IBD.

Aims & Methods: This was a multicenter, retrospective cohort study in 26 institutions. Patients who eradicated HP by proton pump inhibitor and amoxicillin-based triple therapy after the diagnosis of IBD (ulcerative colitis (UC) or Crohn's disease (CD)) from March 2005 to July 2015 were enrolled. Two IBD patients without HP eradication whose gender, age, disease, location, severity, and observation period were matched with each HP-eradicated patient were enrolled in the same institution. Disease activity of IBD at baseline, 2 and 6 months after observation (eradication) was investigated. Exacerbation of IBD was defined as increase/addition of IBD drug, IBD-associated hospitalization or surgery; and physicians' assessment was also analyzed. Factors associated with exacerbation of IBD were assessed by univariate and multivariate logistic regression analysis.

Results: A total of 429 IBD (378 UC and 51 CD) patients, including 144 patients who eradicated HP (eradication group) and 285 control patients (non-eradication group), were enrolled. IBD exacerbation rates in 2 and 6 months of observation were 8.3% (12/144) and 11.8% (17/144) in eradication group, which showed no significant differences compared with those of 4.9% (14/285) and 7.7% (22/285) in non-eradication group. Physicians' assessment showed similar results in terms of disease exacerbation, but in 2 months of observation no patient was improved in eradication group whereas 3.2% (9/285) of patients was improved in non-eradication group ($P=0.019$). Multivariate analysis revealed that the independent factor of IBD exacerbation after HP eradication was active disease at baseline (OR 5.3 (95%CI: 1.5–16.9), $P=0.011$). HP was eradicated in 82.9% (102/123) of patients using clarithromycin as first-line treatment and 90.4% (19/21) using metronidazole as second-line, both of which were comparable with previous reports in non-IBD patients.

Conclusion: HP eradication therapy does not exacerbate disease activity of IBD without affecting eradication rate, but may not improve disease activity, suggesting that careful observation is necessary after eradication, especially for patients with active disease.

P1034 EFFECTIVENESS OF IMMUNOSUPPRESSORS IN CROHN'S DISEASE

L. Kecili¹, N. Kaddache¹, L. Si Salah¹, A. Rebiha¹, S. Khouitar¹, K. Soualah¹, H. Bellimi¹, F. Ihaddadene¹, R. Benbaya¹, K. Bouchaoui², A. Tata², B. Bahaz¹, T. Boucekkine¹, S. Berkane¹

¹Gastroenterology, CHU Mustapha, algiers/Algeria

²EPH Blida, Blida/Algeria

Contact E-mail Address: keli_002000@yahoo.fr

Introduction: The use of immunosuppressors, including Azathioprine (AZT) in inflammatory bowel disease (IBD) is considered reference treatment. They are indicated especially in the case of corticoid dependence, corticoid resistance and in postoperative recurrence. Their efficacy is primarily judged on clinical evaluation and relapses. Few data are available on long-term healing during Crohn's disease (CD). The aim of this study is to evaluate the long-term clinical effectiveness of AZT in luminal Crohn's disease and in prevention of postoperative recurrence with endoscopic evaluation.

Aims & Methods: In this retrospective study, 133 consecutive patients followed for intestinal MC with or without anoperineal involvement were included between 1/1/2016 and 31/03/2016. All patients with Rutgeerts score greater than or equal to 2 received AZT. All patients were under AZT for at least 12 months, maintaining remission for luminal involvement or preventing

postoperative recurrence. All our patients have received clinical (HBI), biological (CRP) and endoscopic evaluation (and MR enterography in some cases). They were checked at different times (during the first 2 years = G1, between 2 and 5 years = G2 and beyond 5 years = G3). Endoscopic remission was defined by the absence of ulceration. Statistical analysis used the Student Fisher and U tests of Mann Whitney.

Results: AZT was prescribed in 46.6% (62/133) cases of luminal involvement and 53.4% of cases to prevent post-operative recurrence. In the luminal disease group, the sex ratio M/F was 1, the age at diagnosis was 27 years \pm 9; A delay in diagnosis was estimated at 1.5 years \pm 2.5 (0–13 years). Smoking was found in 26% of cases (16/61). It was ileocolonic or colonic in 16.4% and 49.2% of cases, phenotype B1 or B2 in 32.8% and 44.6% respectively. 47.5% had more than 2 corticosteroid treatments (CTC), the average time to start AZT was 4 \pm 6 years. The mean duration of treatment was 3.5 \pm 5.2 years. The persistence of endoscopic lesions was observed in 46%, 20% and 25% of cases in G1, G2 and G3 respectively. Loss of response was observed in patient with more than 2 cures of CTC (48% versus 25%, $p=0.042$), and the B2B3 phenotype of the disease [47.2% versus 26% (B1), $p=0.037$] There was no correlation between HBI and endoscopic healing. For postoperative recurrence, sex ratio 2.3 F/1 M, age at diagnosis was 32 years \pm 11 (17–70); The duration of the disease before surgery was 34 months \pm 44 (0–156), the time between surgery and AZT was estimated at 3 years \pm 6 (0–20). 26% of patients were smokers. 63/72 (87.5%) underwent surgery for stenosis and 5.5% after severe flare. 61% had intestinal resection and 20.8% a right hemi colectomy. 6/72 (8.3%) had more than 2 resections. 60/72 had a colonoscopy before and after AZT. The persistence of i2-i4 lesions was observed in 44%, 21% and 19% in G1, G2 and G3 respectively.

Conclusion: In our work, the existence of endoscopic lesions and the absence of symptoms is not uncommon. The prediction after one year of clinical relapse in case of endoscopic lesions is uncertain. The aim of this study, which is still ongoing, is to determine the rate and predictive factors of failure, as well as the modalities of endoscopic control especially concerning timing.

P1035 EVALUATION OF PHARMACOKINETIC PROFILES OF SB2 AS A BIOSIMILAR OF REFERENCE INFLIXIMAB

D. Shin, J.W. Kang, S. Park, Y. Lee, S. Lee

Samsung Bioepis Co., Ltd., Incheon/Korea, Republic of

Contact E-mail Address: sr0427.lee@samsung.com

Introduction: Based on the totality of evidence with similar analytical, pharmacokinetic (PK) and clinical results, SB2 was approved by European Medicines Agency and U.S. Food and Drug Administration as a biosimilar of the reference infliximab (INF) for all indications for which INF has been approved. Here we report the PK profiles of SB2 compared to that of INF in two animal models, healthy subjects and patients with rheumatoid arthritis (RA).

Aims & Methods: The pre-clinical PK profiles were evaluated in single and repeated dose studies (1, 3, and 10 mg/kg of SB2, European Union sourced INF [EU-INF] or United States sourced INF [US-INF]) in two animal models (Sprague Dawley [SD] rat and transgenic Tg197 mouse). The clinical Phase I pivotal study for PK was conducted in healthy subjects¹. The subjects received a single 5 mg/kg intravenous infusion of study drugs (SB2, EU-INF or US-INF) and were observed for 10 weeks. PK equivalence was to be concluded if the 90% confidence interval (CI) for the ratio geometric least squares means (LSMeans) of the primary PK endpoints (area under the concentration-time curve [AUC] from time zero to infinity [AUC_{inf}], AUC from time zero to the last quantifiable concentration [AUC_{last}] and maximum concentration [C_{max}]) were within the standard equivalence margin of 0.8 to 1.25. The steady state PK profile was assessed in a Phase III study in RA patients². In this study, the patients received 3 mg/kg of SB2 or EU-INF at weeks 0, 2, 6 and then every 8 weeks up to 46 weeks. PK analyses were performed up to week 30. Infliximab serum concentration was measured through two different enzyme-linked immunosorbent assays for pre-clinical and clinical studies.

Results: In pre-clinical studies, available PK profiles from animal studies showed no significant differences in C_{max} and AUC_{last} between SB2, EU-INF and US-INF. In healthy subjects, the 90% CIs for the primary PK parameters were within the pre-defined equivalence margin of 0.8 to 1.25 between SB2 and reference products (SB2 vs. EU-INF and SB2 vs. US-INF). In RA patients, the mean trough level was comparable between SB2 (ranging from 1.915 to 17.965 μ g/mL) and EU-INF (ranging from 2.224 to 16.954 μ g/mL) from week 2 to week 30. The PK profiles were also comparable between SB2 and INF when analysed by the presence of ADA in both Phase I and Phase III clinical studies.

Conclusion: Similar PK profiles of SB2 and reference products were confirmed in pre-clinical and clinical studies. Altogether, the previously demonstrated analytical similarity and the data presented here indicate that similar PK are expected in all indications approved for SB2.

Introduction: According to infliximab (IFX) license in inflammatory bowel diseases (IBD), infusion doses are based on patient weight. In daily practice, treatment is prepared by pharmacist after clinical patient assessment, leading to an increased duration of hospital stay and consequently costs. A pharmacokinetic study (1) has shown that a weight-based dose (WBD) strategy does not reduce interindividual variability of IFX trough levels when compared to fixed doses. According to these findings, our hospital implemented dose banding (DB) of IFX infusions, defined by doses rounded up or down according to one of eight pre-determined standard doses with a maximum theoretical deviation of $\pm 5\%$, that allowed to prepare infusions at the pharmacy before patient admission.

Aims & Methods: The aim of the study was to compare hospitalisation length of stay in patients receiving IFX DB as compared to those treated with IFX WBD. From February to March 2017, we conducted a prospective, case-control study in our unit, including all IBD patients admitted for an IFX infusion. Patients who should receive an IFX dose between 250 and 800 mg were included in the DB group (treatment pre-prepared at the pharmacy, sent to the hospital unit before patient admission and administered just after the clinical validation). Patients who should receive an IFX dose below 250 mg or above 800 mg were included in the WBD group (treatment prepared after clinical validation including weight, and then sent to the hospital unit). Patients were analysed only when precise length of stay could be obtained and measured in minutes. Primary objective was to compare the length of stay at hospital in both groups. Secondary objective was to compare the proportion of IFX doses cancelled, reattributed and wasted infusions and the saved or wasted price associated (reimbursement price of one 100 mg IFX vial: 382.28 €).

Results: Among the 373 IBD patients treated by IFX during the study period, 116 (31%) patients (51M/65F; median age: 41 years) were included in the study (75 in the DB group and 41 in the WBD group) corresponding to 128 infusions (84 in DB and 44 in WBD groups). Mean length of hospitalisation stay were 238 ± 21 min in the DB group and 308 ± 32 min in the WBD group, respectively ($p < 0.001$). DB was associated with a mean reduction of length of stay of 23%, corresponding to 70 minutes per patient. DB reduced significantly the mean duration of stay by decreasing the waiting time between clinical assessment and start of the infusion: 16 min vs. 84 min with WBD ($p < 0.001$). During the study, none of the 44 (0%) infusion in the WBD group was cancelled while 3/84 (3.5%) were cancelled in the DB group ($p = 0.55$). Two out these three infusions could be reattributed to other patients, saving 2801 €.

Conclusion: When used routinely in IBD, IFX DB is associated with a shortened length of stay as compared to WBD, with a mean reduction of 70 minutes per patient. As IFX DB seems having similar efficacy to weight-based doses, it may improve functioning of daily hospitalisation units.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Rapidity of response to treatment in CD is now considered a field of major interest, due to the importance of achieving the highest benefit in the shortest possible time. There are no studies specifically designed to evaluate the rapidity of response to ADA neither other anti-TNF therapies. The aim of this trial was to evaluate the rapidity of onset of clinical response to ADA therapy.

Aims & Methods: Adult anti-TNF naïve patients with active luminal (Harvey-Bradshaw Index (HBI) ≥ 8) moderate-to-severe CD (excluding penetrating and stricturing disease), with no response to a full and adequate course of therapy with corticosteroids and/or immunosuppressants, were enrolled in this interventional, prospective, open label, single arm and multicenter clinical trial. Patients received standardized ADA treatment (160 mg – 80 mg – 40 mg eow). The HBI was evaluated to determine the response at day 4 and week 1; and clinical remission at weeks 2, 4 and 12. Response was defined as a decrease of, at least, 3 points in the HBI global score and remission was defined as HBI global score < 5 . CRP (C Reactive Protein) and fecal calprotectin (FC) were analyzed at baseline, day 4, week 1, 2, 4, 12. The modified intention to treat (mITT) population was the primary population for efficacy analysis and consisted of those patients enrolled in the study who had received at least one dose of ADA. Treatment-emergent serious adverse events (AEs) were recorded to assess safety throughout the study until 70 days after last treatment dose. All patients who received at least one dose of ADA were included in the safety population. Statistical analyses were performed by the t-test or the Wilcoxon signed rank test, as applicable. Time to clinical response was analyzed using a Kaplan-Meier survival analysis model.

Results: 86 anti-TNF naïve patients were analyzed. A response at day 4 and week 1, was experienced by 60.5% and 74.4% of patients, respectively. Remission was achieved by 53.5% of patients at week 2, 61.6% at week 4 and 54.7% at week 12. The median time to obtain response was 4.0 days (95% confidence interval (CI): 1.0, 4.0) and the median time to remission was 7.0 days (95%CI: 4.0, 14.0).

	Median CRP levels (mg/L)	Median FC levels (µg/g)	p-value vs baseline for CRP and FC
Baseline	4.87	795	$p < 0.0001$
Day 4	1.70	430	$p < 0.0001$
Week 1	1.50	438	$p < 0.0001$
Week 2	1.56	419	$p < 0.0001$
Week 4	1.98	296	$p < 0.0001$
Week 12	1.68	300	$p < 0.0001$

During the study, 42.5% of the patients suffered from any adverse event (AE). Only 3 patients (3.5%) showed a serious AE.

Conclusion: ADA produces rapid clinical remission and response since day 4 in patients with moderate-to-severe CD unresponsive to therapy with corticosteroids and/or immunosuppressants.

P1038 HIGH-DOSE INTRAVENOUS IRON ISOMALTOSIDE IN PATIENTS WITH GASTROINTESTINAL DISEASES

R. Derman¹, J.F. Dahlerup², W. Reinisch³

¹Thomas Jefferson University, Philadelphia/United States of America/PA

²Department Of Hepatology And Gastroenterology, Aarhus University Hospital, Aarhus/Denmark

³Department Of Internal Medicine III, Medical University of Vienna, Vienna/Austria

Contact E-mail Address: walter.reinisch@meduniwien.ac.at

Introduction: Patients with gastrointestinal diseases such as inflammatory bowel disease (IBD) often suffer from iron deficiency anaemia (IDA) and have a high annual iron need. Intravenous administration of high-dose iron is the most efficient approach to replenish iron stores. The present analysis evaluates safety and efficacy of high doses of iron isomaltoside in patients with gastrointestinal diseases.

Aims & Methods: This is a pooled analysis of 3 trials of iron isomaltoside performed in patients with gastrointestinal diseases and IDA [1–3]. Outcome measures were adverse drug reactions (ADRs) and haemoglobin (Hb) measurements. **Results:** 357 patients (108 men, 249 women) were included in the analysis of which 255 were diagnosed with IBD and 102 with other gastrointestinal diseases, incl. bariatric surgery, gastrointestinal bleeding etc. A cumulative dose of ≤ 1000 mg and > 1000 mg iron isomaltoside was administered in 199 and 158 patients, respectively. ADRs were observed in 13.6% (36 events in 27 patients) and 12.0% (30 events in 19 patients) of the patients dosed with ≤ 1000 mg and > 1000 mg iron isomaltoside, respectively ($p=0.8$). Similar frequencies was observed in the IBD subgroup (14.3% versus 12.1%, $p=0.8$). 0.5% of the patients experienced a serious ADR (2 events in 2 patients; grand mal convulsion and syncope). ADRs with a patient frequency $> 1\%$ are shown in the table below:

ADR	Patients (%)	
	≤ 1000 mg iron isomaltoside N = 199	> 1000 mg iron isomaltoside N = 158
Flushing	3.0	0
Constipation	0	1.9
Increased hepatic enzyme	1.5	0.6
Diarrhoea	0.5	1.3
Dyspepsia	0	1.3
Headache	1.0	1.3
Hypersensitivity	1.0	1.3
Abdominal pain	1.0	0.6
Hypertension	1.0	0
Hypotension	1.0	0.6
Nausea	1.0	0
Urticaria	1.0	0.6

No ADRs of hypophosphatemia were reported. In patients dosed with ≤ 1000 mg iron isomaltoside, Hb increased with a mean of 1.72 (95% confidence interval (CI): 0.12) g/dL from baseline to week 3, 2.00 (0.12) g/dL to week 4, and 2.32 (0.13) g/dL to week 8. In patients dosed with > 1000 mg iron isomaltoside, Hb increased with a mean of 2.04 (0.10) g/dL from baseline to week 3, 2.51 (0.09) g/dL to week 4, and 3.01 (0.12) g/dL to week 8. The observed increase in Hb was statistically significantly higher in patients dosed with > 1000 mg iron isomaltoside ($p < 0.04$). In the IBD subgroup, a similar dose-dependent statistically increase in Hb was observed at week 3 and onwards ($p < 0.02$).

Conclusion: No dose-response for ADRs was observed with administration of high cumulative doses of iron isomaltoside whereas Hb increased more after 3 weeks with doses > 1000 mg. Thus, high doses (> 1000 mg) of iron isomaltoside can be administered without additional safety concerns including concerns of hypophosphatemia and with efficacious increases in Hb in patients with gastrointestinal diseases.

Disclosure of Interest: R. Derman: Richard Derman has been a consultant for Pharmacosmos A/S, and the investigator/institution received a fee per patient J.F. Dahlerup: The investigator/institution received a fee per patient.

W. Reinisch: The investigator/institution received a fee per patient.

Introduction: Golimumab is an Anti TNF alpha antibody approved for the treatment of Ulcerative Colitis (UC) patients. Its efficacy and safety were studied in randomized, double blind trials^{1, 2}, but its effectiveness and safety in daily clinical practice are still little known³.

Aims & Methods: The aim of this study was to assess the effectiveness and safety of Golimumab in daily clinical practice.

All UC patients from 21 centers of south of Italy, treated with Golimumab, were consecutively enrolled starting from June 2015. Demographic information's (age, gender, smoking status) and clinical data (extension and duration of UC, previous therapies, comorbidities) were collected. Clinical, laboratory and endoscopic data during the treatment with Golimumab were collected every three months.

Results: A total of 190 patients (120 males) were enrolled. The mean age at diagnosis and mean duration of disease were respectively 38.8 ± 14.6 years, and 9.1 ± 7.0 years. Only 21 patients were active smokers (11%). About the extension, 111 were pancolitis (58%), 72 had a distal colitis (38%) and 7 a proctitis (4%). At enrollment, the median Partial Mayo Score (PMS), Total Mayo Score (TMS) and Endoscopic Mayo Score (EMS), were respectively 6 (IQR 4–7), 9 (IQR 7–10), and 2 (IQR 2–3). The median values of ESR, C Reactive Protein and faecal calprotectin were respectively 25 mm/1st hour (IQR 15–38), 3 mg/dl (IQR 1–9), and 250 mg/kg (IQR 174–500). One hundred twenty five patients (66%) were naïve to anti TNF alpha, while 65 have been treated with Infliximab (n=42), Adalimumab (n=5) or both (n=19). The indications for Golimumab were: steroid-resistance in 37 patients (20%), steroid-dependence in 130 (68%), extra-intestinal manifestations in 6 (3%), and Anti TNF alpha failure in 17 (9%). Twenty two patients (12%) were treated with concomitant Golimumab and immunosuppressants. A total of 142 patients have been completed at least 3 months of therapy. Of these patients, a significant reduction of mean PMS (n=142; $p < 0.001$), TMS (n=45; $p < 0.001$), EMS (n=45; $p < 0.001$), ESR (n=125; $p < 0.001$), and CRP (n=134; $p < 0.001$) were observed after 3 months. The rate of responders (reduction of > 2 points of PMS) was 60%, while the rate of clinical remission (PMS < 2) was 39%, and the rate of mucosal healing (EMS ≤ 1) was 53%. Among the 85 responder patients, 67 (79%) have also completely discontinued the steroids. At univariate analysis for predictive factors of response (gender, duration of disease, smoking status, previous Anti

TNF, combo therapy, PMS, EMS, TMS, ESR, CRP, calprotectin, and indication to therapy), the naïve status to anti TNF alpha ($p=0.0001$), higher values of CRP ($p=0.0001$), PMS ($p=0.0001$), TMS ($p=0.0001$) and EMS ($p=0.006$) were associated with better response. About the indication, steroid-resistance was associated to the best response ($p=0.002$), while Anti TNF resistance with the worse response ($p=0.002$). At multivariate analysis only TMS ($p<0.001$, OR 1.5 - CI95% 1.2–1.8) and Naïve to Anti TNF alpha ($p=0.015$, OR 3.0 - CI 1.2–7.5) were confirmed associated to better response. To date, only 33 patients have discontinued Golimumab (17%). A total of 15 adverse events (3 serious) were observed. Ten non-responder patients underwent to colectomy (7 of them were refractory to other anti TNF alpha).

Conclusion: Golimumab was effective and safe in induction of response in UC patients in daily clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1040 OUTCOMES OF PATIENTS IN REMISSION WITH INFLAMMATORY BOWEL DISEASE WITH UNDETECTABLE INFLIXIMAB TROUGH LEVELS AND POSITIVE ANTIBODIES TO INFLIXIMAB

G.S.Z. Tun¹, R. W. Downey¹, K. Robinson¹, A. Wright¹, L. Marshall¹, M. F. Hale¹, A. J. Lobo¹

Contact E-mail Address: gloria.tun@sth.nhs.uk

Introduction: The formation of antibodies to infliximab (ATI) is associated with increased drug clearance. Patients with undetectable infliximab (IFX) levels and positive ATI may indicate a group who may no longer be benefitting from the drug. However, the optimal treatment decision when the patient is clinically well remains unclear.

Aims & Methods: The aim was to assess the course of disease of patients in remission, with undetectable IFX levels and positive antibodies. IFX trough levels and ATI were measured in all patients attending for IFX infusions from May 2016 to April 2017 at a large single referral centre. Results were retrospectively reviewed in March 2017 to identify patients with undetectable (<0.8 mg/L) IFX trough levels and positive ATI (>10 mg/L). A local guideline suggested that in well patients of this cohort, patients should be switched to an alternative biologic if duration of IFX treatment was <12 months, or if the duration of therapy was ≥ 12 months to consider withdrawal of IFX or to assess disease activity - with withdrawal of IFX in inactive disease or a switch to an alternative biologic for active disease. Trough levels for IFX and ATI were measured using drug tolerant enzyme-linked immunosorbent assays (Biohit, UK). Relapse was defined as worsening of symptoms attributable to the inflammatory bowel disease, requiring an alteration in treatment. Kaplan-Meier with Tarone-Ware test was used to compare survival curves for relapse and Cox regression model used to analyse the impact of the different treatment decision on the rate of relapse.

