Introduction: Liver cirrhosis is associated with an imbalance between vasodilation and vasoconstriction in the sinusoids. Therefore the investigation of the nitric oxide - cyclic guanosine monophosphate (NO-cGMP) pathway, a key regulator of vascular smooth muscle tone, is essential.

Aims & Methods: The rat model of thioacetamide (TAA) was used to induce liver fibrosis/cirrhosis and alterations of the NO-cGMP pathway and subsequent liver damage were assessed. 25 male Wistar rats were studied (11 untreated controls and 14 TAA treated animals [0.03 g TAA/100 ml drinking water for 16 weeks]). TAA dosage was adjusted weekly based on body weight changes. Hepatic gene expression of endothelial and inducible NO synthase (eNOS and iNOS), phosphodiesterase 5 (PDE5), soluble guanylate cyclase subunit a1 and b1 (sGCa1 and sGCb1) was determined by qRT-PCR. Serum cGMP concentrations were measured by ELISA using blood samples taken from the carotid artery. Likewise liver damage was assessed by liver chemistry (i.e. alanine- and aspartate-amino-transferase (ALAT and ASAT), alkaline phosphatase (AP), albumin and bilirubin). The degree of fibrosis was estimated by histological criteria (i.e. Desmet scores). PDE5-expression was determined by immunohistochemistry. Kruskal-Wallis test was used for statistical analysis of group differences.

Results: 43% (6/14) of TAA-treated rats developed liver fibrosis (Desmet score of 1-3) while 57% (8/14) developed liver cirrhosis (Desmet score of 4). No major differences in ALAT, ASAT, and AP serum concentrations were observed in either group. However, bilirubin was significantly elevated in TAA-treated rats, while albumin concentrations were significantly reduced. Gene expression analysis revealed significantly increased expression of eNOS (1.5fold), PDE5 (7.7fold), and sGCb1 (2.1fold) in fibrotic livers compared to controls. cGMP concentrations in fibrotic animals were slightly decreased (-34%). Significantly increased expression of eNOS (2.2fold), PDE5 (11fold), sGCa1 (1.7fold) and sGCb1 (3fold) was observed in cirrhotic livers compared to controls, while cGMP concentrations were significantly decreased (-40%). iNOS expression was only detected in fibrotic and cirrhotic livers, but absent in controls. Immunohistochemistry revealed markedly increased PDE5-expression in cirrhotic livers, which was predominantly localized in hepatic stellate cells.

Conclusion: The analysis of the animal model of TAA-induced liver fibrosis/cirrhosis revealed alterations of the NO-cGMP pathway, characterized by reduced concentrations of cGMP, a key mediator of vasodilation, due to increased PDE5-expression. These changes reinforce the hypothesis that sinusoids remain in a contractile state in cirrhotic livers, thereby contributing to portal hypertension. Thus, administration of PDE5-inhibitors, possibly combined with sGC-activators, should be further studied in clinical trials as a promising therapeutic approach to target portal hypertension.

Introduction: Mesenchymal stem cell (MSC) therapy is a promising approach that may preclude the need for liver transplantation. Natural killer cells (NK cells) have critical antifibrotic effect in part through killing the activated hepatic stellate cells (HSCs); and the role of NK cells in fibrotic liver treated with MSCs is not thoroughly understood.

Aims & Methods: To investigate the effects of bone marrow MSC transplantation in rats having hepatic fibrosis produced by common bile duct ligation (CBDL) model with a special focus on the changes of NK population in liver and the supernatant of splenocyte culture. Rats were divided into three groups: 1- CBDL rats that were given MSCs (CBDL + MSC), 2- CBDL rats given phosphate-buffered saline (PBS) (CBDL + PBS), 3- Healthy rats that were sham operated and given MSCs (Healthy + MSC). MSCs or PBS were injected via the tail vein of the rats. MSCs were labeled with GFP to check the localization of stem cells and to get idea for the regenerative capacity in the injured liver. Splenocytes were

isolated from spleen and cultured with Anti-CD3 and Anti CD28. Immunologic parameters were analysed with flowcytometry.

Results: Histologically, liver fibrosis developed in CBDL rats while the healthy rats group did not show any alteration in liver architecture. Bilirubin levels were as follows: Grp 1: 6.80 (5.97-8.01), Grp 2: 6.77 (5.95-7.44), Grp 3: 0.15 (0.11-0.14) mg/dl. T-lymphocyte proliferation was suppressed significantly more in CBDL + MSC compared to CBDL + PBS group. By measuring the cytokine levels in supernatants of cultured lymphocytes, we found that CBDL + PBS group had significantly higher IL-1 α , TNF- α and IFN- γ levels than health MSCs. Treatment of those rats with MSCs tended to decrease IL-1 α , TNF- α and IFN- γ levels compared to CBDL + PBS group. The splenocyte supernatants of CBDL + MSC rats showed a tendency towards higher CD4⁺CD25⁺ cell and CD161a cell counts compared to CBDL + PBS. On pathological examination, liver fibrosis was significantly higher in CBDL + PBS compared to CBDL + MSC group. The NK distribution was evaluated both in portal and parenchymal areas of liver. We have found that in the whole liver the NK cells were depressed significantly in CBDL + PBS group compared to healthy + MSC group and furthermore in the CBDL + MSC group, NK cells were significantly increased compared to CBDL + PBS group.

Conclusion: Our findings suggest bone marrow MSCs may be effective in alleviating the hepatic injury by suppressing the T cell proliferation, increasing the circulating peripheral NK cell population and CD4 + CD25 + and suppressing the proinflammatory cytokines in rats. Beneficial effects of MSC treatment is accompanied with significantly alleviated hepatic fibrosis and the significant NK recruitment to liver parenchyme. Thus, MSC injection treatment may appear promising in liver injury and future clinical therapies are warranted.

P0003 SERPINB3 INVOLVEMENT IN THE STIMULATION OF MACROPHAGE ACTIVATION MARKER SCD163 IN HCV INFECTED PATIENTS

A. Martini¹, A. Cappon¹, A. Biasiolo¹, C. Turato¹, P. Pontisso¹

¹Department Of Medicine, University of Padua, Padova/Italy

Contact E-mail Address: andremartini86@gmail.com

Introduction: In chronic HCV infection disease progression is maintained by sustained necroinflammation and fibrosis in the liver. Upon macrophage activation, the soluble marker CD163 (sCD163) is released in serum and its levels correlate with fibrosis and NASH in the liver. The serin protease inhibitor SerpinB3 (or SCCA1), has been shown to be involved in liver fibrogenesis and the circulating SCCA-IgM complex has been depicted as a marker of liver disease progression and of NASH in patients with chronic hepatitis C. Preliminary data suggest that SerpinB3 activates primary monocytes through the Wnt canonical pathway. The purpose of this study was to evaluate the relationship between SCCA-IgM and sCD163 in serum and the possible effect of SerpinB3 on sCD163 and on pro-inflammatory cytokines expression, in primary monocytes.

Aims & Methods: In 91 patients with biopsy-proven chronic hepatitis C, serum samples were tested for sCD163 (ng/ml) and SCCA-IgM (AU/ml) by ELISA. The results were analyzed in relation with clinical and histological parameters. Primary monocytes were isolated from healthy donors, treated with recombinant SerpinB3 (200 ng/ml) and supernatants analyzed after 2 and 7 days. Expression of sCD163 secreted in the supernatant was evaluated by ELISA. In primary monocytes mRNA expression of IL-12, CXCL-10 and TNF-alpha were also analyzed by PCR at different time points.

Results: In patients with chronic hepatitis C sCD163 was found correlated with inflammatory and metabolic alterations (AST, ALT, GGT, HOMA-IR, triglycerides), and was significantly elevated in patients with more advanced histological fibrosis stage (F1-F2 vs. F3-F4 sec. Metavir: p < 0.04). Patients with levels of SCCA-IgM > 200 AU/ml had more elevated serum levels of sCD163 (p < 0.05). In primary monocytes stimulated with recombinant SerpinB3 "in vitro", sCD163 expression increased of 2.5 times and this finding was parallel to an up-regulation of the inflammatory cytokines IL-12, CXCL-10 and TNF-alpha.

Conclusion: In chronic hepatitis C SerpinB3 is involved in monocyte activation, leading to the release of sCD163. These results support the correlation of these two molecules in serum of patients with more severe liver fibrosis and metabolic alterations.

P0004 THE PROTECTIVE EFFECTS OF GROUP 3 INNATE LYMPHOID CELLS ON HEPATITIS B VIRUS RELATED LIVER FIBROSIS COULD BE IMPAIRED BY TH17 CELLS

S. Wang, W. Ma, L. Cheng, W. Jiang

Gastroenterology, Zhongshan Hospital Fudan University, Shanghai/China

Contact E-mail Address: 15211210012@fudan.edu.cn

Introduction: Th17 cells have been proved to contribute to hepatitis B virus (HBV) associated liver fibrosis. Group 3 innate lymphoid cells (ILC3s), which have similar profiles of transcription factor and cytokines to that of Th17 cells, were also suggested to be involved in the progression of liver fibrosis.

Aims & Methods: The study was designed to explore the functions of ILC3s and the relationships between ILC3s and Th17 cells in liver fibrosis. Peripheral blood samples were collected from 60 patients with chronic hepatitis B (CHB), and 50 patients with HBV related liver cirrhosis (LC) as well as 30 healthy controls (HC). The percentages and cytokines secretion of ILC3s (Lin⁻CD127⁺CD117⁺CD294⁺) and Th17 cells (CD4⁺IL-17⁺) were detected by flow cytometry. Peripheral blood mononuclear cells (PBMCs) and PBMCs without ILC3s co-cultured with hepatic stellate cells (HSCs)-LX2 in contact and non-contact manners. Then Th17 cells, which were induced from naïve CD4⁺T cells in vitro, were transferred into Rag1^{-/-} mice with carbon tetrachloride (CCl₄) related liver fibrosis. In addition, ILC3s in Rag1^{-/-} mice were depleted by injecting with anti-CD90.2 antibody.

Results: Compared with HC, the percentage of ILC3s increased in CHB group. The anti-inflammation cytokines secreted by ILC3s such as IL-22 increased, whereas pro-inflammation cytokines of ILC3s such as IL-17A, TNF- α , IFN- γ decreased in CHB patients. However, ILC3s decreased in LC patients with reduced cytokines secretion. Th17 cells frequencies significantly increased both in CHB and LC groups compared with HC. PBMCs without ILC3s, which were collected from CHB and LC patients, promoted the proliferation and activation of HSCs because of less IL-22 secretion. Similarly, compared with wild type mice, ILC3s in spleens and livers of C57BL/6 mice with liver fibrosis increased sequentially at time point of week 2 and week 4 following drug injection. Intriguingly, at week 6, ILC3s decreased compared with previous. However, Th17 cells increased gradually with CCl₄ administration, even at week 6. Transferring Th17 cells into Rag1^{-/-} mice with liver fibrosis made the ILC3s in spleens and livers decrease significantly, and the degree of mice liver fibrosis become more severe than control. Furthermore, ILC3s depletion correlated with reduced expression of IL-22 and more severe liver fibrosis. Transferring purified liver ILC3s into recipient mice could alleviate liver inflammation and reverse liver fibrosis.

Conclusion: Our study has uncovered the protective role of ILC3s in liver fibrosis, which is through secrete IL-22 to reduce proliferation and activation of HSCs. However, the protective functions of ILC3s could be impaired by Th17 cells.

³Gastroenterology And Hepatology, The General Hospital of the Chinese People's Liberation Army, Beijing/China

Contact E-mail Address: zhangtt246@sina.com

Introduction: Internal biliary drainage has been confirmed better than external biliary drainage in alleviating the damage of intestinal mucosa barrier caused by obstructive jaundice, but the relevant mechanism is still unclear.

Aims & Methods: We aimed to investigate the potential relation between the expressions of bile acid receptor and TLR4/NOD2 in intestinal mucosa and its influence on the intestinal mucosal barrier with obstructive jaundice. In this study, we mainly study the expression between FXR and TLR4, TGR5 and NOD2. Sixty male adult Kunming mice were randomly assigned to four groups: SH (shame operation), OJ (obstructive jaundice), ID (internal drainage), ED (external drainage) (n=15 in each group). On the 7th day from the first operation, the OJ and SH mice were executed and specimens of blood and ileal tissue of groups were collected. ED and ID were reoperated on day 8 for biliary drainage procedure. Blood was drawn from heart for liver function test. The terminal ileum specimen was collected for test of histology using haematoxylin-eosin (HE) staining. Western blot (WB) and real-time polymerase chain reaction (RT-PCR) were used to detect the expression of protein and mRNA of FXR, TGR5, TLR4 and NOD2 in intestinal mucosa.

Results: We have successfully established the animal models. The histopathological examination revealed notable inflammatory infiltration and hyperplasia disruption at terminal ileum in OJ mice; significant alleviation of above injuries by ID while little improvement by ED. FXR-TLR4: After biliary obstruction, the expression of protein and mRNA of FXR were significantly increased, while the

expression of protein and mRNA of TLR4 were significantly decreased compared with SH group's (P < 0.001). After ED, compared with OJ group's, the expression of protein of FXR was decreased while TLR4 were increased. The mRNA of both FXR and TLR4 were increased. After ID, the expression of protein and mRNA of FXR were significantly decreased compared with OJ group's but were still higher than that in SH group and were better than ED group's. And the expression of protein and mRNA of TLR4 were significantly increased compared with OJ group's (P < 0.001), but were still lower than that in SH group and were better than ED group's. The trend of TLR4 expression was almost the same between vehicle group and no gavage group. After gavage with FXR agonist, the differences of TLR4 expression of four groups disappeared (P > 0.05). TGR5-NOD2: IHC and WB suggested that after OJ surgery, the protein expression of both TGR5 and NOD2 increased obviously compared to that of SH mice; then the level of TGR5 and NOD2 protein fell remarkably after ID surgery close to SH level while in ED group there was only a slightly reduction from OJ level and still with a high expression of TGR5 and NOD2 protein. Detection of RT-PCR found that TGR5 mRNA and NOD2 mRNA level in OJ group increased several times as that of the SH group; after ID surgery, the expression of TGR5 mRNA significantly reduced, NOD2 mRNA level also fell down consistently, but the effect was not observed in ED mice.

Conclusion: The expression of intestinal FXR and TLR4, TGR5 and NOD2 could be one of the critical mechanism why internal drainage is better than external drainage in restore intestinal barrier function of obstructive jaundice mice.

Introduction: Alterations in the gut microbiota have been correlated to a wide variety of diseases, including liver diseases. Used as probiotics, several strains of Lactobacillus have been associated not only to modulation of intestinal tight junctions but also to amelioration of liver fibrosis. Common bile duct ligation (BDL) results in acute cholestatic injury and secondary biliary fibrosis, associated with early increased intestinal permeability and disturbed bile acid homeostasis. We have demonstrated that the oncogenic microRNA-21 (miR-21) is upregulated in BDL mouse liver, mediating liver fibrosis. We aimed to investigate the role of miR-21 in the response of the small intestinal microbiota to BDL that may explain miR-21 effects in acute liver injury and fibrosis.

Aims & Methods: Three-month-old C57BL/6 wildtype (WT) and miR-21 whole body knockout (KO) mice were submitted to sham or BDL surgeries. After three days, animals were sacrificed and small intestine and its luminal content were carefully removed and preserved. mRNA expression was analysed by qRT-PCR. Bacterial DNA was purified from the small intestinal lumen samples and analysed by next generation sequencing – metagenome analysis. Liver tissue and serum were also collected for biochemical analysis of hepatic damage and fibrosis.

Results: TNF- α and IL-1- β mRNA levels increased in the small intestine of BDL-miR-21 KO mice, compared to WT. TLR-4 and TGF- β expression was increased in both sham- and BDL-miR-21 KO mice which is in accordance with the higher LPS in blood plasma observed. Zona occludens (ZO-1) and occludin mRNA levels were decreased in WT mice after BDL. Strikingly, miR-21 KO reverted mRNA of tight junction proteins to control levels. BDL miR-21 KO mice showed decreased circulating levels of hepatic enzymes, concomitant with decreased fibrogenic gene expression in the liver, in comparison with WT mice, suggesting that miR-21 contributes to BDL-induced liver injury and fibrosis. Further, miR-21 KO not only show a decreased small intestine permeability through a ZO-1 and occludin pathway, as it is associated with development of beneficial strains of Lactobacillaceae that may also contribute to liver protection.

Conclusion: These data suggest that miR-21 depletion is associated with increased inflammatory markers in the small intestine and better immune response to bacterial dysbiosis provoked by the BDL surgery, thus halting liver injury and promoting gut microbiota homeostasis. Contact E-mail Address: nwang@surgery.cuhk.edu.hk

Introduction: Sorafenib is the only approved systemic therapy for advanced hepatocellular carcinoma (HCC). However, the application of Sorafenib in therapy has faced increasing challenges due to drug resistance. Drug resistance is known to be associated with cancer stem cells (CSC). The transcription factor ZBP-89 was reported to be involved in cell growth and apoptosis in tumor and acts as a potential tumor suppressor in HCC. It has shown that high levels of ZBP-89 expression were statistically associated with better survival of HCC patients. Unfortunately, the mechanism of ZBP-89 in modulating sensitivity of Sorafenib in CSC remains unknown.

Aims & Methods: In this study, we investigated the mechanism of Sorafenib resistance in HCC cancer stem cells, and how ZBP-89 reduced drug resistance. The sensitivity of Huh7 and Hep3B parental and sphere-forming cells to Sorafenib was measured by MTT assay. We then examined the expression patterns of Notch1 and liver CSC markers in Huh7 and Hep3B CSC after the treatment with Sorafenib. MTT assay was also used to measure the effects of ZBP-89 overexpression on the sensitivity of Sorafenib in sphere-forming cells. The levels of ZBP-89 and CD44 were measured using q-PCR in human HCC tissue samples. The regulatory effects of ZBP-89 on CSC phenotype were explored by various methods including q-PCR, immunoblotting, tumor sphere formation assay, soft agar formation assay and colony formation assay. Gene expressions and protein interaction in stemness signaling pathways were analyzed.

Results: We found that sphere-forming HCC cells had significant higher resistance to Sorafenib, compared with their parental cells. The expression of Notch1 and EpCAM was increased along with the treatment of low dose of Sorafenib, suggesting that the activation of Notch1 pathway was associated with the drug resistance in liver CSC. Studies further indicated that ZBP-89 overexpression was able to improve the sensitivity of Sorafenib on sphere-forming HCC cells. Furthermore, we found that ZBP-89 expression was negatively correlated with CSC marker CD44 in human HCC tissues. In vitro study indicated that tumor sphere formation capacity was impaired upon stable overexpression of ZBP-89, suggesting that ZBP-89 was involved in suppression of CSC phenotype. Detailed investigation against control cells showed that overexpression of ZBP-89 resulted in reduced expression of CSC markers EpCAM, CD133, Sox2 and c-myc at both mRNA and protein levels. In addition, the overexpression of ZBP-89 or silencing of Notch1 reduced the number of colonies formed by sphere-forming HCC cells, demonstrating opposite effects of these two proteins. Mechanistic studies revealed that ZBP-89 was able to repress the expression of Notch1 and reported Notch1 target genes including HES1, HES6, HEY1 and NRARP. Amino acids Δ6-180 of ZBP-89 could directly bind to the activated Notch1 in the nucleus, resulting in a negative regulation of CSCs and overcome of Sorafenib resistance.

Conclusion: Sphere-forming HCC cells, which contained high levels of Notch1 and EpCAM, were resistant to Sorafenib. The overexpression of ZBP-89 was found to result in the loss of CSC phenotype and improve the sensitivity to Sorafenib in CSC through its interaction with activated Notch1. In conclusion, we believe that targeting ZBP-89 is likely to be a new therapeutic strategy to overcome the resistance to Sorafenib in HCC.

Introduction: Accumulating evidence indicates that gut microbiota participates in the pathogenesis and progression of liver diseases. The severity of immune-mediated liver injury is associated with different microbial communities. *Akkermansia muciniphila* can regulate immunologic and metabolic functions.

However, little is known about its effects on gut microbiota structure and function.

Aims & Methods: This study investigated the effect of *A. muciniphila* on immune-mediated hepatitis and potential underlying mechanisms. Twenty-two C57BL/6 mice were assigned to three groups (N=7–8 per group) and continuously administered *A. muciniphila* Muc^T (ATCC BAA-835) or PBS by oral gavage for 10 days. Mouse feces were collected for gut microbiota analysis on the eleventh day, and acute hepatitis was induced by Concanavalin A (Con A, 15 mg/kg) injection through the tail vein. Samples (blood, liver, ileum, colon) were assessed for liver injury, systemic inflammation, and intestinal barrier function.

Results: We found that oral administration of *A. muciniphila* (Akk) decreased serum ALT and AST and alleviated liver histopathological damage induced by Con A. Serum levels of pro-inflammatory cytokines (IL-2, IFN-γ, IL-12p40, MCP-1, MIP-1a, MIP-1b) were substantially attenuated. Akk significantly decreased hepatic cell apoptosis; Bcl-2 expression increased, but Fas and DR5 decreased. Further investigation showed that Akk enhanced Occludin and Tjp-1, two proteins related to strengthened intestinal barriers. Fecal 16S rRNA sequence analysis indicated that Akk increased microbial richness and diversity. The community structure of the Akk group clustered distinctly from that of the Control and Normal groups. Relative abundance of Firmicutes increased, and Bacteroidetes abundance decreased. Correlation analysis showed that injury-related factors (IL-12p40, IFN-γ, DR5) were negatively associated with specific genera (Ruminococcaceae_UCG-009, Lachnospiraceae_UCG-001, Akkermansia), which were enriched in mice pretreated with Akk.

Conclusion: Our results suggested that *A. muciniphila* Muc^T (ATCC BAA-835) had beneficial effects on immune-mediated liver injury by alleviating inflammation and hepatocellular death. These effects may be driven by the protective profile of the intestinal community induced by the bacteria. The results provide a new perspective on the immune function of gut microbiota in host diseases.

P0009 CLINICAL OBSERVATION ON THE TREATMENT OF NONALCOHOLIC FATTY LIVER WITH PROBIOTICS

W. Wang

Gastroenterology, Beijing Hospital, Beijing/China

Contact E-mail Address: wangwei-beijingyiyuan@hotmail.com

Introduction: With the improvement of living standards, obesity, the prevalence of insulin resistance (IR), hyperlipidemia and diabetes and other metabolic disorders in nonalcoholic fatty liver (NAFLD) in China had increased. NAFLD refers to the factors caused by exclusion of alcohol and other clear liver damage, clinical pathological syndrome, and genetic liver steatosis as the main feature of the link between insulin resistance and other factors closely for acute liver injury of metabolism. Serious illness can develop into liver cancer. NAFLD has become the leading cause of chronic liver disease in developed countries and China. Chronic liver disease is often accompanied by intestinal micro ecological imbalance; studies have shown that the imbalance of intestinal micro ecology led to the transfer of intestinal endotoxin into the blood, and stimulate the production of inflammatory factors aggravate liver damage, thus chronic liver disease. A series of studies show that changes of intestinal microflora, intestinal bacterial overgrowth (small intestinal bacterial overgrowth, SIBO) and intestinal endotoxemia in the occurrence and development of NAFLD plays an important role, and the recovery of intestinal micro ecological balance may have assisted treatment of NAFLD. A series of studies show that changes of intestinal microflora, intestinal bacterial overgrowth (SIBO) and intestinal endotoxemia in the occurrence and development of NAFLD plays an important role, and the recovery of intestinal micro ecological balance may have assisted treatment of NAFLD.

Aims & Methods: We aimed to study the clinical effect of probiotics in the treatment of nonalcoholic fatty liver disease. 200 cases of patients with nonalcoholic fatty liver disease were randomly divided into routine treatment group (A group) and combined treatment 3 groups (B, C, D). All 50 cases were given orally Polyene Phosphatidylcholine Capsules, 456 mg, TID; The combination therapy group B was given orally the Live Combined Bifidobacterium Lactobacillus and Enterococcus Powder, 420 mg, TID; group C, two live combined Bacillus subtilis Enterococcus, 500 mg, TID; D group was given orally the both probiotics above. The course was 1 month. All patients were respectively examined before treatment and seven days and thirty days after treatment, for cholesterol (TC), triglyceride (TG), high density lipoprotein cholesterol (HDL-L), low density lipoprotein cholesterol (LDL-L), alanine aminotransferase (ALT), aspartate aminotransferase (AST), fasting blood glucose (FPG), serum high molecular weight adiponectin (HMW APN) and serum TNF-α. The 4 groups were collected faeces samples, that were tested routine detection, bacterial culture. At the same time all patients were checked with liver ultrasound scan.

Results: In terms of blood lipids and blood glucose, each group improved than before, only HDL-L was not statistically significant, D group showed significant differences in triglyceride. In liver function, blood ALT, AST were significantly lower in D group than A group. TNF-α levels were decreased after treatment, combined treatment D group was statistically significant; group D more than the group A; serum HMW APN increased after treatment, combined treatment group D comparing with routine treatment group A was significant difference.

Conclusion: Intestinal probiotics can regulate the intestinal micro ecological imbalance in NAFLD patients, and reduce the level of serum TNF-α, improve the level of adiponectin, which can further improve the blood glucose, lipid metabolism, and then improve the liver injury of non-alcoholic fatty liver disease.

Introduction: Despite evidence that the microbiota is involved in the pathogenesis of obesity, the microbiota of patients with nonalcoholic fatty liver disease (NAFLD) has not been well characterized. NAFLD is considered a hepatic manifestation of metabolic syndrome and is particularly associated with insulin resistance, obesity, and gut-driven endotoxin.

Aims & Methods: The aim of our study is to assess if there are any differences in the microbiota of patients with biopsy-proven NAFLD and healthy controls (HC). In addition, peripheral blood endotoxin (ET) and gut-permeability was analyzed in NAFLD (mild fibrosis vs severe fibrosis) and HC patients. A total of 201 patients were enrolled in this study: 68 HC and 143 biopsy-proven NAFLD (77 mild fibrosis [F0–2] and 56 severe fibrosis [F3–4]). One stool sample was collected from each participant. All NAFLD patients included in this study underwent percutaneous liver biopsy. Healthy controls were volunteers. The composition of gut bacterial communities was determined by 16S rDNA sequencing. In addition, peripheral blood ET was determined using by endotoxin activity assay (EAA). Gut-permeability was assessed by Lactulose mannitol ratio (LMR). Trial registration: This trial has been registered in the University Hospital Medical Information Network (UMIN) Clinical Trials Registry as UMIN000020917.

Results: Among those taxa with greater than 1% representation in any of the disease groups, it was significantly decreased in *Bacteroidetes* at phylum level in NAFLD compared with HC. At genus level, *Faecalibacterium prausnitzii* (*F.P*) was significantly decreased in NAFLD compared with HC. *F.P* is significantly decreased in NAFLD with severe fibrosis compared with those with mild fibrosis patients. In addition, endotoxin levels were increased in NAFLD with severe fibrosis than those with mild fibrosis. Furthermore, occupation ratio of *F.P* was negative correlation with blood ET levels ($R^2=0.327$, $P<0.0001$). Additionally, it showed a significant correlation among three items of F.B, EAA and LMR (F.B vs EAA: $P<0.0001$, LMR vs EAA: $P<0.0001$, LMR vs F.B: $P<0.0025$).

Conclusion: Our study indicated that the change of the gut microbiota and pathologic connection were suggested in acknowledgment of the decrease on *F.P* in the NAFLD patients. The decreased abundance of *F.B* in NASH with severe fibrosis, elevated blood-endotoxin in NAFLD with severe fibrosis patients suggests a role for ET in the pathogenesis of fibrosis. Moreover, our study showed that the mechanism of fibrotic progression via the endotoxin in NAFLD may relate strongly gut-permeability. We postulate that the distinct composition of the gut microbiota among NAFLD and HC could offer a target for intervention or a marker for disease.

P0011 GUT MICROBIOTA COMPOSITION IN EXPERIMENTAL MOUSE MODELS OF NON-ALCOHOLIC FATTY LIVER DISEASE

B. Zhang, L. Fan, J. Ren

Zhongshan Hospital Affiliated To Xiamen University, Department of Gastroenterology, Xiamen/China

Contact E-mail Address: geezbzbz@xmu.edu.cn

Introduction: Non-alcoholic fatty liver disease (NAFLD) has become the most common liver disease worldwide, and is thought to be strongly associated with gut microbiota. Several diet models were therefore built in mice to try to clarify the molecular mechanisms. However, how and to what extent these diet models alter the composition of the gut microbiota have not yet been clearly elucidated.

Aims & Methods: In this study, we developed three mouse models of NAFLD using methionine-choline-deficient (MCD) diet, high-fat (HF) diet, and choline-deficient-high-fat (CD-HF) diet, evaluated the severity of steatohepatitis, and sequenced the fecal bacteria by targeting 16S V4-V6 regions on Illumina MiSeq using PE 300 reagents.

Results: Histological scores showed that MCD induced the severest steatohepatitis, followed by HF and CD-HF diets. Based on OTUs at cutoff of 97% similarity, there were significant (PERMANOVA, $P=0.001$) differences in overall gut bacterial communities among MCD, HF, CD-HFD, and the Control, forming three major clusters in PCA ordination with HF and CD-HF groups more similar. Furthermore, α -diversity of HF and CD-HF groups, including observed OTU numbers, Shannon index, and Pielou evenness were significantly (ANOVA, $P<0.05$) higher than the Control and MCD group. Overall, mouse gut bacteria were mainly composed of Firmicutes (Ruminococcaceae, Lachnospiraceae, Clostridiaceae) and Bacteroidetes (S24-7, Porphyromonadaceae). More specifically, *Ruminococcus* was significantly reduced in the three NAFLD models than the Control, and was identified as

the biomarker of NAFLD in LEfSe analysis. More biomarkers at genus level (Lachnospira, S24-7, etc.) were identified in pairwise comparison of one mouse model with the Control.

Conclusion: In summary, the composition of gut microbiota varied remarkably between mice administrated different experimental diets to induce non-alcoholic fatty liver disease.

Introduction: Approximately 25% of adult population in western countries have metabolic syndrome (MS). Hyperferritinemia (HF) is frequently present in patients with MS (dysmetabolic hyperferritinemia). Liver steatosis is often suspected in patients with MS.

Aims & Methods: To study the prevalence of hepatic steatosis determined by MRI in these patients. A prospective study of 312 consecutive with HF ($>200 \mu\text{g/L}$ women; $300 \mu\text{g/L}$ men) and/or TSI $>45\%$, confirmed in two determinations, was conducted from December 2010 to April 2013. The MS was defined by the presence of three of the following factors: waist circumference $\geq 94 \text{ cm}$ men/ $\geq 80 \text{ cm}$ women; Triglycerides $\geq 150 \text{ mg/dL}$ or treatment for this dyslipidemia; HDL $<40 \text{ mg/dL}$ women/ $<50 \text{ mg/dL}$ men or treatment for this dyslipidemia; glucose $\geq 100 \text{ mg/dL}$ or Type 2 diabetes; hypertension: blood pressure $\geq 130 \text{ mmHg}/\geq 85 \text{ mmHg}$ or treatment for arterial hypertension (1). LIC was determined by MRI 1.5 Tesla system (SIR method) (2). We systematically performed T1-weighted in-phase and opposed-phase imaging to determine the presence or not of liver steatosis.

Results: 312 patients (272 men/40 women) were included. Mean age 55 (SD 13.5); Mean ferritin 729, 6 (SD 449.6), mean TSI 40, 8 (SD 15.8); 276 patients have all the required criteria to determine the MS presence: 115/240 men (48%) and 20/36 women (55.6%) presented MS; 135 patients with MS (49%); 141 without MS (NMS) (51%). In 286 patients a MR study for the presence of liver steatosis was performed: 196 no steatosis; 90 liver steatosis. 251 patients with MS criteria and MR for steatosis: NMS group (128): no steatosis 103; steatosis 25; MS group (123): no steatosis 72, steatosis 51 (total: no steatosis 175, steatosis 76). When we study if the presence of liver steatosis was more frequent in the MS group, the results obtained were statistically significant, $p=0.000$.

Conclusion: Nearly 50% of the patients referred for hyperferritinemia to the hospitals of our country had MS; the patients with MS had more frequently liver steatosis than the patients without MS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In a previous study from our group (1), in a secondary hospital, we did not find differences in the liver iron concentration (LIC) of the different groups, and we can not predict liver iron overload for hyperferritinemia (HF)

patients with HFE mutations and (transferrin saturation index (TSI) values alone. But we did not have C282Y/C282Y patients in the series.

Aims & Methods: To study the relevance of HFE mutations and TSI in determining LIC for HF patients attending the outpatient clinic at 6 hospitals in the Basque country. Prospective study of 312 consecutive patients with HF. Olynyk et al.(2) described three different groups according to HFE mutations and TSI (Group A: no predisposing mutations (PM) for HH and TSI > 45 %, Group B: PM for HH: C282Y/C282Y; C282Y/H63D, H63D/H63D, and TSI > 45 %; Group C: no PM for HH and normal TSI); Group D: PM and normal TSI. In the Basque country, hereditary hemochromatosis (HH) predisposing mutations differ, with relevance of the H63D/H63D mutation. The LIC was measured by MRI.

Results: In all the patients HFE study was available: C282Y/C282Y 14 (4.49%); C282Y/H63D 25 (8.01%); H63D/H63D 47 (15.06%); H63D/wt 99 (31.73%); wt/wt 98 (31.41%); C282Y/S65C 1 (0.32%); H63D/S65C 2 (0.64%); C282Y/wt 16 (5.13%); S65C/wt 10 (3.21%). LIC was obtained from all the patients by MR. Mean age: 55 ± 13.5, 272 men and 40 women. Group A: 54, Group B: 32 Group C: 160. Group D: 54. The mean LIC in Group A: 37.21 ± 27.89, group B: 70.53 ± 58.67, group C: 35.23 ± 22.62. Group D: 42.67 ± 22.98. We compared the LIC mean values of the 4 groups (bonferroni) with significant differences ($p=0.0000$).

Conclusion: The LIC in different groups of patients referred for HF are significantly different with different predisposition to HH.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Approximately 25% of adult population in western countries have metabolic syndrome (MS). Hyperferritinemia (HF) is frequently present in patients with MS (dysmetabolic hyperferritinemia). There are some publications that support that HF is associated with a raised liver iron concentration (LIC) in these patients, but some doubts persist about this subject.

Aims & Methods: To study the LIC in patients referred for hyperferritinemia to six different hospitals in the Basque Country (multicenter study), Spain, and determine if there are differences between patients with or without metabolic syndrome. A prospective study of 312 consecutive patients with HF (>200 mg/L women, >300 mg/L men) was conducted from December 2010 to April 2013. The Metabolic syndrome was defined by the presence of three of the following factors: waist circumference ≥94 cm men/≥80 cm women; Triglycerides ≥150 mg/dL or treatment for this dyslipidemia; HDL <40 mg/dL women/<50 mg/dL men or treatment for this dyslipidemia; glucose ≥100 mg/dL or Type 2 diabetes; hypertension: blood pressure ≥130 mmHg/≥85 mmHg or treatment for arterial hypertension (1). LIC was determined by MRI (SIR method) (2).

Results: In 276 of 312 patients we have all the data to determine the MS presence: 115/240 men (48%) and 20/36 women (55.6%), 135 patients, presented MS. In all 276 patients MRI for LIC determination (mean ± SD) was performed. (We have LIC results (μmol/g) from the 276 patients). The mean LIC was 30.83 ± 19.38 (women) and 38.84 ± 25.50 (men), with 37.66 ± 24.79 (CI 95%; 33, 44 to 41, 88) for all the MS group. In 141 patients MS was not diagnosed (NMS): 125/240 were men (52%), and 16/36 women (44.4%). The mean LIC was 34.88 ± 16.18 in women, and 44.48 ± 38.16 in men, with 43.39 ± 36.43 (CI 95%; 37, 32 to 49, 46) for all the NMS group. We compare the mean values of LIC from both groups (MS vs NMS) by Pearson's Chi square test and Fisher's exact test: no significant differences were seen ($p=0.12$).

Conclusion: Patients with HF and MS (dysmetabolic hyperferritinemia) present a mean LIC near normal values and their values do not differ from those of patients with HF and without MS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Alternatively activated anti-inflammatory macrophage (also termed M2 Kupffer cell) is important for prevention of the development of steatosis and liver injury in non-alcoholic fatty liver disease (NAFLD). Our previous studies demonstrated that interleukin (IL)-25 was downregulated in NAFLD mice and exogenous IL-25 protected against NAFLD by inducing M2 Kupffer cells.

Aims & Methods: We aimed to explore the intracellular signaling pathways of IL-25 to regulate macrophage polarization and direct effects of IL-25 on Kupffer cells. Mouse model of NAFLD was induced by feeding a high-fat diet (HFD); *In vitro* expansion of mouse Kupffer cells, IL-10 and IL-25 were used to induce M2a Kupffer cells; specific siRNAs were used to knockdown IL-25 receptor mRNA for assessing the direct and specific effect of IL-25 on Kupffer cells; IL-25 induced M2a Kupffer cells were back transfusion into the abdomen of NAFLD mouse to assess the efficacy; Dual-luciferase reporter assays and Chromatin immunoprecipitation assays were used to determine the transcription factor of IL-25 promoter.

Results: Exogenous IL-25 induced expression of type 2 cytokine and alternative activation of Kupffer cell *in vivo*. It could also promote hepatic macrophages to differentiate into M2a Kupffer cells *in vitro*. Interestingly, IL-25 recovered the expression of IL-25 mRNA in the liver of NAFLD mice. Furthermore, IL-25 could induce the expression of IL-25 in cultured hepatocytes by activation of STAT6, rather than MZF1, AP1 or NF-κB. STAT6 was sufficient and necessary for IL-25 expression. Deletion and site-directed mutagenesis of the IL-25 promoter revealed that IL-25 transcriptional activation depended primarily on a putative STAT-binding sequence between nucleotides -682/-674 upstream of the start site. STAT6 binding to this sequence increased in response to IL-25 treatment *in vitro* and *in vivo*. Finally, IL-25 induced M2a Kupffer cells could ameliorate HFD-induced hepatic steatosis by reducing M1 Kupffer cells.

Conclusion: Our results elucidate the molecular mechanisms of IL-25 during amelioration of hepatic steatosis and provide the scientific basis of direct IL-25 treatment or macrophage transfusion therapy for NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: NASH is considered an important risk factor for liver fibrosis. Although literature data indicates that statins may be beneficial when given for NASH treatment, recent reports are controversial¹.

Aims & Methods: To evaluate if statins independently influence the evolution of fibrosis accompanying NASH using the scales of FibroMax, 120 patients with NASH and metabolic syndrome were followed-up for a period of 3 years. We excluded patients taking a series of drugs, with genetic metabolic disorders or impaired intestinal absorption (celiac disease) or alcoholics. Steatosis, fibrosis

and NASH were quantified by using the FibroMax scales at baseline and after three years of statin treatment. Patients were randomized in two groups: the active group of 60 patients receiving low-dose hydrophilic statin (rosuvastatin 5 mg/day) and the witness group of 60 patients, matched by age, gender and sex, receiving placebo.

Results: 97% of subjects fulfilled the follow-up period. The FibroMax staging at baseline showed the following results in the active group: S1–29%, S2–41% and S3–30%; F1–50%, F2–30%, F3–13% and F4–7% of patients, respectively N1–31% and N2–69%. The staging according to FibroTest, SteatoTest and NashTest was similar in placebo group. After 2 years of low-dose hydrophilic statin, the mean ALT level from active group decreased from 72.22 IU/L to 32.80 IU/L, $p < 0.05$ (ss); in the witness group no significant ALT decrease was noticed (69.34 IU/L to 58.17 IU/L, $p > 0.5$). The FibroMax showed an important improvement of steatosis and fibrosis in active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–27%, S1–46%, S2–25%, respectively S3–2% of patients, respectively F0–38%, F1–32%, F2–28%, F3–2%; F4–0% of patients. NashTest also proved a positive evolution under statin treatment, compared with placebo (N0–36%, N1–40% respectively N2–26%, $p > 0.001$, ss). After adjusting for age, BMI, diabetes, LDL-cholesterol and triglyceride levels, statin therapy showed a significant correlation with the steatosis, fibrosis and NASH stages improvement in the active group ($r = 0.92$, $r = 0.87$, respectively $r = 0.95$, $p < 0.005$, ss).

Conclusion: While statins proved to be safe and efficient for the treatment of NASH in our series, larger cohort studies are needed to further demonstrate this potential positive effect on liver fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0017 THE ROLE OF GENETIC FACTORS IN NON-OBESE NASH PATIENTS

F. Ates

Gastroenterology, Mersin University, Mersin/Turkey

Contact E-mail Address: drfehmiates@hotmail.com

Introduction: Methylene tetrahydrofolate reductase (MTHFR) is the key enzyme in homocysteine metabolism. It is thought that MTHFR A1298C and C677T gene polymorphisms contribute to etiopathogenesis of NASH because of their effects in homocysteine metabolism.

Aims & Methods: Our aim in this study is to determine the relationship between the NASH and MTHFR C677T and A1298C gene polymorphisms, especially in non-obese NASH patients. Eighty-eight NASH patients whose diagnoses were confirmed by liver biopsies and 90 healthy volunteers as control group were included in the study. We investigated MTHFR A1298C and C677T gene polymorphisms and compared NASH patients and controls. NASH patients were assigned to two groups according to whether they are obese.

Results: Eighty-eight NASH patients (52M, 36F, mean age 45 years), and 90 healthy controls (53M, 37F, mean age 41 years) were included in the study. According to BMI values of NASH patients, 55 patients were non-obese and 33 patients were obese. There was no statistically significant difference between distribution of MTHFR A1298C polymorphism of NASH patients and controls ($p > 0.05$). The proportion of TT genotype of MTHFR C677T polymorphism of NASH patients was significantly higher than that of controls ($p < 0.01$). Also the proportion of TT genotype of MTHFR C677T polymorphism of non-obese NASH patients was significantly higher than that of controls ($p < 0.01$). However, the proportion of TT genotype of MTHFR C677T polymorphism of obese NASH patients was not significantly different than the control group ($p > 0.05$). MTHFR C677T CC (wild) genotype was significantly lower in non-obese NASH patients than controls ($p < 0.05$).

Conclusion: This study revealed that TT genotype of MTHFR C677T polymorphism is more frequent, especially in non-obese NASH patients than in healthy controls. This finding shows that genetic factors are particularly more important in non-obese NASH patients.

P0018 EVALUATION OF THE RELATIONSHIP OF LEVELS OF C-REACTIVE PROTEIN AND HOMOCYSTEIN IN PATIENTS WITH ABDOMINAL OBESITY AND PATHOLOGICAL CHANGES IN THE LIVER DEFINED BY BIOPROGNOSTIC TEST STEATOSCREEN

E. Chernetcova, N. Denisov

The Second Department Of Therapy Of Improvement Of Doctors, The Federal State Military Educational Institution of Higher Education, Military Medical Academy nam, Saint-Petersburg/Russian Federation

Contact E-mail Address: katemed@list.ru

Introduction: The importance of subclinical inflammation and hyperhomocysteinemia in the development of nonalcoholic fatty liver disease (NAFLD) needs further study.¹ Recent studies have shown that the development of hyperhomocysteinemia and an increase in the level of C-reactive protein contributes to increased oxidative stress, influences the development of metabolic disorders,

which makes it possible to consider these indicators as additional markers for the development of NAFLD in patients with abdominal obesity (AO).

Aims & Methods: We aimed to study the relationship between CRP and homocysteine (HC) levels with pathological changes in the liver, determined with the non-invasive bioprognostic test Steatoscreen in patients with AO. The study included 60 patients aged 18 to 59 years with joints with a waist circumference > 80 cm for women, over 94 cm for men. All patients underwent a bioprognostic test Steatoscreen. Depending on the severity of the pathological changes in the liver, the Steatoscreen scale divided all the patients into 3 groups: steatosis, fibrosis and steato-fibrosis. Depending on the presence or absence of cytolytic syndrome, 2 subgroups were distinguished in each group: subgroups of non-alcoholic steatohepatitis (ALT values, AST above the norm more than 2 times), and steatosis. In all patients, the levels of CRP and GC were studied.

Results: In groups of patients with fibrosis and steato-fibrosis, the levels of CRP and HC were significantly higher than in patients in the steatosis group, and the highest values of these parameters were recorded in patients in subgroups with non-alcoholic steatohepatitis. In the process of correlation analysis, significantly positive interrelations between the levels of CRP and HC were obtained with the levels of severity of pathological changes in the liver on the Steatoscreen scale: $r = 0.6$ и $p < 0.001$; $r = 0.85$ и $p < 0.0016$ for CRP and HC, respectively.

Conclusion: NAFLD in patients with AO is characterized by the development of a complex of metabolic disorders associated with chronic vascular inflammation. This fact can influence the risk of developing the pathology of not only the liver, but also atherosclerosis and proves the need for a more thorough examination of patients with AO and NAFLD for the purpose of early detection and correction of existing metabolic disorders.

Introduction: In the last decade, the notion of non-alcoholic fatty liver disease (NAFLD) has undergone noticeable changes. It is shown that in the liver with fatty hepatosis, insulin and glucose utilization is disrupted, conditions are created for the synthesis of atherogenic fractions of cholesterol and triglycerides. This contributes to the development of violations of carbohydrate and lipid metabolism, the early appearance of atherosclerosis and associated cardiovascular complications. Thus, NAFLD can be considered as an independent, additional risk factor for the development of atherosclerosis. Obviously, the studies devoted to clarifying the nature of the relationship between NAFLD and the early manifestations of atherosclerotic vascular wall lesions are relevant.

Aims & Methods: Study of changes in the vascular wall of the common carotid artery (IMT CCA) and in patients with abdominal obesity (AO) and different forms of nonalcoholic fatty liver disease (NAFLD). The study involved 60 patients with AO between the ages of 18 to 59 years (waist circumference (WC) > 80 cm in women and > 94 cm in men), and NAFLD, in the absence of clinical manifestations, provided written informed consent to participate in the study. All patients underwent an ultrasound examination of the abdominal cavity to determine the size of the liver and signs of steatosis. The level of severity of pathological changes in the liver tissue (fibrosis, steatosis and steatofibrosis) was assessed by non-invasive diagnostic method Steatoscreen. (Biopredictive laboratory, France). Measurement of the CCA IMT was performed according to standard procedures on the machine Voluson 730 Expert, equipped with a linear transducer phased array with a frequency of 7.5 MHz. The presence of early signs of atherosclerosis was defined as a local thickening of the IMT CCA more than 0.9 mm in any point of the carotid artery (CCA IMT max). Depending on the severity of the pathological changes in the liver, the Steatoscreen scale divided all the patients into 3 groups: steatosis, fibrosis and steatofibrosis. Depending on the presence or absence of cytolytic syndrome, 2 subgroups were distinguished in each group: subgroups of non-alcoholic steatohepatitis (ALT values, AST above the norm more than 2 times), and steatosis. In the future, comparative and correlation analysis of the data was carried out.

Results: Signs of early atherosclerosis, in the form of the IMT CCA, were detected in the majority of the patients (52%) and differed between the observed groups. The average thickness of the IMT CCA was significantly higher in patients with abdominal obesity and pathological changes in the liver in the form of severe steatofibrosis on the Steatoscreen scale than in groups of patients with less severe changes in hepatic tissue (0.83 mm for the steatosis group, 0.89 and 0.97 mm for fibrosis and steatofibrosis groups respectively, $p < 0.001$). At the same time, the maximum thickness of the IMT CCA was recorded in the group of patients with non-alcoholic steatohepatitis in the fibrosis group (1.14 mm, $p = 0.002$). In the process of regression analysis, a direct significantly relationship was found between the thickness of the carotid intima-media

complex and pathological changes in the liver, determined by the test Steatoscreen ($r=0.76$; $p<0.0001$). The dependence obtained is confirmed by the equation of simple linear regression.

Conclusion: In patients with AO, there is a direct relationship between the presence of pathological changes in the liver and the initial manifestations of atherosclerosis. The results obtained make it possible to evaluate the individual risk of atherosclerosis in this category of patients. Clinical significance of the results is the need for a more thorough examination of patients with AO and suspicion of liver pathology to assess the development of not only the disease of the liver itself, but also cardiovascular complications.

Introduction: Insulin resistance is the main pathogenic determinant of both NAFLD and diabetes, and it can facilitate triglyceride accumulation in the liver. Overexpression of hepassocin (HPS) increased hepatic lipid accumulation and NAFLD activity scores (NAS), whereas deletion of HPS improved high fat diet-induced hepatic steatosis and decreased NAS in mice.

Aims & Methods: The aim of this study was to explore the relationship between hepassocin and diabetic patients with or without NAFLD. The study included 80 patients that were divided into 4 groups: Group I: included 20 patients who were diagnosed as diabetes mellitus type 2, Group II: included 20 patients who were diagnosed as non alcoholic fatty liver disease, Group III: included 20 patients who were diagnosed as diabetes type 2 and non alcoholic fatty liver disease, Group IV (control group): included 20 healthy person who were matched in age and sex with patients group.

Results: There was statistically significant decrease in mean value of serum hepassocin of group I and IV on comparing with group II and group III. For group III there was statistically significant increase in mean value of serum hepassocin on comparing with other groups. There was a significant serum hepassocin up regulation in patients with type 2 diabetes and non alcoholic fatty liver diseased patients (Group 3) mostly than diabetic patients (Group 1) and even than non alcoholic fatty liver disease (Group 2).

Conclusion: The present study provides evidence that overexpression of HPS may facilitate increased hepatic lipid accumulation with NAFLD and Type 2 Diabetes mellitus.

Introduction: Visceral adipose tissue (VAT) and gut are thought to be the main two sources of damage factors promoting non-alcoholic fatty liver disease (NAFLD). As one part of VAT, mesenteric adipose tissue (MAT) may be unique in VAT for it can affect liver directly via portal vein. However, the relationship of MAT status with different stages of NAFLD is not clear, as well as the role of inflamed MAT in NAFLD.

Aims & Methods: Mice fed with high fat diet or normal diet were sacrificed in time gradients (4w, 8w, 12w). Then, MAT in high fat diet feeding mice was removed or not at 8th week and mice were sacrificed by 12th week.

Results: Mice have developed hepatic steatosis at 8th week and progressed to steatohepatitis by 12th week. Among four parts (mesenteric, epididymal, perirenal and retroperitoneal) of VAT, merely MAT became inflamed (mRNA

expression of TNF- α increased, $P<0.01$ and IL-10 decreased, $P<0.05$) by 8th week, which happened to coincide with the presence of hepatic steatosis. Removal of inflamed MAT significantly worsened liver pathology, as well as resulted in hepatic inflammation (mRNA expression of MCP-1 increased, $P<0.01$ and IL-10 decreased, $P<0.01$) and lipid accumulation (mRNA expression of ACC1 increased, $P<0.01$ and PPAR- α decreased, $P<0.01$). Meanwhile, intestinal permeability was higher in the MAT removal group than that in the Sham group, which was supported by higher lipopolysaccharide ($P<0.05$) in serum and lower mRNA expression of ZO-1 ($P<0.01$) and occludin ($P<0.05$) in small intestine.

Conclusion: These results suggest MAT inflammation arises at the early stage of NAFLD. Removal of inflamed MAT promotes the development of NAFLD and injures the intestinal barrier. Thus, we propose that MAT inflammation seems to be a compensatory response, on the fact that inflamed MAT protects the liver from the gut-derived damage factors via confining them within MAT, rather than aggravates NAFLD.

Introduction: Non alcoholic fatty liver disease (NAFLD) is a broad term describing simple steatosis, non alcoholic steatohepatitis (NASH), NASH cirrhosis and NASH-induced hepatocellular carcinoma (1). Incidence increased in patients with type 2 diabetes mellitus (DM) (2). Different diagnostic modalities have great limitations in differentiating simple steatosis from steatohepatitis (3). Liver biopsy remains the gold standard for diagnosis of NASH, however, it is invasive with potential severe complications (4). Several ultrasound elastography techniques have been described including transient elastography, acoustic radiation force impulse elastography and shear wave elastography (5). Shear wave elastography shows a stepwise increase of liver stiffness as the severity of liver inflammation increases (6).

Aims & Methods: We aimed to evaluate the accuracy of shear wave ultrasound elastography in differentiating simple steatosis from steatohepatitis in patients with type 2 DM. This was a prospective study including 60 patients 30 males and 30 females who visited our outpatient clinic or inpatient department at Specialized Medical Hospital. These patients were diabetic aged more than 30 years old with ultrasound showing fatty liver. Significant alcohol consumption, drugs causing steatosis and hepatic diseases were excluded by history, laboratory investigations and liver biopsy. All patients underwent full detailed history, examination, laboratory investigations (complete blood count, liver functions, kidney functions, random blood sugar, lipid profile, serology for hepatitis B and C viruses). Shear wave elastography was performed to all patients and stiffness of the liver was measured from different areas in kilopascal (kPa) then average stiffness by elastography was calculated. Liver biopsy was done and histopathological examination by Hematoxylin, Eosin and Masson Trichrome stains, then NAFLD activity score (NAS) was calculated.

Roc curve for diagnosis of definitive NASH versus no NASH and probable NASH

Variable	Criterion	AUC	CI	P.	Sensitivity	Specificity	PPV	NPV
Average stiffness by elastography	8.45	0.936	0.871–1	<0.001	90%	90%	81%	94%

Results: Correlation between results of stiffness by elastography and NAS by biopsy revealed that: There was a significant positive association between average stiffness by elastography and definitive NASH (NAS 5 and 6) in patients with type 2 DM. At a level of 8.45 kPa by shear wave elastography, we can differentiate simple steatosis from steatohepatitis (Area Under Curve 0.936, sensitivity 90%, specificity 90%, positive predictive value 81%, negative predictive value 49%).

Conclusion: Shear wave ultrasound elastography is a promising non invasive technique to differentiate simple steatosis from steatohepatitis in patients with type 2 DM.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Nonalcoholic fatty liver disease is a main cause of chronic liver disease worldwide. A quantitative, non-invasive assessment of hepatic steatosis is desirable. Throughout the path of ultrasound (US), attenuation by liver parenchyma is uneven. This is the basis of the controlled attenuation parameter (CAP). However, further accumulation of data is needed to assess the role of CAP in the diagnosis of steatosis. We investigated the diagnostic performance of B-mode image-guided ultrasound attenuation imaging and quantification for assessing hepatic steatosis by a liver biopsy (LB, reference standard). It was compared with the liver-to-spleen ratio (L/S ratio) from computed tomography (CT) and CAP.

Aims & Methods: We prospectively analyzed 112 consecutive patients with chronic liver disease who underwent ultrasound attenuation imaging, CT, and liver biopsy. Ultrasound attenuation imaging was performed using the LOGIQ E9 scanner (GE Healthcare) with a C1-6-D convex array probe (frequency, 4 MHz). We acquired a B-mode image of liver parenchyma. RF signals corresponding to the images were compensated by the reference signal previously measured from the uniform phantom (known attenuation, 0.5 dB/cm/MHz²). The attenuation coefficient (AC) was calculated from the signals' decay slope. Steatosis, liver fibrosis, and necroinflammatory activity were staged and graded during pathological analysis. The steatosis grade was categorised as follows: S0, <5%; S1, 5–33%; S2, 34–66%; or S3, ≥67%. The diagnostic performance of AC for steatosis prediction was assessed using area under the curve (AUC) analysis; it was compared with the L/S ratio or CAP. Univariate and multivariate regression analyses were used to identify variables correlated with AC values.

Results: Patients (51% men; 42% had non-alcoholic fatty liver disease, 58% had hepatitis C virus) had a median body mass index of 26 kg/m². Median AC values for grades S0 (n=38), S1 (n=47), S2 (n=18), and S3 (n=9) were 0.49, 0.55, 0.66, and 0.72, respectively, demonstrating a stepwise increase with increasing steatosis severity (P < 0.0001). AC was significantly correlated with the steatosis percentage (r=0.800, P < 0.0001), L/S ratio (r=-0.670, P < 0.0001), and CAP (r=0.639, P < 0.001). AUCs of AC vs. the L/S ratio for identifying grades ≥S1, ≥S2, and ≥S3 were 0.919 vs. 0.856, 0.957 vs. 0.902, and 0.960 vs. 0.919, respectively, showing significantly better results than those for the L/S ratio and CAP. For the sensitivity and specificity of AC ≥85%, cut-off values were 0.53 dB/cm/MHz for ≥S1, 0.60 dB/cm/MHz for ≥S2, and 0.64 dB/cm/MHz for ≥S3. Steatosis was the only factor independently affecting AC values.

Conclusion: Ultrasound attenuation imaging had a high diagnostic accuracy for detecting hepatic steatosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Individuals with chronic liver diseases may have a mild to moderate iron overload, but the mechanism is not fully understood. Increased contents of iron have been attributed to the progression of liver cirrhosis caused by HCV infection, non-alcoholic fatty liver disease, or alcoholic liver disease. Serum ferritin concentration can be increased in iron overload and shows hepatic necro-inflammation. Recently, raised serum ferritin concentration was shown to predict mortality in patients awaiting liver transplantation in decompensated liver cirrhosis, but according to latest research plasma ferritin levels can help to predict the early mortality of patients with alcoholic liver cirrhosis (ALC).

Aims & Methods: The aim of this study was to determine the association between serum ferritin concentration and the outcomes of patients with ALC. The study included 72 patients with ALC. The diagnosis and etiology of ALC was confirmed by laboratory tests, clinical features, radiological imaging, and percutaneous or transjugular liver biopsy. Alcoholic liver disease was confirmed when daily consumption of alcohol was > 30 g/20 g/day for males/females, respectively, as confirmed by at least 1 family member of affected individual. All patients were divided into three groups by serum ferritin concentration: below 200 µg/L, 200–400 µg/L and above 400 µg/L. Statistical analysis was performed using statistical software SPSS 23.0. ROC (Receiver operating characteristic) scale was used to estimate serum ferritin specificity in predicting early mortality. If the area under the curve (AUC) is greater than 0.5, the test is specific.

Results: The first group consisted of 44 patients, the second group 13 patients, the third group 15 patients. The average age was 57.5 ± 11.7 years. Serum ferritin concentration in first group was 58.2 ± 45.9 µg/L, second 293.5 ± 63.5 µg/L, third – 599.5 ± 221.1 µg/L. AST concentration in first group was 90.8 ± 70.2 IU/L, second – 96.7 ± 58.3 IU/L, third – 133.8 ± 95.5 IU/L. ALT concentration in first group was 66.7 ± 66.8 IU/L, second – 64.5 ± 75.5 IU/L, third – 60.1 ± 49.5 IU/L. Bilirubin concentration in first group was 90.52 ± 85.7 µmol/L, second – 111.9 ± 72.3 µmol/L, third – 140.9 ± 195.0 µmol/L. The biggest mortality rate was in third group – 13 of 15 patients (86.67 %) (p < 0.00001). ROC scale shows a 77% specificity of serum ferritin concentration predicting early mortality in patients with toxic cirrhosis (AUC 0.838, p < 0.0001).

Conclusion: Serum ferritin level above 400 µg/L, elevated liver enzymes and bilirubin concentration shows a poor outcome of patients with ALC (p < 0.0001). Serum ferritin level is a specific indicator for predicting early mortality in ALC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0026 PLASMA RETICULON 4 PROTEIN IS ASSOCIATED WITH PORTAL HYPERTENSION IN PATIENTS WITH LIVER CIRRHOSIS

Introduction: Reticulon 4 (RTN4) protein was first described as a potent neurite growth inhibitor in the central nervous system¹. However, according to recent research, the protein expression is not limited to the cells of nervous system as it was found in various other tissues, including endothelial cells, fibroblasts, muscle cells, hepatocytes^{1, 2, 3}. The diverse location of the protein accounts for various functions, such as vascular remodeling, inflammation and oxidative stress, cell proliferation, carcinogenesis and atherogenesis^{2, 3, 4, 5, 6}. The function and expression of the protein in liver disease is still not clear.

Aims & Methods: In this study we aimed to evaluate plasma levels of RTN4 protein in cirrhotic patients and associate them with clinical parameters and portal hypertension. The pilot study included 72 patients with hepatitis C or alcoholic liver cirrhosis and 22 healthy controls. Liver cirrhosis was diagnosed by laboratory tests, radiological imaging and/or liver biopsy. Portal pressure was assessed by hepatic venous pressure gradient (HVPG) measurement. Plasma levels of RTN4 were determined by enzyme-linked immunosorbent assay. Association of RTN4 with biochemical parameters, Child-Turcotte-Pugh and Model of End Stage liver disease (MELD) score, transient elastography values, esophagogastrophic varices, HVPG, clinically significant portal hypertension (CSPH; HVPG ≥ 10 mHg) and severe portal hypertension (SPH; HVPG ≥ 12) was assessed.

Results: Plasma RTN4 levels were significantly lower in cirrhotic patients than in healthy controls (p < 0.0001). Significant negative correlation was observed between RTN4 and Child-Pugh score (r = -0.301; p = 0.015), MELD score (r = -0.311; p = 0.026), transient elastography values (r = -0.331; p = 0.006). There was significant correlation between RTN4 and AST (r = -0.307; p = 0.005), ALP (r = -0.396; p = 0.001), total bilirubin (r = -0.426; p < 0.0001), thrombocytes (r = 0.534, p < 0.0001), INR (r = -0.357, p = 0.002) concentrations. RTN4 correlated with HVPG (r = -0.298; p = 0.011) and predicted CSPH (p < 0.001) as well as SPH (p < 0.0001). Using a RTN 4 cut-off value of ≤1.7 ng/ml, the AUC for

detection of CSPH was 0.71, with positive predictive value of 75% and negative predictive value of 63%, sensitivity 70% and specificity 71%. RTN4 value of ≤ 1.1 ng/ml was associated with esophagogastric varices (odds ratio [OR] = 3, 63; $p < 0.022$).

Conclusion: Low levels of RTN4 are associated with liver cirrhosis and portal hypertension. RTN4 correlates with liver function. It may be a surrogate marker of CSPH and presence of esophagogastric varices.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Peritoneal carcinomatosis (PCA) has a prognostic role in patients with gastrointestinal cancers. Despite the low sensitivity, cytology remains the gold standard in differential diagnosis of PCA to peritonitis (for example spontaneous bacterial peritonitis, SBP) or uncomplicated ascites due to portal hypertension (no SBP/PCA). MicroRNAs (miRNAs) are considered as promising biomarkers and are commonly dysregulated in cancer.

Aims & Methods: In this proof-of-principle study, we systematically evaluated preanalytical factors and potential of miRNAs as ascites biomarkers. We prospectively examined samples from patients with ascites with benign and malignant conditions including: PCA (n=15), SBP (n=15) and portal hypertension (no SBP/PCA, n=15). Various extraction kits were used to compare the total RNA extraction. Furthermore, we systematically evaluated the influence of storage, stability and sample processing (uncentrifuged, pelleted etc.) on miRNA expression in ascites. MiRNA expression profiling using TaqMan Low Density Array (TLDA) and quantitative RT-PCR (TaqMan/SYBRgreen) were used to evaluate the expression.

Results: Systematic analysis of miRNAs stability confirms that miRNAs in ascites are well preserved from degradation with good short- (0h, 12h, 24h, and 48 h) and long-term stability (-30°C , -80°C for 2 years). Several miRNAs that were selected for the proof-of-principle analysis (miR-21 and miR-16) were reproducibly detectable in ascites samples. MiRNA expression profiling in patients with PCA compared to those with uncomplicated portal hypertension revealed miR-21, miR-186, miR-222 and miR-483-5p to be up-regulated and miR-26b to be down-regulated. MiRNA expression validation analysis confirmed higher expression of miR-21 (mean delta CT \pm SD; -11.11 ± 1.2 vs. -8.46 ± 3.46 vs. -9.65 ± 2.55 for no SBP/PCA, PCA and SBP, respectively, ANOVA, $p=0.026$; posttest no SBP/PCA vs. PCA $p < 0.05$) and miR-186 in patients with PCA compared to no SBP/PCA groups, while miR-222 was significantly upregulated in SBP (mean \pm SD; -12.16 ± 1.56 vs. -10.05 ± 3.19 vs. -6.95 ± 3.56 for no SBP/PCA, PCA and SBP, respectively, ANOVA, $p < 0.0001$; posttest SBP vs no SBP/PCA and vs. PCA $p < 0.05$).

Conclusion: Our data provide novel evidence for the differential expression of miRNAs in ascites in patients with PCA and SBP. Evaluation of ascites-miRNAs may offer an alternative approach for diagnosis of peritoneal carcinomatosis and create an avenue for therapeutic application as well.

Introduction: Pathological bacterial translocation (PBT) in liver cirrhosis (LC) is the pathophysiological hallmark for spontaneous bacterial infections increasing mortality several-fold. Factors known to contribute to PBT in LC are among others an increased intestinal permeability.

Aims & Methods: A clear route of translocation for luminal intestinal bacteria is yet to be defined but we hypothesize that the recently described gut vascular barrier (GVB) is impaired in experimental portal hypertension leading to protein loss and increased accessibility of the vascular compartment for translocating bacteria. For this purpose two different models of experimental portal hypertension, namely partial portal vein ligation (PPVL) and bile duct ligation (BDL) were used in mice under standardized gnotobiotic conditions (sDMDM2). A novel in vivo confocal endomicroscopy technique was established in order to visualize the intestinal vascular leakage. Briefly, 70 kDa FITC-marked dextran was injected intravenously and confocal probe was placed in the intestinal lumen (terminal ileum) to visualize villus-capillaries. Leakage was measured over time (10 minutes) as a ratio between the mean fluorescence intensity outside the vessel (lamina propria) and inside the vessel. Immunofluorescence (IF) stains of the fenestral diaphragms marker plasmalemma vesicle-associated protein-1 (PV-1) were performed for GVB analysis.

Results: Confocal endomicroscopy data revealed an earlier and significantly increased leakage of 70kDa through the intestinal vasculature in both BDL and PPVL mice. FITC-70kDa-dextran did only leak in BDL and PPVL but not in control (sham operated) mice. Interestingly GVB stains showed increased expression of PV1 in intestinal vessels (CD34⁺) of BDL but not PPVL.

Conclusion: Portal hypertension per se has an impact on the GVB increasing FITC-70kDa-dextran leakage from intestinal capillaries to the lamina propria in both BDL and PPVL. However, the IF showed only in BDL an increased PV-1 expression indicative of a wider opening of the fenestral diaphragms than in PPVL. Therefore, different mechanisms appear to be involved in alterations of the gut-vascular barrier in pre-hepatic portal hypertension and biliary cirrhosis.

Introduction: Splenomegaly is a common finding in liver cirrhosis. However, the precise underlying mechanisms behind this phenomenon have not been elucidated, and its effective therapies are limited.

Aims & Methods: We aimed to investigate whether cyclooxygenase-2 (COX-2) is involved as a contributing factor in the pathological process of splenomegaly in cirrhotic rats. Thirty-six male Sprague-Dawley rats weighing 200–250 g were randomized into 3 groups with 12 rats in each group. The control group received intraperitoneal injection of normal saline (1 ml, twice a week); the TAA group received intraperitoneal injection of thioacetamide (TAA, 200 mg/kg, twice a week for 16 weeks); the TAA + celecoxib group received TAA intraperitoneally and celecoxib via gastric gavage (20 mg/kg/day). The portal pressure was measured by portal venous catheterization. Sections from paraffin-embedded spleens were stained with hematoxylin and eosin and Sirius Red, and immunostained with VEGF and CD31. The protein expressions of COX-2, VEGF, PI3K, p-AKT, and AKT in the spleen were assessed by Western blot. The enzyme-linked immunosorbent assay was performed to evaluate the expression of TNF- α and IL-1 β in the spleen.

Results: The ratio of splenic weight to body weight increased by 73.9% in TAA group, while in rats treated with celecoxib, the ratio was significantly reduced. While determined by H&E staining, areas of splenic white pulp in the TAA group enlarged by 27.9%. Yet, compared with that in TAA group, celecoxib obviously decreased the area of splenic white pulp by 37.6%. Besides, the portal pressure elevated by 79.1% in the TAA group; while significant reduction of the portal pressure was observed in the TAA + celecoxib group (by 28.8%). In addition, a considerable amount of collagen was visualized with Sirius Red staining in the splenic red pulp of TAA group. Decreased splenic fibrosis was found in TAA + celecoxib group. Increased COX-2 protein was detected in the spleen of the TAA group compared with that in the control group. However, celecoxib significantly reduced the expression of COX-2 in the TAA + celecoxib group. Besides, compared with the control group, TNF- α and IL-1 β , the two proinflammatory cytokines were found to be greatly increased in the TAA group. On the contrary, in TAA + celecoxib group, the protein expression of TNF- α and IL-1 β was obviously reduced. We also found that the expression of proangiogenic factor VEGF and the neovascular marker CD31 increased in TAA group by Western blot and immunohistology, which indicated a role of angiogenesis in the pathophysiology of splenomegaly. Furthermore, up-regulation of PI3K and p-AKT protein expression was detected in the spleen of TAA group compared

with that of the control group, demonstrating that PI3K/AKT signal pathway was involved in the development of pathological angiogenesis. However, the treatment with celecoxib strongly decreased the protein expression of VEGF, CD31, PI3K and AKT in the spleen of cirrhotic rats.

Conclusion: The present study indicates that COX-2 contributes to splenomegaly by facilitating angiogenesis, fibrosis and inflammation in the spleen. Moreover, inhibition of COX-2 by celecoxib could ameliorate portal hypertension and splenomegaly.

Introduction: Spontaneous bacterial peritonitis (SBP) is a life-threatening complication in advancing liver cirrhosis. Translocation of intestinal bacteria or bacterial products from the gut to mesenteric lymph nodes is crucial for SBP, with *Escherichia coli* (*E. coli*), *Klebsiella pneumoniae* being the most common germs. Small intestinal bacterial overgrowth and a altered microbiota are so far known as risk factors for SBP. However, the exact mechanisms of bacterial translocation need to be identified as they are supposed to contribute to the development of early recognition systems and initiation of antibiosis.

Aims & Methods: With regard to the development of early recognition systems, pathomechanisms and signaling pathways of bacterial translocation in SBP were explored. These insights might lead to an initiation of antibiosis on time and reduced mortality in SBP.

Monolayers of human intestinal epithelial cell lines Caco-2 (p53 mutant) and HCT-116 (p53 wildtype) were cocultured with *E. coli* with different MOI (MOI 0, 1, 5 and 10) for 2 to 4 hours post confluence. Experiments with heat inactivated *E. coli* were performed as controls. Effects of microbial metabolic products were tested by using the supernatant of an overnight culture. qPCR and Western Blot analysis were performed to analyze changes in mRNA and protein levels of Occludin, E-cadherin and the p53 family including p53 and p73.

Results: *E. coli* stimulation of HCT-116 cells resulted in a strong decrease of Occludin, E-cadherin, p53 and p73 protein levels. These changes were dependent on incubation time and bacterial concentration. Following bacterial infection, marginal to no effects were detected on mRNA levels of cellular junctions and p53. Caco-2 cells displayed less reduction of Occludin and E-cadherin protein levels compared to p53-wildtype HCT-116 cells.

Conclusion: By using an *in vitro* model, we demonstrate destabilizing effects of *E. coli* on intestinal cell junctions, p53 and p73. As far as these effects are dependent on incubation time, microbial concentration and living bacteria, these effects might represent a mechanism to protect bacteria from intestinal immune responses and therefore to promote bacterial translocation in SBP.

Introduction: Pathological bacterial translocation (PBT) in liver cirrhosis (LC) is the pathophysiological hallmark for spontaneous bacterial infections increasing mortality several-fold. Factors known to contribute to PBT in LC are among others an increased intestinal epithelial permeability.

Aims & Methods: Since mucus represents one of the major components of this barrier we hypothesize that i) gut mucus is altered in LC and ii) bile could be a modulator of its production. Two different models of experimental LC –namely bile duct ligation (BDL) and the chronic treatment with carbon tetrachloride (CCl₄) – as well as partial portal vein ligation (PPVL) and sham-operated mice were used. Finally the farnesoid X receptor (FXR) agonist obeticholic acid (OCA) was used as treatment in CCl₄-LC and control-animals. Mucus thickness measurement on gut explants and PAS (Periodic acid–Schiff) staining to visualize and count goblet cells (GC) were utilized.