Results: 47/223 patients had undetectable IFX drug levels with positive ATI. Follow-up data was available in 45 patients. 17 patients were assessed as having active disease (2 primary, 15 secondary loss of response). Of the 28 in remission (at time of most recent TDM, median Harvey Bradshaw Index (HBI) 3.5; median Simple Clinical Colitis Activity Index (SCCAI) 2.5). 79% had a HBI/SSCAI <5 but all were deemed to be in remission at time of review. 6/28 patients had received prior anti-tumour necrosis factor- α antagonists and 14/28 were receiving concomitant immunosuppression (thiopurines 12; methotrexate 2). Of these patients in remission, 7 continued on IFX (1 dose escalated), 13 had IFX withdrawn and 8 were switched to an alternative biologic (adalimumab 4; vedolizumab 3; ustekinumab 1). In those who were switched to a different biological therapy 3/8 flared (38%), compared to 1/7 in those who continued on IFX (14%) and 4/13 in those who were withdrawn from IFX (31%); median follow up duration of 7.5 months (range 2–10 months). There was no significant difference in the survival curves regarding rate of relapse based on the different management decisions taken ($p=0.81$; Figure 1). Patients withdrawn from IFX were not at an increased risk of relapse compared to those who continued on treatment (hazard ratio 1.62, $p=0.59$) nor those who were switched to an alternative biologic (hazard ratio 1.42, $p=0.65$). Figure 1. Kaplan Meier of the rate of relapse during follow-up of patients in clinical response with undetectable IFX levels with positive ATI who were continued on IFX ($n=7$), switched to an alternative biologic ($n=8$) and withdrawn from IFX $n=13$ ($p=0.81$).

Conclusion: Initial early experience in our centre suggests that withdrawal of IFX in selected patients with undetectable IFX levels and positive ATI is not associated with an increased risk of flare. Although not statistically significant, the rate of relapses in those who continued on infliximab was lower compared to

those who were switched or withdrawn from therapy, however further follow-up and greater numbers are required in this group.

P1041 PHARMACOKINETIC SIMILARITY OF ABP 710 TO INFLIXIMAB: RESULTS FROM A RANDOMISED, SINGLE-BLIND, SINGLE-DOSE, PARALLEL-GROUP STUDY IN HEALTHY SUBJECTS

V. Chow, N. Zhang, P. Kaur, A. Kaliyaperumal, E. Krishnan
Amgen, Thousand Oaks/United States of America/CA

Contact E-mail Address: vchow@amgen.com

Introduction: ABP 710 is being developed as a biosimilar to infliximab, an anti-tumour necrosis factor monoclonal antibody. Analytical and functional comparisons between ABP 710 and infliximab have been completed. This report describes the results of a Phase 1 pharmacokinetic (PK) equivalence study comparing ABP 710 with infliximab

Aims & Methods: This was a single-blind, single-dose, 3-arm, parallel-group study in healthy adults, 18 to 45 years of age and with a body mass index of 18 to 30 kg/m². Subjects were randomised to receive a 5 mg/kg intravenous (IV) infusion of ABP 710 or infliximab sourced from the EU and the US after pre-treatment with an antihistamine and acetaminophen 30 minutes prior to start of infusion. The primary objective was demonstration of PK similarity of ABP 710 with infliximab EU and with infliximab US based on area under the serum concentration-time curve from time 0 to infinity (AUC_{inf}) as the primary endpoint. The criteria to achieve PK equivalence were for geometric mean (GM) ratio and its 90% confidence interval (CI) to be within the range of 0.80 to 1.25. Secondary endpoints included maximum observed serum concentration (C_{max}), safety, and immunogenicity.

Results: A total of 148 subjects received study treatment (ABP 710: $n=49$; infliximab EU: $n=49$; infliximab US: $n=50$). After a single dose, the adjusted least square (LS) GM of AUC_{inf} and C_{max} were as follows: ABP 710, 33559 μ gh/mL and 123 μ g/mL; infliximab EU, 33706 μ gh/mL and 121 μ g/mL; infliximab US, 37523 μ gh/mL and 127 μ g/mL. Ratios of adjusted LS GM (90% CIs) for AUC_{inf} and C_{max} between ABP 710 and infliximab EU were 0.996 (0.9042, 1.0963) and 1.021 (0.9624, 1.0827) and that between ABP 710 and infliximab US were 0.894 (0.8122, 0.9848) and 0.972 (0.9167, 1.0301). The ratios of adjusted LS GM (90% CIs) of AUC_{inf} and C_{max} between infliximab US and infliximab EU were 1.113 (1.0115, 1.2252) and 1.05 (0.9906, 1.1138). The 90% CIs of these ratios were fully contained within the 0.80 to 1.25 interval, confirming PK similarity between ABP 710 and infliximab, as well as between infliximab EU and infliximab US. There were no deaths, serious adverse events, or treatment-emergent adverse events (TEAEs) leading to discontinuation from the study; 1 subject in the infliximab EU group developed polyarthritis that resolved with treatment and the subject completed the study. The incidence of TEAEs was similar in the 3 groups (ABP 710: 83.7%; infliximab EU: 83.7%; infliximab US: 86.0%); the majority was mild or moderate. The most frequently reported TEAEs were somnolence, headache, nasopharyngitis, upper respiratory tract infection, nausea, and lethargy. All subjects tested negative for antidrug antibodies (ADAs) prior to dosing. At the end of study (Day 57), 40% subjects on ABP 710, 27% on infliximab EU, and 32% on infliximab US were positive for binding ADAs; 13% on ABP 710, 19% on infliximab EU and 10% on infliximab US were positive for neutralising ADAs. **Conclusion:** Results of this study demonstrate PK similarity between ABP 710 and infliximab sourced from the EU and the US, as well as between infliximab EU and infliximab US following a single 5 mg/kg IV infusion in healthy subjects. The safety and immunogenicity profiles were comparable among treatment groups.

Introduction: Complex perianal fistulas (CPF) are common among Crohn's disease (CD) patients and are associated with substantial morbidity. The burden and management of CPF are poorly studied.

Aims & Methods: To systematically review the literature on epidemiology, global disease burden, and treatment outcomes for CPF in CD patients. PubMed, Embase, and Cochrane were searched for relevant articles published from 2000

forward; congress abstracts were searched from 2011 forward. CPFs were defined as fistulas with intersphincteric, transsphincteric, suprasphincteric, extrasphincteric, or horseshoe tracts.

Results: 535 records were reviewed by 2 independent researchers, and 63 relevant articles and abstracts were selected for inclusion (including 3 epidemiology and 3 burden; the rest were treatment guidelines/patterns or treatment outcome studies). The estimated cumulative incidence of CPF in CD, based mostly on studies conducted in referral centres, ranges from 12%–14% (2 studies). CPF can result in significant morbidity and greatly diminished quality of life; up to 59% of patients (1 study) are at risk of fecal incontinence. Treatment options include a combination of medical and surgical interventions. However, across all options identified, a high proportion of patients experience treatment failure (lack of or inadequate response) and relapse (Table). Only 4 identified studies were conducted specifically in patients refractory to anti-tumor necrosis factor (TNF)- α agents—a population with high unmet needs (one study of perianal fistulas of infliximab, and three studies of surgical interventions). Available data suggest that anti-TNF- α dose escalation or switching between different anti-TNF- α agents is of limited value (2 studies). Table – Rates of treatment failure and relapse or reoccurrence among patients with complex perianal fistulain Crohn's Disease^a

Conclusion: CPFs in CD pose substantial clinical burden. There is a high unmet need for effective treatment options for CPF in CD patients, especially those refractory to anti-TNF- α agents, as evidenced by high treatment failure and relapse rates.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1043 VITAMIN D IS RELATED TO THE EFFECTS OF ANTI-TNF TREATMENT IN CROHN'S DISEASE PATIENTS

M. Bafutto¹, M. B.G. Costa¹, K. T.P.E. Silva¹, J. P.V. Costa¹, C.

C.S.O. Reviglio¹, E.C. Oliveira², J. R. Filho¹

²Surgery, Organización Panamericana de Gastroenterología (OPGE), Goiânia/Brazil

Contact E-mail Address: maurobafutto@yahoo.com.br

Introduction: Vitamin D deficiency is common in patients with Crohn's disease (CD). It is believed that this deficiency is related to the CD activity. Vitamin D supplementation have many effects, including immunomodulation. However, the role of Vitamin D (VD) in severe CD patients using Anti-TNF is still unclear.

Aims & Methods: To evaluate the results of the VD replacement at different doses; check possible immunomodulatory action of vitamin D in CD patients with Anti-TNF. We conducted a double-blind, randomized, prospective study. 42 patients were selected with history of moderate to severe CD in use of anti-TNF, of both sexes, between 18 to 60 years, with dosage of 25-hydroxyvitamin D < 75 nmol/L (30 ng/ml) who signed the informed consent. Were excluded patients with less than 18 or over 70 years, pregnant women, chronic kidney or liver disease, sarcoidosis, tuberculosis, hyper- or hypoparathyroidism, neoplasias, use of anticonvulsants; and patients who received calcium supplements or VD in the last 6 months. 30 patients were randomized. Patients were submitted to a questionnaire of sun exposure, quality of life (IBDQ), clinical examination, VD dosage, C-reactive protein (CRP), fecal calprotectin (FC) and were divided into three groups: 1 Group (G1): 10 patients receiving 2,000 U/VD, VO/week for 8 weeks, 2 Group (G2): 10 patients receiving 10,000 U/VD, VO/week for 8 weeks; 3 Group (G3): 10 patients receiving 50,000 U/VD, V.O/week for 8 weeks. At the end of 8 weeks the patients answered IBDQ and were submitted to VD, FC and CRP dosage. All patients were followed for 52w and checked for disease activity recurrence (CDAI > 150, FC > 300, CT scan), FC, CRP and VD levels.

Results: IBDQ improvement was observed in all groups with statistically significant results in G2 (p = 0.04) and G3 (p = 0.01). Increased VD were observed in all groups (mean \pm SD \times mean \pm SD): G1 - (19.5 \pm 5.1 \times 26 \pm 6.7) p = 0.07; G2 - (19.1 \pm 4.1 \times 26 \pm 5.8) p = 0.04; G3 - 19.5 \pm 6.4 \times 46.4 \pm 12.7) p < 0.0001. CRP dosage were reduced, although not statistically significant, at G2 and G3 (5.8 \pm 4 \times 3.9 \pm 2.8) p = 0.18 (5.2 \pm 7.3 \times 2.4 \pm 3.6) p = 0.2; and increased in G1

(8.1 \pm 10, 3 \times 13, 4 \pm 19.9) p = 0.3. There was a significant decrease in FC in G3 (1014 \pm 850 \times 483 \pm 564) p = 0.04, no significant decrease in G2 (767 \pm 751 \pm 823 \times 535) p = 0.2, and increase in G1 (1101 \pm 744 \times 1357 \pm 819) p = 0.4. 52 w follow period showed that recurrent disease activity were predominant in patients with VD < 30 (p = 0.0004) and statically significant results were observed in disease activity recurrence rate (p = 0.006), FC (p = 0.02) and CRP (p = 0.01) when compared patients with VD > 30 and VD < 30.

Conclusion: 50,000 U/week was the best dosage for VD replacement and is related to immunomodulation. Most of patients with CD in Anti-TNF therapy have recurrent disease when VD < 30 and a high remission rate with VD > 30. VD levels are related to the effects of Anti-TNF therapy in CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1045 CLINICAL EFFECTIVENESS OF GOLIMUMAB IN CROHN'S DISEASE – AN OBSERVATIONAL STUDY BASED ON THE SWEDISH NATIONAL QUALITY REGISTRY FOR INFLAMMATORY BOWEL DISEASE

S. Rundquist¹, C. Eriksson¹, L. Nilsson², L. Angelison³, S. Jäghult⁴, J. Björk⁵, O. Grip⁶, H. Hjortswang⁷, H. Strid⁸, P. Karlén², S. Montgomery⁹, J. Halfvarson¹

Introduction: Golimumab is approved for the treatment of moderate to severe ulcerative colitis, but not Crohn's disease (CD). Therefore, its potential efficacy in CD remains largely unknown. Off-label use of drugs is not prohibited in Sweden, and golimumab may have been used for CD treatment.

Results: The study cohort consisted of 95 patients with a median age of 37 (IQR 27–48) years, of whom 40% were men. The majority of the patients (90.5%) had previously experienced treatment failure for at least one anti-TNF agent. At the start of golimumab, 41% were on a concomitant immunomodulator and 16% on corticosteroids. After a median follow-up time of 21 (IQR 10–36) months, 60 (63%) patients had stopped treatment with golimumab. Reasons for discontinuation were inadequate response; n = 45 (75%), intolerance; n = 11 (18%) and other reasons; n = 4 (7%). Estimated drug continuation rates were 73% at 12 weeks and 42% at 52 weeks. Concomitant treatment with corticosteroids at baseline seemed to be associated with a higher risk of discontinuation of golimumab (unadjusted HR: 1.97; 95% CI: 1.04–3.73; p = 0.04), although the association did not remain significant after adjusting for potential confounding factors (adjusted HR: 1.76; 95% CI: 0.84–3.67; p = 0.13).

Aims & Methods: We aimed to describe the CD population that is treated with golimumab in Sweden and to assess the long-term effectiveness, defined as drug continuation rate, as well as identify predictors of drug discontinuation. Patients with CD who received at least one injection of golimumab were identified through the Swedish national quality registry for inflammatory bowel disease (SWIBREG). Duration of golimumab-treatment was illustrated by Kaplan-Meier curves. Univariate and multivariate Cox proportional hazard regression models were used to identify predictors of golimumab discontinuation. The variables sex, age, duration of disease, location, perianal disease, smoking status, previous surgery, concomitant treatment with corticosteroids or immunomodulators at baseline, prior anti-TNF therapy and CRP at baseline were included in the models.

Abstract: P1042

Treatment	Treatment failure ^b			Relapse/recurrence		
	Rates, %	Number of studies	Number of patients per study (range)	Rates, %	Number of studies	Number of patients per study (range)
Anti-TNF- α agents (agent unspecified)	46–60	3	39–66	27	1	66
Infliximab	12–58	4	6–52	41	1	52
Adalimumab	22–73	4	9–38	0	1	9
Surgical interventions	0–69	10	5–40	13–20	3	5–10
Combined medical and surgical management	0–80	15	9–212	0–41	7	9–71
Standard of care ^c	30–68	4	15–250	23–66	3	79–250

^a44 studies reported treatment outcomes for CPF in CD patients. Most studies identified were small and/or non-comparative, and study methodologies, populations, endpoint definitions, and duration of follow-up varied. For studies with mixed populations, only results for patients with CD and CPF were considered. ^bDefined as lack of or inadequate response to therapy (i.e. lack of complete response). ^cDefined as standard of care used at each centre excluding anti-TNFs and surgery in 2 studies and as standard medical care at each centre including anti-TNF and surgery in 2 studies.

Conclusion: Golimumab-treated patients with CD are a treatment-refractory group. Despite this, more than 40% of the patients seemed to have sustained clinical benefit after one year, since they were receiving continued golimumab treatment. Co-concomitant corticosteroid treatment at start of golimumab appears to be associated with worse outcome.

Introduction: Clinical response and patient's quality of life improve as a result of the direct benefit of Crohn's disease (CD) effective treatment. Rapidity of response to treatment in CD is a field of major interest, due to the importance of achieving the highest benefit in the shortest possible time. There are no studies specifically designed for early evaluation of the quality of life in patients with active CD receiving adalimumab therapy. The aim of this study was to evaluate the rapidity of improvement of quality of life in response to adalimumab therapy in adult anti-TNF naïve patients with active luminal (Harvey-Bradshaw Index ≥ 8) moderate-to-severe CD, and with no response to a full and adequate course of therapy with corticosteroids and/or immunosuppressants.

Aims & Methods: To this purpose we designed an interventional, prospective, open label, single arm and multicenter clinical trial. Quality of life was evaluated by using the validated questionnaires EuroQol-5D (EQ-5D) and the 36 items version of the Inflammatory Bowel Disease Questionnaire (IBDQ-36). Questionnaires were administered at baseline, day 4 and weeks 1, 2, 4 and 12 with standardized adalimumab treatment (160 mg – 80 mg – 40 mg eow). The modified intention to treat (mITT) population was the primary population for analysis and consisted of those patients enrolled in the study who had received at least one dose of adalimumab. Statistical analyses were performed by the t-test or the Wilcoxon signed rank test, as applicable.

Results: Eighty-six patients were included. At baseline, the median EQ-5D index score was 0.68. EQ-5D scores improved significantly versus baseline, at day 4 and weeks 1, 2, 4 and 12, with median changes of 0.05 ($p = 0.0005$), 0.05 ($p < 0.0001$), 0.11 ($p < 0.0001$), 0.10 ($p < 0.0001$) and 0.11 ($p < 0.0001$), respectively. Similarly, EQ-5D VAS median scores also improved significantly, compared to baseline (median score at baseline: 55.00), at day 4 and thereafter, with median changes of 5.00, 5.50, 9.50, 10.00 and 12.00, respectively ($p \leq 0.0001$ at all time-points). The comparison, versus baseline, of the IBDQ-36 overall score (median score at baseline: 142.50) at day 4 and weeks 1, 2, 4 and 12, also yielded statistically significant differences, with median improvements of 14.0, 18.0, 29.0, 42.0 and 35.5 respectively ($p < 0.0001$ at all time-points). Restoration of normal health (IBDQ-36 score > 209) was obtained in 9% of patients at day 4 and increased to 35% at week 12.

Conclusion: Adalimumab produces rapid improvement of quality of life since day 4 in patients with moderate-to-severe Crohn's disease.

Introduction: Anti-tumor necrosis factor- α (anti-TNF α) agents are commonly used treatment options for moderate to severe Crohn's Disease (CD) and Ulcerative Colitis (UC). However, despite their clinical effectiveness, few data regarding the role on quality of life (QoL) are available.

Aims & Methods: To prospectively evaluate disease activity and QoL in a single-centre cohort of CD and UC patients, after introduction of anti-TNF α agents (infliximab or adalimumab). All consecutive adult CD and UC patients who started Infliximab (IFX) or Adalimumab (ADA) from 2014 to 2015 at Padua University Hospital were enrolled. Disease severity was evaluated through laboratory tests (Haemoglobin, C-reactive protein (CRP) and Fecal calprotectin) and commonly used scores (Harvey Bradshaw Index (HBI) for CD and Modified Truelove and Witts Severity Index (MTWSI) for UC) for each patient, at anti-TNF α introduction and 12 months thereafter; QoL was assessed through the Short-Inflammatory Bowel Disease Questionnaire (S-IBDQ).

Results: A total of 115 patients were consecutively evaluated, 33 patients were excluded due to non-compliance (11.3%) or drop-out for adverse events or primary non response (17.3%) within 12 months. Eighty-two (71.5%) were included in the statistical analysis (M/F 53/29, median age 43 years, CD/UC 42/40). Forty and 42 patients started IFX and ADA, respectively. QoL was significantly higher in CD than UC at baseline (median S-IBDQ 49 vs 32, $p = 0.004$). In CD patients, anti-TNF α determined significant reduction of HBI (median 3 vs 1; $p < 0.01$), CRP (median 5 vs 2.9 mg/L; $p = 0.004$), fecal calprotectin (median 429 vs 119 $\mu\text{g/g}$; $p < 0.001$) but not haemoglobin (median 13.6 vs 13.2 g/dL, $p = 0.25$). QoL significantly improved (median S-IBDQ 49 vs 59; $p < 0.001$), both in IFX and ADA groups (IFX: $p < 0.001$; ADA: $p = 0.02$). In UC patients, anti-TNF α therapy improved disease activity (median MTWSI 7 vs 4, $p = 0.03$), haemoglobin levels (median 11.6 vs 13.2 g/dL; $p = 0.006$), fecal calprotectin (median 1600 vs 108 $\mu\text{g/g}$; $p = 0.004$), but not CRP (median 5 vs 2.9 mg/L, $p = 0.08$). QoL improved at 12 months (median S-IBDQ: 32 vs 56, $p = 0.001$) both in patients treated with IFX ($p = 0.003$) and ADA ($p = 0.005$). No adverse events were reported during the study period.

Conclusion: Anti-TNF α therapy is safe and improves disease activity and quality of life of UC and CD patients.

Introduction: Anti-TNF agents are widely used in the treatment of inflammatory bowel diseases (IBD). Despite the fact that the intestine is the main therapeutic

target, little or no information is available regarding the ratios of free and TNF-bound infliximab in the intestinal tissue.

Aims & Methods: We aimed to assess the presence of free versus TNF-bound infliximab in the intestinal tissue of IBD patients and its possible association with clinical outcomes. Protein was extracted from frozen intestinal tissues of infliximab-treated patients. Free infliximab and TNF-bound infliximab were detected using ELISA and normalized to tissue protein concentration. Concurrent serum drug levels (SDL), anti-drug antibodies (ADA), serum TNF-bound infliximab levels, patient's pharmacotherapy, clinical response based on physician global assessment, endoscopic appearance (severity determined according to mayo scoring in ulcerative colitis and endoscopist's assessment of ulceration severity, extent of disease and affected area in Crohn's disease) and pathological results (severity determined by observing pathologist graded as normal, mild, moderate and severe disease) at the time of colonoscopy were determined. Correlation were performed using Spearman's rank correlation test.

Results: Twenty four biopsies from 13 patients (11 Crohn's disease and 2 ulcerative colitis patients) were tested. Non-inflamed tissue infliximab levels, but not inflamed tissue levels, correlated with SDL ($R = 0.8499$, $p = 0.0037$, $FDR = 0.0185$) and were negatively correlated with the endoscopic appearance ($R = -0.7214$, $p = 0.0185$) and pathological severity ($R = -0.7959$, $p = 0.0059$). TNF-bound infliximab was measured in both inflamed and non-inflamed specimens and did not correlate with drug levels in the serum or tissue. ADA was only detected in a single patient, precluding statistical analysis. Notably, no TNF-bound infliximab was measured in the serum.

Conclusion: These findings show that pharmacokinetic-pharmacodynamics interaction, as measured by SDL, better reflects drug levels in healthy mucosa rather than the inflamed one, and suggest a more complex drug/target interaction in inflamed tissue, which cannot be explained by target binding only. Future studies assessing SDL dynamic changes during the process of mucosal healing may allow their use as surrogate markers for this purpose.

Introduction: Restorative proctocolectomy (RPC) is considered the treatment of choice in patients with ulcerative colitis (UC) who have failed medical therapy and in some patients with familial adenomatous polyposis (FAP). After RPC, approximately 40% of UC patients develop acute pouchitis at 5 years, for which the mainstay treatment is empirical antibiotics. 10–15% of these patients subsequently develop chronic antibiotic-dependent pouchitis (CADP), and are maintained on long-term antibiotics to maintain clinical remission. *Clostridium difficile* and tendon rupture are recognised significant complications associated with long-term ciprofloxacin. We aimed to evaluate the effectiveness and safety of long-term antibiotic use in patients with chronic pouchitis.

Aims & Methods: A retrospective analysis of patients started on antibiotic therapy between Jan 2007 - Jan 2009 for CADP was performed. 39 patients (30 males) who underwent RPC for UC ($n = 37$) and FAP ($n = 2$) with a diagnosis of CADP (defined as the need for antibiotics for at least one month and with a Pouch Disease Activity Index (PDAI) of greater than 7) were identified. Antibiotic-associated complications and functional outcomes were evaluated. Patients were followed-up at a tertiary referral centre until the last clinic appointment or the development of pouch failure, defined as the need for an ileostomy.

Results: The median follow-up was 102 months (range 9–125); 27 (69%) patients with CADP remained on antibiotics at last follow-up. The most common antibiotics used were ciprofloxacin (30%), metronidazole (19%) or a combination of both (11%). Median 24 h stool frequency was 10 (range 4–25) at last follow-up. This was unchanged from baseline ($p > 0.05$). Reported complications included: 7 (18%) perianal fistula, 12 (31%) anastomotic strictures requiring dilatation, 6 (15%) perianal sepsis, 5 (13%) incontinence and 11 (28%) antibiotic-related side effects. Of 39 patients, 7 (18%) achieved remission while 8 (21%) developed pouch failure requiring an ileostomy or pouch revision, over a median duration of 6 years (range 3–9). Antibiotic resistance was identified from at least one stool sample in 28/36 (78%) patients, however *Clostridium difficile* toxin was not detected in any stool samples. No patient developed tendon rupture. 36 pouch-related hospital admissions occurred in 11/39 (28%) patients. Reasons for admission included: 23 obstructive symptoms, 1 incontinence, 1 bleeding from pouch, 11 elective examinations under anaesthetic.

Conclusion: The management of chronic pouchitis remains challenging despite long term antibiotic therapy. This is the first study to report the long-term outcomes of long term antibiotics on patients with CADP. 69% of patients remained on antibiotics at last follow up. Although the use of antibiotics in chronic pouchitis is justified, the complication rates remain high and pouch failure is an

inevitable consequence and occurs in 21% of our patient cohort. Antibiotic resistance was reported in 78% of patients. The utility of long term antibiotics must therefore be weighed against potential complications associated with pouchitis and antibiotics.

PI051 ANTIBODIES TO INFLIXIMAB OCCUR THROUGHOUT TREATMENT BUT DEVELOPMENT IS DELAYED BY IMMUNOSUPPRESSION

R. W. Downey, G.S.Z. Tun, K. Swallow, G. Wild, A. Wright, K. Robinson, L. Marshall, R. Sargur, M. F. Hale, A. J. Lobo

Gastroenterology, Sheffield Teaching Hospitals NHS Foundation Trust, jf/United Kingdom

Contact E-mail Address: rdowney1@sheffield.ac.uk

Introduction: Infliximab (IFX) is an important agent in the treatment of inflammatory bowel disease (IBD). However, its use may be limited by the development of antibodies to infliximab (ATI). The aim of this study was to assess the timing and significance of ATI development in clinical practice.

Aims & Methods: Since May 2016, all IBD patients receiving intravenous IFX for maintenance treatment, at a large, single, referral centre, have undergone therapeutic drug monitoring (TDM). Serum IFX trough levels and ATI were both measured by drug-tolerant enzymelinked immunosorbent assays (Biohit, UK) from 199 patients at a variable interval following the start of IFX treatment. IFX trough levels were considered undetectable (< 0.8 mg/L), low (0.8 – 2.9 mg/L), therapeutic (3 – 7 mg/L) and supratherapeutic (> 7 mg/L). ATI were considered positive if > 10 mg/L. Clinical remission was defined as a Harvey Bradshaw Index or Simple Colitis Activity Index ≤ 4 . Risk factors for ATI development were assessed by binary logistic regression model, using 522 sera taken from patients on maintenance therapy. Time to develop ATI, undetectable IFX levels and loss of response to treatment was assessed by Cox regression and Kaplan-Meier analysis.

Results: Male sex ($OR = 2.1$; $p < 0.001$), week of treatment (OR for each extra week of treatment $= 0.999$; $p < 0.038$) and use of concomitant immunosuppression (IS) ($OR = 0.373$; $p < 0.001$) were associated with ATI formation. During the period of observation, those not taking IS were more likely to develop ATI at any time throughout their IFX treatment (Hazard Ratio $= 2.4$; $p = 0.03$). 59/199 patients were ATI positive at their first TDM, of whom 2 were in their first 6 months of IFX treatment. 140/199 patients were ATI negative at their first TDM. During follow-up, we observed 32 patients develop ATI (19 patients developed antibodies within 6 months of starting IFX treatment, 5 between 6–12 months treatment and 8 after 12 months). At any given time, patients with positive ATI are 3.4 times as likely ($p = 0.002$) to develop undetectable levels than ATI negative patients. Transient ATI formation was seen in only 5/162 patients. Figure 1. Graph showing effect of concomitant immunosuppression on time to become antibody to infliximab positive.

Conclusion: Although IS therapy protects against ATI formation, the risk of antibody development continues throughout treatment. If concomitant IS is aimed at reducing ATI formation, then this also needs to be continued for the duration of IFX therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI052 A DRUG-RESISTANT ASSAY CAN BETTER DIRECT THE NEED FOR ADALIMUMAB DOSE-ESCALATION AFTER INDUCTION THERAPY IN ANTI-TNF NAÏVE PATIENTS WITH CROHN'S DISEASE

G. Moors¹, B. Verstockt¹, S. Bian², S. Tops², V. Ballet¹, G. Van Assche¹, S. Vermeire¹, A. Gils², M. Ferrante¹

Introduction: Antidrug antibodies (ADA) may develop in up to 35% of patients with Crohn's disease (CD) receiving adalimumab (ADM). Although ADA to ADM are predominantly neutralizing, standard drug-sensitive assays do not allow ADA measurement in patients with detectable trough levels (TL) and drug-tolerant assays are suboptimal in case of high TL.

Aims & Methods: We aimed to identify ADA using a drug-resistant assay, instead of the standard drug-sensitive assay, and to correlate their presence with clinical outcome. Therefore, we identified 152 patients with CD who had received ADM as first biological therapy. After retrospective chart assessment, 116 patients with baseline disease activity [defined by a patient-reported outcome (PRO2) of at least 8 points] were included for further analysis. Clinical remission was defined as an average daily stool frequency ≤ 2.8 and an average abdominal pain score ≤ 1 . Serum samples were available in 70/116 at week 12 after ADM initiation. ADA presence was determined via both a monoclonal drug-sensitive assay in case of undetectable TL, and via an in-house developed drug-resistant assay regardless of TL [1].

Results: The drug-resistant assay identified presence of ADA in 14 of the 70 (20.0%) patients at week 12, whereas a drug-sensitive assay could detect ADA

in just one of these 14 patients (1.4%) ($p < 0.001$). Median (IQR) TL were significantly higher in the ADA negative group compared to the ADA positive group [9.21 (7.00–12.99) vs. 3.45 (1.72–5.44) $\mu\text{g/mL}$, $p < 0.001$]. A significant correlation between TL and ADA levels could be found (Spearman's $\rho = -0.562$, $p < 0.001$). Although the presence of these ADA was not significantly associated with lack of clinical remission at week 12, a clear tendency was observed ($p = 0.136$). During median (IQR) follow-up of 1.46 (0.32–3.48) years, 43 out of 116 patients (37.1%) needed ADM dose-escalation. Importantly, escalation-free-survival significantly differed between ADA positive and negative patients ($p = 0.001$). Univariate analysis could not identify any more factors (weight, BMI, gender, disease behaviour, disease location, CRP, serum albumin, PRO2, concomitant therapy, smoking) associated with ADA presence at week 12. Interestingly, 50% of the ADA positive patients had TL above 4 $\mu\text{g/mL}$ and would not have been dose optimized proactively according to current practice. Though, 3 out of these 7 patients needed dose-escalation afterwards which could have been expected based on the ADA positivity.

Conclusion: A drug-resistant assay can identify ADA to ADM before all drug has been neutralised and TL become undetectable. As these ADA at week 12 are significantly associated with need for dose-escalation and can appear before TL drops below the threshold of 4 $\mu\text{g/mL}$, they may be better to identify those patients who could benefit from dose-escalation. Moreover, the differences in TL between patients at week 12 can finally be explained by the presence of ADA measured with a drug-resistant assay.

P1053 ADHERENCE TO MAINTENANCE THERAPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE BEFORE AND AFTER THE INTRODUCTION OF THE SHARED MEDICATION RECORD

K. Roelsgaard

Department Of Internal Medicine, Randers Regional Hospital, Randers/Denmark

Contact E-mail Address: klaroe@rm.dk

Introduction: Compliance is a significant problem in the medication of patients with chronic diseases, especially during periods where patients are completely unaware of their disease and just take their drugs to prevent disease recurrence. (1) During the last years Shared Medication Record (SMR) was introduced in Denmark (2). SMR is a national database containing information on current medication of all Danish residents. SMR include information on where, when, and how much medicine the patients by at the pharmacies. Therefore with SMR it becomes possible for doctors to see if patients retrieve the prescribed medicine at the pharmacy. Patients with chronic inflammatory bowel diseases (IBD), ulcerative colitis (UC) or Crohns Disease (CD), have periods of flares of the disease but in many cases also long periods when the disease is in remission. The majority of patients need medication to reduce the risk of recurrence of disease activity. This means that they need to take medicine even if they have no symptoms of disease. Previous American studies have shown that a number of patients in this situation do not take their medication and thus are at increased risk for relapse of the disease (1). There are no corresponding data for Danish patients. We wanted to find out the proportion of Danish IBD patients in remission who buy the prophylactic treatment as prescribed, and whether this proportion will change when the patients are informed about that the doctor can see if they pick up the medicine at the pharmacy.

Aims & Methods: The purpose of this study was to investigate whether Danish patients with IBD in remission buy the prophylactic treatment as prescribed, if these patients buy a larger part of their medicine when they know that the doctor can see which medicines they buy at the pharmacy. 100 consecutive patients with UC or CD in remission for at least six months and treated with a fixed dose of Mesalazine, azathioprine, or Mercaptopurine during the preceding six months were enrolled from Randers Regional Hospital Adult Gastroenterological Outpatient Clinic. Patients were randomized 1:1 either to receive information that the doctor could follow their pharmacy refills, or not to get information on this. The patients were not informed that they participated in a study. All patients had a second visit six to 12 months later. Patients who had flares in disease activity during the study period was excluded. Adherence to the treatment

was defined as pharmacy refills according to the prescribed dose for at least 80% of the period of the preceding six months. Fisher's exact test was used as test of independence between groups

Results: 67% of the patients in the study were adherent to their medical treatment during the first study period decreasing to 48% during the second study period ($P < 0.01$). There was no difference in the decrease in adherence between patients informed about SMR and those who were not informed. Younger patients were less prone to adherence compared to older patients at the first study visit (Age groups: 19–39/40–59/60+ Years, adherence 48/71/81%) ($P < 0.05$). We found no differences related to disease (UC/CD), sex, 5-ASA/antipyrins, or administration route (oral/rectal).

Conclusion: Adherence to treatment fell from the first visit when the disease had been in remission for at least six months, to the second study visit when the disease had been in remission for at least 12 months. This was independent of whether the patients were aware that the physician could follow their medication refills or not. This might indicate that adherence to medical treatment of IBD decreases over time when the disease is in remission.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Golimumab (GOL) is a fully human monoclonal antibody to TNF α approved for the treatment of patients with moderate to severe ulcerative colitis (UC) with inadequate response or intolerance to steroids or immunosuppressive therapies. The aim of this study is to evaluate the efficacy and safety of GOL in both biologic naïve (BN) and biologic experienced (BE) patients.

Aims & Methods: Data were prospectively collected from a cohort of UC patients treated with GOL from March 2015 to March 2017 at two centers. Data were analyzed from two patient cohorts, namely BN patients and patients who have already undergone treatment with infliximab or adalimumab (BE). Patients received GOL 200 mg sc. at week 0, GOL 100 mg sc. at week 2, then 50 mg or 100 mg sc. every 4 weeks depending on body weight. The primary outcomes were clinical response rate and incidence of adverse events (AEs).

Treatment failure	37 (69)	16 (67)	21 (70)	0.5

Results: Overall, data from 59 patients were analyzed. Of these, 27 (46%) were BN and 32 (54%) BE. Baseline patient's characteristics and main study results are shown in Table 1. BN and BE patients were comparable in terms of comorbidity profile, age at diagnosis, disease duration, pattern of previous and concomitant conventional therapies, as well as of disease extension and severity. Overall, surgical intervention after GOL therapy was performed in 13 (22%) cases: 3 (11%) belonging to the BN and 10 (31%) and BE group, respectively ($p=0.2$). In 10 (17%) patients AEs were recorded, most of which were genitourinary or herpes simplex infections. Of note, two cases of basal cell carcinoma were registered. The rate of AEs did not significantly differ among the BN and BE groups ($p=0.8$). In 5 (50%) patients AEs were responsible for therapy discontinuation after a median (IQR) period of 4 (1–4) months. Of the 54 (92%) patients who continued therapy, median (IQR) duration of GOL treatment was 7 (4–14) months. At 3 months follow-up, 26 (48%) patients showed clinical response to GOL. Clinical response rate was similar in the BN and BE cohorts ($p=0.8$). 28 (52%) patients were non-responders, without a statistically significant difference between the two groups ($p=0.8$). At March 2017, 17 (31%) patients maintained clinical response, whereas 37 (69%) failed the treatment. No statistically significant differences were noticed between the BN and BE cohorts concerning the clinical response or the treatment failure ($p=0.5$).

Conclusion: In our cohort, clinical response at 3 months follow-up was obtained in almost half of patients while at the last follow-up in one third. BN and BE patients had similar results in terms of clinical response, even though there seems to be a better early response in BN patients. Even if not statistically significant, surgery was required most frequently in the BE group. Rate of AEs was acceptable and similar in both BN and BE patients. Although our findings need to be confirmed in larger series, GOL therapy appears to be safe and to achieve an acceptable disease control in both the biologic naïve and experienced setting.

Introduction: Endoscopic recurrence precedes clinical recurrence after ileocolonic resection for Crohn's disease (CD). Guidelines recommend an ileocolonoscopy within the first year after surgery where timely treatment decisions may be affected. The aim of our study was to describe the endoscopic monitoring and associated treatment decisions within the first year after surgery in a cohort of CD patients operated on between 2007 and 2010.

Aims & Methods: PRACTICROHN was a study that included patients aged ≥ 18 years-old from 26 Spanish hospitals who underwent CD-related ileocolonic resection with ileocolonic or ileorectal anastomosis between January 2007 and December 2010. Clinical data was retrospectively collected from clinical charts during 5 years follow-up after surgery. Categorical variables were compared with the χ^2 test or Fisher's exact test.

Results: Three hundred and fourteen patients were analyzed (mean age 40 years [SD 13], 48% men). Throughout the observational period, 262 patients (83.4%) underwent colonoscopy and 52 patients (16.5%) lacked endoscopic follow-up. First endoscopy was performed mainly within the first year after surgery (45.5%, $n=143$) and the leading reason was a planned monitoring (66.4%, $n=95$). In total, 30.3% of the patients underwent planned endoscopy within first year after

surgery. By year, it was found a positive trend in the number of both total and "planned" endoscopies carried out within this period ($p=0.017$ and $p=0.027$, respectively) (table).

Table

	2007 n = 75	2008 n = 83	2009 n = 77	2010 n = 79	p-value
Patients underwent surgery					
Patients with endoscopy within first year after surgery, n(%)	24 (33.80)	36 (43.90)	36 (46.75)	47 (59.49)	0.017
Patients with "planned" endoscopy within first year after surgery, n(%)	15 (20.00)	25 (30.12)	21 (27.27)	34 (43.04)	0.027

Treatments received by patients at discharge were Immunomodulators (30.8%), antibiotics (21.3%), corticosteroids (19.1%), mesalazine (12.1%) and antiTNFa (0.9%). A total of 235 patients (74.8%) had a medication change throughout the follow-up period, mainly within the first year after surgery (47.1%, $n=148$). Median time to first medication change was 10 (IQR 4–22) months. More often therapeutic decision was the introduction or dose escalation of thiopurines or change to a more potent agent (68.1%, $n=160$) followed by the introduction of an antiTNFa drug or dose escalation (51.4%, $n=121$). Ninety-two out of 95 patients with planned endoscopy within first year after surgery had Rutgeert scoring (RS) available, 37 (40.2%) and 55 (59.7%) showed $RS \geq i2$ and $< i2$ respectively. More patients with a $RS \geq i2$ had a medication change as compared to patients with a $RS < i2$, but the differences didn't reach statistical significance (45.95% vs 36.36%). Reasons for medication change were "endoscopic without clinical recurrence" (52.9% $RS \geq i2$ vs 10.0% $RS < i2$, $p=0.010$), "clinical recurrence" (29.4% $RS \geq i2$ vs 25.0% $RS < i2$) and "others" (23.5% $RS \geq i2$ vs 60.0% $RS < i2$, $p=0.045$).

Conclusion: The number of planned endoscopies carried out within the first year after surgery increased significantly from 2007 to 2010 showing a steadily implementation of guidelines recommendations. Changes in medication within this period were more frequent in the setting of endoscopic recurrence.

Introduction: Etrolizumab, an anti- $\beta 7$ monoclonal antibody targeting $\alpha 4\beta 7$ and $\alpha E\beta 7$ integrins, showed efficacy and safety versus placebo (PBO) during 10 weeks (wk) of induction in patients with moderate-to-severe ulcerative colitis in the Phase 2 EUCALYPTUS trial (Vermeire S. *Lancet*. 2014;384:309–18). Since a reduction in histologic inflammation has been linked with improved long-term clinical outcome (Bryant RV. *Gut*. 2016;65:408–14), and the FDA recommends using both histologic and endoscopic assessments for efficacy evaluation, the effect of etrolizumab on histologic inflammation was evaluated in mucosal biopsies from EUCALYPTUS patients using the Roberts histopathology index (RHI; Mosli MH. *Gut*. 2017;66:50–8) and Nancy histological index (NHI; Marchal-Bressenot A. *Gut*. 2017;66:43–9).

Aims & Methods: 124 patients were randomly assigned (1:1:1) to receive subcutaneous etrolizumab (100 mg at wk 0, 4, and 8, with PBO at wk 2, or 420 mg loading dose at wk 0, followed by 300 mg at wk 2, 4, and 8) or matching PBO. Biopsies were taken using flexible sigmoidoscopy/full colonoscopy from the most inflamed colonic area within 10–40 cm from the anal verge at baseline (BL) and at wk 10. 62 patients provided consent for long-term sample storage for research; batched H&E-stained slides were scored by a single pathologist using the Geboes scale (later converted to RHI) and NHI. At wk 10, mean changes in RHI and NHI scores for pooled etrolizumab or PBO were calculated. Subanalyses explored histologic response (reductions of ≥ 6 or 10 points or $\geq 50\%$ improvement from BL RHI and ≥ 1 or 2 points reduction from BL NHI), remission (no neutrophils, $RHI \leq 4$ and $NHI=0$, ≤ 1 or 2) and correlation with endoscopic improvement.

Results: Analysis included 56 patients with BL data and BL NHI > 1 . At wk 10, RHI and NHI scores decreased by a greater extent with etrolizumab compared with PBO, regardless of anti-tumor necrosis factor α (aTNF) experience ($RHI -8.4$ vs -1.6 ; $P=0.032$ and $NHI -1.2$ vs -0.2 ; $P=0.011$ for all comers). A greater proportion of etrolizumab-treated patients achieved categorical histologic improvement and remission. Of patients with an endoscopic subscore (ES) ≤ 1 at wk 10 ($n=6$), 100% experienced histologic response as assessed by RHI (5/5 with RHI non-missing at wk 10), and 83% (5/6) by NHI. Mean (SD) RHI changes were -19.2 (10.0) in patients with an ES ≤ 1 at wk 10 versus -4.4 (10.1) in patients with an ES > 1 . Mean (SD) NHI changes were -2.5 (1.5) in patients with an ES ≤ 1 at wk 10 versus -0.6 (1.3) in patients with an ES > 1 . Spearman's

correlation coefficients between RHI and NHI were 0.82 at BL and 0.91 at wk 10, while both histologic scores were similarly correlated with ES (0.25–0.28 at BL and 0.38–0.40 at wk 10).

Table 1: Percentage of Patients Achieving Histologic Response and Remission at Week 10

	aTNF-naïve (n = 16)		aTNF-experienced (n = 34)		All comers (n = 50)	
	Etrolizumab	Placebo	Etrolizumab	Placebo	Etrolizumab	Placebo
RESPONSE (decrease from baseline)						
RHI ≥ 6	55%	17%	46%	36%	49%	30%
≥ 10	55%	0%	33%	21%	40%	15%
$\geq 50\%$	36%	0%	25%	7%	29%	5%
NHI ≥ 1	73%	17%	52%	14%	58%	14%
≥ 2	55%	0%	32%	14%	39%	10%
REMISSION (absolute score)						
RHI ≤ 4	36%	0%	8%	7%	17%	5%
No neutrophils	36%	0%	8%	7%	17%	5%
NHI = 0	36%	0%	4%	14%	14%	10%
≤ 1	45%	0%	20%	14%	28%	10%
$\leq 2^*$	73%	33%	56%	21%	61%	25%

*Must have achieved ≥ 1 point improvement

NHI 0 = no histologically significant disease

NHI 1 = chronic inflammatory infiltrate with no acute inflammatory infiltrate

NHI 2 = mildly active disease

Conclusion: Histologic activity assessment using RHI or NHI demonstrates improvement after wk 10 with etrolizumab treatment and was greater in aTNF-naïve patients. Importantly, RHI or NHI reductions were associated with improved ES at wk 10.

Introduction: GO-COLITIS (NCT02092285; 2013-004583-56) is a phase 4, multi-centre, open-label, single-arm trial in the UK assessing efficacy of golimumab (GLM) in induction and maintenance of clinical response in patients with moderate to severe ulcerative colitis (UC) resistant to conventional treatment. Results of the maintenance phase are presented here.

Aims & Methods: Anti-TNF naïve adults with UC ≥ 3 months who responded to induction therapy with subcutaneous GLM at week 6, according to partial Mayo score (PMS), continued to receive a maintenance dose of 50 mg or 100 mg GLM (dependent on the patient's weight) every 4 weeks as per the Summary of Product Characteristics for a total of 54 weeks. Measurements were taken at week 6, week 30 and week 54. The primary endpoint was the proportion of patients meeting PMS response criteria at week 54 (defined as decrease in PMS of ≥ 2 points and $\geq 30\%$ from baseline, plus a decrease in rectal bleeding subscore of ≥ 1 point or absolute rectal bleeding score ≤ 1). Secondary endpoints included proportion of patients meeting PMS remission criteria at week 54 (defined as PMS ≤ 2 and no individual Mayo subscore > 1), change from baseline in IBDQ and EQ-5D at each visit and normalization of CRP.