Results: We have observed a significant reduction in mucus thickness in ileum and colon (Control 101.34 µm ± 9.54 vs BDL 77.49 µm ± 14.31 in Ileum; control 154.38 µm ± 12.51 vs BDL 100.74 µm ± 0.6 in proximal colon) and goblet cell numbers in ileum (Control 0.47 GC/100 µm of villus ± 0.07 vs BDL 0.29 GC/

100 µm of villus ± 0.04) of mice following BDL but not PPVL (Control 0.27 GC/100 µm of villus ± 0.11 vs PPVL 0.30 GC/100 µm of villus ± 0.04). Moreover we have seen that farnesoid X receptor (FXR) agonist obeticholic acid (OCA) partially restored GC loss in CCl₄ treated animals (Control 0.63 GC/100 µm of villus ± 0.08 vs Control OCA 0.65 GC/100 µm of villus ± 0.07 vs CCl₄ 0.49 GC/100 µm of villus ± 0.18 CCl₄ OCA 0.57 GC/100 µm of villus ± 0.09).

Conclusion: All these results suggest that a reduced bile production by the cirrhotic liver and not portal hypertension per se interfere in the goblet cell development and/or maturation. In addition, this effect can be, at least partially, be restored by the FXR agonist OCA. Our study opens the possibility to a, so far, unknown effect of bile salts in the intestinal epithelium development in the context of liver cirrhosis being a clear candidate for mucus layer regulation and hence protective effect against bacterial translocation.

P0032 CAPSAICIN AND SULFORAPHANE PREVENT THE ADVANCEMENT OF LIVER FIBROSIS IN AN EXPERIMENTAL MODEL OF LIVER CIRRHOSIS

E. J. Mendivil¹, A. Sandoval-Rodriguez¹, A. Dominguez-Rosales², L. Zuñiga-Ramos², J. Armendariz-Borunda²

¹Molecular Biology And Genomics, University of Guadalajara, Guadalajara/Mexico

²University of Guadalajara, Guadalajara/Mexico

Contact E-mail Address: edgarmendivil@live.com

Introduction: Liver fibrosis refers to the excessive accumulation of extracellular matrix (ECM) following a chronic liver injury. It is characterised by an increase in gene expression of proinflammatory molecules such as TGF-β1, IL-1 β, IL-6 and TNF-α, as well as excess synthesis in of ECM components such as COL-1. Capsaicin (CAP) is a pungent compound found in chilli peppers which has shown anticarcinogenic, antiinflammatory and antifibrotic properties. Moreover, sulforaphane (SFN) is an isothiocyanate which is in cruciferous such as broccoli and it has exhibit an antioxidant effect in several *in vitro* and *in vivo* models.

Aims & Methods: The objective of this project was to evaluate the antifibrogenic and antiinflammatory effects of a daily supplementation with CAP and SFN in a rat model of liver fibrosis due to carbon tetrachloride (CCl₄) intoxication. 35 male Wistar rats were included (n = 7/group); animals were administrated intraperitoneally 3 times per week during 8 weeks with a mix of CCl₄:mineral oil (1:5/ week 1, 1:4 week 2 and 1:3 week 3-8). Healthy and CCl₄-fibrotic controls received only supplementation vehicle (Tween 2% in PBS). Treated groups receive SFN 5ug/kg, or CAP 2mg/kg, or both supplements daily by oral gavage since the beginning of CCl₄-intoxication regimen until sacrifice. Masson staining and PCR was performed in liver samples. Hepatic enzymes were analysed in serum.

Results: Groups treated with CAP and SFN showed a decrease of ~30points in percentage of liver fibrosis according to Masson staining (p < 0.05), hepatic function improve since AST and ALT serum levels diminish (p < 0.01) also a lower gene expression of TGF-β1, Col-1, TNF-α, IL-1 β and IL-6 was detected in treated animals when compared with fibrotic controls (p < 0.01).

Conclusion: Thus, CAP and SFN seem to exert a hepatoprotective effect in this model of chronic-induced liver damage. These findings suggest that dietary sources of CAP and SFN might be included in dietetic guidelines for the prevention of liver fibrosis.

P0033 DIAGNOSIS OF GASTRIC VARICES BY ENDOSCOPIC ULTRASONOGRAPHY USING COLOR DOPPLER

T. Sato

Gastroenterology, Sapporo Kosei Hospital Dept. of Gastroenterology, Sapporo/Japan

Contact E-mail Address: taka.sato@ja-hokkaidoukouseiren.or.jp

Introduction: Gastric variceal bleeding is common complication, and it is associated with higher morbidity and mortality rates than hemorrhage from esophageal varices. Oesophagogastroduodenoscopy is usually the initial investigation in patients with portal hypertension for the purpose of the distinction between gastric varices and gastric folds. The aim of this study was to investigate endoscopic color Doppler ultrasonography (ECDUS) findings of gastric varices.

Aims & Methods: Two hundred-fifteen patients with gastric varices were evaluated with ECDUS. To begin with, identification of gastric varices was performed with B-mode scanning and then, color flow mapping was done. On B-mode scanning, submucosal gastric varices, and para-gastric collateral veins were obtained as hypoechoic vessels within gastric wall or in the tissue and spaces exterior to the adventitia of gastric wall. ECDUS provides a color display of blood flow and evaluates the flow pattern using fast Fourier transform (FFT) analysis. FFT analysis can indicate the flow pattern and calculate the velocity of blood flow. We monitored the color flow images of gastric varices, and para-gastric or peri-gastric collateral veins. Endoscopic findings of gastric varices were evaluated according to the grading system outlined in The General Rules for

Recording Endoscopic Findings of Esophago-gastric Varices devised by the Japanese Research Committee on Portal Hypertension.

Results: The color flow images of gastric varices and peri-gastric veins were delineated in all 215 patients with ECDUS. Evaluation of blood flow velocity in the 215 gastric varices revealed velocities of 7.7–35.7 cm/s (mean, 18.2 ± 6.0 cm/s). Mean velocity of large, coil-shaped (F3) type gastric varices was 23.7 ± 6.2 cm/s ($n = 52$), while the mean velocity of enlarged tortuous (F2) type gastric varices was 16.7 ± 5.0 cm/s ($n = 163$). The velocities of F3 type gastric varices were significantly higher than those of F2 type ($P < 0.0001$). Next, we evaluated the wall thickness to submucosal gastric varices. Two hundred-fifteen of the gastric varices were 1.0–2.2 mm (1.6 ± 0.4 mm) in gastric wall thickness. Mean thickness of red color (RC) or erosion positive varices was 1.2 ± 0.2 mm ($n = 42$), while the mean thickness of RC or erosion negative varices was 1.7 ± 0.3 mm ($n = 173$). The thickness of RC or erosion positive varices was significantly thinner than that of the negative cases ($P < 0.0001$). Seven cases of the 215 patients had the current history of gastric variceal bleeding, and the other three cases had experienced variceal rupture on follow up (bleeding cases, $n = 10$), and mean thickness of these bleeding cases were 1.2 ± 0.2 mm.

Conclusion: ECDUS is a useful modality for the diagnosis of hemodynamics of gastric varices and may allow the stratification of patients into low, high risk for hemorrhage.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0034 PORTAL HYPERTENSIVE COLOPATHY BUT NOT ILEOPATHY IS COMMON IN EGYPTIANS WITH LIVER CIRRHOSIS

Introduction: Liver cirrhosis and portal hypertension are associated with esophageal varices, gastric varices, small and large intestinal enteropathies.

Aims & Methods: We aimed to study the prevalence of colopathy and ileopathy in patients with portal hypertension secondary to liver cirrhosis. Chronic hepatitis C patients with portal hypertension secondary to liver cirrhosis were enrolled. The severity of cirrhosis was classified by the Child-Pugh score. All patients were evaluated by upper endoscopy and colonoscopy for screening of portal hypertensive complications. Esophageal varices were graded as small, moderate and big varices. Portal hypertensive gastropathy was classified as absent or present, and, if present, it was sub-classified as mild or severe. Colonoscopy was done up to terminal ileum in all patients.

Results: Our study included sixty chronic hepatitis C patients with portal hypertension secondary to liver cirrhosis (53.33% females) their mean age (\pm SD) was $54.75 (\pm 13.13)$ years. Child-Pugh class was A for 2 (3.4%), B for 33 (55.9%) and C for 24 (40.7%). 53 (88.33%) patients had esophageal varices (23 patients had small esophageal varices, 15 had moderate, and 8 had big varices, 2 post-band ligation and 5 obliterated varices). Gastric varices were present in 3 patients (5%). Portal hypertensive gastropathy was noted in 43 patients (71.6 %) and was mild in 38 and severe in 5 patients. Colonoscopy finding up to the terminal ileum revealed that portal hypertensive colopathy was present in 16 patients (26.7%). portal hypertensive ileopathy was noted only in one case (1.7%). No colonic or ileal varices were noted.

Conclusion: Portal hypertensive colopathy but not ileopathy is common in Egyptians with liver cirrhosis. Ileal varices and ileopathy are not common in patients with cirrhosis and PHT.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0035 PREDICTIVE FACTORS FOR THE DEVELOPMENT OF ACUTE-ON-CHRONIC LIVER FAILURE IN PATIENTS WITH GASTROINTESTINAL BLEEDING

C. Cojocariu¹, S. Chiriac², A. Trifan³, C. Stanciu³

Introduction: Acute-on-chronic liver failure (ACLF) is a specific clinical form of liver failure in patients with liver cirrhosis, referred as acute deterioration of liver function associated with an acute specific complication of liver cirrhosis. ACLF is defined by the presence of renal failure or ≥ 2 organ failures according to European Association for the Study of the Liver-International Chronic Liver

Failure consortium: 1) circulatory- need for vasopressor support; 2) renal-serum creatinine value ≥ 2 mg/dL; 3) cerebral- Grade III or IV hepatic encephalopathy; 4) respiratory- $\text{SpO}_2/\text{FiO}_2 \leq 214$.

Aims & Methods: We aimed to identify predictive factors for ACLF development in cirrhotic patients admitted for variceal gastrointestinal bleeding. All patients admitted with gastrointestinal bleeding in the Institute of Gastroenterology and Hepatology Iasi (consisting of 8 secondary hepatology centers) between June and December 2016 were evaluated for ACLF (we excluded from the study the patients presenting ACLF diagnosis criteria on admission). We compared cirrhotic patients who developed ACLF after 12 hours of admission with those who did not.

Results: 99 cirrhotic patients with gastrointestinal bleeding were evaluated. 48.5% of patients admitted with variceal bleeding developed ACLF. Demographic data were similar in patients with ACLF vs. no ACLF in age (54.2 ± 7.3 vs. 56.6 ± 9.5 years), male sex (54 vs. 45), and diabetes (56 vs. 43) and significant difference was found in alcohol consumption (72 vs. 27). In patients with ACLF, the grade 1 was the most frequent (56.3%); grade 2 (33.3%) and 3 (10.4%) of ACLF were more rare and no significant differences between the ACLF subgroups was observed. The patients with ACLF were more likely to be admitted with infections and alcohol consumption, when compared to patients without ACLF. Independent predictors for ACLF development included a high admission MELD ($p < 0.05$), presence of infection and alcohol abuse ($p < 0.001$), hospitalization in the last 6 months ($p < 0.05$). In-hospital and 30-day mortality were significantly higher in patients with ACLF ($p < 0.0001$).

Conclusion: Patients admitted with variceal bleeding, with alcohol consumption, high MELD on admission, previous admission in < 6 months are more likely to develop ACLF and need to be monitored closely for the development of ACLF.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0036 HAEMOSTASIS IN PORTAL VEIN IN CIRRHOSIS: ROLE OF LOCAL ENDOTHELIAL DAMAGE

Introduction: Cirrhosis is characterized by both bleeding and thrombotic complications due to underlying procoagulative haemostatic imbalance [1]. Among thrombotic events, portal vein thrombosis (PVT) is the most common with annual incidence ranging between 4.6% and 12.8% [2, 3]. Demonstrated associated risk factors are severity of portal hypertension and slowed portal flow [4]. However, data regarding haemostasis in the portal venous system of cirrhotics are lacking.

Aims & Methods: To evaluate peripheral and portal venous haemocoagulative state in patients with cirrhosis in comparison with controls, through thrombin generation test (TGT), rotational-thrombelastometry (ROTEM) along with evaluation of endothelial dysfunction by quantification of circulating endothelial-microparticles (MP). Correlate these results with activity levels of local pro and anticoagulant factors. Compare peripheral and portal venous districts in cirrhotics in terms of haemostatic balance. We consecutively enrolled adult patients with liver cirrhosis undergoing liver transplantation (LT) or transjugular intrahepatic portosystemic shunt (TIPS). Patients without liver disease awaiting liver surgery or deceased liver donors were enrolled as controls. The following laboratory tests were performed on citrated peripheral and portal venous blood samples: TGT with and without thrombomodulin (TM), ROTEM, dosage of main pro and anticoagulants factors activity and analysis of circulating endothelial MP.

Results: 25 cirrhotics (15 LT and 10 TIPS) and 6 controls (2 undergoing hepatic resection for benign liver lesions and 4 liver donors) were enrolled. Peripheral blood in cirrhotics showed resistance to activation of PC-pathway at TGT (ETP with/without TM 0.89 (0.78–0.92) vs 0.6 (0.3–0.74), $p < 0.001$), lower clot stability at ROTEM (MCF-NATEM mm: 43.5 (36–51) vs 63 (53–69), $p = 0.042$), and significant increase of endothelial-MP (CD62EMP/L: 1391 (651–2301) vs 582 (380–1161), $p = 0.046$), indicative of higher endothelial damage compared to controls. Similar results were obtained comparing portal blood of cirrhotics and controls (ETP with/without TM 0.89 (0.78–0.92) vs 0.63 (0.33–0.75), $p = 0.001$; MCF-NATEM mm: 46 (39–51) vs 62 (49–66), $p = 0.056$; CD62EMP/L: 1606.5 (680–1885) vs 529.5 (266–781), $p = 0.069$). There was a significant correlation between diminished levels of PC, PS, AT, FII and either TGT or ROTEM parameters. Comparing portal and peripheral blood of cirrhotics, we detected endogenous heparinoids in portal blood (α -angle NATEM 51 (46–57) vs

Introduction: In clinical trials rifaximin- α (RFX) has been shown to reduce recurrence of episodes of overt hepatic encephalopathy (HE) and HE-related hospitalisations. UK real-world data confirmed reductions in hospital admissions and length of stay with RFX use; however, data on use of emergency department (ED; A&E in UK) resources are still scarce. This study assessed the impact of RFX on utilisation of ED resources.

Aims & Methods: Patients from 11 UK hospitals who were prescribed RFX for HE between July-2008 and May-2014 were included in this retrospective observational study. Patient records were reviewed; details of demographic and clinical characteristics, and all-cause ED attendances and admissions were collected in the 6 and 12 months pre- and post-RFX initiation. The analysis included only patients who were alive at the end of the study periods.

Results: Of the 145 patients included, 114 (79%) were alive at 6 months and 102 (70%) at 12 months post-RFX initiation. At RFX start, mean age was 61 years, 63% were male; 67% had alcohol-related liver disease; for patients with available MELD score (70%), the mean was 16; 78% were on lactulose. Use of ED resources in the 6 and 12 months pre- and post-RFX initiation is shown in Table 1. Six patients developed adverse events, none serious.

Conclusion: In UK clinical practice, treatment with RFX for HE is well-tolerated and associated with significant reductions in ED attendances, with or without admission, both within 6 and 12 months of RFX initiation.

P0038 PREDICTING FACTORS FOR HOSPITAL READMISSION AFTER THE FIRST EPISODE OF HEPATIC ENCEPHALOPATHY

M. Silva¹, A. Peixoto², H. Cardoso², S. Lopes², G. Macedo²

¹Gastroenterology, Hospital São João, Oporto/Portugal

²Centro Hospitalar São João, Porto Medical School, Porto/Portugal

Contact E-mail Address: marcocostasilva87@gmail.com

Introduction: Hepatic encephalopathy (HE) is a frequent complication of liver cirrhosis, with necessity of hospital admission in many cases. The economic burden of HE is substantial. After ascites, HE is the second most common reason for hospitalization of cirrhotic patients. HE is also the most common, possibly preventable, cause for readmission.

Aims & Methods: We aimed to assess the factors associated with the increased likelihood of hospital readmission for HE after the onset episode.

We completed a retrospective Retrospective analysis of admissions for HE of patients with liver cirrhosis, between October 2010 and October 2015. Only the onset episode was included. Patients were followed for 1 year or until readmission for HE. All patients were discharged under lactulose therapy. Descriptive statistics, uni and multivariate analysis, logistic regression, and ROC curves analysis were performed using IBM SPSS Statistics 22 with $p < 0.05$ deemed to be statistically significant.

Results: In this study 119 patients were included: 78% men with a mean age of 59 ± 13 years; 8% had hepatocellular carcinoma, and 45% had Child-Pugh C. The most frequent cirrhosis etiologies were alcoholic disease (60%) and HCV infection (12%). The precipitating factors, for the onset episode, more frequently detected were diuretic overdose (36%) and infection (31%). All patients were treated with standard therapy, with an adequate lactulose dose. The readmission rate after the first episode of HE was 72% (75% men). The estimated average time to relapse was 18 weeks. The most frequent causes of readmission were also diuretics overdose (31%) and infection (30%). The patients who were readmitted had a higher MELD score than patients without recurrence (13.9 vs. 11.6 points; $p = 0.015$). This association was verified in the multivariate analysis (OR = 1.1, $p = 0.044$).

Conclusion: In this cohort, there was a high rate of readmission for HE after the inaugural episode, which carries a great impact on individual health and high socio-economic costs. A higher MELD score was independently associated with a high probability of readmission for HE.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The regulations for prescribing interferon-free treatment for patients infected with hepatitis C virus in Romania comprised only patients with F3/F4 fibrosis so the risk of hepatic decompensation and complications was higher compared to other cohorts. In previous interferon-based regimens, thrombocytopenia and hypoalbuminemia as markers for portal hypertension and hepatic synthetic dysfunction, respectively, have been shown to reduce the likelihood of sustained virological response and to increase the rates of serious adverse events.

Aims & Methods: The aim of this study was to evaluate the impact of thrombocytopenia and hypoalbuminemia on treatment outcome and disease complications. We included in this study 855 HCV-infected cirrhotic patients treated with ombitasvir/paritaprevir/r+dasabuvir+ribavirin for 12 weeks in 10 university hospitals in Romania. The following groups were studied: 151 patients (17.7%) with albumin <3.5 g/dl, 239 (28%) with thrombocytopenia (a cutoff of 100000/mmc was used) and 71 patients (8.3%) with both hypoalbuminemia and thrombocytopenia before initiating antiviral treatment. Safety (as AE in >5% and SAE), efficacy (defined as HCV RNA undetectable at week 12 post-therapy and complication rate were evaluated using Pearson's correlation, multivariate analysis and Chi-Square test.

Results: Main patient characteristics were: 100% genotype 1 b, a median age of 60 yo, 466 women (54.57%), high rate of previous interferon based-treatment (36.1%). End-of-treatment and sustained virological response rate were both >99% and there was no correlation with the presence of thrombocytopenia or hypoalbuminemia. The rate of adverse events in the whole cohort was 17.5% at 2 weeks reaching 18% at the end of treatment with only 0.8% severe adverse events with no statistical association with the presence of thrombocytopenia and hypoalbuminemia. The multivariate analysis showed significant association of thrombocytopenia (<100000/mmc) with higher (>1) degree of oesophageal varices ($p < 0.001$), onset of upper digestive hemorrhage during treatment ($p = 0.011$), and prior exposure to interferon based regimens ($p = 0.025$). Low albumin (<3.5 g/dl) also correlated with higher (>1) degree of oesophageal varices ($p < 0.001$) and onset of upper digestive hemorrhage during treatment ($p = 0.002$).

Conclusion: The efficacy and safety of the ombitasvir/paritaprevir/r+dasabuvir+ribavirin (as recommended by national regulations) was not different in cirrhotic patients with hypoalbuminemia and thrombocytopenia, but complications rate was higher so close follow-up and prophylactic measures should be recommended, especially if previously exposed to interferon containing regimens.

P0041 REAL-WORLD IMPACT OF RIFAXIMIN-A USE IN HEPATIC ENCEPHALOPATHY PATIENTS WITH ADVANCED LIVER DISEASE OR CONTINUED ALCOHOL MISUSE: A POST-HOC ANALYSIS OF THE IMPRESS STUDY

M. Hudson¹, P. Di Maggio², R. Cipelli³, R. Aspinall⁴
¹Freeman Hospital, The Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne/United Kingdom
²Uk Medical, Norgine, Harefield/United Kingdom
³pH Associates, Marlow/United Kingdom
⁴Queen Alexandra Hospital, Portsmouth Hospitals NHS Trust, Portsmouth/United Kingdom

Contact E-mail Address: pdimaggio@norgine.com

Introduction: In the UK multicentre, retrospective, real-world study, IMPRESS, rifaximin- α (RFX) use in patients with hepatic encephalopathy (HE) significantly reduced hospitalisations and length of stay in the 6 and 12 months post-RFX initiation compared to the respective periods pre-RFX initiation. This post-hoc analysis of the IMPRESS data compared hospital resource use pre- and post-

RFX initiation in 2 sub-groups of difficult-to-treat HE patients: those with advanced liver disease or ongoing alcohol misuse.

Aims & Methods: Medical records of patients from 11 UK hospitals who were prescribed RFX for HE between July-2008 and May-2014 were retrospectively reviewed; details of demographic and clinical characteristics, and all-cause hospital admissions were collected in the 6 and 12 months pre- and post-RFX initiation. Patients with baseline MELD score ≥ 15 or not abstinent at the end of the study period were included in this analysis. Statistical significance of the mean change (standard error of the mean, SEM) was calculated using paired t-test or Wilcoxon test.

Results: Only patients alive at the end of the 6 and 12 months RFX-treatment periods were included: 114 and 102, respectively. Amongst these, 33/114 (29%, for the 6 months) and 26/102 (25%, for the 12 months) had baseline MELD ≥ 15 ; mean age, 63 years; 70% were male; 66% had alcohol-related liver disease; mean MELD 24. The mean (SEM) number of bed days/patient reduced from 25 (6.0) in the 6 months pre- to 15 (5.5) in the 6 months post-RFX initiation, and from 36 (9.5) in the 12 months pre- to 20 (7.7) in the 12 months post-RFX initiation (p value not significant). At 6 months post-RFX initiation, 15/114 (13%) patients were still actively drinking. At RFX initiation, mean age was 56 years; 73% were male, mean MELD was 19. Despite this, the mean (SEM) number of bed days/patient decreased from 36 (7.9) in the 6 months pre- to 15 (5.4) in the 6 months post-RFX initiation ($p = 0.048$), and the mean of hospitalisations/patient fell from 2.8 (0.8) to 1.2 (0.4) (t-test $p = 0.059$; Wilcoxon test $p = 0.029$). Too few patients with continued alcohol misuse were alive at 12 months to evaluate. Two patients reported adverse events, none serious.

Conclusion: In UK clinical practice, treatment with RFX for HE for 6 or 12 months suggested trends in reduced hospital length of stay in patients with advanced liver disease and in those with continued alcohol misuse. However, larger studies are needed to strengthen these findings.

P0042 BACTERIAL INFECTION IN PATIENTS WITH DECOMPENSATED CIRRHOSIS - A PREDICTOR OF LONG-TERM MORTALITY INDEPENDENT OF DISEASE SEVERITY

M. Sousa, S. Fernandes, J. Silva, A. Ponte, J. Rodrigues, J. C. Silva, L. Proença, J. Carvalho
 Gastroenterology, Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia/Portugal

Contact E-mail Address: mafalda_m_p_sousa@hotmail.com

Introduction: Bacterial infections are common in cirrhotic patients and the pro-inflammatory response superimposed on the hemodynamic dysfunction of portal hypertension predisposes to the development of complications. Some authors suggest that the occurrence of infection should be considered a separate clinical stage, since it alters the natural history of cirrhosis.

Aims & Methods: Retrospective assessment of patients with cirrhosis hospitalized for first episode of decompensation between 2011–2015. The aim was to evaluate the prognostic significance of bacterial infections regardless of the severity of the underlying liver disease.

Results: Sixty-four patients (85% male, mean age 59 years, mean MELD 15, 72% alcoholic cirrhosis) were included with a total of 197 hospitalizations. Hospital admissions were more frequent due to variceal haemorrhage (42%) and encephalopathy (37%). The incidence of bacterial infection was 25%; 41% respiratory, 31% spontaneous bacterial peritonitis and 24% urinary. Of these, 51% were nosocomial and in 20% an infectious agent was isolated. The survival rates at 30 days, 3 months, 6 months and 1 year were 65%, 55%, 34% and 27% in patients with infection and 97%, 90%, 85% and 78% in those without infection ($p < 0.001$). In the multivariate analysis, survival was independently associated with MELD (hazard ratio (HR) 1.073, $p = 0.012$), age (HR 1, 032, $p = 0.012$) and infection (HR 3, 821, $p < 0.001$). Bacterial infection remained an independent predictor of mortality, even when excluding patients with in-hospital mortality and at 30 days (HR 3.093, $p = 0.005$).

Conclusion: Patients with cirrhosis exposed to a bacterial infection are at increased risk of death. This risk remains in the long term when we exclude patients with in-hospital mortality and at 30 days and regardless of the severity of the underlying disease (MELD).

P0043 A PROPORTIONALLY GREATER ELEVATION IN LIVER TRANSPLANT CANDIDACY IN PATIENTS WITH NAFLD AND PORTAL VEIN THROMBOSIS

M. Basaranoglu

Gastroenterology, Bezmialem Vakif University, Istanbul/Turkey

Contact E-mail Address: metin_basaranoglu@yahoo.com

Introduction: NASH progresses to cirrhosis and its complications including hepatocellular carcinoma. It is possible that risk factors for NAFLD-associated cirrhosis and HCC in Eastern countries differ from those in the West. Thus, we aimed to document the characteristics of patients with NAFLD-associated cirrhosis from Turkey, a European country sharing 97% of its borders with Asia. Relative to other Europeans, the Turkish population exhibits a higher rate of obesity that is comparable to that in the United States.

Aims & Methods: To characterize non-alcoholic fatty liver disease (NAFLD) presentation with esophageal varices. **METHODS:** We have kept the records of patients at our hepatology unit and affiliated liver center. Data were collected for esophageal varices only at the advanced endoscopy unit. A cohort of patients with esophageal varices from 2003 to 2014 was reviewed. Eligible patients were ≥ 18 years of age and have had esophageal varices diagnosed by upper gastrointestinal endoscopy examination. They had regular clinical follow-up and endoscopic examinations at our clinic. Efficacy data were based on the last evaluation. Transplanted cases were excluded. The main inclusion criterion was the presence of esophageal varices with or without gastric varices. Only 258 patients with endoscopically defined high-risk varices had reliable data and were included in this study. Each patient was evaluated for fundal varices, PVT, cirrhosis, HCC, and mortality. After the first evaluation, patients were divided into 4 groups: Those with hepatitis B, hepatitis C, NAFLD and others related to autoimmune hepatitis, Wilson Disease, primary biliary cirrhosis, etc.

Results: Primary end-point of the study was to use this cohort of patients with esophageal varices to evaluate the relationship between this disease and several etiologies, including NAFLD, hepatitis B, hepatitis C or other liver-related diseases. Second end-point was to draw this comparison in terms of PVT, HCC, survival and mortality. Of the 258 patients with esophageal varices; NAFLD in 39.0% (101 patients), hepatitis B virus in 29.1% (75 patients) and HCV in 11.2% (29 patients). The mean age of NAFLD was 56.4 ± 16.0 years and 62% of these patients were men. Moreover, 47.5% had PVT, 5.0% had HCC, and 45.5% had fundic varices. The mortality rate was 47.5% during follow-up, but increased to 80% in the presence of HCC. PVT was observed in 47.5% of patients with NAFLD, 29.3% of patients with hepatitis B, 17.2% of patients with hepatitis C, and 62.3% of patients with other liver-related diseases ($P < 0.0001$). Of the 111 patients (43%) that died during the study period, 72 patients (64.9%) had no PVT ($P = 0.057$). HCC was: 5.0% in patients with NAFLD, 26.7% in patients with hepatitis B, 34.5% in patients with hepatitis C, and 5.7% in other diseases ($P < 0.0001$). Of the 38 patients with HCC, 13% had PVT. Moreover, HCC increased the mortality rate in almost all the groups. Of the patients, 50.0% with NAFLD, 33.3% with hepatitis B, 26.3% with hepatitis C, and 58.3% with other diseases were alive at the end of the 5-year period with a significant difference according to the Kaplan-Meier log Rank test ($P = 0.04$). Risk for mortality, measured by risk ratio (RR), did not change per gender (RR: male/female = 43.3%/42.5%, $P > 0.05$) or with the occurrence of cirrhosis (RR: 44.8%/28.6%, $P > 0.05$). However, it changed with the existence of fundic varices (RR: 49.3/35.3, $P = 0.024$ in favor of fundic varices development) and HCC (RR: 78.9%/36.8%, $P < 0.0001$ in favor of HCC development).

Conclusion: Data revealed a proportionally greater rise in liver transplant candidacy due to NAFLD-associated cirrhosis with portal vein thrombosis. The mortality rate of patients with NAFLD-associated cirrhosis did not differ from that in patients with virally caused cirrhosis. We confirmed that NAFLD was the third leading cause of HCC on the transplantation waiting list. Older patients were more prone to developing more cirrhosis, HCC and high mortality rates. These findings should constitute a reliable guideline for evaluating patients at the transplant center and for health policy makers to develop better strategic preventive measures against liver diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.

⁵Centro Hospitalar São João, Porto Medical School, Porto/Portugal

Contact E-mail Address: ruimorais20@gmail.com

Introduction: Bacterial infections are a leading cause of mortality in patients with decompensated cirrhosis.

Aims & Methods: The objective of this study was to evaluate the prevalence of multiresistant bacterial infections, associated risk factors and their impact on prognosis in hospitalized decompensated liver cirrhosis patients.

This was a retrospective study that consecutively evaluated all bacterial infections with confirmed microbiological isolation in patients with decompensated liver cirrhosis admitted to the Gastroenterology ward between January 2009 and May 2016.

Results: There were 308 infections with confirmed microbiological isolates, corresponding to 218 hospitalizations, in a total of 161 patients. The median age of the patients was 63 years (IQR 55-71) and 67% of them were men. Alcoholic liver disease was the major cause of cirrhosis (72%). Among the infections evaluated, 87% were nosocomial and 13% community-acquired. Urinary tract infection was the most common infection (57%). In 27% of patients there were at least two concomitant bacterial infections. Multidrug resistant (MDR) bacteria were isolated in over half of patients. In the multivariate analysis, prophylaxis for spontaneous bacterial peritonitis (OR 2.3, $p = 0.009$), MELD score greater than 19 at admission (OR 1.7, $p = 0.043$), hospitalization in an Intensive/Intermediate Care in the previous month (OR 2.8, $p = 0.001$) and antibiotic therapy for infection in the last 6 months (OR 2.4; $p = 0.001$) were independently associated with MDR infection. From the variables identified in the multivariate analysis, a predictive model of MDR bacterial infection was created. Assuming a sensitivity of 66% and a specificity of 72%, we considered the cut-off of -0.0415 as clinically relevant, regarding likelihood of developing a MDR bacterial infection (AUROC 0.723; 95% CI [0.667-0.780]). The occurrence of a MDR infection was associated with a longer duration of hospitalization ($p = 0.017$). In the multivariate analysis there was no independent association between MDR infection and in-hospital mortality and one month after discharge.

Conclusion: The prevalence of MDR bacterial infections in cirrhotic patients is significant and associated with a longer hospital stay. It is possible to identify predictors of its occurrence in order to implement epidemiological strategies to reduce the risk of these infections.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0045 EFFECT OF TREATMENT OF CHRONIC HEPATITIS C WITH SOFOSBUVIR AND DACLATASVIR IN PATIENTS OLDER THAN 60 YEARS

K. Elnoemany¹, M. Badr²

¹Gastroenterology, National Liver Institute (NLI), Elmenofia gov./Egypt

²Internal Medicine, Menofia University, Shebin Elkom/Egypt

Contact E-mail Address: dr_kareemn@yahoo.com

Introduction: Hepatitis C virus (HCV) diminishes health related quality of life (HRQOL). Currently, there is no published data on assessing of the impact of treatment of chronic hepatitis C with the new antiviral drugs in old-aged patients.

Aims & Methods: The aim is to study the effect of treatment of chronic hepatitis C with the new antiviral drugs in old-aged patients in HRQOL. About 132 patients with chronic hepatitis C (cirrhotic and non-cirrhotic) were enrolled in the study. Age of patients was sixty years old and older. All patients were treated with sofosbuvir/daclatasvir with or without ribavirin for three months. The HRQOL was assessed with sickness impact profile scoring (SIP) before start of treatment, at end of treatment and after three months of end of treatment.

Results: Old chronic hepatitis C patients who were treated achieved primary virological response (end of treatment) with percentage 100% and sustained virological response (SVR) (after 3 months of end of treatment) in about 96% of treated patients. Before treatment, patients with chronic hepatitis C had worse scores especially in work, sleep, rest and recreation and pastimes categories. After treatment, patients who received sofosbuvir/daclatasvir with or without ribavirin had significant improve in work, sleep, rest and recreation and pastimes categories with p -value 0.001. Numerical improvement was observed in total score, physical and psychosocial dimension scores. In patients with SVR, the most improvement was in work and psychosocial dimension scores. There was no significant difference in SIP between scores after end of treatment and after 3 months of end of treatment.

Conclusion: Treatment of chronic hepatitis C in old-aged patients had a significant improvement in HRQOL.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0046 EGY FIBRO-MARK: A PANEL OF ACCURATE LABORATORY PARAMETERS FOR THE IDENTIFICATION HEPATIC FIBROSIS PROGRESSION IN PATIENTS WITH CHRONIC HEPATITIS C

D. Omran¹, A. M. Attallah², M. Omran³, R. Zayed⁴, S. Saif⁵, A. Farid⁵, M. Hassany⁵, A. Yosry¹

⁴Cairo University, Cairo/Egypt

⁵National Hepatology and Tropical Medicine Research Institute, Cairo/Egypt

Contact E-mail Address: dalaiomran@kasralainy.edu.eg

Introduction: Accurate determination of the degree of hepatic-fibrosis is mandatory not only for the diagnosis and prognosis of disease, but also for deciding on the antiviral treatment. Indeed, many studies have been dedicated to the search of non-invasive fibrosis markers capable of providing an accurate information about hepatic fibrosis stage in patients with chronic hepatitis C (CHC). Direct and indirect markers of hepatic fibrosis are useful for prediction of liver cirrhosis but have limited accuracy for the diagnosis of significant fibrosis. Therefore, the development of more advanced scores combining both direct and indirect markers may improve their diagnostic accuracy.

Aims & Methods: This work is concerned with determining the levels of some of fibrosis markers, which are directly involved in deposition and removal of extracellular matrix (ECM), together with other indirect fibrosis markers so as to construct a predictive score capable of identifying the presence of significant fibrosis with a high degree of accuracy. Then, we aimed to estimate its performance against that of the other simple noninvasive tests in chronic hepatitis C patients.

Material and Methods: A total of 148 Egyptian HCV patients were subjected to routine laboratory workup in addition to estimation of serum AFP, hyaluronic acid (HA), platelet-derived growth factor (PDGF), tissue inhibitor of metalloproteinase-1 (TIMP-1) and collagen IV. According to fibroscan, patients were classified into those with non-significant fibrosis ($F < 2$) and significant fibrosis ($\geq F2$).

Results: Based on univariate analysis, ten variables were significantly higher in patients with significant fibrosis. Patients with F2-F4 had 2.08-fold, 2.14-fold, 1.80-fold and 1.90-fold increase in the concentrations of collagen IV, HA, PDGF and TIMP-1, respectively. Multivariate regression demonstrated that only age, AFP, PDGF, collagen IV and TIMP-1 retained significance. Therefore, a five-marker score named Egypt (EGY) Fibro-mark (FM) was developed. A significant correlation was found between its candidate markers and liver fibrosis progression. AFP was found to have highest correlation ($r = 0.47$, $P < 0.0001$) followed by collagen IV ($r = 0.46$, $P < 0.0001$), Age ($r = 0.43$, $P < 0.0001$), TIMP-1 ($r = 0.40$, $P < 0.0001$) and PDGF ($r = 0.40$, $P < 0.0001$). ROC curve was used to estimate and compare the diagnostic accuracy of these candidate variables. As a consequence, these markers were in a decreasing rank: AFP (AUC 0.79), collagen IV (AUC 0.78), age (AUC 0.76), TIMP-1 and PDGF (AUC 0.75). Additionally, Bivariate Spearman's rank correlation coefficient between EGY-FM and its candidate markers was determined for estimating the impact of each marker on the predictive criteria. The diagnostic value of EGY FM was then assessed by ROC curve showing an AUC of 0.89 for diagnosing significant fibrosis at an optimal cut-off point of 4.05 with 77% sensitivity, 83% specificity and 79% efficiency. Next, the area under the ROC curve (AUC) was used as an index to evaluate and compare the performance characteristics of different non-invasive scores. The AUC was greatest for Fibro-mark (0.89), then BRC (0.83), followed by FRT and King's score (0.82), APRI (0.80), Fibro- α (0.70) and finally FibroQ (0.63).

Table 1: The correlation of each score to hepatic fibrosis progression

Index	AUC	Cutoff	Sensitivity	Specificity	Efficiency	Odds ratio (95% CI)
Fibro-mark	0.89	>4.05	77	83	79	16.18 (6.59–39.70)
BRC score ^a (37)	0.83	>7.2	97	30	76	12.86 (3.44–48.13)
FRT ^a (38)	0.82	>4.0	99	11	69	10.71 (1.21–94.60)
King's score (41)	0.82	≥ 12.3	94	45	79	12.25 (4.39–34.19)
APRI ^a (42)	0.80	>1.5	29	94	50	6.13 (1.76–21.30)
Fibro- α score (43)	0.70	>1.28	95	19	72	4.34 (1.33–14.17)
FibroQ (40)	0.63	>1.6	93	13	69	1.80 (0.53–6.04)

Conclusion: EGY Fibro-mark (FM) score, a more sophisticated score combining 'direct' and 'indirect' markers, is a useful tool to improve the staging of liver fibrosis in CHC patients and seems more efficient than BRC, FRT, King's score, APRI, Fibro- α score and FibroQ in this group of Egyptian patients.

Introduction: In patients with chronic hepatitis C, host genetics influence liver fibrosis, particularly modifiers in genes controlling the inflammatory and immune response pathways. In this context, interleukin 28B (IL-28B) rs12979860 single-nucleotide polymorphisms (SNP) is considered the most important. Controversial data suggests that IL-28B SNP relate to the severity of hepatic histology. Some studies showed that rs12979860 C allele may be associated with greater hepatic inflammation, higher alanine aminotransferase levels and increased risk of worse clinical outcomes, other studies have not found this association. Furthermore, other studies found that the T allele affects the severity of liver fibrosis and had a mean staging score higher than other genotypes. Else, none of the previous studies concerned the association between the IL-28B SNP and signs of fibrosis severity.

Aims & Methods: We aimed to evaluate the cirrhotic development in C/T genotypes using FibroScan, extracellular matrix (ECM) proteins and the model for end-stage liver disease (MELD) in order to resolve conundrum regarding the association between interleukin 28B (IL-28B) rs12979860 and disease severity in chronic hepatitis C (CHC). So we assessed the allelic and genotypic frequencies of IL-28B rs12979860 in 272 HCV-infected Egyptian individuals; investigate serum levels of ECM proteins, including hyaluronic acid (HA), laminin, collagen type IV and the N-terminal pro-peptide of collagen type III (PIIINP) as well as its association with liver fibrosis, as assessed by FibroScan, in different IL-28B rs12979860 genotypes; From another view, if C allele has a protective role, we need a precise confirmation, thus we decided to evaluate the difference in cirrhotic behavior using FibroScan, ECM proteins and the MELD score between C/T IL-28B genotypes and evaluate the diagnostic performance of Fibroscan and these ECM proteins in IL-28B rs12979860 genotypes.

Results: IL-28B rs12979860 CT genotype is the commonest genotype among patients constituting $\approx 73\%$ of the studied sample. The CC and TT genotypes constituted $\approx 18\%$ and $\approx 9\%$ respectively. Liver cirrhosis percentage increased with the increasing number of T alleles as it was 10%, 52% and 96% in CC, CT and TT genotypes, respectively. FibroScan values (kPa) gave a strong positive correlation ($r = 0.6$; $P < 0.0001$) with IL28B polymorphism. Similar to FibroScan, HA ($r = 0.5$), laminin ($r = 0.5$), collagen IV ($r = 0.4$) and PIIINP ($r = 0.4$) serum levels showed significant ($P < 0.0001$) positive associations with IL28B polymorphism. There was stepwise increase in the values of fibroscan and ECM proteins from CC to TT genotypes, so that elevated ECM proteins serum levels were associated with the presence of IL-28B T allele. (Table). In comparison with CC genotype, IL-28B rs12979860 T allele had a significant 2.4-fold increase (in case of CT) and 4.7-fold increase (in case of TT) in Fibroscan score values (kPa). The same was true for ECM proteins serum levels. Interestingly, the characteristics of the cirrhotic patients with TT genotype were completely different from the cirrhotic patients with CT genotype as assessed with FibroScan, ECM proteins and MELD score. Among cirrhotic patients, liver stiffness was 31.13 ± 2.28 kPa in TT genotype vs 20.96 ± 0.74 kPa in CT genotype, MELD was 9.6 ± 0.73 in TT genotype vs 3.9 ± 0.41 in CT genotype and ECM proteins were significantly ($P < 0.0001$) higher in patients with TT than CT genotype. AUC values for FibroScan, HA, laminin, collagen IV and PIIINP serum levels to differentiate CC from other IL-28B genotypes were 0.91, 0.85, 0.84, 0.82 and 0.82, respectively. These values rise to 1.0, 0.97, 0.93, 0.98 and 0.93, respectively, when comparing CC to only TT genotype.

Table 1: Distribution of different fibrosis markers in IL-28B CC, CT and TT genotypes

Fibrosis marker	IL-28B genotypes			P value
	CC	CT	TT	
FibroScan (kPa)	6.6 ± 0.4	15.6 ± 0.6	31.1 ± 2.3	0.0001
Hyaluronic acid (ng/mL)	74.6 ± 5.2	147.8 ± 8.2	419.4 ± 95.2	0.0001
Laminin (ng/mL)	60.6 ± 3.2	106.5 ± 4.6	282.1 ± 58.1	0.0001
Collagen IV (µg/mL)	6.1 ± 0.4	11.8 ± 0.9	30.1 ± 6.2	0.0001
PIIINP (ng/mL)	13.3 ± 0.7	25.6 ± 1.7	55.4 ± 10.4	0.0001

Conclusion: FibroScan and ECM proteins prove that the IL-28B rs12979860 T allele affects the severity of liver disease. Coexistence of C allele with T allele reduces cirrhosis severity. This study gives a good deduction that carriage of the IL-28B C allele protects from unfavorable outcomes in CHC. This study shed the light on using FibroScan and ECM proteins as good diagnostic options for liver disease severity in IL-28B genotypes

Introduction: Chronic hepatitis C virus (CHCV) patients with persistently normal transaminases represent a category of patients with mild and slowly progressive disease. Proper management of these patients with direct acting antivirals (DAAs) needs to be investigated in real world treatment settings in Egypt to further validate the accumulating data of the achieved high sustained virologic response (SVR) rates with the use of these drugs in clinical trials.

Aims & Methods: We aimed to report the efficacy of 5 different DAAs regimens for treatment of CHCV genotype 4 patients with persistently normal liver enzymes in real-world Egyptian cohort. Data of CHCV genotype 4 patients with normal liver enzymes who started treatment with different DAAs between September 2014 and September 2016 in a single specialized viral hepatitis treatment center in Egypt were retrieved. Treatment regimens included: Pegylated interferon alpha 2b/Sofosbuvir/Ribavirin (PEG/SOF/RBV), Sofosbuvir/Daclatasvir (SOF/DCV), Sofosbuvir/Daclatasvir/Ribavirin (SOF/DCV/RBV), Sofosbuvir/Ribavirin (SOF/RBV) and Sofosbuvir/Simeprevir (SOF/SIM). All regimens were given for 12 weeks except SOF/RBV which was given for 24 weeks. HCV RNA was tested at week 4 of treatment, and 12 weeks after treatment cessation to check for SVR 12.

Results: Our cohort included 1149 patients (562 males and 587 females). 158 patients were treatment experienced (13.75%) and 146 patients (12.7%) had liver cirrhosis. Regarding the used treatment regimens; 244 (21%) patients were treated with PEG/SOF/RBV, 382 (33.5%) with SOF/DCV, 152 (13.5%) with SOF/DCV/RBV, 117(10%) with SOF/RBV and 254 (22%) with SOF/SIM. The overall SVR rate was 97.5% while the SVR rates for different regimens were: 94.7%, 99.7%, 100%, 91.5% and 98% for (PEG/SOF/RBV), (SOF/DCV), (SOF/DCV/RBV), (SOF/RBV) and (SOF/SIM) respectively.

Conclusion: Different DAAs achieved high SVR rates in treating CHCV genotype 4 with normal liver enzymes in a real-world cohort from Egypt. SOF/DCV/RBV combination was the most effective among the studied regimens.

Introduction: Recently, new direct antiviral agents (DAAs) with different mechanisms of action have been developed to provide much more efficacious and better-tolerated therapeutic strategies for treatment patients with hepatitis C virus (HCV) infection. Several clinical trials have investigated a 12-week therapy with fixed dose of all-oral three-drug combination of daclatasvir (DCV), a potent pan-genotypic nonstructural protein 5A [NS5A] inhibitor, in 60 mg once daily; asunaprevir (ASV), an NS3 protease inhibitor, in 200 mg twice daily; and beclabuvir (BCV), a non-nucleoside NS5B thumb-1 polymerase inhibitor, in 75 mg twice daily (BCV-TRIO) for treatment of patients with HCV genotype 1 infection.

Aims & Methods: This systematic review and meta-analysis aimed to investigate the efficacy and safety outcomes of the three-drug combination of daclatasvir, asunaprevir, and beclabuvir, in treatment of HCV genotype 1 infection. Eleven electronic search engines/libraries, including PubMed, Scopus, Web of Science, Google Scholar, Virtual Health Library (VHL), WHO Global Health Library (GHL), ClinicalTrials, POPLINE, System for Information on Grey Literature in Europe (SIGLE), Cochrane library, and the New York Academy of Medicine (NYAM), were systematically searched for any clinical trial reporting the efficacy and safety of BCV-TRIO for the treatment of HCV genotype 1 infection. Studies were screened for eligibility and data was extracted by two independent reviewers. Sustained virologic response rate after 12 weeks of treatment (SVR₁₂) and commonly reported outcomes were pooled as event rate and risk ratio in the comparison meta-analysis (RR). The meta-analysis was conducted using the Comprehensive Meta-analysis (CMA) platform. The protocol was registered in PROSPERO (CRD42017054391).

Results: Among the included five studies, four studies, with low to moderate risk of bias, were included for the meta-analysis (n = 1096). The BCV-TRIO showed a high-response rate in naïve patients (SVR₁₂ rate = 95.5% (95%CI [93.5–96.9])). This total population was sub-grouped to get SRV₁₂ rates; 89.5% (95%CI [85.8–92.4]), 96.2% (95% CI [93.0–98.0]), 93.5% (95%CI [89.2–96.1]), 91.1% (95%CI [87.6–93.7]), 93.9% (95% CI [86.6–97.3]), and 91.9% (95%CI [89.1–94.0]) for HCV genotype 1a, HCV genotype 1b, IL28B CC genotype, IL28B non-CC genotype, cirrhotic, and non-cirrhotic respectively. The virologic failure occurred in only 40 patients (7%) (95%CI [5.2–9.4]). There was no difference when adding ribavirin to this combination (RR = 0.98, 95% confidence interval (95% CI) [0.90, 1.08], P = 0.70), using this regimen on interferon-experienced patients (RR = 1.03, 95% CI [0.98, 1.08], P = 0.30), or changing the dose of BCV from 75 mg to 150 mg regardless the genotype 1 subtypes or IL28B genotype. Similarly, the minimal failure of treatment showed no difference regarding the main two comparisons regardless the cause of this failure. Increasing the dose or the duration did not show a significant increase in the efficacy. The rates of serious adverse events (AEs) occurrence were; (3.4%, 95%CI [2.3–5.1]), (6.5%, 95%CI [3.2–12.7]), (2.3%, 95%CI [0.6–8.8]), and (2.9%, 95%CI [0.2–33.6]) for BCV-TRIO, (BCV-TRIO + RBV) for 12 weeks, (DCV + ASV + BCV-150 mg) for 12 weeks, and both (BCV-TRIO) and (DCV + ASV + BCV-150 mg) for 24 weeks respectively. For BCV-TRIO, the most-frequent AEs were headache, diarrhoea, fatigue, and nausea with rates; (21.2%, 95%CI [18.4–24.2]), (14.3%, 95%CI [12.0–16.9]), (13.8%, 95%CI [11.2–16.8]), and (13.4%, 95%CI [10.9–16.4]) respectively.

Conclusion: This study reported a high SVR, minimal treatment failure rate, and few AEs with fixed-dose three drug combination of daclatasvir, asunaprevir, and beclabuvir for 12-week duration in HCV genotype 1-infected patients, without adding ribavirin, prior interferon-based therapy, restriction on noncirrhotic patients, restriction on certain IL28B genotype, restriction on baseline resistance-associated variants, or expansion the duration of the treatment to 24 weeks.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0050 GENETIC EPIDEMIOLOGY OF HCV INFECTION IN UPPER & LOWER EGYPT: A MULTICENTRE FAMILY-BASED STUDY

Introduction: Egypt has the highest prevalence of HCV worldwide. Prevalence of HCV was reported to be 13.9% among healthy populations. Adults have higher HCV prevalence (15.7%) than children (4.0%). Geographically, HCV is highly prevalent in the Nile delta (15.8%) than in Upper Egypt (9.02%). The household contacts of HCV seropositive patients had been shown to have a high risk of HCV infection.

Aims & Methods: The aim of this study was to determine the prevalence of HCV infection among household contacts of HCV seropositive index patients. We also aimed to compare HCV genotyping distribution in upper and lower Egypt. In this Multicentre hospital case control based study a total of 4894 Egyptian individuals were recruited to the hospitals from different Egyptian population in Upper & lower Egypt (mainly from Dakahlia, Cairo and Assuit governorates). The index HCV patients were 1106 cases whereas the families or close household contacts of these index cases were 3788 cases. Ideally family was selected on the basis of containing at least one positive HCV index, one positive HCV member and other one negative HCV member with no history of any liver complications or disorders (first and second degree consanguinity, living and sharing usual life activity and having at least 15 years of exposure to the index case). The positive cases (whether index or contact cases) in the family were selected with inclusion criteria of 1-HCV positive by PCR RNA > 6 months, 2-Adults (above 18 years) of both sexes 3-Any stage of HCV related liver diseases. While cases were diagnosed as spontaneously cleared the virus (SVC) based on the following criteria: positive Anti-HCV but negative PCR HCV RNA in 2 successive samples at least 6 months apart with no prior history of antiviral therapy. Each participant was subjected to routine clinical and laboratory investigations in addition to molecular diagnosis and PCR HCV to confirm HCV infection. Sequencing analysis of the 5' UTR of HCV was performed using an ABI Prism 310 Genetic Analyzer (PE Applied Biosystems, Germany). The sequencing reaction was performed using Big Dye Deoxy Terminator method as recommended by the manufacturer (PE Applied Biosystems). Genotypes were determined according to the published reference sequences.

Results: The prevalence of Anti-HCV +ve cases among household contacts was 20.71% but when PCR HCV was performed only 17.83% were +ve while 2.9% were spontaneously cleared the virus (SVC). The HCV prevalence among household contacts was 17.29% & 19.17% while the SVC was 2.49% & 1.55% in lower & Upper Egypt respectively. When the genotyping of the positive cases were performed it was found that the following pattern was noticed in the upper & lower Egypt respectively: (genotype 4a (90.3% & 70.1%), 4m (4.8% & 11.8%) 4n (0.5% & 3.2%) 4o (0.2% & 2.9%) 4i (0.5% & 1.9%) 4v (0.8% & 1.2%) & 1a (2.9% & 8.3%) as shown in the following table.

HCV genotype	Upper Egypt (%)	Lower Egypt (%)
4a	90.3	70.1
4m	4.8	11.8
4n	0.5	3.2
4o	0.2	2.9
4i	0.5	1.9
4v	0.8	1.2
1a	2.9	8.3
1g	0.0	0.3
1b	0.0	0.3

Conclusion: The prevalence of HCV was found to be 18.5% among household contacts of Egyptian families. The genotype 4 was predominant in upper Egypt (97.1%) more than lower Egypt (91.7%). On the other hand genotype 1a was higher in lower Egypt (8.3%) more than upper Egypt (2.9%).

Disclosure of Interest: All authors have declared no conflicts of interest.

³Microbiology Department, Mansoura Faculty of Medicine- Mansoura University, Mansoura/Egypt

Contact E-mail Address: mmelbendary@gmail.com

Introduction: Red blood cell distribution width (RDW) is a numerical measure of the variability in size of red cell It reflects variability in the size of circulating RBCs. RDW can be used as a prognostic marker in heart failure. In hepatic patients it was approved to be an independent predictor of liver fibrosis in patients with chronic HBV infection, and it is higher in patients with alcoholic liver disease and non alcoholic liver cirrhosis. The gold standard for assessing the histological out come of liver disease is liver biopsy. This procedure is costly and carries a small risk of complications due to sampling error, invasiveness and requires hospitalization of at least 6–18 h. These limitations have stimulated the development of non- invasive techniques for assessing the presence and the degree of liver fibrosis. Several laboratory scores composed of routine laboratory markers that are readily available have been proposed for non-invasive prediction of liver fibrosis in chronic hepatitis C (CHC) patients.

Aims & Methods: The aim of this work is to use RDW as a marker for non-invasive prediction of the stage of hepatic fibrosis in patients with chronic hepatitis C genotype4. 100 patients with chronic hepatitis C were subjected to routine laboratory & radiological investigations in addition to using KX-21 Sysmex automated hematology analyzer to measure RDW& RPR (RDW%/Platelet ratio). Comparing with other biomarkers of liver fibrosis like APRI (AST-to-Platelet ratio index) FIB-4 equation (using platelet count, AST, ALT, age) to perform this test. PCR HCV RNA, genotyping & liver biopsy (using METAVIR scoring system where cases were classified into early fibrosis (F1 + F2):68 patients & late fibrosis (F3 + F4): 32 patients]were done.

Results: RDW & RPR were significantly higher in patients with late fibrosis > early fibrosis (P < 0.0001) while platelets count was significantly lower in late fibrosis > early fibrosis (p < 0.001). By applying ROC curve it was found that the cut off value of RDW was 16.5, with sensitivity 86.4% specificity 85.9% & accuracy 86% & the cut off value of the platelets was 196.5 with sensitivity 81.8%, specificity 62.8% accuracy 67%, while RPR cut off value was 0.0897 with sensitivity 90.9%, specificity 85.9% & accuracy 87%. As regard APRI test it was found that the cut off value was 40.5with sensitivity 72.7%, specificity 66.7% & accuracy 68% While FIB-4 equation showed cut off value 1.685 with sensitivity 77.3%, specificity 66.7% and accuracy 69%. In conclusion the area under the ROC curve for, RDW & RPR were excellent but for platelets, FIB-4 & APRI were fair. When applying regression analysis it was found that the RDW (OR:3.903, 95% CI: 1.538–9.904) & Platelets (OR:0.953, 95% CI: 0.913–0.995), so as the level of RDW increase by one unit the risk late fibrosis will increase by 3.9 on the other hand when the platelets increase by one unit the risk of late fibrosis will decrease by 0.953.

Conclusion: RDW & RPR may be used as simple, non-invasive predictors of advanced fibrosis in patients with with chronic HCV genotype-4.

Disclosure of Interest: All authors have declared no conflicts of interest.

⁴Department Of Gastroenterology, Kyoto Medical Center, Japan, Kyoto/Japan

Contact E-mail Address: e-bun@umin.ac.jp

Introduction: The incidence of liver cancer and its recurrence have been reported frequently at an early stage in patients who underwent interferon (IFN)-free direct-acting antiviral (DAA) therapy [1]. The underlying mechanisms of

cancer incidence following DAA therapy may include the rapid clearance of hepatitis C virus, reconstitution of the immune system, and reduction of cancer immunosurveillance [2]. These changes may in fact have an impact on the development of cancer in other organs.

Aims & Methods: We conducted a retrospective analysis to compare the cancer incidence in patients treated with IFN-free DAA therapy with those treated with IFN therapy. All patients who achieved sustained viral response 12 following antiviral therapy between 1992 and 2016 in our hospital were investigated retrospectively. Patient records were examined to identify new cases of cancer, as diagnosed by pathology or medical imaging, in organs other than the liver following antiviral therapy. The date of diagnosis was determined based on the records, and the cancer incidence was compared between patients treated with DAA therapy and those treated with IFN therapy using the Kaplan-Meier method and Cox regression analysis. Patients with recurrent cancer were excluded from the analysis. Propensity score analysis followed by inverse probability of treatment weighting (IPTW) was used to correct for the effects of confounding factors.

Results: There was a significant difference in the age and sex of the patients treated with DAAs (n=324, median age: 70, male: 41%) and those treated with IFNs (n=445, median age: 58, male: 60%). Median lengths of the observation period for the DAA and IFN groups were 1.3 and 6.2 years, respectively. There were 12 and 22 cases of cancer occurring in organs other than the liver in the DAA and IFN groups, respectively. These cancer cases occurred the most frequently in the gastrointestinal tract, followed by the urinary organs, hematopoietic organs, biliary tract/pancreas, lungs, and others. The median periods from the start of the antiviral therapy to the time of diagnosis were 0.9 and 6.8 years in the DAA and IFN groups, respectively. Cumulative rates of cancer after 1 and 2 years were 3.0 and 5.0% for the DAA group, and 0.2 and 0.9% for the IFN group, respectively. The difference between the groups was significant (p=0.02) based on Cox regression analysis using IPTW.

Table: Cox regression analysis for cancer incidence other than the liver in IPTW samples

	Hazard Ratio	95% CI
Treatment		
IFN (Ref.)	1	
DAA	4.491	1.264–15.96

CI: confidence interval, IPTW: inverse probability of treatment weighting, IFN: interferon, DAA: direct acting antiviral

Conclusion: Because cancer detection in organs other than the liver can be challenging in management of hepatitis, some cases with cancer found after the treatment might have been diagnosable before the treatment, possibly leading to an overestimation of the incidence after the treatment. The number of newly diagnosed cancer cases was small in the present study, resulting in a low statistical power. Nevertheless, the cancer incidence in organs other than the liver was significantly higher in patients treated with DAA therapy than those treated with IFN therapy. This difference persisted after correcting for possible confounding factors including the age and sex of the patients. Our findings suggest that patients need to be carefully examined after DAA therapy for the development of cancer in various organs, including but not limited to the liver.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The shift from therapy with interferon to Direct antiviral agents (DAAs) has been a watershed for the management of HCV-related chronic liver diseases. In fact, treatment with second-generation DAAs cures the great majority of subject with HCV chronic infection, with the exception on genotype 3 cirrhotic patients

Aims & Methods: The present report focuses on HCV genotype 3 cirrhotic patients treated with second-generation DAAs in order to identify which of the several treatment schedules recommended for genotype 3 would constitute the best option. Methods: 1. Twenty-four Italian centers (ITAL-C consortium) were involved in this real-life study where HCV genotype 3 patients treated with DAAs. Eligible patients were >18 years-old with chronic HCV infection, either naïve or treatment-experienced. Patients with any of the following features were excluded: infection with HCV genotypes other than 3, active HCC on imaging, HIV and/or HBV co-infection, liver-transplant recipients, patients with an estimated glomerular filtration rate <30 ml/min. 2. With the intent to delineate a treatment schedule with the new DAAs that would offer the higher chance of SVR to patients with HCV genotype 3, a systematic search of the literature data was implemented and the retrieved information was pooled and evaluated by a meta-analytical approach. Electronic, systematic review of the available evidence in the published literature was undertaken to identify all studies. The systematic literature review was performed via Medline from 2012 to 2016 by the following search keys: HCV Genotype 3 AND [(DAA)OR (sofosbuvir) OR (daclatasvir) OR (Ledipasvir) OR (Velpatasvir)].

Results: 1. A total of 233 HCV genotype 3 patients were enrolled. In the entire population, the SVR rate was achieved by 205 subjects (88.0%). A successful treatment outcome was documented in 79.0% of patients treated with sofosbuvir in combination with RBV, in 92.0% of those who received sofosbuvir/daclatasvir with or without RBV, and in all 7 patients treated with sofosbuvir/ledipasvir with or without RBV. At the univariate analysis, baseline predictors of the SVR12 were gender (female patients being more responsive than males), BMI < 30 and the treatment schedule. Of relevance, age, stage of liver disease (whether advanced fibrosis or cirrhosis), RBV use, and treatment length were irrelevant to SVR12. At the stepwise logistic regression analysis, the only two factors independently associated with SVR12 were regimens containing sofosbuvir in combination with daclatasvir or ledipasvir (OR = 4.25; 95%CI: 1.81–9.97; p=0.001), and the BMI < 30 (OR = 2.64; 95%CI: 1.04–6.72; p=0.041). 2. The systematic review of literature provided data of 3311 patients from 17 full text article and two abstracts. The mean weighted SVR12 rate was 84.4% (CI:80.4–87.8); the rates varied from 79.0% (CI:70.9–85.3) with sofosbuvir/ribavirin, to 83.7% (CI:66.2–93.1) with sofosbuvir/ledipasvir, and to 88.2% (CI:83.3–91.7) with sofosbuvir/daclatasvir.

Conclusion: HCV genotype 3-infected patients, and in particular those progressed to cirrhosis, should be no more considered difficult-to-treat individuals, provided that an optimal therapeutic schedule is applied. Patients without cirrhosis should be treated with sofosbuvir and daclatasvir for 12 weeks. Patients with cirrhosis should be treated with sofosbuvir and daclatasvir for 24 weeks with or without ribavirin

P0054 IS THERE AN INCREASE IN THE INCIDENCE OF HEPATOCELLULAR CARCINOMA IN CIRRHOTIC PATIENTS WITH HEPATITIS C TREATED WITH THE DIRECT-ACTING ANTIVIRALS?

J. C. Branco, R. Carvalho, S. Alberto, A. Martins

Gastroenterology, Hospital Professor Doutor Fernando Fonseca, Lisboa/Portugal

Contact E-mail Address: cbranco.joana@gmail.com

Introduction: The impact of the virological cure on the evolution of cirrhotic patients treated with direct-acting antivirals (DAA) is not yet well established. Recently, some papers reported an elevated incidence of recurrence of hepatocellular carcinoma (HCC)^{1–4} and others a possible rise on the de novo incidence of HCC in the first year after treatment with DAA^{5–6}, but not others^{7–9}.

Aims & Methods: This is a prospective study of cirrhotic patients treated with DAA between february/2015 and january/2017, under HCC screening with ultrasonography according to international guidelines. The main endpoint of the study was to determine the incidence of “de novo” and recurrent HCC. The second endpoint was to search for possible predictive factors associated with the occurrence of HCC. Statistical analysis performed on SPSSv.24.

Results: 106 cirrhotics (73% mean; 54.5 ± 8.8 years), MELD 7.3 ± 2.6, 60% with portal hypertension (n=64) and 22% with decompensated cirrhosis (n=23, 22 Child-Pugh B). Two patients with previous HCC, stage Barcelona Clinic Liver Classification (BCLC) A, inviable after loco-regional treatment. The sustained virological response at week 12 was 89.9% (71/79): 4 deaths, 1 relapse, 1 therapeutic failure and 2 losses to follow-up (FU). In 11 ± 7 months of FU, we registered 5 HCC, 4 “de novo” and 1 recurrence, which corresponded to an incidence of 3.8% of “de novo” HCC (13% in decompensated cirrhosis). The BCLC staging was: 2 stage A, 2 stage B and the one with the recurrence was stage D. A Child-Pugh B class (p=0.004), low platelets level (p=0.001) and hospitalization for decompensation (p=0.045) were associated with the occurrence of HCC; the genotype did not have association. The mean time to HCC development was 7.5 months (2–14).

Conclusion: In this cohort the “de novo” incidence of 3.8% of HCC after the treatment with DAA occurred mainly in patients with decompensated cirrhosis, not eligible for treatment with interferon in the past, and in a short interval of time after treatment. These results alert for an eventual need to increase the frequency of screening in the post-treatment period and carefully evaluate the best timing for liver transplantation. We could not conclude about recurrence due to the small number of patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease associated with autoimmune phenomena targeting intrahepatic bile duct cells (cholangiocytes). Although PBC etiopathogenesis remains still obscure, development of anti-mitochondrial auto-antibodies against pyruvate dehydrogenase complex-E2 (PDC-E2) is a common feature. MicroRNA (miR) dysregulation occurs in liver and immune cells of PBC patients, but their functional relevance is largely unknown. We previously reported that miR-506 is overexpressed in PBC cholangiocytes and directly targets both Cl/HCO₃⁻ anion exchanger 2 (AE2) and type III inositol 1, 4, 5-trisphosphate receptor (InsP3R3), leading to cholestasis.

Aims & Methods: The regulation of miR-506 gene expression and its role in cholangiocyte pathophysiology and immune activation was studied. Different sizes of miR-506 promoter were cloned in a luciferase expression vector, which were transfected in human cholangiocytes (H69 cells) and the role of pro-

inflammatory cytokines, bile acids, estrogens and glucocorticoids was evaluated on the promoter activities. MiR-506 or a negative control miRNA sequence were also cloned in an expression vector under the regulation of the CMV promoter; these constructs were stably transfected in H69 human cholangiocytes, and cholangiocyte pathophysiology and immune activation were evaluated.

Results: Several pro-inflammatory cytokines overexpressed in PBC livers [such as IL-8, IL-12, IL-17, IL-18 and TNFα] stimulated miR-506 promoter activity in human cholangiocytes, as revealed by luciferase reporter assays. Experimental overexpression of miR-506 in cholangiocytes dysregulated the cell proteomic profile (by mass spectrometry) affecting proteins involved in different biological processes including mitochondrial metabolism. In cholangiocytes, miR-506: i) induced dedifferentiation with downregulation of biliary and epithelial markers together with upregulation of mesenchymal and pro-inflammatory markers; ii) impaired cell proliferation and adhesion; iii) increased oxidative and endoplasmic reticulum (ER) stress; iv) caused DNA damage; and v) sensitized to caspase-3-dependent apoptosis induced by cytotoxic bile acids. These events were also associated with impaired energy metabolism in mitochondria (proton leak and less ATP production) and PDC-E2 overexpression. Co-culture of miR-506 overexpressing cholangiocytes with PBC immunocytes induced activation and proliferation of PBC immunocytes.

Conclusion: Different pro-inflammatory cytokines enhance the expression of miR-506 in biliary epithelial cells. MiR-506 induces PBC-like features in cholangiocytes and promotes immune activation, representing a potential therapeutic target for PBC patients.

Introduction: Liver biopsy is recognized as the definitive diagnostic tool for the diagnosis and treatment of liver diseases. The transjugular pathway (TJLB) is commonly used in the presence of contraindications to the percutaneous route.

Aims & Methods: The objective was to report the current experience with this technique, as well as its diagnostic acuity and impact in the approach to the patient. Retrospective study of 265 consecutive patients submitted to TJLB between 2010 and 2016.

Results: We included 265 patients with mean age 56 years (+/-12.4), with the majority (60.1%) being male. One hundred and eleven patients (41.9%) were hospitalized. In 40.1% of cases there was previously known liver disease, especially alcoholic disease, hepatitis C and non-alcoholic steatohepatitis. In 80.5% of the cases the purpose of TJLB was for diagnosis and in the remaining cases for staging liver disease. Eighty-five patients (32.1%) had cirrhosis prior to biopsy. In a fourth of the cases the biopsy was performed in the context of acute hepatitis, being in 12.6% for diagnosis of alcoholic hepatitis. The reasons for the percutaneous route included: coagulopathy/anticoagulation (32.2%), thrombocytopenia (17.8%), ascites (17.8%), and failed percutaneous liver biopsy (13.6%). The technical success was 92.4%. Sampling was considered adequate in 92.2% of cases, which was associated with diagnostic purpose (94.9% vs. 80.4%, p=0.001) and evidence of acute hepatitis (98.4% vs. 89.8%, p=0.03). Most patients (60.4%) had histological criteria for cirrhosis. In 76.2% of patients TJLB allowed a histological diagnosis, mainly alcoholic and non-alcoholic steatohepatitis. Ability to provide a histological diagnosis was associated with adequate sample (80.8% vs. 21.1%, p<0.001), presence of cirrhosis (83.9% vs. 71.6%, P=0.023) and >1 passage (82.1% vs. 68.3%, p=0.012). Findings were normal in 4.8%. In 70.9% of the situations the TJLB was considered to have an impact on the subsequent approach. No major complications were recorded.

Conclusion: TJLB is a safe diagnostic tool with high diagnostic acuity, allowing a change in strategy in a high percentage of cases.

P0057 OPTIMAL NUMBER OF MEASUREMENTS IN REAL-TIME SHEAR WAVE ELASTOGRAPHY TO ASSESS LIVER FIBROSIS IN PATIENTS WITH CHRONIC HEPATITIS C VIRUS INFECTION

H. Numao, K. Shimaya, M. Ryoma, S. Igarashi, K. Hasui, K. Kanazawa, M. Munakata, N. Hanabata

Gastroenterology, Aomori Prefectural Central Hospital, Aomori/Japan

Contact E-mail Address: qqqc2c79@celery.ocn.ne.jp

Introduction: Real-time shear wave elastography (SWE) is an established method of evaluating liver stiffness with excellent diagnostic accuracy. However, no consensus exists on the number of measurements or whether mean or median value should be used when reporting results.

Aims & Methods: In this study, we sought to estimate the most appropriate reporting method for SWE results in practice. Overall, 200 consecutive patients with hepatitis C virus infection who underwent liver biopsy between June 2015 and March 2017 were enrolled. Ten SWE measurements (GE Healthcare, USA) and liver biopsies were performed on the same day. Fibrosis was staged from liver biopsies based on METAVIR scores. SWE results were reported using eight methods: (A) one measurement; (B) the mean of two measurements, (C) three, (D) five, (E) ten; and (F) the median of three, (G) five, and (H) 10 measurements.

Area under the curve and receiver operator characteristic (AUROC) comparisons were used to compare the diagnostic accuracy of the eight methods. The interquartile range (IQR) and median of 10 SWE measurements using body mass index (BMI) and age were analysed using the Mann-Whitney *U* test.