Results: Overall, 205 patients enrolled in GO-COLITIS and received at least one dose of GLM. Of these, 140 patients responded in the induction phase and received GLM in the maintenance phase. Clinical response was maintained through week 54 in 52/140 patients (37.1%; 95% CI, 29.1% to 45.7%) and 42/140 patients were in remission at week 54 (30.0%; 95% CI, 22.6% to 38.3%). Improvements in PMS subscores from baseline to week 54 were noted in stool frequency (mean change, -1.9 ; SD, 1.1 [n = 59]), rectal bleeding (mean change, -1.5 ; SD, 0.8 [n = 59]), and physician's global assessment (mean change, -1.8 ; SD, 0.8 [n = 57]). Normal CRP levels at week 54 were seen in 50/59 patients (response rate, 84.7%; 95% CI, 73.0% to 92.8%). IBDQ and EQ-5D results are summarised in the Table. Serious adverse events (SAEs) occurred in 49/205 patients (23.9%), with 3 SAEs considered treatment-related.

Table: Mean (SD) Change from baseline to week 54 in IBDQ and EQ-5D.

	n	Baseline	n	Week 54	n	Change From Baseline
IBDQ total score	138	116.4 (32.7)	59	186.2 (27.1)	59	66.8 (36.7)
EQ-5D index score	136	0.7 (0.2)	60	0.9 (0.2)	58	0.2 (0.3)

Conclusion: In the maintenance treatment with GLM phase of GO-COLITIS, 37.1% and 30.0% of patients with moderate to severe UC in the UK demonstrated clinical response and remission at week 54, respectively. Improvements in patient-reported quality of life measures (IBDQ/EQ-5D) were seen; the degree of improvement in IBDQ total score exceeded the IBDQ increase cutoff (i.e. > 20) for patient defined-remission previously identified as representative of a patient-defined improvement in an assessment of UC clinical endpoints.¹ Adverse events were consistent with previous observations.

Contact E-mail Address: oh.young@gene.com

Introduction: Only a third of patients (pts) with inflammatory bowel disease (IBD) treated with current pharmacological options achieve clinical remission at 1 year, and most experience drug-related adverse events (AEs). Herein we characterise the clinical and economic burden of IBD treatment limitations in terms of AEs of interest, medical resource utilisation (MRU) and associated medical costs.

Aims & Methods: Using pts taking only aminosalicylates (ASA) as a reference, we compared AE incidence, MRU and medical costs in pts with ulcerative colitis (UC) or Crohn's disease (Crohn's) who initiated treatment with oral corticosteroids (OCS), immunosuppressants (IS), anti-tumor necrosis factor agents (aTNF) or with combinations thereof. Eligible pts (aged > 18 years) in the IMS PharMetrics insurance claims database between 7/1/10 and 6/30/15 had ≥ 2 medical claims (≥ 7 days apart) and a diagnosis of UC (ICD-9-CM: 556.x) or Crohn's (ICD-9-CM: 555.x), with > 1 qualifying claim in the year preceding treatment. Univariate comparisons included statistical tests of significance (χ^2 , F test, or Kruskal Wallis). Multivariate analyses were based on Cox proportional hazards regression, negative binomial regression, logistic regression or linear regression

analysis adjusted by significant socio-demographic, clinical and disease severity covariates.

Results: This analysis included 30,676 (Crohn's: N = 14,528; UC: N = 16,148). OCS monotherapy was the strongest predictor of any AE occurring for pts with Crohn's or UC (Crohn's: HR, 1.62 [1.51–1.73]; UC: HR, 1.57 [1.49–1.66]). A similar pattern was observed for severe infection (Crohn's: HR, 2.43 [2.07–2.85]; UC: HR, 2.37 [2.07–2.72]) and bone-related conditions (Crohn's: HR, 1.88 [1.74–2.03]; UC: HR, 1.77 [1.67–1.89]). The strongest predictors for serious hepatic events were IS+OCS (Crohn's: HR, 2.38 [1.72–3.31]; UC: HR, 2.36 [1.75–3.18]) and OCS (Crohn's: HR, 2.09 [1.65–2.66]; UC: HR, 1.92 [1.57–2.34]). Pts with UC or Crohn's receiving OCS or IS+OCS were more likely to have emergency department visits; IBD-related hospitalisation, visits or procedures; and gastrointestinal surgery compared with pts receiving other therapies. Annualised total medical costs were greatest for aTNF+IS or aTNF therapy in both Crohn's and UC. However, annualised medical service costs (that exclude IBD drug costs) were highest for pts initiating OCS-containing therapies (Crohn's: OCS, \$27,041 and OCS+IS, \$23,332; UC: OCS, \$19,659) followed by other index therapies (Crohn's: ASA, \$10,823 and aTNF+IS, \$19,151 [P < 0.001]; UC: ASA, \$7,980 and aTNF+IS, \$18,771 [P < 0.001]).

Conclusion: Chronic OCS use was associated with increased risk of severe infection, bone conditions, and serious hepatic events compared with other therapies. Consistent with an increased AE risk, OCS regimens were associated with higher rates of MRU and medical service costs compared with other therapies. Although limiting the use of OCS regimens may be more costly initially, treatment decisions should consider downstream benefits of alternate options.

Contact E-mail Address: bellageyshit@gmail.com

Introduction: Infliximab has been shown to induce and maintain long-term clinical remission in inflammatory bowel disease (IBD) patients. However, 10–30% of patients show no clinical benefit by the end of induction (week 14) and are considered primary non-responders. The mechanisms underlying primary non-response have not yet been clearly defined.

Aims & Methods: In this study we aimed to evaluate to which extent pharmacokinetics (early induction infliximab and anti-infliximab-antibody (ATI) levels) are associated with primary non response. A retrospective observational case-control study of patients with IBD attending the Gastroenterology Department of Sheba medical center and treated with infliximab between 2009 and 2016 was performed. Clinical scores were determined and sera were collected prospectively before infusions. Infliximab and ATI levels were measured by our previously described drug-tolerant ELISA assay.

Results: Thirty five primary non responders have been identified and matched at 1:3 ratio with 105 primary responders for a total of 140 patients. Both week 2 and week 6 infliximab levels were significantly lower among primary non-responders compared to responders (week 2: median level 7.2 µg/ml vs. 13.5 µg/ml, p = 0.0019, week 6: median level 2.2 µg/ml vs. 9.5 µg/ml, p < 0.0001, respectively). ATI appeared more frequently (either week 2 or 6, OR = 4.6, CI 2–10.8, p = 0.0004) and at higher levels in non-responders compared to responders (week 2: median ATI 7.3 µg/ml-eq vs. 3.8 µg/ml-eq, p = 0.005, week 6: 10.8 µg/ml-eq vs. 4.4 µg/ml-eq, p = 0.008, respectively). Moreover, week 2 ATI levels > 4.3 µg/ml-eq (AUC = 0.78, p = 0.0004, sensitivity 77%, specificity 71%) and infliximab levels < 6.8 µg/ml (AUC = 0.68, p = 0.002, sensitivity 50%, specificity 86%) were predictive of primary non-response. In analyses of various demographic and clinical factors correlated with primary non-response the only independent factors found significant on multivariable analyses were lower infliximab and higher ATI levels at either week 2 or 6, infliximab monotherapy and previous IBD-related surgeries. Sub-analyses according to IBD type demonstrated that in addition to lower drug and higher ATI levels, older age and previous surgeries increased the risk for primary non-response among Crohn's disease patients. Monotherapy was the only other factor significant among ulcerative colitis patients, although multivariate analysis was not performed due to limited sample size (n = 32).

Conclusion: Although direction of causality cannot be ascertained, infliximab levels below 6.8 µg/ml and ATI levels above 4.33 µg/ml-eq before the second infusion (week 2) are predictive of primary non response, in addition to previous CD-related surgeries and infliximab monotherapy. These findings suggest that preemptive interventions in a subset of patients might minimize this phenomenon.

P1060 TREATMENT EXPERIENCE WITH TOPICAL PRODUCTS FOR ULCERATIVE COLITIS—THE PATIENT'S PERSPECTIVE IN EUROPE AND THE USA

T. Bayrhammer¹, A. Thompson², T. Knittel³

¹DBA Effimed Research LLC, San Francisco/United States of America/CA

²Brera Life Sciences, Guildford/United Kingdom

³InDex Pharmaceuticals, Stockholm/Sweden

Contact E-mail Address: thomas.knittel@indexpharma.com

Introduction: Topical therapies for ulcerative colitis have shown evidence of good efficacy and can induce better responses and earlier improvement in distal ulcerative colitis (UC) when compared with oral therapies. Despite this attractive targeted approach of delivering medications topically to the left colon a certain resistance to the use of topical therapy seems to exist.

Aims & Methods: The goal of this market research was to assess the familiarity with and perceptions of patients towards topical products. A qualitative market research study was performed in the USA and 3 European countries (Germany, UK and Italy). The primary patient recruitment sources were online web portals, e-mail campaigns and social networking sites. Informal feedback gathered from outspoken patient activists to identify the right sources was also used. In order to select UC patients with more advanced disease and/or a longer disease history current or past steroid medication was mandatory as a qualification for inclusion in the market research. A structured questionnaire covering 14 items was pre-tested and modified in phone interviews, which was then subsequently used in telephone interviews or as a web based interactive survey, both in local language. A total of 148 patient responses were obtained via 10 phone interviews and 138 web-survey, 60 patients came from the US, 27, 25 and 36 from Germany, UK and Italy, respectively.

Results: In this survey cohort patients had been diagnosed with UC for > 5 years on average, 2/3 of patients had left-sided disease and less than a third had extensive disease. The majority of patients experienced at least 1–2 flare-ups each year and less than 18% of patients had them only rarely. ASA and steroids were the most commonly used medications in all countries, biological treatments were reported as highest in 35% (US) to the lowest 16% (UK) as stated by the patients. The vast majority of patients stated that they had treatment experience with rectal products at some point during their treatment journey with only a slightly lower number in the US (83%) compared to the EU countries (Range 89–92%). Rectal enemas were the most common formulation delivery for topical ASA products in all markets (79%) followed by suppository (25%) and foam (13%). A total of 53% of patients were not concerned about the rectal mode of administration, while 47% reported some concerns. These mainly comprised the need to hold the enema in place, a generally uncomfortable feeling with rectal medications and painful administration.

Conclusion: Despite a certain resistance to use topical therapy almost all patients stated to have used rectally administered products at some point during their disease journey and even patients in the USA were very familiar with these medications. Although physicians see patients as the primary driver for the resistance to use topical products in UC, less than 50% of the patients were actually concerned about the use of topical therapy in this study, thereby calling for better physician-patient communication.

P1061 SELF-MANAGEMENT IN INFLAMMATORY BOWEL DISEASE: A PERSPECTIVE OF NURSES AND PHYSICIANS

S. P. Van Den Burg, N. M.s. Peek, A. E. Van Der Meulen - De Jong,

J.P.w. Maljaars

Gastroenterology And Hepatology, LUMC, Leiden/Netherlands

Contact E-mail Address: s.p.van_den_burg@lumc.nl

Introduction: Over the last years, self-management (SM) has been advocated as an instrument to empower and enable patients, increase patient involvement and reduce healthcare costs in chronic diseases. Although many SM programs have been developed for inflammatory bowel disease (IBD) patients, little research has been performed on needs and wishes of IBD physicians, nurses and patients. Nurses and physicians play an important role in providing and stimulating SM.¹⁻³

Aims & Methods: This study aimed to gain insight in what caregivers consider good SM-options, and which patient- or disease-related factors they consider of influence on the degree of SM a patient is willing to apply. During a nurses IBD day at our hospital, a survey regarding SM was distributed among 46 nurses. Also, 50 IBD-interested gastroenterologists were invited to respond to the same survey by email with a link to the survey. The survey contained questions regarding the caregivers' views on ways for patients to apply SM in an outpatient setting (12 options were given). Caregivers were asked to state whether they thought these options would be valuable to patients or not, and to name their top three options. Also, caregivers were asked their views on factors that could

influence the degree of SM a patient is willing to apply, such as: disease duration, activity and perception, health literacy, self-efficacy, patients' age, and level of trust between patient's and their IBD team. Caregivers were asked per item whether they thought this factor would be of influence and to name the three most important factors.

Results: 38 nurses (mean age 42 years) and 32 physicians (mean age 44 years) responded to the survey. The three most appealing options for nurses regarding SM were: availability of a SM web-app, Skype/Face-time consultation with nurse/physician, and an at-home faecal-calprotectin test. Physicians preferred the availability of a SM web-app, an at-home faecal-calprotectin test, and making patients in charge of their patient records. When comparing the value of each of the 12 possible choices in which patients could apply SM, only one option was valued differently between nurses and physicians. 56% of physicians favoured patients being in charge of patients records compared to 18% of nurses ($p=0.001$). Physicians thought that the 3 most important factors influencing SM in patients were: level of trust between physician and patient, self-efficacy, and disease perception. Also, 41% of the physicians found health literacy to be an important factor. Nurses suggested that self-efficacy, disease perception and disease activity were most important. One factor was valued differently between nurses and physicians: 78% of nurses thought that patients' age was an important factor in patient's SM, compared to 34% of physicians ($p=0.000$).

Conclusion: Overall, nurses and physicians agree on many aspects of SM in IBD-care. However, more physicians are in favour of making patients in charge of their patient records. Nurses and physicians agree that patient characteristics, in contrast to disease characteristics, influence SM, with self-efficacy being the most important. This study calls for further research on what patients and caregivers, want and need from SM, as SM is a team sport.

P1062 DISTINCT PATTERNS OF SHORT-CHAIN FATTY ACIDS IN PATIENTS WITH ULCERATIVE COLITIS EXPERIENCING A FLARE DURING TREATMENT WITH MESALAMINE OR A HERBAL COMBINATION OF MYRRH, CHAMOMILE FLOWERS AND COFFEE CHARCOAL

J. Langhorst¹, A. K. Koch¹, A. Rueffer², G. Dobos³

Introduction: The combination of myrrh, chamomile flowers, and coffee charcoal has shown first evidence for potential efficacy in maintaining remission in ulcerative colitis (UC). SCFA are end products of the microbial fermentation of dietary fibers in the gut. They are involved in the regulation of the gut immune system, promote mineral absorption, lipid metabolism, mucin production and expression of antimicrobial peptides. UC patients often show reduced occurrence of SCFA especially during flare. This might lead to unfavorable health impairments including higher risk of inflammation and heightened cancer risk.

Aims & Methods: The purpose of the present study was to evaluate the influence of mesalazine and of the herbal preparation on SCFA in ulcerative colitis. Analyses was proceeded as sub-study of a randomized double-blind, double-dummy, controlled clinical trial that has been published previously. Patients were treated with the herbal preparation consisted of 100 mg myrrh, 70 mg chamomile extract and 50 mg coffee charcoal (Myrrhinil-Intest®; Repha GmbH, Hannover, Germany) 4tblx3/d or the gold standard treatment with mesalazine 500 mg 3xd. Clinical activity was monitored with the CAI (Rachmilewitz) with a CAI >4 indicating a clinical flare. Fecal samples were collected, gas chromatography was performed and SCFA (butyrate, acetate, propionate, iso-valerate and iso-butyrate) were measured at baseline, in the event of a clinical flare or at the end of the 12-month time interval.

Results: A total of n = 89 patients were included in the study. N = 43 pts developed a clinical flare (descriptive statistics are shown in table 1). Patients who were treated with mesalazine showed a significant decline of the SCFA (M baseline = 66.12; SD = 39.59; M flare = 29.83; SD = 15.05; 95% BCI [18.86–58.60]) in the event of a flare. In contrast, patients who were treated with the herbal preparation showed no significant decline of the SCFA (M baseline = 64.80; SD = 53.74; M flare = 48.09; SD = 35.90; 95% BCI [-71–42.28]) in the event of a flare. There was no significant decline in SCFA in the patients in remission neither for the herbal preparation (n = 19; M baseline = 65.77; SD = 43.38; M 12month = 48.63; SD = 23.23; 95% BCI [-7.02–

39.95]) nor for mesalazine (n = 27; M baseline = 57.01; SD = 34.40; M 12 month = 42.01; SD = 19.84; 95% BCI [-34–29.54]).

Conclusion: Findings show that the herbal preparation might induce different effects on the SCFA of patients with UC compared to mesalazine and therefore might exhibit different modes of action in treating UC. Since a decline of SCFA might lead to unfavorable health impairments like higher cancer risk, treatment options like the herbal preparation might yield additional beneficial effects in the treatment of UC. A combination of the two treatment modalities might be useful and should be investigated in further studies.

P1063 GRANULOCYTE-MONOCYTE APHERESIS (GMA) IN DIFFICULT- TO-TREAT INFLAMMATORY BOWEL DISEASE (IBD). A SINGLE-CENTER REAL-LIFE EXPERIENCE

A. Caroli, F. Lamboglia, I. Franceschet, C. Pozzan, D. Checchin, F. Bortoluzzi, R. Cappuccio, A. Vitalba

UOC di Gastroenterologia, Ospedale dell'Angelo, Mestre; Ospedale SS Giovanni Paolo, Venezia, Mestre-Venezia/Italy

Contact E-mail Address: alessandro.caroli@ulss12.ve.it

Introduction: Selective GMA using Adacolumn® device is a non-pharmacological therapeutic option for patients affected by IBD, but its precise role among the various treatments available and its true effectiveness are still debated. In particular, steroid-dependent patients, refractory or intolerant to immunosuppressant and biologics, represent a sub-group of patients with limited options of treatment. Recently, a multicentric open-label trial [the ART trial *] showed, for the first time, a clinical benefit of GMA in these problematic patients.

Aims & Methods: The aim of this study was to further evaluate, in our real-life clinical experience, the efficacy and safety of GMA in these difficult-to-treat patients. We retrospectively reviewed the clinical data of patients treated with GMA-Adacolumn® in our center between 1/1/2008 and 31/12/2016. Only steroid-dependent and/or AZA/IFX/ADA-resistant or intolerant cases were considered. GMA was performed once a week for a minimum of five consecutive weeks. Occasionally, one or two additional sessions were performed. A clinical response was defined as a ≥ 3 points reduction of the clinical activity index (CAI) for ulcerative colitis (UC) and a ≥ 100 points reduction of the Crohn disease activity index (CDAI) for Crohn disease (CD) after 12 weeks from the beginning of the treatment.

Results: The study population included a total of 30 patients (17 males, 13 females, mean age 49 years, range 21–73) affected by UC (20 patients) and CD (10 patients). Eight patients (5 UC, 3 CD) were excluded from the final analysis for incomplete data. In the remaining 22 pts a clinical response, at week 12, was observed in 15 (68%). The response was better in UC (11/15 = 73%) than in CD (4/7 = 57%). A steroid-sparing effect was observed in all responsive patients. GMA was generally well tolerated, as only 4 patients (13%) reported mild adverse events (headache in two, hypotension in one, vascular procedure complication in one) and no patients discontinued the apheresis due to the adverse events.

Conclusion: In our real-life single-center experience, focused to a selected group of difficult-to-treat patients affected by IBD, GMA with Adacolumn® seems to be, in a short-time evaluation, a useful and safe option of treatment, supporting the recent data from the ART trial. Prospective randomized trials in larger sample of patients and with more extended follow-up are needed to confirm these results.

Introduction: The herbal medicinal product Myrrhinil-Intest®, a combination of myrrh (*Commiphora molmol* E.), chamomile flower (*Matricaria chamomilla* L.) and coffee charcoal (*Coffea Arabica* L.) is used for the treatment of gastrointestinal complaints. Clinical data suggest its use for the maintenance therapy of inflammatory bowel disease [1]. Despite existing clinical data, pharmacological data supporting the observed efficacy remain insufficient.

Aims & Methods: The present study aims to investigate the influence of the single and combined herbal extracts with regard to its antispasmodic and immune-modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine (IL8; CXCL10; CXCL13) release from cytokine-(10 ng/mL TNFα; 5 ng/mL IL1β; 10 ng/mL IFNγ)-challenged intestinal epithelial cells (Caco2) and LPS-challenged human macrophages (THP-1) was investigated respectively using an ELISA test system. Budesonid served as positive control. To characterize the combined effect, concentration-response relations of single components and the herbal combination were compared and IC₅₀ values derived. Interpretation of the data was based on a dose reduction index (DRI; = IC_{50-single}/IC_{50-comb.}) which estimates the extent to which the dose of one or more components in the combination can be reduced to achieve effect levels that are comparable with those achieved with single component.

Results: Myrrh and chamomile flower extract exerted spasmolytic effects by inhibiting acetylcholine-induced contractions in rat small intestinal preparations (IC₅₀: myrrh = 144 µg/mL; chamomile flower = 383 µg/mL). In combination, chamomile flower and myrrh interacted additively (IC₅₀: myrrh = 74 µg/mL; chamomile flower = 196 µg/mL) resulting in a DRI of 1.9. All three plant components inhibited CXCL13 release from LPS-stimulated human macrophages (IC₅₀: myrrh = 19 µg/mL; chamomile flower = 82 µg/mL; coffee charcoal = 106 µg/mL). Synergistic effects exerted by the herbal combination in inhibiting CXCL13 release significantly reduced IC₅₀ values (IC₅₀: myrrh = 5 µg/mL; chamomile flower = 22 µg/mL; coffee charcoal = 29 µg/mL) resulting in a DRI of 3.7. Cytokine induced CXCL10 release from Caco2 cells was reduced by all herbal components (IC₅₀: myrrh = 41 µg/mL; chamomile flower = 364 µg/mL; coffee charcoal = 447 µg/mL) with comparably high IC₅₀ values. However, application of the herbal combination, significantly reduced the IC₅₀ of the plant extracts (myrrh-IC₅₀ = 25 µg/mL, DRI = 1.7; chamomile flower-IC₅₀ = 124 µg/mL, DRI = 2.9; coffee charcoal-IC₅₀ = 124 µg/mL, DRI = 3.6). IL8 release from cytokine-challenged Caco2 cells was inhibited after myrrh (IC₅₀ = 3 µg/mL; 28% max inhib.) and coffee charcoal (IC₅₀ = 218 µg/mL; 75% max inhib.) but increased after chamomile flower treatment (EC₅₀ = 39 µg/mL; 29% max stim.). Treatment with all three plant extracts resulted in a moderate IL8 inhibition with an inverted U-shape concentration-response curve (IC₅₀: myrrh = 56 µg/mL; coffee charcoal = 281 µg/mL; 77% max. inhib.).