Results: The study population consisted of 106 men and 94 women with a mean age of 64.7 ± 10.8 years and mean BMI of 23.3 ± 3.64 kg/m². Fibrosis severity was F0/F1/F2/F3/F4 in 7/50/33/24/23 patients, respectively. The median SWE (m/s) of 10 measurements in patients with F0, F1, F2, F3, and F4 were 1.33, 1.57, 1.73, 1.95, 1.98, respectively. The median IQR/median was 0.21. Furthermore, we found that obesity (BMI ≥ 25 : 0.24, < 25: 0.20, $p = 0.124$) and older patients (age ≥ 65 : 0.22, < 65: 0.20, $p = 0.012$) indicated significantly greater IQR/median. There was no significant difference in the diagnostic accuracy between using the median or mean of three, five, and 10 measurements. The AUROCs to diagnose patients with significant fibrosis ($\geq F2$) ranged from 0.778 (A) to 0.876 (H). AUROC increased based on the number of measurements. A significant difference between 1 and 5 ($p < 0.05$), 1 and 10 ($p < 0.01$), 2 and 10 ($p < 0.05$) measurements was observed in pairwise comparison. Likewise, AUROCs to diagnose patients with severe fibrosis ($\geq F3$) ranged from 0.782 (A) to 0.923 (G). A significant difference ($p < 0.05$) was seen between one and 10 measurements. In the cohort of IQR/median < 0.3, the diagnostic accuracy of $\geq F2$ and $\geq F3$ ranged from 0.806 (A) to 0.877 (H), and from 0.832 (A) to 0.928 (H), respectively. In the cohort of obese (BMI ≥ 25) and old patients (age ≥ 65), the diagnostic accuracy of $\geq F2$ and $\geq F3$ ranged from 0.752 (A) to 0.862 (D), and from 0.735 (A) to 0.903 (H), respectively. Comparing the AUROC of one measurement, IQR/median < 0.3 cohort showed greater AUROC than those of other cohorts, however, the AUROCs of ten measurements were similar in each cohort. **Conclusion:** No difference was found between reporting mean or median SWE measurements. The diagnostic performance of SWE increased with the number of measurements taken. Our results suggest that 10 measurements are recommended to ensure the accuracy of SWE measurements in a practical setting. **Disclosure of Interest:** All authors have declared no conflicts of interest.

P0058 APPARENT DIFFUSION COEFFICIENT IN EVALUATING THERAPEUTIC EFFICACY AFTER RADIOFREQUENCY ABLATION FOR HEPATOCELLULAR CARCINOMA: PROMISING RESULTS

Introduction: Percutaneous radiofrequency ablation (RFA) is a commonly used locoregional interventional procedure in treatment of hepatocellular carcinoma (HCC). There is growing evidence that apparent diffusion coefficient (ADC) value can be used in evaluating RFA therapeutic efficacy in treatment of HCC and thus represent a reliable predictor of local HCC recurrence after treatment.

Aims & Methods: We aimed to determine the therapeutic efficacy RFA in patients with hepatocellular carcinomas using ADC value. A total of 52 patients with 58 HCCs were included, and were treated with RFA according to the guidelines. All lesions were evaluated by diffusion weighted imaging (DWI) and ADC value measurement before and after RFA treatment. DWI was obtained using axial a single-shot echoplanar imaging with two *b*-values (500, 1000 mm²/s) using 3 tesla MRI machine. Quantitative ADC maps were calculated using commercially available software and an imaging workstation. Diagnosis of HCC relied on triphasic CT and MRI, showing enhancement at the arterial phase of dynamic contrast enhanced CT or MRI with rapid washout at the portal venous & delayed phases. Follow-up post ablation by triphasic CT and/or MRI with ADC value measurement was done after one and three months to determine responsive cases (no residual tumoral activity) and non-responsive cases with residual tumor activity.

Results: Forty-eight lesions responded to treatment and 10 lesions had shown no response. ADC values were significantly higher in lesions that responded to RFA than in non-responding lesions. The mean ADC value before treatment was $1.26 \pm 0.16 \times 10^{-3}$ mm²/s (mean \pm SD), while after treatment it was $1.46 \pm 0.12 \times 10^{-3}$ mm²/s with a statistically significant difference ($P = 0.003$) using *b* value 500. The mean ADC of the lesions using *b* value 1000 before treatment was $1.32 \pm 0.28 \times 10^{-3}$ mm²/s, and increased after treatment in responding lesions to reach $1.52 \pm 0.1 \times 10^{-3}$ mm²/s with a statistically significant difference ($P = 0.003$). Using *b* value 500, the mean ADC value before treatment didn't show significant difference between responding ($1.26 \pm 0.16 \times 10^{-3}$ mm²/s) and non-responding lesions ($1.26 \pm 0.12 \times 10^{-3}$ mm²/s; $P = 0.97$). While using *b* value 1000, there was a significant difference with higher mean ADC values before RFA in responding lesions than in non-responding ($1.32 \pm 0.28 \times 10^{-3}$ mm²/s in responding lesions and $1.09 \pm 0.14 \times 10^{-3}$ mm²/s in non-responding, respectively; $P = 0.03$) The change in ADC in responding lesions is significantly higher than in non-responding lesions, and it was 19.6% vs. 6.2%, respectively ($P = 0.01$) using *b* value 500 and was 23.7% vs. 21.2%, respectively ($P = 0.001$) using *b* value 1000.

Conclusion: ADC is a good quantitative measurement allows effective evaluation of the therapeutic efficacy of RFA for treatment of patients with HCC and can be used as good non-contrast alternative to conventional imaging methods in post ablation follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0059 NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD) IMPACT ON RESULTS OF SHEAR WAVE ELASTOGRAPHY FOR HEPATIC FIBROSIS STAGING

Introduction: To study the effect of NAFLD on the results of shear wave elastography (SWE) in patients with chronic diffuse liver disease.

Aims & Methods: We have performed outcome analysis in 100 patients with diffuse hepatic disease which were treated from 2015 to 2016. There were 41 male patients (41%), and 59 female patients (59%), age Me (LQ-UQ) 49 (39–56), minimal age was 18 years, maximal age was 77 years. All patients were found to have chronic diffuse hepatic diseases and were hospitalized for morphological assessment and diagnosis verification. All patients had shear wave elastography (SWE) with quantitative measure tissue stiffness, Metavir score staging for received results.

Results: Based on the obtained morphological results, we have formed the following subgroups of patients: F0 - F1-31 people, F2-9; F3-15 and F4-45 patients. Given that patients with a degree of fibrosis on the scale METAVIR F0 and F1 do not require active conservative therapy, we combined the data of the group into one F0-F1. The obtained results of shear wave elastography are presented in the form of quantitative variables. Median stiffness with interquartile range (25%-75%) in groups: F0 - F1-5, 4 (4, 8–7, 2) kPa, F2-8, 5 (8, 3–8, 9) kPa, F3-13, 5 (10, 1–14, 8) kPa and F4-22, 0 (18, 2–28, 5) kPa. The parameters of liver elastometry in the various groups on the METAVIR scale differed statistically significantly between $p < 0.05$. When carrying out a correlation analysis between the stiffness indices of the liver parenchyma and the morphological stage of fibrosis, a strong correlation was revealed: the Spearman coefficient was $r = 0.81$ $p < 0.1 \times 10^{-6}$. Cutoff values in the general group were: for stage F2-7, 75; F3-13, 25; F4-14, 9 kPa. In 10 patients, results for SWE differed from morphological conclusion. Analyzing reasons we observed that in 8 (80%) patients there was NAFLD found and in 6 cases more than 66% was. To study fatty degeneration impact on elastography outcomes we excluded patients with the given disease (16 patients) from the secondary statistical processing. Stiffness median in patients without fatty hepatic degeneration was: F0 - F1-5, 0 (4, 5–6, 5) kPa, F2-8, 4 (7, 55–8, 7) kPa, F3 -11, 7 (9, 8–14, 2) kPa and F4-22 (18, 0–28, 5) kPa. According to ROC analyses threshold values were: for stages F2-7, 4; F3-9, 8; F4-14, 85 kPa. However, stage correlation for hepatic fatty disease with elastography results was none: $r = 0.11$ $p = 0.246214$.

Conclusion: Quantitative indicators of SWE in patients with diffuse liver disease in combination with steatosis are higher than in patients without it. When interpreting the results of SWE in patients with diffuse liver disease, the possibility of fatty dystrophy should be taken into account, since an underestimation of this fact can lead to false-positive results in the staging of fibrosis by METAVIR. The SWE method can't be recommended for evaluation of the degree of hepatic steatosis, in the absence of correlation with elastometry data.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0060 FEASIBILITY AND REPRODUCIBILITY OF NON-INVASIVE LIVER AND PANCREATIC STIFFNESS ASSESSMENT IN A COHORT OF PATIENTS WITH ALCOHOL-RELATED LIVER DISEASE

C.B. Conti¹, N. Weiler², M. Fraquelli¹, G. Casazza¹, D. Conte¹, M. Colombo¹, S. Zeuzem², M. Friedrich-Rust²

¹Università degli Studi di Milano, Milan/Italy

²Department of Internal Medicine 1, J.W. Goethe-University Hospital, Frankfurt am Main/Germany

Contact E-mail Address: benedetta.conti1@gmail.com

Introduction: The estimation of liver stiffness (LS) has recently been evaluating by new elastographic techniques, such as Shear Wave Elastography (SWE), with a wider applicability than transient elastography (1). No studies evaluated LS in patients with alcoholic liver diseases (ALD) by using the elastographic methods. Moreover, exploring the possibility to assess the elasticity of other tissues, few studies evaluated the pancreatic stiffness (PS) by using transabdominal elastography (2,3), observing that chronic pancreatitis and alcoholic etiology had higher PS values (2).

Aims & Methods: The present study aimed at assessing the feasibility and reproducibility of SWE at measuring LS and PS in a cohort of patients with alcohol abuse and known ALD and investigating the possible correlation between LS or PS with the some clinical and laboratory data. Over a 6-months period 86 patients undergoing LS and PS measurement by SWE were consecutively enrolled. 65 healthy volunteers (HV) were also examined. SWE was blindly performed by two different raters. Liver and pancreatic ultrasound were performed by a single operator. The comparison of stiffness values between patients and HV was performed. Interobserver agreement for SWE was assessed by intraclass correlation coefficient (ICC). The effect of clinical and imaging data was evaluated on log-transformed PS or LS, with univariate and multivariate linear regression model, with PS or LS as dependent variable. *P* values < 0.05 were considered statistically significant.

Results: LS and PS by SWE were obtained in all the patients and HV. No failure was observed. LS and PS were significantly higher in patients than in HV: 22.1 kPa (95% CI, 16.9–36.2) vs 5.7 kPa (95% CI 5.2–6.4) for LS and 15.4 kPa (95% CI 12.2–19.9) vs 12.4 kPa (95% CI 9.5–13.6) for PS, $p < 0.001$. ICC for LS was good: 0.64 (95%CI, 0.50–0.45). ICC for PS was fair to good: 0.40 (95%CI,

0.21–0.57). At univariate analysis LS was associated with: liver cirrhosis ($p < 0.0001$), steatosis ($p = 0.0003$), liver surface nodularity ($p = 0.0003$), active alcoholic consume ($p = 0.015$), alcohol consumption/day ($p = 0.0134$), diabetes ($p = 0.0223$). At multivariate analysis cirrhosis ($p < 0.0001$) and steatosis ($p = 0.0073$) were independently associated with LS. At both univariate and multivariate analysis, PS was significantly correlated only with liver cirrhosis ($p = 0.0058$).

Conclusion: The present is the first series assessing LS and PS in ALD patients by using SWE. The feasibility of the technique was excellent. The reproducibility was good for LS and fair for PS. SWE was a good predictor of liver fibrosis in the ALD cohort. Liver cirrhosis was the only independent variable correlating with PS, whose estimation could be useful to detect alcohol-related pancreatic damage in patients with severe ALD.

Introduction: miR-224 was found regulated progression of liver cancer in our previous studies, IL-6/STAT3 pathway play key role, but the precise underlying mechanism remains to be explored. It was found exosomes are the vesicles released by the tumor cells into tumor microenvironment, they are a powerful diagnostic tool due to relative stability and composition covering the whole range of cancer-related biomarkers including proteins, metabolites, DNA, DNA modifications, coding and non coding RNA. Thus, study the roles of exosomal miRNA could be useful for therapy and prognosis prediction of hepatocellular carcinoma (HCC).

Aims & Methods: The expression of miR-224, IL-6, STAT3 and SMAD4 in tumor as well as adjacent tumor tissues of HCC were detected by RT-PCR. Then the role of miR-224 in HCC progression was assessed *in vitro* as well as *in vivo*, and the expression of miR-224 and genes related to HCC invasion and migration were detected by RT-PCR and immunohistochemistry methods in the transplantation tumor of nude mice. Furthermore, the supernatant exosome from HCC cells was isolated and the translocation roles of exosome was studied by confocal. Finally, the expression of miR-224 and genes in STAT3/SMAD4 pathway in the exosome isolated from the supernatant of HCC cells induced by IL-6 were detected.

Conclusion: This study provides the novel mechanism of regulatory roles of miR-224 in HCC, and from the study, exosomal miR-224 showed as the novel target and predictor for HCC prevention and treatment in future clinic.

Results: It was found miR-224, IL-6 and STAT3 were up regulated in the tumor tissues of HCC patients but the SMAD4 showed the down regulated when compared with adjacent tumor tissues. Over expression of miR-224 can promote growth, proliferation, migration and invasion capability of HCC cells *in vitro*. Furthermore, *in vivo* study, miR-224 was found accelerated transplantation tumor growth in nude mice, and the up regulation of miR-224, IL-6/STAT3 and down regulation of SMAD4 were also found in the transplantation tumors which were induced by miR-224. The Exosome from the supernatant of HCC cells can be found translocated into HCC cells conversely, when the HCC cells were induced by IL-6, the overexpression of exosomal miR-224 and STAT3 and decrease of exosomal SMAD4 were detected. It was speculated miR-224 can regulated HCC progression through IL-6/STAT3/SMAD4 pathway by exosomal way.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0062 EXPRESSION ANALYSIS OF LIVER-SPECIFIC CIRCULATING MICRORNAS IN HCV-INDUCED HEPATOCELLULAR CARCINOMA IN EGYPTIAN PATIENTS

L. Mourad¹, E. El-Ahwany², M. Zoheiry², H. Abu-Taleb², M. Hassan², A. Abdel Rehim², M. Hassan², S. Zada¹

Introduction: The prevalence of hepatocellular carcinoma (HCC) in Africa is higher compared to the rest of the world due to the high incidence of chronic

infection with hepatitis C virus (HCV). In Egypt, HCV infection is the leading cause for the high HCC incidence, which is usually diagnosed at late stages. Due to the absence of reliable and accurate biomarkers for early detection of liver cancer, circulating microRNAs have recently emerged as great candidates for early diagnosis of HCC. These small non-coding RNA molecules are responsible for regulating gene expression and RNA stability. Therefore, the aim of this study is to investigate the potential of liver-specific circulating microRNAs as an accurate non-invasive diagnostic tool for the early detection of HCV-induced HCC.

Aims & Methods: Seven main miRNAs (miR-125a, miR-139, miR-34a, miR-221, miR-16, miR-145 and miR-199a) were selected due to their expression patterns in HCC as well as their contribution to the development of hepato-carcinogenesis. A total of 165 patients were enrolled in this study, from which serum samples were collected and categorized into four main patient groups: 42 chronic hepatitis C (CHC) without cirrhosis, 45 CHC with cirrhosis (LC), 38 HCC with HCV patients, and 40 healthy controls. The expression profile of the seven miRNAs was analyzed using TaqMan real-time reverse transcription-polymerase chain reaction. Additionally, the conventional markers for HCC α -fetoprotein (AFP) and des- γ -carboxyprothrombin (DCP) were measured using commercial kits.

Results: Serum levels of miR-125a, miR-139, miR-145 and miR-199a were significantly decreased ($P < 0.01$) in HCC than in the CHC and LC groups (Table 1). On the other hand, miR-16 and miR-34a were significantly increased ($P < 0.01$) in HCC patients compared to the normal group. However, no significant difference was shown in the expression of miR-16, miR-34a, and miR-221 between the CHC, LC, and HCC groups. As a single biomarker, miR-34a showed the highest sensitivity and specificity among all miRNAs investigated, followed by miR-221, miR-125a, miR-139, miR-145, and miR-199a.

Table 1: Expression levels of serum microRNAs of the patient groups

MicroRNAs	Normal	CHC	LC	HCC
miRNA-16	14.26 \pm 0.69	24.09 \pm 0.44**	23.29 \pm 0.46**	22.35 \pm 0.54** ^a
miRNA-34a	27.32 \pm 0.19	32.69 \pm 0.34**	30.01 \pm 0.54** ^b	32.50 \pm 0.94**
miRNA-221	22.82 \pm 0.38	27.17 \pm 1.44**	28.22 \pm 0.41**	28.51 \pm 0.46**
miRNA-125	20.57 \pm 0.54	96.01 \pm 4.36**	100.54 \pm 0.81**	29.96 \pm 0.57** ^d
miRNA-139	29.96 \pm 0.57	94.63 \pm 0.38**	86.02 \pm 0.40** ^c	30.03 \pm 0.43
miRNA-145	20.65 \pm 0.52	85.31 \pm 0.53**	80.74 \pm 0.59**	20.64 \pm 0.57
miRNA-199	80.23 \pm 0.72	330.38 \pm 0.74**	311.98 \pm 0.72**	66.16 \pm 0.44 ^c , ^d

** $p < 0.01$ significant increase than control; ^a $p < 0.01$ significant decrease than CHC; ^b $p < 0.01$ significant decrease than CHC and HCC; ^c $p < 0.01$ significant decrease than control; ^d $p < 0.01$ significant decrease than CHC and LC; ^e $p < 0.01$ significant decrease than CHC

Conclusion: These results indicate that measuring the expression levels of liver-specific circulating microRNAs can be used as a reliable diagnostic and prognostic tool for HCC. Our results demonstrated that the up-regulation of miR-16, miR-34a, and miR-221 can differentiate between normal individuals and patients with liver disease ranging from fibrosis, cirrhosis, and HCC. Meanwhile, the noticeable down-regulation of miR-125a, miR-139, miR-145 and miR-199a in the HCC patient group indicates that these microRNAs can differentiate HCC from CHC and LC.

Introduction: Primary hepatocellular carcinoma (HCC) is one of the most common malignancies all over the world. HCC is associated with poor prognosis. However, the mechanism of HCC initiation and development remains unclear. In our previous work, high-throughput microarray assay in collected clinical HCC samples followed by bioinformatic analysis suggested that Metallothionein 1G (MT1G) might be one of the key factors in HCC.

Aims & Methods: We detected the MT1G expression in paired HCC samples and HCC cell lines by RT-qPCR and Western blot. Then MSP (Methylation specific PCR) and BGS (Bisulfite genomic sequencing) were performed to evaluate methylation status of MT1G in HCC. The functional significance of MT1G in HCC was investigated by overexpression or knockdown in HCC cell lines. The effects of MT1G re-expression were also determined by flow cytometry.

Results: MT1G was inactivated in all (6/6) HCC cell lines tested, but was readily expressed in immortalized liver cell line LO2. The expression of MT1G was down

regulated in cancer tissues compared with the adjacent non-tumor tissues ($P < 0.001$). The gene expression level of MT1G in the liver cancer cell lines was closely correlated to the promoter hypermethylation status. The MT1G expression in silenced HCC cell lines could be restored by demethylation agent. We generated HCC cell lines overexpressed MT1G. Ectopic re-expression of MT1G by stable transfection in SMMC-7721 and Hep3B cells inhibited colony formation ($P < 0.001$), suppressed cell motility and invasiveness ($P < 0.05$), concomitant with up-regulation of E-cadherin; and down-regulation of PCNA, MMP2, MMP13 and Vimentin. The in vivo growth of HCC cells in nude mice was also markedly inhibited after stable expression of MT1G ($P < 0.001$). MT1G over-expression in HCC cells induced the cell apoptosis ($P < 0.01$).

Conclusion: Our results demonstrate that MT1G promoter methylation directly mediates the transcription down-regulation and commonly occurs in HCC. MT1G gene can act as a functional tumor suppressor in liver carcinogenesis by playing an important role in depression of cell proliferation, migration, invasion, and induction of cell apoptosis.

Introduction: Hepatocellular adenoma (HCA) and focal nodular hyperplasia (FNH) may be confused on medical imaging. Both tumours are not connected to the biliary tree, however only FNH accumulates bile salts, suggesting that hepatocellular uptake and secretion of bile constituents differs in FNH and HCA. Therefore, one would anticipate changes in the Farnesoid X receptor (FXR) expression. However, the expression of FXR and its targets in HCA and FNH is relatively unknown. Targets of FXR regulate uptake and excretion of hepatobiliary contrast agents, possibly altering the presentation of FNH and HCA on medical imaging. We studied the expression of FXR and its targets in HCA and FNH and compared this with the appearance of lesions on MRI.

Aims & Methods: Tumour tissue and normal tissue from 7 patients with HCA and 7 patients with FNH was obtained. Diagnosis was confirmed by histopathological examination in all patients. Reverse transcription of the mRNA to cDNA was performed, using random primers and MultiScribe Reverse Transcriptase (Life Technologies, Carlsbad, Ca). The cDNA was used as template for PCR amplification by Taqman® assay analysis (Applied Biosystems, Foster City, CA). The expression of all the target genes in the FXR pathway (SHP, NTCP, OATP1B1, OATP1B3, BSEP, CYP7A1, CYP8B1, BAAT, SLC27A5, CYP3A4, SSULT2A1, UGT2B4, FGFR4, MRP2, MRP3, MDR3) were compared to the expression of UBC which functioned as internal reference in both normal and tumour tissue. Matched case comparisons were made for tumour and normal tissue. DNA expression of FNH and HCA was compared to MRI findings.

Results: FXR was downregulated in both HCA and FNH. NTCP was significantly downregulated in FNH, and not significantly in HCA, although showing a trend towards down regulation. Three patients (1 FNH 2 HCA) show aberrant expression of NTCP compared to all the other patients. All these three patients had also an unclear or incorrect diagnosis based on MRI scan with gadoxetic acid as compared to final diagnosis by histopathological examination. OATP1B1 was downregulated in both HCA and FNH, except again for the three patients with the aberrant imaging. Expression of OATP1B8 and SHP in HCA and FNH did not significantly differ from expression in healthy liver tissue. MRP2 was significantly downregulated in HCA, but not in FNH. However, this may again be due to the patients with the aberrant expression pattern. OATP1B3 was significantly downregulated in HCA. CYP3A4 and CYP2A1 were very strong downregulated in HCA, but not in FNH. FGFR 4 was heavily downregulated in HCA, but not in FNH. BAAT was significantly downregulated in HCA.

Conclusion: Limited by sample size, this study suggests that misdiagnosis based on medical imaging might actually correlate with aberrances on hepatocyte transporter level. This seemed to account for NTCP (bile salt importer), OATP1B1 (bile salt importer) MRP2 (efflux pump of conjugated compounds). Although FXR itself was downregulated in both FNH and HCA, its downstream targets differed in expression between tumours. FXR receptor activity might be altered even though expression is not different, or downstream targets might be influenced by factors outside the FXR pathway. Future research could provide a more profound insight into this mechanism.

P0065 CUX1 CONTROLS ENDOPLASMIC RETICULUM STRESS AND AUTOPHAGY-RELATED CELL DEATH

G. Metzger¹, P. Di Fazio¹, D. Bartsch¹, T.M. Gress², T. T. Wissniewski²

¹Department Of Visceral Thoracic And Vascular Surgery, Philipps University Marburg, Marburg/Germany

²Klinik Für Gastroenterologie, Endokrinologie, Stoffwechsel Und Infektiologie, Philipps Universität Marburg, Marburg/Germany

Contact E-mail Address: giulia_metzger@web.de

Introduction: CUX1 (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of proapoptotic genes. Its aberrant expression in tumor turns its role as foe.

Aims & Methods: Here, we analyze the role exerted by CUX1 during deacetylase inhibitors mediated cell death in liver cancer cells. CUX1, endoplasmic reticulum (ER) stress and autophagy markers were analyzed by RT-qPCR in two liver cancer cell lines HepG2 and Hep3B. Protein level was measured by western blotting. Cells were transfected with siRNA for CUX1 and furthermore treated with deacetylase inhibitors panobinostat, SAHA and trichostatin A. Thapsigargin, an endoplasmic reticulum stress inducer, served as positive control.

Results: CUX1 knock down caused a suppression of ER stress and autophagy markers BiP, CHOP, ATF4, ATF6, Beclin1, MAP1LC3B, UVRAG and TFEB at early time point (6 hours) in both cell lines. Prolonged transfection did not alter the expression of the above mentioned markers; BiP was the only one suppressed in HepG2 after 24 hours. Interestingly, the deacetylase inhibitors are able to promote CUX1 over-expression after 6 hours of treatment, whereas they show to lose this ability after 24 hours. CUX1 knock-down reduced not significantly its protein level after treatment with deacetylase inhibitors. CUX1 knock down counteracts the accumulation of BiP protein after 24 hours of treatment with deacetylase inhibitors. Thapsigargin induced BiP independently from CUX1.

Conclusion: ER stress and autophagy markers are under the control of CUX1. The cell death induced by deacetylase inhibitors is strictly connected with CUX1 expression and activity. Further studies are needed to clarify the exact mechanism exerted by CUX1 in this scenario.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0066 CUX1 CONFERS RESISTANCE TO APOPTOTIC CELL DEATH IN LIVER CANCER CELLS

E. Hofmann¹, P. Di Fazio¹, D. Bartsch¹, T.M. Gress², T. T. Wissniewski²

¹Department Of Visceral Thoracic And Vascular Surgery, Philipps University Marburg, Marburg/Germany

²Klinik Für Gastroenterologie, Endokrinologie, Stoffwechsel Und Infektiologie, Philipps Universität Marburg, Marburg/Germany

Introduction: CUX1 (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of proapoptotic genes. Its aberrant expression in tumor turns its role as foe.

Aims & Methods: Here, we analyze CUX1 activity in TRAIL (Tumour necrosis factor related apoptosis inducing ligand) mediated cell death in liver cancer cells. CUX1 was knocked down in HepG2 and Hep3B cells. Cells were further treated for 48 hours with a strong ligand (superkiller) binding DR4 and DR5 (TRAIL death receptors). The cell death events were analyzed by FACS analysis. RT-qPCR was performed to detect the expression of apoptotic markers. Caspase activity was measured by luminescence. Apoptosis array was performed. Western blotting was performed for caspase 8 and Flip detection.

Results: Treatment with superkiller TRAIL, at 50 and 100 ng/ml, caused cell death in HepG2 and Hep3B cells after 48 h proven by an accumulation of 40% of sub-G1 events. CUX1 knock down caused a sensitization of liver cancer cells to TRAIL effect by increasing, significantly, the percentage of sub-G1 events (60% with 100 ng/ml). CUX1 knock down did not change the expression of TP53, KRT18, CDKN1A and CDKN1B. Interestingly, silencing CUX1 increased the activity of caspase 3/7 after treatment with soluble TRAIL. The effect was neutralized by pan-caspase inhibitor zVAD. Apoptosis array evidenced an increased protein level of un-cleaved caspase 3 after CUX1 knock down. Caspase 8 uncleaved form was down-regulated at protein level after CUX1 knock down and treatment with TRAIL. Its cleaved forms were up-regulated. FlipL decreased in favor of FlipS also.

Conclusion: CUX1 mediates the resistance of liver cancer cells to TRAIL signaling. Knock down of CUX1 restores the potential of TRAIL to trigger cell death.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0067 SERUM SQUAMOUS CELL CARCINOMA ANTIGEN LEVEL IN CIRRHOTIC CHRONIC HEPATITIS C PATIENTS WITH AND WITHOUT HEPATOCELLULAR CARCINOMA

W. I. Ellakany

Gastroenterology, Hepatology And Infectious Tropical Medicine, Faculty of Medicine, Alexandria University, Egypt, Alexandria/Egypt

Contact E-mail Address: walidellakany@yahoo.com

Introduction: Hepatocellular carcinoma (HCC) is a primary malignancy of the liver. HCC is the fifth most common malignancy in the world and the third most common cause of cancer-related deaths worldwide. It is a major health problem in Egypt with the incidence expected to rise continuously in the next decade. [1–2] The diagnosis of liver cancer depends on both screening with alpha-fetoprotein (AFP) and radiological imaging studies. Generally, normal levels of AFP are below 10 ng/ml but AFP greater than 200 ng/ml is suggestive of HCC. The sensitivity of AFP for liver cancer is about 67%; therefore a normal AFP does not exclude HCC. Searching another tumor marker, that together with AFP could improve the diagnostic utility of HCC.[3]

Squamous cell carcinoma antigen (SCCA), a member of the high molecular weight family of serine protease inhibitors named serpins which are physiologically found in the granular layers of normal squamous epithelium but found to be typically expressed by neoplastic cells of epithelial origin in a number of different cancers for example cancer cervix, lung, and head and neck cancers hence, it can be used as a clinical marker of these malignancies. [4]

The structure of the serpin ovalbumin revealed the archetype native serpin fold that typically have three β -sheets (termed A, B and C) and eight or nine α -helices (hA-hI). Serpins also possess an exposed region termed the reactive centre loop (RCL) that includes the specificity determining region and forms the initial interaction with the target protease.

Recently much attention has been focused on the role of SCCA in HCV cirrhotic patients suggesting that high levels of SCCA can assess HCC development. [5] The aim of this study was to assess the serum level of squamous cell carcinoma antigen (SCCA) in cirrhotic chronic HCV patients with and without hepatocellular carcinoma in relation to alpha feto protein (AFP).

Aims & Methods: The aim of this study was to assess the serum level of squamous cell carcinoma antigen (SCCA) in cirrhotic chronic HCV patients with hepatocellular carcinoma in relation to alpha feto protein (AFP). These groups were from both sexes who are admitted to the inpatient ward and the outpatient clinic of Tropical Medicine Department, Faculty of Medicine, Alexandria University. This study was carried out on:

Group A: 100 cases of hepatocellular carcinoma without interventions.

Group B: same 100 cases of group A before and 3 months after successful interventions.

Group C: 100 cases of established cirrhosis.

Group D: 100 cases with chronic hepatitis C virus infection without established cirrhosis.

Group E: 100 healthy individuals as controls.

All patients in this study were subjected to: complete blood picture, liver biochemical profile, serum alanine aminotransferase (ALT), serum aspartate aminotransferase (AST), serum alkaline phosphatase, total and direct serum bilirubin, prothrombin time and activity, serum albumin blood urea nitrogen (BUN), serum creatinine, Fasting blood sugar. Serum alpha fetoprotein (AFP).

Determination of squamous cell carcinoma antigen (SCC-Ag) Sera from selected patients and controls were used for estimation of SCC-Ag using CanAg SCC EIA. The CanAg SCC EIA is a solid phase, non-competitive immunoassay based upon the direct sandwich technique. Calibrators and patient samples are incubated together with biotinylated Anti-SCC monoclonal antibody in Streptavidin coated microstrips. After washing buffered Substrate/Chromogen reagent (hydrogen peroxide and 3, 3', 5, 5' tetra-methylbenzidine) is added to each well and the enzyme reaction is allowed to proceed. During the enzyme reaction a blue colour will develop if antigen is present. The intensity of the colour is proportional to the amount of SCC present in the samples. The colour intensity is determined in a microplate spectrophotometer at 620 nm (or optionally at 405 nm after addition of Stop Solution). Calibration curves are constructed for each calibrator. The SCC concentrations of patient samples are the read from the calibration curve.

Results: Table 1 shows a statistical significant difference between different studied groups regarding alpha feto protein (P=0.000).

Table 1: Comparison Between Different Studied Groups Regarding Alpha Feto Protein

	Mean	Std. deviation	Minimum	Maximum
Gp. A	263.0	96.02	150.	438
Gp. B	209.4	64.7	145.	380.
Gp. C	154.5	48.16	75.	210.
Gp. D	7	1.82574	5	9
Gp. E	1.22	0.27406	0.8	1.6
F			38.208	
P			0.000*	

Table 2 shows a statistical significant difference between different studied groups regarding SCCA level (P=0.000).

Table 2: Comparison Between Different Studied Groups Regarding SCCA Score

	Mean	Std. deviation	Minimum	Maximum
Gp. A	5.53		2.16	2.5
Gp. B	5.3		1.5	3.3
Gp. C	3.3		1.6	1.2
Gp. D	0.824		0.15897	0.6
Gp. E	0.646		0.23172	0.3
F				28.897
P				0.000*

Also, Positive significant correlation was found between AFP and SCCA in both groups (Table 3).

Table 3: Correlation Between AFP and SCCA

AFP			
HCC without intervention HCC with intervention			
SCCA	r	0.629*	0.525*
	p	<0.001	<0.001

Note. r: Pearson coefficient, *: Statistically significant at $p \leq 0.05$

When combined sensitivity of both markers were calculated in our study at the best-chosen cutoff values (SCCA 3.2 ng/ml and AFP 200 ng/ml) sensitivity improved to 93% (Table 4).

Table 4: AUC for AFP, SCCA and SCCA + AFP

	AUC	p
AFP + SCCA	0.930*	0.001
AFP	0.890*	0.003
SCCA	0.820*	0.016

Conclusion: In the present study patients with HCC either with or without therapeutic intervention have significantly higher level of AFP in comparison to chronic HCV, cirrhotic and control groups this is in agreement with Awadallah et al.[6] who reported a statistically highly significant elevation in the serum AFP in HCC group when compared with control group. Moreover, the mean serum level of AFP in group A (HCC before intervention) was 263 ng/ml that decreased to 209.4 ng/ml in group B after therapeutic intervention and this agreed with Feng et al.[7] and Molinari et al.[8] Also, at AFP level of 200 ng/ml, the sensitivity was 90%, while the specificity was 60%.

Our results showed that SCCA level ranged from 2.5–10 with a mean of 5.53 in HCC patients without interventions, 3.3–7.6 with a mean of 5.3 in patients with HCC with therapeutic interventions, 1.2–5.6 with a mean of 3.3 in cirrhotic group, 0.6–1.05 with a mean of 0.824 in chronic HCV group while healthy control group had much lower values ranging from 0.3–0.95 with a mean of 0.646. Thus, a highly significant increase in serum SCCA level in patients with HCC before and after therapeutic intervention when compared to cirrhotic, chronic HCV and control groups ($P < 0.001$). These results were in accordance with Hussein et al. [9] and El Ezawy et al.[10] SCCA was also higher among patients with HCC before intervention compared to patients with HCC after intervention as found by Bin et al.[11]

Applying the ROC curves analysis showed the best cut-off value to differentiate HCC patients from cirrhotic patients was 3.2 ng/ml for SCCA yielded 80% sensitivity and 90% specificity. These results were in agreement with Trevisani et al.[12] Patients with HCC, in our study were none randomized selected as BCLC stage B (either one HCC lesion <5 cm in size or 3 lesions <3 cms) so no statistical correlation was done between serum AFP level and tumor size.

Our results showed a significant positive correlation between serum SCCA and AFP among patients with HCC before and after therapeutic intervention. Our data are in agreement with that of Hussein et al.[9] and El Ezawy et al.[10] who detected that SCCA were positively significantly correlated with AFP level. When combined sensitivity of both markers was calculated in our study at the best-chosen cutoff values (SCCA 3.2 ng/ml and AFP 200 ng/ml) sensitivity improved to 93%. Matching results were found by Gianluigi et al.[4]

Introduction: Hepatocellular carcinoma (HCC) is the first most common primary malignant tumor of the liver, the fifth common cancer and the third most common cause of cancer-related death worldwide. (1) Early detection of HCC provides the best chance for a curative treatment which in turn improves patients survival. However, more than 60% of HCCs are diagnosed at a late stage (2). This could be explained by poor compliance of cirrhotic patients to the surveillance programs and lack of a sensitive and specific tumor marker. Serum AFP – commonly used for HCC diagnosis has a low sensitivity, and specificity for HCC detection (3).

Aims & Methods: The aim of this study was to develop Hepatocellular Multidisciplinary clinic – Cairo University (HMC-CU) score and test its accuracy in HCC detection in comparison to the widely used AFP. In the current study, we reviewed the data of 2363 Egyptian patients with HCV genotype-4 related chronic liver disease CLD; 1291 patients were diagnosed to have HCC while 1072 patients were diagnosed to have HCV related liver cirrhosis with no HCC on top. All the patients were recruited from the HCC multidisciplinary clinic, Cairo University Focal hepatic lesions detected by abdominal ultrasound (US) and/or rising AFP assays were further evaluated by tri- phasic multiphase computed tomography (CT) or contrast-enhanced magnetic resonance imaging (MRI). Lesions showing enhancement in the arterial phase were diagnosed as HCC. Diagnosis of HCV related liver cirrhosis was based on clinical, laboratory and imaging evidence of chronic liver disease in addition to detection of HCV antibodies and HCV RNA by PCR technique. Each patient signed an Informed consent and the study was carried out according to the ethical guide-lines of 1975 Helsinki Declaration.

Results: On bivariate analysis, the HCC patients were significantly older, anemic and showed significant thrombocytopenia, hyper- bilirubinemia, elevated serum AST and AFP serum levels. Serum albumin was significantly lower in HCC patients. Consequently, we entered these significant variables in a multivariate regression model that demonstrated that only age, gender, hemoglobin, albumin, AFP and INR were independently associated with HCC development.

Table: Multivariate analysis for calculation of the HMC-CU score.

	OR	95% C.I.		P- value
		Lower	Upper	
Age Gender Hb INR	1.164	1.141	1.188	<.001
Alb AFP Constant	2.653	1.959	3.594	<.001
	0.886	.819	.959	.003
	0.498	.267	.931	.029
	0.347	.268	.448	<.001
	1.022	1.016	1.028	<.001
	0.080			.010

The best overall formula that could best predict HCC was then constructed Hepatocellular Multidisciplinary clinic – Cairo University (HMC-CU) score is as following: Logit probability of HCC = $-2.524 + 0.152 \times \text{age} - 0.121 \times \text{Hb} - 0.696 \times \text{INR} - 1.059 \times \text{Alb} + 0.022 \times \text{AFP} + 0.976 \times \text{Gender}$ Gender Male = 1 Female = 0 The diagnostic value of HMC-CU was then assessed by ROC curve. At a cutoff point of 0.56 HMC-CU enabled the correct identification of patients with HCC with 90% sensitivity, 80.6% specificity. AUC was 0.93 and the 95% confidence interval was 0.917–0.94. On comparing the diagnostic performance of HMC-CU to the performance of serum AFP for early diagnosis of HCC, it was found that serum AFP was able to diagnose HCC at cutoff value of 11.9 ng/ml with sensitivity of 68% and specificity 66%. AUC was 0.76 and the 95% confidence interval was 0.74–0.78

Conclusion: The HMC-CU score constructed from routine parameters is accurate in early diagnosis of HCC in patients with HCV-related CLD. The elegance of our score is based on its simplicity, being based on routine laboratory parameters and serum AFP which is being used for screening of patients in many centers all over the world. Our score will not impose extra costs for the patients because it utilizes only routine laboratory parameters. The HMC-CU score may be useful during surveillance programs for HCC. Our study included large number of HCC and non HCC patients all are Egyptians with a background of HCV type 4 related CLD. A prospective validation study is being planned and further studies are invited to validate this score on patients of other races infected with other HCV genotypes.

P0069 MULTIPLE BIPOLAR RADIOFREQUENCY ABLATION IN TREATMENT OF MEDIUM TO LARGE HEPATOMAS – EXPERIENCE IN A REGIONAL HOSPITAL

P. Hsieh, C. Yen

Division Of Gastroenterology And Hepatology, Chang-Gung Memorial Hospital Keelung branch, Keelung/Taiwan

Contact E-mail Address: b8802050@gmail.com

Introduction: Monopolar radiofrequency ablation (RFA) treatment for hepatomas has been unsatisfactory with local tumor recurrent rates of 8–40% in tumors ≥ 3 cm. Bipolar RFA devices have been developed to overcome the limitations of monopolar RFA devices.

Aims & Methods: This study aimed to evaluate the therapeutic effect and long term survival in medium and large hepatomas using multiple bipolar radiofrequency ablation system (Celon). The study subjects had a Child-Pugh classification of A or B. The patients who were ineligible for surgical intervention or preferred RFA over surgery were treated with percutaneous bipolar electrodes. A total of 30 consecutive cirrhotic patients (48 tumors) with hepatomas ≥ 3 cm were enrolled between January 2011 and November 2012. The follow-up period was 30 months after RFA. The complete necrosis rate, tumor recurrence rate and long-term survival rate were analyzed and compared between medium and large hepatomas using Kaplan-Meier survival and the prognostic factors were using multivariate analysis.

Results: 30 patients were divided equally into two groups with 15 patients in each of medium and large hepatoma groups. 17 patients underwent artificial ascites (56.3%). The complete necrosis rate after ablation was 93.3% (14/15 patients) for either medium or large hepatomas. The local tumor progression rate and distant tumor recurrence rate of 40% and 60% ($p = 0.098$) vs 73.3% and 80% ($p = 0.652$) for medium and large hepatomas during 30 months follow up were not statistically significant. The overall survival rates of 80%, 66.7% vs 60%, 46.7% at 12 and 30 months, respectively, was not statistically significant ($p = 0.390$). By multivariate analysis, BCLC stage (HR = 3.904, $p = 0.023$), MELD score (HR = 1.220, $p = 0.021$) and pre-treatment AST level (HR = 1.028, $p = 0.019$) were independent prognostic factors for overall survival.

Conclusion: Multiple bipolar RFA system can achieve high complete tumor necrosis rate and low complication rates in treating medium to large hepatomas with shorter duration. Pre-treatment BCLC stage, MELD score and AST level were independent prognostic factors for overall survival. The therapeutic effect and long term survival for large hepatomas (≥ 5 cm) was not inferior to that of medium hepatomas by multiple bipolar RFA.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0070 RECENT TRENDS IN HEPATOCELLULAR ADENOMAS: CLINICAL FEATURES, DIAGNOSIS AND OUTCOMES

M. Silva, A. Peixoto, R. Coelho, G. Cardoso, G. Macedo
Gastroenterology, Hospital São João, Oporto/Portugal

Contact E-mail Address: marcocostasilva87@gmail.com

Introduction: Hepatocellular adenomas (HCA) are rare, benign tumors of presumable epithelial origin, that occur predominantly, but not exclusively, in young women taking oral contraceptives (OC) or other estrogens. The Bordeaux adenoma tumour markers are a promising method of identifying the high-risk HCA of malignant transformation into hepatocellular carcinoma (HCC).

Aims & Methods: Aims: The authors propose to evaluate the demographics, etiology, clinical manifestations and prognosis of HCA.

We undertook retrospective analysis of patients with HCA, histologically confirmed (by guided biopsy or surgical resection), between 2008 and 2016, in a tertiary referral centre. When feasible, the subtype classification of HCA proposed by the Bordeaux group, was performed. Descriptive statistics, uni and multivariate analysis were performed using IBM SPSS Statistics 22, with $p < 0.05$ deemed to be statistically significant.

Results: In this study 27 patients were included, 2 men and 25 women, with a median age of 38 ± 11 years, followed for a mean time of 78 ± 36 weeks (lost follow-up in 7 cases). Three cases of hepatic adenomatosis were included. Forty-one percent of the women used OC and 38% of the patients had dyslipidemia. The mean size of the HCA was 70 ± 42 mm; 63% of the patients had abnormal liver tests at diagnosis, 46% were symptomatic and in 21% the diagnosis was performed due to ruptured HCA. Surgical resection was performed in 88% of the cases; complete resection was achieved in 75% of the cases. Of the 19 patients who performed abdominal-CT scan or abdominal-MRI before histological confirmation, only 29% had an imagiological diagnosis of HCA. In 12 (44%) cases, immunohistochemical analysis was performed. According to the Bordeaux classification of HCA, 8 (67%) cases were classified as inflammatory, 2 (17%) as HNF-1 α -mutated, 1 (8%) as β -catenin mutated and 1 (8%) as unclassified. During follow-up, 1 (4%) patient died due to hemorrhagic shock related with HCA rupture and in 2 (10%) was necessary surgical revision due to incomplete resection. There was no HCC cases diagnosed during the follow-up. The median size of the HCA that weren't completely resected and also of those presenting with HCA rupture was significantly higher: (110 vs 55 mm [$p = 0.035$] and 105 vs 47 mm [$p = 0.037$], respectively). The 2 male patients had inflammatory HCA ($p = 0.011$).

Conclusion: In this cohort, HCA were prevalent in female taking OC and the inflammatory type HCA was the most common. In many cases, abdominal imaging is insufficient for a correct diagnosis, and biopsy specimen or surgical resection should be performed for a correct diagnosis. Lesion size was associated with the risk of rupture and incomplete surgical resection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Currently, the standard treatment using transarterial chemo-embolisation (TACE) for patients showing solitary large (≥ 40 mm) hepatocellular carcinoma (HCC) is unsatisfactory with high rate of recurrence. Data from literature suggest the alternative use of thermal ablation.

Aims & Methods: We aimed to evaluate the efficacy and safety of Laser Ablation (LA) in comparison to TACE in patients with large tumor size HCC. Between January 2009 and December 2012, 41 cirrhotic patients (29/12 M/F; median age 72 yrs, range 54–88, Child-Pugh A/B: 37/4) with a single nodule of HCC ≥ 40 (median size 46 mm, range 40–75) were enrolled in this study. The patients were treated with multifiber technique of LA. The control group consisting of 41 patients (29/12 M/F; mean age 72 yrs, range 49–86; Child-Pugh A/B: 34/7; median size of the nodule 50 mm, range 40–80, treated with TACE, was obtained from the ITA.LI.CA database and observed in the same period of time. No statistically significant difference between the 2 groups was observed. The diagnosis of HCC was done according to the international guidelines and patients were staged according to BCLC Staging System (BCLC stage A/B: 27/14 and 18/23, for LA and TACE, respectively). Response to therapy was evaluated according to the mRECIST criteria. Survival was calculated from the time of cancer diagnosis to death with values censored at the date of the last follow-up.

Results: Twenty-six (63.4%) patients of LA group and 8 (19.5%) patients of TACE group showed a complete response after treatment ($p < 0.001$). The superior efficacy of LA was confirmed in all categories, also after the stratification of the nodules according to the nodules size (40–50 mm, 51–60 mm and > 60 mm). Disease recurrence, during a mean \pm SD period of follow-up of 37.4 ± 20.7 months, was observed in 13 (24%) LA-treated patients (24%) and in 24 (58.5%) TACE-treated patients ($p = 0.00515$). Overall survival probability rate at 1 and 3 years was 90.2% and 55.4% in LA group and 85.4 and 48.8. in TACE group.

Conclusion: LA is a more efficacious therapeutic option than TACE in patients with solitary large HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0072 ENDOSCOPIC ULTRASOUND GUIDED BIOPSY FOR LIVER MASS USING CORE BIOPSY NEEDLE

H.K. Chon¹, T.H. Kim¹, K.H. Choi²

¹Internal Medicine, Wonkwang College of Medicine, Iksan/Korea, Republic of

²Pathology, Wonkwang College of Medicine, Iksan/Korea, Republic of

Contact E-mail Address: ktw@wku.ac.kr

Introduction: Endoscopic ultrasound (EUS)-guided fine needle aspiration (EUS-FNA) is one of the alternative methods for tissue sampling of liver solid mass. However, the diagnostic efficacy using cytology alone was limited.

Aims & Methods: In this study, we evaluated the feasibility and diagnostic accuracy of EUS-guided fine needle biopsy (EUS-FNB) for hepatic solid masses in patients with suspected malignancy. The EUS-FNB using 20G, 22G or 25G ProCore needle (PCN) was performed to evaluate the patient with solid liver mass. The primary outcome was the diagnostic accuracy of EUS-FNB for malignancy, and adequacy of the specimen for histology. The secondary outcomes were (1) the proportions of patients in whom immunohistochemical (IHC) stain was possible, and (2) compared diagnostic yield of FNB according to the needle size, and (3) safety of EUS-FNB

Results: Forty-one patients (13 women; mean age, 67.9 ± 10.3 years [range, 46–86]) underwent evaluation with EUS and identified hepatic lesions ranging in size from 0.7 cm to 15 cm. EUS-FNB with 20G ($n = 10$), 22G ($n = 24$) or 25G PCN ($n = 7$) was performed (right lobe: $n = 10$, left lobe: $n = 31$). The median number of needle passes was 2.4 ± 0.8 (range, 1–5). Technical success rates for tissue acquisition were 97.6%, but both specimen adequacy for histology and available IHC stain was 92.6%. Three (7.3%) were non-diagnostic and subsequently proved to be malignant; 2 by smear cytology and 1 after surgical resection. The diagnostic yield, sensitivity and specificity of EUS-FNB for the diagnosis of malignancy were 92.6%, 92.6% and 100%, respectively. The diagnostic yield in 20G PCN and 22G PCN was significantly superior to the 25 G PCN ($p = 0.045$). There was one bleeding complication, but controlled with endoscopic hemostasis with endoclips.

Conclusion: EUS-FNB with core biopsy needle may be a safe and useful modality in the management of patients with hepatic solid mass. Moreover, 20G and 22G FNB may be adequate for liver biopsy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0073 COMPARISON OF METHODS TO ESTIMATE LIVER FUNCTION IN NEWLY-DIAGNOSED HEPATOCELLULAR CARCINOMA PATIENTS WITH ASCITES

Y. Ko

Internal Medicine, Samsung Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: bs2-32@hanmail.net

Introduction: Liver function is a key element in determining outcome of patients with hepatocellular carcinoma (HCC). For HCC with ascites, estimation of liver function is particularly important, as they already have decreased liver function.

Aims & Methods: We aimed to find out best method to predict outcome of HCC patients with ascites. A total of 437 newly-diagnosed HCC patients with ascites (mean age = 56.0 y, male = 74.8%, hepatitis B virus = 73.2%) were analyzed. We compared Child-Pugh score, Model for End-Stage Liver Disease (MELD) score, MELD-Na score, and the Albumin-bilirubin (ALBI) grade for overall survival.

Results: During a median 9.0 months of follow-up (range; 0.1 ~ 154.0), mortality was observed in 373 (85.4%) patients. MELD-Na showed highest time-dependent area under receiver-operating characteristics curves (AUROCs) at 1 year (0.672) that was significantly higher than ALBI grade (0.605), MELD score (0.580), and Child-Pugh score (0.580). The median survival was significantly lower for those with MELD-Na ≥ 12 than MELD-Na < 12 (median: 13.6 vs. 3.7 months, $p < 0.001$). Overall, 350 patients received treatment, and most commonly used modality was transarterial chemoembolization (62.3%), followed by radiofrequency ablation (15.7%) and resection (13.4%). Overall survival was significantly different for those who received treatment than those who did not (median survival: 13.3 vs. 2.4 months, $p < 0.001$). When patients were further stratified by mUICC stage and MELD-Na score, treatment was not associated with better outcome for mUICC stage IV patients with MELD-Na ≥ 12 (median survival: 2.2 vs. 1.8 months for treatment vs. best supportive care, $p = 0.15$), while treatment was associated with better outcome in other subgroups.

Conclusion: In HCC patients with ascites, treatment was associated with better survival, except for subgroup with advanced tumor with decreased liver function, indicating that ascites *per se* is not absolute contraindication for HCC treatment. For these patients, MELD-Na showed better performance than MELD, Child-Pugh score and ALBI score for predicting overall survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0074 DIAGNOSTIC AND PROGNOSTIC ROLE OF SQUAMOUS CELL CARCINOMA ANTIGEN IN HEPATOCELLULAR CARCINOMA: SEROLOGICAL AND TISSUE DETERMINATION

F. Pelizzaro¹, L. Ferrara¹, R. Cardin¹, M. Piciocchi², G. Peserico¹, P. Todesca¹, A. Imondi¹, C. Pozzan³, F. Farinati¹¹Department Of Surgery, Oncology And Gastroenterology, University of Padova, Padova/Italy²Uos Sperimentazioni Cliniche, Biostatistica E Nucleo Ricerca Clinica, Istituto Oncologico Veneto IOV-IRCCS, Padova/Italy³Gastroenterology, Ospedale dell'Angelo, Venezia-Mestre/Italy

Contact E-mail Address: filippo.pelizzaro@gmail.com

Introduction: The ideal serological marker in hepatocellular carcinoma (HCC) has not been identified yet since Alpha-fetoprotein (AFP) has unsatisfactory characteristics. Squamous Cell Carcinoma Antigen (SCCA) is expressed in tissue and serum of HCC patients and when determined immunocomplexed with IgM (SCCA-IgM) has satisfactory diagnostic and prognostic performance.

Aims & Methods: Aim of our study was to evaluate, in HCC patients, the diagnostic and prognostic role of SCCA determination in tissue and in serum samples. SCCA-IgM levels were determined in 409 sera obtained from 196 HCC patients and 213 cirrhotics. SCCA tissue expression was analyzed in a subgroup of 62 patients with biopsy available at diagnosis. Sensitivity, specificity, correlation with clinical and tumor parameters, response to treatment and survival were evaluated.

Results: HCC patients had SCCA-IgM levels significantly higher than cirrhotics ($P < 0.0001$). Sensitivity, specificity, positive and negative predictive values were 76%, 52%, 60% and 70%, respectively. In comparison, sensitivity and specificity of AFP were 54% and 85%. SCCA-IgM values were correlated to HCC etiology and size. A cut-off of 130 AU/mL (validated in literature) was used for the prognostic analysis: patients with SCCA-IgM levels < 130 AU/mL showed a slightly better survival ($p = ns$); in long-term survivors (> 24 months) and in Child A patients the difference in survival was statistically significant ($p = 0.036$ and $p = 0.01$, respectively). A drop in SCCA-IgM levels after TACE correlated with mRECIST response to treatment. Child-Pugh status was the only independent predictor of survival at Cox multivariate analysis. A better survival

trend in HCC with low serpin tissue expression was documented (31 vs 24 months, $p = ns$). No correlation was found between tissue and serum levels. Stratifying patients by gender, SCCA-IgM levels showed an opposite behavior in the prognostic prediction: in males a better survival was documented with levels < 130 AU/mL while in females with SCCA-IgM ≥ 130 AU/mL. In males, SCCA-IgM levels and Child-Pugh status were identified as independent predictors of survival. SCCA-IgM levels were directly correlated with tumor size and BCLC stage in females and with etiology in males.

Conclusion: SCCA-IgM is a sensitive marker of HCC but lacks in specificity. As reported in literature, SCCA-IgM levels identify patients with better prognosis (especially in long-term survivors) and the marker confirms its ability in detecting treatment responders. Lower levels of tissue SCCA seem to be related with less aggressive tumors, given that the longer survival of these patients. The gender-based differences observed in our patients, especially with respect to the SCCA-IgM prognostic role and correlation with clinical and tumor parameters, are intriguing and focused studies on the point are needed.

Introduction: The BCLC algorithm is the standard system for clinical management of HCC. Data on adherence to this therapeutic paradigm are scarce. The aim of this field-practice study is to provide a description of HCC patients in Southern Italy, to evaluate the adherence to BCLC guidelines and its impact on patients' survival.

Aims & Methods: We analyzed the region-wide Italian database of Progetto Epatocarcinoma Campania, which includes data of HCC patients, prospectively collected from January 2013 to December 2015 in 16 regional centers.

Results: Overall 1008 HCC patients were enrolled: 70.6% patients received therapies recommended by BCLC algorithm, while 29.4% underwent different treatments. Among patients who were treated in adherence to guidelines, a higher rate of diagnosis on surveillance programs, better liver function, lower rate of AFP > 200 ng/mL, more early stage and monofocal HCC, lower frequency of nodules > 5 cm, portal vein thrombosis and metastases were observed. The multivariate analysis showed that non-adherence to treatment guidelines was independently associated to the BCLC stage B, Child-Pugh classes B-C, and to the presence of neoplastic thrombosis and metastases. The mean overall survival in patients treated according to BCLC indications was 35.5 months, while in patients managed differently was 31.9 months ($p < 0.0001$).

Conclusion: Adherence to BCLC algorithm in field-practice was high in early and end stage HCC patients, but it was poor in intermediate and advanced patients. This may be due to the wide heterogeneity of intermediate-stage patients, and to the limited use of sorafenib in advanced-stage patients. Strategies to improve treatment and stratification of HCC patients are required.

P0076 A QUESTIONNAIRE SURVEY ON QUALITY OF LIFE WITH ANXIETY AND DEPRESSION SELF-RATING IN PATIENTS OF LIVER CIRRHOSIS

Y. Zhang¹, X. Li¹, N. Cui², Y. L. Liu¹¹Dept. Of Gastroenterology, Peking University People's Hospital, Beijing/China²Dept. Of Respiratory, Beijing Hospital of Chinese Traditional and Western Medicine, Beijing/China

Contact E-mail Address: medicalyuan@qq.com

Introduction: Liver cirrhosis is a great public health burden for Chinese health system. The most common causes are HBV, HCV, alcohol consumption and non-alcoholic fatty liver disease, et al. The quality of life of liver cirrhosis patients is impacted by the physical symptoms and psychological symptoms such as anxiety as depression.

Aims & Methods: We aimed to investigate the quality of life of patients with cirrhosis, as well as depression and anxiety. A questionnaire survey was carried out in 95 patients in our gastroenterology department, Peking University People's Hospital from May to August in 2016. The patients were divided into two groups, cirrhosis group and control group. The patients in cirrhosis group

were diagnosed liver cirrhosis without complications. The control group included the digestive polyps patients without other diseases. The questionnaire included the World Health Organization Quality of Life (WHOQOL)-BREF, Self-rating Anxiety Scale (SAS) and Self-rating Depression Scale (SPS). The questionnaire scores of the two groups were analyzed.

Results: A total of 95 valid questionnaires were collected and divided into cirrhosis group ($n=40$) and control group ($n=45$). In the cirrhosis group, there were 22 males and 18 females, average age 57.97 ± 10.448 years. In the control group, there were 45 males, 23 males and 22 females, with an average age of 61.47 ± 13.081 , showing no difference from cirrhosis group. WHOQOL includes four domains: physiological domain, psychological domain, social relationship domain, environment domain. The scores of liver cirrhosis group: physiological field (22.23 ± 3.312), psychological field (19.59 ± 3.925), social relationship field (9.64 ± 2.497), environment domain (26.23 ± 7.534) and control group (22.96 ± 3.275 in physiological field, 19.87 ± 3.152 in psychological field, 10.58 ± 2.061 in social relation field and 28.36 ± 5.091 in environmental field), they had no significant difference between the two groups ($P > 0.05$). The depression self-rating score of cirrhosis group (47.86 ± 10.782) was significant higher ($P = 0.034$) than that of control group (42.61 ± 11.564). Meanwhile, there was no significant difference between the Self-rating Anxiety Scale scores of the cirrhosis group (38.46 ± 11.917) and control group (37.00 ± 12.521) ($P > 0.05$) (Table 1).

	cirrhosis group	control group	P value
Age	57.97 ± 10.448	23.85 ± 7.406	0.196
Male(n)	22	18	0.808
Female(n)	23	22	0.736
WHOQOL-BREF			
physiological domain	22.23 ± 3.312	22.96 ± 3.275	0.317
psychological domain	19.59 ± 3.925	19.87 ± 3.152	0.721
social relationship domain	9.64 ± 2.497	10.58 ± 2.061	0.063
enviroment domain	26.23 ± 7.534	28.36 ± 5.091	0.129
Self-rating Depression Scale(SDS)	47.86 ± 10.782	42.61 ± 11.564	0.034*
Self-rating Anxiety Scale(SAS)	38.46 ± 11.917	37.00 ± 12.521	0.584

* $P < 0.05$: cirrhosis group vs control group

Conclusion: The quality of life and anxiety score in cirrhosis group had no significant difference from the control group, but the depression score was higher than that of the control group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0077 THE IMPORTANCE OF INDIVIDUAL CORRECTION OF EATING BEHAVIOR IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

Y. Nikiforova

Department For The Study Of Diseases Of The Liver And Gastrointestinal Tract (from 05.2016 Year - Department Study Of Digestive Diseases And Their Comorbidity With Non-communicable Diseases), SI «L.T. Mala Therapy Institute of NAMS of Ukraine», Kharkov/Ukraine

Contact E-mail Address: dr.jana@mail.ru

Introduction: At the present stage, the treatment of patients with non-alcoholic fatty liver disease has insufficient effectiveness due to the simultaneous availability of a number of recommendations and the lack of an individual approach. Not enough attention is paid to the study of nutritional behavior and the role of nutrients, as additional risk factors for the development of non-alcoholic fatty liver disease. While eating disorders are a modifiable risk factor.

Aims & Methods: We aimed to study the dynamics of metabolic parameters in patients with non-alcoholic fatty liver disease (NAFLD) as a result of individual correction of eating behavior (EB).

52 patients (22 men and 30 women) with NAFLD and visceral obesity were examined. All patients studied EB (questionnaire DEBQ), physical activity (PhA), were determined: waist circumference (WC), lipid and carbohydrate metabolism studies were performed, a visceral obesity index (VOI) was calculated, the body composition was monitored (determination of % visceral adipose tissue (VAT)) and computed tomography of the abdominal cavity (CT AC) with measurement of the area (S, cm²) of VAT and percutaneous adipose tissue (PAT). Patients were divided into 2 reciprocal comparison groups ($p > 0.05$): 1st group. ($n = 26$) was assigned individual correction of EB based on nutriogenetic examination (determination of nucleotide polymorphisms of PPARG2 and ADRB3 genes) taking into account the revealed features of EB and PhA, 2nd group ($n = 26$) - standard non-drug treatment was prescribed according to the general recommendations of the European Association For the Study of the Liver et al. EASL-EASD-EASO Clinical Practice Guidelines for the management of non-alcoholic fatty liver disease (2016).

Results: It was found that after 6 months of compliance with individual recommendations for EB in patients of the 1st group anthropometric and metabolic parameters improved ($p < 0.05$): the WC was decreased by 8.9% [8.6; 9.1], the %

of VAT decreased to 8.0% [6.0; 9.0] and S of VAT -up to 84 [82;89] cm², VOI - up to 1, 7 [1; 3;2; 4], the lipidogram parameters improved (decreased TG, LDL and HDL increased) ($p < 0.05$), the index of NOMA-IR ($p < 0.05$) was decreased against the background of a 10.8% decrease in body weight [10.1; 11.2]. 100% compliance of patients of 1 group was noted to adhere to the appointed recommendations. In the next 6 months in patients 1 st group ($P < 0.05$) decrease in VAT/PAT (VAT/PAT $< 0.6\%$ in 96.2% of patients) and VOI (VOI < 1 in 92.3% of patients), in contrast to the dynamics of the corresponding parameters in the patients of the 2nd group.

Conclusion: Thus, the appointment of an individual correction of eating behavior can increase the adherence of patients to treatment and achieve a reliable positive dynamics of metabolic indicators.

With the purpose of increasing the effectiveness of non-drug therapy of patients with non-alcoholic fatty liver disease, methods for studying the characteristics of eating behavior should be applied more widely, which will allow timely appropriate correction. A more extensive study of nutrigenetics will make it possible to designate a personified diet, taking into account the detected polymorphisms, which will make it possible to achieve a significant improvement in metabolic parameters in this category of patients.

P0078 NON-GOVERNMENTAL HCV SCREENING IN A VILLAGE IN NILE DELTA IN DAAS ERA IN EGYPT

A. Sadek¹, A. Salem², W. Wafy³, A. Abdelfattah⁴

¹Gastroenterology- Hepatology, Theodor Bilharz Research Institute, Giza/Egypt

²Gastroenterology&hepatology, Naser Institute, Cairo/Egypt

³Public Health, Theodor Bilharz Research Institute, Giza/Egypt

⁴Free Physician, Cairo/Egypt

Contact E-mail Address: ahmedsadek48@yahoo.com

Introduction: HCV is highly endemic in Egypt with a prevalence of 12%. The ministry of health through the national committee for hepatic viruses has done an extra-ordinary effort since the beginning of the DAAs era which resulted in treatment of almost one million infected patients till now. Still this looks as the summit of the iceberg and there is still estimated more than 10 million Egyptians infected with the virus, the majority of them are still undetected.

Aims & Methods: The aim of this work is to give an example of non-governmental efforts which can be done to solve this tough national problem. A group of young medical and non-medical volunteers all from El Salam village in Mansoura, Dakahlia governorate, Egypt have worked together. They contacted mosques and pharmacies in the village and distributed brochures to announce for the free of charge screening for the virus in the village. They contacted businessmen in the village to sponsor the campaign. They contacted the laboratory of the village to do the HCV Ab test with nonprofit price.

Results: A total of 2220 citizens have visited the referral lab to do the antibody test. Only 419 persons proved positive. This gives an estimated prevalence in the village of 19.0%. 119 patients were insurance patients and they went to treatment and did not complete the study. The rest 300 Ab +ve patients completed the study. All patients were HBs Ag -ve. 132 PCR -ve (44%) patients from the 310 HCV Ab +ve group. The rest 168 patients were +ve for HCV RNA (56%). 18 patients of the HCV PCR -ve had previous HCV treatment (6.5%). Only 2 patients of the 168 HCV RNA +ve. (1.2%) were previously treated. The PCR -ve patients without previous treatment were 114 patients (38.0%). So only 62.0% of the HCV Ab +ve in the community are PCR +ve and require treatment. The total cost for the screening of the 2220 patients was 40.000 L.E. which means 18.0 L.E per person (almost one Dollar).

Conclusion: The screening costs for HCV Ab positivity can be markedly reduced if it is done in each village depending on volunteers from the same village working in related fields like medical, pharmacists, laboratory and social jobs. Only 62.0% of the HCV Ab +ve in the community are PCR +ve and require treatment.

Contact E-mail Address: liya73@mail.ru

Introduction: Non-alcoholic fatty liver disease (NAFLD) is liver disease with histological signs of accumulation of cholesterol excessive amount in hepatocyte in the absence of alcohol consumption by the patient (due to causes other than). The search for accessible, non-invasive and effective methods of screening for this pathology, allowing to detect NAFLD at early, potentially reversible stages of development is relevant. The purpose of the work was frequency estimation of the prevalence steatosis according to elastometry with controlled attenuation parameter (CAP®) among young people and associated with them specific body composition.

Aims & Methods: 59 volunteers (students of medical university) at the age of 19–28 years (the median age of 20.5) have participated in research. There were 22 (37.3%) men and 33 (62.7%) women among them without verified liver diseases. The survey was conducted in order to exclude or detect risk factors. Determining the presence and degree of steatosis and the stage of liver fibrosis was performed with the apparatus FibroScan 502 Touch. The final figures of elasticity of the liver were estimated in kPa (METAVIR). The controlled attenuation parameter (CAP®) in dB/m was used for the severity of steatosis. Moreover, there was the bioelectrical impedance analysis of body (BIA), evaluated: body mass index (BMI), body fat.

Results: The signs of violations of the structure of the liver were diagnosed in 15 people out of 59 (25.4%). The signs of steatosis were founded in 12 (20.3%) students (CAP® > 215 dB/m). The signs of liver fibrosis were recorded in 7 (11.9%) people (E > 5, 8 kPa). At the same time the combination of liver fibrosis and steatosis was diagnosed in 4 (6.8%). After analyzing data of BIA it was revealed that body weight above normal in 23 (40, 3%); wherein fat body composition above normal values in 19 (33, 4%). Results of binary regression analysis showed that the chance of development of hepatic steatosis in case of excess adipose tissue increase 28 times ($p = 0, 045$), influence of BMI, gender, age was statistically insignificant.

Conclusion: Based on the results obtained, it can be concluded that there is high enough level of distribution of liver steatosis among young people. Transient elastography (TE) with controlled attenuation parameter (CAP®) is a fast, reliable, repeatable non-invasive method for the assessment of NAFLD. The development of hepatic steatosis among practically healthy young persons validly associated with the increase the amount of adipose tissue in the body. Confirmed the importance of evaluation of body composition and lack of information of using only BMI when evaluating the chances of development of NAFLD.

P0080 SALVAGE TECHNIQUE USING A MICRO GUIDEWIRE FOR DIFFICULT BILIARY CANNULATION IN ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY

A. Mori, S. Ito, S. Hayashi, T. Shibuya, M. Sawada, H. Hachiya, T. Yumura, N. Ohashi

Ichinomiya Nishi Hospital Dept. of Gastroenterology, Ichinomiya/Japan

Contact E-mail Address: a-mori@anzu.or.jp

Introduction: Biliary cannulation is indispensable for therapeutic endoscopic retrograde cholangiopancreatography (ERCP) in patients having biliary disease. Selective biliary cannulation is often difficult due to anatomical constraints. Numerous techniques have been attempted to overcome such problems. Although a wire-guided selective cannulation technique into the bile duct is a useful approach, conventional guidewires (0.025 or 0.035 inch) are relatively rigid to pass through the long curved narrow distal segment (NDS) or malignant stricture and sometimes get flicked off the NDS in such cases. It may be better to use finer and more flexible guidewire. Hence, we developed a novel guidewire technique (GTWt) using a micro guidewire (GT wire; 0.016 inch, 300 cm, TERUMO, Japan) designed for super-selective angiography in difficult cases of selective biliary cannulation.

Aims & Methods: We aimed to assess usefulness of GTWt for salvage technique in biliary cannulation. We studied 240 consecutive ERCP-naïve patients between August 2014 and February 2017. We have tried to perform GTWt to ERCP-difficult-cases that was defined as patients of unsuccessful cannulation despite attempts over 15 min with conventional techniques including wire-guided cannulation or pancreatic guidewire placement with conventional guidewire (0.025 or 0.035 inch). Following the unsuccessful attempts, the guidewire was changed to GT wire and selective biliary cannulation was performed under fluoroscopic control. We assessed the number of patients who benefited from GTWt and whether overall success rate of biliary cannulation in ERCP was improved.

Results: Among 240 ERCP-naïve patients, 40 were ERCP-difficult-cases (success rate with conventional technique: 200/240; 83%). Among 40 ERCP-difficult cases, GTWt was successful in 32 patients (success rate with GTWt: 32/40;

80%). Overall success rate of ERCP-naïve patients improved from 80% to 97% (232/240 patients). After ERCP with GTWt, four patients developed mild acute pancreatitis, which resolved in a few days. No serious procedural accidents were reported. The 40 ERCP-difficult cases included 22 patients with a long curved NDS, six patients with juxtapapillary duodenal diverticulum, six patients with malignant stricture, and four patients with difficult front view of papilla. Among eight patients who failed with GTWt, seven were successful performing precut papillotomy or endoscopic ultrasound-guided biliary drainage and one was interrupted because of developed serious condition.

Conclusion: GTWt as a salvage technique for unsuccessful selective biliary cannulation cases improves the success rate of ERCP, and could be attempted before performing a precut papillotomy, endoscopic ultrasound-guided techniques or other cumbersome procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0081 ERCP IN VERY ELDERLY PATIENTS AGE 85 OR OLDER

M.T. Ayoubi Khajekini¹, F. Castellino¹, N. Leone¹, M. Berrutti¹, G. Sansoè¹, L. Framarin¹, A. Repici²

¹Gi Endoscopy Unit, Humanitas Gradenigo Hospital, Torino/Italy

²Dept. Of Gastroenterology, Ist. Clinico Humanitas Rozzano Dept. of Gastroenterology, Milano/Italy

Contact E-mail Address: ayoubi@libero.it

Introduction: To evaluate the safety and effectiveness of this procedure (ERCP) in patients age 85 years and older.

Aims & Methods: From first January 2010 until end of December 2016 in our digestive endoscopic unit 3153 patients underwent ERCP, including 351 (11.13%) patients over 85. Characteristics of these patients: The mean age was 89 (range 85–99), 117 males and 234 females. 43 (12.2%) were in treatment with antithrombotic drugs. The initial diagnosis in 218 patients (62.1%) was choledocholithiasis, malignant CBD stenosis in 92 patients (25.9%), postoperative leak in 11 patients (3, 13%) and unknown CBD stenosis in 31 patients (8.83%). All patients underwent the following clinical evaluation before and after ERCP. 34 patients (9.4%) were sedated with Propofol and anesthetists assisted. The rest of the patients 90.6% were sedated with the intravenous combination of midazolam and Fentanyl with standardized monitoring (pulse oximetry, heart rate, non invasive blood pressure measurements) during the procedure. Drug infusion was performed by the nursing staff and an attending endoscopist.

Results: Deep biliary cannulation was successful in 330 patients (94%). In 127 patients (36.18%) Vater papilla was associated with duodenale diverticula. The post-ERCP complication rates were as follows: Hyperamylasemia in 28 patients (7.9%), Mild pancreatitis in 12 patients (3.4%), Minor bleeding in 10 patients (2.8%), Major bleeding in 2 patients (0, 56) and cholangitis in 6 patients (1, 7%).

Conclusion: ERCP is an acceptable procedure in patients of 85 or older in terms of safety, success and complication rates.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0082 ALCOHOL CONSUMPTION CAN REDUCE THE RISK OF GALLSTONE DISEASE: A SYSTEMATIC REVIEW WITH DOSE-RESPONSE META-ANALYSIS OF CASE-CONTROL AND COHORT STUDIES

B.H. Cha¹, M. Jang²

¹Sheikh Khalifa Specialty Hospital, Ras Al Khaimah/United Arab Emirates

²Medical Research Collaborating Center, Seoul National University Hospital, Seoul/Korea, Republic of

Contact E-mail Address: doctorhyo@gmail.com

Introduction: Gallbladder stone (GBS) is a common gastrointestinal disease can progress to severe cholecystitis and is a strong risk factor for gallbladder cancer (GBC). Recently, clinical epidemiologic studies revealed that the alcohol consumption has a preventive effect for development of gallstone diseases.

Aims & Methods: To evaluate the relative risks of alcohol consumption for the gallbladder stone diseases development. Systematic searching was performed using MEDLINE, EMBASE and Cochrane library from January 1st, 1996, to December 31st, 2016 for studies assessed the relationship between alcohol consumption and gallbladder stone diseases development risk. The eligibility criteria was included: 1) studies involving the patients with gallbladder stone with or without cholecystitis; 2) cohort or case-control studies investigated the association between alcohol consumption and gallstone disease development. Newcastle-Ottawa Scale was used to assess the methodologic quality of each studies. Data was obtained from each selected studies regarding: 1) baseline characteristics of the study (cohort, case-control); 2) number of participants; 3) participants' clinical features; 4) country; 5) publication year; 6) Risk or odds ratio with confidence intervals for various levels of alcohol consumption and risk of gallstone. The random effect model was used to estimate the pooled relative risks (RR) with 95% confidence intervals (CIs).

Results: Twenty-five cohort and case-control studies were included, and total 12, 581 cases with gallstone diseases among those 172, 509 controls. Alcohol consumption indicated a decreased risk of GSD development (Pooled RR = 0.84 [0.79–0.90], $P < 0.001$). Subgroup analyses according to the alcohol doses (g/d) confirmed a gradual risk-reduction effect on GSD compared to non-drinkers (Light: RR = 0.97 [0.94, 1.00], $p = 0.864$; Moderate: RR = 0.82 [0.79, 0.86], $p = 0.777$; Heavy: RR = 0.70 [0.62, 0.80], $p < 0.01$).

Conclusion: In this systematic review with meta-analysis, alcohol consumption has dose-dependent negative co-relationship with the risk of gallstone disease development.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: m-kida@kitasato-u.ac.jp

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) remains challenging in patients who have undergone surgical reconstruction of the intestine. In 2001, double-balloon enteroscopy (DBE) was reported by Yamamoto et al to be an effective procedure for the diagnosis and treatment of small intestinal lesions. In 2005, DBE-assisted ERCP was first successfully by Haruta et al used to treat a late anastomotic stricture in a patient who undergone biliary reconstruction by R-Y choledochojejunostomy after liver transplantation. After that, several studies with long enteroscopy have reported that balloon enteroscopy-assisted ERCP (BEA-ERCP) is a safe and effective procedure with about 69–100% of reaching the blind end. However long type enteroscopy allows us to use limited number of ERCP devices because of its length 200 cm. Then Olympus Co. introduce the prototype of short single balloon enteroscopy (SBE) with bigger channel 3.2 mm in diameter was developed. We will present its usefulness and limitation.

Aims & Methods: In order to investigate the usefulness and limitation of short-type SBE, we have performed totally 183 cases/302 procedures of ERCP with short-type SBE in patients with B-II (24 cases, 30 procedures), R-Y gastrectomy (RY: 94, 138), Hepatico-Jejunostomy without gastrectomy (HJ: 29, 58), and Child/Whipple (CW: 36, 76) from 2009 to 2016. We have investigated its rate of reaching blind end, time of procedure, success rate of therapeutic procedure, complications and its limitations.

Results: Using short type SBE, the rate of reaching blind end is B-II: 97% (29/30), RY: 91% (126/138), HJ: 72% (39/58), CW: 93% (71/76), and 88% (totally). Success rate of therapeutic procedure in reached blind end cases, is B-II: 100% (27/27), RY: 96% (104/108), HJ: 94% (34/36), CW: 100% (67/67), and 97% (232/238) totally. The average time of procedure is B-II: 38.6 min, RY: 47.2, HJ: 38.5, and CW: 44.3, respectively. The reason of unreached cases in HJ without gastrectomy group is not enough scope length: 68% (13/19), stricture: 21% (4/19), adhesion: 11% (2/19). And using long-type SBE, it is practicable to do therapeutic procedure in 85% in not enough scope length group (11/13). Concerning about complication, pancreatitis 3% (8/302), Perforation 1% (4/302), bleeding 0.8% (2/302), and cholangitis 0.8% (2/302).

Conclusion: ERCP with short-type SBE in patients with surgically anatomy is practicable with high success rate, except for cases with HJ without gastrectomy. However, even in these cases, most of cases can be performed with long-type SBE.

Introduction: Patients undergoing endoscopic retrograde cholangiopancreatography (ERCP) and duct clearance for common bile duct stones (CBDS) should be followed up with an early cholecystectomy to prevent recurrent biliary complications (1, 2) and acute gallstone pancreatitis. Recently the National Confidential Enquiry into Patient Outcome and Death (NCEPOD) recommended that definitive eradication of gallstones by cholecystectomy prevents the risk of a recurrent attack of acute pancreatitis (AP). For patients with an episode of mild acute

pancreatitis, early definitive surgery should be undertaken, either during the index admission or within two weeks (3, 4).

Aims & Methods: 1) To determine time frame between ERCP/duct clearance and cholecystectomy (CCX) in non-pancreatitis group. 2) To determine time frame between ERCP/duct clearance and CCX in pancreatitis group. 3) To determine re-admission rate while awaiting CCX. All patients who underwent ERCP for CBDS between 01/01/2014 to 31/12/2014 were included in the study. Patients who had previously undergone CCX (de novo stones) were excluded. All patients were followed up for a minimum period of 2 years following their ERCP.

Results: A total of 273 patients underwent ERCP for CBDS. Out of these 21.2% (n = 58) had previously had CCX and were excluded. Out of the remaining 215 with gall bladder (GB) in situ, 87.4% (188/215) underwent successful duct clearance at index or subsequent ERCP. Of these, 47.3% (89/188) underwent CCX 1% (2/188) patients are currently awaiting CCX and 51.6% (97/188) did not undergo CCX. The outcomes in remaining 13.4% (n = 27) patients in whom duct clearance was not achieved are discussed later. In the CCX group, the median time between ERCP/duct clearance and CCX was 123 days (range 0–820 days). In this group, 15 patients had gall stone pancreatitis (GSP) on presentation and the median time between ERCP and CCX in the GSP group was 136 days (range 35–287 days); 12 of these had mild pancreatitis with a median time to CCX of 140 days (range 60–287 days). 4 patients re-presented with CBDS while awaiting CCX after duct clearance; 1 had pancreatitis on readmission. 51.6% (97/188) patients who did not undergo CCX after duct clearance are referred to as non-cholecystectomy (non-CCX) group. This was mainly secondary to high ASA grade. We compared patient demographics and presentation with the CCX group and the results were as follows:

Value	CCX group (n = 89)	Non-CCX group (n = 97)
Median Age	61 years	79 years
Median ASA grade	1	2.8
Female patients	67%	56%
Male patients	33%	44%
Pancreatitis on presentation	17%	11.4%
Readmission with CBDS	4.5%	5.4%

In 27 patients duct clearance was not achieved; 26% (7/27) underwent surgical management (CBD exploration/on table cholangiogram and CCX). The remaining 74% (20/27) patients were deemed unsuitable for invasive intervention and were either for symptomatic stent change only or conservative management.

Conclusion: The time period between duct clearance and CCX was longer than anticipated, especially in patients with mild acute pancreatitis as none of them underwent CCX during index admission or within 2 weeks of ERCP/duct clearance. Some patients re-presented with CBDS while awaiting CCX. We looked into potential causes of delay in CCX – delayed referral to surgery, long waiting time for elective CCX and patient choice. We propose to develop a local pathway for patients with CBDS and gallstones and induct a robust system for referring patients for CCX following duct clearance. This would help to minimize readmission and potential complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The placement of self-expandable metallic stent has become the treatment of choice to restore luminal patency in the palliative treatment of unresectable malignant biliary stricture. Currently, drug-eluting stents (DESS) are developed to prevent tumor invasion into the stent and to prolong stent patency. However, the capacity of drug per unit area varies with the position in membrane, and the control of drug release is impossible in current available DESS.

Aims & Methods: The aim of current study is to develop the multi-layer drug eluting membrane using ultrasonic spray coating method, which have uniform capacity of drug and be able to control the drug-release capacity.

Methods: The drug eluting membrane was made using ultrasonic spray coating machine (MediCoat-2JX). The membrane consists with two kinds of coating material. One is silicone (MED-6640), that was used to basic structure of membrane and the other coating agent is polyurethane (tecophilic, tecothane, Tecoflex and pellethane). The gemcitabine was used as antitumor drug, and coated to membrane by mixed form with polyurethane (gemcitabine, 250ug/ml; polyurethane, 500ug/ml). The thickness of membrane and the capacity of drug in membrane were measured at the proximal and distal end, and mid portion. The drug release capacity and duration was measured by using drug releasing test in vitro for 3 days.

Results: The mean thickness of membrane was 50um. The mean capacity of drug per unit area was 100 ug/cm², and the amount was constant in all tested area (Standard deviation, 5 ug/cm²). In drug release test, the capacity of releasing drug was different depended on the kinds of polyurethane. The total amount of released drug in 24 hours was 919 ug, 836 ug, 681 ug, and 580 ug in tecophilic coating, tecothane coating, tecoflex coating, and pellethane coating. The total of released drug amount depended on polyurethane was described in table 1.

Table 1: The total of releasing drug amount in 72 hours

Coating Polymer	Drug release amount		
	Gemcitabine (ug)		
	24 hrs	48 hrs	72 hrs
Tecophilic	919	927	933
Tecothane	836	859	868
Tecoflex	681	690	698
Pellethane	580	604	622

Conclusion: The ultrasonic spray coating technique could be applied to make multi-layer drug eluting membrane with regular thickness. The membranes contained the uniform capacity of drug in all tested area. The releasing drug capacity is able to control by applying different kind of polyurethane.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0086 THE ANTI-TUMOR EFFECT OF PACLITAXEL, GEMCITABINE AND MITOMYCIN C ELUTING MEMBRANE IN ANIMAL MODEL

J. Park¹, D.H. Lee², S. Jeong¹

Introduction: Local treatment of primary bile duct cancer is a challenge and endoscopic stent insertion is widely used to maintain the bile duct patency. Drug eluting stent is currently developed to add the ability of antitumor effect.

Aims & Methods: We aimed to evaluate the antitumor effect of the paclitaxel, gemcitabine, and mitomycin C-eluting polyurethane membrane in a tumor model. Total of 24 mice were used in current study and divided into four groups, each group had six mice. Membranes containing different antitumor drugs (paclitaxel, gemcitabine, mitomycin C, 100µg/disc) were inserted beneath the tumor mass in mouse models. Tumor size and body weight of the tumor model were monitored for 22 days after insertion of the membrane. The results were compared with the tumor model which was inserted only silicone membrane (control).

Results: Tumor volumes on day 22 of membrane treatment were decreased in all drugs, that were significantly different compared to those of control (paclitaxel, 291.77mm³, P value = 0.4116; gemcitabine, 63.38mm³, P value = 0.0001; mitomycin C, 119.02 mm³, P value = 0.0029; control 1362.62mm³). The antitumor effect of gemcitabine was tended to be superior compared to other drugs. However, it was not statistically difference. No significant difference in body weight change was observed among groups.

	Membrane only	Paclitaxel	Gemcitabine	Mitomycin C
Mouse weight (g)	24.28	21.05	19.56	20.67
Tumor volume (mm ³)	1362.62	291.77	63.38	119.02
Tumor weight (mg)	1025	524	496	443

Conclusion: The drug-eluting membrane showed significant antitumor activity. However, the effect was not different according to kinds of the antitumor drugs.

P0087 ADVANCES IN CYTOLOGY FOR THE EARLY DIAGNOSIS OF PANCREATICO-BILIARY MALIGNANCY

C. Meredith¹, P. Irandoost², P. Baird²

¹Gastroenterology And Hepatology, Bankstown-Lidcombe Hospital, Bankstown/Australia/NSW

²Cytology, Laverty Pathology, Ryde/Australia/NSW

Contact E-mail Address: drmeredith@gmail.com

Introduction: Liquid-based sample preparations for cytology have improved the cellular yield in pancreatobiliary (PB) malignancy⁽¹⁾. The SurePath (SP) methodology produces a pellet of concentrated cellular material which enables additional slides for immunohistochemical (IHC) staining for tumour markers Ki67, p53 and CDX2. The presence of the mitosis-related marker, Ki67, in high concentration and with a specific pattern adds a level of confidence in diagnosing malignancy using cytological preparations. The aim of this study was to assess Ki67 staining in biliary epithelium obtained from patients with bile duct obstruction.

Aims & Methods: Brushings were obtained from the common bile duct during endoscopic retrograde cholangiopancreatography (ERCP) in patients presenting with biliary obstruction. After collecting the sample, the brush was placed immediately into a SurePath vial and shaken vigorously to fix and suspend the cells. In the cytology laboratory, the vial (with brush included) was agitated on a platform vortex for 10 minutes to shake the cells off the brush into the solution. The high cellular content enabled the preparation of multiple slides for IHC and these slides were reviewed independently by two senior cytopathologists.

Results: Thirty-four (34) consecutive patients with bile duct obstruction were included in the study. The cohort had a mean age of 70.2; 41% were female. Adenocarcinoma was identified in 19 (56%) and atypical/reactive cells in 9 (26%). Ki67 positive nuclei were present in 90–100% of the cells in malignant cell clusters, while sheets of normal cells had positive nuclei in less than 20% of cells. Atypical cells sheets had an intermediate percentage range.

Conclusion: SP is superior to conventional slide-based cytology preparations in the diagnosis of malignant bile duct strictures. Advantages include ease of collection, no requirement for a cytology technician, a sizable pellet of intact cells for the cytopathologist to examine and the ability to undertake IHC staining. Ki67 is a marker of cell division and cells stained with Ki67 are increased significantly in adenocarcinoma as confirmed by this study. The presence of a large number of cells stained with Ki67 as well as the pattern of intracellular staining adds a level of confidence for the cytopathologist to diagnose malignancy, particularly when there is no clinical or scan evidence of a tumour mass. Early diagnosis is the key for curative surgery and specific cell tumour markers &/or their pattern may impact significantly on the outcome.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0088 IMPACT OF PALLIATIVE BILIARY DRAINAGE BETWEEN METAL STENT AND PLASTIC STENT ON SURVIVAL RATE IN UNRESECTABLE DISTAL MALIGNANT BILIARY STRICTURE IN SOUTH OF THAILAND

T. Pattarapuntakul, B. Ovarltanporn, N. Netinatsunton
Faculty Of Medicine, Prince Of Songkla University, NKC Institute of Gastroenterology and Hepatology, Hadyai/Thailand

Contact E-mail Address: tanawat_kuey@hotmail.com

Introduction: Palliative biliary drainage was used to improving obstructive jaundice, nutritional status, quality of life along with survival rate in unresectable distal malignant biliary stricture patients. The ERCP with biliary drainage with or without systemic chemotherapy are mainstay of treatment in these patients. The benefits of biliary stent type, which are different in cost on survival rate, nutritional status and efficacy of biliary drainage in DMBS patients are still questionable in limit health budget country.

Aims & Methods: We aimed to assess the impact of endoscopic palliative biliary drainage stents on survival rate, nutritional status and efficacy of biliary drainage of patients in distal biliary malignant stricture patients.

All of the computerized medical records of distal biliary malignant stricture patients, who were undergoing to endoscopic biliary drainage from January 01, 2012 to December 30, 2015 in Songklanagarind hospital were retrospectively review. ERCP with biliary drainage stents was undertaken at the discretion of attending physicians. The overall survival rate, nutritional status (body weight), efficacy of biliary drainage (level of total bilirubin) after biliary drainage between the metal stent group, plastic stent group and plastic stent followed with metal stent group were compared.

Results: Sixty eight patients (45 males, mean age 63.7 +/-14.8 years) were enrolled, 35 patients were classified into the plastic stent group, 18 patients were classified into the metal stent group and 15 patients were classified into the plastic stent followed to metal stent group. Demographic data, primary malignancy, tumor staging and ECOG score, initial total bilirubin and stricture length were similar between 3 groups. The median survival time was 5.4 months 95%CI (3.2–8.5) and overall survival rate was lowest in the metal stent group (median 3.2 months 95%CI 1.8–6.9). Mean weight reduction and the declining of total bilirubin after biliary drainage were not significantly different between biliary

Abstract No: P0088

Table1.: Demographic data

Variable	Group 1 Plastic stent	Group 2 Metal stent	Group 3 Plastic – metal stent	P value
Number	35	18	15

Initial TB (mg/dL)	20	17.6	17.6	0.599
Body weight (kg)	51.8 (10.2)	46 (7.9)	53 (11.6)	0.082
Stricture length (mm)	23	20	17.8	0.481
CMT (yes, %)	6 (17.1%)	5 (27.8%)	4 (26.7%)	0.587
Complications ERCP Biliary stent	2 4	1 2	1 3	1
Cost of ERCP (bath)	26, 531 (9, 069)	22, 113 (7, 732)	38, 424 (10, 268)	<0.01
Cost biliary stents (bath)	2, 480 (1, 495)	29, 539 (5, 564)	29, 965 (6, 382)	<0.001
Cost of total procedure (bath)	28, 917 (10, 018)	55, 471 (14, 398)	69, 262 (12, 135)	<0.001

stent types. The plastic stent group had lowest cost of total ERCP statistically significance. The complications rate was not different between biliary stent types. **Conclusion:** Palliative biliary drainage with plastic stent in unresectable distal malignant biliary stricture was slightly better on survival rate and was not different in nutritional status, efficacy to drainage and complication rate compared with metal stent or plastic followed with metal stent. But the plastic stent group had lowest cost of total procedure.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0089 PROGNOSTIC VALUE OF EARLY CA19-9 RESPONSE DURING CHEMOTHERAPY IN PATIENTS WITH ADVANCED OR RECURRENT BILIARY TRACT CANCER

N. Takahara¹, Y. Nakai¹, K. Saito¹, T. Nakamura¹, T. Sato¹, T. Takeda¹, R. Uchino¹, S. Mizuno¹, H. Kogure¹, S. Matsubara¹, M. Tada¹, H. Isayama², K. Koike¹

¹Dept. Of Gastroenterology, The University of Tokyo, Tokyo/Japan

²Dept. Of Gastroenterology, Juntendo University, Tokyo/Japan

Contact E-mail Address: naminatsu.takahara@gmail.com

Introduction: The most widely used standard for determining the effectiveness of chemotherapy is a set of rules called Response Evaluation Criteria in Solid Tumors, or RECIST. However, it is often difficult to evaluate radiologic response to chemotherapy especially in patients with biliary tract cancer (BTC) mainly because of the pathognomonic tumor progression along bile duct and/or inflammatory reaction induced by indwelling biliary drainage. Therefore, quantitative evaluation using tumor markers is expected to play complementary roles to assess treatment efficacy, however, the prognostic value of carbohydrate antigen 19-9 (CA 19-9) kinetics in patients with advanced or recurrent BTC receiving chemotherapy remains to be elucidated.

Aims & Methods: Between January 2006 and March 2016, a total of 185 advanced or recurrent BTC patients receiving a first line systemic chemotherapy for at least two cycles were retrospectively studied. Serum CA 19-9 was measured

at baseline (CA19-9_Pre) and after two cycles of chemotherapy, and patients were categorized into three groups based on CA19-9 response: CA19-9 decrease group ($\geq 30\%$ decrease), stable group ($< 30\%$ decrease and $\leq 20\%$ increase) and increase group ($\geq 20\%$ increase). The Cox proportional hazards model was used to analyze the prognostic factors for OS and PFS, using the landmark method.

Results: The primary tumors were located as follows: 68 (37%) in intrahepatic bile duct, 43 (23%) in extrahepatic bile duct, 64 (35%) in gallbladder and 10 (5%) in ampulla. As for chemotherapeutic regimen, single-agent or combination therapy was given in 49 (26%) or 136 (74%), respectively. After 2 cycles of chemotherapy, partial response was achieved in 29 (16%) and stable disease in 112 (60%), giving response rate of 16% and disease control rate of 76%. The median CA 19-9 levels at baseline and after two cycles were 264 IU/mL and 194 IU/mL, respectively. After 2 cycles of chemotherapy, CA19-9 decrease was obtained in 77 (42%), stable in 56 (30%), and increase in 52 (28%). The median PFS and OS were 5.62 months (95% confidence interval [CI], 5.29–13.28) and 13.71 months (95% CI, 11.38–22.06). There was a statistically significant trend for CA 19-9 and RECIST responses ($p=0.05$). Compared with CA19-9 decrease group, hazard ratios for stable and increase groups were 1.22 (95% CI, 0.79–1.87) and 2.42 (95% CI, 1.57–3.72) for PFS, respectively (p for trend <0.001), and 1.04 (95% CI, 0.68–1.59) and 2.54 (95% CI, 1.68–3.85) for OS (p for trend 0.060). Multivariable analyses showed that CA19-9 response was prognostic both for OS and PFS in addition to CA19-9_Pre and performance status.

Conclusion: CA 19-9 response after two cycles as well as baseline served as a prognostic factor for OS and PFS in patients with advanced and recurrent BTC on systemic chemotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0090 BILIARY DRAINAGE IN PATIENTS WITH UNRESECTABLE PERIHILAR CHOLANGIOCARCINOMA HAS A VERY HIGH COMPLICATION AND FAILURE RATE

Introduction: Patients with unresectable perihilar cholangiocarcinoma (PHC) typically present with obstructive jaundice. They require percutaneous or endoscopic biliary drainage for symptom relieve and eligibility for palliative systemic chemotherapy. However, biliary drainage in unresectable PHC is complex with a high failure and complication rate even in tertiary referral centers.

Aims & Methods: The aim of this study was to investigate the failure and complication rate of the initial drainage procedure in patients with unresectable PHC. Consecutive patients with unresectable PHC on imaging in two tertiary referral centers between 2002 and 2014 were identified. Patients were included if a biliary drainage procedure was performed. Baseline patient and tumor characteristics

Abstract No:P0090**Table 1:** Definitions of failure of drainage and other severe drainage related complications

Cholangitis	Elevation in temperature more than 38, 5°C and Leukocytes $\geq 10 \times 10^9/L$, thought to have a biliary cause, without concomitant evidence of acute cholecystitis, requiring invasive intervention.
Acute cholecystitis	Radiologic evidence of cholecystitis, elevation in temperature more than 38.5°C and Leukocytes $\geq 10 \times 10^9/L$, and requirement of percutaneous drainage or emergency cholecystectomy.
Failure of drainage or Reintervention	Rising or steady bilirubin level after therapeutic success had initially been obtained, without signs of cholangitis or cholecystitis, requiring new cannulation of the tumor. Bilirubin levels $> 50 \mu\text{mol/L}$ within 14 days after the initial procedure. Unsuccessful cannulation during the initial drainage procedure.
Acute pancreatitis	Second drainage procedure ≤ 14 days after the initial procedure. Abdominal pain and a serum concentration of pancreatic enzymes (amylase or lipase) ≥ 3 times the upper limit of normal, that requires ≥ 1 one night of hospitalization.
Biliary injury	Injury to the bile duct documented by any radiographic technique requiring intervention.
Duodenal perforation	Perforation of the duodenum documented by any radiographic technique requiring intervention.
Cardiopulmonary complications	Any pulmonary or cardiac abnormality occurring during the drainage or in the post-intervention period that produces identifiable disease or dysfunction which is clinically significant and adversely affects the clinical course.

and data on the biliary drainage procedure were collected from medical records. Definitions of failure of drainage or other severe drainage related complications are shown in table 1.

Results: In total, 187 patients were included. Initial drainage was performed in a non-referral center in 125 patients (66.8%). The initial drainage procedure was endoscopic in 158 patients (84.5%) and percutaneous in 29 patients (15.5%). A stent was placed in 91 patients (61.5%) at the initial drainage procedure. The highest bilirubin level in the 2 weeks prior to drainage was 248 (IQR 138–377) $\mu\text{mol/L}$. Only 14 (8.1%) patients had cholangitis prior to the initial drainage procedure. Failure of drainage or other severe complications related to the initial drainage procedure were noted in 117 (62.6%) patients. Failure of drainage or reintervention was most common and was noted in 95 patients (50.8%). Bile duct injury occurred in 3 (1.6%) patients, acute pancreatitis in 5 (2.7%) patients and cholangitis in 11 (5.9%) patients. Two (1.1%) patients had cardiopulmonary complications and 1 (0.5%) patient had a duodenal perforation. The median period between the initial and second drainage procedure was 13 (5–31) days and the bilirubin level dropped below 50 $\mu\text{mol/L}$ in 27 patients (14.4%). After initial drainage, 20 patients (10.7%) died within 30-days and 66 patients (35.3%) within 90 days. The median OS after initial drainage was 6.6 (95% CI: 2.0–15.2) months.

Conclusion: Patients with unresectable PHC on imaging have a very high failure and complication rate after initial biliary drainage.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0091 BRUSH CYTOLOGY GUIDED BY ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY OF BILIARY STRICTURES

A. Peixoto, P. Pereira, M. Silva, F. Vilas-Boas, E. Rodrigues-Pinto, P. Moutinho-Ribeiro, J. Lopes, G. Macedo
Centro Hospitalar De São João, Porto/Portugal

Contact E-mail Address: armandoaf5@gmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP)-guided brush cytology has become the most widely used method, although with limitations, in the initial diagnostic evaluation of patients with biliary strictures.

Aims & Methods: The objective of the study was to evaluate if the systematic use of 10 brush passages improves the diagnostic yield of brush cytology guided by ERCP of bile strictures. ERCPs between 2012 and 2015 involving brush cytology of bile strictures for suspected malignancy were included in the study. Cytologies were obtained using the Brush Master V (Olympus Medical System). Histological evaluation was performed by two experienced cytopathologists.

Results: In total, 62 patients underwent cytology of biliary strictures, with a median age of 69 years (IRQ: 55–81). The cytological analysis was compatible with adenocarcinoma in 30.6% of the cases, low grade dysplasia in 3.2%, high grade dysplasia in 1.6% and adenoma in 1.6%. In 26 patients the cytology was negative (41.9%) and in 13 cases it was considered inconclusive (21%). Fifteen patients were subsequently submitted to surgery (24.2%). In 34 cases (54.8%) there was a correlation between the cytology and the final diagnosis. In the univariate analysis, previous history of cholecystectomy (73.7% vs. 26.3%, $p=0.047$), cytology suggestive of malignancy/adenocarcinoma (89.5% vs. 10.5%, $p<0.001$) and final non-equivocal diagnosis (14.3% vs. 85.7%, $p=0.002$) were associated with positive correlation. If the cytology and final diagnosis are coded as "malignant," "benign," or "inconclusive," the correlation increases to 67.7%. In this situation, the univariate analysis showed that the presence of malignancy in cytology (87.5% vs. 10.5%, $p=0.009$) and final non-equivocal diagnosis (35.7% vs. 64.3%, $p=0.012$) were associated with a positive correlation. If the cases identified as undetermined cytology were excluded, there was no increase in correlation with the final diagnosis (56.5%).

Conclusion: The systematic use of 10 passages in the cytology of the biliary tract modestly increases the accuracy of the detection of malignant versus benign situations.

Introduction: Endoscopic biliary stenting is widely accepted as effective palliation therapy for unresectable malignant hilar biliary obstruction (MHBO). Although draining more than 50% of liver volume is associated with better outcomes, insertion of multiple stents is technically difficult.

Aims & Methods: The aim of this study was to evaluate differences in technical feasibility and clinical efficacy between unilateral and bilateral stent-in-stent (SIS) placement of metal stents for MHBO. We retrospectively reviewed 23 consecutive patients with MHBO who underwent endoscopic biliary drainage with self-expandable metal stents (SEMS) at our institution from March 2012 to March 2017. Unilateral metal stenting was performed in 15 patients (Uni group) and bilateral metal stenting was performed in 18 patients (Bi group). In the Uni group, we placed uncovered SEMS. In the Bi group, we placed cross-wired metal stents with the SIS technique. Technical success rates, complication rates and stent patency were compared between groups.

Results: There were no significant differences between the Uni group and the Bi group in technical success rate (100% vs. 94%), complication rate (0% vs. 0%), stent occlusion rate (15% vs. 18%) or median stent patency period (102.5 days vs. 98 days). There was no significant difference in cumulative stent patency between the groups ($p=0.669$).

Conclusion: Endoscopic bilateral SIS placement of metal stents for palliative treatment of MHBO had a high technical success rate and low complication rate, similar to those of unilateral placement.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0094 CLINICAL ASSESSMENT OF THE SAFETY AND EFFICACY OF A NOVEL BIODEGRADABLE STENT IN PATIENTS WITH BILIARY OBSTRUCTION: A PILOT STUDY

Introduction: The commonest indication for biliary stent is for the treatment of obstructive jaundice and for the management of bile leak. The currently available stents are made of either plastic or metal alloy. The stents can be inserted endoscopically to provide internal drainage of the bile into the duodenum. Among the disadvantages of plastic stents are recurrences of jaundice due to biofilms formation, which require a repeat ERCP procedure to remove the stent before 3 months. We have embarked to study the safety and feasibility of a biodegradable biliary stents (BBS), which can treat biliary obstruction without the need to undergo a repeat endoscopic procedure to remove the stents.

Aims & Methods: This is a pilot study enrolling 30 subjects with symptomatic jaundice and pruritus caused by either benign or malignant biliary obstructions that were amenable to treatment by ERCP guided stenting. Primary objective was technical success and safety. Procedural and technical successes were assessed during the stenting procedure. Adverse events or complications were monitored throughout the studies. The secondary endpoints were clinical success, which was measured by a reduction of at least 20% of the initial serum bilirubin level at Day 7 post stenting. A simple self-assessment scale from 0 to 10 was used to assess quality of life before and after the stenting.

Results: 30 patients had the Biodegradable Biliary Stent (BBS) implanted, 18 patients (60%) were males, the mean age was 56.9 years, 26 patients (86.7%) had benign biliary duct disease and 4 (13.3%) patients had malignant condition.

Table 1: Patients' Demography

	n = 30 (%)
Gender: males, females	18 (60%), 12 (40%)
Indication: Benign Biliary Obstruction, Malignant Biliary Obstruction	26 (86.7%), 4 (13.3%)
Age (mean \pm sd)	56.9 \pm 18.9

9 patients had the fast and medium degradation stents respectively and 12 had the slow degradation stents implanted. All stents were 3.4 mm in diameter and the length ranges from 60 to 120 mm depending on the level of obstruction. It took an average of 29.6 minutes to complete each procedure, and the mean stent deployment duration was 6.0 minutes. It ranges from 13.5 minutes in the initial phase and improved to 1.5 minutes in the later phase. Biliary sphincterotomy was not necessary for inserting single biodegradable stent, but however, all patients with biliary stone had sphincterotomy to facilitate retrieval of the stones. Serum bilirubin level (SBL) showed reduction of 52% from the mean SBL of 54.9 μ mol/L prior to stenting to 26.2 μ mol/L at Day 7. Quality of life score improved from 2.0 up to 8.5 after stenting. The BBS ranks high in terms of loadability, trackability over guide-wire, and pushability with push catheter. There was minimal force required to implant it and it has good visibility by fluoroscopy. The BBS is as flexible as the conventional plastic stents and can be accurately deployed under fluoroscopy. Technical success or completion of the ERCP and stent deployment was achieved in all 30 patients.

Conclusion: This pilot study has shown encouraging results. It benefit the patient to avoid the burden of a second ERCP procedure for plastic stent removal. However, these results should be interpreted with caution as this is a pilot study to assess the safety and efficacy of the biodegradable stent on limited number of volunteers with symptomatic jaundice. We plan to conduct a phase 2 study involving a larger number of cohorts with a more specific indication of benign and malignant biliary stricture.

Disclosure of Interest: H. Othman: The Biodegradable Biliary Stents used for this study is sponsored by amg International GmbH, Winsen, Germany. The authors have no financial relationship with the company which could inappropriately influence or bias the content of this presentation.

All other authors have declared no conflicts of interest.

Introduction: Stellate cells contribute significantly to the development of several diseases. In particular, liver stellate cells are responsible for liver fibrogenesis and further for cirrhosis that culminates into cancer development eventually. In pancreas, it is known that stellate cells sustain the tumor cells via autophagy mechanism.

Aims & Methods: This study aimed to clarify the involvement of Toll-like receptor 5 (TLR5) in the activation of human stellate cells. LX-2 liver stellate cells and HPSC (human pancreatic stellate cells) were treated for 48 hours with 2.5 ng/ml TGF-beta 1. The analysis of activation markers was performed by RT-qPCR, western blotting and immunofluorescence. Real-time cell monitoring with Incucyte was performed. TLRs PCR Array was performed. TLR5 knock down was obtained with commercially validated siRNAs.

Results: Treatment with 2.5 ng/ml TGF-beta 1 caused the activation of both LX2 and HPSC cells. Over-expression of alpha smooth muscle actin (a-SMA) and collagen 1 (COL1A1) transcripts was observed. The protein level of a-SMA and COL1A1 significantly increased also. Interestingly, SNAIL 1, SLUG, TLR5 and TLR3 transcripts were induced by treatment with TGF-beta 1 in both cell lines. SNAIL 1 was over-expressed at protein level also. Knock down of TLR5 neutralized the activity of TGF-beta 1 by keeping the expression of the above markers at basal level or even not expressed.

Conclusion: TLR5, for the first time, has been identified as key player of the activation of stellate cells. Its contribution represents a new aspect in terms of interaction between immune system and stellate cells and could represent a

potential new target for the diseases of the gastrointestinal tract involving the activity of stellate cells. TLR5 and its natural agonist flagellin could be a key link between impairment of microbiota and organo-fibrosis in the gastrointestinal tract.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0096 THE IMPAIRED FUNCTION OF THE PLASMA MEMBRANE CA²⁺ PUMP RESULTS IN CA²⁺ OVERLOAD AND CELL DAMAGE IN CFTR KNOCK OUT PANCREATIC DUCTAL CELLS

Introduction: The cystic fibrosis transmembrane conductance regulator (CFTR) has a major role in pancreatic ductal secretion and its genetic defects damage the pancreas. It is known that intracellular Ca²⁺ homeostasis is disturbed in bronchial epithelial cells in cystic fibrosis (CF), but the connection of CFTR and the intracellular Ca²⁺ signaling has never been suggested in pancreatic damage in CF before.

Aims & Methods: Our aim was to characterize the Ca²⁺ homeostasis of CFTR-deficient PDC. Wild type (WT) and CFTR knockout (KO) mouse pancreatic ductal and acinar cells and iPSC (induced pluripotent stem cell) derived human organoids from 2 CF patients and controls, human CF pancreatic cell line (CFPAC-1; ΔF508 mutant) were used for intracellular Ca²⁺ measurements. Mitochondrial membrane potential (ΔΨ_m) and mitochondrial morphology was assessed in isolated pancreatic ducts. Immunofluorescent staining and quantitative PCR measurements were performed to detect changes of mRNA and protein expressions.

Results: The plateau phase of the agonist-induced Ca²⁺ signal was elevated in CFTR-deficient PDC, which was caused by decreased function of the plasma membrane Ca²⁺ pump (PMCA). The functional inhibition of CFTR had no effect on the PMCA activity. Human CF organoids have shown decreased PMCA function compared to control while the 24 h treatment of the CF organoids with VX-809 have restored the PMCA function to the control level. Similarly native CFPAC-1 cells and PDEC treated with siRNA to inhibit the expression of CFTR showed the same PMCA dysfunction. Viral transfection of CFPAC-1 with CFTR gene completely restored PMCA function. Sustained [Ca²⁺]_i levels decreased ΔΨ_m and induced cytochrome c release in CFTR KO PDEC without significant alterations in mitochondrial morphology.

Conclusion: Dysfunction of PMCA leads to disturbed Ca²⁺ homeostasis in CFTR-deficient PDC and the consequent cellular Ca²⁺ overload impairs mitochondrial function contributing to the pancreatic damage in CF.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0097 EXPDF IMPACTS PANCREATIC DIFFERENTIATION OF HUMAN PLURIPOTENT STEM CELL DERIVED PANCREATIC ORGANIDS

Introduction: Given their capability to differentiate to every cell type of the human body, human induced pluripotent stem cells (hiPSCs) provide a unique platform for developmental studies and regenerative medicine. The generation of pancreatic progenitor (PP) cells from pluripotent stem cells follows the sequential induction of virtually pure definitive endoderm (DE), foregut endoderm (GTE) and pancreatic endoderm (PE). We have recently reported the generation of a novel three-dimensional pancreatic organoid culture system that generates functional acinar-/ductal-like structures from pluripotent stem cells (Hohwieler et al, *GUT*, 2016).

Aims & Methods: In the current study we implemented this culture system to understand the role of exocrine differentiation and proliferation factor (Exdpf), a signalling molecule proposed to be involved pancreatic differentiation in zebrafish. CrisprCas9 technologies were used to ablate Exdpf in human embryonic stem cells, while a piggy bac engineering approach allowed us timed expression to study the role of both loss and gain of Exdpf function during pancreatic differentiation.

Results: First, a limited role of Exdpf was observed until the PE stage, while PP formation was strongly diminished. Moreover, a dramatically altered organoid morphology was observed upon Exdpf knock out leading to mostly cystic structures. Phenotyping for ductal and acinar lineage allowed to investigate these

changes in more detail and genome wide expression profiling helped us to understand the role of Expdf in more detail.

Conclusion: Thus, we report a novel signalling molecule playing a critical role during human pancreas development based on a pluripotent stem cell differentiation platform.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0098 MELATONIN METABOLITE; N1-ACETYL-N2-FORMYL-5-METHOXYKYNURAMINE STIMULATES PANCREATIC ENZYME SECRETION VIA CCK RELEASE. STUDY ON THE RATS

J.M. Jaworek

Dept. Of Medical Physiology, Jagiellonian University CM, Krakow/Poland

Contact E-mail Address: jolanta.jaworek@uj.edu.pl

Introduction: N¹-acetyl-N²-formyl-5-methoxykynuramine (AFMK), melatonin metabolite, has been demonstrated recently as effective pancreatic protector against acute inflammation. AFMK significantly attenuated acute pancreatitis; however, its effect on pancreatic exocrine function has not been investigated yet. **Aims & Methods:** 1. To investigate the effects of intraduodenal (i.d.) application of AFMK on pancreatic enzyme secretion under basal conditions and following the stimulation of this secretion with diversion of pancreato-biliary juice (DPBJ) and to examine the role of CCK in this process. 2. To assess the effect of AFMK on CCK receptor in pancreatic acinar cell line AR42J. **Material and methods:** For in vivo study Wistar rats weighing 300 g were employed. Under pentobarbital anesthesia the animals were surgically equipped with silicone catheters, inserted into pancreato-biliary duct, and into duodenum. AFMK (5.10 mg/kg i.d.) was given to the rats under basal conditions or following stimulation of pancreatic secretion with DPBJ. Lorglumide, the CCK1 receptor antagonist (1 mg/kg i.d.) was administered 15 minutes prior to the application of AFMK. Samples of pancreato-biliary juice were collected to measure the amylase outputs. The blood samples were taken for determination of CCK by ELISA kit. For in vitro study pancreatic acinar cells AR42J were incubated in presence of AFMK alone or in combination with CCK. The protein signal of CCK receptor was determined by Western blot.

Results: AFMK given i.d. produced the dose-dependent increases of pancreatic amylase secretions both; unstimulated, as well as that induced by DPBJ. The rises of pancreatic amylase outputs were accompanied by significant increase of CCK plasma levels. Administration of lorglumide, a CCK1 receptor blocker, completely abolished the stimulation of pancreatic exocrine function induced by AFMK. This melatonin metabolite failed to affect protein signal for CCK receptor in AR42J cells.

Conclusion: The stimulatory effect of AFMK on pancreatic enzyme secretion in the rats is indirect and dependent on the release of CCK by this melatonin metabolite.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0099 INVESTIGATION OF THE FUNCTION OF TRPM2 IN MOUSE PANCREATIC ACINAR CELLS

J. Fanczal¹, P. Biró¹, T. Madacsy¹, P. Hegyi², J. Maléth¹

Introduction: Aberrant intracellular Ca²⁺ signaling is the hallmark of acute pancreatitis (AP) inducing mitochondrial damage, intraacinar digestive enzyme activation and cell death. Thus prevention of toxic cellular Ca²⁺ overload is a promising therapeutic target. The transient receptor potential melastatin 2 (TRPM2) is a non-selective cation channel that plays major role in oxidative stress induced cellular Ca²⁺ overload in different cell types. Although likely, its role in pancreatic acinar cells and the pathogenesis of AP was not investigated yet.

Aims & Methods: Our aim was to characterize the functional activity of TRPM2 in pancreatic acinar cells. In our experiments pancreatic acinar cells (PAC) were isolated from wild type (WT) and TRPM2 knockout (KO) mice with enzymatic digestion. The changes of the intracellular Ca²⁺ level was measured with fluorescent microscopy using FURA2-AM.

Results: The intracellular Ca²⁺ signals evoked by 100 μM carbachol were not different in WT and TRPM2 KO PAC. On the other hand, 1 μM H₂O₂ induced significantly higher intracellular Ca²⁺ elevation in WT PAC compared to the TRPM2 KO. In Ca²⁺ free extracellular solution the Ca²⁺ signal in response to 1 μM H₂O₂ was markedly reduced in WT PAC confirming that H₂O₂ activates dominantly extracellular Ca²⁺ influx.

Conclusion: Our result confirmed the functional activity of the TRPM2 channel in pancreatic acinar cells. In our further investigations we aim to clarify the pathogenetic role of TRPM2 in AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0100 INVESTIGATION OF THE PANCREATIC DUCTAL ION SECRETION IN PANCREATIC DUCTAL ORGANOID CULTURES

Introduction: Pancreatic ductal fluid and HCO₃⁻ secretion are crucially important in the physiology and pathophysiology of the exocrine pancreas. However, the study of human pancreatic secretory processes is great challenge due to the limited access to human pancreatic ductal cells. The recently developed three-dimensional pancreatic organoid cultures (OC) may help to overcome this limitation. However, the ion secretory processes in pancreatic OC is not known.

Aims & Methods: Our aim was to characterize the ion transport processes in mouse pancreatic OCs. Mouse pancreatic ductal fragments were isolated by enzymatic digestion. The isolated ducts were grown in Matrigel on 37°C for a week in OC media. Changes of the intracellular pH was measured to characterize the ion transporter activities of the epithelial cells in OC.

Results: Basolateral administration of 20 mM NH₄Cl in standard HEPES or CO₂/HCO₃⁻ buffered solution resulted in rapid intracellular alkalization, which was followed by a recovery phase. Removal of NH₄Cl induced rapid acidification followed by regeneration to the resting pH levels. The regeneration phase was inhibited by the removal of extracellular Na⁺. The administration of 10 μM CFTR_{inh}172, a selective inhibitor of cystic fibrosis transmembrane conductance regulator decreased the regeneration from alkali load. Basolateral administration of 20 mM amiloride and 20 mM H₂DIDS decreased the intracellular pH suggesting the activity of Na⁺/H⁺ exchanger and Na⁺/HCO₃⁻ cotransporter on the basolateral membrane.

Conclusion: The ion transport activities in mouse OC are similar to those observed in freshly isolated primary tissue. This suggest that OC will be suitable to study human ductal epithelial ion transport.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0101 INVESTIGATION OF THE ORAI1 MEDIATED CA2+ ENTRY IN MOUSE PANCREATIC DUCTAL CELLS

Introduction: Acute pancreatitis (AP) is the most common inflammatory disorder in the gastrointestinal tract with an overall mortality of 20–30% in severe cases. The treatment of AP is not resolved yet, urging the identification of novel drug targets. Toxic cellular Ca²⁺ overload was highlighted as a key event in pancreatic acinar and ductal cells during the pathogenesis of AP. In addition, the inhibition of Orail in pancreatic acinar cells markedly decreased the Ca²⁺ toxicity and the severity of AP. However, We have no information regarding the role of Orail in pancreatic ductal physiology or pathophysiology.

Aims & Methods: Wild type FVB/N mice were used for the isolation of pancreatic ductal fragments. The intracellular pH and Ca²⁺ level of the pancreatic ductal cells (PDC) were measured by microfluorimetry. The effect of selective Orail inhibitors provided by CalciMedica was evaluated.

Results: The tested compounds dose-dependently inhibited Ca²⁺ influx during the carbachol induced Ca²⁺ signal in PDC. Inhibition was complete at a concentration of 10 μM (CM-B: 99.87%, CM-C: 95.29%). Next, endoplasmic reticulum Ca²⁺ stores were depleted with cyclopiazonic acid and the inhibition of store-operated Ca²⁺ entry (SOCE) was investigated after the re-addition of extracellular Ca²⁺. Under these conditions CM-B and CM-C significantly, but not completely, decreased SOCE in PDC (55.96% and 55.03% respectively). The removal of extracellular Na⁺ to abolish activity of the Na⁺/Ca²⁺ exchanger had no effect on the inhibition of SOCE by CM-B or CM-C. We also showed that the inhibition of Orail has no effect on the basal secretion of HCO₃⁻ by PDC, which is the main physiological function of these cells.

Conclusion: We showed that Orail has a significant role in the Ca²⁺ signaling of PDC. In the next step we will evaluate the pathophysiological relevance of the channel.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute pancreatitis (AP) is among the most difficult diseases faced by gastroenterologists and surgeons. In some cases it is difficult to understand etiology of AP. Hereditary pancreatitis (HP) is an autosomal dominant genetic disorder characterized by recurrent attacks of acute pancreatitis.

Aims & Methods: We analyzed medical records of patients who were diagnosed with juvenile pancreatitis and pancreatitis of unknown etiology (PUE) at the Center for Digestive Diseases at Karolinska University Hospital from January 2008 to December 2016.

Results: During the observation period, 44 patients (17 male and 27 female) were registered with the ICD code chronic or relapsing pancreatitis, and onset of symptoms before the age of twenty. At time of first visit, the mean age was 36.7±26.9 years, range 24–57. The average period between the occurrence of first symptoms and diagnosis was 14.6 years (range 1–39 years). All patients (100%) clinically presented with recurrent acute pancreatitis. There were 28 (63.7%) patients with genetic mutations. Five out of 28 genetic positive patients (17.9%) had a definitive diagnosis of genetic etiology of pancreatitis. Seven out of 28 genetic positive patients (25%) had complications: in five patients endoscopic treatment due to pancreatic duct stenosis was performed; one patient had pancreatic and bile duct stenosis and one patient (female, age 28, CFTR heterozygous mutation) a pancreatic tumor (mucinous cystadenoma with high dysplasia that was successfully surgically treated with R0 resection). One patient died due to non-pancreatic related disease (kidney cancer). None of the patients reported alcohol overconsumption. Four out of 28 genetic positive patients (14.3%) were active smokers. Fecal elastase-1 (FE-1) was tested in 28 (63.6%) patients: 16 (57.1%) in genetic positive and 12 (75%) in genetic negative group of patients. Pancreatic exocrine insufficiency (PEI) was found in 5 out of 12 (41.7%) of genetic negative patients and in 5 out of 16 (31.2%) genetic positive patients. Average age at onset of PEI was 38 years (range 27–53). Diabetes mellitus (DM) was diagnosed in one patient in group with genetic alterations and 2 patients in group without genetic alterations.

Conclusion: We found high proportion of genetic alterations in patients with juvenile pancreatitis and PUE. In patients in whom pancreatitis remains unexplained after excluding of the most often etiologies and presence of genetic alteration, hereditary pancreatitis seems as reasonable explanation even in patients with mutations in other genes than PRSS1. Routine follow-up of patients with regular testing on pancreatic exocrine insufficiency and diabetes mellitus and pancreatic cancer surveillance is necessary.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0103 THE FACTORS FOR PREDICTING HOSPITAL MORTALITY IN EARLY STAGE OF SEVERE ACUTE PANCREATITIS

Introduction: Severe acute pancreatitis has high mortality and needs intensive care. However it is difficult to stratify the severity of acute pancreatitis in early stage because revised Atlanta classification requires persistent organ failure lasting at least 48 hours.

Aims & Methods: We searched factors to predict hospital mortality in early stage of severe acute pancreatitis. This was a retrospective cohort study of all consecutive patients with severe acute pancreatitis who admitted at 44 institutions between June 1, 2009 and December 31, 2013. We evaluated ten factors which associated with mortality in previous study.

	Odds ratios and 95% confidence intervals	P value
Respiratory failure	3.13(2.01–4.89)	<0.001
Advanced age	2.64(1.78–3.93)	<0.001
Renal failure	2.02(1.29–3.15)	0.002
High lactate dehydrogenase	1.63(1.03–2.58)	0.04

Results: The mortality was 12.7% (142/1114 patients). All ten factors were associated with mortality in univariable analysis. In multivariable analysis, four factors, namely "partial pressure of oxygen in blood ≤60 mmHg (room air) or mechanical ventilation", "age ≥70 years", "blood urea nitrogen ≥40 mg/dL (or creatinine ≥2.0 mg/dL) or oliguria (daily urine output <400 mL even after adequate intravenous fluid resuscitation)", and "lactate dehydrogenase ≥2 times upper limit of the normal range" were associated with mortality. The other factors, namely "base excess ≤-3 mEq/L", "platelet count ≤100,000/mm³", "serum calcium ≤7.5 mg/dL", "c-reactive protein ≥15 mg/dL", "number of positive measures in systemic inflammatory response syndrome criteria ≥3" and "computed tomography grade" were not associated with mortality.

Conclusion: Advanced age, respiratory failure, renal failure and high lactate dehydrogenase could predict mortality in early stage of severe acute pancreatitis. The patients with these factors require transport to a hospital with intensive care unit.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cholecystectomy during the index admission may reduce risk of recurrent biliary events but concerns have been raised about complications if surgery is performed too early. The objectives of this study were to compare gallstone- and cholecystectomy-related complications and patient reported quality-of-life and pain if cholecystectomy was performed before discharge or scheduled 6 weeks from the initial episode.

Aims & Methods: Patients admitted with biliary pancreatitis at the Karolinska University Hospital were assessed for eligibility. Patients with mild pancreatitis were enrolled into either index- or scheduled cholecystectomy (IC vs. SC). IC was performed when patients showed recovery and within 48 hours from randomization. SC was planned after 6 weeks from randomization. The primary outcome was recurrent biliary events. Secondary endpoints were cholecystectomy complications within 1 months, the proportion of common bile duct stones at cholecystectomy requiring ERC and patients reported quality-of-life and pain.

Results: Sixty-four patients between May 2009 and March 2017 were randomized into IC (n=31) or SC (n=33). Recurrent pancreatitis occurred in one and six patients in the IC and SC groups respectively (3.2% vs. 18.7%, P=0.049). Higher proportion of common bile duct stones were found in the IC group during cholecystectomy requiring ERC (23.3% vs. 10.7%, P=0.30). There was no difference in pain measure between the groups at randomization and follow-up.

Conclusion: Delaying cholecystectomy in mild gallstone pancreatitis is associated with increased risk for recurrent gallstone-related events. Cholecystectomy performed at the index admission is safe and feasible.

P0105 COMPARISON OF PREDICTIVE SYSTEMS TO PREDICT DEATH, SEVERE AND MILD ACUTE PANCREATITIS ACCORDING TO THE REVISED ATLANTA CLASSIFICATION

R. Pique Becerra, F.J. García Alonso, F. García Durán, M. Hernández Tejero, A. Granja Navacerrada, P. Bernal Checa, P. Bernal Checa, F. Bermejo Aparato Digestivo, Hospital Universitario de Fuenlabrada, Fuenlabrada/Spain

Contact E-mail Address: ruben.pique@salud.madrid.org

Introduction: The course of acute pancreatitis (AP) ranges from life threatening to mild disease, so accurately predicting its outcome is important. The revised Atlanta classification breaks the previous mild/severe dichotomy, so the absence of predictors of severity does not preclude a mild course. Studies designed according to the new classification evaluating existing predictors are still scarce.

Aims & Methods: Our study aims at evaluating the diagnostic accuracy of easily available prognostic scores to predict mortality, persistent organ failure (severe AP) and mild AP. We analyzed a single-center retrospective cohort including all adult patients admitted between 2010 and 2015. Patients with a previous episode of AP in the six months before admission, with other primary diagnosis at discharge and those partially attended at other institutions were excluded. Severity and local complications were defined according to the 2012 Atlanta classification. Four different scores (BISAP, SIRS, APACHE II and HAPS) and the following predictors: C reactive protein (CPR) at 24h, hematocrit and BUN at admission

and their evolution after 24 h were evaluated. Accuracy was measured using diagnostic tests and receiver operating characteristic analyses.

Results: Of the 817 eligible patients, 118 were excluded, most for a previous episode before admission. We analyzed 699 patients with a median age of 57.5 years (IQR: 45.1–72.7), 57.4% males. Most frequent comorbidities were: diabetes (16%), ischemic heart disease (8.6%) and COPD (7.7%). Median length of stay was 7 (5–10) days. Most common causes were: biliary (53.9%), idiopathic (21.8%) and alcoholic pancreatitis (14.3%). A CT scan was performed in 56.1% identifying local complications in 36.2% of them, acute fluid collections in 30.1% and acute necrotic collections in 16.8%. There were 42 (6%) severe and 196 (28%) moderately severe cases. Overall mortality was 2.4% (1, 5–3, 9%), 35.7% (23–50.8%) among severe cases. BUN at admission AUC: 0.88 [0.85–0.90]), BISAP score (AUC: 0.88 [0.85–0.90]) and APACHE II (AUC: 0.87 [0.83–0.90]) outperformed all other evaluators in predicting death. APACHE II presented the highest sensitivity, 100% (81.6–100%), while the BISAP score presented the highest specificity, 93.1% (90.6–94.8%). BUN at admission (AUC: 0.89 [0.86–0.91]) and the BISAP score (AUC: 0.87 [0.84–0.89]) also presented the best performance for severe AP. The BISAP score presented the highest specificity, 94.2% (92.2–95.8%), although with a low PPV, 32.1% (21.4–45.2%). On the other hand, diagnostic accuracy for mild AP was poor, as all predictors presented an AUC < 0.7. The HAPS score reached the highest specificity, 87.8% (83–91.4%), but presented a very poor sensitivity (28.9% [24.3–33.9%]).

Conclusion: The revised Atlanta classification accurately identifies those patients at higher risk of death. Among the available predictors of severity, BISAP and BUN at admission presented an excellent performance, with an AUC of nearly 0.9. New scores are needed to predict a mild course, as none of the available indexes presented an AUC > 0.7.

P0106 PANCREATIC DUCT ASCARIASIS

P. Somani, M. Sharma

Department Of Gastroenterology, Jaswant Rai Speciality Hospital, Meerut/India

Contact E-mail Address: dr_piyushsomani@yahoo.co.in

Introduction: Although uncommon in the West, *Ascaris lumbricoides* is a common cause of acute pancreatitis in developing countries. The mechanism of acute pancreatitis in ascariasis may be due to obstruction of papilla of Vater, invasion of common bile duct (CBD), or pancreatic duct (PD). The invasion of pancreatic duct occurs rarely owing to its smaller calibre. Ultrasonography (USG) is an effective tool for the diagnosis of biliary and pancreatic ascariasis; however, the diagnosis may be false negative in up to 30% of cases. Pancreatic ascariasis is a rare entity. Only case reports have been described in literature. We present our retrospective data of last 10 years of 15 cases of pancreatic ascariasis.

Aims & Methods: During a study period of 10 years, 15 cases of pancreatic ascariasis were diagnosed by USG or endoscopic ultrasonography (EUS). EUS was performed with a linear or radial echoendoscope. 13 patients presented with symptoms of acute pancreatitis. Out of 13 patients, 9 presented with first episode of idiopathic pancreatitis while 4 presented with idiopathic recurrent acute pancreatitis (IRAP). One patient had biliary colic and one patient presented with acute cholangitis. 12 patients had mild pancreatitis while only one had moderate pancreatitis. Patients were treated with parenteral fluids, analgesics, antibiotics, and albendazole. Only 2 cases were diagnosed with USG while 13 patients were diagnosed with EUS. The patients underwent side viewing endoscopy/ERCP under the same sedation after EUS if EUS revealed biliary/pancreatic ascariasis. Out of 15 patients, 14 underwent side viewing endoscopy with removal of live single/multiple worms with rat tooth forceps/biopsy forceps/dormia basket in 13 patients. 2 patients were managed conservatively with repeat USG showing absence of ascariasis. There were no complications.

Results: The patient characteristics are described in table. 2 patients had associated bile duct ascariasis. Sonographic characteristics of *A. lumbricoides* were single or multiple echogenic nonshadowing linear, tubular structures and curved strips with anechoic tubular central lines. EUS features were single or multiple linear hyperechoic structure without acoustic shadowing in the PD or CBD ("single-tube sign" or "strip sign") or with central hypoechoic tube representing alimentary canal of the worm ("double tube sign" or "inner tube sign") and movements of worms inside the duct. Live roundworms were removed from PD without undertaking sphincterotomy. In endemic areas, sphincterotomy facilitates the risk of migration of worms into the CBD or PD.

Conclusion: Ascariasis-induced acute pancreatitis is usually mild and EUS is the investigation of choice. The recurrence is rare and treatment is side viewing endoscopy with removal of worms. EUS significantly improves the diagnostic yield for idiopathic acute pancreatitis (IAP). Our retrospective study shows that EUS is a highly accurate method to diagnose the etiology of IAP with reference to biliopancreatic ascariasis. Although USG is quite sensitive for diagnosing BPA, its sensitivity significantly falls when the worm is thin, in the PD, or the CBD is non-dilated. EUS is more sensitive for diagnosis of ascariasis in the pancreatic duct than other radiologic investigations. The probable reasons are excellent imaging of pancreas by EUS and in and out movement of ascaris which might be missed by other investigations. Endoscopic retrograde cholangiopancreatography, considered the gold standard for diagnosis of biliary ascariasis, should be reserved for therapeutic rather than diagnostic use as papillotomy can lead to reentry of the worm into the common bile duct. EUS should be used early in the work-up of IAP after the first episode. We propose EUS to be investigation of choice for PD ascariasis. Most of the episodes are of mild pancreatitis with no mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The severity of acute pancreatitis varies widely, from a mild self-limited disease to one with a severe clinical course complicated by multiple organ-system failure¹. No pharmacologic therapy has been shown to improve the prognosis of patients with severe acute pancreatitis, while the quality of supportive care including early fluid resuscitation is critically important^{1, 2}. Fluid resuscitation maintains adequate intravascular volume by compensating for fluid shifts to the third space³. However, there is a lack of consensus regarding the details of optimal fluid administration such as the type of fluid, infusion rate and volume of administration, and the physiologic goals of fluid resuscitation⁴.

Aims & Methods: The aim of this study is to evaluate the association between the volume of fluid administered and clinical outcomes in patients with severe acute pancreatitis. We conducted a secondary analysis of data from a multi-centre retrospective study of patients with severe acute pancreatitis in Japan, which was registered with the University Hospital Medical Information Network Clinical Trials Registry (Registry number 000012220) and approved by the Institutional Review Board or the Medical Ethics Committee at each institution⁵. The diagnosis of severe acute pancreatitis was based on criteria of the Japanese Ministry of Health, Labour and Welfare (Japanese Severity Score)⁶. Patients were stratified into two groups: administered fluid volume <6000 ml and ≥6000 ml in the first 24 hours. We evaluated the association between the two groups and clinical outcomes using multivariable logistic regression analysis. The primary outcome was in-hospital mortality. As a sensitivity analysis, we conducted an identical analysis for subgroup patients with severe acute pancreatitis diagnosed according to the revised Atlanta classification⁷.

Results: We analysed 1097 patients, and the mean fluid volume administered was 5618 ± 3018 ml (mean ± standard deviation), with 708 and 389 patients stratified into the fluid <6000 ml and fluid ≥6000 ml groups, respectively. Overall in-hospital mortality was 12.3%. The fluid ≥6000 ml group had significantly higher mortality than the fluid <6000 ml group (15.9% vs. 10.3%, *p* < 0.05). However, in multivariable logistic regression analysis, conversely fluid ≥6000 ml within the first 24 hours was significantly associated with reduced mortality (OR 0.58, 95%CI 0.34–0.98). We performed subgroup analyses for patients diagnosed with severe acute pancreatitis based on the revised Atlanta classification⁷. One hundred sixty-seven patients were classified in the fluid <6000 ml group, and 201 patients classified in the fluid ≥6000 ml group. There were no significant differences between the two groups with regard to in-hospital mortality (fluid <6000 ml: 35.3% vs. fluid ≥6000 ml: 28.4%, *p* = 0.18). In multivariable logistic regression analysis, administered fluid ≥6000 ml within the first 24 hours was associated with significantly less mortality (OR 0.56, 95%CI 0.32–0.98).

Conclusion: In patients with severe acute pancreatitis, administration of fluid ≥6000 ml within the first 24 hours is associated with decreased mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There is no definite prognostic marker of post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP). Previous animal study reported that serum phosphate correlated with severity of acute pancreatitis.

Aims & Methods: In this study, we aimed to evaluate the efficacy of serum phosphate as a prognostic factor for PEP in human. Between January 2005 and December 2016, 176 patients who underwent serum phosphate test among patients with PEP were included in the study. Serum phosphate was measured between 12 and 24 hours after ERCP. PEP was defined as new abdominal pain with at least 3-fold increase in serum amylase or lipase levels. The severity of the pancreatitis was determined according to consensus guidelines.

Results: A total of 176 patients with mild (n=69; 39.2%), moderate (n=80; 45.5%), or severe (n=27; 15.3%) PEP were included. Serum phosphate was associated with severity of PEP. Serum phosphate levels in mild, moderate and severe PEP were 2.9, 3.0, and 3.3 mg/dL, respectively (P=0.035). In the linear regression analysis, only the serum phosphate was associated with the duration of hospitalization (P=0.016). Hematocrit, blood urea nitrogen, and high sensitivity C-reactive protein were not significantly associated with admission duration.

Conclusion: According to our retrospective data, serum phosphate is associated with the severity of PEP, and its role as a prognostic factor for PEP can be considered.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0109 BISAP AND RANSON AS PREDICTORS OF SEVERE ACUTE PANCREATITIS AND MORTALITY IN A EUROPEAN COHORT

F. Valverde López¹, E. Fernández-Fernández¹, R. Jiménez-Rosales¹, A.M. Matas-Cobos¹, E. Ortega-Suazo², E. Redondo-Cerezo¹

¹Gastroenterology And Hepatology, University Hospital Virgen de las Nieves, Granada/Spain

²Gastroenterology, "Virgen de las Nieves" University Hospital, Granada/Spain

Contact E-mail Address: fcovalverde89@gmail.com

Introduction: The 2012 revised Atlanta Classification in 2012 has established an important change in Acute Pancreatitis (AP) definitions, comprising 3 grades of severity depending on the presence and persistence of organ failure (1). Thereby, patients with severe acute pancreatitis (SAP) include the vast majority of mortality in this disease (2–4).

Aims & Methods: Our goal was to know the predicting ability of BISAP and Ranson in a European cohort with the latest Atlanta Classification. Patients diagnosed of AP in University Hospital Virgen de las Nieves from June 2010–June 2012 were included. BISAP was calculated on admission and Ranson was calculated with parameters of the first 48 hours. We assessed the presence of SAP and mortality, receiving operating curves (ROC) and area under the curve (AUC) were calculated, selecting the best cut-off value in terms of sensibility, specificity, positive predictive value (VPP) and negative predictive value (NPV).

Results: 269 patients were included, 52.8% female and 47.2% male, 17 presented SAP (6.3%), 8 deaths (3%). Etiology: 65% biliary, 10.4% alcoholic, post ERCP 3%, drugs related in 0.7%, metabolic in 1.1%, idiopathic 15.2%, mixed (alcoholic + biliary) 1.1% and others in 2.6% BISAP showed an AUC 0.9, with sensitivity of 70%, specificity of 94%, PPV 41.4%, NPV 97.9% and overall accuracy of 91.8% for the prediction of SAP. Regarding mortality prediction, it exhibited an AUC of 0.97, sensitivity of 100%, specificity 92%, PPV 27.6%, NPV 100% and accuracy 92.2% (Tables 1a and 1b) RANSON showed AUC 0.85, sensitivity of 88% and specificity of 79%, PPV 22.1%, NPV 99% and accuracy of 79.6% for SAP prediction. With the respect of mortality prediction, it presented an AUC of 0.94, sensitivity of 100% and specificity of 77%, PPV 11.8%, NPV 100% and accuracy of 77.7% for mortality prediction (Tables 1a and 1b)

Conclusion: Our study analyzed the prediction ability of BISAP and Ranson in a European cohort using de updated classification of Atlanta 2012 and showed good results in terms of sensitivity and specificity in both scores when predicting SAP and death. As they are low prevalent outcomes in our sample, PPVs are low but it gives interesting information, since 41% of patients with BISAP ≥ 3 on admission will develop SAP. On the other hand, NPVs are very high so in patients with BISAP < 3 or Ranson < 4, SAP and mortality can be considered very unlikely. Although both scores have similar results, Ranson needs more than 48 hours to be completed, so it does not provide enough information on admission to warrant the patient aggressive therapies or ICU admission in the earliest stage of the disease. Multicenter studies in European cohorts are needed to confirm our findings.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0110 POST-ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY PANCREATITIS: MORBIDITY AND PREDICTORS OF SEVERITY

E. El-Hanafy¹, A. El Nakeeb²

¹Faculty Of Medicin, Mansoura University, gastroenterology surgical center, Cairo/Egypt

²Faculty Of Medicin, Mansoura University, gastroenterology surgical center, Cairo/Egypt

Contact E-mail Address: dr_ahab_elhanafy@yahoo.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is increasingly used for therapeutic management of various biliary and pancreatic diseases[1]. However, ERCP is not a procedure without morbidities[2]. Post-ERCP pancreatitis (PEP) remains the most common and serious complication after ERCP[3].

Aims & Methods: To detect risk factors for post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) and investigate the predictors of its severity. This is a prospective cohort study of all patients who underwent ERCP. Pre-ERCP data, intraoperative data, and post-ERCP data were collected. **Results:** The study population consisted of 996 patients. Their mean age at presentation was 58.42 (±14.72) years, and there were 454 male and 442 female patients. Overall, PEP occurred in 102 (10.2%) patients of the study population; eighty (78.4%) cases were of mild to moderate degree, while severe pancreatitis occurred in 22 (21.6%) patients. No hospital mortality was reported for any of PEP patients during the study duration. Age less than 35 years ($P=0.001$, $OR=0.035$), narrower common bile duct (CBD) diameter ($P=0.0001$) and increased number of pancreatic cannulations ($P=0.0001$) were independent risk factors for the occurrence of PEP.

Conclusion: In conclusion, PEP is the most frequent and devastating complication after ERCP. PEP is associated with higher morbidity and mortality beside its effect in increasing the consumption of hospital resources. Age less than 35 years, narrower median CBD diameter and increased number of pancreatic cannulations are independent risk factors for the occurrence of PEP. Patients with these risk factors are candidates for prophylactic and preventive measures against PEP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The revision of Atlanta Classification in 2012 has established an important change in Acute Pancreatitis (AP) definitions, comprising 3 grades of severity depending on the presence and persistence of organ failure (1). Thereby, patients with severe acute pancreatitis (SAP) include the vast majority of deaths in this disease (2–4).

Aims & Methods: Our aim was to know the predicting ability of lactate and other single biomarkers in a European cohort with the revised Atlanta Classification in terms of severe acute pancreatitis (SAP) and mortality. Patients diagnosed of AP in the University Hospital "Virgen de las Nieves" from June 2010 to June 2012 were included. Blood sample including hematological parameters, biochemical test, BUN, CRP and venous gasometry including lactate were performed on admission. We assessed the presence of SAP and mortality during admission, receiving operating curves (ROC) and area under the curve (AUC) were calculated, selecting the best cut-off value in terms of sensibility, specificity, positive predictive value (VPP) and negative predictive value (NPV).

Results: 269 patients were included, 52.8% female and 47.2% male, 17 presented SAP (6.3%), 8 (3%) patients died. Etiology: 65% biliary, 10.4% alcoholic, post ERCP 3%, drugs related in 0.7%, metabolic in 1.1%, idiopathic 15.2%, mixed (alcoholic + biliary) 1.1% and other in 2.6% The results in terms of sensitivity, specificity, PPV, NPV and AUC are summarized in Table 1a and 1b. BUN had the highest AUC in terms of SAP predictions whereas Lactate had was the best in terms of mortality prediction.

Conclusion: Biomarkers are quick but incomplete tools for SAP prediction, which can be easily obtained at any moment throughout the disease. Our study shows good values of specificity and AUC for BUN, Cr and lactate but not for CRP concerning SAP and mortality prediction on admission, but since they are low prevalent outcomes in our sample, PPVs are low and not very reliable. Although many of these parameters has been analyzed in previous studies, we present lactate as a new biomarker with similar performance than that of Cr and BUN, suggesting a possible role for scores building or outcome monitoring.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0112 COTTON VS. REVISED ATLANTA CRITERIA TO DEFINE SEVERITY OF POST-ERCP PANCREATITIS

X. Smeets¹, A.C. Tan², J.P.h. Drenth¹, E. Van Geenen¹

¹Gastroenterology & Hepatology, Radboudumc, Nijmegen/Netherlands

²Canisius Wilhelmina Hospital Dept. of Hepatogastroenterology, Nijmegen/Netherlands

Contact E-mail Address: xaviersmeets@gmail.com

Introduction: The Cotton criteria (1) and the revised Atlanta classification (2) are advocated to define post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) severity (3). Whereas Cotton puts the emphasis on length of hospitalisation, Atlanta focuses on the presence of local (necrosis) and systemic (organ failure) complications. The number of hospitalization days may not be a proper representation of PEP severity, because it is influenced by other diagnoses such as ERCP complications and comorbidity. The goal of this retrospective cohort study is to compare the Cotton and Atlanta criteria for the severity of PEP.

Aims & Methods: All ERCP procedures from a Dutch university medical centre and a teaching hospital between 2012 and November 2016 were checked retrospectively for patients with PEP. Patients were eligible if they met the Cotton criteria or Atlanta criteria for acute pancreatitis. All records were checked up to 48 hours after ERCP to capture delayed PEP. Patients were excluded if they had acute pancreatitis prior to ERCP or had chronic pancreatitis. In the primary analysis, mild/moderate and severe PEP were compared between Cotton and Atlanta with Fischer's exact test. Atlanta was regarded as the golden standard. Secondly, we compared the sensitivity and specificity of both definitions for mortality.

Results: Out of a total 2156 ERCPs, 66 patients (3%) had PEP. Two patients were excluded due to missing data for hospital stay. Of the 64 patients analysed, 39 (60.9%) were female, mean age was 60.6 years and the most common indication for ERCP was choledocholithiasis (n=33, 51.6%). Four patients (6.3%) developed organ failure, 3 patients (4.7%) died. The table below depicts the PEP severity distribution according to Cotton and Atlanta. No significant differences were found (p=0.64). Of the 25 severe patients according to Cotton, 23 were categorized due to hospital stay exceeding 10 days, but were mild according to Atlanta. In 11 patients (44%), concomitant disease (syndrome of inappropriate antidiuretic hormone secretion, cholangitis, pneumonia, perforation or biliary leakage) was the cause for prolonged stay.

Severity of PEP according to Cotton and Atlanta

		Atlanta Mild-moderate	Severe	Total
Cotton	Mild-moderate	37 (62%)	2 (50%)	39 (61%)
	Severe	23 (38%)	2 (50%)	25 (39%)
Total		60 (94%)	4 (6%)	64 (100%)

All 3 patients that died had severe PEP according to Atlanta due to persistent organ failure. Cotton classified them as mild, moderate and severe based on hospitalization. Two patients died within 10 days of early multiple organ failure. No other Cotton criterion for severity was met. Thus, the Cotton criteria due not capture early deaths due to multiple organ failure. The sensitivity and specificity of Atlanta and Cotton for mortality were 100%, 98.4%, 33.3% and 60.7%, respectively.