Conclusion: The herbal components myrrh, chamomile flower and coffee charcoal influenced chemokine signalling of stimulated intestinal epithelial cells and activated macrophages. Myrrh and chamomile flower additionally exerted antispasmodic effects. Synergistic and additive effects between the plant extracts justify the combinatory composition of the traditional herbal medicinal product (Myrrhinil-Intest®) and its application for the treatment of inflammatory intestinal disorders.

³University of Santiago de Compostela, Santiago de Compostela/Spain

Contact E-mail Address: manubarro@hotmmail.com

Introduction: Therapeutic drug monitoring of infliximab (IFX) and adalimumab (ADA) in inflammatory bowel disease are commonly used if patients show loss of response, but there are scarce data about the influence of trough levels on prognosis.

Aims & Methods: The aim of the study was to evaluate the relationship between drug concentration of anti-TNF and treatment failure and duration of treatment in a real life environment. **METHODS** A prospective observational study was performed in a cohort of patients with inflammatory bowel disease. Patients were included consecutively through visits to the hospital to receive IFX or ADA. Inclusion criteria were all age >18 year patients, being treated with one of the study drugs at standard dose as maintenance therapy and giving consent to

participate in the study. In the first visit, blood samples were extracted for drug concentration determination. Patients were followed-up for the next 2 years. Trough drug concentrations and drug antibodies were measured by an ELISA technique (Promonitor). Patients with IFX levels <3 mcg/mL and ADA <5 mcg/mL were considered under lower limit of therapeutic range (LLTR). After the follow-up period, the number of patients that continued (success) or discontinued (failures) the treatment were analyzed. Any change in dosage (intensification) or in the type of drug was considered as discontinuation of the treatment. Chi square test was used to analyze the dependence between the categorical variables and t-student for continuous variables with normal distribution.

Results: 134 patients were consecutively included, 53 male (40%), 92 (68%) patients with Crohn's disease (CD) and 42 (32%) with ulcerative colitis (UC), 82 (61%) received maintenance treatment with IFX and 52 (39%) with ADA. Mean age was 43 [19–71] years. After finishing the follow-up, 107 (79%) patients continued the same treatment regimen (success). A total of 59% of this group of patients were with drug concentrations above LLTR. The remaining 27 patients changed their treatment (failures). In the failure group, only 41% of the patients were above LLTR, 18.2% less with respect to success treatment group. These results did not reach statistical significance (p = 0.09), but are in agreement with current evidence. When type of inflammatory disease was analyzed, a greater percentage of patients below the LLTR were found in the UC group (41.3% vs 52.4%, CD and UC respectively), but the difference did not reach statistical significance. Regarding the duration of the treatments, the duration was similar in the group of patients with low concentrations compared to the group with high drug concentrations (46.6 vs 42.6 months). However, when the duration of treatment was analyzed in patients who discontinued, significant differences were observed (43.8 vs 20.2 months in the <LLTR and >LLTR groups respectively). Therefore, there are patients who relapse rapidly even with drug levels above LLTR. We observed 14 patients with positive antibodies, all of them with drug concentrations below the LLTR.

Conclusion: The percentage of patients who continue treatment was higher when drug concentrations were above LLTR. However, these high levels did not prevent the early relapse of some of them.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1066 IMMUNOSUPPRESSIVE CO-TREATMENT WITH INFLIXIMAB AND ADALIMUMAB IS NOT SUPERIOR TO ANTI-TNF MONOTHERAPY TO PREVENT TREATMENT FAILURE AND TREATMENT DISCONTINUATION IN ULCERATIVE COLITIS

S. Vieujeau¹, E. Louis², C. Reenaers¹

¹Gastroenterology, CHU Liège, Liège/Belgium

²University Hospital CHU of Liège, Liège/Belgium

Contact E-mail Address: catherine.reenaers@chu.ulg.ac.be

Introduction: In Crohn's disease there is clear benefit from combination therapy with infliximab (IFX) and immunosuppressive drugs (IS), while the benefit seems more limited for adalimumab (ADA). Although some studies suggest a benefit of combination therapy with IFX in ulcerative colitis (UC) few data are available [1].

Aims & Methods: Our aim was to compare real life efficacy of anti-TNF monotherapy (IFX and ADA) and anti-TNF + IS for UC maintenance. This was a retrospective study of patients with UC treated with IFX or ADA in 2 Belgian academic and regional Hospitals. Treatment periods were divided into 6-month semesters. A combination therapy semester was defined as anti-TNF + IS for at least 3 months, a failure semester as anti-TNF withdrawal for secondary loss of response, intolerance or surgery, a treatment optimisation semester as anti-TNF dose escalation or steroids start. Semesters with and without failure and with or without optimisation were compared through univariate and multivariate analysis. Patients receiving 6 months anti-TNF + IS during the first semesters were separately analysed.

Results: 478 semesters in 60 patients with IFX and 175 semesters in 33 patients with ADA were included. The mean IFX and ADA treatment duration were respectively 49 (±33) months and 38 (±19) months. Within patients treated with IFX, 32/60 patients received IFX + IS during the first semester. IFX was administered as monotherapy in 361/478 semesters (76%). Respectively 218/478 (46%) and 78/478 semesters (16%) with IFX required dose escalation and corticosteroids course. IFX + IS was associated with more semesters with failure (5% vs 3%, p = 0.02) and numerically more semesters with dose escalation (64% vs 28%, p = 0.06). There was no difference in corticosteroids use (p = 0.63). IS during the first semester was not associated with lower risk of IFX failure (p = 0.41) nor with a longer survival without IFX withdrawal (p = 0.20). Continuing the IS treatment beyond the first semester was not associated with fewer semesters with failure (p = 0.18). Within patients treated with ADA, 19/33 patients received IFX + IS during the first semester. ADA was administered as monotherapy in 93/175 semesters (53%). Respectively 84/175 (48%) and 42/175 (24%) semesters with ADA required dose escalation and corticosteroids course. ADA + IS was not associated with less semesters with failure (7% vs 5%, p = 0.58), less semesters with corticosteroids use (p = 0.63). More semesters with ADA + IS required ADA dose escalation (61% vs 30%, p = 0.01). IS during the first semester was not associated with lower risk of ADA failure (p = 0.84) nor with a longer survival without ADA withdrawal (p = 0.78). Continuing the IS treatment beyond the first semester was not associated with fewer semesters with failure (p = 0.20).

Conclusion: In this real-life experience, combination therapy of IFX or ADA with IS during the first semester or prolonged after the first semester was not associated with less dose escalations, steroid courses or treatment failures.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The objective of the present study was to evaluate the effectiveness and safety of adalimumab (ADA) in children with ulcerative colitis (UC) who experienced previous infliximab (IFX) failure or intolerance.

Aims & Methods: This retrospective study included all children with UC from a national pediatric registry who received ADA therapy. The primary endpoint was the rate of corticosteroid (CS) free remission (PUCAI < 10) at week 52. Secondary outcomes were: the rate of continuous clinical response and remission, primary non-response and loss of response at Weeks 12, 30, and 52 and rate of mucosal healing (MH) at week 52.

Results: A total of 32 children with UC received ADA (median age 10 ± 4 years). Median disease duration before ADA therapy was 27 months. All patients received previous IFX therapy (43% intolerant, 50% not-responders, 7% positive anti-IFX antibodies). Fifty-two weeks after ADA initiation 13 patients (41%) were in CS-free remission. MH occurred in 9 patients (28%) at 52 week. The cumulative probability of clinical relapse-free course was 69%, 59% and 53% at 12, 30 and 52 weeks, respectively. Ten patients (31%) had a primary failure and 5 (15%) loss of response to ADA. No significant differences in terms of efficacy were reported between not-responders and intolerant to IFX ($p = 1.0$). Overall, 19 patient (59%) maintained ADA therapy during 52-week follow-up. Seven patients (22%) experienced an adverse event. No serious side effects were observed and none resulted in ADA discontinuation.

Conclusion: In this cohort of children with UC ADA had a favorable short- and long-term efficacy, allowing to recover a significant percentage of patients intolerant or not-responding to IFX. The efficacy was not related to the cause of IFX discontinuation (intolerance/failure). Overall, the safety profile was good. Larger, prospective, controlled trial with longer follow-up should be suggested to better clarify the role of ADA in pediatric UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1068 LOW FODMAP DIET IMPROVE DISEASE ACTIVITY AND QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

Introduction: Inflammatory Bowel Diseases (IBD), Crohn Disease (CD) and Ulcerative Colitis (UC), are idiopathic autoimmune conditions whose pathogenesis is still unknown. It has been hypothesized that, in genetic predispose subjects, a deregulated immune response associated to an increase of intestinal permeability may lead to bowel damage and clinical manifestations. Thus, environmental

factors and, in particular, food intake may play a pivotal role in IBD pathogenesis.

Aims & Methods: The aim of this prospective study was to evaluate the effects of a 6-week low fermentable Oligosaccharides, disaccharides, monosaccharides and polyols (FODMAP) diet on disease activity and quality of life in patients with IBD. At first visit (T0), patients were clinically evaluated by a gastroenterologist and a nutritionist, filled a questionnaire on quality of life (the IBD-Q) and underwent blood tests as well as fecal calprotectin assessment. Disease activity was defined using the Mayo score and the Harvey Bradshaw Index (HBI) for UC and CD, respectively. After the baseline visit, patients were randomized into two groups: A) patients underwent a low FODMAP diet; B) patients underwent a diet with normal FODMAP amount. A food diary was used to assess patients' adherence to the different diets. After six weeks (T1), patients had a second visit to assess disease activity, complete the IBD-Q, and repeat blood tests as well as fecal calprotectin assessment.

Results: In this prospective, interventional, cohort study, we enrolled 55 consecutive IBD patients who agreed to participate from an initial cohort of 127 IBD patients. Twenty-six patients were randomised to a low FODMAP diet (group A), while 29 patients to a standard FODMAP diet (group B). Among CD patients ($n = 35$, 63.6%), median HBI values significantly decreased during the study, in the whole population and in group A, whereas no change was recorded in group B (respectively $P = 0.02$; $P = 0.02$; $P = 0.3$). Among UC patients ($n = 20$, 36.4%), median Mayo scores did not significantly decrease during the study, both considering the whole population and the two groups ($P = 0.3$, $P = 0.3$, and $P = 0.8$, respectively). Moreover, despite no statistically significant difference in quality of life in both groups at T0, in group A quality of life improved after the diet compared to group B (respectively, $P = 0.06$, $P = 0.05$ and $P = 1$).

Conclusion: We demonstrated that a low FODMAP diet, for a limited period of 6 weeks, is able to improve both disease activity, at least for CD, and quality of life in IBD patients. Further, larger multicentre studies are needed to confirm these preliminary data.

Introduction: Ustekinumab has shown a good safety profile and efficacy to induce and maintain remission in adult patients with refractory Crohn's Disease (CD). Data are lacking in children.

Aims & Methods: All CD patients under 18 years who received ustekinumab were included in this retrospective observational study performed in a single tertiary pediatric centre.

Results: See table.

Conclusion: Subcutaneous ustekinumab is effective to induce and maintain remission in severe pediatric CD refractory to anti-TNF antibodies.

Disclosure of Interest: All authors have declared no conflicts of interest.

From January 2015 to May 2016, twelve CD patients were treated with ustekinumab, all because of failure of several lines of therapies including anti-TNF antibodies. All but one patient were followed at least one year. An initial response was achieved in 9 (75%) patients, and remission in 5 (42%). At one year, the nine responders were still receiving ustekinumab with clinical benefit and without steroids need. Seven of them (58%) were on clinical remission. One patient experienced a serious adverse event and the treatment was stopped after the first injection.

P1070 TROUGH LEVELS TO INFLIXIMAB AT W6 ARE PREDICTIVE OF REMISSION AT W14, IN PEDIATRIC CROHN DISEASE

C. Martinez-Vinson, O. Courbette, C. Aupiais, J. Viala, J. Hugot
Gastroentérologie Pédiatrique, Hôpital Robert Debré, Paris/France

Contact E-mail Address: christine.martinez-vinson@aphp.fr

Introduction: Loss of response to anti-tumor necrosis factor (TNF) agents is a common clinical problem. 40% of patients lose response within 12 months of therapy initiation. This retrospective study aimed to analyse factors associated with remission after 14 weeks of induction treatment by IFX in children with CD.

Aims & Methods: All patients aged from 2 to 18 years old with CD meeting European Crohn's and Colitis Organisation criteria and treated for the first time by IFX between January 2002 and March 2014 at a single tertiary pediatric center were considered for inclusion in this retrospective study. The following baseline characteristics were anonymously recorded for each patient: gender, age at CD onset, age at inclusion, duration of disease, CD classification according to Paris classification, prior exposure to CD treatments, previous intestinal resections and reasons for anti-TNF initiation. At each infusion visit (week 0, 2, 6 and 14) disease activity was determined using Pediatric Crohn's disease Activity Index (PCDAI). Four blood samples were obtained for each patient (at W0, W2, W6 and W14). The following laboratory tests were recorded: ESR, CRP, hemoglobin, hematocrit, albumin, blood levels of lymphocytes, Trough levels to IFX (TR1) and antibodies to IFX (ATIs). Children were classified in three groups according to response at week 14: (1) remission was defined by a Crohn's Disease Activity Index under or equal to 10; (2) partial response was defined by a PCDAI decreased by more 12.5 points since inclusion without a remission as defined above; (3) absence of partial response or remission.

Results: We analyzed 107 patients with CD, with a total of 428 visits until W14. The principal reason to start infliximab was failure of immunosuppressive therapy (60%). Infliximab proved to be an effective treatment in our cohort since 75.7% (n = 81) patients were responders to infliximab and 40% (n = 42) were in clinical remission whereas 24.3% (n = 26) were non responders at W14. At week 14, 107 patients were divided in three groups related to the clinical activity of their disease: lack of clinical response, partial clinical response, clinical remission. It concerns respectively 26, 39 and 42 patients. Major baseline characteristics were not associated with clinical remission: sex, age at diagnosis, disease location, time between diagnosis and induction, age at induction. Drugs associated with infliximab at W0, W2, W6 or W14, whether it was immunosuppressive agents or corticoids were not associated with remission. Patients with low albumin levels had a worse response at induction Activity score at induction was also statistically associated with clinical remission: each decreasing of 10 points of activity score at induction increase of 0.48 times the risk to obtain clinical remission. Trough residual of infliximab > 8.5 µg/ml at w6 increase of 11.3 times the risk to obtain clinical remission at w14. Lack of growth retardation at induction increased of 3.98 times the risk to obtain clinical remission at w14.

Conclusion: Infliximab measurement in combination with evaluation of clinical severity (low body weight, growth retardation, hypoalbuminemia, severe disease) appears to be a reasonable strategy for predicting both short- and long-term treatment outcomes with IFX in the initial stage of treatment. Early detection of response to IFX is critical for the management of CD, especially in acute severe patients: it seems that the infliximab trough level at week 6 (more than 8.5) is predictive of a remission at week 14. Second, some patients, especially patients with low body weight, growth retardation, hypoalbuminemia and severe disease may require higher doses than standart doses.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1071 INFLIXIMAB INDUCED PSORIASIS IN A COHORT OF CHILDREN WITH INFLAMMATORY BOWEL DISEASE: A 12 YEARS FOLLOW-UP STUDY

C. Martinez-Vinson, O. Courbette, C. Aupiais, J. Viala, J. Hugot
Gastroentérologie Pédiatrique, Hôpital Robert Debré, Paris/France

Contact E-mail Address: christine.martinez-vinson@aphp.fr

Introduction: In adult Inflammatory bowel disease (IBD), skin adverse reactions have an estimated prevalence of 1.6 to 22%. This side effect occurs more frequently in patients treated with infliximab (IFX) for IBD. Data in the pediatric population are lacking so far.

Aims & Methods: All patients aged 2 to 18 years, with Crohn's disease (CD) or Ulcerative colitis (UC) and treated for the first time by IFX between January 2002 and March 2014, were considered for inclusion in this monocentric retrospective study.

Results: Baseline Patients: 115 patients were treated with IFX for CD and 23 for UC. IFX treatment was initiated at the age of 14, about 2 years after diagnosis. The indication for treatment was in 61.6% (n=85) resistance to conventional therapy, in 26.8% (n=37) a perianal fistulizing disease and in 11.6% (n=16) a severe colitis. At the first injection, the median PCDAI was 35 (25; 45) for CD and the median PUCAI 35 (25; 45) for UC. The duration of treatment with IFX ranged from 45 days to 8 years and median was 23.9 months (11.6; 36.5). Psoriasis: 20 patients (14% of the cohort) had an IFX-induced psoriasis. 70% of them (n=14) of patients were in remission when the psoriasis was diagnosed. Psoriasis was diagnosed at the 8th injection (6; 15), though 355 (239; 532) days after the start of biotherapy. 20% of patients had a combo therapy: 50% of them were treated by 6-mercaptopurine, 25% by azathioprine and 25% by methotrexate. The median IFX trough levels (TRI) when psoriasis occurred was 4.7 mcg/mL (1.8; 9.6) and 4.1 mcg/mL (2.1; 8.8) at the previous visit. Median Antibodies to IFX (ATI) rate was 0%. All were supported by local treatments. No patients discontinued biotherapy following the psoriasis. Personal or family history of psoriasis, and the smoking status have not been collected. We compared the population of patients with psoriasis (n=20) and without psoriasis (n=127) with an univariate model. All children in the psoriasis group were followed for a CD. There was more perineal location of CD in psoriasis group with a significant difference (p=0.033).

Conclusion: 14% of our IBD patients treated with IFX developed psoriasis during follow-up. All were CD, more frequently it occurred for CD with perineal lesions, at the 8th injection in median, with no ATI.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1072 PLATELET ABNORMALITIES AND ANEMIA IN PAEDIATRIC IBD: ARE THEY LINKED?

M. Votto¹, F. Viviano², F. Viola²

¹Pediatric, IRCCS Policlinico San Matteo, PAVIA/Italy

²Pediatric, E Neuropsichiatria Infantile, Università La Sapienza, Roma/Italy

Contact E-mail Address: martinavotto@gmail.com

Introduction: Crohn's Disease (CD) and Ulcerative Colitis (UC) are two major forms of Inflammatory Bowel Disease (IBD). In children with IBD anemia is common and is a combination of iron deficiency and anemia of chronic disease (ACD). IBD are associated with several alterations of platelets, including number, shape, and function¹. In clinical practice, the most common platelet alteration is thrombocytosis. In IBD, thrombocytosis is associated with iron deficiency anemia and chronic inflammation². The importance of platelet function is due to the substantially increased incidence of thromboembolic phenomena in IBD³.

Aims & Methods: The aim of the study is to demonstrate the link between anemia, thrombocytosis and platelet aggregation in pediatric IBD patients. This study includes 51 children and adolescents recruited from the Pediatric Gastroenterology Unit of Policlinico Umberto I in Rome. Patients younger 6 years, with inherited platelet defects, hemoglobinopathies, and receiving therapies that alter platelet function, are excluded. We collect disease activity scores (Pediatric Crohn's Disease Activity Index [PCDAI], Pediatric Ulcerative Colitis Activity Index [PUCAI]). The laboratory investigations include: complete blood count, mean corpuscular volume (MCV), mean platelet volume (MPV), mean corpuscular haemoglobin concentration (MCHC), levels of hemoglobin (Hb) and levels of serum ferritin (SF), transferrin and iron. Diagnostic criteria for anemia are based on ECCO guidelines. Platelet aggregation is evaluated on platelet-rich plasma in an AggRAM aggregometer with Born's Method. The results were reported as the maximal percentage of aggregation observed after 4 min stimulation in response to collagen (1 µg/mL) and adenosine diphosphate (ADP 0.8 µM and ADP 2 µM).

Results: The study include 51 children and adolescents, 24 with UC and 27 with CD (median age is 15.3 years ± 3.5). Iron deficiency anemia combined to ACD is the most common type (58.3% in UC and 50% in CD). Hemoglobin levels are significantly lower in patients with UC compared to CD patients (p=0.0320). No significant differences are observed between mean values of red cells, MCV, MCHC, RDW, iron, transferrin and serum ferritin both in CD and UC. Thrombocytosis prevails in UC compared to CD patients, but no significant correlation was found. No differences are observed between mean values of PDW and MPV in both groups. In patients with UC, a negative correlation was found between mean values of hemoglobin and platelet count (p=0.0134). Moreover in patients with CD, disease activity was positively correlated with platelet count (p=0.0040). Platelet aggregation results higher in anemic patients. In anemic children, mean baseline platelet aggregations - induced by ADP 0.8 µM and collagen 1 µg/mL - are significantly higher in UC compared to CD (p=0.001 and p=0.030 respectively). Another significant correlation is observed between platelet aggregation - induced by ADP 0.8 µM and ADP 2 µM - in anemic UC patients compared to non-anemic UC patients (p=0.002 and p=0.040 respectively). Platelet aggregation-induced by ADP 0.8 µM is significantly higher in anemic UC patients with active disease (PUCAI > 20) compared to same patients whose disease is in remission (p=0.042) and compared to patients with active CD (p=0.054).

Conclusion: In our cohort, mixed anemia (iron deficiency anemia combined to anemia of chronic disease) is the most common type of anemia. Thrombocytosis is a condition more frequent in anemic IBD patients, specially in UC. In UC, anemia and disease activity are significant correlated with platelet hyperaggregation. Therefore UC patients—specially with active disease and anemia—might present major risk of thrombosis, independently from acquired or inherited hemostasis defects.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1073 RELATIONSHIP BETWEEN CLINICAL COURSE OF ULCERATIVE COLITIS (UC) DURING PREGNANCY AND OUTCOMES OF PREGNANCY: A RETROSPECTIVE EVALUATION STUDY

A. Ito, O. Teppei, T. Katutishi

Dept. Medicine, Inst. Gastroenterology, Tokyuu Womens Medical University, Tokyo/Japan

Contact E-mail Address: itoayumi@ige.twmu.ac.jp

Introduction: Ulcerative colitis (UC) is a chronic, intractable disease with a long clinical course. UC has a marked influence on the lifestyle of patients, and its effects on pregnancy and childbirth can especially become a problem for women in their child-bearing years. Various studies have suggested that it is desirable for pregnant women with UC to give birth while remaining in a state of remission.

Aims & Methods: The present study evaluated pregnant women with UC attending our hospital who became pregnant during remission, in order to examine the factors that contributed to recurrence of UC during pregnancy. We investigated 40 pregnant patients in remission (44 cases) attending our hospital between January 2008 and July 2016 who had remained in remission for one year prior to pregnancy. After becoming pregnant while in remission, patients who stayed in remission until delivery were classified into the ongoing remission group (35 cases) and patients with recurrence during pregnancy were classified into the recurrence group (9 cases). Remission was defined as a Lichtiger clinical activity index (CAI) of less than 4. Relapse was defined as a CAI ≥ 5 with the need for initiation or dose escalation of steroids or administration of biological agents during pregnancy. Items examined: Clinical characteristics (age at onset, disease duration, age of becoming pregnant, disease type, and treatment), the CAI in the first, second, and third trimesters, and whether or not patients continued treatment during pregnancy were examined and compared between the two groups. The reasons for discontinuation of treatment were also investigated.

Results: There were significant differences between the two groups with respect to the age of becoming pregnant (32.9 ± 4.6 years in the ongoing remission group vs. 28.3 ± 7.0 years in the recurrence group), the CAI in the second trimester (2.9 ± 4.6 vs. 3.5 ± 1.6), the CAI in the third trimester (2.9 ± 0.7 vs. 5.4 ± 2.0), and whether oral treatment was continued (continuation of treatment [yes:no]; 30:5 in the ongoing remission group vs. 5:4 in the recurrence group). Regarding the discontinuation of oral treatment, two patients in the ongoing remission group and one patient in the recurrence group discontinued it on their own judgment, while two patients in the recurrence group discontinued it due to hyperemesis. Discussion: The present study revealed that factors influencing the recurrence of UC during pregnancy were the age of becoming pregnant and the continuation of oral treatment. Our results showed that younger women were more susceptible to recurrence. As expected, discontinuing oral treatment was a factor that contributed to recurrence. However, the reasons for discontinuing treatment during pregnancy differed from those for non-pregnant women. Some patients discontinued treatment on their own judgment because they were concerned about adverse effects on the fetus, while others had difficulty with continuing treatment due to hyperemesis. With regard to the effects of medications on the fetus, medical staff should provide an explanation about the safety of treatment and should be aware that patients may have various concerns about drug therapy. If patients have difficulty continuing oral treatment due to severe hyperemesis, administration of local therapy should be considered.

Conclusion: During pregnancy, it is important to continue treatment for UC so that patients can give birth while remaining in remission. Accordingly, intervention by medical staff is particularly necessary in order to provide pregnant women with information and explanations regarding treatment.

P1074 USE OF STEROIDS IN ADULTS AND ADOLESCENTS WITH INFLAMMATORY BOWEL DISEASE IN THE BIOLOGICS ERA

I. Parisi¹, L. Whitley¹, C. Murray², F. Kiparissi³, F. Rahman¹, S. Mehta¹, E. Seward¹, D. Graham¹, H. Kwok¹, S. Mcartney¹

Introduction: Corticosteroids have been effectively used for decades for the rapid induction of clinical remission in patients with Inflammatory Bowel Disease (IBD). However their adverse event profile is well-known, particularly with long-term use and in younger populations, and they have no role in maintenance of remission. Steroid-sparing agents and more recently biological therapy have reduced systemic steroid use but the true incidence of steroid prescriptions especially in the outpatient setting is not known.

Aims & Methods: The aim of this study was to capture real-life steroid use in both adult and adolescent populations older than 13 years old who attend a dedicated IBD clinic in a tertiary referral centre. We tried to identify risk factors associated with appropriate or excessive steroid use in the whole cohort and in the two subgroups separately. All consecutive IBD patients who were followed up for at least one year in the adult and adolescent clinic in UCLH and attended their IBD appointment during February and March 2017 were included in the study. A steroid assessment questionnaire was completed by the clinician during the visit for eligible patients. Use and type of steroids prescribed during the past year was recorded, as well as appropriate bone protection and disease activity based on Physician Global Assessment.

Results: 60 adolescents and 59 adults were included in the study. Two thirds of adolescents had Crohn's disease while in the adult population Crohn's and ulcerative colitis (UC) were equally distributed. 57 (95%) adolescents had been exposed to thiopurines and 47 (78%) to anti-TNFs as opposed to 69% ($p=0.002$) and 39% ($p<0.001$) of adults respectively. Vedolizumab exposure was similar in adults and adolescents. The percentage of patients with moderate to severe disease at last visit was comparable between two groups (18/60, 30% adolescents vs 18/59, 31% adults, $p=NS$). 27/119 (23%) of patients were offered steroids during the past year and the incidence was the same in the adult and adolescent populations. 4/27 (15%) received excessive steroids, ie >2 courses within the preceding 12 months. Of the 27, 17 (62%) had Prednisolone and the rest received Budesonide, while the choice of steroid was associated with a diagnosis of Crohn's disease and was not different between the two groups. One third of patients did not receive bone protection with the steroid prescription, however this was mainly observed with Budesonide rather than Prednisolone (7/10 vs 2/17, $p=0.003$). Steroid use overall was not associated with the age group or initial diagnosis but was expectedly associated with severity of disease (severe $>$ moderate $>$ mild, $p<0.001$). The use of thiopurines or anti-TNFs did not affect steroid prescriptions, but interestingly the majority of Vedolizumab users received steroids in contrast to Vedolizumab naïve patients (7/9, 78% vs 20/109, 18%, $p<0.001$). This association remained significant even after adjustment for disease severity and other co-factors, suggesting possibly the higher need for 'bridging' steroids due to the slow-acting effect of Vedolizumab therapy (binary logistic regression showed naïve to Vedolizumab patients were protected against steroid use, OR 0.043 CI 95% 0.005–0.382, $p=0.005$).

Conclusion: The use of steroids in an outpatient population with IBD is still common regardless of age group and use of anti-TNFs, as almost 1 in 4 patients received some type of oral steroid during a period of one year. Newer biologics, such as Vedolizumab, may predispose patients to higher steroid use, possibly due to slow induction of remission.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1075 REMISSION INDUCTION IN CORTICOSTEROID NAÏVE CHILDREN AND ADOLESCENTS WITH ULCERATIVE COLITIS BY ADSORPTIVE LEUCOCYTAPHERESIS AS MONOTHERAPY OR IN COMBINATION WITH A LOW DOSE PREDNISOLONE AFTER FAILURE OF FIRST-LINE MEDICATIONS

T. Tanaka¹, M. Akagi², T. Iiboshi², H. Goishi², T. Kajihara², A. R. Saniabadi³, T. Miura²

Introduction: In patients with active ulcerative colitis (UC), myeloid lineage leucocytes are known to be elevated with activation behaviour.¹ including the CD14+CD16+DR++ monocyte phenotype, which is a major source of tumour necrosis factor- α .² Therefore, selective depletion of myeloid leucocytes by adsorptive granulocyte/monocyte apheresis (GMA) with an Adacolumn is expected to promote remission, or enhance drug efficacy. Potentially, GMA should be a relevant treatment option in patients in whom drug therapy has limitations.

Aims & Methods: Our major objective was to apply GMA as remission induction therapy in paediatrics and adolescents UC setting when first-line 5-aminosalicylates had failed. Thirty consecutive patients with active ulcerative colitis (UC), age 11–19 years, body weight 33–55.5 kg were given mesalazine ($n=23$) or sulphasalazine ($n=7$) as the first-line medication. Twenty patients relapsed while receiving the first-line medications or did not respond, and received GMA with the Adacolumn, at 2 sessions in the first week, then weekly, up to 11 sessions. Patients who achieved ≥ 5 decrease in the clinical activity index (CAI) after 5

GMA sessions continued with GMA while non-responders received GMA in combination with a low dose prednisolone, 0.5 to 1.0 mg/kg bodyweight. At entry and week 12, patients were clinically and endoscopically evaluated with each patient serving as her or his own control.

Results: At entry, all 30 patients were corticosteroid naïve and none had deep colonic lesions or extensive loss of the mucosal tissue at the affected sites (GMA non-responder features). Ten patients achieved stable remission with the first-line medications and did not receive GMA. Six patients did not respond well to the first 5 GMA sessions and received prednisolone together with GMA, while 12 patients responded well to GMA, and achieved stable remission, but 2 patients withdrew to receive high dose prednisolone (up to 2 mg/kg bodyweight). At entry, the average CAI was 14 ± 0.4 . Prednisolone was tapered to 0 mg within 3 months in those who received. Therefore, at week 12, all 30 patients were in remission, majority with mucosal healing.

Conclusion: In this treatment design, GMA in young corticosteroid naïve patients with active UC refractory to the first-line 5-aminosalicylates was associated with clinical remission and mucosal healing, while in non-responders to GMA monotherapy, addition of a low dose prednisolone enhanced the efficacy of GMA and tapering of the prednisolone dose was not associated with relapse. Therefore, the majority of young steroid naïve UC patients who fail to respond to first-line 5-aminosalicylates should respond well to GMA and avoid pharmacologicals. Additionally, GMA has a good safety profile, which is a very favourable feature in growing patients.

P1076 EARLY SCREENING FOR INFLAMMATORY BOWEL DISEASE IN CHILDREN WITH AUTOIMMUNE LIVER DISEASE

D. Thangarajah, E. Cernat, B. Vadmalayan, D. Hadzic, M. Samyn
Paediatric Liver, GI And Nutrition Centre, King's College Hospital, London/
United Kingdom

Contact E-mail Address: anthiburt@gmail.com

Introduction: Autoimmune liver disease (AILD), in particular autoimmune sclerosing cholangitis (ASC) is associated with inflammatory bowel disease (IBD). Little is known about the effect of IBD on the outcome of AILD. Faecal calprotectin (FC), a stool biomarker, screens for bowel inflammation without the need for invasive endoscopic evaluation and is easy to collect.

Aims & Methods: The aim of this study was to review the investigations and outcomes of IBD and AILD in children with a primary diagnosis of AILD and to identify possible risk factors for development of IBD in children with AILD. Children with AILD were identified from electronic case notes between 2007 and 2010 and those with a diagnosis of IBD prior to AILD excluded. AILD was diagnosed and treated as per centre protocol. Diagnostic endoscopy for IBD was performed, based on GI symptoms and/or elevated FC (> 60 U/g). Data were documented at time of liver diagnosis; endoscopy and last liver follow up. Patients were classified as AILD-IBD or AILD. Mann Whitney and Chi squared test were used to analyse data where appropriate, significance $p < 0.05$.

Results: Out of 37 (12 male) children, diagnosed with AILD (ASC 11), 23 underwent diagnostic endoscopy after a median time from diagnosis of 27.6 [20.1 to 53.9] weeks. 20/23 reported GI symptoms and FC was elevated in 13/18 tested. At endoscopy 57% (13/23) a diagnosis of IBD (AILD-IBD group) (UC (n = 12), IBD-U (n = 1)) was made, 10/23 were within normal limits (AILD group). There was no difference in gender or diagnosis of ASC between the 2 groups. At presentation of AILD, children in the AILD-IBD group were significantly leaner in terms of weight and BMI, had lower haemoglobin, with a trend for younger age at presentation (table 1). GI symptoms and FC > 60 U/g were significantly more prevalent in the AILD-IBD group. At the time of endoscopy, 22 were on treatment for AILD with prednisolone and 13 with an additional agent (azathioprine or mycophenolate mofetil). Biochemical remission for AILD was achieved in 45% at endoscopy and in 74% at last liver follow-up (median 4.1 [3.5 to 5.0] years) with no difference for both groups. All patients are alive; however, in the AILD-IBD group 1 underwent an isolated liver transplantation (LT) and 1 required a subtotal colectomy. One girl underwent LT combined with subtotal colectomy after decompensation of her liver disease.

Table 1: Diagnostic parameters of AILD at presentation median [IQR]/*p value < 0.05

	AILD-IBD	AILD
n (male)	13(5)	10(3)
Age (years)	12.5 [10.3 to 14.6]	14.4[12.0 to 15.5]
ASC (n)	6	2
Weight (kg)	48.8 [38.8 to 55.9]	61.5 [52.9 to 75.4]*
Height (cm)	160.7 [152.3 to 168.0]	164.0 [154.4 to 168.8]
BMI (kg/m ²)	19.2 [18.2 to 20.2]	22.5 [19.5 to 27.3]*
Haemoglobin (g/l)	113.0 [90.5 to 122.0]	127.5 [118.5 to 146.5]*

(continued)

Table 1: Continued

	AILD-IBD	AILD
AST(IU/l)	235.0 [113.5 to 470.5]	461.0 [241.0 to 1039.0]
IgG (g/l)	25.3 [16.2 to 37.8]	25.1 [19.2 to 30.1]
Faecal calprotectin (U/g)	298.5 [114.5 to 439.8]	42.5 [34.6 to 66.3]*
GI symptoms (n)	12	8
Faecal protectun > 60 U/g (n/total)	11/12	2/6

Conclusion: In our cohort 35% of children presenting with AILD were subsequently diagnosed with IBD. Possible risk factors for development of IBD in AILD are low haemoglobin, being leaner and younger at diagnosis. An elevated FC and the presence of GI symptoms are useful to assess the need for diagnostic endoscopy when considering diagnosis of IBD in the context of AILD. As concurrent immunosuppression may mask mild symptoms and signs of IBD a lower threshold for endoscopy should be considered in these patients.

Italy

Contact E-mail Address: giuliodarcangelo87@gmail.com

Introduction: We aimed to identify early clinical and laboratory predictors of sustained clinical and endoscopic remission in children with Crohn's disease (CD) under infliximab (IFX).

Aims & Methods: Prospective study conducted in children with moderate-to-severe CD starting IFX treatment. All patients underwent endoscopy, weighted pediatric CD activity index (wPCDAI) assessment, C-reactive protein (CRP) at week 0 and 52. wPCDAI and CRP were also evaluated at 14 weeks. The primary outcome was to determine the ability of 14-week wPCDAI and CRP to predict steroid-free sustained remission and mucosal healing at 1 year. As a secondary outcome we sought to evaluate the concordance between wPCDAI and Simple Endoscopic Score for CD (SES-CD) at week 52.

Results: Forty-one children were enrolled (median age 13.5 ± 2.7 , females 41.5%). At 1 year, 21 (51%) and 16 (39%) were in clinical (wPCDAI < 12.5) and endoscopic (SES-CD < 3) remission, respectively. Fourteen-week wPCDAI didn't differ between patients who achieved both clinical and endoscopic remission at 1 year ($p = 0.21$ and $p = 0.35$, respectively). By using a multivariable logistic regression model, neither week-14 wPCDAI nor CRP were predictors of 1-year clinical ($p = 0.83$ and $p = 0.30$, respectively) and endoscopic remission ($p = 0.22$ and $p = 0.48$). wPCDAI resulted significantly correlated with 1-year SES-CD ($r = 0.38$, $p = 0.01$). The concordance between wPCDAI and SES-CD was excellent and good for severe disease and remission (kohen 0.87 and 0.76), moderate and absent for mild and moderate disease, respectively.

Conclusion: Based on our results, 14-week post induction wPCDAI and CRP are not predictors of 1-year sustained steroid-free clinical and endoscopic remission in children with CD under biologic therapy. Continuous wPCDAI shows a good correlation with SES-CD, particularly for patients in remission and with severe disease.

Contact E-mail Address: 15968807972@163.com

Introduction: Gastrointestinal angiodysplasia, either inherited or acquired, is an important and challenging cause of acute gastrointestinal haemorrhage, particularly in the elderly, sometimes refractory to treatment. Although multiple treatment modalities, both medical and surgical, are being used, there is no established medical treatment available for these patients. Thalidomide is a potent inhibitor of angiogenesis in experimental models. As angiodysplasias are a result of unregulated vessel growth, antiangiogenic treatment may inhibit growth of angiodysplasias. But its benefits and risks nevertheless remain unclear.

Aims & Methods: This retrospective study evaluates the efficacy, safety, and side-effect of thalidomide in the treatment of patients with refractory gastrointestinal bleeding from angiodysplasias. Patients with recurrent gastrointestinal bleeding of angiodysplasia who were from Hangzhou First people's Hospital from October 2012 to July 2015 were collected for this open and nonrandomized study. Thalidomide was started with 50 mg/day and then increased incrementally by 100 mg/day, if tolerated, and continued for 6 months. Adverse events, hemoglobin, blood chemistry, the changes of coagulation and blood transfusion were monitored during the treatment and for 6-months post-treatment.

Results: Twenty-one patients with chronic refractory angiodysplasia bleeding were recruited in this study, included 10 women, aged between 40–85; 11 cases of male, aged between 31–70. One patient with colic vascular malformation died of massive hemorrhage due to self withdrawal. Among the remaining 20 patients who were given thalidomide regularly for 6 months. (1). Eight patients come across constipation, sleepiness and dry mouth. There were no skin rashes, peripheral neuropathy and any other adverse reactions during the treatment. All side-effects resolved when thalidomide was discontinued. (2). The red blood cell after treatment ($3.76 \pm 0.56 \times 10^9/L$) compared with before treatment ($3.38 \pm 0.60 \times 10^9/L$); hemoglobin after treatment ($94.7 \pm 13.15 g/L$) compared with before treatment ($83.2 \pm 19.76 g/L$); HCT after treatment (0.32 ± 0.05) compared with before treatment (0.29 ± 0.06); the difference was statistically significant ($P < 0.05$). (3). The ALT after treatment ($32.9 \pm 18.5 U/L$) compared with before treatment ($30.6 \pm 12.8 U/L$); AST after treatment ($28.1 \pm 8.56 U/L$) compared with before treatment ($28.0 \pm 12.4 U/L$); γ -GT after treatment ($34.4 \pm 8.4 U/L$) compared with before ($35.6 \pm 12.7 U/L$); AKP after treatment ($85.5 \pm 19.8 U/L$) compared with before ($83.0 \pm 20.8 U/L$); ALB after treatment ($36.2 \pm 3.1 g/L$) compared with before ($36.3 \pm 4.3 g/L$); there was no statistically significant difference ($P > 0.05$). (4). Prothrombin time (PT) after treatment ($12.1 \pm 1.3 s$) compared with before ($11.8 \pm 1.4 s$); APTT after treatment ($30.2 \pm 3.7 s$), compared with before ($31.0 \pm 6.2 s$); the difference was not statistically significant ($P > 0.05$). (5). 6 cases of colonic capillary malformation review colonoscope, and the vascular malformation improved significantly after treatment.

Conclusion: Thalidomide, with its antiangiogenic mechanism of action, seems to be a promising drug in bleeding angiodysplasias as a treatment option for patients unable to benefit from other available modalities of treatment. the study drug was well tolerated.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colonic diverticular bleeding is the most common cause of lower gastrointestinal bleeding. We have reported the preliminary safety results of endoscopic detachable snare ligation (EDSL), a new method for diverticular hemorrhage¹. The bleeding diverticulum was ligated with a detachable snare. Unlike the endoscopic band ligation, removal of the scope to attach a ligation device and reinsertion for treatment are not needed in this method. We performed a clinical trial to evaluate the efficacy and safety of EDSL.

Aims & Methods: This multicenter single arm phase II study was conducted in 12 Japanese institutions. Patients suspected of diverticular bleeding were enrolled from June 2015 to March 2017. Patients with serious heart, renal, or liver failure, sepsis, disseminated intravascular coagulation, and high-dose steroid use (prednisolone dosage $> 10 mg/day$) were excluded. The primary endpoint was the early (within 1 month) rebleeding rate in patients who were treated with EDSL.

The secondary endpoints were overall early rebleeding rate in patients who had confirmed diverticular bleeding (intention to treat: ITT), success rate of EDSL, total procedure time, EDSL procedure time, identification rate of bleeding diverticula, and adverse events. This study was approved by the ethics committee of each participating hospital and conformed to the Helsinki Declaration and the Japanese Clinical Research Guidelines.

Results: Of 123 patients with diverticular hemorrhage, 101 were treated with EDSL and the early rebleeding rate was 5% (5/101). The rebleeding rate in ITT population was 9% (11/123). Success rate of EDSL was 78% (96/123). The median total procedure time and EDSL procedure time were 40 (15–150) and 4 (1–57) min, respectively. The identification rate of bleeding diverticula was 60% (123 in 205 enrolled patients). Two mild adverse events occurred; colonic diverticulitis cured with antibiotics and temporary abdominal pain during EDSL.

Conclusion: EDSL is an effective, safe, and convenient treatment method for colonic diverticular hemorrhage.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1080 RISK FACTORS FOR EARLY AND LATE RE-BLEEDING IN PATIENTS WITH COLONIC DIVERTICULAR BLEEDING

Y. Sato, H. Yasuda, S. Nakatsu, M. Yamashita, Y. Matsuo, H. Yamamoto, F. Itoh

Gastroenterology And Hepatology, St. Marianna Medical University, Kawasaki/Japan

Contact E-mail Address: y2satou@marianna-u.ac.jp

Introduction: Incidence of colonic diverticular bleeding has increased in recent years. Colonic diverticular bleeding is problematic because of the following reasons: the low detection rate of the bleeding source by endoscopy and frequent re-bleeding. At our hospital, we have a policy of performing emergency lower gastrointestinal endoscopy for all patients with colonic diverticular bleeding within 24 h of their admission. We have reported that the following factors can contribute to the successful identification of the bleeding source: extravasation revealed by abdominal contrast computed tomography (CT), and mounting of a hood to the tip of an endoscope during lower gastrointestinal endoscopy. However, risk factors for re-bleeding in patients with colonic diverticular bleeding were still unknown.

Aims & Methods: In this study, we examined the risk factors for early and late re-bleeding in patients with colonic diverticular bleeding. From January 2004 to April 2016, we admitted 432 patients (285 men and 147 women, mean age: 71 ± 13 years) to our hospital for treatment following a diagnosis of colonic diverticular bleeding based on abdominal CT and endoscopy findings. Early and late re-bleeding was defined as macroscopically bloody stools as a result of colonic diverticular bleeding during hospitalization and after discharge, respectively. Risk factors for early and late re-bleeding were retrospectively examined using univariate and multivariate analysis.

Results: Early re-bleeding occurred in 112 patients (26%; 86 men and 26 women, mean age: 71 ± 12 years). The mean duration until re-bleeding was 3.9 ± 2.4 days, and on average, early re-bleeding recurred 1.7 ± 1.2 times. On average, lower gastrointestinal endoscopy was performed 2.7 ± 1.2 times and endoscopic hemostatic treatment was performed 1.0 ± 1.0 times. In the univariate analysis, significant differences were seen in males ($P = 0.005$), in the use of oral antiplatelet agents ($P = 0.012$), and in patients not undergoing endoscopic hemostasis ($P = 0.004$). In the multivariate analysis, male gender ($P = 0.006$; odds ratio 2.06, 95%CI 1.23–3.44), the use of oral antiplatelet agents ($P = 0.008$; odds ratio 1.85, 95%CI 1.17–2.93), and patients not undergoing endoscopic hemostasis ($P = 0.005$; odds ratio 1.5, 95%CI 0.31–0.81) were independent risk factors for early re-bleeding. Late re-bleeding was seen in 72 of 345 patients who were able to follow up (21%; 46 men and 26 women, mean age: 73 ± 12 years). The mean duration until late re-bleeding was 41 ± 40 months, and on average, late re-bleeding recurred 1.5 ± 1.2 times. Only the use of oral antiplatelet agents ($P = 0.05$; odds ratio 1.72, 95%CI 0.98–2.98) was identified as an independent risk factor for late re-bleeding in the univariate and multivariate analysis.