Conclusion: The Cotton criteria for PEP overestimate disease severity, but underestimate mortality. Therefore, the Atlanta criteria should be used for defining PEP severity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute pancreatitis (AP) is a common but potentially lethal pathology due to the multiplicity and severity of its complications¹. Infected pancreatic necrosis (IPN) occurs in 30% of patients with necrotizing AP and is associated with an increase in mortality ranging from 15% to 39%¹. While interventional drainage and/or removal of the infected tissue remain the mainstay of therapy of IPN, important progresses have been achieved over the last decade and minimally-invasive interventional treatments have been developed. The aim of this study

was to identify factors associated with IPN and to describe outcomes and management.

Aims & Methods: This was a retrospective study of collected data from all patients admitted in Intensive Care Unit (ICU) in a single centre from 2012 to 2015 for a severe AP. Baseline characteristics of the overall population were expressed as frequencies (percentages) for categorical variables, as mean \pm standard deviation (SD) for continuous data. For the analysis of mortality, multivariate analysis with Cox proportional hazards regression modeling was used to identify independent predictors. Association between IPN and patients' characteristics at baseline was evaluated using logistic regression.

Results: In total, 148 patients were included in this study. Overall mortality was 17%. Body mass Index, computed Tomography Severity Index (CTSI) and persistent (>48H) organ failure (OF) were independently associated with overall mortality. 4/16 patients died of documented mesenteric ischemia during the early phase (≤ 8 days) and 3/10 patients during the late phase (>8 days). IPN was present in 62 patients (43%), all requiring an intervention (i.e. radiological, endoscopic, and/or surgical). 35% of patients (22/62) had only one modality of drainage (radiologic or transgastric) and did not required any necrosectomy. For 30 patients (48%), additional necrosectomy was needed because of lack of improvement after drainage alone. 10 patients (17%) had only necrosectomy without prior drainage procedure. Complications such as hemorrhage and perforation of visceral organ occurred more frequently in the IPN group (1.4% vs 19.4%, $p < 0.001$ and 0% vs 8.5%, $p = 0.02$ respectively). The late phase mortality (>8 days) was significantly higher in the IPN group (14.5% vs 1.4%, $p < 0.01$). In multivariate analysis, factors associated with IPN were number of OF and portosplenomesenteric venous thrombosis (table 1). 39 patients (68%) received anticoagulants with a median time of 6 [3–6] months and among them. 25 patients developed cavernoma, irrespective of whether or not they receive systemic anticoagulation ($p = 0.31$).

Table 1: Multivariate analysis of factors associated with infected pancreatic necrosis

	OR _{adjust} [IC95%]	P
Cause of pancreatitis		
Alcohol abused Biliary Others	1 2.43[0.79–7.45] 5.36[1.59–18.12]	0.02
Number of organ failure (OF)		
No OF 1 or 2 OF multiple OF (≥ 3)	1 4.44[1.07–18.40] 28.67[6.23–131.96]	<0.001
Postosplenomesenteric vein thrombosis	8.16 [3.06–21.76]	<0.001

Conclusion: In conclusion, this study performed in routine practice conditions showed that IPN occurs in almost half of patients hospitalized in ICU for severe AP, and is associated with increased mortality and complications rates. Overall mortality was 17.6%, and factors associated with mortality were a high BMI, CTSI and persistent OF. Those results are consistent with previous studies^{1, 2}, but we reported a high rate of mesenteric ischemia (7/26 patients deceased) while this complication is occasionally described. IPN patients required an intervention for drainage of infected tissue removal, which was performed using minimally-invasive techniques in the vast majority of cases, with no complication or severe side effect. 35% of patients were treated with drainage alone without any additional necrosectomy. Finally, PSMVT and early OF appeared to be associated with the risk of developing an IPN but anticoagulation for PSMVT did not protect for cavernoma occurrence and can expose to intestinal bleeding. Our results also suggest that the optimal and early management of OF and detection of PSMVT might prevent IPN and/or its complications. Such hypothesis will need to be tested in large multicentre prospective studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0114 EARLY PREDICTORS AND OUTCOMES OF FLUID SEQUESTRATION IN ACUTE PANCREATITIS

S. Goyal

Gastroenterology, Banaras Hindu University, VARANASI/India

Contact E-mail Address: drsundeepgoyal@gmail.com

Introduction: Although it is well known that some patients with AP have an increased need for fluid therapy, it is not clear who should get fluids aggressively. Changes in hematocrit, BUN and serum creatinine, has been documented to limit necrosis and improve outcome. The early prediction of fluid sequestration may help to select patients for more or less aggressive fluid resuscitation¹.

Aims & Methods: 1) To determine early variables as predictors of fluid sequestration in the first 48 hours. 2) To determine outcome associated with fluid sequestration. In this prospective cohort study 300 consecutive patients of acute pancreatitis were included. Fluid sequestration was calculated by adding the total amount of fluid administered and subtracting the total amount of fluid lost in the first 48 hours of hospitalization. Local complications were defined

according to the revised Atlanta classification. Univariate and multivariate analysis were performed.

Results: The median fluid sequestration in the first 48 h after hospitalization was 4.7 liter (2.8–6.8 L). It was 3.2 l (1.4–5 l), 6.4 l (3.6–9.5 l) in those without necrosis and those with necrosis, and 7.5 l (4.4–12 l) in those with persistent organ failure. The univariate and multivariate analysis showed that alcohol etiology, an increasing number of SIRS criteria and Hematocrit were significantly associated with increased fluid sequestration (Table). Body mass index, APACHE II score, sodium, creatinine and blood urea nitrogen levels did not help predict fluid sequestration. Patients with and without acute fluid collections had a median sequestration of 7.2 and 4.2 L ($p < 0.001$), respectively. 22 patients died (7.33%); median fluid sequestration in the patients who died was 6.5 L compared to 4.2L among the patients who survived ($p = 0.05$). Increased fluid sequestration was associated with prolonged hospital stay ($p < 0.01$). (table) Association between variables determined at admission and fluid sequestration.

Variable		Fluid sequestration (48 hours) (L)	Univariate analysis, p value	Multivariate analysis, p value
Age (years)	<35	5.3 (2.7–8.9)	0.06	<0.05
	35–45	5.6 (2.9–7.6)		
	45–55	4.9 (3.1–7.9)		
	55–65	5.3 (2.7–6.9)		
	>65	4.5 (2.7–6.2)		
Sex	Male	5.1 (2.7–8.9)	<0.01	>0.05
	Female	4.8 (2.8–7.4)		
Etiology	Alcohol	5.5 (2.7–8.8)	<0.001	<0.001
	Biliary	5.2(2.4–8.1)		
	Idiopathic	4.8 (2.8–7.2)		
	Others	4.6 (2.7–6.4)		
Hematocrit (%)	<35	3.6 (2.7–4.9)	<0.001	<0.01
	35–40	3.3 (2.7–5.1)		
	40–45	3.8 (3.1–7.5)		
	>45	4.7 (3.8–8.9)		
SIRS score	0	5.3 (2.7–4.1)	<0.001	<0.01
	1	5.3 (2.2–4.4)		
	2	5.3 (2.9–6.5)		
	3	5.3 (3.1–7.2)		
	4	5.3 (3.8–8.9)		

Conclusion: Alcohol etiology, increased number of SIRS criteria, hemoconcentration and younger age were independent predictors of increased fluid loss. Patients with increased sequestration of fluid are at higher risk of local complications and prolonged stay.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: hayashishiro1976@yahoo.co.jp

Introduction: Post ERCP pancreatitis (PEP), that can potentially result in procedure-related death is still great concern in pancreato-biliary endoscopists because it may be a potentially preventable complication but it is difficult to prevent. Among reported prophylactic procedures for PEP, placement of prophylactic pancreatic stent (PPS) is known as a promising one to decrease the risk of PEP in high-risk patients. It is, however, still unclear what high-risk patient is a good candidate for PPS. We have previously reported the two predictive factors for PEP; the cannulation time longer than 13 min and 2-hour amylase level over 264 IU/L (*World J Gastrointest Endosc* 2016; 8: 777–784). In the present study, we evaluated if PPS for PEP was useful in high-risk patients with using the propensity score matching method.

Aims & Methods: This is a retrospective single center cohort study of consecutive patients that underwent ERCP from January 2010 to December 2015. A total of 2298 patients (average age 73 ± 11, female 41.2%) were enrolled. Of them, 174 cases with the following conditions were excluded: 1) gallstone pancreatitis, 2) unreachable to papilla, 3) missing data of procedure time or serum amylase

levels. Finally, 2124 cases were analyzed. Overall, 86 of 2124 cases developed PEP (4.0%). Pancreatic guidewire in addition to the cannulation time longer than 13 min were revealed as significant high-risk factor of PEP using a univariate analysis. There were a total of 216 patients with above two risk factors (HR group). Of them, 30 patients developed PEP (13.9%). Using logistic regression, propensity scores were used to prevent selection bias between with and without PPS. The covariates entered in the propensity model were age, gender, native papilla, endoscopic biliary stent, endoscopic metallic stent, pancreatic guidewire, pancreatic injection, endoscopic sphincterotomy, precut, endoscopic papillary balloon dilation, pancreatic duct brush. Subsequently, 1-to-1 matched PPS and non-PPS group (each group N = 64) were extracted from the cohort using the closest matching score.

Results: After matching, mean propensity matching score in PPS and non-PPS group were 0.46 ± 0.2 and 0.46 ± 0.2 respectively. There were 62 female (48.4%) with a mean age of 71 in each group. A total of 17 patients with HR developed PEP (13.2%). The PEP rate in PPS group was significantly lower than in non-PPS group (6.3% vs 20.0%; $p = 0.019$). Mean post-ERCP 2 h amylase levels were also lower in PPS group than non-PPS group (178 vs 352; $p = 0.0214$).

Conclusion: Using a propensity analysis revealed that PPS significantly reduce the risk of developing PEP in high-risk patients with longer cannulation time and pancreatic guidewire. Consequently, we considered patients with above two risk factors be a good candidate for PPS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Combination of two-hour post-endoscopic retrograde cholangiopancreatography amylase levels and cannulation times is useful for predicting post-endoscopic retrograde cholangiopancreatography pancreatitis Shiro Hayashi et al. *World J Gastrointest Endosc* 2016; 8: 777–784

P0116 AUTOIMMUNE PANCREATITIS CLASSIFIED AS NOT-OTHERWISE SPECIFIED (NOS) ACCORDING TO THE INTERNATIONAL CONSENSUS DIAGNOSTIC CRITERIA: CLINICAL FEATURES AND OUTCOMES IN 47 PATIENTS

N. De Pretis, A. Brandolese, L. Brozzi, F. Vieceli, A. Amodio, M. Ruffini, S. Crinò, A. Gabbriellini, L. Frulloni
Gastroenterology, University of Verona, Verona/Italy

Contact E-mail Address: martina.ruffini@libero.it

Introduction: Autoimmune pancreatitis (AIP) is a well-recognized fibro-inflammatory disease of the pancreas characterized by a dramatic response to steroid therapy.(1) Three different types have been identified according to the International Consensus Diagnostic Criteria: type 1, type 2 and type not-otherwise specified (NOS).(2) Despite the significant number of studies published on AIP type 1 and 2, (3, 4) no studies have been focused on AIP type NOS and therefore very little is known about clinical features and long-term outcomes of these patients.

Aims & Methods: Aim was to investigate clinical features, risk of other organ involvement, risk of relapse and long-term outcomes of AIP type NOS-patients. Patients classified by International Consensus Diagnostic Criteria (ICDC) as AIP type NOS at clinical onset included in our database prospectively maintained since 1995 have been evaluated. AIP type 1 (168 patients) and AIP type 2 (63 patients) were excluded. Epidemiological and clinical data have been collected and analyzed.

Results: 47 patients fulfilled inclusion criteria. Symptoms at clinical onset were mainly weight-loss (40, 5%), jaundice (34%) and pancreatitis (29.8%). Six patients (12, 8%) had other organs involvement (5 proximal biliary involvement and 1 salivary involvement) and only two (4, 3%) patients had serum IgG4 levels > 140 mg/dL at clinical onset. Six patients (12, 8%) developed ulcerative colitis (UC) during follow-up and were therefore reclassified as AIP type 2. The mean time between the clinical onset of AIP-NOS and development of UC was 14 months (range 4–48). Eight patients (17%) experienced a relapse after steroid treatment and two (4, 3%) needed immunosuppressive drugs (Azathioprine) because of recurrent relapses. None underwent resective surgery despite 30 patients (63, 8%) had a focal pancreatic involvement of the pancreas at imaging. **Conclusion:** Patients suffering from AIP type NOS have own clinical features. The risk of relapse is low (17%) but not irrelevant, as well as the risk of developing UC (12, 8%) during follow-up switching the diagnosis to AIP type 2.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0117 698 CASES OF PANCREATIC DISEASES TREATED BY EPDBD (ENDOSCOPIC PANCREATIC DUCT BALLOON DILATION) – ITS USEFULNESS AND SAFETY

T. Tsuji

Gastroenterology, Saitama Kyoudou Hospital, Kawaguchishi/Japan

Contact E-mail Address: t-tsuji@mcp-saitama.or.jp

Introduction: We started our original EPDBD (endoscopic pancreatic duct balloon dilation) therapy for pancreatic diseases in 1996. In these 22 years, 698 cases were treated by this method. We would like to show its usefulness and safety.

Aims & Methods: The balloon (6 mm diameter, 15 mm long -Boston Scientific) was inflated in the stenotic portion of the pancreas duct at 6atm. pressure for 1 minute several times. Then stone removal or EPS (endoscopic pancreatic stenting) was done. Following were evaluated; 1. The stone free rate and stone relapse rate in 568 pancreatic stone cases treated by EPDBD 2. The prognoses of 114 EPS-successful pseudocyst cases treated by EPDBD 3. The prognoses of 16 EPS-successful divisum cases (complete type 6, incomplete type 10) treated by EPDBD respectively. Complications after these therapies are also evaluated.

Results: The purpose of EPDBD therapy for pancreatic stone was to ease endoscopic procedures in the pancreatic duct and stone removal, and to reduce stone relapse rates. 568 cases of pancreatic stone were treated by EPDBD. They consisted of 90 cases treated by endoscopic method alone (via major papilla 62, minor papilla 28), and 478 cases treated by ESWL+ endoscopic method (via major papilla 381, minor papilla 97). After EPDBD therapy, the stone free rate was 75.3%, the pain free rate 97.1%. The stone relapse rate was 5.7% - this is a much lower result compared to other reports. We think that EPDBD contributes to this good result. Complications of EPDBD therapy were only minor bleeding from orifice at the therapy and mild pancreatitis after therapy for several days. Case A; 22 y/o male. idiopathic chronic pancreatitis, pancreas stone: After 4th ESWL, small stones remained in the head duct which can't be removed by basket catheter and severe pain continued, so EPDBD was done under good informed consent. After several dilation of the orifice and the head duct, stones were removed easily. This is our first case of EPDBD. In our hospital, EPS and ENPD (endoscopic nasal pancreatic drainage) are the preferred choice for pancreatic pseudocyst therapy after dilation of the stenotic duct. 114 cases were successfully treated without major complications, and their prognoses were good. Case B; 29 y/o female. alcoholic chronic pancreatitis, pancreatic stone: ERP via minor papilla revealed the duct rupture in the body portion and contrast medium flowed out into thoracic and abdominal cavity. After dilation of the stenotic duct in the body, EPS placement was done and she recovered quickly. The 16 cases of divisum consisted of 6 complete and 10 incomplete type. After EPDBD, EPS was successful in 2 cases via major papilla, and 14 cases via minor papilla with good prognoses. Case C; 72 y/o male. alcoholic chronic pancreatitis, pancreatic stone: ERP revealed type 2 incomplete divisum. After ESWL and EPDBD, stones were removed via minor papilla, then EPS was placed into minor papilla successfully.

Conclusion: By EPDBD therapy, the relapse rate of pancreatic stone decreased, and the success rate of endoscopic drainage and stenting in pseudocyst and divisum increased markedly with minor complications, and their prognoses were good. EPDBD is a safe and favorable procedure for pancreatic diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0118 ENDOSCOPIC ULTRASOUND AS A PREDICTOR AND GUIDE TO SUCCESSFUL ENDOTHERAPY IN CHRONIC PANCREATITIS

M. Sharma, P. Somani

Department Of Gastroenterology, Jaswant Rai Specialty Hospital, Meerut/India

Contact E-mail Address: sharmamalay@hotmail.com

Introduction: Pancreatic calculi (PC) are a sequelae of chronic pancreatitis (CP) and may obstruct and produce ductal hypertension leading to pain, the cardinal feature of CP. The rationale for endoscopic treatment of obstructing PC is based on the observation that pain subsides when the stone(s) is removed and drainage of pancreatic secretion is restored. Indications for endotherapy include stones <5mm size, stones in head of pancreas which are not impacted and absence of downstream strictures. The assessment prior to the procedure is done by MRCP or CT. However, problems are encountered during ERCP clearance which are not anticipated despite MRCP/CT. The problems are, possible impacted stones, hard stones, indeterminate stricture, and change of finding during ERCP. Hence, controversy exists. EUS can help by providing concordance or discordance with MRCP images and may help in further clarification.

Aims & Methods: We aimed to evaluate the role, feasibility and management changes of EUS prior to ERCP in patients planned for endotherapy in CP. Another objective was to evaluate whether EUS features of pancreatic duct (PD) stones can serve as a predictor of successful removal during ERCP. The data of 412 patients during the study period (2009–2016) with CP was retrospectively analysed. 143 were associated with stones in head/papillary region of pancreas. Out of these, 75 were excluded and remaining 68 were evaluated by EUS using a linear/radial echo endoscope prior to ERCP.

Results: Out of 68 cases, 48 were associated with hard stones with acoustic shadowing while 20 were associated with soft stones without acoustic shadowing. In 20 soft stones cases, ERCP was successful in 18 patients. In 48 patients with hard stones, there was failure of endotherapy in 40 patients which required ESWL/surgery. The remaining 8 patients required multiple sessions of ERCP for successful removal. Three patients had ampullary/papillary stones which were removed with precut sphincterotomy with immediate relief of pain. Four patients had ventral duct obstruction by calculi and hence underwent ERCP through minor papilla with successful removal of stones in 3 patients. In three

patients, there were calculi in pancreatic parenchyma and pancreatic duct simultaneously (ducto-parenchymal stones) and hence endotherapy was avoided. Three patients had pancreas divisum diagnosed on EUS and hence underwent minor papillotomy with stone removal. Three patients also had biliary obstruction with CBD stone/sludge and underwent biliary endotherapy. Four patients had pancreatic mass in head and underwent EUS-FNA with two patients diagnosed with pancreatic cancer who were referred for surgery. The remaining two were also referred for surgery. Four patients were found to have strictures on EUS and hence were referred for surgery. The presence of large (≥ 5 mm), hard, immobile stones were negative predictors of successful endotherapy. Small (<5 mm), ampullary/papillary stones were positive predictors.

Conclusion: Present study suggests that EUS can differentiate "soft PD stones" (without an acoustic shadow) from "hard PD stones" (with an acoustic shadow). This differentiation can help in predicting successful removal during ERCP. "Hard PD stones" diagnosed on EUS are better managed by ESWL. An EUS can influence important therapeutic decisions before endotherapy and can prevent unsuccessful attempts at ERCP and thus improve overall success/prognosis. An EUS has an additional advantage of making a diagnosis of ampullary/papillary stones and biliary obstruction which can be treated endoscopically. It can guide whether endotherapy needs to be performed through major or minor papilla. EUS by diagnosing pancreatic tumour/strictures missed on other imaging modalities allows early surgical reference and hence improves long-term prognosis. It can prevent unsuccessful attempts at endotherapy and its possible risks/costs. We conclude that EUS before endotherapy plays an important role regarding further management decisions in patients with CP.

P0119 UTILITY OF SERUM APOPTOSIS INHIBITOR OF MACROPHAGE FOR DIFFERENTIATING IGG4-RELATED DISEASE FROM MALIGNANT DISEASE

S. Tanoue, S. Hashimoto, S. Arima, Y. Nasu, F. Sasaki, S. Kanmura, A. Ido

Contact E-mail Address: tanoue@m.kufm.kagoshima-u.ac.jp

Introduction: IgG4-related disease (IgG4-RD) is characterized by the infiltration of inflammatory cells, such as plasma cells and macrophages, and fibrosis in tissues. We previously reported that apoptosis inhibitor of macrophage (AIM), which is secreted by macrophages, is related to the progression of hepatic fibrosis in chronic hepatitis C. Some studies have observed a relationship between IgG4-RD and malignancy. IgG4-RD is considered to represent a premalignant state or paraneoplastic condition.

Aims & Methods: To clarify the significance of the serum AIM levels in patients with IgG4-RD, we measured these levels in 22 healthy controls, 32 patients with IgG4-RD, and 36 patients with other pancreatic diseases (chronic pancreatitis [CP], intraductal papillary mucinous neoplasm [IPMN], pancreatic cancer [PC]). We also analyzed the prevalence of malignancy, the relationship between the appearance of malignancy and the diagnosis of 42 IgG4-RD, the type of cancer, and related factors, and we compared the age, gender, laboratory data, and AIM level.

Results: Fifteen malignancies were seen in 12 of 42 patients (28.6%). These diagnoses were made before the diagnosis of IgG4-RD for 10 malignancies in 8 patients (mean 4.8 years earlier, range 1–16 years), and after the diagnosis of IgG4-RD for 3 malignancies in 2 patients (mean 2 years later, range 1–3 years). Two malignancies in 2 patients were diagnosed at the same time as IgG4-RD. The AIM level was significantly higher in the IgG4-RD patients with malignancy than in those without malignancy. No significant differences were seen in the mean age or gender between patients with and without malignancies. The IgG4-RD group had significantly higher serum AIM levels than the healthy control or IPMN groups, and the levels tended to be higher than in the PC group.

Conclusion: Macrophages are reportedly related to IgG4 class switching in B cells and fibrosis in IgG4-RD. The serum level of AIM, which is secreted by macrophages, is considered a useful biomarker for evaluating the pathology and differentiating IgG4-RD and malignant diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endosonography (EUS) is one of the main diagnostic tools for the differential diagnosis of pancreatic masses. The aim of our study was to determine pitfalls of this technique in patients suspected of having pancreatic cancer.

This was done in consideration of the current knowledge about lesions mimicking cancer in the setting of a normal pancreatic parenchyma or existence of signs for pancreatitis

Aims & Methods: Retrospective analysis of prospectively collected data in our tertiary University center. From March 2007 to October 2015, 218 (124 men, 94 women; mean age 60 ± 14 years) patients underwent EUS for suspected solid pancreatic neoplasm because of cross sectional imaging results, idiopathic acute pancreatitis, weight loss, pancreatic hyperenzymemia, painless jaundice and elevated Ca 19-9 values. Cystic pancreatic lesions, pseudocysts and cystic pancreatic neoplasms were excluded from the analysis.

Results: Malignant lesions were diagnosed in 98 (45%) patients. 54 patients (24.8%) underwent surgery and 61 patients (28% of all patients) underwent clinical follow-up (16.5 ± 27.3 months, 18 needed surgery). 43 lesions not undergoing surgery needed EUS follow-up before achieving final diagnosis: pancreatic cancer ($n=6$, 9.8%), neuroendocrine tumor (NET) ($n=10$, 16.4%), paraduodenal pancreatitis ($n=5$, 8.9%), chronic pancreatitis ($n=13$, 21.3%), necrosis ($n=3$, 4.9%), autoimmune pancreatitis (AIP) ($n=3$, 4.9%), microcystic serous neoplasia ($n=1$), ventral/dorsal split ($n=1$), lipomatosis ($n=1$). EUS showed sensitivity and specificity for malignancy of 91.4% and 97.7%, respectively, in the non-pancreatitis group ($n=121$) and 44% and 87.1% in the pancreatitis group ($n=97$). Ca 19-9 elevation, rapid onset jaundice, double duct sign are useful indicators of malignancy both in the setting of normal and inflamed pancreas. Patients without pancreatitis the presence of enlarged lymphnodes or a mass in EUS, weight loss and worsening diabetes are predictor of malignancy. In patients without pancreatitis and without jaundice Ca 19-9 sensitivity for malignancy was 95% and specificity was 39%. In the pancreatitis group, Ca 19-9 sensitivity for malignancy (in patients without jaundice) was 45% and specificity was 86%. IgG4 elevation presented a sensitivity of 83.3% and a specificity of 77.8% for AIP, where one false elevation was seen in a distal cholangiocellular carcinoma.

Conclusion: Diagnostic accuracy of EUS is lower in the presence of pancreatitis. Focal autoimmune pancreatitis and paraduodenal pancreatitis are still confused with pancreatic cancer, also in the setting of a not inflamed pancreatic parenchyma. EUS in the setting of a normal parenchyma is an excellent tool to exclude pancreatic cancer. Tumor markers like Ca 19-9 and IgG4 values should be measured in the evaluation of pancreatic masses, also in the setting of chronic pancreatitis. In unclear cases, clinical and imaging follow-up with more than one modality (usually EUS with CT) were necessary for achieving a definitive diagnosis. If there is a high clinical suspicion of pancreatic neoplasm in a patient that does not undergo surgery and if EUS or other available imaging modalities are negative, repeated EUS after 2–3 months may be useful for detecting an occult pancreatic neoplasm.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic cancer is characterized by a high density of stroma. Interactions between tumor and stromal cells play a critical role in tumor progression and there is increasing evidence that pancreatic stellate cells (PSC), a main component of the stroma, may participate in the development of pancreatic cancer [1]. However, details of the mechanism underlying the interaction between PSCs and pancreatic cancer cells (PCC) are poorly understood.

Stromal cell-derived factor-1 (SDF-1 or CXCL12) belongs to the CXC chemokine family and is the ligand of CXCR4 [2]. It has been implicated in promoting the metastatic potential of breast, gastric, ovarian, prostate, lung and pancreatic cancer cells. Although SDF-1 reports of SDF-1 in pancreatic cancer cell lines are rare, it has been identified in pancreatic cancer tissue samples [3], suggesting that SDF-1 produced in activated PSCs may be an integral factor in tumor-stromal interactions.

Galectin-1 mediates communication between cells by binding to glycol-conjugated proteins on the cell surface. Studies have shown that it is involved in multiple cancer-related processes, including immunosuppression, angiogenesis and metastasis [4]. We previously reported that Galectin-1 was highly expressed in pancreatic cancer tissues; furthermore, the primary source of Galectin-1 was in activated PSCs within the stroma of cancer cells [5]. It has previously been hypothesized that Galectin-1 may also induce activation of PSCs and stimulate secretion of chemokines [6]; however, the biological mechanism and its activities in PCCs are unclear.

Aims & Methods: The purpose of this study was to identify the effect and elucidate the biological mechanism of Galectin-1 in PSCs and its role in tumor progression in pancreatic cancer.

Results: By conducting a chemokine antibody array assay and transwell invasion and migration assays we were able to show that Galectin-1 induced secretion of SDF-1 in PSCs leading to increased migration and invasion of PCCs. An NF- κ B activity assay indicated that the mechanism involved activation of NF- κ B. These observations were confirmed by qRT-PCR, ELISA and immunofluorescent assays, and were further verified by knockdown of Galectin-1 through lentiviral transfection and by employing inhibitors to block SDF-1, its ligand CXCR4 and NF- κ B. The in vitro findings were supported in an in vivo mouse model. In combination, our results demonstrated that Galectin-1 stimulated production of SDF-1 in PSCs through activation of NF- κ B, and that SDF-1 promoted invasion and migration of PCCs.

Conclusion: This study suggested that enhanced expression of Galectin-1 in stromal PSCs promotes metastasis in PDAC, thereby offering a potential target in the treatment of pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Intraductal papillary mucinous neoplasms (IPMN) are common pancreatic cystic neoplasms often detected by chance, and are sometimes precursors to invasive pancreatic cancer, resulting in a poor prognosis. These neoplasms are distinct from pancreatic ductal adenocarcinoma (PDA), conventional pancreatic cancer. In some IPMN cases, they cannot be detected before invasive and metastatic carcinoma develops. Knowledge of genetic backgrounds may lead to the discovery of IPMN with poor prognosis. Although whole-genome sequencing by next-generation sequencing (NGS) has become popular, the use of minute samples obtained by EUS-FNA is scarce. The value of NGS of pancreatic cystic fluids or walls has not been clear relative to imaging impressions. On the other hand, in some kinds of cancer, genetic analysis by NGS was used to select the treatment method. In this study, we analysed whether minute clinical samples from EUS-FNA are useful for genetic analysis and whether that aids in deciding the adequate treatment.

Aims & Methods: We analysed IPMN or PDA tissues using NGS and assessed the impact of NGS on clinical diagnosis. From January to December 2015, 14 tissue samples of undiagnosed pancreatic tumours (from 8 male patients, 6 female patients; mean age, 79.3 years; age range, 85–100 years; mean tumour size, 29.6×17.9 mm; tumour size range, 10–66 mm) were collected by EUS-FNA. The locations of the tumours were the head (3), body (4), and tail (5); we obtained their samples through the stomach or duodenum. EUS-FNA was performed using a curvilinear echoendoscope (GF-UCT 260; Olympus Medical Systems, Tokyo, Japan) and 22- or 25-gauge needles (ProCore; Cook Japan, Tokyo, Japan/Expect; Boston Scientific, Tokyo, Japan). Both slow-pull and negative pressure techniques were used to obtain specimens. We performed whole-genome sequencing of DNA obtained from IPMN or PDA using the Comprehensive Cancer panel, and compared their genetic mutations. Additionally, in the case of IPMN, we compared the differences in results between mural nodules and cystic fluids or walls.

Results: Pathological diagnoses showed 2 adenocarcinomas, 3 intraductal papillary mucinous carcinomas, 7 intraductal papillary mucinous adenomas; the remaining 2 cases could not be diagnosed. We used minute specimens obtained from EUS-FNA, and analysed genetic mutations of 10 cases using NGS. Homogenous genetic mutations were approximately 18% and heterogenous genetic mutations were approximately 25%. Five of the cases had mural nodules inside the cysts. We could analyse genetic mutations of cystic fluids or walls by the same way as of mural nodules. For the gradually growing IPMN without

mural nodules, it is useful to analyse genetic mutations of cystic fluids or walls. Currently, adequate samples from EUS-FNA were unavailable, and in some cases, we could not make a pathological diagnosis. Even in such cases, genetic analysis and the subsequent diagnoses of malignant or benign tumours may be possible. We could identify several cancer-related genes, such as *GNAS*, *KRAS*, *TP53*, and *BRAF*.

Conclusion: In this study, we performed whole-genome sequencing of samples obtained from IPMN or PDA using EUS-FNA. Consequently, genetic analysis by NGS may be effective in addition to pathological diagnosis when deciding the management of pancreatic tumours.

Introduction: The ubiquitously expressed non-receptor protein tyrosine phosphatase SHP2, encoded by *PTPN11*, is involved in the regulation of multiple signaling cascades. SHP2 was the first reported oncogenic tyrosine phosphatase, although more recently demonstrated tumor suppressive properties as well. SHP2 has been proven to be required for proper wild-type RAS activation, yet studies addressing the relevance of SHP2 for mutated KRAS dependent cancers, such as pancreatic and lung cancer are lacking.

Aims & Methods: Employing mutant *Kras*^{G12D} driven genetically engineered murine models (GEMM) of pancreatic ductal adenocarcinoma (PDAC) and non-small cell lung cancer, CRISPR/Cas9 mediated gene knockout in vitro, and patient derived tissue xenografts.

Results: In mutant *Kras*^{G12D} driven genetically engineered murine models (GEMM) of pancreatic ductal adenocarcinoma (PDAC) we detected a pivotal requirement of Shp2 for pancreatic carcinogenesis. Spontaneous as well as cerulein-triggered accelerated formation of premalignant lesions, and consequently PDAC, was almost completely abrogated in GEMM lacking *Ptpn11* in the pancreas. Even in *Ink4a/Arf* and *Trp53* deficient mutant *Kras*-driven tumors PDAC formation was dependent on Shp2 expression. Survival in these mice was substantially prolonged. Functional and transcriptional analyses revealed Shp2-dependent regulation of Ras-activity and its main downstream effectors, and of the mutant *Kras* related oncogenic transcriptional program. Importantly, oncogenic transformation of the pancreas by constitutive active mutants of Map2k1 or Pik3ca was not impaired by deletion of *Ptpn11*, confirming a striking dependency of oncogenic *Kras* on Shp2 expression. These findings were corroborated in mutant *Kras*-driven lung adenocarcinoma GEMMs, in which the lack of *Ptpn11* significantly delayed carcinogenesis suggesting a central role for Shp2 across organs. In contrast, spatiotemporal genetic deletion or pharmacologic inhibition of SHP2 in established *Kras*-mutant pancreatic and lung tumors or tumor cells had limited effect on growth capacity indicating that SHP2 is dispensable for tumor maintenance. However, focused pharmacologic screening using various substances revealed synergistic effects of SHP2 and MEK-inhibitors. In fact, co-inhibition of SHP2 and MEK prevented tumor relapse upon MEK monotherapy in endogenous GEMM and demonstrated synergistic potency in the treatment of patient-derived PDAC organoids and tissue xenografts.

Conclusion: Thus, as an integrator of RTK-Ras-MEK-ERK signaling downstream of almost all RTKs, SHP2 may hold promise as a therapeutic target not only in RTK-driven, but also in *Kras*-mutant tumors.

Introduction: Circular RNAs (circRNAs) are a novel class of noncoding RNAs that formed by a junction of the 5' end and 3' end. Increasing reports have shown that circRNA is dysfunction in neuro system diseases, cardiological heart diseases, human cancers and many other diseases. CircRNA have been demonstrated involving in tumorigenicity, proliferation, apoptosis, angiogenesis, migration, invasion and metastasis in human carcinoma. CircRNA can act as microRNA (miRNA) sponge and regulate the targets of miRNA. Circular RNA HIPK3 (circHIPK3) is originated from second exon of HIPK3 gene, which is upregulated in gastric, liver, esophageal. However, the mechanism remains unclear. Previous studies revealed that signal transducer and activator of transcription 3 (STAT3) as an oncogene that was activated in pancreatic carcinoma. Phosphorylation of STAT3 (p-STAT3) is a downstream target of interleukin 6 receptor (IL6R). Activation of STAT3 leads to malignancy of tumorigenesis, cell proliferation and migration. Knockdown STAT3 induces cell apoptosis by Bcl-xL, c-Myc, cyclinD1, etc. CircHIPK3 regulates BxPC3 cell proliferation through IL6R/STAT3 pathway. It may be a new target for the therapy of pancreatic carcinoma.

Aims & Methods: Our research is to study whether circHIPK3 can promote proliferation of pancreatic carcinoma cell line, BxPC3, and to explore the mechanism of circHIPK3 in cell proliferation. Cell viability was determined by cell counting kit-8 (CCK-8). Transient knockdown of circHIPK3 using specific siRNA targeting the conjunction of circHIPK3. Overexpression of miR-124 was transfected with synthetic miRNA mimic. Real-time quantitative reverse transcription-polymerase chain reaction (qRT-PCR) was performed to detect circHIPK3, miR-124 and mRNAs. The expressions of STAT3, p-STAT3, IL-6R were measured by Western blot. Overexpression of STAT3 was transfected with STAT3 plasmid. Dual-Luciferase Reporter Assay was performed to detect the interaction of circHIPK3 and miR-124.

Results: CircHIPK3 was upregulated in BxPC3 compared to human pancreatic duct epithelial cells (HPDE6-C7). Knockdown of circHIPK3, which didn't affect the linear transcript, significantly decreased cell viability of BxPC3. Bioinformatic analysis and luciferase assay demonstrated that circHIPK3 interacted with miR-124. QRT-PCR and Western blot confirmed that knockdown of circHIPK3 caused decreasing of mRNA levels of STAT3 and IL-6R and protein levels of STAT3, p-STAT3 and IL-6R. Previous studies confirmed that miR-124 negatively regulates STAT3, IL-6R via interacting with 3'-UTR (untranslated region). Ectopic expression of miR-124 decreased the expression of STAT3, p-STAT3, IL-6R. Indeed, miR-124 repressed BxPC3 cell proliferation which was consistent with si-circHIPK3. In addition, overexpression STAT3 abolished the si-circHIPK3 and miR-124 mimic induced cell suppression. QRT-PCR and Western blot confirmed that circHIPK3 and both STAT3, p-STAT3 and IL-6R were upregulated in BxPC3 cells than HPDE6-C7 cells while miR-124 was downregulated. MiR-124 was negatively correlated with circHIPK3 and STAT3, p-STAT3 and IL-6R.

Conclusion: In this study, we identified circHIPK3 promotes BxPC3 pancreatic carcinoma cell proliferation by targeting miR-124 and its target genes STAT3 and IL-6R. We found that miR-124 was a negative regulator of proliferation in BxPC3. And overexpression of STAT3 could attenuate the anti-proliferation of si-circHIPK3 and miR-124. These results demonstrated that circHIPK3 regulates BxPC3 cell proliferation by acting as miR-124 sponge.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Intraductal papillary mucinous neoplasms (IPMNs) are precursors of pancreatic ductal adenocarcinoma (PDA) and are also associated with multicentric lesions (field defect), where concurrent *de novo* PDA, independent of index IPMN lesion, can also develop. However, there are cases where PDAs arise adjacent to the index IPMNs, and occasionally they are pathologically indistinguishable whether the carcinoma developed from IPMN or was coincidental to the IPMN. A genetic approach can be useful to clarify the origin of each tumor compartment to determine if they shared molecular signatures.

Aims & Methods: Twenty concomitant PDAs and IPMNs (39 samples, including concurrent lesions) from surgically resected patients were enrolled in this study. Resected pancreata were sliced at 5-mm intervals for whole-section histological analysis, and the distance between PDA and IPMNs was measured after precise pathological mapping. Target amplicon sequencing that covers 18 PDA-associated genes including *KRAS*, *GNAS*, *TP53*, *SMAD4*, *CDKN2A/p16*, *CTNNB1* and *RNF43*, was performed using Ion PGM™ system (Thermo Fisher Scientific). Protein expression of TP53, SMAD4, p16, b-catenin, and RNF43 was also analyzed immunohistochemically.

Results: *KRAS* mutations were detected in 19/20 (95%) of PDAs and in 38/39 (97%) of IPMNs. "Adjacent" concomitant PDAs, defined as those that are 5 mm or less away from the IPMN (n=11), tended to harbor identical *KRAS* mutations as the index IPMNs (*KRAS* identical; n=8, 72%, *KRAS* different; n=3, 27%). All three cases with contiguous neoplastic lesions via the main pancreatic duct between PDAs and IPMNs had identical *KRAS* mutations. In contrast, 7 of 9 "distant" concomitant PDAs, defined as those greater than 5 mm away from the IPMN (n=9), possessed distinct *KRAS* mutations from the index IPMNs (78%). Mutations in *GNAS* were demonstrated in 14/20 (70%) of index IPMNs and in 29/39 (74%) of all IPMNs, but not in PDAs, supporting *de novo* carcinogenesis rather than progression from the IPMNs. PDAs harboring identical mutations in *KRAS* as IPMNs were significantly closer to the IPMNs (*KRAS* identical n=16, 0–35 mm, average 9 mm) relative to cases with distinct *KRAS* mutations in the PDAs and IPMNs (n=23, 0–75 mm, average 20 mm, p=0.0397). The *KRAS* identical group had a better prognosis than the *KRAS* different group (disease-free survival p=0.0245, overall survival p=0.205). Curiously, the molecular signature of 18 PDA-associated genes was not significantly different between two groups.

Conclusion: Multiple clones with distinct *KRAS* mutations were identified in pancreata during initiation and progression of IPMNs, and a subset of PDAs arising within the field defect share the same *KRAS* mutation with index IPMN lesions. Interestingly, PDAs adjacent to IPMN tend to have identical *KRAS* mutations, suggesting PDAs and index IPMNs may arise from a common founder. The *KRAS* identical group appears to have better prognosis relative to the *KRAS*-different group, implying distinct molecular programs may govern their biological behavior.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: igrigorieva@ngs.ru

Introduction: The pancreatic cancer is a leading cause of death in cancer carriers worldwide.

Aims & Methods: To study the polymorphism of the TP53 gene on the suppressor in the blood serum and to evaluate proinflammatory cytokines (IL-1 β , TNF- α), insulin blood serum levels at patients with various pathologies of the pancreas (cancer (PCa), acute and chronic pancreatitis (OP and CP)) with various genotypes of TP53. 150 patients were followed in a one-stage clinical trial (42 patients with OP, 81 with CP, and 27 with PCa). The diagnosis has been verified by clinic methods, ultrasonography, CT. The mean age of patients with PCa was 63.6 \pm 4.9 years. In patients with OP, blood sampling was carried out in the first 5 days after admission to hospital, patients with CP were examined at the stage of exacerbation. The concentration of IL-1 β , TNF- α , serum insulin was determined by ELISA using the ELISA kit and Monobind Inc., USA. The frequencies of genotypes and alleles of the TP53 gene by exon (exon 4, Arg72Pro) polymorphism were studied by PCR.

Results: The incidence of Arg/Arg genotypes of the TP53 gene was 65% in patients with PCa, 49% in the control group. In patients with PCa there was no homozygotic genotype Pro/Pro, in the comparison group - 13%, p < 0.05. The frequency of Arg/Pro genotypes was 35% in patients with PCa and 38% in the comparison group. The frequency of alleles of the TP53 gene in patients with PCa and in the comparison group was: Arg (82.5% and 68%), Pro (17.5% and 32%). The concentration of insulin in different genotypes in patients with PCa did not differ significantly and was 7.5 \pm 2.2 μ U/ml in Arg/Arg, Arg/Pro - 11.0 \pm 5.9 μ U/ml, p > 0.05. In the comparison group, the serum level of insulin was 5.7 \pm 1.8 μ U/ml. In patients with PCa, the glucose level was significantly higher, compared with patients with OP and CP (8.5 \pm 1.4 mMol/l, 5.4 \pm 0.3 and 5.1 \pm 0.1 mMol/l, respectively, P < 0.05). The level of IL-1 β was significantly higher in patients with OP than in patients with CP and PCa (5.1 \pm 1.7, 2.0 \pm 0.3 and 1.3 \pm 0.2 pg/ml, respectively), p < 0.05. The level of TNF- α in the serum of patients with OP was 3.5 \pm 0.5 pg/ml, and did not significantly differ from the serum level of patients with CP and PCa - 4.3 \pm 0.7 and 1.1 \pm 0.2 pg/ml, respectively. In patients with PCa, the level of TNF- α was significantly lower than in patients with CP, p < 0.05. The levels of IL-1 β in the serum of patients with PCa with different genotypes of the TP53 gene did not differ significantly and amounted to 1.1 \pm 0.2 pg/ml in patients with the Arg/Arg genotype, with

Arg/Pro genotypes of 1.2 \pm 0.3 pg/ml, p > 0.05. The level of TNF- α in the serum of patients with PCa with the Arg/Arg genotype was - 1.2 \pm 0.2 pg/ml, and did not significantly differ from the level in the serum of patients with the Arg/Pro genotype - 1.3 \pm 0.1 pg/ml.

Conclusion: The Pro/Pro genotype of the TP53 gene was significantly more common in the comparison group than in the patients with PCa. We detected significant differences in serum insulin levels in the comparison group and in patients with heterozygous genotypes, p < 0.05. The level of TNF- α in patients with PCa, CP was significantly lower than in patients with OP, and the level of IL-1 β was significantly lower in patients with PCa than in patients with CP.

Contact E-mail Address: kobatak@med.kobe-u.ac.jp

Introduction: Pancreatic cancer (PC) is one of the most lethal diseases due to the difficulty of early detection. There is no effective blood biomarker for screening. Recently metabolomics is considered to be a promising approach to discover disease biomarkers. We previously reported that the serum/plasma levels of some metabolites in PC patients were significantly changed compared with those of healthy individuals.

Aims & Methods: The aim of this study is to confirm and develop our candidate metabolomic biomarkers in blood of PC patients. Blood samples from PC patients and healthy volunteers (HV) were collected by two independent groups consisting of multiple institutions. The 1st set was included 55 PC in stage I and II and 58 HV. The 2nd set was included 16 PC and 16 HV. Sixteen candidate metabolites were selected from previous report. Quantitative analyses were performed by gas chromatography/tandem mass spectrometry (GC/MS/MS) together with their corresponding stable isotopes. In the 1st set, diagnostic models were constructed via multivariate logistic regression analysis. These results were validated using the 2nd set.

Results: In the 1st set, the levels of 11 metabolites differed significantly between PC and HV. Model Y consisting of 2 metabolites; i.e., histidine and xylitol showed high sensitivity (70.4%) than CA19-9. Furthermore, combination of model Y with CA19-9 increased its sensitivity (90.7%) and specificity (89.5%). In the 2nd set, combination of model Y with CA19-9 demonstrated high sensitivity (81.3%) and specificity (93.8%). In particular, it displayed very high sensitivity (100%) for PC in a resectable state.

Conclusion: Quantitative analysis using GC/MS/MS confirmed the possibility of metabolomics-based screening methods for PC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0128 COMBINED HISTO-CYTOLOGICAL ANALYSIS OF EUS-FNA SAMPLES FROM SOLID LESIONS USING STANDARD FNA NEEDLES GIVES BETTER DIAGNOSTIC YIELD AND ACCURACY

A. K. Banerjee¹, A. Cairns², L. Sanni², B. Paranandi¹, M. Huggett¹

Contact E-mail Address: ashwinibanerjee@gmail.com

Introduction: Diagnostic yield from EUS-FNAC (fine needle aspiration cytology) has improved in the past few years with better tissue acquisition techniques. Core biopsy needles are now available but are more expensive than FNAC needles. We assessed the diagnostic yield and accuracy of FNAC samples processed for both cytology and histology.

Aims & Methods: EUS-FNA samples of solid lesions (from September 2014 to September 2016) were included in a prospective audit of practice. Between September 2014 and January 2016 the standard practice was to send FNAC samples for cytology only. After this date, FNAC samples were filtered through a cassette. The solid material was sent in formalin to histology and the effluent to cytology for cytospin and cell block as previously. Cellularity was graded as adequate or inadequate. Final diagnosis was obtained from MDT outcomes.

Results: A total of 211 patients (118 male) were included. Samples were sent to cytology (n = 135; 107 pancreas, 10 biliary, 7 lymph nodes, 11 other), or cytology & histology (n = 76; 56 pancreas, 12 biliary, 5 lymph nodes, 3 other). Sample adequacy was 80.7% and 98.7% (p = 0.0004). Diagnostic yield (64.4%, 94.7%) and accuracy (81.3%, 96.1%) was significantly better in the combined (histology & cytology) group (p < 0.0001, p = 0.003). Within the combined group, diagnostic yield and accuracy improved by 20.5% (p = 0.007) and 26% (p = 0.0002) respectively when the sample was processed for both cytology and histology.

Conclusion: Our study confirms significant improvement in diagnostic yield and accuracy when samples were sent for both cytology and histology using standard FNAC needles.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0129 VERIFICATION OF INTERNATIONAL CONSENSUS GUIDELINES 2012 - SURGICAL INDICATION FOR BRANCH DUCT INTRADUCTAL PAPILLARY MUCINOUS NEOPLASM OF THE PANCREAS (BD-IPMN) WITH WORRISOME FEATURES

Introduction: In the revised international consensus guidelines of 2012 for the management of IPMN of the pancreas, resection is recommended for all main pancreatic duct IPMN. While in branch pancreatic duct IPMN (BD-IPMN), the indications for resection are more conservative. Cyst size >30 mm without "high-risk stigmata" can be observed without immediate resection. And EUS observation is recommended to decide a treatment strategy.

Aims & Methods: The present study was a retrospective investigation of surgical indication for BD-IPMN with worrisome features (WF). 466 patients with IPMN underwent pancreatic resection at 3 high volume centers in Japan between 1996 and 2014. Among them, 156 patients with BD-IPMN were enrolled in this study. The investigation of predictors of malignancy was done for 10 factors: age at time of surgery, sex, presence or absence of symptoms, serum amylase, CA19-9, CEA, tumor location, size of mural nodules (MN), diameter of main pancreatic duct (MPD), and cyst size of branch pancreatic duct (BPD). In preoperative examination, endoscopic ultrasonography (EUS) and computed tomography (CT) were considered to be essential. As for size of MN, EUS measurements were used in all 156 cases. For diameter of MPD and cyst size of BPD, the CT measurement values were used in all cases. In this study, BD-IPMN was defined as cases with cystic dilatation of BPD and the MPD diameter was considered <5 mm (*International Consensus Guidelines 2012*). According to the WHO histological classification of IPMN (2000), pathological diagnosis is classified as adenoma (IPMA), borderline (IPMB), and noninvasive and invasive carcinoma (IPMC). A central review of pathological diagnosis was done in the cases of IPMB and IPMC. Patients were categorized as benign (IPMA and IPMB) or malignant (IPMC).

Results: Pathological diagnosis was benign IPMN in 91 cases (58%) and malignant in 65 (42%). In univariate analysis CA19-9, MPD diameter, the sizes of MN and BPD cysts were significant factors. In multivariate analyses, size of MN ($p < 0.0001$) and cyst size of BPDs ($p = 0.0004$) were independent predictors of malignancy, and in ROC analysis AUC for these factors was 0.74 and 0.72, respectively. Among 78 cases with WF (BPD cyst size ≥ 30 mm), 45 cases (58%) had malignant IPMN. The rate of malignancy was significantly higher than that of patients without WF (26%) ($p < 0.0001$). Among 78 WF patients, 54 cases had MN with EUS observation. The rate of malignancy in patients with MN was significantly higher than that of WF patients without MN (69% vs 33%). With 7 mm taken as the cutoff value for the size of MN, the diagnosis of malignant IPMN had sensitivity of 76%, specificity of 73% and accuracy of 74%. Carcinoma without MN was present in 8 patients (8/45 = 17%) among 78 WF patients. Pathological findings of these patients were noninvasive carcinoma in 6, invasive carcinoma 2.

Conclusion: Algorithm for the management of BD-IPMN of *International Consensus Guidelines 2012* was acceptable. Mural nodules observed with EUS showed high predictive ability in BD-IPMN patients with WF. However, about 15% of carcinoma patients did not have nodules, and the handling of the diagnosis in such cases is a problem for the future.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cystic lesions of the pancreas represent a diagnostic dilemma as some of the lesions are non-neoplastic or benign, whereas others are malignant or have potential for malignant transformation. As indicated in a recent meta-analysis on diagnostic accuracy of endoscopic ultrasound (EUS) guided fine-needle aspiration (FNA) cytology, it is often impossible to obtain sufficient cellular material when diagnosing these lesions with current modalities [1]. Recently, a novel biopsy forceps (Moray™, US Endoscopy, Mentor, USA) has become available. It can be introduced through a 19 G FNA-needle, enabling the endoscopists to obtain histological specimens from the pancreatic cyst wall for the first time [2].

Aims & Methods: The aim of this study was to evaluate the use of the novel micro-forceps in a multicenter clinical setting. The patients referred for EUS evaluation of pancreatic cysts were included retrospectively from five European tertiary centers. Inclusion criteria were age of 18 or above and a pancreatic cyst of a size that allowed for FNA puncture. Exclusion criteria were pregnant or lactating females. A standardized data collection sheet including the information about patient demographics, cyst size, EUS/FNA findings, technical and clinical success, and the results of the biopsies taken was sent to the collaborating centers. Technical success was defined by successful puncture of the pancreatic cyst, subsequent successful mounting of the micro-biopsy forceps, and extraction of at least one micro-biopsy. Clinical success was defined by obtaining useful histological results.

Results: Twenty patients were included. There was a slight overrepresentation of female patients ($n = 12$, 60%) and the median age was 65 (range: 41–80). The patients had a median cyst size of 30 mm (range: 15–130 mm) and a median procedural time was 30, 5 min (range: 17–58 min). We report a technical success rate of 85% ($n = 17$) - technical failure was only seen in transduodenal puncture ($n = 3$, 15%). Biopsies were generally of good quality and contributed to the diagnosis in 14 patients (clinical success of 82%). Among these, there were ten cases of intraductal papillary mucinous neoplasia, two serous cystic adenomas, one mucinous cystic adenoma, one mucinous cystadenocarcinoma, and one pseudocyst. Two mild adverse events were recorded (10%), a case of re-admission due to non-specific abdominal pain and a mild acute pancreatitis.

Conclusion: The use of micro-biopsy forceps was until now only reported in case reports. This is a first larger-scale feasibility study. We conclude that the use of the micro-forceps seems feasible and safe with acceptable rates of technical and clinical success. However, prospective studies are needed in order to determine diagnostic potential of this instrument compared to the other modalities currently used.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0131 PANCREATIC DUCTAL CYTOLOGY: AN UNDERUSED DIAGNOSTIC TOOL

A. Peixoto, P. Pereira, E. Rodrigues-Pinto, F. Vilas-Boas, J. Lopes, G. Macedo
Centro Hospitalar De São João, Porto/Portugal

Contact E-mail Address: armandoafp5@gmail.com

Introduction: The diagnosis of pancreatic malignancy can be performed by brush cytology of the common bile duct or main pancreatic duct (MPD) during endoscopic retrograde cholangiopancreatography (ERCP). Preliminary data suggest that cytologic brushing of the MPD is safe and has a sensitivity equal to or slightly higher to that of bile duct cytology, although its clinical application is not defined.

Aims & Methods: In this work we report our experience in the execution of MPD brush cytology. ERCPs between 2014 and 2015 that involved brush cytology of pancreatic strictures were included. Cytologies were obtained using the Brush Master V (Olympus Medical System). Histological evaluation was performed by two experienced cytopathologists.

Results: Of the 18 patients evaluated, 16 were men and 2 women, with a median age of 62 years (range: 43–89). All patients underwent abdominal computed tomography and 3 patients had magnetic resonance imaging. In addition to pancreatic strictures, abdominal CT revealed cephalopancreatic lesions in 61%, findings suggestive of chronic pancreatitis in 28%, pancreas divisum in 6%, and pancreatic inflammatory features in 6%. The distribution of the strictures was: head - 16, head and body - 1, tail - 1. The pancreatic duct was dilated in 16 patients with a median of 7.5 mm (IQR: 6–15). The diagnostic values of MPD brush cytology for pancreatic cancer were: sensitivity - 81.8%, specificity - 100%, positive predictive value - 100%, negative predictive value - 77.8%, acuity - 88.9%. Sixty-one percent ($n = 11$) of the patients had a final diagnosis of pancreatic adenocarcinoma, 5.6% ($n = 1$) of neuroendocrine tumor and 33.3% ($n = 6$) inflammatory stricture. All the adenocarcinomas lead to strictures in the head of the pancreas. The diagnosis of neuroendocrine tumor was made by

endoscopic ultrasonography fine needle aspiration. One patient developed mild pancreatitis (5.6%).

Conclusion: In patients with suspected cephalopancreatic adenocarcinoma referred for ERCP, MPD brush cytology may be performed beyond biliary cytology, as it may improve cytologic diagnosis of malignancy without increasing complications rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic metastases (PM) account for 1–2% of pancreatic tumors. Several cancer types metastasize to the pancreas, but even recently developed cross-sectional imaging modalities have difficulties distinguishing PM from primary pancreatic tumors. Moreover, their prognostic significance is poorly defined.

Aims & Methods: The aims of this study were to clarify the incidence of primary tumors leading to PM, the clinical characteristics, and prognoses, and to define the prognostic factors for survival. A retrospective analysis was performed at 39 Japanese tertiary referral hospitals between January 2005 and August 2015, after receiving approval from the institutional review board of each hospital. We identified the patients based on data obtained from each institutional database, and analyzed patient and tumor characteristics, and survival time. All the patients enrolled in the analysis were histopathologically or cytopathologically diagnosed with PM. Kaplan-Meier analysis and Cox's proportional hazard models were applied to evaluate overall survival and survival analysis, respectively.

Results: We enrolled 159 patients (median age 74.5 years) with a pathologic diagnosis of PM. The most common primary tumor was renal cell carcinoma (38.4%, n=61), followed by lung cancer (24.5%, n=39), colorectal cancer (11.3%, n=18), sarcoma (6.3%, n=10), breast cancer (6.3%, n=10), and other cancer (n=21). At the time of the diagnosis of PM, 38 patients (24%) had at least one tumor-related symptom. Additional extra-pancreatic metastases were diagnosed in 94 patients (59%). Sixty-four patients (40%) underwent surgical resection, and no surgical resection was performed in 95 patients (60%). Additional therapies were chemotherapy (n=69), chemoradiation (n=4), radiation (n=3), palliative care, and unclear (n=2). Eight patients were lost during follow-up and 151 patients were included in the statistical analysis. All patients with PM had a median overall survival of 43.0 months, with 3- and 5-year survival rates of 52.5% and 42.6%, respectively. Among the five frequent primary sites of PM, prognoses of RCC, breast cancer, and colorectal were better than those of lung cancer and sarcoma. Univariate Cox proportional regression analysis identified four prognostic factors: pancreatic resection (hazard ratio [HR] 0.31, 95% confidence interval [CI] 0.18–0.57, $p < 0.001$), extra-pancreatic metastases (HR 3.07, 95%CI 1.71–5.51, $p < 0.001$), tumor-related symptoms at PM diagnosis (HR 3.88, 95%CI 2.29–6.56; $p < 0.001$), and pathologic diagnosis of primary tumors ($p < 0.001$). Multivariate Cox proportional regression analysis identified three independent prognostic factors: extra-pancreatic metastases (HR 2.13, 95%CI 1.11–4.07, $p = 0.02$), tumor-related symptoms at diagnosis (HR 5.39, 95%CI 2.92–9.91, $p < 0.001$), and pathologic diagnosis of primary tumors ($p < 0.001$).

Conclusion: Treatment strategies and prognoses for PM completely differ according to the primary tumor type. A definitive pathologic diagnosis of PM is essential for selecting the appropriate treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: National Comprehensive Cancer Network (NCCN) guidelines recommend chest x-ray or chest computed tomography (CT) for the staging of potential resectable pancreatic adenocarcinoma (PDA). However, there is limited data supporting these guidelines, and the prevalence of lung metastasis is not well defined on staging CT scans. We report our findings of patients with lung metastasis during initial staging and follow-up of patients with PDA.

Aims & Methods: Data was prospectively collected from May 2013 to September 2016 for PDA patients who were presented at a multidisciplinary pancreas conference (MDPC) at a large tertiary care center. All patients were staged with CT pancreatic protocol, CT chest and Endoscopic Ultrasound. Patients with findings of lung lesions on initial staging chest CT were followed prospectively. Metastatic lung lesions were determined based on definite imaging characteristics with clinical consensus or lung biopsy results.

Results: A total 278 PDA patients referred to MDPC were staged with CT chest (Table 1). Out of these, 36 (12.6%) patients were found to have either malignant (N=6) or indeterminate (N=30) lung lesions on initial staging CT chest. Out of the six malignant lung lesions, 5 (1.8%) patients had metastatic PDA lesions, and 1 (0.35%) patient had incidental primary lung cancer. On a follow-up of 30 patients with indeterminate lung lesions, 8 patients (26.7%) were later determined to be lung metastasis. The overall prevalence of definite lung metastasis was at least 4.8% (13/278). The prevalence of lung metastasis in pancreatic head cancer was 3.0%, while body and tail masses was 10.5%. Lung metastasis was almost four times more likely in the body, and tail masses (OR=3.83, CI 1.2–11.8, $p=0.02$) compared to head. Overall CT chest resulted in change in management plan in 9 (2.9%) patients due to change in the stage to metastatic (8) and diagnosis primary lung cancer (1). Staging with CT chest changed otherwise resectable disease to unresectable/metastatic in 5 patients (1.8%) and borderline resectable to metastatic disease in 2 (0.7%) patients. Prevalence of isolated PDA lung metastasis without any other metastasis was 2.8% (8/278).

Table 1: Comparison of patient and tumor characteristics.

Characteristics	Patients without Lung metastasis N = 265	Patients with LungMetastasis N = 13	P value
Age (yrs), mean (S.D)	68.6	64.8	0.22
Male (%)	48.4	69.2	0.14
Race, Caucasian (%)	90.2	100	0.36
Mass size (mm), mean (S.D)	26.9	31.1	0.16
Mass Location			
Head (%)	76.7	46.2	0.01
Body/Tail (%)	23.3	53.8	
CA 19-9, mean (S.D)	899 (1528)	961 (482)	0.90

Conclusion: Our study showed that the prevalence of pulmonary metastasis in PDA was clinically relevant to mandate routine staging with CT chest. Prevalence was significantly higher for pancreatic body and tail cancers compared to the head. Staging CT chest resulted in a change in the stage of PDA and management decisions.

Introduction: New lesions (metachronous pancreatic cancer) and recurrence may develop in the remnant pancreas after initial resection for pancreatic cancer and Intraductal Papillary Mucinous Neoplasm (IPMN). Endoscopic ultrasonography (EUS) is proved as a more specific and sensitive method for pancreatic lesion. However, there is no report about EUS after pancreatectomy. If it is possible to observe from the anastomotic part to remnant pancreas under the EUS, remnant pancreatic cancer may be pointed out an early stage.

Aims & Methods: The aim of this study was retrospectively to investigate the observation ability of EUS for remnant pancreas. In this retrospective study, 44 patients who underwent EUS for remnant pancreas were enrollment. The definition of observation under the EUS for remnant pancreas was as follows, total observation for remnant pancreas observed from liner white line (anastomotic part) to opposite side pancreas, otherwise it was insufficient observation. We compared the detection rate of EUS findings and that of CT or MRI findings.

Results: Among the 395 patients who underwent pancreatectomy at the JA Onomichi General Hospital between December 2002 and March 2016, the enrolled patients were 44 who underwent EUS for remnant pancreas. In the surgical procedure, pancreaticoduodenectomy (PD) including pylorus-preserving PD (PPPD) and subtotal stomach-preserving PD (SSPPD) was 20 cases and distal pancreatectomy (DP) was 24 cases. Total observation of remnant pancreas was possible in 41 cases (93%). Seven of 44 cases showed the lesion of recurrence in the remnant pancreas. Although CT or MRI was able to point out it in only 2 cases, EUS was able to point out it in the remnant pancreas of all cases. Stage of six cases were as follows, 1 case of stage 0, 2 cases of stage Ia, 3 cases of stage IIB. The other case was IPMN. We were able to perform EUS-FNA for lesion in the remnant pancreas in all cases. Pathological results were positive in 5 cases. One of the other 2 cases was negative (class III), but it was a recurrence by surgery. The other case was strongly suspected to recurrence by Positron emission tomography (PET). Second pancreatectomy was performed in 4 out of 7 cases. The sensitivity of EUS-FNA was 71.4% (5/7), the specificity was 85.7% (6/7) and the accuracy was 71.4% (5/7). In addition, a comparison of detection ability of EUS and CT or MRI findings showed that EUS was significantly superior to CT or MRI ($P < 0.01$)

Conclusion: EUS was able to observe remnant pancreas in almost cases. We were able to perform EUS-FNA for lesion in the remnant pancreas. In addition, the detection ability of EUS was significantly superior to that of CT or MRI. We believe that EUS and EUS-FNA should be underwent for lesion in remnant pancreas, and that remnant pancreatic cancer may be pointed out an early stage.

Introduction: Number of studies reported that patients with intraductal papillary mucinous neoplasms of pancreas (IPMNs) are at the increased risk for occurrence of extrapancreatic malignancies (EPMs). We have conducted a study in order to assess the prevalence and incidence of EPMs in a cohort of Italian patients diagnosed with IPMN and to identify risk factor for their occurrence.

Aims & Methods: A hospital based single-centre study was conducted in hospital Santa Maria della Misericordia, Udine, Italy. Hospital records were screened in order to identify all new diagnosed IPMN cases in period January 1st 2009 – December 31st 2015, as well as those seen during the follow-up. Data were extracted for all the cases identified on demographics, clinical characteristics, treatment and outcomes. Furthermore we searched for any EPMs diagnosed previous, synchronous or metachronous in relation to IPMN diagnosis. We compared the distribution of the demographics clinical characteristics, treatment and outcomes among patients with and without EPMs by univariate analysis. The ratio of the observed (O) number of patients with EPMs to the expected (E) number was calculated along with 95% confidence interval (CI).

Results: Number of 198 patients with IPMN was included in the study. Patients were predominantly female (59.1%) and age 70–79 (47.2%). IPMNs were predominantly branch duct (79.2%), multifocal (66.2%) and were not subjected to surgical treatment (89.9%). We identified 72 EPMs in 63 patients with IPMN (31.8%). Eight patients have had 2 EPMs and 2 patients have had 3 EPMs. Among identified EPMs, 51 (70.8%) were diagnosed previous to IPMN, 17 (23.6%) synchronous to IPMN and 4 (5.6%) metachronous to IPMN. Among most frequently diagnosed were colorectal cancer (12 patients, 6.1%), breast cancer (8 patients, 4.0%), renal cell cancer (8 patients, 4.0%) and prostate cancer (7 patients, 3.5%). O/E ratios for EPMs were significantly increased for

cancer in general (3.66, CI 95%: 2.39–5.37) as well as for renal cell carcinoma (9.62, CI 95%: 1.98–28.10) and prostate cancer (4.91, CI 95%: 1.59–11.45), while borderline significance was observed for colorectal carcinoma (3.59, CI 95%: 0.98–9.19) and breast cancer (3.16, CI 95%: 1.03–7.37) (Table 1). We did not identify any of the demographics and clinical characteristics to significantly influence EPM occurrence among patients with IPMN.

Table 1: Observed and expected number of patients with extrapancreatic malignancies in 60 patients with intraductal papillary mucinous neoplasms

	Observed	Expected	O/E	CI 95%
ALL	26	7, 096	3, 66	2.39–5.37
prostate cancer	5	1, 019	4, 91	1.59–11.45
breast cancer ^a	5	1, 583	3, 16	1.03–7.37
colorectal cancer	4	1, 115	3, 59	0.98–9.19
renal cell cancer	3	0, 312	9, 62	1.98–28.10

^aCalculated for females.

Conclusion: We report an increased prevalence of EPMs in Italian patients with IPMN, especially for renal cell carcinoma, prostate, colorectal and breast cancer. A systematic surveillance of IPMN cases for such cancer types would be advised.

P0136 CLINICAL CHARACTERISTICS OF SECOND PRIMARY PANCREATIC CANCER

J.H. Jo, I.R. Cho, H.S. Lee, M.J. Chung, S. Bang, S.W. Park, S.Y. Song, J. Chung, J.Y. Park

Department Of Internal Medicine And Institute Of Gastroenterology, Yonsei University Health System Dept. of Internal Medicine Dept. of Gastroenterology, Seoul/Korea, Republic of

Contact E-mail Address: woforce@naver.com

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is known to have an extremely poor prognosis. Several studies reported the increased risk of second primary pancreatic ductal adenocarcinoma (2nd PDAC) in cancer survivors. However, data on the characteristics of 2nd PDAC are insufficient. Studies of PDAC in the setting of second primary cancer can provide etiologic clues to understand PDAC.

Aims & Methods: The aim of this study was to investigate the clinical characteristics of the patients with second primary PDAC compared to patients with first primary PDAC. This retrospective cohort study included 1759 patients with PDAC. They were classified as having 2nd PDAC or first primary PDAC (1st PDAC) according to a prior diagnosed cancer that originated from different organ and diagnosed at least 6 months before the diagnosis of PDAC. Comparative analysis and multivariate survival analysis were used to evaluate the characteristics of the 2nd PDAC.

Results: A total of 1759 patients with PDAC were included in the cohort. Forty-three patients were classified as having synchronous 2nd PDAC and excluded from the analysis. There were 110 patients (6.4%) with 2nd PDAC and 1606 (93.6%) patients with 1st PDAC. The median interval between the diagnosis of the 2nd PDAC and the diagnosis of the prior cancer was 8.4 years (range 0.7–31.4 years) in the 2nd PDAC group. In the comparison of baseline characteristics between the 1st PDAC and 2nd PDAC groups, patients with 2nd PDAC presented significantly older age at diagnosis (66.5 vs. 62.2 years, $p < 0.001$), lower rate of alcohol consumption (25.5 vs. 36.8%, $p = 0.017$), higher rate of resectability of PDAC (26.4 vs. 15.9%, $p = 0.004$), and higher rate of receiving surgery as initial treatment (26.4 vs. 15.9%, $p = 0.018$) than patients with 1st PDAC. The most common origin of prior cancers was the stomach (22 of 110, 20.0%), followed by the thyroid (21 of 110, 19.1%), breast (19 of 110, 17.3%), colon (12 of 110, 10.9%), and others. The overall survival (OS) was slightly longer in patients with 2nd PDAC; however, the difference was not significant (11.8 vs. 12.3 months, $p = 0.068$). Multivariate analysis without resectable status showed that 2nd PDAC (HR 0.73, 95% CI 0.56–0.94, $p = 0.016$), age at diagnosis (HR 1.02, 95% CI 1.01–1.02, $p < 0.001$), and alcohol consumption (HR 1.28, 95% CI 1.13–1.47, $p < 0.001$) were significantly related to OS (Table 1). When resectable status was included in multivariate analysis, age at diagnosis (HR 1.02, 95% CI 1.01–1.02, $p < 0.001$), alcohol consumption (HR 1.25, 95% CI 1.11–1.42, $p = 0.001$), and resectable status at diagnosis (HR 0.30, 95% CI 0.25–0.36, $p < 0.001$) were significantly associated with OS. However, 2nd PDAC (HR 0.85, 95% CI 0.66–1.09, $p = 0.198$) was no longer significantly associated with OS after adjusting for resectable status. This analysis suggested that the association between 2nd PDAC and survival was owing to the higher resectability rate. When subgroups were separately analyzed according to initial treatment modality, the effectiveness of surgery and chemotherapy were similar between 2nd and 1st PDAC. In the subgroup of patients who received curative surgery, the median OS was 28.5 months (95% CI, 23.0–34.1) in the 1st PDAC group com-

pared with 33.1 months (95% CI, 9.0–27.2) in the 2nd PDAC group (N: 259 vs. 29, $p=0.860$). In the subgroup of patients who received chemotherapy, the median OS was 10.7 months (95% CI, 10.0–11.4) in 1st PDAC compared with 10.8 months (95% CI, 9.2–12.3) in 2nd PDAC (N: 1094 vs. 66, $p=0.952$).

Table 1: Cox proportional analysis for the contribution of clinical factors to overall survival

	Univariate		Multivariate		Multivariate	
	HR (95% CI)	p-Value	HR (95% CI)	p-Value	HR (95% CI)	p-Value
Second PDAC	0.81 (0.63–1.04)	0.093	0.73 (0.56–0.94)	0.016	0.85 (0.66–1.09)	0.198
Age, mean (SD)	1.02 (1.01–1.02)	<0.001	1.02 (1.01–1.02)	<0.001	1.02 (1.01–1.02)	<0.001
Male sex	1.12 (0.99–1.27)	0.056	1.04 (0.90–1.19)	0.627	1.03 (0.90–1.19)	0.645
Alcohol	1.23 (1.08–1.39)	0.001	1.28 (1.13–1.47)	<0.001	1.25 (1.11–1.42)	<0.001
Resectable status	0.30 (0.25–0.35)	<0.001	Not included		0.30 (0.25–0.36)	<0.001

Abbreviations: PDAC, pancreatic ductal adenocarcinoma; SD, standard deviation; HR, hazard ratio; CI, confidence interval.

Conclusion: Second primary pancreatic cancer had a higher rate of resectability, and there was no difference in the effectiveness of curative surgery and chemotherapy between 2nd and 1st PDAC. Therefore, when curative surgery for 2nd PDAC is possible, it should be conducted similarly to curative surgery for 1st PDAC. Considering the increased risk of 2nd PDAC in cancer survivors and the fact that surgery is the only curative treatment for this fatal cancer, more efforts are needed to develop screening programs for second primary pancreatic cancer in cancer survivors.

Introduction: The development of new technology including next-generation sequencing has accelerated seeking new biomarkers and implementation “precision medicine”. Generally, formalin-fixed paraffin-embedded tumor tissues obtained by surgery are used for molecular testing. The problem is that surgery is invasive, therefore, acquisition of adequate specimen by less-invasive procedure is getting significant factor. Endoscopic ultrasound-guided fine-needle aspiration and biopsy (EUS-FNAB) is the standard technique for diagnosing pancreatic solid tumor. There are several studies that have assessed the diagnostic yield of EUS-FNAB, comparing different needle sizes. Whereas, few reports had evaluated the sample volume of EUS-FNAB depends on the needle size. Therefore, we investigated the accuracy and assessed the adequacy of sample volume for “precision medicine”, evaluating EUS-FNAB specimens obtained by 22-gauge needles (22G) and 25-gauge needles (25G).

Aims & Methods: The aim of our study was to verify the accuracy and sample volume obtained by EUS-FNAB using 22G and 25G, evaluating the feasibility for immunohistochemistry (IHC) staining. This was a retrospective study in a single tertiary referral center. Between October 2006 and November 2015, we investigated 153 patients of pancreatic ductal adenocarcinoma (PDAC) undergone diagnostic EUS-FNAB before neoadjuvant gemcitabine-based chemoradiotherapy. EUS-FNAB was performed with rapid on-site evaluation. We reviewed the sampling rate, the accuracy rate, and the success rate of IHC staining between 22G and 25G.

Results: 153 patients underwent EUS-FNAB; 70 patients in 22G group and 83 patients in 25G group. The overall sampling rates on cytology and histology were 100% (153/153) and 98.0% (150/153), respectively. Both 22G and 25G groups had high sampling rates on cytology and histology, and the sampling rate did not differ between 22G and 25G groups. The overall diagnostic accuracy rates on cytology and histology were 94.8% (145/153) and 79.7% (122/153), respectively. The accuracy rates of 22G and 25G on cytology were 94.3% (66/70) and 95.2% (79/83), whereas those on histology were 80.0% (56/70) and 79.5% (66/83), respectively. The overall accuracy rate on combined analysis both cytology and histology was 96.7% (148/153). The accuracy rates on combined analysis of 22G and 25G were better than the accuracy rates on cytology or histology alone; 97.1% (68/70) for 22G and 96.4% (80/83) for 25G. The diagnostic accuracy on cytology, histology and combined analysis did not differ significantly between 22G and 25G groups. We performed hENT1 IHC analysis using the remaining cell blocks followed by cytological/histological diagnosis for PDAC. 69% (106/153) of PDAC provided sufficient specimens for IHC staining. The success rate of IHC staining did not differ significantly between 22G (67%, 47/70) and 25G (71%, 59/83) ($p=0.60$).

Conclusion: In the present study, both 22G and 25G diagnostic yields were high; the accuracy rate on histology of 25G was equivalent to that of 22G. Moreover, EUS-FNAB specimens obtained by both 22G and 25G can be adequate for IHC

analysis. Further investigations such as EUS-FNAB needle design and novel cell block preparation are needed for acquiring of adequate material not only for diagnosis, but for “precision medicine”.

P0138 FEASIBILITY OF GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION WITH CONTINUOUS LOW-DOSE ASPIRIN FOR PATIENTS ON DUAL ANTIPLATELET THERAPY

H. Harada, S. Suehiro, D. Murakami, R. Nakahara, T. Ujihara, T. Shimizu, Y. Katsuyama, K. Hayasaka

Gastroenterology, New Tokyo Hospital, Matsudo, Chiba/Japan

Contact E-mail Address: nerimaendo@hotmail.co.jp

Introduction: Endoscopic submucosal dissection (ESD) for gastric neoplasms with continuous low-dose aspirin (LDA) is comparatively acceptable according to recent guidelines [1–3]. This study aimed to evaluate risk factors for post-operative bleeding after gastric ESD with continuous LDA for patients on dual antiplatelet therapy (DAPT).

Aims & Methods: This retrospective study was conducted at New Tokyo Hospital. A total of 597 gastric neoplasms (496 with early gastric cancers and 101 with gastric adenomas) in 571 consecutive patients were treated with gastric ESD between January 2010 and October 2016. A total of 102 lesions were excluded from this study: 51 lesions due to anticoagulation therapy; 25 lesions in patients receiving antiplatelet therapy excluding single-LDA and DAPT; and 26 lesions in patients who underwent ESD for more than two lesions at the same time. Thus, a total of 495 patients were enrolled in this study. The patients were categorized according to antiplatelet therapy (APT). APT was defined as follows: oral administration of single-LDA (aspirin [100 mg/day]) or DAPT (aspirin [100 mg/day] plus clopidogrel [75 mg/day]). Logistic regression analysis was performed for risk factors of bleeding after gastric ESD.

Results: The patients were categorized into two groups: no APT ($n=370$) and APT ($n=125$). APT included single-LDA ($n=74$) and DAPT (LDA plus clopidogrel; $n=51$). Among them, 46 received continuous LDA on single-LDA and 40 received continuous LDA on DAPT. The postoperative bleeding rate in the APT group was significantly higher than that in the no APT group (16.0% vs. 5.9%; $P=0.001$). Postoperative bleeding occurred in seven and nine patients in the continuous single-LDA group (15.2%) and the continuous LDA on DAPT group (22.5%), respectively. In multivariate analysis, specimen size of ≥ 40 mm (odds ratio [OR] 3.19; 95% confidence interval [CI], 1.65–6.16; $P<0.001$) was a sole independent risk factor for postoperative bleeding (Table.1). In subgroup univariate analysis among continuous LDA users, continuous single-LDA and continuous LDA on DAPT were not related to postoperative bleeding. Table.1 Multivariate analysis for postoperative bleeding after ESD.

	Odds ratio	95% CI	P-value
Coronary artery disease	1.52	0.61–3.78	0.370
CKD with hemodialysis	3.21	0.97–10.60	0.056
Continuous LDA	2.13	0.83–5.45	0.116
Specimen size ≥ 40 mm	3.19	1.65–6.16	<0.001

Conclusion: This study suggests that continuous LDA may be acceptable for gastric ESD in patients on DAPT. However, patients with continuous LDA on DAPT should be monitored carefully for postoperative bleeding after gastric ESD because the rate of postoperative bleeding in the continuous LDA on DAPT group was higher than that in the other groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Peroral endoscopic myotomy (POEM) has received wide acceptance as a highly effective and safe treatment for esophageal achalasia. Short-term and small-scale studies are ample but long-term large-scale studies are few.

Aims & Methods: The aim of this study was to systematically analyze our long-term results of POEM, with particular emphasis on POEM failures and associated risk factors. This is a single center study. Consecutive POEM patients between Aug. 2010 and Dec. 2012 were included. Kaplan-Meier survival function was used to estimate clinical success rate at each year. The Cox proportional hazards model was used to analyze risk factors related to recurrence.

Results: A total of 564 patients were included. Mucosa injuries happened in 93 patients (16.5%) and 36 patients (6.4%) experienced major perioperative adverse events. The Eckardt score and lower esophageal sphincter (LES) pressure were significantly decreased after POEM (median Eckardt score 8 to 2, $p < 0.05$; median LES pressure 29.7 mm Hg to 11.9 mm Hg, $p < 0.05$). During a median follow-up period of 49 months (range 3–67 months), fifteen failures occurred within 3 months, 23 between 3 months and 3 years, and 10 after 3 years. The estimated clinical success rates at 1, 2, 3, 4, and 5 years were 94.2%, 92.2%, 91.1%, 88.6% and 87.1%, respectively. Multivariate Cox regression revealed long disease duration (≥ 10 years) and history of prior interventions to be risk factors for recurrence. Clinical reflux occurred in 37.3% (155/416) patients.

Conclusion: POEM is a highly safe and effective treatment for esophageal achalasia with favorable long-term outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0140 PATIENTS WITH CHRONIC GASTROINTESTINAL ISCHEMIA HAVE AN ALTERED SUBLINGUAL MICROCIRCULATION

Introduction: Chronic gastrointestinal ischemia (CGI) results of insufficient blood supply to the gastrointestinal tract¹. The majority of CGI patients has systemic disorders of the circulatory system including hypertension, diabetes and other cardiovascular risk factors². Studies in patients with acute gastrointestinal ischemia found a correlation between intestinal ischemia and sublingual microcirculatory alterations³. However, little is known about microcirculatory alterations in patients with CGI. We hypothesized that patients with CGI may reveal sublingual microcirculation alterations. We further hypothesized that such alterations will be amplified when challenging the patient to enteral caloric challenges. This would provide a patient-friendly means to identify CGI.

Aims & Methods: Consecutive patients with CGI and healthy controls were prospectively included between September 2014 and August 2015. All patients received the standard work-up for CGI, consisting of assessment of medical history and symptoms, radiological imaging of the gastrointestinal arteries, and endoscopic visible light spectroscopy (VLS) for assessment of gastroduodenal mucosal oxygen saturation. The sublingual microcirculation was evaluated before (T0) and 20 minutes after enteral feeding (T1). Total vessel density (TVD (mm/mm²)), perfused vessel density (PVD (mm/mm²)), proportion of perfused vessels (PorPV (%)), and microvascular flow index (MFI (AU)) were assessed.

Results: We included 12 consecutive patients (63.2 (IQR 48.8–70.4) years, 67% male) with CGI and 12 controls (32.7 (IQR 27.7–38.1) years, 42% male). At baseline, patients with CGI had a decreased PORPV of the sublingual small vessels (median 84.77% vs 95.70%, $p = 0.006$), PORPV of all vessels (median 85.38% vs 95.27%, $p = 0.007$) and MFI of all vessels (median 3.00 vs 2.80, $p = 0.039$) compared to healthy controls. After caloric challenge, PVD increased significantly in both in small (PVD_s) vessels and all vessels (PVD_a) in patients with CGI (PVDs (T0) median 16.3 (IQR 13.3–22.1) mm/mm² vs (T1) 19.9 (IQR 14.2–26.2) mm/mm², $p = 0.008$; PVDa (T0) median 19.1 (IQR 16.2–23.6) mm/mm² vs (T1) 22.2 (16.5–28.9) mm/mm², $p = 0.02$; PorPVs (T0) median 84.8% (IQR 75.3–90.4) vs (T1) 91.0% (80.1–93.8), $p = 0.01$). In contrast, no significant changes in microcirculatory parameters were observed after caloric challenge in the healthy controls.

Conclusion: Patients with CGI have impaired sublingual microcirculation compared to healthy controls. They also show significant alterations in the sublingual microcirculation after oral caloric challenge compared to healthy controls. Sublingual microcirculation visualization may offer a fast non-invasive diagnostic opportunity to diagnose patients with CGI.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0141 CONVENTIONAL NARROW BAND IMAGING HAS GOOD CORRELATION WITH OLGA STAGING OF GASTRITIS

A. Gawish¹, A. Elbahrawy¹, S. Mabrouk¹, M. Abdellah¹, M. El Fayoumie¹, A. Aboelfotoh¹, M. Eldahshan¹, F. Al Ghamry¹

¹Internal Medicine, Al Azhar University, Cairo/Egypt

Contact E-mail Address: dr.ahmedgawish1988@gmail.com

Introduction: The operative link of gastritis assessment (OLGA) staging system is widely used to assess the risk for gastric cancer on the basis of several biopsy samples taken from the antrum and corpus.

Aims & Methods: In this study we attempted to evaluate whether gastritis staging using conventional narrow band imaging (NBI) endoscopy is equivalent to that determined by histopathology. Fifty (50) consecutive patients with *Helicobacter Pylori* (H. Pylori) related gastric atrophy selected according to NBI endoscopic findings 1. The diagnosis of H. Pylori based on direct detection of the organism by histopathology assessment. The NBI grade of lower gastric atrophy scored from 0 to 3. The histopathological assessment of lower gastric atrophy was based on OLGA scoring system. Furthermore, we assessed the presence or absence of antral intestinal metaplasia. The NBI and histology stages of gastric atrophy were assessed using a combination of scores for the antrum and corpus. These stages further classified into low risk (stage 0, I and II) and high risk (stage III and IV). Finally the degree of correspondence between NBI and histopathology, in prediction of gastric cancer risk, was assessed.

Results: The mean age of included patients was 38.7 ± 15.6 years, they were 21 (42%) males and 29 (58%) females. 38 (76%) and 13 (26%) patients have pseudopyloric and intestinal metaplasia respectively. Overall 41 (82%) and 9 (18%) patients have low and high gastric cancer risk respectively. The sensitivity of NBI in diagnosis of *Helicobacter Pylori* infection, gastric atrophy and intestinal metaplasia were 96% ($n = 48/50$), 100% and 61.5% ($n = 8/13$) respectively. The degree of correspondence between the scores obtained by NBI and by histology was 58% (29/50) for the lower gastric body atrophy and 86% ($n = 43/50$) for the antral intestinal metaplasia. The degree of correspondence between the high risk and low risk groups determined on the basis of NBI endoscopy on one hand and histopathology on the other hand was 80% ($n = 40/50$).

Conclusion: NBI is able to approximate histopathological staging of gastritis to good extent. More studies and training will further improve the performance of our suggested new staging method.

Introduction: Endoscopic submucosal dissection (ESD) is a standard treatment for early gastric cancer. Development of the ESD device has been conducted recently. Splash M-Knife®, the new multi-functional ESD device was invented to achieve complete ESD with a single device. It achieves clear marking, better hemostasis and smoother operation during a procedure without replacing the knife.

Aims & Methods: The aim of this study was to investigate clinical outcome of ESD for early gastric cancer with a new device (Splash M-knife®). In total, early gastric cancer treated by ESD with a needle-type knife between January 2012 and August 2016 at Kitakyushu Municipal Medical Center were retrospectively reviewed. Lesions treated by ESD with a conventional needle-knife (ESD-C, $n = 76$) and by ESD with a new device (ESD-N, $n = 73$) were compared. Multivariate analyses and propensity score matching were used to compensate for the differences in age (≥ 75 years vs < 75 years), sex (male vs female), underlying disease (none vs with cardiopathy or cirrhosis), antithrombotic drugs (not receiving or discontinuation vs continuation), tumor size (≥ 21 mm vs < 21 mm), lesion location (in the upper or middle third of the stomach vs in the lower stomach), lesion position (in the lesser curvature of the stomach vs others), macroscopic type (flat or depressed vs elevated), presence of ulceration (presence vs absence) and operator level (experience of ≥ 50 vs experience < 50). As primary endpoint, the rate of the lesions that need hemostatic forceps was compared

among two groups. As sub-analyses, the cutting time, rate of en-block/complete resection and rates of adverse events were evaluated among two groups.

Results: Propensity score matching analysis created 46 matched pairs. Adjusted comparisons between two groups showed a significantly smaller usage rate of hemostatic forceps in ESD-N than that in ESD-C (4.35% vs 84.8%, $p < 0.001$), and similar treatment outcomes (en-block resection rate: 100% in both groups; complete resection rate: 97.8% vs 100%, $p = 1$; cutting time: 84.6 min vs 83.0 min, $p = 0.89$; perforation during ESD: 0% in both groups).

Conclusion: Splash M-Knife® achieved better hemostasis and safer ESD for early gastric cancer. It may contribute to reduce cost for ESD by reducing usage of hemostatic forceps during ESD procedure.

Introduction: Intubation failure (IF) occurs when a trained endoscopist is unable to progress into the upper oesophagus via the oropharynx. The incidence is unknown, but estimated at 1.8%.^[1] There have been no studies exploring IF and follow-up findings. We aimed to assess the incidence, causes of IF, predictors of pathology in patients with IF, and follow-up findings.

Aims & Methods: We retrospectively identified all gastroscopies performed at a district general hospital between August 2010–August 2016 from an endoscopy database, and reviewed cases with IF. We excluded patients who had achieved oesophageal intubation. Data on sedation use, endoscopist status, indications, radiological and endoscopic findings were recorded. Procedural limitations were classified into 2 groups: ‘failure to tolerate’ (e.g. pulling out scope, anxiety) and ‘failure to progress’. Statistical analyses were made using Pearson’s χ^2 and Wilcoxon signed rank test.

Results: The incidence of IF was 0.95% (248/26130). 238 patients were identified, with a mean age of 63.2 (SD 16.1), with ‘failure to progress’ in 41 and ‘failure to tolerate’ in 197. Subsequent investigations included barium radiology (59.7%, $n = 142$), CT (21%, $n = 50$), repeat gastroscopy (29.4%, $n = 70$) and no further investigations (19.7%, $n = 47$). Structural pharyngeal abnormalities were detected in 41 (28.9%), comprising of cricopharyngeal hypertrophy (CPH) [49%], Zenker’s diverticulum (ZD) [14.6%], pharyngeal web (12.2%), ZD with CPH (9.8%), cervical spondylosis (7.3%) and other (7.3%). Endoscopist status was a predictor of IF (OR for medical vs. non-medical endoscopist 0.7, 95% CI: 0.5–0.9, $p = 0.007$). Within the IF cohort, predictors of structural causes on barium radiology included: dysphagia (OR 5.5, 95% CI: 2.5–11.8, $p < 0.001$), failure to progress (OR 5.2, 95% CI: 2.3–12.0, $p < 0.001$) and age ≥ 65 (OR 4.0, 95% CI: 1.8–8.9, $p < 0.001$). Repeat gastroscopy was successful in 63/70 (2 using nasendoscope) after increasing midazolam dosage (mean increase = 1.5 mg, 95% CI: 1.0–2.0 mg, $p < 0.001$). Diagnostic yield for barium radiology, CT and repeat gastroscopy were 69.0%, 54.0% and 64.3% respectively. The concordance of endoscopic indication and pathology on further investigation for IF was 110/192 (57.3%). In patients undergoing barium radiology and repeat gastroscopy, the false negative rate for endoscopy was 17/30 (56.7%), consisting of pharyngeal pathology ($n = 9$), dysmotility ($n = 4$) and significant reflux ($n = 4$).

Conclusion: We present novel data regarding IF, and report an incidence of $\approx 1\%$. Patients should be investigated further owing to the high risk of underlying pathology, particularly if associated with age ≥ 65 , dysphagia, and failure of endoscopic progression. Barium radiology is comparable to repeat gastroscopy in terms of diagnostic yield, and may be more helpful in evaluating pharyngeal and functional pathology.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The aim of this study was therefore to determine the usefulness of the Kyoto classification for diagnosis of HP infection status. A total of 498 subjects were recruited during the period from January to October in 2015 for this study after providing informed consent in writing. HP infection status was determined by the presence of HP-IgG antibody (E-plate II *H. pylori* antibody, Eiken Chemical Co., Ltd., Tokyo, Japan) and history of eradication therapy. HP infection status was judged to be “eradicated” if there was a definite history of

eradication therapy. Without a history of eradication therapy, HP infection status was judged to be “uninfected” for an HP antibody titer of less than 3 U/ml, “eradicated” for an HP antibody titer of 3–10 U/ml and “infected” for an HP antibody titer of more than 10 U/ml. Seven endoscopists (5 well-experienced endoscopists and 2 trainees) who were blinded to history of eradication therapy performed the examinations. The following endoscopic findings were assessed according to the Kyoto gastritis classification: diffuse redness, regular arrangement of collecting venules (RAC), fundic gland polyp (FGP), atrophy, xanthoma, hyperplastic polyp, map-like redness, intestinal metaplasia, nodularity, mucosal swelling, white and flat elevated lesion, sticky mucus, depressive erosion, raised erosion, red streak, and enlarged fold. HP infection status was diagnosed on the basis of the findings. An Olympus H260 and Xp260NS were used for endoscopy. The diagnostic accuracy rate of the Kyoto classification and the sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and diagnostic odds ratio (DOR) for endoscopic findings were determined. This study was registered as a clinical trial in UMIN (UMIN000016674) and was conducted with the approval of the ethics committee in our institution.

Introduction: Since *Helicobacter pylori* (HP) eradication therapy is necessary to prevent the development of gastric cancer, evaluation of HP infection status (uninfected, infected, eradicated) by endoscopy has become important. For that purpose, the Japan Gastroenterological Endoscopy Society proposed the Kyoto classification for gastritis. However, the usefulness of the classification in daily clinical practice has not been sufficiently evaluated.

Results: The 498 subjects included 376 males and 122 females with a mean age of 53.1 years. HP status was unaffected in 315 subjects, eradicated in 104 subjects and infected in 79 subjects. The diagnostic accuracy rate was 82.9%. The sensitivity, specificity, PPV, NPV and DOR were 88.3%, 92.9%, 95.5%, 82.1% and 98.6, respectively, for uninfected status, 78.8%, 90.0%, 69.5%, 94.2% and 37.0, respectively, for eradicated status, and 67.1%, 91.4%, 59.6%, 93.6% and 21.7, respectively, for infected status. High DORs were obtained for the following endoscopic findings: 32.2 for RAC, 7.7 for FGP and 4.7 for red streak in subjects with uninfected status, 12.9 for map-like redness in subjects with eradicated status, and 26.8 for diffuse redness, 13.3 for mucosal swelling, 10.2 for sticky mucus and 8.6 for enlarged fold in subjects with infected status.

Conclusion: The Kyoto classification is useful for diagnosis of HP infection status. Particularly important findings are RAC, FGP and red streak for uninfected status, map-like redness for eradicated status, and diffuse redness, mucosal swelling, sticky mucus and enlarged fold for infected status.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0145 A RETROSPECTIVE AUDIT OF OUTCOMES AND CURRENT CLINICAL PRACTICE POST-BALLOON TAMPONADE FOR ACUTE SEVERE VARICEAL BLEEDING: HAVE THINGS IMPROVED OVER TIME?

C. Keung¹, A. Jackson², M. Swan¹

¹Department Of Gastroenterology And Hepatology, Monash Health, Melbourne/Australia

²Department Of General Medicine, Monash Health, Melbourne/Australia/VIC

Contact E-mail Address: c.keung1@gmail.com

Introduction: Balloon tamponade, such as with Sengstaken-Blakemore tubes (SBT), remains the main immediate salvage therapy for acute variceal bleeding uncontrolled by variceal ligation or injection therapy. Previous cohort studies from the 1970–1980s report success rates of 40–94% for initial haemostasis but high re-bleeding rates of 40–70% on removal [1–3]. Despite guidelines recommending balloon tamponade as initial therapy in treating endoscopically uncontrollable variceal bleeding, specialists and trainees feel uncomfortable with SBT insertion [4] given the perceived difficulties and complications [5].

Aims & Methods: We aimed to describe the current practices surrounding insertion of SBT for acute variceal bleeding, the outcomes and to identify areas requiring improvement. A retrospective audit of all patients from 2008–2016 who required SBT insertion for control of acute variceal bleeding was undertaken at Monash Health, a large tertiary Australian centre. These patients were identified from coding classifications. Details regarding their admission were obtained via electronic records.

Results: Approximately 14% of all patients with variceal bleeding required insertion of a SBT. Of these 42 patients, the majority were male (71%) with a median age of 55 years (range 34–78). Alcohol was the most common aetiology for cirrhosis (62%), with 65% actively drinking. Most patients had cirrhosis severity scores of Child-Pugh B (67%) or Child-Pugh C (29%) and a median MELD score of 16 (range 8–39). At the index variceal bleed, 67% were haemodynamically unstable and 29% were encephalopathic. All received standard medical therapy with octreotide or terlipressin, antibiotics and blood products as required. The time to initial endoscopy from 1st onset bleeding was prompt (median 6.62 hours). Most bleeding varices were oesophageal (90%). Initial ligation/injection was performed in 64% with the remaining patients having such large volumes of blood in the UGI tract that satisfactory views were unable to be obtained. The current practice surrounding SBT insertion is shown in the table

below. Re-look endoscopy post-SBT insertion was performed in 86% patients at a median of 39 hours after insertion with further endoscopic therapy in 47%. Complications of SBT insertion occurred in 31% and included minor oesophageal ulceration (9), significant oesophageal ulceration (3), aspiration pneumonia (4) and oesophageal perforation (1).

Current practice surrounding Sengstaken-Blakemore Tube insertion

Variable	Results (n = 42)
Indication for SBT insertion	Incomplete haemostasis 74%, poor view 50%
SBT insertion site	Oral 32, nasal 8
Confirmation of position	Direct endoscopic visualisation 13, imaging 25, none 6
Volume of balloon inflation	Gastric balloon - 306 ml mean (60–450 ml) Oesophageal balloon - 25–300 ml (n = 15)
Duration of balloon inflation (median hours)	Gastric balloon - 35.1 (1–140.3) Oesophageal balloon - 16 (1–62.8)
Time to re-look endoscopy after SBT (median hours)	39.3 (11.5–348.2)

Re-bleeding occurred in 45% patients during the admission despite SBT insertion, of which 79% did not survive. Seven other patients subsequently underwent a TIPS procedure but 4 of these still died. Survival at discharge and at 12 months was 50% and 41% respectively. The median duration of hospitalisation, intensive care and mechanical ventilation was 13 days (1–56), 6.2 days (0.3–36.2) and 120 hours (1–708) respectively.

Conclusion: Primary haemostasis was achieved in 93% of patients; however, re-bleeding occurred in 45% and was associated with a poor survival rate of 20%. Short and longer-term survival overall has not significantly improved since studies in the 1970s–1980s despite advances in pharmacological therapy. Current practices surrounding SBT insertion are variable and would benefit from further education. Rates of direct visualisation of balloon position prior to inflation with endoscopy should be improved as with referrals for early TIPS.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0146 CONSCIOUS SEDATION FOR ENDOSCOPIC SUBMUCOSAL RESECTION BY USING DEXMEDETOMIDINE

M. Esaki, M. Hattori, I. Matsuzaki, K. Hirose, C. Izumi, M. Yoshikawa, H. Yamauchi, S. Nakazawa

Department of Gastroenterology, Yamashita Hospital, Ichinomiya/Japan

Contact E-mail Address: e.m.6089@gmail.com

Introduction: To evaluate the feasibility and safety of the dexmedetomidine (DEX) for conscious sedation during endoscopic submucosal dissection (ESD). **Aims & Methods:** This study was a prospective trial, and was conducted at the Yamashita Hospital in Japan. Between January 2016 and December 2016, all 50 patients were enrolled in this study. The inclusion criteria for the study was the presence of esophageal, gastric or duodenal tumors. The criteria for exclusion from this study is as follows: patients who were allergic to the drugs used, a baseline heart rate less than 50 beats/minutes, patients who could not use anticholinergic drugs, and lack of patient's consent. A total 50 patients who underwent ESD by using DEX for esophageal, gastric or duodenal tumor. The patients were sedated with DEX (an initial bolus infusion of 3.0 µg/kg/hour intravenously over 10 minutes, followed by a continuous infusion at 0.4 µg/kg/hour titrated). During sedation, midazolam (0.03 mg/kg) and pethidine (17.5 mg) were added intravenously as needed. If the level of sedation dropped to less than RASS -3, the intravenous DEX injection rate was reduced by 0.1 µg/kg/hour. If heart rate was less than 50 beats/minutes or systolic blood pressure was less than 80 mmHg, the intravenous DEX injection rate was reduced by 0.1 µg/kg/hour. If the patient's heart rate was less than 50 beats/minutes, the patient was intravenously infused with atropine sulfate hydrate (0.125 mg–0.25 mg). During procedure, the following parameters were measured continuously, and recorded every 5 minutes: heart rate, blood pressure, hemoglobin oxygen saturation (SpO₂), respiratory rate and RASS. As the achievement rate of conscious sedation during procedure, the percentage of the time that the depth of sedation from

RASS –1 to –3 during procedure were evaluated. Body movement leading to the interruption of ESD were recorded appropriately. After the procedure, all patients were intravenously infused with flumazenil (0.3 mg) and observed until the Aldrete score reached 9 points.

Results: During this study period, 50 patients with esophageal, gastric and duodenal tumors were identified as potentially eligible for participation. There were 37 males and 13 females, and the mean age was 67.5 ± 8.6 y. 27 patients regularly consumed alcohol and 5 patients use sleeping drugs regularly. Tumors were located in the following locations: 9 cases in the esophagus, 38 cases in the stomach, 3 cases in the duodenum. The mean tumor size was 23.8 ± 16.9 mm and the procedure time was 88.0 ± 59.5 minutes. The histologic results of ESD were squamous cell carcinoma (n = 9), adenoma (n = 17) and adenocarcinoma (n = 24). ESD by using DEX were successfully performed in all 50 tumors. No adverse events that were the results of procedures occurred. The mean achievement rate of conscious sedation during procedure was 84.7 ± 16.5%. The median frequency of disturbance by patient's movement was 0 times (range 0–3 times). 33 cases reduced and 14 cases discontinued a continuous infusion of DEX. In 23 cases, there was a decreased heart rate less than 50 beats/minutes. In 16 cases, the patient required an infusion of atropine sulfate hydrate. Thirteen cases of 16 cases required an infusion of atropine sulfate hydrate after the procedure and 3 cases required it during procedure. The median time that the final administration of an atropine sulfate hydrate was 35 min (range 5–140 min) after procedure. There was no case in lowering of systolic blood pressure less than 80 mmHg. Although in 7 cases, the patient's SpO₂ level dropped to less than 90%, however, they recovered after the administration of oxygen into the nasal cannula. The mean time that the Aldrete score reached 9 or over 9 was 7 ± 4 minutes. The median endoscopist and patient's satisfaction score was 9 points (range 2–10 points) and 8 points (range 2–10 points). There were 30 patients (60%) who have a memory during procedure.

Conclusion: Conscious sedation with DEX is effective, safe and a high level of satisfaction for endoscopists and patients for upper gastrointestinal ESD.

Contact E-mail Address: tm-ueda@koto.kpu-m.ac.jp

Introduction: Preoperative diagnosis of invasion depth of superficial esophageal squamous cell carcinoma (SESCC) is very important to select appropriate therapeutic procedure. The Japan Esophageal Society (JES) classification using narrow-band imaging with magnification (M-NBI) was efficient for predicting invasion depth of SESCO¹. Blue laser imaging (BLI) is an image enhanced endoscopy consisted of two different lasers with wavelength 410 and 450 nm as light source, which can enhance mucosal vascular and surface structure. In previous study, BLI with magnification (M-BLI) was useful for evaluating gastrointestinal neoplasms such as predicting invasion depth or tumor detection².

Aims & Methods: We aim to investigate the diagnostic value of M-BLI by comparing that of M-NBI. Our study was single center retrospective study and approved by the Ethical Review Committee of Kyoto Prefectural University of Medicine, and performed in accordance with the World Medical Association's Declaration of Helsinki. All patients provided informed consent for undergoing both M-NBI and M-BLI. Consecutive 166 patients underwent endoscopic submucosal dissection (ESD) for esophageal tumor at Kyoto Prefectural University of Medicine between April 2014 and March 2016. Endoscopic images of SESCOs were recorded by both M-BLI and M-NBI prior to ESD. SESCOs were pathologically diagnosed by ESD specimens. Three endoscopists with no information of the lesions evaluated invasion depth of SESCOs using M-BLI and M-NBI images according to JES classification. The diagnostic value of each procedure was evaluated.

Results: 124 SESCOs were analyzed in this study. The numbers of male/female were 104/20, respectively. Median age was 68.5 years old. Median size of tumor was 17.6 mm. The proportion of tumor location at Ut/Mt/Lt was 13/70/17(%), respectively. The proportion of macroscopic type for 0-I/0-IIa/0-IIb/0-IIc was 1/10/66/23(%), respectively. The proportion of invasion depth of the lesions sub-classified as EP or LPM, MM or SM1, and SM2 were 80, 13 and 7(%) respectively. The overall diagnostic accuracy of BLI and NBI were 88.7% and 83.9% (P = 0.35), respectively. The interobserver variability of three endoscopists with BLI and NBI was 0.679/0.560/0.559 and 0.568/0.822/0.560, respectively. The intraobserver variability with BLI and NBI was 0.839/0.718/0.531 and 0.517/0.514/0.441, respectively.

Conclusion: M-BLI was efficient for diagnosing invasion depth of SESCO according to JES classification, similar to M-NBI.

Contact E-mail Address: vjoshi@ochsner.org

Introduction: Endoscopic Ultrasound (EUS) has been found to be an effective tool in diagnosing pancreatic cystic neoplasms (PCN). Carcinoembryonic antigen (CEA) tumor marker has also been used to differentiate PCN and is the most accurate marker of mucinous cystic neoplasms. Recently, needle-based confocal laser endomicroscopy (nCLE) has been increasingly used for the diagnosis of PCN. nCLE allows for evaluation of pancreatic cysts with results similar to that of a pathological diagnosis. In this study, we will compare our standard of care, EUS, with combined CEA and nCLE to determine which combination of diagnostic modalities is a better predictor of PCN.

Aims & Methods: In this retrospective chart review, 22 patients with pancreatic cysts were evaluated. Specificity and Negative Predictive Value (NPV) of EUS alone or EUS with CEA and nCLE combined were evaluated and diagnostic accuracy was compared with pathology using McNemar's test. Worrisome features (increased cyst size, wall thickness, main pancreatic duct size, and presence of non enhanced mural nodules, abrupt changes, distal atrophy and lymphadenopathy) were tested by determining dissimilar calculations using Euclidean distance and later were used in hierarchical clustering to create two clusters based on Euclidean distance.

Results: Diagnosis of PCN using EUS alone had a specificity of 0.75 and a NPV of 0.88. EUS and CEA combined had a specificity of 0.95 and a NPV of 0.90. Finally, EUS with CEA and nCLE combined had a specificity of 0.80 and a NPV of 0.94. Worrisome features clustering was able to predict pathology, $p = .000289$.

Conclusion: We concluded that specificity and NPV of EUS predicting PCN are positively impacted by the addition of CEA and nCLE. We also found that clustering of worrisome factors predicts pathology, however, a larger cohort is required for future studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Full-spectrum esophagogastroduodenoscopy (FUSE-EGD) provides a 245-degree field of view with double CCE imagers on the front and left side of the endoscope.

Aims & Methods: The aim of this study is to determine the usefulness of FUSE-EGD for upper gastrointestinal screening. The primary endpoint was comparison of the success rates of entire visualization of the ampulla of Vater and the secondary endpoint was comparison of success rates of visualization of the anal side of the pyloric ring between FUSE-EGD and conventional forward-viewing EGD. The additional endpoint was possibility of close-up visualization of the squamo-columnar junction (SCJ). Between April 2016 and September 2016, 88 healthy individuals (46 male and 42 women; median age of examination, 68 years;

range, 26–91) underwent FUSE-EGD, and 818 healthy individuals (423 male and 395 women; median age of examination, 67 years; range, 19–97) underwent conventional EGD for upper gastrointestinal screening. Among them, 40 individuals who underwent FUSE-EGD with a previous history of conventional EGD were interviewed about the degree of pain at insertion, during and after the FUSE-EGD examinations using the visual analog scale (VAS) (0, comfort; 50, equal to the last conventional EGD; and 100, painful). Furthermore, we evaluated 3 patients with familial adenomatous polyposis (FAP) and 2 with the ampullary tumors using FUSE-EGD.

Results: Entire visualization of the ampulla of Vater was successful at 90.4% (47/52) with FUSE-EGD, compared to 41.2% (174/422) with conventional EGD ($P < 0.001$). Visualization of the anal side of the pyloric ring was successful at 88.5% (46/52) with FUSE-EGD, compared to 8.5% (6/70) with conventional EGD ($P < 0.001$). Close-up visualization of SCJ was successful at 92.0% (81/88) with FUSE-EGD. VASs at insertion, during and after examinations were 51.2 (10–75), 46.9 (0–75), and 45.2 (10–50) points, respectively, which were equivalent to conventional EGD. The ampullary adenoma was observed in all 3 patients with FAP, and the openings of the biliary and pancreatic ducts of the ampulla of Vater were observed in all 2 cases with the ampullary tumors with FUSE-EGD. There were no adverse events associated with FUSE-EGD.

Conclusion: FUSE-EGD seems safe and effective for upper gastrointestinal screening, especially when the precise observation of the ampulla of Vater and/or the anal side of the pyloric ring is necessary.

Introduction: Endoscopic submucosal dissection (ESD) is accepted as the treatment of intestinal-type early-stage gastric cancer. However, ESD occasionally results in unfavorable outcome due to technical difficulties. Therefore, predictions of difficulties in ESD would preclude complications associated with ESD.

Aims & Methods: The aim of this study is to determine the predictive factors of procedural difficulties in ESD. Between January 2009 and July 2016, 577 consecutive patients who underwent ESD for gastric neoplasms were enrolled. These patients were classified into 3 groups: group S, group L, and others. Group S comprised 30 patients who underwent ESD for the shortest duration (10–16 min). Group L comprised 30 patients who underwent ESD for the longest duration (149–215 min). Multivariate analysis was performed between Groups L and S using the following factors: location (cardia, posterior wall of angle, lesser curvature of lower gastric body and others), macroscopic type (protruded, depressed or mixed), size of the resected specimen, preoperative scar, number of preoperative biopsies, /others), and as predictor for submucosal fat tissue, body mass index, waist circumference, visceral fat tissue measurements on CT, blood test findings (glycated hemoglobin, triglyceride and total cholesterol), blood pressure, and heart rate before ESD.

Results: Significant differences were found regarding the number of biopsies (group L, 8.5; group S, 6.8, $P = 0.0211$), (group L, 616.7mm²; group S, 99.2mm², $P = 0.0286$), biopsy diagnosis ($P = 0.0292$), and location ($P = 0.0086$). Based on these factors and odds ratio, we prioritized sensitivity to avoid missing cases with removal difficulties during ESD and suggested predictive factors for removal difficulties during ESD. Preoperative scar: 3 points, the size of the resected specimen >800mm²: 3 points, difficult location: 2 points, the number of biopsies >7 pieces: 1 point, Group 5 on biopsy diagnosis: 1 point. Cases of 6 points or more was regarded as difficult to remove that takes over 70 minutes. When examining 43 patients who underwent ESD for gastric neoplasms between August to November 2016 the sensitivity was 87.5% and the specificity was 80%.

Conclusion: Our results suggest that the number of biopsies, size of the resected specimen, biopsy diagnosis, preoperative scar and biopsy location are predictive factors for difficulties in ESD.

Introduction: Timely detection of early gastric cancer (EGC) is important in performing endoscopic submucosal dissection (ESD). We attempted to know the location characteristics where EGC is frequently detected and analyzed EGC characteristics associated with the location.

Aims & Methods: We retrospectively reviewed the medical records of patients with EGC treated by ESD between November 2008 and August 2016. We retrospectively investigated and analyzed 647 EGC lesions.

Results: The patients' mean age was 66.7±10.8 years. The patient population was predominantly male (77.1%, 499/647). A well to moderately differentiated carcinoma was observed in 97.2% of patients. The common site was the lower part of the stomach (89.6%, 580/647). The highest percentage of EGC was found

in the lesser curvature (43.9%, 284/647). Posterior EGC was more frequent in the mid-to-upper part of the stomach than the anterior part (20.4%, 31/67 vs. 16.4%, 11/67, respectively). For EGC characteristics compared between the lower and mid-to-upper parts, submucosal invasive EGC was found to be significantly different (odds ratio, 1.919; confidence interval, 1.014–3.623; $p=0.045$).

Conclusion: Most of the EGCs resectable with ESD were found in the lower part of the stomach and lesser curvature of the stomach. The incidence of the posterior part in the mid-to-upper part of the stomach was higher than that of anterior part. The EGC located in the mid-to-upper part of the stomach was found to have a higher incidence of invasive cancer.

P0152 A STUDY OF THE RECOGNITION OF ENDOSCOPIC IMAGES BY MACHINE LEARNING WITH CONVOLUTIONAL NEURAL NETWORK AND DEEP LEARNING

R. Yamakawa, M. Harada, K. Kawachi, S. Nuzuki, M. Iwata
Gastroenterology, Kaetsu Hospital, Niigata/Japan

Contact E-mail Address: yamakawa_r@niigata-min.or.jp

Introduction: The recognition of general images by machine learning (ML) with the convolutional neural network (CNN) and deep learning (DL) is good. However, the possibility of the recognition of endoscopic images by ML with CNN and DL is undetermined.

Aims & Methods: The aim of this study was to clarify the possibility of the recognition of endoscopic images by ML with CNN and DL.

We selected 816 endoscopic images of 8 categories which include laryngopharynx (LP), thoracic esophagus (TE), abdominal esophagus (AE), gastric fundus (GF), gastric body (GB), gastric antrum (GA), duodenal bulb (DB) and descending part of the duodenum (DD). Each category had approximately 100 images.

These images were randomly separated into two groups, 60% (489 images) for learning and 40% (327 images) for testing. We increased the learning group images to 8313 by adding additionally rotated images of each five degrees.

We made an ML model with three CNN layers, three Activation Function layers, two Max-Pooling layers and two Dens layers by TensorFlow and Keras.

We trained the ML model with the learning group images ($n=8313$) and then tested it with the testing group images ($n=327$) to determine whether it can recognize the endoscopic site. Two members of our hospital staff performed the same test utilizing the same images.

Results: It took 73 minutes for the ML model to learn and 6 seconds to answer the test. The percentage of correct answers of the ML model was 70.6% in all categories ($n=327$), 77.1% in LP ($n=48$), 91.5% in TE ($n=47$), 64.4% in AE ($n=45$), 73.7% in GF ($n=38$), 61.5% in GB ($n=39$), 52.8% in GA ($n=36$), 65.6% in DB ($n=32$) and 71.4% in DD ($n=42$). The average percentage of correct answers of humans was 95.4% in gastroenterologists ($n=5$), 85.2% in junior residents ($n=2$), 81.2% in endoscopy nurses ($n=5$), 54.4% in medical clerks ($n=5$) and 51.8% in floor nurses ($n=4$).

The percentage of correct answers of the ML model was lower than those of humans who have knowledge about endoscopic images. However, it was higher than those of other humans who do not.

Conclusion: The results suggest the possibility of the recognition of endoscopic images by ML with CNN and DL. Further study is necessary to confirm the ability of it because this study was conducted in a simple ML model with three CNN layers and a small number of images.

Introduction: To clarify whether traction assist improves technical outcomes of endoscopic submucosal dissection (ESD).

Aims & Methods: A superiority, randomized phase 3 trial was conducted at 14 institutions across Japan. Patients with single gastric neoplasm meeting the indication of the Japanese gastric treatment guidelines were enrolled and assigned to conventional ESD or dental floss clip traction ESD (DFC-ESD) by a computer-generated random sequence with stratification by institution, tumor location, tumor size and operator's proficiency. The primary endpoint was ESD procedure time, which was defined as the time from the start of submucosal injection to the end of tumor removal.

Results: Between July 2015 and September 2016, 640 patients underwent randomization. 316 patients assigned to conventional ESD and 319 patients assigned to DFC-ESD were included in the analysis set. Mean ESD procedure time was 60.7 minutes in the conventional ESD group and 58.1 minutes in the DFC-ESD group ($p=0.45$). Perforation was less frequent in the DFC-ESD group (conventional ESD vs. DFC-ESD: 2.2% vs. 0.3%, $p=0.04$). Among the lesions in the greater curvature of the upper or middle stomach, mean procedure time in the DFC-ESD group was shorter than the conventional ESD group (conventional ESD vs. DFC-ESD: 104.1 vs. 57.2 minutes, $p=0.01$).

Conclusion: This study reveals that traction-assisted ESD does not result in quicker procedures in the entire population, but it can reduce the risk of perforation. Selectively applied to the lesions in the greater curvature of the upper or middle third stomach, traction assist contributes to a remarkable reduction of procedure time.

Introduction: The vessel plus surface (VS) classification system proposed by Yao is widely used for endoscopic diagnosis of early gastric cancer¹. However, this diagnosis is performed by visual observation and no quantitative index exists.

Aims & Methods: In this study, a method for automatically detecting early gastric cancer lesions by narrow-band imaging (NBI) using a magnifying endoscopic image in the stomach is proposed to support diagnosis. The proposed system quantitatively shows the demarcation line (DL) of lesions in narrow-band images. Machine learning is introduced into the VS classification and image processing is performed. In the literature, texture analysis, which is a type of image processing, is used to assess the mucosal surface². In addition, the proposed system uses a color feature that quantitatively expresses mucosal vessels. Furthermore, the narrow-band image contained 200 superpixels, and each superpixel contained texture and color features; a superpixel is a collection of pixels with similar features. Finally, lesions were identified by a support vector machine, which is a model for machine learning, and DL was detected. In this computational experiment, the utility of the system was verified by identifying 25 early-stage gastric cancer lesions (50 endoscopic images) using NBI-magnified observation at the Department of Gastroenterology, Murakami Memorial Hospital, Asahi University, Gifu.

Results: The average detection rate of the lesion area greatly improved to 63.0% with the proposed method compared with 28.8% with the conventional method. In addition, the obtained DL was similar to that indicated by an experienced medical physician. Based on these results, the proposed system enabled the automatic detection of early gastric cancer DL in narrow-band images, suggesting that the proposed system is useful for the determination of DL.

Conclusion: In this study, a method to assess features of gastric lesions combined with the use of superpixels was proposed. The average detection rate of the lesion range using the proposed method greatly improved compared with that using the existing method, enabling the detection of DL without depending on a physician's experience.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Post-sleeve gastrectomy fistulas (PSGF) are major complication of bariatric surgery. Endoscopic management evolved from a fistula closure to an internal drainage (ID) strategy within the 2013 year. The main objective of this study was to evaluate these different endoscopic approaches.

Aims & Methods: This retrospective study included all patients treated for PSGF in a referral center. "Closure" management was defined as: initial treatment using covered-metal-stent and endoclips. ID management was defined as: initial treatment by nasocystic drain and/or double-pigtail-stent. The failure was defined as: need for surgery, or death.

Results: Between 2007 and 2015, 100 patients (women: N=78; mean age: 42±12years) were included. The mean delay between SG and the first endoscopy was 82±125 days. Overall success of endoscopic treatment was 86% within 6±27months. Two patients died. Primary success of ID and closure management occurred in 19/22 (86%) and 49/77 (63%) patients, respectively. Among patients in failure of closure management, 22 had secondary ID (18 being successful). Success of initial management was significantly higher for ID ($p < 0.05$). Factors associated with failure of closure management were in multivariate analysis: collection > 5 cm ($p = 0.013$, OR = 3.8 95%CI[1.3–10.9]). Factors associated with duration of management over 6 months were in multivariate analysis: reoperation before endoscopy ($p = 0.044$, OR = 3.9 95%CI[1.0–14.9]) and purulent flowing at endoscopy ($p = 0.043$, OR = 4.6 95%CI[1.0–20.4]). Factors associated with post-2013 management were in multivariate analysis: first endoscopy within 30 days ($p = 0.016$), Clavien-Dindo-type 4 and 5 ($p = 0.016$), and absence of glue sealing ($p = 0.027$).

Conclusion: Endoscopic management of PSGF healed in 86% of cases. In case of collection greater than 5 cm, an internal drainage should be proposed first. A second surgical procedure before endoscopy is associated with longer care. Management in our center has changed over time with earlier first endoscopy and management of more severe patients.

P0156 CLOSURE BY USING OVER-THE-SCOPE CLIPS AFTER ENDOSCOPIC FULL-THICKNESS RESECTION

J. Guo

Endoscopy Center, Shengjing Hospital of China Medical University, Shenyang/China

Contact E-mail Address: guojt@sj-hospital.org

Introduction: Endoscopic full-thickness resection (EFTR) is a mini-invasive technique for gastrointestinal subepithelial tumors, which enables a full-thickness resection of tumors and can provide a complete basis for pathological diagnosis. Gastrointestinal fistula closure after EFTR is a challenge for endoscopists. In this study we introduced EFTR with fistula closure using the over-the-scope clip (OTSC) system for gastrointestinal subepithelial tumors originating from the muscularis propria.

Aims & Methods: We aimed to evaluate the feasibility and safety of fistula closure with OTSC by a retrospective analysis on the cases of EFTR with defect closure using OTSC for gastrointestinal subepithelial tumors in our hospital. The patients were selected who underwent EFTR for gastrointestinal subepithelial tumors originating from the muscularis propria (tumor diameter ≤3cm) in our hospital from May 2014 to December 2016. After a full-thickness resection of tumors, one or two OTSCs were released to close the defect. The success rate of defect closure with OTSC was observed and the endoscopic follow-up was performed at 1 week, 1 month, 6 months, 24 months after operation to check OTSC closure.

Results: In total 49 patients were included into the study. The full-thickness resection rate of gastrointestinal tumors in the muscularis propria was 100% (49/49), the success rate of defect closure was 100%, and the average time of defect closure was 7.3 min (range: 3–27 min). All patients experienced no postoperative complications such as bleeding and perforation. The postoperative follow-up time was 1–24 months (mean: 11 months), and no late complications was found.

Conclusion: OTSC can be used to perform EFTR with defect closure for gastrointestinal tumors in the muscularis propria (tumor diameter ≤3cm). It is simple, convenient, safe and effective.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0157 EFFICACY OF ORAL MIXTURE OF HYDROCORTISONE SODIUM SUCCINATE AND ALUMINUM PHOSPHATE GEL FOR THE PREVENTION OF STRICTURE AFTER ≥2/3 CIRCUMFERENTIAL ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR ESOPHAGEAL CANCER—A SINGLE CENTER PILOT STUDY FROM CHINA

Y. Huang, X. Yan, H. Chang, Y. Zhang, W. Yao, K. Li

Gastroenterology And Hepatology, Peking University Third Hospital, Beijing/China

Contact E-mail Address: 13911765322@163.com

Introduction: ESD has been performed on many patients with early stage esophageal cancer. However, postoperative stricture after ≥2/3 circumferential ESD is the most important issues for quality of life in patients which is drastically decreased and repeat, periodic endoscopic balloon dilatation (EBD) is usually required over long periods. It is well known that hormone for external use is more easily absorbed in broken skin. Accordingly, We explore an innovative strategy with oral mixture of hydrocortisone sodium succinate and Aluminum phosphate gel for prevention of the stricture

Aims & Methods: To evaluate the efficacy of this mixture in single center of Beijing, China.

Patients and Methods: In total, 13 patients who underwent more than 2/3 circular or complete circular ESD for esophageal superficial squamous cell carcinoma were included in this study. They all received preventative strategy for stricture and were divided into three groups chronologically. Four patients received systemic steroid treatment (ST group), three patients received endoscopic intraluminal steroid (IT + ST group), six patients received oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel (OHA group). We compared the two groups in terms of stricture rate and total number of endoscopic balloon dilatation (EBD) sessions. ST groups started with 30 mg/day prednisolone on the second day post-ESD, and continued with a gradually tapering prednisolone dose, finally discontinuing systemic steroid administration 8 weeks later. IT + ST group started with 80 mg intraluminal steroid at the end of ESD procedure, and 30 mg/day prednisolone on the second day post-ESD which exactly was the same as ST group of tapering process. OHA group started with mixture of hydrocortisone sodium succinate 50 mg and aluminum phosphate gel 20 g, qid for 2 weeks and continued with a gradually tapering OHA dose on the second day post-ESD. Esophagogastroduodenoscopy (EGD) was performed on demand whenever patients complained of dysphagia. Among those cases, EBD was performed when patients experienced persistent dysphagia. If the patient had no complaint of dysphagia, EGD was performed 8 weeks after ESD to evaluate any possible stricture. The primary end point in this study was the stricture rate after ESD followed by oral prednisolone. The secondary end point was the number of EBD sessions required to resolve the stricture. A stricture was defined as a difficulty in swallowing solids or an inability to pass an EGD (9.2 mm diameter endoscope).

Results: There were two complete and two 75% circular ESD in ST group, one complete and two 75% circular ESD cases in IT + ST group, and one complete and five 75% circular ESD cases in OHA group. 12 cases were resected en bloc with tumor free lateral and basal margins. No complications were seen after this procedure. The stricture rates of ST, IT + ST, OHA group after ESD were 100% (4 of 4 patients), 33% (one of three patients), 0% (none of six patients), respectively. One patient with stricture after ESD had lateral recurrence at the margin of ulcer. One EBD was performed in three patients in ST group and one patient in IT + ST group with esophageal stricture. One patient in ST group underwent operation in response to patient demand.

Conclusion: Short period, oral I mixture of hydrocortisone sodium succinate and aluminum phosphate gel showed promising results for the prevention of stricture after ESD for early stage esophageal cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0158 LONG-TERM OUTCOMES OF COLD POLYPECTOMY FOR NONAMPULLARY DUODENAL ADENOMAS

D. Maruoka, M. Arai, N. Akizue, K. Okimoto, T. Matsumura, T. Nakagawa, T. Katsuno, N. Kato
Department Of Gastroenterology, Graduate School of Medicine, Chiba University, Chiba City/Japan

Contact E-mail Address: d-maruoka@biscuit.ocn.ne.jp

Introduction: Endoscopic resection for superficial nonampullary duodenal epithelial tumors (SNADETs) has a high incidence of complications such as perforation in endoscopic mucosal resection (EMR) as well as in endoscopic submucosal dissection (ESD), compared with resection of other parts of the digestive tract. We had written the first report on the safety and efficacy of cold polypectomy (cold forceps polypectomy [CFP] and cold snare polypectomy [CSP]) for sporadic SNADETs. However, there is no report on the long-term outcomes of cold polypectomy for sporadic SNADETs. In this study, we aimed to assess the long-term outcomes of cold polypectomy for sporadic SNADETs.

Aims & Methods: Patients without polyposis syndrome who underwent cold polypectomy for one or more SNADETs ≤ 6 mm in size and were diagnosed with adenomas between March 2015 and November 2016, and were followed up by endoscopy for more than 1 year were analyzed. All patients subsequently underwent upper gastrointestinal endoscopy 3 months after the intervention. The presence of residual tumors was evaluated by conducting endoscopic examinations and histopathological tests with tissue samples obtained from the cold polypectomy scars. Subsequently, patients underwent upper gastrointestinal endoscopy annually, and when residual tumors could not be denied, biopsies were taken from the scars.

Results: A total of 43 lesions in 33 patients were removed using cold polypectomy. Twenty-four lesions in 20 patients were followed up for more than 1 year. The mean follow-up period by upper gastrointestinal endoscopy was 13.1 (12–18) months. Of these 20 patients, 12 (60%) were men and the mean age of the subjects was 63 ± 11 years. The number of lesions were 5, 16, and 3 (21%, 67%, 13%) per lesion location (1st, 2nd, and 3rd portion), respectively, and 2, 3, 13, 4, and 2 (8%, 13%, 54%, 17%, 8%) per macroscopic appearance (Isp, Is, IIa, IIa + IIc, and IIc), respectively. Nine lesions in 8 patients were resected using CFP, while 15 lesions in 12 patients were resected using CSP. Seven of 9 (78%) and 14 of 15 (93%) lesions were removed en bloc using CFP and CSP, respectively; the other 3 lesions were removed by piecemeal resection in 2 pieces. All specimens resected using both CFP and CSP were successfully retrieved. Histopathologic analysis showed that 21 of 24 lesions (88%) were low-grade adenomas, and 3 (13%) were high-grade adenomas. The mean size of the adenomatous lesions was 4.0 ± 1.3 mm (2–6 mm). Eleven of 24 adenomas (46%) were R0 resections; 3 of 9 (33%) and 8 of 15 (53%) were R0 resections using CFP and CSP, respectively. Delayed bleeding and intraprocedural/delayed perforation were not observed in any case. The scars were identified and biopsied at follow-up endoscopy performed 3 months after cold polypectomy, and no residual or recurrent tumor was detected morphologically or histopathologically. Although there was no recurrent case during the follow-up period, one patient died 6 months after resection because of heart failure.

Conclusion: Cold polypectomy is a safe and effective treatment for diminutive and small sporadic SNADETs that have been subjected to long-term follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0159 ENDOSCOPIC TREATMENT OF BOERHAAVE SYNDROME: A SURPRISINGLY QUICK HEALING

G. Sakizlis, D. Karagiannis
Gastroenterology, Iatrikon Medical Center, Athens/Greece

Contact E-mail Address: sakizlis@gmail.com

Introduction: Endoscopic Treatment of Boerhaave Syndrome: A Surprisingly Quick Healing

Aims & Methods: A 48-year-old male was presented at the emergency room complaining of severe chest pain, which began after several episodes of vomiting, following a meal. Upon his arrival a severe episode of haematemesis was reported. The electrocardiogram showed tachycardia with a ventricular rate of 128 bpm. The computed tomography of the chest demonstrated a hydrothorax, as well as mediastinal free air. Due to the hemorrhage we performed an emergency upper endoscopy after we obtained the patient's consent. We observed an esophageal opening, 11 cm long, with a Mallory-Weiss tear at the distal end. We clipped the visible vessel and decided to close the opening with clips (Figure 1). We used twelve clips and successfully stopped the bleeding while also closing the esophageal opening. Thoracic surgeons placed a thoracic drainage tube. The patient received a conservative therapy, complemented by a withdrawal of oral intake and administration of broad spectrum antibiotics.

Results: The next day we performed a follow-up upper endoscopy to inspect the closure and hemostasis. We observed an amazing healing (Figure 2). The chest tube was removed at the fourth day and the patient started oral feeding on the sixth day. The patient was discharged from the hospital with no complications on the eighth day. We performed an upper endoscopy after one month with no strictures

Conclusion: Boerhaave syndrome has an estimated mortality rate of 20% to 40%. The standard of care is multidisciplinary; surgical, endoscopic or conservative approaches are acceptable. No consensus exists regarding the best strategy. Endoscopic treatment consists of closure with endoscopic clips—the through-the-scope (TTS) clip and the over-the-scope clip (OTSC)—or stenting with removable stents. This paper explores the case of a spontaneous esophageal rupture after vomiting, which was treated with TTS clips. We note the extremely fast rate of healing of the wound.

Introduction: Esophagogastroduodenoscopy (EGD) is of growing importance in the diagnosis of *Helicobacter pylori* (HP) gastritis, because HP infection is strongly associated with gastric carcinogenesis¹. However, the accuracy of endoscopic diagnosis of HP infection may vary according to the experience and technique of the attending endoscopist. Here, we challenged to establish a computer aided endoscopic diagnosis system for HP infection using two novel technologies. First is a Linked color imaging (LCI). It is a new Image-enhanced endoscopy (IEE) using a LASER light source to enhance slight differences in mucosal color. Second is an Artificial Intelligence (AI) technology. Deep Learning has attracted attention in diagnostic imaging. It is a type of AI which imitates neural network in the brain.

Aims & Methods: The aim of this study was to establish an AI diagnosis of HP infection using LCI. We designed a prospective study of all patients who underwent EGD and were tested for serum anti-HP IgG antibodies at our medical clinic. Subjects who had a history of HP eradication therapy were excluded in this study. A total of 220 examinees were candidates who underwent EGD and serum test of anti-HP IgG antibodies (HP-positive examinees were 112). The HP IgG antibody titer of each subject was taken as the gold standard for HP infection status for this study. During EGD an endoscopist took 3 LCI pictures of the lesser curvature, greater curvature and antrum of the stomach by EG-L580NW (FUJIFILM Co., Japan). Finally, we used a total of 639 LCI pictures in the study. The specifications of the AI used in this study were as follows: Operating system: Linux (Ubuntu 14.04 LTS), Neural network: GoogLeNet², Framework: Caffe³, and Graphic processor unit: Geforce GTX TITAN X (NVIDIA Co., USA), and we used R (version 3.3.2) for all statistical analyses.

Results: The area under the curve (AUC) of receiver operating characteristics (ROC) was 0.95 for the lesser curvature. Compared to this, the AUC of the greater curvature and antrum was 0.81 and 0.67, respectively. The AUCs obtained in the lesser curvature was significantly larger than that in the greater curvature and antrum ($P < 0.01$).

Conclusion: The results demonstrate that the AI has excellent ability to diagnose HP infection using LCI in the lesser curvature. The authors believe that AI technology with IEEs is likely to become a useful image diagnostic tool.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Current guidelines (MAPS) suggest that intestinal metaplasia (IM) should be staged using OLGIM¹ (Operative Link on Gastric Intestinal Metaplasia) and that patients with stages OLGIM 3 and 4 should be followed-up². High-resolution narrow band imaging (HR-NBI) was previously shown to be accurate to diagnose IM³. Recently a new endoscopic classification (Endoscopic Grading of Gastric Intestinal Metaplasia - EGGIM) has been proposed to assess the risk phenotype of patients by the evaluation of IM in the antrum and in the corpus with the use of HR-NBI scopes^{4, 5}.

Aims & Methods: We aimed at determining the accuracy of EGGIM classification, compared with the pathological evaluation of gastric biopsies expressed according to OLGIM classification. Two centers (Italy, Portugal) consecutively included 78 adult patients (female 56%; median age 61 (20–84) years; 8 with 1st degree family history of gastric cancer). All patients were evaluated by High-

Resolution White Light Endoscopy (HR-WLE) followed by HR-NBI. A careful evaluation of the antrum and corpus mucosa was performed and EGGIM score was calculated. Five different areas were considered (lesser and greater curvature in the antrum, lesser and greater curvature in the corpus and incisura) and in each area 0 (no IM), 1 (focal IM, less or equal than 30% of the area) or 2 points (extensive IM in that area, more than 30% of the area) were attributed for a total of 10 points. Biopsies were taken where the endoscopists observed IM and, if IM was not present, random biopsies were taken using the updated Sydney System protocol. Biopsies from the different sites were sent for histopathologic evaluation in separate jars. The diagnostic performance of EGGIM was then compared to OLGIM (gold standard) and sensibility, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated.

Results: IM was staged as OLGIM 0, 2, 3 and 4, respectively: 32 (41.0%), 23 (29.5%), 17 (21.8%), and 6 (7.7%) pts (no patients with OLGIM 1 were found). Table 1 shows detailed the EGGIM scores compared to OLGA. Compared to OLGIM as gold standard for the evaluation of IM, sensitivity, specificity, PPV and NPV of EGGIM classification were 97.8%, 81.2%, 88.2% and 96.3%, respectively. Three of the 6 patients with false positive results using the EGGIM classification were *H. pylori* positive. Analyzing the subgroup of patients with OLGIM 3 and 4, the diagnostic performance of EGGIM was: sensibility 95.6%, specificity 90.9%, PPV 81.5% and NPV 98.0%. Two of the 5 patients who resulted false positive using the EGGIM classification were *H. pylori* positive. A high agreement between EGGIM and OLGIM scores was observed (83.3%).

% of total (within each OLGIM grade)	EGGIM score				
	0	1–2	3–4	5–7	8–10
OLGIM	0	33 (81)	5 (12)	3 (7)	0
	I	0	0	0	0
	II	1 (4)	8 (26)	14 (48)	4 (13)
	III	0	0	1 (6)	17 (76)
	IV	0	0	0	4 (50)
Extent of intestinal metaplasia	Absent	Focal	Moderate	Extensive	Extensive

Conclusion: The EGGIM classification showed a high diagnostic performance compared to OLGIM, in particular in patients with OLGIM 3 and 4. A possible confounding factor leading to overestimation of presence of intestinal metaplasia might be the presence of *H. pylori* infection. This approach could be used to simplify the surveillance of these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Percutaneous transesophageal gastrotubing (PTEG) was developed as an alternative route to access the gastrointestinal tract for the patients that Percutaneous Endoscopic Gastrostomy was contraindicated with conditions such as prior gastrectomy, gastric anterior wall malignancies, or massive ascites. PTEG will be an ideal method as the palliative care for the patients with malignant disease.

Aims & Methods: The aim of this study is to evaluate the clinical usefulness of PTEG supported by endoscopy for the patients who need decompression from gastrointestinal tract due to malignancies. A rupture-free balloon (RFB) catheter

is inserted into the upper esophagus. Percutaneous balloon puncture with a specialized needle is then performed from the left side of patient's neck under ultrasonographic control. A guide wire is inserted through the needle into the RFB, followed by a dilator and sheath. A placement tube is then inserted through the sheath, and the sheath is removed. Double Balloons equipped Over tube type RFB were used instead of primary RFB in five cases that the puncture needle is punctured into the over tube through the balloon. We perform PTEG in a total of 62 patients (37 men and 25 women, mean age 61.8 years) in whom PEG was not feasible for decompression. Every patient suffered discomfort to the prior insertion of nasal tube. Fifty-three patients had peritoneal dissemination and 7 patients had gastrointestinal tract obstruction, and 2 patients need biliary drainage.

Results: Satisfactory results were achieved in all 62 patients. Median follow-up was 60.5 days in patients who received decompression because of the obstruction due to malignancies. All patients could free from nasal tube prior insertion. Oral ingestion could be achieved in 48.6% and home care could achieved in 63.9% of those patients. Complications were minor oozing bleeding in three patients that did not require blood transfusion, thyroid puncture in three patients, which were managed conservatively. No patient required surgical treatment or died after PTEG.

Conclusion: PTEG is feasible, safe, and useful. PTEG could be an only procedure to be free from a nasal tube especially for the patients with carcinomatous peritonitis. PTEG is the ideal solution for the patients with malignant gastrointestinal obstruction. PTEG is one of the best tool in palliative care for the patients with malignant disease.

Introduction: Gastrostomy is the current method of choice for medium and long-term enteral feeding. Available techniques include Percutaneous Endoscopic Gastrostomy (PEG) and Percutaneous Radiologic Gastrostomy (PRG). Both techniques are preferred over surgical gastrostomy. Previous studies that have compared outcomes between PEG and PRG are limited due to small sample sizes, high risk of confounding and selection bias. Our primary aim was to retrospectively analyse data from our centre with respect to complications and mortality between PEG and PRG procedures in relation to indications. These data may help to predict which technique is best for an individual patient.

Aims & Methods: A retrospective analysis including all adult patients receiving initial PRG (January 2010 until April 2016) and PEG (January 2008 until April 2016) placement in our university hospital, was performed.

Outcomes were complications (early (≤ 30 days) and late), success rates and mortality (procedure related, 30-day, and overall). Chi², Fisher's exact and t-tests were used. Multivariate logistic regression and Cox proportional hazards regression analysis were performed.

Results: A total of 760 initial procedures (469 PRG and 291 PEG) were included in the analysis (62.9% male, mean age 62.8yrs [SD 12.64]). Most common indications were head and neck malignancy (HN, PEG 38.8%, PRG 69.9%, $p < 0.001$), Cerebrovascular Accident (CVA, PEG 13.7%, PRG 2.1%, $p < 0.001$) and Motor Neuron Disease (MND, PEG 2.7%, PRG 9.8%, $p < 0.001$). Success rates for placement were 91.2% for PEG (failure mostly due to absence of transillumination, $n = 14$) and 97.1% for PRG ($p = 0.001$). Major complications (e.g. abscess, buried bumper, peritonitis) and infections did not differ amongst groups, neither did procedure-related mortality, which was 1.7% in PEG ($n = 5$) vs. 0.4% in PRG ($n = 2$, $p = 0.113$). One case of tumour (HN) seeding occurred after PRG placement. Tube related complications (including dislocation, obstruction, leak and tube defects) were lower in PEG than PRG, both within 30 days (2.7% vs. 26.4% of patients, $p = < 0.001$ and after 30 days (8.6% vs. 31.5%, $p = < 0.001$).

The 30-day mortality was higher in patients who received PEG (11.3%: 27 deaths due to underlying conditions, 5 related to the procedure (1 massive bleeding, 4 aspiration pneumonia)) compared to those with PRG (4.48%, 19 deaths due to underlying conditions, 2 related to the procedure (both aspiration pneumonia), $p = < 0.001$). The 30-day mortality was related more to the patients' general condition, than to the procedure itself

Overall survival was 46.7% vs. 44.1% (PEG vs. PRG; $p = 0.049$, OR 1.224 [1.000–1.498]). Positive predictive factors for overall survival were PEG, ALS and a higher BMI before placement (adjusted OR for all three factors together 1.292 [1.027–1.626]).

Conclusion: PRG appears favourable with respect to 30 day mortality while PEG appears favourable over PRG in terms of complications (such as dislocation, pain, and irritation). A higher initial success rate and the possibility of placement in case of a narrow lumen favour PRG placement. More adequate patient selection and more thorough procedure selection prior to gastrostomy is therefore required.

P0165 COMPREHENSIVE EVALUATION OF THE LEARNING CURVE FOR PERORAL ENDOSCOPIC MYOTOMY: LESSONS FROM 1346 PATIENTS

Z. Liu¹, X. Zhang¹, Q. Li¹, P. Zhou¹

¹Zhongshan Hospital, Endoscopy Center and Endoscopy Research Institute, Zhongshan Hospital, Fudan University - Zhongshan, Shanghai/China

Contact E-mail Address: liuzq16@fudan.edu.cn

Introduction: Peroral endoscopic myotomy (POEM) is being increasingly performed worldwide. However, studies on its learning curve are limited. A comprehensive evaluation based on risk factors is needed.

Aims & Methods: This study was aimed to evaluate the impact of various factors on the learning curve of POEM. From August 2010 to July 2015, 1346 POEM performed in Zhongshan Hospital were analyzed. The primary outcome of the study was a composite outcome of aborted procedures and complication. The secondary outcomes included procedure time and hospital stay. The impact of risk factors was assessed by backward conditional logistic regression on primary and secondary outcomes. The risk-adjusted CUSUM and moving average methods were used to evaluate the outcomes.

Results: Fifty-four (4%) patients had the composite outcome with 10 aborted procedures and 44 adverse events. The composite outcome was related to case number, full-thickness myotomy and procedure time in the multivariate logistic regression. Adjusted for these risk factors, the CUSUM analysis showed that the composite outcome gradually decreased after 150 cases. The procedure time was higher in the early stage and decreased after 71 cases. Case number, in representative of the operative experience, is also an independent risk factor for a longer procedure time and hospital stay.

Conclusion: For POEM operators, seventy cases might be considered a threshold for faster operation, i.e., technical proficiency. A hundred-and-fifty cases might be considered a threshold for the decrease of aborted procedures and adverse events, i.e., technical reliability.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0166 CLINICAL CURATIVE EFFECT ANALYSIS OF 162 GASTRIC STROMAL TUMORS RESECTED BY ENDOSCOPIC TREATMENTS

L. Liu, W. Liu, Z. Fan

¹Digestive Endoscopy Center, the First Affiliated Hospital of Nanjing Medical University, Nanjing/China

Contact E-mail Address: kit9178@sina.com

Introduction: Gastrointestinal stromal tumor (GIST) is one of the most common tumors originating from mesenchymal tissue of gastrointestinal tract, which accounts for about 0.2% of gastrointestinal tumors. Gastric stromal tumors are more common, accounting for about 40%~70% of GIST. At present, the endoscopic treatments of gastric stromal tumors includes endoscopic submucosal dissection (ESD), endoscopic full-thickness resection (EFR) and combined endoscopic and laparoscopic surgery.

Aims & Methods: Our study is aimed to assess the safeness and effectiveness of endoscopic treatments for gastric stromal tumor. Clinical data of 162 patients with gastric stromal tumor who underwent endoscopic treatments from June 1st 2011 to July 31st 2015 were analyzed retrospectively. The mean diameter of the tumors was 1.5cm (0.3~5.0cm). 104 patients received endoscopic submucosal dissection, 58 patients received endoscopic full-thickness resection. Among them, 4 operations were completed under the monitor of laparoscopy.

Results: Complications were observed in 8 patients (4.9%): bleeding during operations: 3 patients, post-operation perforation: 3 patients, respiratory tract infection: 2 patients. The mean post-operation feeding time was 2.67 days (range 1-9 days) and post-operation hospital stays were 5.39 days (range 2-10 days). The mean time of follow-up was 26.4 months (range 5-51months). The follow-up showed that 6 patients kept on treating with oral administration of imatinib. No patient was found recurrence or death.

Conclusion: Endoscopic treatments were demonstrated as safe and effective ways to resect gastric stromal tumors in this study.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0167 GASTROENTEROLOGY REGISTRAR OF THE WEEK: A SOLUTION FOR AUGIB ENDOSCOPY TRAINING?

S. Budihal¹, P. Wurm¹

¹Digestive Diseases Centre, University Hospitals Leicester, GB/United Kingdom

Contact E-mail Address: shivbudihal@yahoo.co.uk

Introduction: Much concern surrounds Gastroenterology Specialist Registrar (StR) endoscopy training, especially in regards to endoscopic management of Acute Upper Gastrointestinal Bleeding (AUGIB). Recent evidence suggests there has been a decline in exposure and experience in AUGIB endoscopy¹. In July 2013 our University Hospital introduced a Consultant-led and Registrar-supported Monday to Friday, 9 to 5pm in-reach service. It comprises of a morning visit to the acute medical units and a daily inpatient emergency list. This study looked at registrar AUGIB endoscopy training after its implementation.