Conclusion: Not undergoing endoscopic hemostasis and male gender were identified as risk factors for early re-bleeding, indicating the importance of choosing measures and hemostatic treatments to improve the detection rate of bleeding sources during endoscopy. The use of oral antiplatelet agents was a risk factor for both early and late re-bleeding, suggesting the need for patient management through multi-departmental cooperation.

Introduction: Acute lower gastrointestinal bleeding (ALGIB) constitutes an important gastroenterological emergency. A new score (NOBLADS) that intends to determine the risk of severe ALGIB was recently developed. We aimed to assess the validity of this score in a cohort of patients with ALGIB.

Aims & Methods: Retrospective study. Emergency consecutive admissions for ALGIB were reviewed. Severe ALGIB was defined as transfusion of ≥ 2 units of packed red blood cells (PRBC) and/or hematocrit decrease of $\geq 20\%$ within the first 24 h and/or recurrent bleeding after 24 h of stability. NOBLADS score was calculated and its discriminative capacity for severe ALGIB as well as for other outcomes was assessed.

Results: Included 118 patients with a mean age of 73 ± 14.4 years and 52.5% males. Most frequent etiologies for ALGIB were diverticular bleeding (23.7%) and post-polypectomy (21.2%). ALGIB was severe in 38.1% of patients. NOBLADS score showed a weak discriminative capacity to determine severe ALGIB (AUC=0.68, $p < 0.01$). However, when comparing patients with NOBLADS < 4 and ≥ 4 , patients with higher scores were significantly older (69.2 ± 15.7 years vs 78.6 ± 10.0 years, $p < 0.01$), had lower hemoglobin levels at admission (11.8 ± 2.6 g/dL vs 10.2 ± 2.5 g/dL, $p < 0.01$), were transfused with more units of PRBCs during the first 24 hours and during hospital in-stay (0.4 ± 0.9 vs 1.1 ± 1.3 , $p < 0.01$ and 1.0 ± 2.2 vs 3.0 ± 3.3 , $p < 0.01$, respectively) and were more frequently admitted to intermediate care units (35.2% vs 59.6%, $p < 0.01$). No differences were found between the two groups regarding in-stay length, rebleeding rate, need for surgery or death.

Conclusion: NOBLADS score showed a weak discriminative capacity to determine severe ALGIB however, patients with NOBLADS ≥ 4 had greater PRBCs transfusion need and were more frequently admitted to intermediate care units. New or improved scores that can predict severe ALGIB are needed to determine more precisely appropriate care and to allow for a standardized approach.

Introduction: In Japan, CRC screening was launched as a national policy for all people aged over 40 years in 1992. 2-day FIT has been widely accepted, and has been recommended performing in every year.

Aims & Methods: The aim of this study is to verify the validity of an annual 2-day FIT. This analysis was performed by the OC-SENSOR DIANA (EIKEN, JAPAN) automated analyzer with cut-off value of $20 \mu\text{g Hb/g stool}$. Between 2011 and 2014, 957 CRCS and 12,290 polyps were detected. 957 CRCS were analyzed by screening history about sizes and Dukes' stage. The person who had undergone 2-day FIT 1 year before was defined as repeated group. And hadn't undergone more than 5 years before was defined as first-time group.

Results: The number of FIT positive participants was 9,370 for the first time group and 25,595 for the repeated group. With regard to CRCS and benign polyps, 457 CRCS and 3,010 benign polyps were detected for the first time group, and 500 CRCS and 9,280 benign polyps were detected for the repeated screening group. The positive predictive value (PPV) for CRCS was higher by the first time group than by the repeated group. The PPV for benign polyps was higher by the repeated group than by the first time group. 393 cases in the first time group and 438 cases in the repeated group were reported for sizes. In the first time group, 231 cases were 1–24 mm, 110 cases were 25–49 mm, and 52 cases were over 50 mm. In the repeated group, 288 cases were 1–24 mm, 117 were 25–49 mm, and 33 cases were over 50 mm. The size of detected cancers by the repeated group was significantly smaller than by the first time group. In the first time group, 187 cases were intra-mucosal Dukes A, 109 cases were Dukes A, 65 cases were Dukes B, 61 cases were Dukes C, 21 cases were Dukes D. In the repeated group, 258 cases were intra-mucosal Dukes A, 127 cases were Dukes A, 36 cases were Dukes B, 54 cases were Dukes C, and 7 cases were Dukes D. As a result, Dukes' stage was higher in the first group, and was lower in the repeated group.

Table 1: Dukes

	Intra-mucosal A	A	B	C	D	Unknown
First-time group (40.9%)	187	109 (23.9%)	65 (14.2%)	61 (13.3%)	21 (4.6%)	14 (3.1%)
Repeated group (51.7%)	258	127 (25.5%)	36 (7.2%)	54 (10.8%)	7 (1.4%)	16 (1.5%)
P value	0.0008	0.5666	0.0004	0.2304	0.0035	0.6477

Conclusion: Repeated FIT screening might be more efficient to detect benign polyps, smaller CRCS, and CRCS of intra-mucosal Dukes A. We'll go on researching CRCS locations about screening history.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1083 ANALYSIS OF THE CONCENTRATION OF FIT FOR COLORECTAL CANCERS FROM THE SCREENING (2000–2014) IN IBARAKI, JAPAN

Y. Saitoh, I. Hyodo, H. Suzuki, M. Kaneko

Dept. of Gastroenterology, Ibarakiken Medical Center, Ibaraki, Japan, Mito/Japan

Contact E-mail Address: saitoitsyo@yahoo.co.jp

Introduction: In Japan, CRC screening has been launched as a national policy for all people aged over 40 years since 1992. 2-day FIT has been widely accepted, and has been recommended performing in every year. It is demanded that CRC screening is performed effectively depending on the capacity of colonoscopies. We will show so much data on fecal hemoglobin concentration (referred as concentration) and progress of colorectal cancer among them.

Aims & Methods: The aim of this study is to analyze the concentration of FIT for colorectal cancers (CRCS) from the screening. The cut off value is adapted $20 \mu\text{g Hb/g stool}$ and the rate of further examination is around 75% for many years. In Ibaraki prefecture, CRCS were detected 3,421 cases from the screening (2000–2014) with 2-day FIT. The concentration of FIT was grouped in 20–80, 80–140, 140–200 and over $200 \mu\text{g Hb/g stool}$. Screening have been performed with the OC-SENSOR DIANA (EIKEN, JAPAN) automated analyzer. CRCS were analyzed with age group (40–49, 50–59, 60–69, over 70 year-old), size (1–24, 25–49, over 50 mm), location (proximal, distal), Dukes' classification (Dukes A-m, A-invasive, B, C, D) depending on the concentration. The chi-squared test was used to compare of each group.

Results: There was no difference in gender and age group for concentration. The concentration of CRCS in the distal colon was significantly higher in the proximal colon [distal 39% (861/2,200) and proximal 32% (337/1,053) with over $200 \mu\text{g Hb/g stool}$]. The concentration of CRCS with larger size was significantly higher than smaller size [1–24 mm 27% (533/1,961), 25–49 mm 54% (439/818) and over 50 mm 64% (169/263) with over $200 \mu\text{g Hb/g stool}$]. The concentration of invasive CRCS was significantly higher than intra-mucosal CRCS [intra-mucosal 23% (370/1,617) and invasive 50% (888/1,793) with over $200 \mu\text{g Hb/g stool}$]. The concentration of Dukes B, C and D were significantly higher than Dukes A except for intra-mucosal. There was no difference between Dukes B and D [Dukes A except for intra-mucosal 36% (325/910), B 68% (247/363), C 60% (232/385) and D 69% (61/89) with over $200 \mu\text{g Hb/g stool}$].

Table 1: Fecal Hb concentration and progress of colorectal cancer

	Age					Size(mm)		Location			Dukes				
conc. (µg/g)	40–49	50–59	60–69	70–	1–24	25–49	50–	proximal	distal	A-m	A	B	C	D	
20–80	48	190	588	605	993	224	53	495	871	885	375	61	82	15	
80–140	14	51	185	199	268	107	16	146	286	230	140	32	38	6	
140–200	17	33	117	100	167	48	25	75	182	132	70	23	33	7	
200–	55	177	529	497	533	439	169	337	861	370	325	247	232	61	
total	134	451	1,419	1,401	1,961	818	264	1,053	2,200	1,617	910	363	385	89	

Conclusion: In 20–80 $\mu\text{g Hb/g stool}$, there were CRCS with smaller size, no invasion, in the proximal colon, Dukes A except for intra mucosal CRCS and so on. When the cut off value is raised over $80 \mu\text{g Hb/g stool}$, the detection of early stage CRCS and proximal CRCS may be lost. There were many advanced CRCS with concentration over $200 \mu\text{g Hb/g stool}$. Therefore, when the participants, who are positive with high concentration of FIT, need to take a further examination as soon as possible. Why concentration of CRCS in the distal colon were higher than in the proximal colon? It may be related to the fact that the number of detectable CRCS in the distal colon are more than in the proximal colon. We will go on researching mechanism about this.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Hodgkin lymphoma (HL) survivors treated with abdominal radiotherapy and/or alkylating chemotherapy have an increased risk of colorectal cancer. This study evaluated the prevalence of colorectal neoplasia in HL survivors.

Aims & Methods: The primary aim of this multicenter cohort study was to assess the diagnostic yield of advanced colorectal neoplasia detected by a first surveillance colonoscopy among HL survivors treated with abdominal radiotherapy and/or procarbazine. Advanced colorectal neoplasia was defined as an advanced adenoma (high-grade dysplasia, $\geq 25\%$ villous component, or ≥ 10 mm diameter), an advanced serrated lesion (dysplasia or ≥ 10 mm diameter), or CRC. Results were compared with a Dutch general population cohort that underwent a primary screening colonoscopy ($n = 1276$ asymptomatic individuals between 50–75 years of age). This study demonstrates the results of a predefined interim analysis.

Results: A colonoscopy was performed in 101 HL survivors, who were significantly younger than general population controls (median 51 years (interquartile range 45–57) vs. 60 years (interquartile range 55–65), $p < 0.001$). A mean of 3.5 neoplastic lesions was detected per HL survivor (standard deviation 4.9) vs. 1.1 per control (standard deviation 1.8, $p < 0.001$). Despite their young age, the prevalence of advanced neoplasia was higher in HL survivors than in controls (25% (95% confidence interval 16–33%) vs. 12% (10–14%), $p < 0.001$). Advanced adenomas were detected in 14% (8–21%) of HL survivors and 9% of controls (7–10%, $p = 0.08$). The prevalence of advanced serrated lesions was higher in HL survivors than in controls (12% (6–18%) vs. 4% (3–5%), $p < 0.001$). Serrated polyposis syndrome was present in 6% (2–11%) of HL survivors and absent in controls ($p < 0.001$).

Conclusion: HL survivors treated with abdominal radiotherapy and/or procarbazine have a high prevalence of advanced colorectal neoplasia. Colonoscopy surveillance should therefore be implemented as standard of care.

²Department Of Biostatistics, The Catholic University of Korea, Seoul/Korea, Republic of

Contact E-mail Address: sincere24@naver.com

Introduction: Colorectal cancer is one of the most common cancers diagnosed worldwide, and prostate cancer is also the most common malignancy in men and a major cause of cancer deaths. Both colorectal cancer and prostate cancer also tend to occur more frequently in developed countries. There have been several reports on the association between colorectal cancer and prostate cancer, but the conclusions are inconsistent.

Aims & Methods: We aim to investigate the incidence of prostate cancer as a second primary malignancy among patients with prior primary colorectal cancer (CRC) using a nationwide population-based dataset. This study is a nationwide population-based retrospective cohort study. We followed up with patients

registered in the Republic of Korea National Health Insurance Corporation who were diagnosed with colon cancer between 2007 and 2014 and investigated the incidence of prostate cancer (one year lag period). The incidence of prostate cancer was also evaluated in age and gender-matched controls using a cohort of patients diagnosed with colorectal cancer during the same period. The incidence rate (IR) was defined as the number of newly diagnosed prostate cancer patients per 1000 person-years. To assess the role of detection bias-related to the follow-up of CRC, follow-up started at the date of CRC diagnosis and continued until the earliest date of prostate cancer diagnosis, death, loss to follow-up, or the 2015 year-end. We used Cox proportional hazards models to identify prostate cancer occurrences among CRC patients. We also performed the multivariable analysis. Multivariable models included the variables of age, sex, body mass index, hypertension, diabetes mellitus, dyslipidemia, and income.

Results: We analyzed a total of 85,462 first primary CRC survivors. During the follow-up period of 494,222 person-years, 2005 (2.3%) developed prostate cancer (incidence rate 4.06/1,000 person-years). The median duration of follow-up was 5.78 years. Compared with the general population, CRC patients had a significantly increased risk of secondary prostate cancer (HR = 2.30, 95% CI = 2.182–2.426; $P < 0.001$). Multivariate analysis (including age, sex, body mass index, hypertension, diabetes mellitus, dyslipidemia, and income) showed that age < 55 years (HR = 20.85, 95% CI = 11.88–36.59; $P < 0.001$) is a significant independent predictor of prostate cancer development.

Conclusion: Men who develop colorectal cancer are at an increased risk of prostate cancer, with the greatest risk in men under the age of 55. This data suggests that CRC patients under 55 years old require regular screening for prostate cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1086 SITE AND STAGE DISTRIBUTION OF SCREEN DETECTED AND CLINICALLY DETECTED COLORECTAL CANCERS IN THE NETHERLANDS

E. Toes-Zoutendijk¹, A. Kooyker¹, M. A. Elferink², V. Lemmens²,

M. E. Van Leerdam³, I. Lansdorp-Vogelaar⁴

Introduction: To reduce the burden of colorectal cancer (CRC) mortality, screening has been introduced. Screening can be beneficial if cancers are detected in an earlier stage or in a pre-malignant stage, as survival rates of these patients will improve.

Aims & Methods: In this study stage distribution of screen detected CRCs were compared with clinically detected CRCs in the Netherlands. All CRCs detected in men and women aged 55 to 75 years in the Netherlands in 2015 were included in the analysis. Data were gathered from the Dutch Cancer Registry. The current analysis is based on 70% of these cancers that had staging information available at initial data retrieval. Data will be updated in May 2017. Proportions of site and stage distribution of screen detected and clinically detected CRCs were compared.

Results: A total of 6,517 CRCs in 2015 with staging information were available for the preliminary analysis. Of those, 2,591 (39.8%) were diagnosed as a result of CRC screening (screen detected), 3,463 (53.1%) presented with symptoms (clinically detected), 118 (1.8%) were detected during surveillance colonoscopy, 202 (3.1%) as coincidental finding and of 143 (2.2%) the method of detection was unknown. Screen detected cancers were more often diagnosed in an earlier stage (stage I and II) compared with clinically detected cancers, 1,687 (66.5%) and 1,355 (39.6%) respectively ($p < 0.001$). Screen detected cancers were more often diagnosed in the left side of the colon compared with clinically detected cancers, 46.2% vs 31.5% ($p < 0.001$). Comparison of stage distribution by location showed that left sided cancers were most often diagnosed in an early disease stage with 59.0% of the CRCs in stage I or II, followed by the right sided cancers with 52.8% of the CRCs in stage I or II. The CRCs of the rectum were most often diagnosed in a late disease stage, only 39.4% in stage I or II. Table 1 shows the comparison of stage distribution by location and method of detection. With screening, 68.8% of the right sided cancers, 71.0% of the left sided cancers, and 56.5% of the rectum CRCs were diagnosed in an early disease stage (stage I and II) which was all higher than clinically detected cancers ($p < 0.001$).

Table 1: Stage distribution of screen detected and clinically detected colorectal cancers by location and method of detection

	Screen detected			Clinically detected		
	Right sided	Left sided	Rectum	Right sided	Left sided	Rectum
Stage	n (%)	n (%)	n (%)	n (%)	n (%)	n (%)
I	254 (38.3%)	637 (54.5%)	316 (45.7%)	147 (12.2%)	217 (20.2%)	188 (17.0%)
II	203 (30.6%)	193 (16.5%)	75 (10.8%)	381 (31.7%)	277 (25.7%)	130 (11.8%)
III	166 (25.0%)	262 (22.4%)	257 (37.1%)	344 (28.6%)	310 (28.8%)	543 (49.1%)
IV	41 (6.2%)	77 (6.6%)	44 (6.4%)	329 (27.4%)	272 (25.3%)	245 (22.2%)

Conclusion: Screen detected CRCs show a more favourable stage distribution compared with clinically detected cancers, with two third of the cancers

diagnosed in stage I or II. As those patients will have better survival rates, it is expected that screening will decrease CRC mortality rates.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1087 LOCATION AND SEX PREDOMINANCE OF MISMATCH REPAIR DEFICIENT COLORECTAL CANCER IN IVORY COAST DIFFER FROM ITS EUROPEAN COUNTERPART

L. Bienfait¹, B. Doukoure², N. D'Haene¹, I. Salmon¹, P. Demetter¹, L. Verset¹

¹Department Of Pathology, Erasme Hospital, Université Libre de Bruxelles, ULB, Brussels/Belgium

²Pathology, Université Félix Houphouët-Boigny, Abidjan/Côte d'Ivoire

Contact E-mail Address: lucie.bienfait@erasme.ulb.ac.be

Introduction: According to European and American series,^{1,2} up to 20% of colorectal cancers are characterised by instability at microsatellite sites and have deleterious mutations in mismatch repair (MMR) genes (MLH1, MSH2, MSH6 and PMS2) or hypermethylation of the MLH1 promoter gene. MMR deficient colorectal cancers are predominantly found in the right colon. Although an increasing rate of colorectal cancer has been observed in many low- and middle-income countries including in West-Africa,³ data on epidemiology and biology of colorectal cancer in native Africans from this region are scarce.

Aims & Methods: We aimed to study the incidence of MMR deficiency in Ivory Coast and to compare the data with those from a tertiary center in Belgium. Immunohistochemistry for MLH-1, MSH-2, MSH-6 and PMS-2 was performed on paraffin-embedded tissue samples from 83 colorectal cancers (54% males) operated in Abidjan and from 343 colorectal cancers (48% males) from the Erasme University Hospital in Brussels. Immunohistochemical staining was interpreted as normal or loss of expression.

Results: Colorectal cancer is occurring at a younger age in Ivory Coast compared to Belgium (median age: 53 vs. 66). In both populations, MMR deficiency was detected in 13% of cases (11 and 43 cases, respectively). Whereas MMR deficient cancers in Brussels were mainly found in women (26/43 i.e. 61%), only 3/11 (27%) of the MMR deficient cancers from the Abidjan series occurred in female patients. Moreover, the predominant location of MMR deficient tumours was different between both series: in the Brussels patients group, MMR deficient tumours were mainly located in the right colon (33/43 i.e. 77%) whereas in the Abidjan group they were predominant (10/11 i.e. 91%) in the left colon. With regard to the involved proteins, 6/11 (55%) of the MMR deficient cases from Ivory Coast were characterised by loss of expression of MSH2 and MSH6 whereas this immunohistochemical staining pattern was observed in only 9/43 (20%) cases from Belgium.

Conclusion: Our pilot study reveals marked differences in presentation of MMR deficient colorectal cancer between the two geographic regions. In contrast to Europe, MMR deficient colorectal cancer in Ivory Coast is mainly found in male patients and in the left colon. Moreover, there are differences with regard to the involved mismatch repair proteins. Together with the younger age at presentation, these data suggest differences in epidemiology and biology of colorectal cancer in native Africans from West Africa compared to the European population.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Lynch syndrome (LS) is the most common hereditary cause of colorectal cancer (CRC). Identifying LS carriers and their affected family members is of great importance for prevention of CRC. Routine screening for LS by immunohistochemical staining (IHC) in CRC patients ≤ 70 years of age is recommended. LS screening in adenoma patients could yield more benefit, since CRC can still be prevented in these patients. A small number of participants of the national CRC screening program is expected to have LS. We aimed to assess the diagnostic yield of IHC for LS in patients with advanced and multiple adenomas

or CRC within the Dutch national fecal immunochemical test (FIT)-based CRC screening program.

Aims & Methods: We included participants of the national CRC screening program, referred to our center after a positive FIT from December 2013 to December 2016. IHC for MLH1, MSH2, MSH6 and PMS2 protein was performed on advanced adenomas and CRCs found at colonoscopy. Adenomas were considered advanced if they had a villous component, high-grade dysplasia or were ≥ 10 mm in size. Also, in cases with ≥ 4 non-advanced adenomas, IHC was performed on the largest adenoma. MLH1 hypermethylation analysis was used to distinguish sporadic MLH1 deficiency from MLH1 deficiency suspect for LS. Patients with IHC suspect for LS were offered germline mutation analysis. If no pathogenic mutation was found, we performed somatic mutation analysis.

Results: A total of 1006 patients (54% male; mean age of 67 years (± 6 years)) with positive FIT were included in the study. At colonoscopy, 352 (35%) patients (63% male; mean age of 67 years (± 6 years)) had a CRC and/or adenoma eligible for IHC. A total of 322 adenoma patients were analyzed. None had aberrant IHC. Of the examined adenomas, 151 (47%) had a villous component and/or high grade dysplasia (132 (41%) with villous component and 37 (11%) with high grade dysplasia). Out of 48 CRC patients, 7 (15%) showed loss of protein expression. All seven cases had loss of MLH1 and PMS2 protein. Five cases had MLH1 promoter hypermethylation. The two patients without MLH1 promoter hypermethylation were referred for genetic counselling. Both patients had no family history suspect for LS. In both cases no germline MLH1 mutation was found and somatic mutation analysis showed that both had a likely sporadic tumor.

Conclusion: Our results indicate that routine LS screening by IHC and MLH1 hypermethylation in patients with advanced and multiple adenoma within a national FIT-based screening CRC program is not an effective strategy. The diagnostic yield of LS screening in younger adenoma patients should be assessed. Also, our results imply that MLH1 promoter hypermethylation may be a late event in oncogenesis, since none of the adenomas had aberrant IHC.

Contact E-mail Address: d.caroli@libero.it

Introduction: Colorectal cancer (CRC) is a leading cause of cancer mortality in the Veneto Region (North-eastern part of Italy). Population screening of adults between 50 and 75 for CRC was begun in 2002, and it became standard practice in all 21 local health units (LHU) of the region in 2008, 14 LHU provided also follow-up colonoscopies and 7 LHU no. The current retrospective cohort study was carried out to evaluate the impact of CRC screening on the rate of surgical oncology procedures to treat colon and rectal cancer.

Aims & Methods: Data from hospital discharge records (HDR) regarding CRC patients hospitalized between 2000 and 2015 were collected. All CRC patients whose principal diagnosis was colon and/or rectal cancer were included in the study. The number of patients studied rose approximately 18% reaching 1,547,097 for the last year (2015). The Standardized Hospitalization Ratio (SHR) using five-year age groupings was calculated and expressed per 10,000 population.