Aims & Methods: Endoscopy reports of patients presenting with haematemesis, melena or both who had undergone gastroscopy during the period of 1st of March 2015 to 31st August 2015 were retrieved using the endoscopy reporting tool Unisoft and analysed. Reports where StRs were the primary operator were considered. Number of procedures, haemostatic intervention and nature of haemostasis was analysed. This was then compared to data from the year before implementation (01/03/2012 to 31/08/2012)

Results: A total of 7 StRs (5 Full Time and 2 Less than Full Time) performed gastroscopies on AUGIB patients as first operators under Consultant supervision. Over the 6-month period a total of 166 gastroscopies were undertaken (Mean 24). On 26 occasions, endoscopic intervention (EI) was performed (Mean 4). On average, 16% of the AUGIB patients required EI. In cases of Non Variceal Bleeding, Dual therapy was applied in 87.5% of the cases. In the remaining cases Haemospray was used. On average each StR was able to perform one case of oesophageal variceal banding and one case where Haemospray was utilised. Data from the 2012 cohort in comparison showed a total of 66 gastroscopies over 6 months with 13 EI. On average 13 procedures and 2.6 EIs were performed by each StR. Dual therapy was applied in only 28.5% of the cases

Conclusion: The introduction of the Registrar of the Week Service provides a valuable opportunity for StRs to be trained in endoscopic haemostasis and acquire exposure to AUGIB patients. As per this study each StR on an average performed endoscopy on 24 AUGIB patients. If this is extrapolated, each StR will be able to perform 48 procedures in 1 year and 240 procedures over 5 years. In the case of EI, on average a StR can perform around 4 interventions over 6 months, which comes to 8 per year and 40 in a 5 year programme which is significantly better than in the previous cohort and other centres¹. Hospitals should consider developing similar services not only to meet demands for 24/7 Consultant led AUGIB endoscopy service but provide adequate endoscopic training provision for current specialist registrars in order to ensure future competent and confident consultants.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0168 HIGH PERCENTAGE OF VISIBLE LESIONS IN PATIENTS WITH BARRETT'S ESOPHAGUS REFERRED WITH DYSPLASIA IN RANDOM BIOPSIES

I. C. Noordzij¹, W. L. Curvers¹, I. Van Lijnschoten², C. J. Huysentruyt², E.J. Schoon¹

¹Gastroenterology And Hepatology, Catharina Hospital, Eindhoven/Netherlands
²Laboratory Of Pathology And Medical Microbiology, PAMM, Eindhoven/Netherlands

Contact E-mail Address: irma.noordzij@catharinaziekenhuis.nl

Introduction: Endoscopic recognition of dysplasia or early cancer in Barrett's esophagus (BE) is difficult. Experience in recognition of early neoplastic lesions is thought to increase the detection of visible dysplastic lesions. A previous study reported that endoscopists in community hospitals detect neoplastic lesions at a significant lower rate than referral centres. The aim of the study we want to assess the significance of dysplasia in random biopsies in BE, in the absence of reported visible lesions as well as the final outcome of pathology.

Aims & Methods: We retrospectively analysed all patients referred from 19 community hospitals to our tertiary referral centre with the diagnosis of BE with dysplasia or early adenocarcinoma (EAC) between February 2008 and April 2016. All patients underwent a dedicated imaging endoscopy with high-definition endoscopy supplemented with virtual chromoendoscopy and/or acetic acid staining at the discretion of the endoscopist. All procedures were performed by an endoscopist with extensive experience in the detection of early neoplastic lesions in BE. During endoscopy all visible lesions were noted and biopsied and/or removed by endoscopic resection (ER). Patients were included for analysis in case of absence of reporting visible lesions at referral.

Results: In total 184 patients were referred with dysplasia or EAC of which 82 patient (80.5% male, age 42-81 years (median (68))) did not show a visible lesion upon referral endoscopy. Referral diagnosis of these 82 patients was 32 low-grade dysplasia (LGD), 43 high-grade dysplasia (HGD) and 7 EAC. In three of 32 patients (9.4%) referred with LGD, a visible lesion during imaging endoscopy was detected. Two cases of histology proved EAC and one confirmed LGD. In twenty-six of 43 patients (60.5%) referred with HGD, a visible lesion with histology specimens corresponding to HGD (10) and EAC (16) were found,

respectively. All cases of EAC were detected (7/7). In 18/75 (24%) patients referred with dysplasia (LGD/HGD) without a visible lesion, the referral diagnosis was thus upstaged to EAC. Overall, 41/82 (50%) lesions were found additionally.

Conclusion: The presence of any grade of dysplasia in random biopsies in BE screening in community hospitals is a potential marker for more severe final pathology after endoscopic work-up in an expert centre. Training in Barrett imaging is mandatory for non-expert endoscopists.

P0169 ENDOSCOPIC MANAGEMENT OF BENIGN ESOPHAGO-RESPIRATORY FISTULAS

A. Debourdeau, J. Gonzalez, A. Benezec, M. Barthet
Gastroenterology, Aix Marseille University, AP-HM, Hôpital Nord, Marseille/France

Contact E-mail Address: antoinedebourdeau@hotmail.com

Introduction: Nonmalignant esophago-respiratory fistulas (ERF) are rare but frightening clinical situations. They usually involve surgery, but the morbidity and the mortality is high. The knowledges about the modalities and outcomes after endoscopic management of ERF remain limited.

Aims & Methods: The aim of this study was to describe and assess the endoscopic management of benign ERF in our center. This was a retrospective study involving patients manage for benign ERF in our tertiary center between July 2012 and December 2016. The inclusion criterion was the presence of communication between esophagus and bronchial tree diagnosed confirmed and treated by endoscopy, and malignant ERFs were excluded. The ERFs were classified into three groups of sizes: punctiform (if the orifice was no larger than a straight catheter), medium and large (with visibility of bronchial tree). The primary endpoint was to document the clinical success defined as the closure of the fistula confirmed by endoscopy and persisting >6 months. The secondary endpoints were to document the characteristics of endoscopic treatment, the functional success and death, and to identify factors associated with success and death.

TABLE 1: - Demographics & Results

	Clinical failure	Clinical success	p value
Number of patients n = 22	n = 12	n = 10	
Gender			
Male/Female	6/6	7/3	0.342
Etiology			
Post-surgery	7	6	0.665
Post-dilatation	0	3	0.062
Post-radiation	2	0	0.138
Post-invasive ventilation	3	2	0.534
Pulmonary location			
Trachea	10	7	0.127
Right bronchus	2	1	0.534
Left bronchus	0	2	0.138
Orifice size			
Punctiform	3	6	0.193
Medium	3	3	1
Large	6	1	0.17
Timing of closure			
Resolution at 3 months	0	7	< 10 ⁻³
Resolution at 6 months	0	8	< 10 ⁻³
No resolution at 6 months	12	2	< 10 ⁻³
Endoscopic treatment			
Mean number of esophageal stents	3.6 (±3.9)	2.3 (±2.7)	0.069
Mean number of OTSc	1.2 (±1.8)	0.4 (±0.7)	0.082
At least one esophageal stent	11	9	0.892
At least one OTSc	6	2	0.146

Results: A total of 22 patients were included and analyzed. The etiologies of ERF were esophageal surgery in 12 patients (54.5%), esophageal dilatation in 3 (13.6%), invasive ventilation in 3 (13.6%), radiation therapy in 2 (9.1%) and tracheostomy in 2 (9.1%). A total of 93 procedures were performed with a mean of number of endoscopies of 4.2 ± 4.5 per patient. At some point of the management, twenty-one patients (95%) had esophageal stents placement, eight patients (36%) had over the scope clips (OTSC) placement and seven had OTSC associated with esophageal stent. The clinical success rate was 45.5% (n = 10), and 55% of the patients had a functional success (n = 12). Serious adverse events occurred in 9 patients (40.9%) such as gastrointestinal bleeding (4 patients, 18.2%), stent migration (4 patients, 18.2%), thoracic spondylodiscitis (2 patients, 9.1%) alimentary esophageal impaction (1 patient, 4.5%), stent mucosal impaction (1 patient, 4.5%), major chest pain (1 patient, 4.5%). Six patients died (27%). Clinical success was reached for 67% of punctiform ERF (p = 0.193), 50% of medium ERF (p = 1) and 14% of large ERF (p = 0.17). The factor associated with the failure of endoscopic treatment was the persistence of the

fistula after 6 months (OR = 44; IC95: 3.38–573, 4; p = 0.004 multivariate analysis). The orifice's size was associated with the mortality with 71% of death among large fistulas (p = 0.001 univariate analysis).

Conclusion: Conclusions: Endoscopic treatment of ERF can lead to 45.5% of clinical success and 55.5% of functional success. However, this outcome appears to depend on the size of the fistula. Moreover, the absence of resolution after 6 months of endoscopic treatment dramatically decreases the chance for ERF healing. In conclusion, the endoscopic approach seems reasonable for small or medium orifices, and has to be attempted during six months. After this time or for larger orifices, surgery or palliative therapy should be considered.

P0170 CLINICAL UTILITY OF NARROW BAND IMAGING MAGNIFYING ENDOSCOPY FOR MM/SM1 ESOPHAGEAL SQUAMOUS CELL CARCINOMA

M. Inoue¹, T. Omori¹, K. Natsu¹, K. Aiura¹

¹Department Of Surgery, Kawasaki Municipal Kawasaki Hospital, Kawasaki/Japan

Contact E-mail Address: masaz.inoue@gmail.com

Introduction: Esophageal squamous cell carcinoma (ESCC) is common in Asia. Predicting invasion depth of superficial ESCC is crucial in determining the precise treatment because the rate of lymph node metastasis increases in proportion of the invasion depth of the carcinoma. According to Japanese guidelines for diagnosis and treatment of esophageal cancer, superficial invasions are divided into 5 categories: carcinoma in situ (EP), tumors invades lamina propria mucosa (LPM), lamina muscularis mucosa (MM), the submucosa to a depth of 200 µm or less from the muscularis mucosa (SM1), and the submucosa to a depth more than 200 µm (SM2). The rate of lymph node metastasis is extremely low in EP/LPM tumors, and endoscopic resection (ER) is certified as precise treatment. On the other hand, the rate of lymph node metastasis in MM/SM1 tumors are reported to 10–20%, and both operation and ER are considered as their treatment. Accurate pretherapeutic diagnosis of MM/SM1 tumor is very important for selection of appropriate treatment and interests of patients. In this point, endoscopic diagnosis is very important diagnostic approach.

Aims & Methods: The purpose of this study is to investigate the utility of Narrow Band Imaging (NBI) magnifying endoscopy for the diagnosis of MM/SM1 ESCC. From January 2011 to April 2017, 23 patients were diagnosed as pathologically MM/SM1 ESCC in our hospital. We retrospectively analyzed their endoscopic findings and pathological findings. The depth of invasion was diagnosed by NBI magnifying endoscopy according to the Japan Esophageal Society (JES) magnifying endoscopic classification¹. Diagnostic criteria are based on the degree of microvascular irregularity in the target lesion observed by NBI magnifying endoscopy. Microvessels are grouped into 2 types. Type A microvessels are normal intrapapillary capillary loops or abnormal microvessels without severe irregularity. Type B microvessels are abnormal vessels with severe irregularity or highly dilated abnormal vessels, and subclassified into B1, B2, and B3 based on the running pattern or degree of dilation of severely irregular microvessels. When target lesions have B1 vessels, the invasion depth is predicted as EP or LPM. When B2 or B3 vessels are seen, the invasion depth is predicted as MM or SM1 and SM2 or deeper, respectively.

Results: In 23 pathologically MM/SM1 cases, clinical type diagnosed by endoscopy was 0-IIc in 16 cases (70%), 0-IIa in 3 cases (13%), 0-IIb in 3 cases (13%), and 0-Ip in 1 case (4%). Predicted depth of invasion by NBI magnifying endoscopy based on the JES classification was EP in 2 cases (9%), LPM in 7 cases (30%), MM in 10 cases (43%), SM1 in 3 cases (13%) and SM2 in 1 case (4%). Total diagnostic accuracy of MM/SM1 was 57% (13/23). When the B2 vessels were observed, diagnostic accuracy of MM/SM1 was 90% (9/10). In the cases that MM or SM1 invasion remained pathologically quite localized, B2 vessels could not be observed by NBI magnifying endoscopy. And also, in the cases with inflammation or keratinizing epithelium, precise diagnosis of microvessels were difficult.

Conclusion: Our data indicate that diagnosis of MM/SM1 ESCC by NBI magnifying endoscopy based on the JES classification is useful when the abnormal microvessels are observable, and NBI magnifying endoscopy is essential method for pretherapeutic examination.

Introduction: Gastroparesis is a chronic, debilitating motility disorder. Effective treatment is challenging especially in patients with severe symptoms. POEP is an

emerging modality for refractory gastroparesis with promising preliminary results.

Aims & Methods: The aim of this prospective case series was to assess our first (single center) experience with POEP. Main outcomes were: 1) the efficacy defined by improvement of GCSI score; 2) gastric emptying evolution and 3) safety. Since Nov 2015, a total of 7 patients underwent POEP. The etiology of gastroparesis was post-operative in 4, diabetic in 2 and idiopathic in 1 patient. One patient underwent POEP for gastroparesis following a multivisceral transplantation; one patient underwent both POEP and POEM (as a single procedure) for coexisting refractory idiopathic gastroparesis and achalasia. All patients had severe gastroparesis as defined by elevated GCSI score and delayed gastric emptying scintigraphy. Follow visit at 3, 6, 12-months were completed in 7/7 (100%), 5/7 (71%) and 1/7 (14%) patients, respectively. Upper GI endoscopy and scintigraphy were performed 3 months after the procedure.

Results: POEP was successfully performed in all patients. Mean procedure time was 70 minutes (range 63–106). After POEP, mean GCSI decreased from 3.0 ± 1.2 to 0.8 ± 0.7 (at 3-months) and 0.9 ± 0.8 (at 6-months). One woman finished the 12-months follow maintaining excellent outcome. Treatment success was reached in 6/7 (85%) of patient, one female patient with diabetic gastroparesis did not have a major symptomatic improvement despite normalisation of gastric emptying study. Gastric scintigraphy normalized in all patients, mean half emptying time decreased from 108 ± 30 min to 62 ± 23 min; and mean bolus retention at 4 hours decreased from $17 \pm 9.2\%$ to $2.0 \pm 2.0\%$. One patient developed bleeding ulcer 10 days after POEP, this adverse event was successfully managed endoscopically (clips) and by parenteral proton pump inhibitor.

Conclusion: We report our first experiences with POEP for refractory gastroparesis, demonstrating its feasibility and safety with promising clinical efficacy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0172 BLUE LIGHT IMAGING FOR BARRETT'S NEOPLASIA CLASSIFICATION (BLINC): THE DEVELOPMENT AND VALIDATION OF A NEW ENDOSCOPIC CLASSIFICATION SYSTEM TO IDENTIFY BARRETT'S NEOPLASIA

Introduction: Neoplasia in Barrett's can be subtle and difficult to identify. Blue light imaging (BLI) by Fujifilm is a novel advanced endoscopic technology that provides high-intensity contrast imaging for superior visualisation of mucosal surface and vessel patterns. This can improve the identification of Barrett's neoplasia. To date there is no formal classification system that enables the characterisation of neoplastic and non-neoplastic Barrett's for BLI.

Aims & Methods: The aim of our study was to develop and validate a classification to identify Barrett's neoplasia using BLI. 3 expert endoscopists formed a working group to identify criteria characterising neoplastic and non-neoplastic Barrett's on BLI using a modified Delphi method. A simple classification system utilising pit, vessel pattern and colour was developed using a database of 40 images. 6 experienced endoscopists then assessed a library containing 45 images of neoplastic and non-neoplastic Barrett's using the proposed criteria. Sensitivity, specificity, positive (PPV) and negative predictive values (NPV) were calculated to assess its performance. The same parameters were then evaluated for each component criteria.

Results: The BLINC classification descriptors are as follows: **Non Neoplastic Barrett's:** Pit pattern: circular, tubular or branching with normal density; Vessel pattern: regular, pericryptal non dilated vessels with normal density; Colour: pale **Neoplastic Barrett's:** Pit pattern: irregular, crowded with increased density; Vessel pattern: irregular, non cryptal, dilated vessels with increased density; Colour: focal darkness The overall sensitivity and specificity, negative and positive predictive values with corresponding 95% confidence intervals are as follows: 96.7 (92.4–98.9)%, 96.7 (91.2–99.1)%, 97.3 (93.3–99.0)% and 95.9 (90.7–98.2)% respectively in the classification of Barrett's neoplasia. When each category in the classification was analysed separately the predictive values of pit and vessel pattern in neoplasia characterisation were high compared to colour (as shown in the table below).

	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95%CI)
Pit pattern	96.0 (91.5–98.5)%	98.3 (94.1–99.8)%	98.6 (94.8–99.7)%	95.2 (89.9–97.7)%
Vessel Pattern	94.7 (89.8–97.7)%	93.3 (87.3–97.1)%	94.7 (90.1–97.2)%	95.2 (89.9–97.7)%
Colour	86.7 (80.2–91.7)%	78.3 (69.9–85.3)%	83.3 (78.0–87.6)%	82.5 (75.6–87.7)%

Conclusion: We have developed the first internally validated simple classification system for the diagnosis of Barrett's neoplasia using BLI. The classification criteria demonstrated high sensitivity and specificity particularly with regards to mucosal pit and vessel patterns. We aim to use the proposed classification in future studies for real time optical diagnosis of Barrett's neoplasia.

P0173 TREATMENT OF MULTIPLE GASTROINTESTINAL SUBMUCOSAL TUMORS BY SUBMUCOSAL TUNNELING ENDOSCOPIC RESECTION

J. Liu, W. Qin, Y. Huang, Z. Ren, P. Zhou

Endoscopy Center And Endoscopy Research Institute, Fudan University Zhongshan Hospital, Shanghai/China

Contact E-mail Address: liu.jingzheng@zs-hospital.sh.cn

Introduction: Submucosal tunneling endoscopic resection (STER) is a novel technique to remove the gastrointestinal submucosal tumors. Previous studies mainly focused on technical feasibility for patients with one single gastrointestinal submucosal tumor. No systematic studies about multiple upper gastrointestinal submucosal tumors synchronously removed by STER are addressed. The aim of this study was to evaluate the safety and outcome of STER in treatment of multiple gastrointestinal submucosal tumors.

Aims & Methods: From January 2011 to January 2017, 42 patients with multiple gastrointestinal submucosal tumors undergoing STER were included. Variables of each tumor and patient were analyzed. Detailed tumor characteristics included max size, sum of max size and number of tumors, and longest distance of tumor. While detailed technique information included number of tunnels, tunnel length, hospital stay, procedure time, complication, follow-up, recurrence, and metastasis.

Results: Among all the cases, 96 lesions of upper gastrointestinal submucosal tumors were removed by STER. The median procedure time was 50 min (range 13.6–84.9 min). The median number of tumors was 2 (2–4). The median max size of each tumor was 1.8 cm (range 0.7–3.5 cm) and the median sum of max size of each tumor of each patient was 3 cm (range 1.3–8 cm). Six patients had perioperative complications (14.2%), with 3 pneumothorax/hydrothorax (7.2%), 1 mucosal injury (2.4%), 1 pneumonia (2.4%), and 1 major bleeding (2.4%). Patients with different number of tunnels had similar tumor characteristics and techniques. There were significant differences in longest distance of tumors comparing two groups ($p < 0.001$). No local recurrence or distant metastasis was detected with a median follow-up of 33 months.

Conclusion: STER is a safety and feasible technique for multiple upper gastrointestinal submucosal tumors no matter in one tunnel or two tunnels resection. Based on the longest distance of tumors, different number of tunnels can be performed with similar procedure technique and prognosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: LCI is a new imaging technique based on 4 independently acting LEDs that is enhancing the mucosal vascular pattern and surface pattern morphology. To date, chromoendoscopy with acetic acid is considered the gold standard for diagnosis of Barrett's esophagus.

Aims & Methods: The aim of this prospective study was to evaluate the recently introduced LCI technique compared to conventional dye spraying with acetic acid for diagnosis of Barrett's esophagus. Therefore, consecutive patients with Barrett's esophagus were categorized according to the Prague classification and prospectively included. All Barrett segments were carefully evaluated by using high-definition white-light imaging, followed by LCI and acetic acid spraying. At each examination targeted biopsies were taken from all visible lesions, followed by random four-quadrant biopsies were applicable.

Results: The diagnostic yield of conventional dye spraying was significantly higher for diagnosis of Barrett's esophagus compared to high-definition white-light endoscopy ($P < 0.05$). Of note, no significant difference for diagnosis of Barrett's esophagus was noted between acetic acid chromoendoscopy and the LCI technique. LCI diagnosis was always consistent to traditional dye spraying (100% concordance). The random four-quadrant biopsy protocol did not add any new information to the one already obtained by using LCI.

Conclusion: The newly introduced LCI technique is superior to high-definition white light endoscopy for diagnosis of Barrett's esophagus and equally effective to acetic acid dye spraying. Therefore, the LCI technique has the potential to facilitate the diagnosis of Barrett's esophagus and to overcome the limitations of a random 4-quadrant biopsy protocol.

P0175 ALBERTA FAMILY PRACTICE ELECTRONIC ENDOSCOPY STUDY (AFPEE)

M. Kolber¹, L. Green¹, N. Olivier¹, R. Torrie², O. Babenko¹

¹Family Medicine, University of Alberta, Edmonton/Canada/AB

²Taber Medical Clinic, Taber/Canada/AB

Contact E-mail Address: mkolber@ualberta.ca

Introduction: In Canada, gastroenterologists and general surgeons perform 97% of the colonoscopies. There are a small number of rural Canadian Family Physicians who perform colonoscopies. These endoscopists may improve access for rural patients who require endoscopy and help improve provincial endoscopy wait times. Although some studies demonstrate that adequately trained Family Physicians are able to perform quality endoscopy, other studies question the quality of colonoscopies performed by non-gastroenterologists.

Aims & Methods: The Alberta Family Physician Electronic Endoscopic (AFPEE) study aimed to examine the quality of colonoscopies performed by Family Physicians in Alberta, Canada. Primary outcomes include the proportion of successful cecal intubations; proportion of patients 50 years and older having a first time colonoscopy with an adenoma; and immediate complication rates. Prospective, multi-centred observational study with real-time electronic data collection and pathological reconciliation. Using IPADs,™ data was inputted in real time into an REDCap™ based electronic record developed by the study team. Individual physician and group results of key quality indicators were compared to standard colonoscopy quality benchmarks.

Results: In this six-month study, 9 Family Physicians performed 1769 colonoscopies in 11 rural Alberta sites. The proportion of successful cecal intubations was 97.9% (95% CI: 97.2, 98.5). All physicians had over 90% successfully completed colonoscopies (ranging from 95.2 to 100%) The proportion of males and females ≥ 50 years old with an adenoma on a first-time colonoscopy was 67.4% (95% CI: 62.4, 72.7) and 51.1% (95% CI: 45.5, 56.7) respectively. All physicians achieved benchmarks of 30% of males and 20% for females having at least one adenoma. From all colonoscopies in the study there were 2099 pathologically confirmed adenomas or SSAs, 628 advanced adenomas and 17 cancers, corresponding to 120 adenomas, 36 advanced adenomas and 1 colon cancer per 100 colonoscopies. There were 2 post-polypectomy bleeds, no perforations and no deaths.

Conclusion: Alberta Family Physician colonoscopists are meeting benchmarks in colonoscopy quality. Ongoing electronic collection of endoscopy quality markers should be encouraged. Supporting and training rural Family Physicians who perform endoscopy may help alleviate current wait times and improve access for rural Canadian patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In a randomised controlled trial, flexible sigmoidoscopy (bowel scope) reduced colorectal cancer incidence and mortality in a population aged 55-64.[1] Patients progressed to colonoscopy based on 'high risk' features (Table 1).[1] Based on these pivotal findings, the UK bowel scope (BS) surveillance programme was introduced in 2013 to individuals aged 55. The Wolverhampton Bowel Cancer Screening Centre was the first UK site to fully roll out the programme. The correlation between BS findings and subsequent colonoscopy has not previously been evaluated in this specific cohort.

Aims & Methods: We prospectively collated data from all BS patients at our centre and identified those undergoing colonoscopy between August 2013-2016. We assessed conversion rates, compliance with BS protocol and correlated endoscopic and histological findings to identify predictors for detection of pathology at colonoscopy. Univariate analysis was performed using Pearson's chi².

Results: 11,711 bowel scopes were performed, with an adenoma detection rate (ADR) of 8.5%, and conversion to colonoscopy in 421 patients (3.6%). 386 were included for analysis after excluding incomplete colonoscopy/histology. All patients were aged 55 (64.8% male). Additional ADR at colonoscopy was 35.2%, with malignant diagnoses in 1.5% (all detected at BS). The adenoma miss rate at BS was 5.2%. On univariate analysis (Table 1), polyp ≥ 10 mm was the only indication associated with increased ADR at colonoscopy (OR 2.13, $p < 0.001$). Additional predictors identified included villous (not tubulovillous) histology (OR 4.41, $p = 0.02$), and male gender (OR 2.35, $p < 0.001$). These factors also significantly predicted new ≥ 10 mm adenoma. 57 (14.8%) underwent colonoscopy outside protocol, which reduced ADR (OR 0.29, $p = 0.03$). After excluding high risk indications, changing the conversion criteria from any villous to villous only histology altered sensitivity from 27.2% to 83.3%, and specificity from 84.5% to 80.5%.

Table 1: Indications for progression from BS to colonoscopy (in bold), [1] and likelihood of new adenoma detection. *Patients in multiple categories are included multiple times. ** $p < 0.05$

Indication	N*	New adenoma	OR (95% CI)	p-value
At least 3 polyps	78	45 (57.7%)	1.46 (0.88-2.43)	0.14
Size at least 10 mm	196	86 (43.9%)	2.13 (1.39-3.27)	<0.001**
High grade dysplasia	16	5 (31.3%)	0.82 (0.28-2.41)	0.72
Any villous component	190	69 (36.3%)	1.09 (0.72-1.67)	0.66
> 20 hyperplastic polyps	3	0	NA	NA
None of the above	57	9 (15.8%)	0.29 (0.14-0.62)	0.001**
Villous only histology	10	7 (70.0%)	4.41 (1.12-17.36)	0.02**

Conclusion: At BS, male gender, ≥ 10 mm polyps, and villous histology are predictors of proximal colonic pathology. Further analyses are required to clarify the benefits of converting low-risk tubulovillous adenomas at BS to colonoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cold snare polypectomy is an established method for the resection of small colorectal polyps (SCPs); however, significant incomplete resection rates still leave room for improvement. We aimed to assess the efficacy of cold snare polypectomy with submucosal lift (SL-CSP), compared to endoscopic mucosal resection (EMR), for nonpedunculated polyps 6–10 mm (ClinicalTrials.gov NCT02678663).

Aims & Methods: Dual-center, randomized, noninferiority trial. Consecutive adult patients with at least one nonpedunculated polyp 6–10 mm were enrolled. Eligible polyps were randomized (1:1) to be treated with either SL-CSP or EMR. The primary noninferiority endpoint was histologic eradication, with a noninferiority margin of –10%. Evaluation of histologic complete resection relied on a postpolypectomy biopsy protocol (4 biopsies obtained in a 4-quadrant fashion from the polypectomy site margins; 1 biopsy from the base). Secondary outcomes included occurrence of intraprocedural bleeding (IPB; defined as any immediate episode requiring endoscopic haemostasis), clinically-significant postprocedural bleeding (CSPPB; any episode requiring emergency department presentation, hospitalization, or reintervention within 30 days of the procedure) and perforation.

Results: Among 689 patients screened, 155 patients with 164 eligible polyps (SL-CSP; n = 83, EMR; n = 81) were included. The overall rate of histologic complete resection was 92.8% (77/83) in the SL-CSP group and 96.3% (78/81) in the EMR group (difference 3.5%; 95%CI, –4.15 to 11.56), showing noninferiority of SL-CSP compared with EMR. The SL-CSP technique was noninferior to EMR both for polyps measuring 6–7 mm (SL-CSP, 93.3%; EMR, 100%; 95%CI, –7.95 to 21.3) and those 8–10 mm (SL-CSP, 92.5%; EMR, 94.7%; 95%CI, –7.91 to 13.16). By multivariate analysis, female gender (OR, 0.15; 95%CI, 0.02–1.06; P = 0.06) and Paris 0-IIa morphology (OR, 0.12; 95%CI, 0.01–1.19; P = 0.07) were marginally significant predictors correlating negatively with complete resection. Rates of IPB were similar between the two groups (SL-CSP; 3.6%, EMR; 1.2%, p = 0.3). No CSPPB or perforation occurred in either group.

Conclusion: SL-CSP appears to be an effective modification of standard cold snare technique, obviating the need to use diathermy for 6–10 mm colorectal polyps.

Introduction: Colonoscopic polypectomy effectively reduce the incidence of colorectal cancer. Variations in the technique have been implicated in the effectiveness of the resection and in the complication rates. However, there is no consensus regarding the optimal polypectomy technique for diminutive (≤5 mm) and small (6 to 9 mm) polyps. There are scarce of data about polypectomy practices among European endoscopists

Aims & Methods: To determine the different techniques used by Spanish endoscopists for resection of sessile or flat colorectal polyps smaller than 20 mm.

A 70-item survey was sent by email to all Gastroenterology Departments in all Spanish hospitals (1678 gastroenterologists). The survey was conducted from December 2015 to February 2016.

Results: The rate of participation was 20.3% (341/1678). All physicians indicated they were practicing gastroenterologist (none were trainees). Most respondents (60%) were males and 50% had more than 14 years in practice. The mean number of colonoscopies per week was 21 ± 12.3. Half of participants performed endoscopies for ≥3 days per week and 49.6% did not performed advanced

therapeutic endoscopy. The techniques used for the excision of polyps smaller than 20 mm by Spanish clinicians are summarized in Table 1. Significant differences were noted in the polypectomy techniques used for the resection of polyps 1–3 mm, 6–9 mm and 10–19 mm in diameter; being cold forceps, hot snare and endoscopic mucosal resection (EMR), the preferred techniques respectively for the different sizes. However, for polyps 4–5 mm in size, both the cold snare and cold forceps were the most commonly used techniques, though no method was use more often than the other. Years in practice, colonoscopy volume per week and performing advanced therapeutic endoscopy were associated with different choices of polypectomy technique. For polyps measuring 4–5 mm, cold snare was the favourite method among endoscopists who performed ≥20 colonoscopies per week (≥20 colonoscopies/week vs. <20 colonoscopies/week, 42.4% vs. 26.6%, p < 0.05), among those who performed endoscopies ≥3 days/week (≥3 days/week vs. <3 days/week, 40% vs. 25.7%, p < 0.05) and among those who performed advanced endoscopy (advanced endoscopy vs no advanced endoscopy, 40.4% vs. 29.2%, p < 0.05). However, cold forceps was the preferred technique among endoscopists who performed endoscopies <3 days per week (38.9% vs. 29.2%, p < 0.05) and among those who did not perform advanced endoscopy (37.3% vs. 28.1%, p < 0.05). For small polyps (6–9 mm), cold snare polypectomy was most frequent among endoscopists who performed more colonoscopies (≥20 colonoscopies/week vs. <20 colonoscopies/week, 28% vs. 13%, p < 0.05) and among those with less than 10 years in practice (<10 years vs. ≥10 years, 27.2% vs. 17.7%, p < 0.05). However, hot snare polypectomy was most frequent among endoscopists who performed less than 20 colonoscopies/week (<20 colonoscopies/week vs. ≥20 colonoscopies/week, 56.7% vs. 44.7%, p < 0.05) and among those with more than 10 years in practice (≥10 years vs. <10 years, 53.8% vs. 44.7%, p < 0.05).

Table 1: The techniques used for the excision of colorectal polyps smaller than 20 mm

Resection Method	1–3 mm	4–5 mm	6–9 mm	10–19 mm
Standard cold biopsy forceps	70.5%	32.7%	3.3%	0.3%
Jumbo biopsy forceps	7.3%	6.8%	1.9%	0%
Hot biopsy forceps	1%	1.9%	2.5%	2%
Cold snare	16.2%	34.8%	21.2%	1.1%
Hot snare	4.1%	19.6%	50.4%	38.9%
Endoscopic mucosal resection	0.6%	3.9%	19.7%	57%

Conclusion: There is a remarkable heterogeneity in the techniques used for removal of polyps <20 mm among Spanish endoscopists. Cold forceps, hot snare and EMR are the preferred methods for removing diminutive polyps, small polyps and polyps measuring 10 to 19 mm, respectively. The use of cold snare for removing small and diminutive polyps is most frequent among gastroenterologists with a greater dedication to endoscopy (colonoscopy volume per week and performing advanced endoscopy) and among endoscopists with less than 10 years in practice.

Introduction: Early diagnosis of colorectal cancer whether through a symptomatic or screening pathway results in better outcomes for patients. Various studies have reported barriers to screening amongst non-responders as well as delays in diagnostic pathways. Current constraints in the NHS in colonoscopy capacity are a compounding factor and all these factors contribute to delays in diagnosis. We hypothesise that changing the diagnostic paradigm through community or primary care based semi-automated robotic colonoscopy is a method of improving access to and engagement with non-responders (1, 2).

Aims & Methods: This project forms part of the development of a training programme with the use of a simulation based training model to understand the specific training needs and methods of fulfilling these for the potential ultimate users of community-based robotic colonoscopy. This study involved participants with varying degree of skills and background knowledge in the field of colonoscopy. We enrolled three expert endoscopists, three trainee endoscopists, two novices and two experienced video gamers. All participants performed colonoscopies on a validated 'colonoscopy suitcase' model developed at Welsh Institute for Minimal Access Therapy (WIMAT) centre. Before testing each participant received both verbal and written instructions on the goals of the study and information about the semi-automated robotic endoscope along with a familiarisation period with the device. Quantitative parameters were recorded related to procedure times and lesion detection during the procedure. Afterwards participants filled out a questionnaire evaluating the robotic

colonoscope. Some operators participated in a follow up session in order to analyse the learning curve of the robotic endoscopy.

Results: On average, experts required the shortest time to reach the caecum, followed by video gamers, trainees then novices. Polyp detection rate (as a proportion of total number in the model simulator colon) was the highest in the novice group (91.67%) followed by the experts (86.11%), then equally, trainees and video gamers (79.17%). Four out of nine participants attended the second session where they were asked to repeat the procedure from the first session. Each participant had a lower caecal intubation time during session 2 in comparison with session 1, with range of improvement between 30% and 70%. Each of the participants also had the same or higher polyp detection rate with range of improvement between 0% and 25%. Qualitative assessment of feedback from all participants indicated that most operators felt that the role of the novel test was likely to be greater as a diagnostic procedure in an out of hospital setting. Expert operators felt that training in the device was easier but also provided less ability to torque steer due to automated sequences.

Conclusion: This project is the first step in identifying specific training needs and potential roles of robotics in early diagnosis of cancer. This study also shows a potential to reduce the length of time for skills acquisition associated with standard colonoscopy training through the use of semi-automated robotic devices.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Yao et al. observed gastric epithelial neoplasms and chronic gastritis mucosa using magnifying endoscopy with narrow-band imaging (M-NBI), and reported a phenomenon in which a white opaque substance (WOS) present in the epithelium did not allow passage of the projected light and obscured the subepithelial microvasculature (1). Furthermore, the morphology of the WOS is a useful marker for differentiating between adenoma and carcinoma in gastric epithelial neoplasms (1). Recently, we reported for the first time that WOS is also detected in colorectal epithelial neoplasms (2). However, it is unclear whether the morphology of the WOS in colorectal epithelial neoplasms is useful in the differential diagnosis of adenoma and carcinoma. We, therefore, conducted a prospective observational study to determine whether it is possible to differentiate between carcinoma and adenoma based on the morphology of the WOS in colorectal epithelial neoplasms (UMIN000021167).

Aims & Methods: The subjects were consecutive patients with colorectal epithelial neoplasms (adenoma, early colorectal cancer) who underwent endoscopic or surgical resection at Fukuoka University Chikushi Hospital from December 2015 to November 2016. Prior to treatment, the entire lesion was observed using M-NBI, and endoscopic images were taken and recorded in a filing system. After the endoscopy was completed, a determination was made regarding the presence or absence of WOS on the endoscopic images. The morphology of the WOS was determined for cases in which WOS was present and in whom WOS was seen in more than half of the region before the results of histopathological examination of the lesions were known. The morphological characteristics of the WOS were classified as regular WOS or irregular WOS according to our previous report (1). The primary endpoint was the diagnostic performance of morphological analysis of the WOS (accuracy, sensitivity, specificity) for early colorectal cancer taking irregular WOS as an indicator. The secondary endpoint was the difference in the prevalence of irregular WOS between mucosal (M) or SM-s cancer (the depth of submucosal invasion is limited 1000 micrometers) and SM-m (the depth of submucosal invasion is over 1000 micrometers).

Results: Five hundred twenty-nine lesions in 296 patients were included in this study. Of these lesions, 404 were excluded, according to the following conditions: 268 negative for WOS, 72 in which WOS was seen in less than half of the region 34 that were diagnosed histologically as hyperplastic polyp, and 30 that could not be investigated because of rich mucus. The analysis was conducted using 125 lesions from 96 patients. Of these 125 lesions, 33 were determined to have irregular WOS and 92 to have regular WOS. Of the 33 lesions showed irregular WOS, 30 (90.9%) were early cancer and 3 (9.1%) were adenoma. Of the 92 lesions demonstrated regular WOS, 13 (14.1%) were early cancer and 79 (85.9%) were adenoma. The prevalence of irregular WOS in early cancer was significantly higher than that in adenoma ($p < 0.001$, chi-square test). The diagnostic accuracy for the differentiation between early cancer and adenoma using irregular WOS as an indicator of cancer was 87%. The sensitivity was 91% and specificity was 86%. The frequency of irregular WOS in M or SM-s cancer and SM-m cancer was 67.8% (21/31) and 75% (9/12), respectively. There was no significant difference in the prevalence between irregular WOS in M or SM-s cancer and SM-m cancer ($p = 0.727$, chi-square test).

Conclusion: These findings suggest that in colorectal epithelial neoplasms in which the microvasculature cannot be visualized because of WOS, the morphology of the WOS may be a useful marker in the differential diagnosis of adenoma and carcinoma using magnifying endoscopy.

Introduction: To reduce costs of colorectal cancer screening, a resect and discard strategy has been proposed for small polyps. The American Society of Gastrointestinal Endoscopy (ASGE) recommends achieving a diagnostic accuracy $\geq 90\%$, before implementing it (1). Narrow band imaging (NBI) is increasingly available and the NICE classification is frequently used to reach real time histologic classification. Endoscopists usually rely on short sessions, online courses or self-education for training in NBI, so we evaluated the learning curve in subjects with no previous endoscopic experience and their subsequent performance in patients with polyps ≤ 7 mm.

Aims & Methods: Participants (4th or 5th year medical students) attended one training session regarding NBI and NICE classification. Learning curves were posteriorly evaluated employing LC-CUSUM curves, with each participant individually assessing 100 lesions. Polyps were ordered by a computer-generated random sequence and divided into 6 sets of images (presenting 2 sets every week) consisting of 16–17 polyps. After evaluating each polyp, they received the correct diagnosis and a short explanation. The main outcome was a correct NICE diagnosis. A 90% accuracy defined an adequate performance and 80% was considered inadequate. A virtual cohort of 15000 evaluators was used to estimate a cut-off of 3, 45 for the LC-CUSUM curve. To assess the diagnostic performance, consecutive patients with lesions ≤ 7 mm were included. Patients with polyps lacking histological assessment, polyps > 7 mm or incomplete polypectomies were excluded. All participants received the same white light and NBI still images from 10 patients every week, including all polyps excised. Colonoscopies were presented in the same order as they were included in the study. Histological results were available with a 2-week delay. Evaluators predicted each polyp's histology, giving their level of confidence, and recommended a surveillance interval for each patient. Diagnostic accuracy was evaluated at polyp level and for follow-up intervals.

Results: Thirty-eight evaluators (median age: 22.1 years, 71.1% women) completed the study. Of the 100 lesions (8.5 mm, IQR: 5–17.5) included in the learning curve evaluation 19 were NICE 1.71 were NICE 2 and 10 NICE 3. Median diagnostic accuracy was 86% (IQR: 84–91%, range: 76–96%), increasing from 81.8% (IQR: 78.8–87.9%) in the first 33 lesions to 87.9% (IQR: 84.8–93.9%) in the last 33. According to the LC-CUSUM curve, 20 evaluators (52.6%) reached diagnostic competence. During the diagnostic performance assessment, a total of 180 patients were included, presenting 307 polyps (range: 1–8 polyps/patient), with a median size of 3 mm (IQR: 2–5); 71.3% were adenomas, 21.8% hyperplastic 2.6% serrated adenomas and 4.2% presented other diagnoses. Overall diagnostic accuracy was 76.9% (76.2–77.7%), reaching 81.3% (80.5–82.1%) in high-confidence diagnoses. Sensitivity for adenomas was 83% (82.2–83.8%), while for hyperplastic polyps it was 62.6% (60.8–64.5%). Surveillance intervals were correct in 78% (77–79%) of patients, 81.3% (80.2–82.4%) in those presenting highly confident diagnoses. Only 2 (5.3%) evaluators reached the 90% recommended threshold. Larger polyp size was associated with higher accuracy ($p < 0.001$), but neither competence according to the LC-CUSUM test ($p = 0.99$) nor frequent review of the histological results ($p = 0.74$) improved the evaluators' accuracy.

Conclusion: Self-formation after a single training session did not allow most evaluators to reach the ASGE suggested thresholds, mainly due to the low sensitivity for hyperplastic polyps. Further studies are required to address if specific training for small polyps or different formation methods might make NBI assisted optical diagnosis a plausible option for small polyps outside expert centers.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0183 HIGH CLEANSING EFFICACY OF NER1006 ALSO IN THE ELDERLY: POST HOC SUBGROUP ANALYSIS OF RANDOMISED PHASE 3 TRIALS

R. Jover¹, R. Ng Kwet Shing², P. Uebel³

¹Hospital General Universitario de Alicante, Alicante/Spain

²Clinical Development, Norgine Ltd, Harefield/United Kingdom

³Internistische Gemeinschaftspraxis, Ludwigshafen/Germany

Contact E-mail Address: rodrigojover@gmail.com

Introduction: Effective colonoscopy requires effective bowel cleansing. Inadequate cleansing may decrease diagnostic sensitivity, necessitate repeat procedures and delay appropriate treatment. Successful colon cleansing is harder to achieve in patients aged over 65 than in younger patients. NER1006 is the first 1L polyethylene glycol (PEG) -based bowel preparation, a patented combination optimised for effective bowel cleansing. Here, the efficacy of NER1006 at cleansing the colon in preparation for colonoscopy is compared to three active comparators, with attention to their efficacies in patients aged ≤65 years and >65 years who had a readable colonoscopy.

Aims & Methods: Colon cleansing efficacy of NER1006 was compared to three currently used bowel preparations in patients aged ≤65 years and in patients aged >65 years. NER1006 was compared to sodium picosulfate + magnesium citrate (NaPic + MgCit), trisulfate and 2L PEG with ascorbate (2L PEG + Asc), in three multicentre randomised Phase 3 clinical trials: DAYB¹, NOCT² and MORA³, respectively. 2L PEG + Asc was administered over 2 days and in the MORA trial, the doses of NER1006 were administered either both in 1 day morning-only (N1D) or, as with 2L PEG + Asc, split over 2 days (N2D). In the DAYB study, NER1006 was administered evening-only the day before colonoscopy (NDB). Treatment-blinded central readers rated colon cleansing according to the Harefield Cleansing Scale. Following segmental scoring, overall colon cleansing was graded from A to D. Grades A and B were judged as successful cleansing; grades C and D were judged as failed cleansing.

Results: Pooling the data from the three trials to assess colon cleansing in the two age groups showed successful cleansing in 80.5% (1158/1438) of patients aged ≤65 and in 79.6% (277/348) of patients aged >65 (difference of 0.9%; P=0.698; 95% CI: -3.7–5.6%). Within each trial the difference in colon cleansing in the age groups indicated that the effect of increased age on cleansing efficacy was lesser in the NER1006-treated patients than in patients treated with the active comparators (Table 1). For example, in patients treated with NER1006 the rate of successful colon cleansing in patients aged >65 was 5.2% higher than in patients aged ≤65, whereas in patients treated with NaPic + MgCit, there was 3.5% lower successful cleansing rate in patients aged >65 than in patients aged ≤65.

Conclusion: NER1006 was efficacious in successful colon cleansing in patients aged >65 (in whom successful colon cleansing is harder to achieve) as well as in patients aged ≤65. Statistical significance was not reached in these comparisons.

Contact E-mail Address: raf.bisschops@uzleuven.be

Introduction: Effective colonoscopy requires effective bowel preparation. For detection of polyps larger than 5 mm, an 'adequate' segmental cleansing level has recently been defined as 2 or more on the Boston Bowel Preparation Scale (BBPS).¹ The Phase 3 trial MORA compared NER1006 as an evening/morning split-dosing or a morning-only dosing regimen, against 2L PEG with ascorbate as an evening/morning split-dosing regimen (2L PEG + Asc). Treatment-blinded central readers assessed the bowel cleansing efficacy using both the Harefield Cleansing Scale (HCS) and the BBPS. This post hoc analysis shows the BBPS scores for the two primary endpoints, in those patients who had a readable colonoscopy.

Aims & Methods: In the MORA trial, ² 849 patients aged 18–85 were randomised to bowel preparation with morning-only or evening/morning split-dosing using either NER1006 or 2L PEG + Asc. Adequate level cleansing success was assessed according to the BBPS for both overall colon (all segments ≥2) and right colon cleansing (segmental score ≥2). The analysis includes all subjects for whom colonoscopy videos were available for assessment by central readers.

Results: A total of 792 patients were analysed. When using an evening/morning split-dosing, 249/262 (95%) patients on NER1006 achieved adequate level overall colon cleansing compared to 232/260 (89%) on 2L PEG + Asc (Table 1). Using morning-only dosing, 243/270 (90%) patients on NER1006 achieved the same. Using evening/morning split-dosing, 254/262 (97%) patients on NER1006 achieved adequate level right colon cleansing compared to 242/260 (93%) on 2L PEG + Asc. Using morning-only dosing, 253/270 (94%) patients on NER1006 achieved adequate level right colon cleansing. Adequate level cleansing success was achieved significantly more often with NER1006 evening/morning split-dosing than 2L PEG + Asc, both in the overall colon (P=0.013) and in the right colon (P=0.042). The slight improvement seen with NER1006 morning-only dosing in the cleansing rate of the overall colon and right sided colon was not statistically significant. Table 1: Adequate level cleansing of the overall colon and right colon (BBPS segmental scores 2–3) as determined by treatment-blinded central readers

Conclusion: NER1006 demonstrated an exceptionally high adequate level bowel cleansing efficacy. A significant improvement was shown for both the overall colon and the clinically relevant right sided colon versus 2L PEG + Asc when administered using the same dosing regimen. The morning-only dosing regimen of NER1006 delivered a very high success rate, similar to that of 2L PEG + Asc.

Introduction: The European Colonoscopy Quality Investigation (ECQI) Group comprises expert colonoscopists and investigators from Europe and aims to raise awareness of the need for improvement in colonoscopy standards across Europe. Recently, the European Society of Gastrointestinal Endoscopy (ESGE) has developed key performance measures for lower gastrointestinal colonoscopy.¹

Aims & Methods: To assess the quality of colonoscopy in current clinical practice, through the use of online questionnaires, compared with recently published ESGE performance indicators. The development of the online practitioner and procedure questionnaires has been previously described.^{2,3} Data collection is an ongoing process. We analysed data collected between 2/6/16 and 17/4/17 and compared with the ESGE performance measures.

Results: 40 of 50 practitioners completed the practitioner questionnaire. 2094 colonoscopies were documented across 8 European countries by 47 practitioners. The ESGE sets a minimum standard of $\geq 90\%$ of patients with adequate bowel preparation, defined as Boston Bowel Preparation Scale score ≥ 6 . From our data, 81% (n = 1692) of procedures had adequate bowel cleansing (data unavailable for 96.4.6%). The ESGE recommends a minimum standard of $\geq 90\%$ of all diagnostic and screening colonoscopies visualize the whole caecum (excluding those that have no indication to reach the caecum). Only 55% of practitioners routinely record caecal intubation rate. The caecum was the intended endpoint in 66% of procedures. For those diagnostic and screening colonoscopies where the caecum was the intended endpoint (n = 1390), 93% reached the endpoint but only 70% had this endpoint photo-documented. The ESGE recommends that adenoma detection rate (ADR) should be used as a measure of adequate inspection at screening or diagnostic colonoscopy in patients aged 50 years or more. ADR was routinely recorded by only 18% of practitioners. Polyp removal rate is routinely recorded by 30% of practitioners, and polyp retrieval rate by 23%.

Conclusion: Our findings indicate that some important performance measures recommended by ESGE are not currently being achieved in practice. By providing a self-assessment tool and as a next step, by individual consultations with national Group members, ECQI hopes to improve clinical practice standards. Further information on the ECQI Group initiative can be found on www.ecqigroup.eu

P0186 SEDATION IN GASTROINTESTINAL ENDOSCOPY: CURRENT PRACTICES OF GREEK GASTROENTEROLOGISTS

A. Protopapas, E. Stournaras, G. Neokosmidis, A. Protopapas

1st Department Of Propaedeutic Internal Medicine, Ahepa Hospital, Thessaloniki/ Greece

Contact E-mail Address: adopro@hotmail.com

Introduction: When it comes to gastrointestinal endoscopy, considerable heterogeneity is observed between gastroenterologists regarding the use of sedation and the preferred sedative agents. The sedation protocol used by a gastroenterologist may have a significant effect on endoscopic quality, patient cooperation and both the doctor's and the patient's satisfaction with the procedure.

Aims & Methods: The aim of this study was to document current endoscopic practices of Greek gastroenterologists and investigate whether they use sedation to perform gastrointestinal endoscopy and which pharmaceutical agents are usually involved. A 39-item online questionnaire was devised, addressing demographic data, use of sedation in endoscopy and monitoring practices. It was subsequently made available to 509 Greek gastroenterologists by e-mail.

Results: A total of 195 questionnaires were successfully completed (38.3%). 49 gastroenterologists did not use sedation to perform esophagogastroduodenoscopy (EGD) or colonoscopy (25.1%). The younger gastroenterologists were more likely to use sedation (p = 0.005). Among those using sedation, midazolam was the most frequently used agent in EGD (50%) and the combination of midazolam/fentanyl was the most frequently used in colonoscopy (24.6%), followed by midazolam (21.9%). Out of 137 physicians using benzodiazepines (midazolam, diazepam) as part of their endoscopic sedation regimen, 91 (66.4%) routinely used flumazenil to facilitate pharmacological antagonism after the completion of the endoscopy. In total, 45 physicians, 23.1% of the participants and 30.8% of those using sedation, used propofol or a combination of propofol and other agents. 30 gastroenterologists routinely administered propofol without the aid of an anesthesiologist (66.6%). Medicolegal issues (33%), inadequate training in the use of propofol (26.4%) and risk of cardiopulmonary complications (23.6%) were cited as the main reasons for not using propofol. As far as monitoring practices go, the majority of gastroenterologists observed heart rate and oxygen saturation (96% and 97% respectively). Regarding the safety equipment available to the gastroenterologists, 160 (82%) reported having access to regimens of pharmaceutical resuscitation, 145 (74%) to oropharyngeal airway devices or laryngeal airway masks, 92 (47%) to endotracheal intubation equipment and 86 (44%) to a defibrillator. When asked to rate their level of satisfaction with their preferred sedation regimen (or with not using sedation) in a scale of 1 to 10, 72 physicians rated their satisfaction level as 9 or 10 (36.9%) and 92 as 7 or 8 (47.1%). While there was no significant difference in terms of satisfaction between the doctors that used sedation and those who did not, there was a statistically significant difference between the gastroenterologists that used propofol (alone or in combination with other agents) and those who used other sedative agents (p = 0.003). When asked on their preferred method of sedation, if they were themselves subjected to gastrointestinal endoscopy, 104 physicians opted for propofol-based sedation regimens (53.3%).

Conclusion: Gastrointestinal endoscopy is performed with the use of sedation by the majority of Greek gastroenterologists. Propofol-based regimens are seldom used in everyday clinical practice, despite a vast number of Greek gastroenterologists identifying them as their preferred regimen, in case they themselves should undergo endoscopy. Compared to a past survey, Greek gastroenterologists are still hesitant about using propofol. However, an increasing tendency towards administering propofol without the aid of an anesthesiologist is observed. Also, physicians using propofol seem to be more satisfied with their sedation practices than the doctors using other sedation regimens. Absence of a distinct legal framework, inadequate training and fear of cardiopulmonary complications are identified as the main reasons preventing Greek gastroenterologists from using propofol.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Indicators for colonoscopy quality assessment were developed and promoted during this last decade. However technical and human resources constraints limit local implementation of continuous recording of endoscopic quality indicators (QI). Automatic system of data extraction and presentation could help endoscopy units in their seek for quality improvement. We hereby report our local experience in implementing colonoscopy QI record trough an automatic data extraction from two separate databases (DB), and assess the colonoscopy quality at unit and individual levels.

Aims & Methods: We locally adapted a company reporting system for colonoscopy by adding in a dedicated tab, selected procedure indicators. Endoscopic QI data from reporting system DB and pathological results from another DB were extracted and merged together in a separated DB. On a regular period basis or on request, key QI are calculated and extracted. It includes adenoma detection rate (ADR), polyp detection rate, caecal intubation rate, quality of bowel preparation (using the Boston bowel preparation scale) and type of sedation. During a first period of 6 months starting in January 2016, endoscopists were encouraged to fulfill the dedicated tab on a voluntary basis. In a second period, filling of QI was turned to be mandatory. The completeness of QI recording was evaluated across both periods, and results from second period are presented. Performance measures of all endoscopists were compared to global results of our department and to published targets.

Results: During the 6 months "mandatory-filling" period (July-December 2016), 1802 colonoscopies were performed with a QI tab fully filled in 100% of cases compared to 63.1% after the "free-filling period" ($p < 0.0001$). The global caecal intubation rate for screening colonoscopy was 92.9%. Mean Boston bowel preparation score was 7.2 ± 0.76 with 86.9% of cases with adequate preparation (Boston score > 5 ; 89.9% among outpatients and 81.9% among inpatients). Colonoscopies were performed under propofol sedation in 94.1%. During this second period, the global ADR was 32.4% (range: 0%-55.7%). The polyp detection rate was 44.4% with a mean of 1.19 polyp removed by colonoscopy.

Conclusion: This study illustrates that quality indicators for colonoscopy assessment in a Belgian tertiary hospital endoscopy unit could be easily implemented with limited human resources by adapting a company reporting system and link it to the pathology department database. Mandatory filling of QI items is the key for system implementation success. Our results were consistent with goals required by international guidelines. This system allows giving feedback to individual endoscopists for self-performance assessment and might be easily adapted in the future following guidelines updates.

P0188 LARGE RECTAL ADENOMAS - EMR VERSUS ESD: WHAT IS THE BEST APPROACH?

H.H. Nietsch

Department Of Gastroenterology, St. Elisabeth Krankenhaus Med. Klinik 1, Halle/Germany

Contact E-mail Address: nietsch2@yahoo.com

Introduction: Since the advent of screening colonoscopy we diagnose a lot more asymptomatic large rectal polyps > 5 cm in diameter. With the introduction of EMR (endoscopic mucosal resection) and ESD (endoscopic submucosal dissection) we have now endoscopic means to resect those lesions effectively. It is however still unclear whether EMR or ESD is superior in terms of complete resection and safety.

Aims & Methods: We will compare the outcome (perforation, bleeding, complete resection, recurrence rate) in two cohorts of patients with lateral spreading rectal adenomas > 5 cm who were either treated by EMR or ESD in our centre.

Results: 62 large laterally spreading rectal adenomas in consecutive patients (age 45–84 years) were completely resected endoscopically. ESD en-bloc resection was performed in 23 patients. All other lesions were excised by piecemeal EMR. Prior to resection a careful examination under white light and NBI was performed using the Paris classification. In comparison ESD took about three times as long as EMR (average procedure time 98 min. vs 37 min) with comparable intra- and postoperative bleeding rates (5% in each group). No perforations were encountered. All en-bloc ESD specimens were R0 on histology. In one patient deep submucosal invasion of the submucosa ($> 1000 \mu\text{m}$) was present. The patient underwent surgical resection 6 weeks after the endoscopy without evidence of remaining tumor or lymph node invasion. The most striking difference in the two groups was seen regarding recurrence of adenomas during 6 months follow-up: 0% in the ESD cohort and 12% in the piecemeal EMR group. All recurrent adenomas after EMR could however be easily resected by snare polypectomy without any further recurrence over the next 12 months. The calculated average equipment cost for ESD (hook knife, dual knife, injectate, transparent cap) was significantly higher compared to EMR (687\$ vs. 39\$).

Conclusion: EMR and ESD are equally effective in resecting large lateral spreading adenomas of the rectum. The higher rate of post-EMR adenoma recurrence

did not impact the patients overall cure rate after one year. ESD is significantly more time consuming and costly.

P0189 COMPUTED TOMOGRAPHY COLONOGRAPHY VERSUS COLONOSCOPY FOR THE DIAGNOSIS OF COLORECTAL CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

R. B. Duarte, W. M. Bernardo, C. M. Sakai, G. L.R. Silva, H. G. Guedes, R. Kuga, E. Ide, R. K. Ishida, P. Sakai, E. G.H. De Moura
Gastrointestinal Endoscopy Unit, Clinical Hospital of São Paulo University Medical School, Sao Paulo/Brazil

Contact E-mail Address: ralphbduarte@hotmail.com

Introduction: Colorectal cancer (CRC) is a significant cause of morbidity and mortality; it is third in terms of incidence and cause of death among both men and women in the United States. In Brazil, CRC incidence has reached 19–21 cases per 100,000 individuals. CRC has several precursory lesions, and patient survival depends largely on disease stage at diagnosis. Thus, CRC screening is vital for decreasing CRC incidence and disease-specific mortality. Optical colonoscopy (OC) is the first-choice investigation for colonic conditions and it is excellent for CRC screening and surveillance. Newer technologies such as computed tomography colonography (CTC) may also be useful in CRC screening.

Aims & Methods: This systematic review compares the benefits of CTC and OC for CRC screening. This systematic review includes all available randomized clinical trials available comparing CTC and OC for CRC screening in asymptomatic patients. We assessed study quality using the revised version of the Quality Assessment of Diagnostic Accuracy Studies. In this meta-analysis, we compared, in the form of Forest Plots, patient participation rate and the detection rates for advanced colorectal neoplasia (ACN) between the two methods. The positive predictive value (PPV) of CTC in terms of the outcome "detection of ACN" was also calculated, comparisons were made after considering patients in all included studies.

Results: A total of 386 articles were identified in the initial search. Of these, three were included in the systematic review and submitted for meta-analysis. A total of 16,592 patients were invited to undergo screening programs, but only 3881 underwent the procedures. In the analysis of participation rates, only 2333 of 8104 patients invited underwent CTC and only 1486 of the 7310 patients invited underwent OC. The absolute risk difference in participation rate in the two procedures was 0.1 (95% CI, 0.05–0.14) in favor of CTC. In the analysis of ACN detection rates, 2357 patients undergoing CTC and 1524 patients undergoing OC were included. Of these, 135 patients who underwent a CTC and 130 patients who underwent an OC were diagnosed with ACN. The absolute risk difference in ACN detection rate in the two procedure types was -0.02 (with a 95% CI between -0.04 and -0.00) in favor of OC.

Conclusion: CTC is an option for the exercise of CRC screening in asymptomatic patients. However, as a CTC has proved inferior in detecting advanced colorectal neoplasia, the method should not replace a OC, which remains as gold standard.

Disclosure of Interest: All authors have declared no conflicts of interest.

²Graduate School Of Informatics, Nagoya University, Nagoya/Japan

Contact E-mail Address: misawaanny@gmail.com

Introduction: High adenoma detection rates (ADRs) for colonoscopy are associated with a lower risk of colorectal cancer. ADR is therefore treated as a quality indicator of colonoscopy. However, ADR varied among endoscopists and depend on their skill. To facilitate high-quality clinical practice that is not dependent on endoscopists' skill, we have been researching a computer-aided diagnosis system^{1, 2}. This time, we developed an automated polyp detection system based on deep learning (one of the latest artificial intelligence technologies).

Aims & Methods: The aim of this study was to develop a computer-aided detection (CAD) algorithm for colonoscopy using deep learning. To evaluate the developed CAD algorithm, we retrospectively viewed colonoscopy videos from a previous randomized controlled study (UMIN000017083) conducted from April 2015 to October 2015. All examinations were performed using CF-HQ290ZI (Olympus Corp., Tokyo, Japan). Each case was recorded with full high-definition quality using HVO-1000MD (Sony Corp., Tokyo, Japan). In this study, two endoscopists (M.M., Y.M.) manually annotated 43 colonoscopy videos with 238 min of 17,903,967 frames. These videos included 75 polyps (48 neoplasms, 27 non-neoplasms), and annotations were made on the presence or absence of polyps in every frame. Forty-three videos were divided into 300 short video for machine learning and validation process. Among 300 short videos, 246 were used for the machine-learning process. The remaining 54 (33 included a lesion) were used to validate the CAD algorithm. A modified version of Caffe with 3-Dimensional Convolutional Networks (a kind of deep learning) was used for the CAD algorithm. The validation samples were analyzed using the CAD algorithm and its output as the probability of the presence of a lesion in each validation video. A receiver operating characteristic (ROC) analysis was performed to evaluate the efficacy of the CAD algorithm.

Results: The mean probability of a polyp-positive video was $62.1 \pm 27.9\%$, whereas that of a polyp-negative video was $18.1 \pm 24.6\%$ ($P < 0.001$). The area under the ROC curve was 0.887. If a cutoff probability was set at 20.4%, the present CAD algorithm could detect a polyp with 90.9% sensitivity and 76.2% specificity.

Conclusion: Our preliminary results showed that state-of-the-art artificial intelligence has the potential for achieving automatic detection of colorectal polyps. A prospective study is now planned after more machine-learning sessions.

Acknowledgment: This study was supported by JSPS KAKENHI Grant Number JP 17K15971.

P0191 MOTORIZED SPIRAL COLONOSCOPY (MSC) – A FIRST FEASIBILITY TRIAL

T. Beyna, M. Schneider, D. Pullmann, H. Neuhaus

Department Of Internal Medicine, Evangelisches Krankenhaus Düsseldorf, Düsseldorf/Germany

Contact E-mail Address: torsten.beyna@evk-duesseldorf.de

Introduction: Colonoscopy is widely accepted for the diagnosis and treatment of colonic diseases. Accepted quality parameters for colonoscopy include a cecal intubation rate of $\geq 90\%$. 10% of all colonoscopies are difficult and intubation of the cecum can sometimes be impossible. The novel motorized endoscope was recently developed (Olympus Medical Systems Corporation, Tokyo, Japan) and represents a disruptive new technology in endoscopy. It is currently being evaluated for antegrade enteroscopy. Spiral technique offers the potential to overcome some of the limitations of standard colonoscopy with push technique by actively pleating the bowel onto the endoscope with motorized rotation of the spiral overtube. This may have advantages in cases of difficult standard colonoscopy to facilitate cecal intubation on the one hand and in all colonoscopies in terms of patients comfort, sedation and ease of use also in therapeutic situations.

Aims & Methods: To evaluate feasibility and safety of MSC for diagnostic colonoscopy. Secondary endpoints were ileum intubation rate, procedure time, need for sedation and external compression, patients' pain and satisfaction, adenoma detection rate (ADR) and feasibility of therapeutic interventions. 30 consecutive patients with indication for colonoscopy meeting the inclusion criteria at a single tertiary referral center were enrolled in the trial between December 2016 and January 2017. The study was conceived as proof of concept trial with the primary aim to achieve a cecal intubation rate of at least 90% according to quality guideline recommendations.

Results: 13 male and 17 female patients were enrolled. Mean age was 68.9 years (30–90), health status was ASA-1: 16.7%, ASA-2: 36.7% and ASA-3: 46.6%. 43.3% of the patients had diverticula. Indications for colonoscopy were clarification of indeterminate iron deficiency anemia (IDA, n=5), lower gastrointestinal bleeding (GIB, n=6), surveillance after previous polypectomy (n=6), screening for polyps and colorectal cancer (n=11) and others (n=2). Sedation level (ESGE-Guideline, Level 1–3) in all patients was 3 (deep sedation). Mean amount of propofol was 305 [130–880] mg. Mean procedure time was 20.8 [11.4–55.3] min. Cecal intubation rate (technical success) was 96.7% (29/30). One incomplete colonoscopy occurred due to an unexpected postinflammatory stricture of the sigmoid. All colonoscopies reaching the cecum also successfully intubated the ileum (96.7%). Only in one case external compression was needed. Adenoma detection rate was 46.7%. EMR was performed in 9 cases, 5 patients had forceps polypectomy. One case of incidental finding of submucosal invasive adenocarcinoma in EMR specimen was histologically proven to have R0 en-bloc resection. All other therapeutic interventions could also successfully be conducted (clip n=3, argon plasma coagulation n=1, tissue sampling n=2). Two

mild adverse events were recorded (mild superficial mucosal lesions without clinical symptoms). No severe adverse occurred.

Conclusion: This study represents the first clinical evaluation of the novel motorized spiral endoscope for examination of the colon. Our data show that it is effective and safe for diagnostic and therapeutic colonoscopy. It may also have potential advantages over standard colonoscopy technique in terms of effectiveness and convenience of colonoscopy.

P0192 TREATMENT OUTCOMES OF COLD FORCEPS POLYPECTOMY FOR PATIENTS WITH DIMINUTIVE POLYPS: A PROSPECTIVE FOLLOW-UP STUDY

H. Hasegawa¹, S. Bamba¹, H. Ban¹, H. Imaeda¹, A. Nishida¹, O. Inatomi¹, M. Sasaki¹, M. Sugimoto¹, A. Andoh¹

¹Dept. Of Gastroenterology, JCHO Shiga Hospital, Otsu/Japan

Introduction: The results of the National Polyp Study are premised on the removal of all adenomatous lesions. Cold forceps polypectomy (CFP) using jumbo biopsy forceps is a simple and safe technique used for diminutive polyps (≤ 5 mm). The recurrence rate after CFP for patients with diminutive polyps has not been elucidated.

Aims & Methods: We have prospectively enrolled patients with diminutive polyps treated by CFP from June 2015 to March 2017. Magnifying colonoscopy was used for all procedures. The location, size, endoscopic findings and procedures were recorded. The patients who have undergone CFP had their follow-up colonoscopy in one year after CFP.

Results: CFP was performed for total 515 polyps from 277 patients. The size of the polyps was < 3 mm/4 mm/5 mm=379/101/35. The rate of one-bite polypectomy for adenoma was < 3 mm/4 mm/5 mm=79%/54%/33%. There was no significant difference in the one-bite rate between endoscopists' experience. No cancer was observed in histology. Rates of delayed bleeding after CFP was 0.19% (1/515). Concomitant use of anticoagulation use of antiplatelet drugs was found in 14% (72/458), and none of them experienced delayed bleeding. No perforation occurred. Seventy-five patients had their follow-up colonoscopy so far. There are no polyps suspecting residual or recurrent lesions. Among 75 patients, 62 patients had less than two polyps removed at their first colonoscopy (Group A). On the other hand, 13 patients had more than three polyps removed at their first colonoscopy (Group B). Follow-up colonoscopy revealed that the rates of newly discovered polyps in the same segment were 8% and 23% in groups A and B, respectively. The rates of newly discovered polyps in the different segment were 27% and 61% in groups A and B, respectively. When the initial CFP was performed by the endoscopist with the experience of < 5 years/5–9 years/more than ten years, the rates of newly discovered polyps found at follow-up colonoscopy was 54% (14/26)/42% (8/18)/37% (11/30), respectively.

Conclusion: The rate of one-bite polypectomy was significantly higher for diminutive polyps especially less than 3 mm. Importantly there are no polyps suspecting residual or recurrent lesions in the follow-up colonoscopy. CFP is a safe and effective option for diminutive polyps (5 mm). Although the rate of one-bite polypectomy was not related to the endoscopists' experience, adenoma detection rate is seemed to be low in young endoscopists. Since achievement of "clean colon" is difficult with a single colonoscopy, multiple colonoscopic examinations are necessary to achieve "clean colon" especially if the patients have more than two polyps at the first examination.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colonoscopy is the most effective method for preventing colorectal cancer, as it offers easy detection and resection of polyps. Cimetropium bromide

results in colonic spasmolysis and may improve polyp detection. We studied the effect of cimetropium bromide on polyp detection during colonoscopic withdrawal.

Aims & Methods: Patients undergoing colonoscopy for screening examinations were included and randomized at cecal intubation to receive either 5 mg cimetropium bromide or placebo. We evaluated the polyp detection rate (PDR), adenoma detection rate (ADR), and advanced ADR (AADR) in the right side colon as well as in the colorectum.

Results: A total of 181 patients were analyzed in this study. Cimetropium group consisted of 91 patients, and control group consisted of 90 patients. PDR, ADR, and AADR were not significantly different in cimetropium and control groups (62.6% vs. 66.6%, $P=0.571$; 51.6% vs. 47.7%, $P=0.603$; 3.2% vs. 7.7%, $P=0.187$; respectively). Similarly, PDR and ADR in the right side colon were not significantly different between the groups (46.1% vs. 47.7%, $P=0.827$; 32.9% vs. 35.5%, $P=0.714$; respectively).

Conclusion: Cimetropium bromide does not improve the PDR or ADR in the right side colon or the colorectum. Thus, administration of cimetropium bromide can be used selectively in screening colonoscopy.

²Gastroenterology Trinity Academic Gastroenterology Group (TAGG), AMNCH Tallaght, Dublin/Ireland

Contact E-mail Address: neil.moran@amnch.ie

Introduction: Colorectal cancer (CRC) accounts for up to 11% of all cancers in women and 14% of men in Ireland, and is the second most common cancer across sexes. The adenoma-carcinoma sequence of colorectal carcinogenesis lends itself to screening with the aim of complete excision of polyps. It has been estimated that incomplete resections of polyps are involved in 19–31% of interval cancers. ESGE guidelines state that polyps 5 mm or greater should be removed by snare resection. Previous studies report inappropriate resection techniques employed in up to 46% of cases. The aim of this study was to investigate polypectomy techniques and to assess adherence to guidelines in a tertiary referral, University teaching hospital in Dublin, Ireland. We also investigated the differences between subspecialty and consultants versus trainees.

Aims & Methods: The study included all patients who underwent colonoscopy in Tallaght Hospital (Dublin, Ireland) between January 2012 and December 2015 for any indication. From this, a list of patients with colonic polyps was compiled. Demographics and other information including number and site of polyps, resection and retrieval rates, method of resection and specialty of endoscopist were included.

Results: 11,400 colonoscopies were performed during the study period. To date, the records of approximately 7000 (61%) procedures have been reviewed. 2337 (22.5%) patients were identified with polyps, with 1027 females (43.4%), 1310 males (56.6%) and a mean age of 60.6 years. The indication for colonoscopy included symptoms (47.2%), polyp surveillance (22.3%), CRC cancer screening (9.2%), family history of CRC (4.4%) IBD surveillance (3.8%), with no indication noted in 12.95%. The mean number of polyps per patient was 2.2. 47.7% of patients had one polyp identified. In 52.5% ($n=1227$), polyps were left-sided, and were right-sided in 23.1% ($n=540$). In all 15.72% of polyps > 5 mm were resected by forceps and not by snare resection. Non-adherence to guidelines was observed in 17.56% and 17.3% of procedures completed by medical and surgical trainees respectively. Medical (12.3%) and surgical (12.1%) consultants had a higher adherence rate.