Results: During the study period, 30,399 surgical procedures for colorectal cancer were performed (colon 63%, rectum 36%, secondary malignant neoplasm 1%) with a SHR of 139.1; the number was higher in males (1.69 vs. 1.02; OR: 1.66; CI 95%: 1.62–1.7; $p < 0.05$). An analysis of the annual SHR distribution uncovered two distinct phases: during the first phase there was a rising tendency that reached a maximum value in 2007 (166.9; X2 trend: 46.731; $p < 0.05$) and during the second there was a falling tendency that reached its minimum value in 2015 (102.3; X2 trend: 429.791; $p < 0.05$). When the cancer sites were analyzed, it was seen that despite the peak in 2007, the rate of surgical procedures of the proximal colon during the last year was the same as the 2000 value (41.5); there was, instead, a relevant decrease in the rate of procedures on the distal colon and rectum which fell from 94.4 to 59.2 (–37.3%). The study also shows that there was no significant difference in the reduction in surgical procedures for CCR in LHU in which the screening program included a follow-up colonoscopy (SHR 2015: 139.8; –29%) with respect to those centers where it was not foreseen (SHR 2015: 138.5; –28%).

Conclusion: Study findings confirmed that CRC screening was effective in reducing the number of oncological surgical oncology procedures particularly with regard to the distal colon and rectum. Data analysis showed that the screening seemed to accelerate reaching the peak rate in surgical procedures that took place in 2007. After that time point the number of operations began to fall as far as the distal colon was concerned (it fell by 37.3%). Finally our data suggest that the real benefit in reduction of oncological surgery procedures is due to the first screening colonoscopy.

P1090 ETHNIC VARIATION IN ADENOMA DETECTION IN THE UK FLEXIBLE SIGMOIDOSCOPY BOWEL CANCER SCREENING PROGRAMME

D. N.F. Lim, S. Mellor, S. Szarvas-Jones, D. Bools, H. Whitsey, B. Miri, A. Mapiye, P. Wurm, R. J. Robinson
Digestive Diseases Centre, University Hospital of Leicester NHS Trust, Leicester/United Kingdom

Contact E-mail Address: dennis.lim@uhl-tr.nhs.uk

Introduction: The NHS bowel scope screening programme was introduced in 2013 with all adults aged 55 invited for a 'one-off' flexible sigmoidoscopy followed by a colonoscopy if significant adenomas are detected. University Hospitals of Leicester Bowel Cancer Screening Centre serves an ethnically diverse community with approximately 25% of the population eligible for sigmoidoscopy screening being British Asian Indians and 45% being British Whites¹. Within the faecal occult blood based bowel cancer screening programme we have previously reported a lower polyp detection rate (PDR) and adenoma detection rate (ADR) in Asians undergoing colonoscopy compared to White British². This study aims to evaluate PDR, ADR and cancer detection (CDR) in British Asian Indians taking part in the bowel scope screening programme.

Aims & Methods: Patients who underwent screening sigmoidoscopy between February 1st 2015 to 28th Feb 2017 were included. All individuals participating in screening sigmoidoscopy routinely report their self-selected ethnic origin. This database was cross referenced with the endoscopic and histology findings from the 'Exeter' online database. The findings in British Asian Indians were compared with British Whites.

Results: A total of 4287 patients underwent screening sigmoidoscopy over the 2-year period. 1169 individuals had polyps (500 adenomas). Overall polyp detection rate (PDR) was 1169/4287 (27.3%), adenoma detection rate (ADR) was 500/4287 (11.7%), hyperplastic polyps were 642/4287 (15%), sessile serrated lesions were 13/4287 (0.3%), and other polyps were 14/4287 (0.3%) (Inflammatory polyps 13, Juvenile polyp 1). Cancer detection rate was 6/4287 (0.14%). During the period studied, 3509 British white individuals (82%) and 778 British Asian Indians screened. Six cancers were detected in British white (CDR = 0.17%) but none in British Asian Indians.

	British White	British Asian Indians	P value
PDR	30.8% (95% CI 26.7–34.9%)	11.4% (95% CI 10.1–12.4%)	<0.001
ADR	12.0% (95% CI 8.0–16.0%)	9.0% (95% CI 6.7–11.2%)	<0.01
Conversion to colonoscopy	4.0% (95% CI 2.8–5.2%)	1.8% (95% CI 0.9–3.2%)	<0.001

Conclusion: This study found no cancers and significantly lower PDR and ADR in British Asian Indians compared to British White participants in the bowel scope screening programme. Further long term evaluation of these differences is needed and may shed light on factors contributing to the development of bowel cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: We identified for the first time that DDX27 (DEAD box polypeptide 27) gene was amplified in colorectal cancer (CRC) by whole genome sequencing. Amplification of DDX27 was detected in 47% (47/100) of primary CRC tumors and positively correlated with its mRNA overexpression. DDX27 plays a pivotal oncogenic role in colorectal carcinogenesis by promoting cell proliferation and inhibiting apoptosis. In this study, we investigate its function, mechanism of action and clinical implication in CRC.

Aims & Methods: Downstream effectors and pathways of DDX27 were identified by promoter luciferase reporter assay, RT² Profiler PCR array and western blot. The interacting partners of DDX27 were screened by BioID method and further validated using immunoprecipitation assay and immunofluorescence staining method. Clinical implication of DDX27 was assessed in two human CRC cohorts by quantitative PCR method and immunohistochemical staining of tissue microarrays.

Results: Promoter luciferase reporter assays revealed that DDX27 mainly activated nuclear factor kappa B (NF-κB) pathway in CRC cell lines (HCT116 and SW480). Ectopic expression of DDX27 promoted transcription of NF-κB signaling targets including BCL2A1, BIRC3, CCL20, CXCL3, NFKBIA, TNF and TNFAIP3. Conversely, silencing of DDX27 showed an opposite effect on NF-κB signaling. Treatment of NF-κB inhibitors CAPE and JSH-23 abrogated the promoting effect of DDX27 on CRC cells growth. We revealed that DDX27 enhanced and prolonged NF-κB signaling via reducing the accumulation of nuclear IκBα, which negatively regulates transcriptional activities of NF-κB and transport NF-κB proteins back to the cytoplasm. DDX27 overexpression markedly increased the recruitment of NF-κB p65 inside nuclear and promoted NF-κB activity in CRC cells under TNF-α stimulation. NPM1 was identified as a potential binding partner of DDX27 by BioID method to screen for protein-protein interactions. The interaction of NPM1 and DDX27 inside nucleus was further validated by endogenous immunoprecipitation assay and immunofluorescence staining. Knockdown of NPM1 abrogated DDX27-activating NF-κB signaling, as well as its tumor-promoting function. Kaplan-Meier curves showed that higher DDX27 expression was significantly associated with shortened survival in patients with CRC of two independent cohorts (N=199 for Beijing cohort using quantitative PCR method, and N=275 for Shanghai cohort using immunohistochemical staining of tissue microarrays; both P < 0.05).

Conclusion: DDX27 plays an important oncogenic role in promoting CRC tumorigenicity via activation of NF-κB pathway. Higher expression of DDX27 is correlated with poor prognosis in CRC patients.

P1092 CLINICOPATHOLOGICAL STUDY OF SERRATED LESIONS OF THE COLORECTUM

M. Sugimura, M. Iwabuchi, K. Ukai
Gastroenterology, Sendai Medical Center Dept. of Gastroenterology, Sendai/Japan

Contact E-mail Address: msugimura@snh.go.jp

Introduction: Serrated lesions of the colorectum are the precursors of microsatellite unstable carcinomas. However, their clinical and pathologic features are still unclear and need further exploration.

Aims & Methods: The aims of this study was to clarify the clinicopathological features of colorectal serrated lesions. We reviewed clinical charts and pathology files of 5352 endoscopically resected specimens performed during January 2007 and December 2016 in our hospital. A total of 463 serrated lesions (8.7%) resected were classified into three categories: HP (hyperplastic polyp), SSA/P (sessile serrated adenomas/polyps), and TSA (traditional serrated adenoma), according to the WHO criteria. We examined the features of these cases and evaluate the morphologic characteristics by using immunochemical staining for Ki-67 and the expression of MUCs (MUC2, MUC5AC and MUC6) in differentiating serrated lesions.

Results: Of these 463 lesions, a total of 241 (52.1%) were HP, 102 (22.0%) SSA/P, and 120 (25.9%) TSA. Male to female ratio (M/F) was 2.38 for HP, 0.98 for SSA/P, and 2.45 for TSA. Mean size of SSA/Ps (13.1 mm) and TSAs (10.4 mm) were significantly larger than that of HP (8.1 mm) (p < 0.005, respectively). SSA/Ps were located predominantly in the proximal colon, whereas HP and TSA were mainly located in the sigmoid colon and rectum. 84% of SSA/Ps were flat in macroscopic appearance. SSA/Ps and HPs were whitish or almost the same as adjacent mucosa in color, whereas TSAs had a tendency to be reddish. Magnified colonoscopy showed Type II open pit pattern as characteristic of SSA/Ps, whereas pinecone-shaped pit pattern as that of TSAs. Incidences of concomitant carcinomas in HP, SSA/P, and TSA were 0% (0 out of 241), 2.9% (3 out of 102), and 4.2% (5 out of 120), respectively. Ki-67 positive cells in HP showed regular, symmetric distribution, and those in SSA/P did irregular asymmetrical pattern, whereas most of those cells in TSA distributed in the so-called ectopic crypts. Expression levels of MUC2, MUC5AC and MUC6 were

significantly different between serrated lesions, SSA/Ps and HPs were positive for MUC5AC in comparison with TSAs.

Conclusion: Our studies showed the three types of serrated lesions have their own distinct features and could be helpful to distinguish between them. SSA/P and TSA are premalignant lesions of colorectum and we should detect these lesions and completely remove endoscopically.

Introduction: It is generally accepted that exosomes, small, membrane-bounded vesicles are formed in multivesicular bodies (MVBs) which fuse with plasma membrane resulting in the release of individual exosomes into the extracellular space. Recently, sporadic in vitro observations of a novel, unconventional mechanism have been reported in which the exosome-like vesicles remain in one block during their secretion.

Aims & Methods: Our aim was to examine this phenomenon in migrating colorectal cancer (CRC) cells *in situ*. Immunohistochemistry (IHC) examination of migrating, individual cancer cells was performed in surgically removed, metastatic CRC samples (n=38). We used epithelial specific cytoplasmic (cytokeratin/CK) and cell membrane (E-cadherin) markers for the identification of migrating CRC cells as well as ALIX and CD63 proteins for the detection of exosomal transport. Samples were analyzed with confocal and stimulated emission depletion (STED) microscopy-based 3D reconstructions.

Results: 3D reconstructions showed ALIX-positive and CD63-positive exosome clusters (ECs) with 0.62 to 1.94 µm diameter (mean ± SD: 1.17 ± 0.34 µm) localized partially inside, and/or outside the cytoplasm in 85.96% (n=98/114) of migrating CRC cells. E-cadherin IHC showed that ECs were not only captured during their exit from the cytoplasm and localized among plasma membrane proteins, but they were also detected extracellularly, in the plasma membrane-stroma interface. STED-microscopic images showed that released ECs were composed of smaller, distinguishable ALIX-positive spheroids of 98 to 150 nm diameter (mean ± SD: 128.96 ± 16.73 nm), which fall into the size ranges of exosomes.

Conclusion: Our study demonstrates *in situ* for the first time that besides conventional exosome release, migrating CRC cells also secrete large, extracellular ECs. These structures might fundamentally contribute to the autocrine/paracrine regulation of cancer development, which effect may differ from that mediated by conventionally secreted exosomes.

Introduction: The semi-essential amino acid arginine is important for intestinal epithelial cell proliferation and is an essential dietary component delivered by solid food. In homeostatic proliferating adult intestinal enterocytes arginine is catabolized, by the enzyme arginase 2. During embryonic development, the demand for arginine increases, due to rapid growth. Arginine is lacking from milk and arginine therefore has to be synthesized de novo to sustain epithelial expansion in the rapidly growing intestinal tube. Neonatal enterocytes are capable of de novo synthesis of arginine from citrulline. The rate-limiting enzyme in this process is argininosuccinate synthetase 1 (ASS1). Similarly to postnatal development, hyperproliferative epithelium is a hallmark of tumorigenesis and wound healing.

Aims & Methods: The aim of this study is, to investigate, whether de novo arginine synthesis via ASS1 plays a role in intestinal carcinogenesis and repair.

We performed immunohistochemistry on intestines from APC^{fl/fl} mice, and C57BL/6 mice that either underwent colonic biopsies or irradiation of the intestine. Intestinal organoids from APC^{fl/fl} mice were transduced with a shRNA for ASS1. RNA and protein levels of ASS1 were measured by qPCR and western blot. Arginine concentrations were determined by HPLC. Protein synthesis was measured by [35S]-methionine labelling.

Results: ASS1 expression is highly increased in adenomas and hyperproliferative crypts during epithelial repair after mechanical wounding and irradiation wounds, compared to homeostasis. Variable expression of ASS1 is seen in different colorectal cancer cell lines, and expression correlates with resistance against arginine deprivation. In APC^{-/-} organoids generated from the APC^{fl/fl} genotype, ASS1 RNA and protein are highly expressed, with concomitant increase of intracellular arginine. Upon knockdown of ASS1 in APC^{fl/fl} organoids, protein synthesis is reduced and organoid growth is compromised. Furthermore, knockdown of ASS1 decreases overall protein synthesis.

Conclusion: In a hyperproliferative state, intestinal epithelial cells synthesize arginine via ASS1. Our data suggests this plays a functional role to support growth and protein synthesis during intestinal carcinogenesis and repair.

Introduction: Toll-like receptors have a pivotal role in natural immunity but their role is indefinite and, sometimes controversial, in tumor development. TLR4 signalling through MyD88 has been linked to tumour growth and progression in mice models, whereas in humans TLR4/MyD88 signalling seems to correlate with colorectal cancer poor prognosis [1]. On the other hand, TLR4 signalling seem to be correlated to adaptive immunosurveillance in inflammatory related colonic carcinogenesis [2].

Aims & Methods: The aim of this study was to define the role of TLR4 in the immune surveillance mechanisms in a non-inflammatory model of colonic carcinogenesis. The azoxymethane (AOM) induced colon carcinogenesis mouse model was used. Colonic mucosal samples were collected from wild type (WT) C57bl/6 and TLR4 knock out (KO) mice before AOM administration (T0), at 4 and at 8 months after the first AOM injection. Colons were removed and examined for occurrence of adenoma and inflammatory infiltrate. Macroscopic tumor load was assessed counting the number of polyps. Flow cytometry on colonic mucosa single cell suspensions for CD8+ lymphocytes expressing CD28, CD38 or CD69, for CD4+ lymphocytes expressing CD25 or CD25 and FoxP3 and for epithelial cells expressing CD80 or MHC-I or MHC-II were performed. Non parametric statistics was used.

Results: In TLR4KO mice sacrificed at 8 months, 1.4 polyps/mouse were observed while none was observed at T0 or at 4 months (p=0.006). In TLR4KO mice at 8 months, the rates of epithelial cells expressing CD80, CD86, MHC-I and MHC-II 8 months were significantly lower than in those at T0 or at 4 months (p=0.01, p=0.003, p=0.003, p=0.001, respectively). Moreover, at 8 months, 5/7 TLR4KO mice compared to 0/7 WT ones had at least a colonic adenocarcinoma (p=0.02). At this time point, CD4+CD25+, CD4+CD25+FoxP3+, CD8+CD28+, CD8+CD38+ cells rate was significantly lower in TLR4KO mice than in WT ones (p<0.001, p<0.001, p=0.01, p=0.002, respectively). Similarly, at 8 months the rate of epithelial cells expressing MHC-I and MHC-II were significantly lower in TLR4KO than in WT mice (p=0.02, p<0.001, respectively).

Conclusion: TLR4 deficiency significantly accelerate the progression of colonic carcinogenesis through a progressive decline of antigen presentation and lack of co-stimulation at later stages. These impairments are associated to a decline of T cell response in all its form (Treg, T helper and cytotoxic). All these findings are coherent with a pivotal role of TLR4 in the immune surveillance mechanism.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Less than a hundred polyps defines attenuated familial adenomatous polyposis (AFAP). APC or MUTYH involvement has been described in 60% of the cases. The natural history of AFAP without identified genetic defects is not enough evaluated. In our study we compare clinical and endoscopic features of polyposis in patients carrying APC or MUTYH mutation and wild type patients.

Aims & Methods: 102 cases (35 F, 67 M; mean age 51; range 28–79) of AFAPs were registered at our Institution between 1996 and 2014. They had no cancer family history and presented more than 10 adenomas at index colonoscopy. Genetic testing for APC and MUTYH genes was performed. Patients were put in a program, after having cleaned the colon, consisting in colonoscopy after one year and then the colonoscopic interval was based on the number of polyps from 1 to 3 years. Odds Ratio test was used to compare APC or MUTYH mutated and wild-type patients.

Results: Out of 102 patients with AFAP we identified a genetic defect in 36 patients (35.3%; 12 with APC and 24 MUTYH) and 66 (64.7%) were wild-type. The mean endoscopic follow up was 10 years (2–31) in the mutated group and 9.7 years (2–23) in the wild-type group. Table 1 describes endoscopic and clinical features between the two groups. We observed some statistically differences between groups: the mutated group was younger than 50 years of age with a higher number of polyps, right colon was mainly involved and endoscopic follow-up was mostly every year. Patients of wild-type group never underwent to colectomy during follow-up and they displayed few adenoma recurrences in 24% of cases. On the other hand 14% of mutated patients underwent colectomy for dense polyposis and 28% had more polyps than at index colonoscopy and 11% no polyps at all. These 11% displayed mutation in MUTYH. Regarding extra-colonic manifestations we observed duodenal adenomas in 5 (13.8%) patients and desmoids tumor in one patient of mutated group. Two gastric cancers and one melanoma were diagnosed in the wild type group.

Table 1: Comparison of clinical and endoscopical feature between APC or MUTYH carriers versus wild type patients.

Burden polyps in follow up					

(continued)

Table 1: Continued

	APC or MUTYH mutation = 36		Wild type = 66		Statistics
	Number	%	Number	%	
no	4	11,11	36	54,55	OR 0.0936 95% CI: 0.0274 to 0.3197 P = 0.0002
less than at index colonoscopy	4	11,11	16	24,24	
more than at index colonoscopy and dense polyposis	15	41,67	0		
Tot	36	100,00	66	100,00	

Conclusion: We observed a different behavior between mutated and wild-type patients. Patients with genetic involvement still developed adenomas during the follow-up and some needed colectomy. Instead, wild-type patients had mostly no recurrence. Constitutional genetic background could be suspected in wild-type patients when a continuous development of new polyps has observed and further genetic investigation should be offered by multi-gene testing.

Introduction: Besides local hypermethylation on promoters of certain tumor suppressor genes, global DNA hypomethylation is characteristic in various types of cancers including colorectal cancer (CRC). The DNA methylation level of long interspersed nuclear element-1 (LINE-1) repetitive retrotransposon sequences constituting 17% of the human genome can be used to estimate global methylation level.

Aims & Methods: We aimed to analyze the alterations of the global DNA methylation levels along the colorectal normal-adenoma-carcinoma sequence progression on the basis of LINE-1 methylation and to study the methyl-cytosine pattern in tissue samples. Genomic DNA was isolated from 10 colorectal adenoma, 10 CRC and 30 normal colonic biopsy samples. Bisulfite conversion of DNA samples was performed using EZ DNA Methylation-Direct Kit (Zymo). For methylation level quantification of the LINE-1 retrotransposable element, bisulfite-specific PCR (BS-PCR) was applied, and 146 bp long PCR products were sequenced on Pyromark Q24 system (Qiagen). Tissue localization of 5-methylcytosine (5-mC) in normal, adenoma and CRC tissues was analyzed by immunohistochemistry using mouse monoclonal anti-5mC antibody (GeneTex).

Results: According to the LINE-1 bisulfite sequencing results, significant ($p < 0.01$) global DNA hypomethylation was detected both in CRC ($63 \pm 8.7\%$) and adenoma samples ($67 \pm 5.1\%$) compared to normal tissue ($72 \pm 1.4\%$). 5-mC labeling of both the epithelial and stromal components of normal samples was strong (scoring values: +2 and +3) with diffuse and nuclear staining. In adenomas, decreased nuclear 5-mC staining (scoring value: +2) was detectable in the epithelium and the stroma compared to normal epithelium. In CRC samples significantly lower 5-mC levels could be observed than in normal tissue samples ($p < 0.05$).

Conclusion: Global DNA hypomethylation could be shown in CRC compared to healthy normal tissue samples both by LINE-1 bisulfite-sequencing and by 5-mC immunohistochemistry. Genome-wide DNA methylation decrease occurs already in adenoma stage of colorectal carcinogenesis.

Introduction: MiRNAs have a critical relevance in regulation during tumorigenesis. The expression profiles of miRNAs alter along tumor progression moreover; these miRNA may spread into tumor macro- and microenvironment.

Extracellular miRNAs are stable and its expression is less characterized in plasma. Altered and overlapped miRNA profiles between tissue and plasma are less explored.

Aims & Methods: The present study was designed to characterize the tissue and circulating miRNA profile through colorectal adenoma-carcinoma sequence in human specimens and also in mice peripheral blood samples. Furthermore, the purpose of our study was to determine the origin of detected miRNAs in tumor-adherent C38/C57BL/6 and non-adherent CBAJ mice tumor models. To achieve that goal, human peripheral blood and biopsy of normal (N), tubular (AT), tubulovillous adenoma (ATV) and colorectal cancer (CRC) were selected and plasma were also collected two times a week over 45 days from C57BL/6-C38, CBAJ mice. MiRNAs were isolated and Affymetrix GeneChip miRNA array analysis was performed for screening of the altered miRNA profile. RT-qPCR method was used for validation.

Results: In the case of human samples out of 1733 detectable miRNAs, 306 miRNAs were expressed in normal, 334 in adenoma and 321 in CRC. Characteristic miRNA expression alteration was observed in the comparison of AD vs. CRC (miR-149*, miR-3196, miR-4687) in plasma. In the case of N vs. CRC, overexpression of miR-612, miR-1296, miR-933, miR-937 and miR-1207 was validated by RT-PCR ($p < 0.05$). Partial co-expression of these miRNAs was observed in tissue pairs as well. We identified high plasma levels of 94 miRNAs in healthy animals and 176 miRNAs in late tumor stages. Based on CBAJ-C38 mice model experiment where the injected tumorous cells could not adhere miR-676 found to be a host originated while miR-92a was a tumor-derived miRNA. MiR-676 and miR-92a shown significant overexpression (388x and 37x $p < 0.05$) in plasma samples based on real-time PCR and microarray results.

Conclusion: Circulating miRNAs alteration could observe in animal models and in the human circulatory system. Cancer-associated miRNAs in the circulation may originate from the immunologic system or from other metastatic regions far from the primer tumor location.