Conclusion: European guidelines have yet to be universally implemented. Previous cohort studies report non-adherence rates of up to 46%. Our study shows a non-adherence rate of 12–18% amongst trainees and Consultants. The low polyp detection rate likely represents the varied case mix. A greater emphasis on ESGE guidelines could improve awareness and enhance compliance which is suboptimal. A follow up study to determine the effect on interval cancers in these groups is planned.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Sedation for colonoscopy by using intravenous propofol has become standard in many Western countries.

Aims & Methods: While gender-specific differences have been shown for general anaesthesia used in dentistry, no such data exist as yet for gastrointestinal endoscopy. In a prospective observational study at an Academic teaching hospital of Hannover Medical School 219 patients (108 women and 111 men) scheduled for colonoscopy were included. Propofol sedation using EEG monitoring during a constant level of sedation depth (D0 to D2) performed by trained nurses or physicians after bodyweight adjusted loading-dose.

Main outcome measures: Primary endpoint was the presence of gender-specific differences in wake-up time (time from end of sedation to eye - opening and the complete orientation of the patient); secondary outcome parameters analysed were total dose of propofol, sedation associated complications (bradycardia, hypotension, hypoxia, apnoea), patient cooperation and patient satisfaction. Multivariate analysis was performed to correct confounding factors such as age and BMI.

Results: Women awake significantly faster compared to men with a time to eye opening of 7.26 ± 3.69 versus 8.39 ± 3.43 min. ($p=0.005$) and time until complete orientation 9.14 ± 3.88 versus 10.4 ± 13.71 min ($p=0.008$); propofol dosage was not significantly different, with some trend towards more propofol per kg body weight in women (3.98 ± 1.81 mg versus 3.72 ± 1.75 mg, $p=0.232$, n.s.).

Conclusion: The effect of gender aspects should be taken into account upon propofol induced sedation for gastrointestinal endoscopy. That includes adequate dosing for female as well as cautiousness regarding potential overdosing of male patients.

Trial registration: ClinicalTrials.gov (Identifier: NCT02687568). Data were presented at a national meeting (DGEV) in Germany.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0196 EFFECT OF PREOPERATIVE COLONOSCOPIC TATTOOING USING BOTH SIDE INJECTION OF INDOCYANINE GREEN FOR IMPROVEMENT OF LYMPH NODE HARVEST IN COLORECTAL CANCER

H.W. Kim, J.S. Lee, D.H. Kang, C.W. Choi, S.J. Kim, H.S. Nam, D.G. Ryu, C.W. Yeo, S.H. Choi, B.J. Kwon

Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of

Contact E-mail Address: mdkhwook@gmail.com

Introduction: Consensus guidelines suggest to assess at least 12 lymph nodes for adequate staging of colorectal cancer and the correlation between number of lymph nodes retrieved and the patient survival has been formerly reported. To facilitate the retrieval of lymph nodes, preoperative endoscopic tattooing to mark the site of the tumor has been proposed. In this study, we aimed to evaluate the effect of preoperative colonoscopic tattooing (PCT) using indocyanine green (ICG) for lymph node harvest in colorectal cancer. Additionally, we evaluated the effect of both side injection of ICG for improving the rate of adequate lymph node harvest.

Aims & Methods: 1023 patients who underwent curative resection for colorectal cancer between Jan 2013 and Aug 2016 at the Pusan National University Yangsan Hospital in Korea were retrospectively divided into the tattooing group and the non-tattooing group depending on whether PCT using ICG was done. Pathological findings and lymph node harvest were compared between the two groups.

Results: The rate of adequate lymph node harvest (retrieval of more than 12 lymph nodes) was similar in tattooing group and non-tattooing group (91.9% vs. 91.4%). However, when comparing the both side injection group and

nontattooing group, both side injection group was better result (96.2% vs. 91.4%, OR 2.348, p-value 0.229). Most results did not have statistical association with higher lymph node yield in colorectal cancer. But in T1 cancer, the rate of adequate lymph node harvest was higher in the both side injection group, statistically (94.7% vs. 81.0%, OR 4.235, p-value 0.047).

Conclusion: PCT using ICG was associated with higher lymph node harvest in colorectal cancer, especially in T1 cancer. And both side injection of ICG increased the rate of adequate lymph node harvest. Further studies and methods are needed to harvest adequate lymph nodes in colorectal cancer.

Introduction: Cold snare polypectomy (CSP) has grown in popularity worldwide due to its ease and safety with a low incidence of adverse events, such as hemorrhage and post-polypectomy syndrome¹⁻³. However, there are concerns regarding tumor residue with CSP because it does not use electrocautery, thereby eliminating its burning effect. European Society of Gastrointestinal Endoscopy (ESGE) clinical guideline suggests CSP for subcentimetre sessile polyps because of its safety profile, despite lack of evidence for efficacy compared to HSP⁴. The aim of this study was to investigate the success rate of CSP for complete resection of subcentimetre colorectal adenomatous polyps compared to that of HSP.

Aims & Methods: This was a prospective, multicentre, randomised controlled, non-inferiority trial conducted in 12 Japanese endoscopy units. Patients aged ≥ 20 years, undergoing elective colonoscopy/polypectomy, and who provided written informed consent were included. Patients who were taking anti-thrombotic agents and undergoing hemodialysis were excluded, as well as those with inflammatory bowel diseases, polyposis, and pregnancy. Endoscopically diagnosed sessile adenomatous polyps, 4–9 mm in size, were randomly assigned to the CSP or HSP group. After complete removal of the polyp using the allocated technique, biopsy specimens from the resection margin after polypectomy were obtained. The primary endpoint was the complete resection rate, defined as no evidence of adenomatous tissue in the biopsied specimens, among all pathologically confirmed adenomatous polyps (full analysis set: FAS). Pre-planned subgroup analyses for the size of polyp were also conducted. The sample size was calculated according to the incomplete resection rate seen in previous articles and the required sample size was estimated at 780 lesions, including drop out cases. The protocol was approved by the institutional review board in each institution.

Results: A total of 796 eligible polyps were detected in 538 of 912 patients screened for eligibility between September 2015 and August 2016. Three hundred and ninety-four lesions were assigned to the CSP group and 402 lesions were assigned to the HSP group. One hundred and nine lesions (56 in the CSP group and 53 in the HSP group) were excluded for FAS analysis. Background characteristics of the lesions (size, location, morphology, and institution) were similar in both groups. The complete resection rate for CSP was 98.2%, compared to 97.4% for HSP. The between-group difference in complete resection rate was +0.8%, favouring CSP (90% C.I. of $-0.8.2.7$; $p < 0.0001$). Resection time, overall, was significantly shorter with CSP than with HSP (60 s versus 83 s, respectively; $p < 0.001$). Postoperative bleeding requiring endoscopic haemostasis occurred only in the HSP group (0.5%, 2 of 402 cases). Subgroup analysis according to the size of the polyp (4–5 mm and 6–9 mm) showed a comparable complete resection rate for CSP and HSP for both subgroups of polyps.

Conclusion: The complete resection rate of CSP is not inferior to that of HSP. CSP can be one of the standard techniques for subcentimetre colorectal polyps. (Study registration: UMIN000018328)

Introduction: Prevention of complications secondary to endoscopic resection techniques (EMR or ESD) requires avoiding deep thermal damage and increase mucosal healing. Platelet-rich plasma (PRP) has demonstrated efficacy in pre-clinical endoscopic resection models [1]. The EndoPRP study was a prospective single-center study to assess the efficacy of PRP on endoscopic resection of large sessile lesions (larger than 35 mm). (Study registered at ClinicalTrials.gov: NCT02931149)

Aims & Methods: In the EndoPRP study 15 patients (males and females, aged 52–80) were assigned to receive PRP (6–18 mL): i) Endoscopic Shielding Technique (EST, $n = 4$), applying PRP as a shield after standard resection technique, or ii) Submucosal injection (SMI, $n = 11$), performing a submucosal injection of PRP prior to EMR or ESD. Patients were informed and accepted to participate with a written consent. PRP was obtained from a sample of patient's blood (18–36 mL) drawn at the time of endoscopy. Patients underwent endoscopic follow-up at 4 weeks. The efficacy of PRP was assessed by the incidence of adverse events (delayed bleeding or perforation). Mucosal healing rate (MHR) was defined as a percentage of mucosal restoration after 4 weeks.

Results: Shielding technique with PRP was performed in 4 lesions at rectum ($\bar{A} 53.7 \pm 20.6$ mm, range 35–80 mm). Submucosal injection of PRP was used in 11 lesions (2 at antrum, 3 at rectum, and 8 at colon) ($\bar{A} 41.6 \pm 9.6$ mm, range 35–70 mm). Delayed bleeding occurred after EMR of 1 lesion (no required blood transfusion or endoscopic treatment; 6.6% of all lesions: 1 patient at EST group, 0 patients at SMI group). MHR was significantly higher in patients treated with SMI than EST (87.5% vs. 78.6%; $p = 0.03$).

Conclusion: PRP applied as a shield over the scar or as submucosal fluid cushion has proved clinical efficacy in endoscopic resection of large lesions. Submucosal injection of PRP has showed better mucosal healing rate as comparison with shielding technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0199 INTERVENTIONS AND COSTS ASSOCIATED WITH SIVA-DEFINED ADVERSE EVENTS DURING PROCEDURAL SEDATION IN FIVE COUNTRIES

R. Saunders¹, J. Davis¹, R. Weissbrod², D. Whitaker³, P. Kranke⁴, J. R. Lightdale⁵

¹Health Economics, Coreva Scientific, Freiburg/Germany

²Medtronic, Jerusalem/Israel

³Manchester Royal Infirmary, Manchester/United Kingdom

⁴University of Würzburg, Würzburg/Germany

⁵University of Massachusetts, Worcester/United States of America

Contact E-mail Address: rhodri@coreva-scientific.com

Introduction: Procedural sedation is commonly used during gastrointestinal endoscopy procedures to improve patient comfort. It comes, however, with the risk of sedation-related adverse events (AEs) as defined by World SIVA.¹ The cost of AEs and their impact on healthcare resource use and efficiency is currently unknown.

Aims & Methods: The aim of our study is to quantify and compare the costs of AEs during procedural sedation in France, Germany, Italy, UK, and USA. Online interviews were conducted with providers (nurses, physicians, and anaesthesiologists) and payers. Respondents were screened to ensure that they had the expertise and experience to complete the survey. The provider survey covered topics such as guidelines, sedation agents, monitoring, and patient outcomes following AEs. Each provider reported on current clinical practice, the incidence of AEs, and the standard treatment and outcomes for 100 hypothetical patients

with a defined AE. Treatment options, including none required, were taken from SIVA-defined lists. Outcomes examined included delayed procedures, unplanned hospital admission, and death. Payers were surveyed about costs for interventions, provider time, hospital administration, and admissions. Outliers were identified using Dixon's Q test. The mean treatments and outcomes per AE per country were calculated, with responses weighted by the AE frequency reported by physicians and the outliers replaced by global means. Mean costs were calculated per intervention and outcome, with outliers removed.

Results: 101 providers and 26 payers completed the surveys, with a minimum of 20 providers and 5 payer responses per country. Over 62% of providers were gastroenterologists and anaesthesiology nurses. Local guidelines determined practice in most cases, and propofol and midazolam were the main sedation agents employed. The most common AEs reported were hypotension and bradycardia, with 9% and 4% of respondents, respectively, estimating each to occur during >10% of procedures. Mean provider time required to treat AEs ranged from 1.7 minutes for mild desaturation in Germany to 31.0 minutes for cardiac arrest in the USA. Accounting for interventions and provider time, the mean direct cost per AE ranged from EUR 12 for bradycardia in Germany to USD 3,877 for cardiac arrest in the USA (Table). When costs were "fully loaded" these became EUR 39 and USD 19,722, respectively. Although of low direct cost, bradycardia in Germany was reported to cause procedure termination or substantial delay in 3.8% of cases. In Euro countries, the median of mean direct costs for an AE was EUR 40 (IQR: 29–67). When costs of outcomes of AEs were included the median "fully loaded" cost reached EUR 301 (IQR: 115–738).

Table: Costs of select adverse events by country. FL: Fully-loaded (costs including hospital administration, time, inpatient stays, delays, and cancellations, but excluding legal costs)

Country, currency	Hypotension Direct; FL	Mild desaturation Direct; FL	Severe desaturation Direct; FL	Bradycardia Direct; FL	Prolonged apnoea Direct; FL	Cardiac arrest Direct; FL
France, EUR	32; 173	23; 471	79; 1994	17; 131	53; 490	137; 11,936
Germany, EUR	23; 193	18; 212	92; 1268	12; 39	118; 807	274; 4765
Italy, EUR	41; 111	32; 98	59; 201	33; 93	43; 99	101; 1195
UK, GBP	69; 537	34; 606	93; 1258	35; 362	80; 631	658; 8984
US, USD	247; 841	463; 1456	529; 1715	83; 358	394; 1262	3877; 19,722

Conclusion: Costs of sedation-related AEs can be substantial regardless of country of origin. Disruption of patient flow and provider efficiency may add to the cost burden. Even relatively minor events may prompt additional intervention, increasing the overall cost of care.

Introduction: Performing CR-ESD remains challenging in Western countries and surveillance studies in this setting are not fully described. KAR has been advised as a reasonable strategy for non-expert endoscopists and difficult lesions. However, some KAR eventually requires a piecemeal resection (p-KAR). A direct comparison between these two techniques is lacking. Additionally, when the specimen is resected *en bloc* regardless of what procedure is used, and the only pathological risk factor for recurrence is lateral margin (LM) involvement, its implications concerning the recurrence rate should be assessed.

Aims & Methods: 1.) To compare the recurrence rate after R0 and R1/Rx endoscopic resection (ER), on an ESD "intention-to-treat" basis, in a Western European setting where CR-ESD is performed by non-experts. 2.) To evaluate

the impact of LM involvement on local recurrence when neoplasms without risk factors for lymph node metastasis are resected *en bloc*. We prospectively included 89 consecutive CR neoplasms planned for ESD from September 2008 to December 2015. When technical difficulties arose or for patient's safety reasons, we performed a KAR. Kaplan-Meier survival curves were used to assess the recurrence rate over time. The end of follow-up was considered when a local recurrence occurred or at the end of the surveillance period in those patients who did not develop the event. Comparisons were made using the log-rank test. The recurrence rate during follow-up was stratified considering advanced histology, *en bloc* resection and R0 resection.

Results: The ER was aborted in 5 cases (perforation n=3; technical difficulties n=2). Surgical intervention was needed after ER because of submucosal or lymphovascular invasion in 4 patients. Five out of the remaining 80 cases, were lost to follow-up. Finally, 75 CR neoplasms were included in 74 patients (43 male; 58.1%). Median age was 71 years (range: 37–93). Median size of the lesions was 32 mm (range 10–100). Histology was 26 (34.7%) Vienna category 3; 46 (61.3%) Vienna 4 and 3 (4%) sml-Vienna 5. *En bloc* resections were obtained in 44 cases (58.7%): 33 ESD (44%) and 11 KAR (14.7%). The ER finished as p-KAR in the 31 remaining lesions (41.3%). R0 resections (n=23; 30.7%) were achieved in 18/33 ESD and 5/42 KAR [OR=8.9 (CI 95%: 2.8–28.3); p<0.0001]. The median follow-up period was 16 months (1–91). Local recurrence occurred in 11 cases: 9 of the latter throughout the first year (81.8%). No surgery was needed because of recurrence. The overall recurrence rate at 36 months was 15%. The recurrence rate at 3 years showed a statistical significant difference when R0 resections were compared with R1/Rx: 0% vs. 21.5% (p=0.03). When results were stratified according to histology and *en bloc* resections, no significant differences were found in the recurrence rate. When *en bloc* resections in pT1a/T1b (sml); ly (-); v (-); pVM0 lesions (n=44) were analysed separately, LM distribution was: 23 LM0 (52.3%); 18 LM1 (40.9) and 3 LMx (6.8). There was a non-significant trend concerning the recurrence rate when LM0 (n=23) lesions were compared with LM1/LMx (n=21): 0% vs. 14.8% at 3 years; p=0.06.

Main characteristics of the resected lesions by procedure

	ESD	en bloc KAR	p-KAR	p
Mean tumor size, mm; median (range)	28 (11–50)	20 (11–65)	42.1 (17–100)	0.002
Length of procedure, min; median (range)	225 (62–340)	175 (60–300)	270 (75–400)	0.11
Rectal location; n (%)	22 (68.7)	5 (41.6)	21 (67.7)	0.38
Vienna category ≥4; n (%)	23 (71.8)	6 (50)	20 (64.5)	0.66
Follow up - months; median (range)	16.3 (2.6–62.7)	16.9 (8.0–91.3)	13.8 (1.1–44.6)	0.59

Conclusion: ESD R0 resections were 9 times greater than that of KAR on an ESD "intention-to-treat" basis. R0 resections were associated with lower recurrence rates in comparison with R1/Rx resections. LM involvement increased the recurrence rate but without a statistical significance when it was the only pathological risk factor for recurrence and the specimen was resected *en bloc*.

P0201 ASSOCIATION BETWEEN SIZE, LOCATION AND HISTOLOGICAL CHARACTERISTICS OF COLORECTAL LATERALLY SPREADING TUMORS

F. L. Mota¹, J. F. Loureiro¹, L. S.N. Da Costa²

¹Digestive Endoscopy, Hospital Sirio-Libanês, SAO PAULO/Brazil

²Digestive Endoscopy Department, Hospital Sirio Libanes, Sao Paulo/Brazil

Contact E-mail Address: lucasndc@gmail.com

Introduction: Laterally spreading tumors (LST) are important precursors of colorectal cancer (CRC)¹. The endoscopic characteristics of the LSTs, such as size and location, appear to correlate with the histological findings^{2,3}, which is an essential data for the decision of the best therapeutic procedure to be carried out^{4,5}.

Aims & Methods: To determine the association between size, location and the histological characteristics of colorectal LSTs by reviewing of the colonoscopy and histopathological reports of the LSTs endoscopically removed between October 2013 and June 2015 at the digestive endoscopy department of a tertiary hospital. The Vienna revised classification was used for the adenomatous lesions⁶, and the World Health Organization (WHO) classification for the "sessile serrated adenomas" (SSA)^{7,8}. The regions of the colon were referred to

as either “proximal” or “distal” colon. Thereafter the division into six anatomical segments was considered (cecum, ascending, transversal, descending, sigmoid and rectum).

Results: A total of 218 LSTs were included in this study. Most patients (59.4%) were female. The mean age was 66.1 years, and the average size of the LSTs included was 1.69 cm. The proximal colon was the most common site (73.4%) of occurrence of the LSTs, with 34% being at the ascending colon. The most common histological type was the low grade dysplasia adenoma (Vienna 3), followed by the SSA without dysplasia with 21.6%. There was significant correlation between size and histology ($p < 0.005$), where the adenomatous lesions were found to be larger than the other categories. The SSAs, however, did not show this association. We identified association between location and histological type ($p < 0.005$): the adenomas with low grade dysplasia were most prevalent in the proximal colon. However, when the subdivision of the colon into anatomical segments was considered, the SSA without dysplasia was the most common type at the ascending colon.

Conclusion: There is association between the size and the histological characteristics of colorectal LSTs. Adenomas with high grade dysplasia were found to be larger than the other classifications. This association, however, is not observed between SSAs lesions. There is association between location and histology; with the SSAs without dysplasia being the predominant type at the ascending colon.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0202 SAFE AND SUCCESSFUL RESECTION OF DIFFICULT GI LESIONS USING A NOVEL SINGLE-STEP FULL-THICKNESS RESECTION DEVICE (FTRD)

P.V. Valli, J. Mertens, P. Bauerfeind

Division Of Gastroenterology And Hepatology, University Hospital Zurich, Zurich/Switzerland

Contact E-mail Address: piero.valli@usz.ch

Introduction: Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are well-established and effective techniques for the endoscopic resection of mucosal neoplasms along the gastrointestinal (GI) tract. However, these procedures are limited to superficial lesions. In the case of deeper ingrowth into the gut wall as well as anatomic sites prone to perforation, the novel full-thickness resection device (FTRD®) opens a new dimension of possibilities for endoscopic resection.

Aims & Methods: Sixty patients underwent therapeutic endoscopic full-thickness resection (eFTR) at our institution. The procedures were carried out as follows: First, the target lesion is marked with electrocautery and the endoscope is then retracted. The full-thickness resection device (FTRD, Ovesco® Endoscopy AG, Tübingen), is fitted onto a therapeutic endoscope. The endoscope with the FTRD® is advanced to the previously marked lesion. Grasping forceps are used to take hold of the target lesion and carefully pull it into the plastic cap of the FTRD®. Immediately after deployment of the OTSC®, eFTR is performed using the hyperthermic snare within the plastic cap. The full-thickness specimen is retrieved and processed for histopathological examination. Safety, learning curve, R0 resection rate and clinical outcome of all 60 interventions were studied.

Results: eFTR was performed for the following indications: 1. **Recurrent adenomas** (n = 22.37%) with a non-lifting sign after previous incomplete polypectomy and adenomas with a primary **non-lifting sign** on saline injection (n = 2.3%). 2. **Non-lifting base** after extensive piecemeal resection of a spreading adenoma (n = 10.17%). 3. Polyps in a **diverticulum** (n = 2.3%). 4. Polyps the **cecal appendix** (4.6.7%). 5. **Submucosal lesions** (n = 5.8.3%). 6. **Early carcinoma** (n = 7.12%). 7. **Follow-up resection of a malignant polyp** (n = 6.10%) had. 8. **eFTR over endoloop resection** (n = 2.3%). In 97% (58/60) of the interventions, the FTRD®-mounted endoscope reached the previously marked lesion and eFTR was performed (technical success). Full-thickness resection was achieved in 88% of the cases, with an R0 resection on histological examination in 79%. The clinical success rate based on follow-up histology was even higher (88%). The following adverse events occurred: Appendicitis of the residual cecal appendix after eFTR of an appendicular adenoma (1/58.2%). Minor bleeding at the eFTR site (2/58.3%). eFTR performed accidentally without proper prior deployment of the OTSC® (1/58.2%). There was no secondary perforation or eFTR-associated mortality.

Conclusion: In conclusion, after specific training, endoscopic full-thickness resection is a feasible, safe and promising resection technique. It allows complete resection of lesions affecting layers of the gut wall beneath the mucosa, without the risk of perforation. In the future, eFTR may become a valuable alternative to a surgical approach in cases where endoscopic resection was previously thought impossible.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0203 VASCULAR AND PIT-PATTERN ANALYSIS ACCORDING TO KUDO, SANO AND NICE CLASSIFICATIONS SIGNIFICANTLY IMPROVES AFTER AN IMAGE-BASED TRAINING PROGRAM

Introduction: Narrow Band Imaging (NBI) and chromoendoscopy with methylene blue are enhancing techniques which are helpful in differentiating vascular and pit patterns of colorectal neoplasms. Therefore, they have a key-role for the adequate management of the lesions which might be candidates for endoscopic resection.

Aims & Methods: The aim of our study was to measure the interobserver agreement and the diagnostic accuracy in an endoscopy unit using methylene blue and NBI for the evaluation of the pit and vascular pattern according to the Kudo, Sano and NICE classifications of colo-rectal neoplasms, before and after an image-based training program. We retrospectively collected consecutive endoscopic images (NBI and with methylene blue) of colo-rectal neoplasms from the internal database. The image set was then evaluated by our gold standard composed by two expert endoscopists. Their evaluation resulted confident with histology reports in 88% of cases. The images set was then evaluated by the 9 endoscopists of the unit, before and after a 30-minutes image-based training program on enhancing techniques and surface colorectal patterns. NBI and colonic neoplasms' surface and vascular patterns. Interobserver agreement was calculated using the kappa statistic by Cohen. By using the gold standard evaluation as criterion standard, the accuracy of colo-rectal neoplasms' evaluation before and after the training was also calculated using the McNemar test. A value of $p < 0.05$ was considered statistically significant.

Results: A total of 30 images were obtained (see Table). Before the training process, the interobserver agreement was minimal for Kudo (0.10 ± 0.03) and Sano (0.12 ± 0.04), and poor for the NICE classification (0.24 ± 0.05). Diagnostic accuracy was 0.33 ± 0.07 , 0.54 ± 0.12 and 0.60 ± 0.10 for Kudo, Sano and NICE classifications, respectively. After the image-based training program, interobserver agreement moved to moderate for the Kudo classification ($p < 0.0001$) and to good for Sano and NICE classifications ($p < 0.0001$). Diagnostic accuracy increased significantly, too, with values of 0.60 ± 0.05 , 0.76 ± 0.05 , 0.80 ± 0.05 for Kudo, Sano and NICE classifications, respectively ($p < 0.0001$).

Classification	Type	N°
Kudo	I	0
	II	2
	III l	1
	III s	6
	IV	12
	V i	5
	V n	4
SANO	I	2
	II	19
	III a	5
NICE	III b	4
	I	2
	II	19
	III	9

Conclusion: To the best of our knowledge, we present the first study on the ability of an image-based training program in increasing the interobserver agreement and diagnostic accuracy in differentiating pit and vascular patterns of colo-rectal neoplasms using all the available endoscopic classifications (Kudo, Sano and NICE classifications). Such training seems mandatory for endoscopists using enhancing techniques especially when advanced lesions are planned to be treated endoscopically.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0204 YIELD OF 2ND SURVEILLANCE COLONOSCOPY IN “INTERMEDIATE RISK” PATIENTS. COULD SURVEILLANCE INTERVALS BE REFINED?

M. Balakrishnan, B. Adeoti, S. Cerys, S. Catnach, A. King, B. Macfarlane, J. Landy
Gastroenterology, West Hertfordshire Hospitals NHS Trust, Watford/United Kingdom

Contact E-mail Address: jonathan.landy@whht.nhs.uk

Introduction: Data regarding the yield of 2nd surveillance colonoscopy after index procedure findings of advanced colonic neoplasia (ACN) are limited. The yield of ACN at 2nd surveillance is associated with high risk index or 1st surveillance findings (1). However, previous studies are heterogeneous and definitions of ACN include characteristics of both “intermediate” (IR, >3 adenomas or any adenoma >10 mm) and “high risk” groups (HR, >5 adenomas or >3 adenomas with at least 1 >10 mm) as defined by BSG guidelines.

Aims & Methods: We aimed to evaluate the differences in yield of advanced colonic neoplasia at 2nd surveillance colonoscopy (S2) between “intermediate” and “high” risk patients at index colonoscopy in our unit. ACN was defined as ≥5 adenomas, any adenoma ≥1 cm, tubulovillous histology or high grade dysplasia, or cancer. Patients with HR or IR index procedures undertaken by 3 experienced, accredited bowel cancer screening colonoscopists and at least 2 surveillance colonoscopies, were identified from our local database between 2008 and 2016. Findings at 1st and 2nd surveillance procedures were assessed for the presence of ACN. Statistical analysis was undertaken using Graphpad Prism 5 using Fisher’s exact test. All tests were two tailed and a p value of ≤0.05 was considered significant. ORs with a 95% CI were calculated for significant findings.

Results: 218 patients meeting inclusion criteria were identified. 53% of patients had IR index findings. The median time to S2 was 49 months (IQR 48–49 m) for HR index patients and 72 m (IQR 70–73 m) for IR index patients. 11% of all patients had ACN at S2. 4% of IR patients v 18% of HR patients had ACN at S2, OR 0.4 (95% CI 0.2–0.6). 3% of IR patients without ACN at S1 had ACN at S2 v 15% of IR patients with ACN at S1 (ns). 11% of HR patients without ACN at S1 v 37% with ACN at S1 had ACN at S2; OR 0.2 (95% CI 0.07–0.6).

Conclusion: Stratification of high-risk index findings into HR and IR groups as per BSG guidelines differentiates a low-risk group at second surveillance colonoscopy. The second surveillance interval for IR patients without ACN at first surveillance might be increased as ACN is infrequently detected in this group.

Disclosure of Interest: J. Landy: Educational support from Norgine.

P0205 SAFETY OF COLD SNARE COLON POLYPECTOMY IN PATIENTS ON ANTITHROMBOTIC MEDICATION

M. Matsumoto
Dept. Of Gastroenterology, Hokkaido Medical Center, Sapporo/Japan

Contact E-mail Address: miosakra@outlook.jp

Introduction: Cold snare polypectomy (CSP) has been increasingly used in recent years because post- polypectomy bleeding is less common with this technique than with conventional polypectomy. According to the 2012 update of the Japanese guideline for periprocedural management of antithrombotic medications issued by the Japan Gastroenterological Endoscopy Society, procedures with a low risk of hemorrhage may be performed with a short interruption or continuation of antithrombotic medication. However, the guideline does not refer to periprocedural antithrombotic management for CSP.

Aims & Methods: The objective of this study was to determine the safety of CSP in patients on antithrombotic medication. The subjects were patients who underwent CSP at this hospital between April 2014 and March 2016. Post-CSP bleeding rates were examined in relation to the use of antithrombotic medication. CSP

was indicated for non-pedunculated polyps smaller than 10 mm, excluding lesions with submucosal invasion and suspected of being cancerous at the preprocedural diagnostic evaluation.

Results: CSP was performed to remove 2466 polyps in 1003 patients; cancerous lesions accounted for 0.2% of them, but all had negative margins. There were 549 polyps (22.3%) in 186 patients who had been taking antithrombotic medication before CSP (antithrombotic group), and 1917 (77.7%) in 817 patients not taking antithrombotic medication (non-antithrombotic group). In the antithrombotic group, 106 patients with 283 polyps continued taking the antithrombotic medication; specifically, aspirin in 41 patients with 113 polyps, clopidogrel in 13 patients with 17 polyps, dual antiplatelet therapy (DAPT) in 13 patients with 18 polyps, antiplatelet agents other than clopidogrel in 17 patients with 68 polyps, anticoagulant agents in 20 patients with 56 polyps, and antiplatelet plus anticoagulant combination therapy in 2 patients with 11 polyps. Heparin bridging was used in 13 patients with 38 polyps. Post-CSP bleeding occurred in 0.54% (3/549) of the interventions in the antithrombotic group and in 0.10% (2/1917) of those in the non-antithrombotic group, showing no significant difference (p=0.08). Endoscopic hemostasis was successful in all cases of bleeding, without requiring blood transfusion. As for the 3 cases of post-CSP bleeding in the antithrombotic group, the specific antithrombotic medication being used was aspirin in 1 patient with 1 polyp (0.88%, 1/113), and aspirin and clopidogrel a patient with 2 polyps (11.1%, 2/18). No post-CSP bleeding occurred in patients on other antiplatelet or anticoagulant agents, or on heparin bridging. Clipping after CSP was more likely used in the antithrombotic group (i.e., 13.5% vs. 4.6%; p < 0.01). No significant difference in post-CSP bleeding rate was observed between lesions with and without clipping (0% with clipping vs. 0.34% without clipping; p=0.55)

Conclusion: CSP is a safe procedure even in patients on antithrombotic medication. The risk of bleeding after CSP was not high compared with that after biopsy in patients on antithrombotic medication (post-procedural bleeding rate, 0.09–0.61%), suggesting that CSP can be virtually categorized as a procedure with a low risk for hemorrhage in the guideline for periprocedural antithrombotic management.

P0206 OPTICAL ENHANCEMENT FOR THE IN VIVO PREDICTION OF COLORECTAL POLYP HISTOLOGY

E. Klenske, C. Neufert, A. Nägel, S. Zopf, M. F. Neurath, T. Rath
Department Of Medicine ¹University Hospital of Erlangen, Erlangen/Germany

Contact E-mail Address: entcho.klenske@uk-erlangen.de

Introduction: Diminutive polyps are a common finding among surveillance colonoscopies without having high prevalence of advanced histology, making their standardized removal cost-, time- and risk-intensive. Based on these considerations, the American Society of Gastrointestinal Endoscopy (ASGE) proposed the so called PIVI statement, in which diagnostic thresholds are defined that new technologies used for the real-time assessment of colorectal polyp histology should meet. Optical enhancement (OE) is a novel endoscopic pre-processing optical filter technology, in which the spectrum of the emitted wavelengths is reduced, thereby leading to enhanced visualization of the mucosal and vascular pattern.

Aims & Methods: In this study we aimed to assess whether OE can accurately predict the histology of diminutive colorectal polyps according to the ASGE PIVI criteria. A total of 106 colorectal polyps from 49 patients undergoing diagnostic or surveillance colonoscopy were included. The in vivo histology prediction using OE was compared to results of histopathology as a reference standard.

Results: The overall accuracy of OE for real-time prediction of polyp histology was 94.3% with a sensitivity, specificity, positive (PPV) and negative prediction value (NPV) of 100%, 95.3%, 85.4% and 100%, respectively. When including only high confidence (HC) predictions, the accuracy of OE increased to 96.5%. Sensitivity, specificity, PPV and NPV were 100%, 94.5%, 91.2% and 100%, respectively. In distal colorectal polyps the accuracy was 93.3% with sensitivity, specificity, PPV and NPV being 100%, 91.3%, 80% and 100%, respectively. The post-polypectomy colonoscopy surveillance intervals were predicted correctly in ≥90% of patients with OE.

Conclusion: Optical enhancement allows to accurately predict the histology of diminutive colorectal polyps in vivo in real-time and meets the PIVI thresholds for resecting and discarding diminutive polyps without histological assessment and for leaving distal diminutive colorectal polyps in place. Hence, optical enhancement can potentially reduce time, risk and costs associated with removal and histopathological assessment of diminutive polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0207 BLUE LASER IMAGING OPTICAL DIAGNOSIS OF COLORECTAL POLYPS: ACCURACY OF THE NICE, SANO AND WASP CLASSIFICATIONS

S. Ribiere, J. Dreanic, M. Barret, M. Camus, M. Dior, B. Brieau, S. Leblanc, F. Prati, R. Coriat, S. Chaussade
 Department Of Gastroenterology, Cochin Hospital, Assistance Publique-Hôpitaux de Paris, Paris/France

Contact E-mail Address: sophieclm.riberie@gmail.com

Introduction: Blue Laser Imaging (BLI) is a new image-enhanced endoscopic technique, meant, in association with magnification endoscopy, to help differentiating between neoplastic and non-neoplastic colorectal polyps. A variety of endoscopic classifications have been developed to guide optical diagnosis of colorectal polyps. The aim of our study was to evaluate NICE, WASP and Sano classifications for the optical diagnosis of colorectal polyps using Blue Laser Imaging and magnification.

Aims & Methods: Between May 2014 and December 2015, 181 colorectal polyps in 65 patients were imaged and resected in our single center study. Each polyp was evaluated using white light endoscopy, BLI with and without magnification. An independent expert reviewed the pictures and the videos of the polyps and staged them using NICE, Sano and WASP classifications: his conclusions were compared with the actual histology of the polyps. Diagnostic performances of BLI and magnification were calculated with each endoscopic classification.

Results: 181 polyps were studied, among which 125 adenomas, 24 sessile serrated adenomas/polyps, 25 hyperplastic polyps, 2 adenocarcinomas and 11 normal colorectal mucosal samples. The median polyp size was 7mm. Overall, the NICE, Sano and WASP classifications were comparable in terms of diagnostic performances for the optical diagnosis of colorectal adenomas ($p=0.7$). However, the WASP classification provided the best results with a sensitivity, specificity, positive and negative predictive value, and diagnostic accuracy for the diagnosis of adenoma of 0.93 (95% CI 0.86 to 0.97), 0.80 (95% CI 0.66 to 0.91), 0.93, 0.80 and 0.9. In the rectosigmoid, negative predictive values for the diagnosis of adenoma were 0.77; 0.91; and 1.0 using NICE, Sano and WASP classifications.

Conclusion: Our work suggests that BLI with magnification is a promising technique for the optical diagnosis of colorectal polyps with a diagnostic accuracy of 86–90%. Our study did not establish significant difference between the three classifications. However, the ASGE criteria for the implementation of the "resect and discard" strategy were met for the classifications of Sano and WASP with a negative predictive value for the diagnosis of adenoma beyond 90% in the rectosigmoid.

Introduction: Colonoscopy is difficult procedure, largely due to unpredictable looping during insertion. If the endoscopist is able to see the colonoscope on the image display, fewer attempts are needed to straighten the shaft of the scope. A prototype Fiber Brag Grating(FBG) scope guided endoscopy provides a facility for continuous viewing on a monitor of the position of the colonoscope during examination.

Aims & Methods: The aim of this study was to evaluate the accuracy and feasibility of the innovative 3D Colonoscope using FBG. In the first part of the study, the FBG sensor was inserted into the working channel of a routine colonoscope in the first 70 cm from the tip of the scope. Then, the scope was placed in front of the monitor to confirm movement of the scope in all three dimensions. We evaluated loop formation such as N loop, alpha loop, reverse alpha loop, with the 3D imaging monitor. In the second part of the study, 5 patients underwent colonoscopy with a FBG sensor, the colonoscope can be displayed in anteroposterior or lateral view, or in both positions together. Fluoroscopy was used in all investigations for comparison.

Results: In the first part of the study, the results showed that the shape sensor was reliable at a maximum bending curvature of 80mm⁻¹. The average tip position error was 1.722±1.678 mm, which corresponds to 1.50±1.46% of the total length of the sensor. Scope movement and loops were detected correctly in all cases through the monitor. The prototype used in the second part of the study showed a high correlation and little discrepancy with the comparative findings at fluoroscopy.

Conclusion: Scope-guided endoscopy using FBG sensor can be successfully used to display colonoscope configuration. This flexible, thin and almost weightless shape sensor would be a novel technique for identification of colonoscope shape.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0209 REAL-TIME MORPHOLOGIC CHANGE ON NUCLEUS & MITOCHONDRIA OF COLON CANCER CELL BY IRREVERSIBLE ELECTROPORATION: DETECTED BY PROBE-BASED MULTIPHOTON MICROSCOPY

Introduction: Irreversible electroporation (IRE) is a promising novel technique for tumor ablation using energy current pulses. IRE can effectively remove unwanted cells without thermally damaging surrounding tissues. We used multiphoton microscopy for evaluated the response of cancer cell to IRE ablation and found apoptotic process after applying IRE.

Aims & Methods: By using multi-photon (MP) probes, that is ABI-Nu for nucleus and PMT for mitochondria, we were focusing on these two vital intracellular organelles for examining the real-time phenomenon of IRE-induced apoptosis. The study was conducted in three stages. Colon cancer cell lines and normal colon mucosa and colon neoplasm tissues obtained during colonoscopic biopsy from 10 patients were stained with multi-photon (MP) probes that is ABI-Nu for nucleus and PMT for mitochondria. We evaluated the feasibility of using multiphoton microscopy (MPM) to observe IRE response. First, the IRE responses of colon cancer cell lines were compared before and after IRE. Electrical pulses were administered with a Harvard apparatus, and the changes in the intensity of the nucleus and mitochondria were observed with time. Second, the IRE response of normal colon and colon cancer tissue obtained from same patient were evaluated before and after IRE same with previous method. Also, the 3-D images of the tissues co-labelled with ABI-Nu and PMT were reconstructed. Third, to assess apoptosis, colon cancer cells were stained with the fluorescent dye Annexin V or propidium iodide (PI) after applying electroporation at the same energy used earlier. Also, in order to determine whether IRE induce apoptosis, membrane blebbing of colon cancer cell lines were examined after apply IRE.

Results: MPM images of cancer cells stained with MP probes revealed that ABI-Nu stained quicker after IRE ablation. At the tissue level, nuclear staining was present earlier and was more prominent after IRE was applied. In addition, IRE had a relatively stronger effect on cancer than normal. We obtained MPM images for each tissue slice, including four MP images for every 150 sections at a depth of 90–150 µm along the z-direction. Using the same electroporation energy, staining was positive for Annexin V and PI, providing the evidence of apoptosis. Also, blebs, which are distinctive of apoptotic cells were developed after IRE in the colon cancer cell. However, bleb formation was not appeared in the control group.

Conclusion: Here, we observed using MPM that nuclear staining occurred quickly due to increased cell membrane permeability and bleb was formed after electric pulse exposure. These results are expected to challenge the understanding of the

permeability process after IRE by providing the real-time images. Additionally, MPM can replace other apoptosis assessment methods, including Annexin V-FITC and PI staining. This MP probe protocol would dramatically increase the accuracy of diagnostic techniques by providing in vivo cell images.

Introduction: Endoscopic mucosal resection (EMR) is an established therapeutic option for large (> 30 mm) colonic polyps. We aimed to assess characteristics and outcomes of this cohort. Primary outcomes consisted of rates, predictors and durability of EMR success, whilst secondary outcomes included complications, malignant risk, and conversion to surgery.

Aims & Methods: We prospectively identified patients referred for large polyp EMR from a polyp multidisciplinary team meeting between August 2008–2016) in a district general hospital with tertiary EMR expertise. Data on demographics, polyp site, morphology, size, accessibility (SMSA), histology and follow-up endoscopy were retrospectively collected. Binary logistic regression modelling was performed using SPSS, with components comprising of year, individual SMSA components, and histology. The Kaplan-Meier approach was used to measure durability of EMR success.

Results: Large polyp EMR was performed in 91 patients out of 125 MDT referrals (73%). Patients had a median age of 72 (interquartile range [IQR] 14.4), and were predominantly male (60%). Polyps were sessile (46%), flat (49%) or pedunculated 4 (4%), with a median size of 40 mm (IQR 20.5 mm), and were left-colonic in 81%. Bleeding occurred in 16.5%, all of whom achieved haemostasis. The 30-day complication rate was 1.1% (delayed bleeding in 1 patient). 54 (59%) were fully resected in one session, with overall EMR successful in 75 (81.5%) after an average of 1.5 sessions. On multivariable analysis, significant predictors of complete resection at first attempt (Table 1) included: increasing year, sessile vs. flat morphology, and non-malignant histology. Malignant histology ($p < 0.001$) predicted overall EMR failure, but not age, gender, year of EMR, SMSA score, or concomitant argon plasma coagulation. Of the EMR failure group, 11/16 (69%) underwent surgical resection, of which 7/11 (64%) harboured adenocarcinoma. Of the EMR success group, 4/80 were malignant polyps with R0 endoscopic resection. The overall malignant histology rate in this cohort was 11/91 (12%). In this cohort, the R0 EMR success rates was 4/11 (36%), with no recurrence after 60 months of follow-up. The overall 12-month recurrence rates following complete EMR was 1.5%, with no significant factors affecting EMR durability identified.

Table 1: Predictors of complete resection on first EMR attempt. p-values derived from bivariate regression, with bold values significant if < 0.05 . *Increase in OR for each increase in year. **p-value < 0.05 considered statistically significant.

Factor	Odds Ratio	95% Confidence Interval	p-value
Year	1.41*	1.04–1.90	0.048**
Size (3–3.9 cm vs. >4.0 cm)	2.96	0.85–10.3	0.088
Site (left vs. right colon)	0.46	0.09–2.48	0.367
Access (easy vs. difficult)	1.39	0.38–5.14	0.619
Morphology (sessile vs. flat)	3.38	1.04–11.0	0.043**
Non-malignant histology	41.5	3.74–461	0.002**

Conclusion: Large polyp EMR is a safe and effective alternative to surgical resection of large polyps. Endoscopist experience, polyp morphology, and benign histology predict complete resection at index EMR. Further data are required to evaluate the longer-term outcomes of malignant polyps.

Introduction: Though numerous research has enabled decrease of the bowel preparation solution volume, it is still a major complaint of patients preparing

colonoscopy. There have been studies that additional administration of laxatives could lessen the amount of aqueous formula with prokinetic effect. Prucalopride is a serotonin (5-HT₄) receptor agonist which stimulate colonic mass movements and provide main propulsive force for defecation.

Aims & Methods: The aim of this study is to compare 2-L PEG-Asc and 1-L PEG-Asc plus prucalopride for quality of bowel cleansing while preparing for colonoscopy and patient compliance. Two hundred patients were prospectively enrolled. Patients referred for colonoscopy were divided into group A (the split-dose 2-L PEG-Asc) and group B (1-L PEG-Asc + prucalopride) randomly. During colonoscopy, each patient's bowel preparation quality was evaluated with The Boston Bowel Preparation Scale (BBPS) and Aronchick Preparation Scale (APS). The tolerability and satisfaction of patients was determined based on a questionnaire-based survey.

Results: One hundred patients received either 2-L PEG-Asc or 1-L PEG-Asc with prucalopride. Regarding colon cleansing outcome (BBPS and APS), the 1-L PEG-Asc with prucalopride group showed similar, but non-inferior results compared to the 2-L PEG-Asc group on both BBPS (7.65 ± 1.27 vs 7.52 ± 1.40 , $p = 0.586$) and APS scales (93.3% vs 95% , $p = 0.717$). Tolerability was similar for both 1-L PEG-Asc with prucalopride and 2-L PEG-Asc.

Conclusion: 1-L PEG-Asc plus prucalopride preparation showed comparable result to traditional 2-L PEG-Asc preparation. 1-L PEG-Asc plus prucalopride preparation method could be an alternative method for bowel preparation which can relieve patient discomfort.

Introduction: Endoscopic mucosal resection (EMR) is an effective and safe treatment for large (≥ 20 mm) laterally spreading colorectal lesions. Although colon EMR has been established as a minimally invasive technique for treatment of large colorectal lesions, risk of adenoma recurrence is the main limitation. Current guidelines recommend first follow-up at 3–6 months; however, there are no well-designed prospective studies published establishing an optimal system to ensure SC1 (first surveillance colonoscopy after initial exam) is scheduled and executed in the appropriate timeline. Inadequate or absent scheduling of SC1 can have an impact on the detection of recurrent adenomas, increasing potential patient morbidity, adding unnecessary costs and potentially leading to repeated and avoidable procedures. The aim of this study was to conduct a quality improvement initiative aimed at increasing compliance in SC1 by understanding the current scheduling process and developing strategies to standardize our endoscopy center practices.

Aims & Methods: Single tertiary referral center quality improvement project started in January 2017 and currently still in progress. We present here the interim data. Consecutive patients who had undergone or would have EMR of lesions ≥ 20 mm were eligible for inclusion. The process of following-up patients after EMR was divided at two levels: A dedicated team member generated a monthly report identifying patients who underwent colon EMR using our endoscopy procedure documentation program. The appropriate timeline for SC1 for each patient that underwent colonoscopy EMR was identified and orders and scheduling for the colonoscopy follow-up were carried out. Evaluation of follow-up: A dedicated team member reviewed the status of patients who underwent colon EMR six months prior to the start of the QI study. If patient did not show up on their scheduled follow-up, phone calls were placed to contact the patients. Patients who had followed-up with their local gastroenterologists were recorded. All the data in intervention group was compared retrospectively with nonintervention group who were not tracked through quality improvement process. Mean follow-up time and follow-up rate (%) at 6–9 months at SC1 after index EMR was compared between the two groups.

Results: Per-protocol 25 patients included in intervention group were compared to 60 patients in the nonintervention group. Mean age was 62 years in intervention group and 66 years in non-intervention group ($p = 0.04$). There were no differences in distribution in size of lesion, gender, EMR site, and polyp histology between two groups (Table 1). The mean follow-up time in intervention group was 8.2 months (± 2.6) and nonintervention group was 10.4 months (± 9.1). There was increase in rate of 6–9 months follow-up in intervention group when compared to the nonintervention group (88%, 95% CI [0.80%–0.94%] vs 64%, 95% CI [0.54%–0.73%]) (Table 1).

Table 1: Demographic, clinical characteristics, follow up rates

Variables	Intervention group (n = 25)	Non-intervention group (n = 60)
Age, Mean (SD)	62 (8.7)	66 (10.5)
Sex, Male (%)	38% (10)	58% (35)
Size of polyp(mm), Mean (SD)	35 (18)	30 (12)

(continued)

Table 1 Continued

Variables	Intervention group (n = 25)	Non-intervention group (n = 60)
Site of polyp resection		
Rectum	8% (2)	5% (3)
Sigmoid	4% (1)	7% (4)
Recto-sigmoid	0%	2% (1)
Descending colon	0%	3% (2)
Transverse colon	15% (4)	12% (7)
Hepatic flexure	15% (4)	8% (5)
Ascending colon	23% (6)	37% (22)
Mid ascending colon	0%	5% (3)
Cecum	23% (6)	13% (8)
Cecum with appendiceal orifice	8% (2)	0%
Ileocecal valve	4% (1)	8% (5)
Polyp histology		
Sessile serrated adenoma	23% (6)	30% (18)
Tubular adenoma	35% (9)	35% (21)
Tubular adenoma with HGD	8% (2)	2% (1)
Tubulovillous adenoma	31% (8)	32% (19)
Tubulovillous adenoma with HGD	4% (1)	0%
Adenocarcinoma	0%	2% (1)
Follow-up Rates		
Median(range)	7.3 months (6–15 months)	7.3 months (4–66 months)
Mean (±SD)	8.2 months (2.6)	10.4 (9.1)
Colon EMR follow-up rate of 6–9 months, % (n)	88%, 95% CI [0.8%–0.94%], (22)	64%, 95% CI [0.54%–0.73%], (35)

Conclusion: These preliminary results suggest significant improvement in SCI compliance with our intervention. We believe that continuing these efforts and further refining the intervention process, requiring less personnel resources, may be helpful to improve the follow-up time until 3–6 months interval while also enduring as a sustainable change for our practice.

P0214 META-ANALYSIS SUGGESTS: INSPECT TWICE TO INCREASE RIGHT COLON ADENOMA DETECTION RATE

Introduction: Missed adenomas in the right colon are of major concern for interval colon cancer (CRC) development. There is evidence from cohort and randomized controlled studies (RCTs) that a second examination of the right colon – either in direct view or in retroflexion- increases the diagnostic yield of the procedure. However, data are not accepted unanimously.

Aims & Methods: The aim of this meta-analysis was to examine the effect of a second, back-to-back mucosa inspection on the diagnostic yield of colonoscopy in the cecum and the ascending colon. We performed literature searches in MEDLINE to identify studies evaluating the effect of a second pass endoscopic examination on adenoma detection rate (ADR) and advanced ADR (AADR) in the right colon. Study outcomes effect sizes were calculated using RevMan 5.3 software fixed or random effect model, as appropriate, and they are presented as OR[95%CI]. Heterogeneity was measured using the I² statistics. Publication bias was assessed by Funnel plots inspection and the quality of the meta-analyzed studies was assessed using the Jadad criteria.

Results: We identified 8 studies (5 cohort and 3 RCT, with 9 sets of data and 5639 subjects – mixed CRC screening/surveillance and symptomatic population) that

reported on the aforementioned outcomes. Two sets of data examined the yield of the second direct view as compared to that of a single inspection, one set examined the cumulative yield of two passes compared to that of an extended (timely) inspection of the right colon and six sets of data evaluated the yield of the second examination of the right colon with scope retroflexion compared to that of the single direct view. They were moderate risk of bias studies; suspicion for publication bias was detected in the direct view arm of the analysis. As compared to a single pass, the second right colon inspection significantly increased ADR (1.31 [1.15–1.49], I²=49%). The effect size of ADR was higher in the direct view second pass arm (1.73 [1.41–2.12], I²=0%) as compared to the retroflexion arm (1.17 [1.06–1.29], I²=0%). Sensitivity analysis with removal of one study each time did not identify a single study responsible for the detected heterogeneity. Our analysis did not show significant increase in right colon AADR (1.5 [0.76–1.56], I²=0%) after the second exam.

Conclusion: In comparison to a single pass, the second inspection of the right colon either in direct view or with scope retroflexion increases ADR in this colon segment. However, results should be interpreted cautiously due to the small number of meta-analyzed studies with mixed indications populations, and the detected moderate levels of heterogeneity and risk for bias.

Introduction: Endoscopic treatment of malignant colorectal polyps is often challenging, especially for early rectal cancer (ERC) localized close to the dentate line. Conversely, the surgical approach may result in temporary or definitive stoma and in frequent post-surgical complications [1–2]. Endoscopic Full Thickness resection (EFTR) is a novel technique that, besides having other indications, appears to be promising for wall-thickness excision of intestinal T1 carcinoma following incomplete endoscopic resection [3–4].

Aims & Methods: Follow-up data on patients treated with this device are scarce, particularly for ERC. We enrolled six consecutive patients with T1-ERC. They were treated with the EFTR, after appropriate staging, and their long-term outcomes were evaluated based on a detailed clinical and instrumental assessment.

Results: The endoscopic *en bloc* full-thickness resection was technically feasible in all patients. The histopathologic analysis showed a complete endoscopic resection in all cases, and a full-thickness excision in four. Neither complication, nor disease recurrence was observed during the one-year follow-up performed.

Conclusion: EFTR is a promising tool for treating ERC featuring a residual risk of disease recurrence after incomplete endoscopic mucosal resection in patients unfit for surgery or refusing surgical approach.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal Endoscopic Submucosal Dissection (CR-ESD) is technically difficult, time-consuming, and has a long learning curve for Western endoscopists. Several factors related with greater difficulty while performing this technique have been described. Generally, during the learning curve phase, we select simple lesions while initiating the technique.

Aims & Methods: Our goal was to assess those factors associated with greater difficulty during untutored DSE-CR without prior selection of less difficult lesions. All patients who attended the complex colorectal polyps consultation were included consecutively. No polyps regardless of their size, morphology, location or any characteristic of greater technical difficulty were ruled out. All CR-ESDs were performed by an endoscopist with previous animal model experience. The demographic and clinical characteristics of the patient, the morphology of the lesion and factors related to the technique were collected. A complex technique

was defined as that dissection that is not done en block and/or had complications.

Results: 112 lesions were selected, discarding 4 due to deep invasion. We evaluated in this study 108 DSE-CR, 27 (25%) of which were compatible with our definition of "complex" ESD. In Table 1 you can see the characteristics of each group. Univariate analysis showed that variables such as size over 35 mm [63% vs. 27.2%; OR 4.56 (95% CI: 1.81–11.46); $P=0.001$], absence of CO₂ [55.6% vs. 19.8%; OR 5.08 (95% CI: 1.99–12.94); $P<0.001$], presence of serious fibrosis in the submucosa [48.1% vs. 7.4%; OR 11.61 (95% CI: 3.78–35.69); $P<0.001$] and presence of fatty tissue in the submucosa [59.3% vs. 22.2%; OR 5.09 (95% CI: 2.01–12.90); $P<0.001$] were related to a "complex" ESD. Finally, in the multivariate analysis, those variables were associated with a complex technique with an Odds Ratio of 7.42 for severe fibrosis ($p=0.039$), 6.34 for non-CO₂ insufflation ($p=0.030$), 5.78 in the presence of fatty tissue in the submucosa ($p=0.035$) and 5.74 in size greater than 35 mm ($p=0.025$). There was no relation with the complexity of the technique, the demographic-clinical characteristics of the patient, nor the location-morphology of the lesions. The duration of the technique was an average of 48 minutes longer in cases of a complex technique.

Conclusion: In our series the difficulty of CR-ESD was associated with factors described in other studies such as the size, the non-insufflation of CO₂ and the presence of severe fibrosis in the submucosa. Our results describe the presence of fatty tissue in the submucosa as a new predictor of technical difficulty. In our study, we did not select the location to begin the technique, and in our learning curve we did not find significant differences in the performance of ESD in the proximal colon, distal or rectum.

P0217 PERSISTENT PAIN AFTER COLONIC ENDOSCOPIC MUCOSAL RESECTION: PREDICTORS, A MANAGEMENT ALGORITHM AND OUTCOMES

L. Desomer, D. J. Tate, H. Awadie, L. Pillay, G. Ahlenstiel, M.J. Bourke
Department Of Gastroenterology And Hepatology, Westmead Hospital, Sydney/Australia/NSW

Contact E-mail Address: lobkedesomer@gmail.com

Introduction: Endoscopic mucosal resection (EMR) of large (≥ 20 mm) laterally spreading colonic lesions (LSL) is safe, effective and superior to surgery. This advantage is based on a day stay model of care; however, the most common adverse event is abdominal pain and this is a major impediment to its efficiency. No prospective data exist on the optimal selection of analgesics, the necessary recovery period or the triggers that should alert the practitioner to a more serious trajectory and the need for escalation of care.

Aims & Methods: We aimed to characterise potential predictors for PP and develop a simple and effective management algorithm for patients with PP based on the need for analgesics in recovery. Data on consecutive patients with a LSL referred for EMR at a single, tertiary referral centre were included. Patient and lesion characteristics and peri-procedural data were prospectively collected. Standard post EMR care included 2 hours in first stage recovery followed by 1 hour in 2nd stage recovery where clear fluids were given and discharge after if the patients were well. Persistent post-procedural pain (PP) was graded from 0 to 10 using a Visual Analogue Scale (VAS). If PP occurred >5 minutes, 1 gram of acetaminophen was administered parenterally and outcomes were monitored. If pain settled the patient was transferred to second stage recovery after medical review. PP >30 minutes lead to clinical review and upgrade of analgesics to fentanyl, with a starting dose of 25 micrograms (mcg) up to a maximum of 100 mcg. Investigations, admission and interventions for PP were recorded.

Results: 166 patients with 166 lesions were included between February and April 2017. 34/166 (20.5%) of patients had PP requiring intervention (median VAS 5, IQR 3–6). 27/34 (79.4%) had resolution of pain with acetaminophen only and were ultimately discharged without sequelae. 7/34 patients (20.6%) required fentanyl (25 mcg of fentanyl in 3 patients, 50 mcg in 1.75 mcg in 1 and 100 mcg in 2).

A CT scan was performed in the 2 patients requiring 100 mcg of fentanyl, showing serositis in 1 patient and no abnormalities in the other. Both patients were admitted and managed conservatively (discharge day 6 and 2 respectively). The other 5 patients were discharged home on the same day after extended recovery. Predictors of PP were lesion size ≥ 45 mm ($P=.003$), Paris classification ($P=.022$) and intra-procedural bleeding requiring endoscopic control (IPB, $P=.042$). Lesion size ≥ 45 mm and IPB were also independent variables on multivariate analysis with an odds ratio of 2.8 (95% confidence interval 1.3–6.3, $p=.012$) and 2.3 (95% confidence interval 1.0–5.2, $p=.042$ respectively (Table 1).

Conclusion: Pain after EMR occurs in 20% of patients and is associated with larger lesion size and intraprocedural bleeding requiring endoscopic control in a multivariate analysis. If pain subsides after parenteral acetaminophen and does not recur the patient can be safely and confidently discharged to the step down recovery area and after medical review allowed to leave hospital. PP despite parenteral acetaminophen heralds a more serious scenario and imaging should be considered when stronger analgesics do not relieve the pain.

Introduction: Some high-quality, large-scale cohort studies proved removals of colorectal neoplasms achieved prevention of colorectal cancer incidence and deaths. We introduced a strategy of removing all neoplastic polyps in single session colonoscopic examinations using cold polypectomy was started.

Aims & Methods: The aim of this retrospective study was to investigate about achievement of colorectal polyp remove in our clinical practice setting. Scheduled colonoscopic examinations for 40–79 years outpatients who had at least one colorectal neoplasm between January 2015 and December 2016 were collected from our endoscopic data base. Exclusion criteria were as follows; patients who had colorectal neoplasm larger than 20 mm, pre-examination of colorectal surgery or endoscopic submucosal dissection, inflammatory bowel disease, familial adenomatous polyposis, uncontrolled malignancies, by trainee endoscopists (<500 colonoscopies), no agreements of polyp removal, and/or patients with continuation of anti-thrombotic agents. Outcome measurements were polyp removal rate (per-lesion analysis), complete polyp removal rate (per-patient analysis) and complications. Proportions of each endoscopic removal method according to size were also analyzed.

Results: A total of 2527 patients (mean age 66.8 y, 799 females) with 8203 colorectal neoplasms (CRNs) (7675 adenomas, 423 serrated polyps and 105 Tis and T1 cancers) who met inclusion and exclusion criteria were analyzed. Mean number of CRNs per patients was 3.2. Mean size was 4.7 (± 2.9) mm. Polyp removal rate (per-lesion) and complete polyp removal rate (per-patient) were 97.0% (7955/8203) and 94.7% (2394/2527), respectively. Post-polypectomy bleeding requiring endoscopic hemostasis occurred in 7 patients (0.27%) and all origins of bleeding were endoscopic mucosal resection (EMR) and hot snare polypectomy (HSP). Post electrocoagulation syndrome requiring admission was occurred in one patient (0.04%) after pre-cutting EMR. Mean procedure time was 27.4 (± 13.3) min. Proportions of each endoscopic removal method according to size were presented in an attached table. In 1–4 mm CRNs, both cold snare polypectomy (CSP) (51.8%) and cold forceps polypectomy (CFP) (45.8%) for 1–4 mm CRNs were main methods. In 5–9 mm CRNs, CSP was a leading method (73.8%) and EMR was the second one (24.1%). CRNs larger than 10 mm were almost removed by EMR (94.4%).

Abstract No:P0217

Table 1: Baseline and lesion characteristics. Comparison between the patients with and without pain post endoscopic mucosal resection of a large (≥ 20 mm) laterally spreading lesion. SD: standard deviation, IQR: interquartile range, *left colon: distal to hepatic flexure, #using thermal therapy.

	No pain (n = 132)	Pain (n = 34)	P-value	Multivariate
Baseline characteristics				
Age (years, mean, SD)	69.2 (10.6)	69.6 (10.7)	.944	
Sex (%) Male Female	73 (55.3) 59 (44.7)	14 (41.2) 20 (58.8)	.141	
Lesion characteristics				
Size (mm, %) 20–44 mm ≥ 45 mm	103 (78.0) 29 (22.0)	18 (52.9) 16 (47.1)	.003	.012
Location (%) Left colon* Right colon	53 (40.2) 79 (59.8)	17 (50.0) 17 (50.0)	.300	
Paris classification (%) 0-Is 0-IIa 0-IIa + Is Others	6 (4.5) 84 (63.6) 40 (30.3) 2 (1.5)	1 (2.9) 14 (41.2) 16 (47.1) 3 (8.8)	.022	
Procedural data				
Submucosal fibrosis (%)	38 (28.8)	9 (26.5)	.789	
Intra-procedural bleeding requiring endoscopic control [#] (%)	59 (44.7)	23 (67.6)	.017	0.042
Intra-procedural perforation (%)	6 (4.5%)	0 (0%)	.348	

Proportions of each endoscopic removal method according to size

Size(mm)	CFP	CSP	HSP	EMR
1–4 (N = 5046)	45.8%	51.8%	0.5%	1.9%
5–9 (N = 2294)	0.6%	73.8%	1.5%	24.1%
10–20 (N = 612)	0%	4.9%	0.7%	94.4%

Conclusion: In our clinical practice setting, the polyp removal rates were satisfactory level in single session colonoscopic examinations using cold polypectomy.

P0219 META-ANALYSIS AND OWN EXPERIENCE IN THE TREATMENT OF RECTO-UROGENITAL FISTULA USING THE OVER-THE-SCOPE CLIP (OTSC)

M. Raithel¹, M. Vetter², A. Braun¹, T. Vasilakis², A. F. Hagel²

¹St. Marien Waldkrankenhaus, Erlangen/Germany

²University Clinical Center Erlangen, Erlangen/Germany

Contact E-mail Address: martin.raithel@waldkrankenhaus.de

Introduction: The transmural OTSC is used to achieve a full-thickness, serosa-to-serosa apposition (emergency & elective cases) for closure of GI wall defects (perforation, leak, fistula) with reported mean closure rates of 62–100% (range 0–100%), depending on the size of perforation, type and nature of lesion and the endoscopists' experience^{1–3}. However, recto-urogenital fistula may arise from a variety of etiologies and are mostly leaks or fistula of chronic nature, rarely acute perforations with vital wound tissue. They may occur in Crohn's disease, but can also be a consequence of abdominal surgery, traumatic lesions or post-radiation damage.

Aims & Methods: To further explore the role of the OTSC in this particular type of fistula we analyzed own cases and 21 reports from the literature dealing with any type of recto-urogenital fistula. In total, 25 patients, were identified with closure of a recto-urogenital fistula using the OTSC, but there was considerable heterogeneity, because of the fistula location (rectocutaneous n = 2, rectovaginal n = 10, rectovesical n = 7, rectourethral n = 2, other rectal fistula n = 3).

Results: In most situations a previous interdisciplinary discussion was reported before an OTSC attempt, or patients refused to undergo re-operation. However, special characteristics of these leaks were reported to make more difficult the OTSC procedure compared with other GI locations, e.g. the site of the fistula is nearby located to L. dentata and anal sphincter, it includes a localization with little space for endoscopic manipulation, fibrous and scar tissue is around the fistula in rectum or anastomosis and there may be sometimes suture material in situ. Thus, the tissue is often fixed and there is not so much tissue for grasping tissue into the OTSC.

The diagnosis of recto-urogenital fistula was usually made by endoscopic visualization and radiologically documented extravasation of contrast media into the vagina, urethra, bladder or into other adjacent tissue. For fistula closure traumatic OTSC was mostly used, but sometimes other adjuvant therapeutic modalities were also combined locally (e.g. histoacryl injection, fibrin glue, argon plasma coagulation, brushing etc) or systemically (e.g. ascorbic acid 7.5 g i.v.) to stimulate wound healing. The procedural success of occluding various types of recto-urogenital fistulae by the OTSC system was found to be successful in 71% (0–100%) in the short-term, while a durable clinical success was found in only 52% (0–100%) of all 25 patients. The success rate was lower in cases of highly fibrotic chronic fistulae, after dislocation of clips and when using the atraumatic clip. Thus, even in this distal problematic site usage of a traumatic OTSC should be tried in experienced hands before surgical repair.

Conclusion: In conclusion, recto-urogenital fistula may be a potential indication for OTSC application, after interdisciplinary consensus, when re-operation is avoided, deemed to be too risky or cumbersome. Although this type of fistula carries some difficulties because of little space, tissue tension and fibrous or postop changes, long-term success may be achieved in around half of all patients. Further improvements should focus on increasing healing potency of the fistula or better after performing anastomosis creation (ascorbic acid?), to avoid post-operative recto-urogenital leaks.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colonoscopy plays a key role in the prevention and diagnosis of colorectal cancer (CRC), and the quality of it influences interval cancer. However, we have little information on compliance with quality standards in Spain.

Aims & Methods: Knowing quality indicators fulfillment may lead to apply measures to improve the efficiency in the colonoscopy. Hence the aim of this study was to know the quality indicators of colonoscopies in a sample of centers in Spain. A total of 6912 colonoscopies performed between January and November 2016 were prospectively included in the QUALISCOPIA project, an observational, multicenter and prospective study, developed in 12 centers in Spain. Patients between the ages of 40 and 80 years with indication for colonoscopy due to digestive symptoms, post-polypectomy surveillance, positive fecal immunochemical test (FIT+) and direct colonoscopy of colorectal cancer were included. The exclusion criteria were patients with diagnosis of colorectal cancer or adenomas in the last 6 months, incomplete excision or post-excised adenomas, treatment of colon stenosis, abdominal or rectal mass, inflammatory bowel disease and hereditary cancer syndrome.

Results: 51.9% (3586) patients were men and the median age was 61 years. Regarding the colonoscopies indications, thirty one percent (2971) of the patients presented gastrointestinal symptoms, 20.3% (1398) were admitted due to post-polypectomy surveillance, 28.3% (1949) presented positive fecal immunochemical test (FIT+), and 8.4% (578) due to direct screening. 70.4% (4869) of the explorations were performed in the morning shift. Respecting the bowel preparation, 48.4% used polyethylenglycol (PEG) 2L, 27.5% (1902) used sodium picosulphate/magnesium citrate, and 19.5% (1347) PEG4L. Digital chromoendoscopy was used for lesion seen in 4.7% (322) and panchrome in 0.1% (7). CO2 was used in 42% (2906) of the procedures. Colon cleansing was good-excellent in 86.1% (5512) and cecal intubation was performed in 95.8% (6590). 92.8% (6260) of the colonoscopies were performed under sedation, and the gastroenterologist was responsible for it in 80.1% (4995). The most used drugs for sedation were propofol in 63.9% (4417), midazolam in 44.1% (3045) and fentanyl in 31.1% (2149). Olympus was used in 69.2% (4732), Pentax in 21.8% (1492) and Fuji in 8.3% (569). Polyps were found in 50.9% (3515) of the procedures, and CRC was found in 4.1% (281). The total number of adenomas was 6249, and the total number of traditional and sessile serrated adenomas was 224. The adenomas detection rate (ADR) was 39.6%. The sessile and traditional serrated polyps detection rate (SDR) was 2.2%. And for advanced adenomas, detection rate (AADR) was 21.5% and for colorectal cancer 4.1%.

Conclusion: In Spain, there is good compliance with the quality indicators of colonoscopies.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0221 ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) IN THE COLORECTUM: FEASIBILITY IN AN EUROPEAN SINGLE CENTER CASE SERIES

R.M. Lackermeier¹, M. Meiborg¹, S. Schürle¹, C. Aubele¹, E. Tsegai-Eh¹, M. Edelmann¹, H. Kitterer¹, S. Leykauf¹, M. Hack², G. Kleber³

¹1st Department Of Medicine, Ostalb-Klinikum, Aalen/Germany

Contact E-mail Address: regina.lackermeier@uni-ulm.de

Introduction: While ESD in the upper GI tract is well established, it is as yet not standard of care in the colorectum. Contrary to Japan, western experience is limited and only relatively few case series have been published in Europe (e.g. Dessain et al. 2017).

Aims & Methods: For the period 5/2012–1/2017 the first fifty-one consecutive patients with colorectal (n = 18/17/16 rectum/left/right hemicolon) neoplasias (diameter 27 ± 13 mm, x ± SD; low grade dysplasia: n = 8/9/14 serrated/tubular/villous; high grade dysplasia: n = 12; malignant: n = 4) or hyperplastic polyps (n = 4) receiving ESD according to a predefined protocol (hook or dual knife, Olympus Medical Systems, Hamburg, Germany; procedure time 162 ± 63 min; x ± SD) are reported. ESD was performed by a single investigator (G.K.) trained previously by Japanese experts and in experimental models. ESD was complete (n = 22) or complemented by snare resection of a remaining stalk (n = 25) or cancelled (n = 4) with subsequent alternative treatment.

Results: According to endoscopic or pathologic judgment resection was complete in 40 or 30 patients, respectively. During hospital follow-up (2–14; median 4 days) abdominal pain, fever or local peritonitis were noted in 6 and bleeding in 3 patients (hypotension in 1) with antibiotics/transfusions/surgery needed in 4/0/0 patients. There was no hospital mortality. Among those with histologic incomplete resection (n = 21), surgery or FTR was performed in 5 patients, endoscopic follow-up is pending in 7 and revealed no residual neoplasia in 9. Among those with cancelled ESD or endoscopic incomplete resection (n = 11), surgery or FTR was performed in 5, endoscopic follow-up is pending in 2 and revealed no residual neoplasia in 4.

Conclusion: After appropriate training, even in low volume European case series ESD in the colorectum appears to be safe and partially effective.

Introduction: Colorectal cancer is the second leading cause of cancer death in US [1]. Its incidence can be mitigated by detecting its precursor lesion, the polyp, before it develops into cancer. Colonoscopy is still the gold standard for colon screening though some polyps are still missed. This can be explained by technical limitations of colonoscopes (camera orientation, field of view, etc.), but also by human factors (such as experience). Several computational systems, being the majority still-frame-based, have been proposed to assist clinicians in this task [2] but, to the best of our knowledge, none of them is being used in the exploration room due to not meeting real-time constraints (40 ms max per image). In this abstract, we present a methodology to adapt and evaluate a real-time still frame-based method [3] to video analysis.

Aims & Methods: The still frame detection system used as reference [3] was based on an active learning method. We base the adaptation to video analysis on two aspects: (i) influence of the type of information used for polyp candidate characterisation, and (ii) introduction of spatio-temporal coherence. The former studies whether the combination of different types of information may lead to improve system performance whereas the latter fosters stability in the position of the detector output between consecutive frames. The learning stage of the method used a public still-frame database (CVC-Clinic, 612 images) whereas the testing was done on a new set of 18 sequences with a polyp (10,294 images) collected with an Olympus colonoscope CIF-H190 at Hospital Clínic, Barcelona. Performance was evaluated using two groups of metrics: (i) standard image/video metrics: Precision, Recall and F1-Score (ii) ad-hoc clinical metrics (assessing the clinical usability). Among the latter group we define: a) Polyp Detection Rate (PDR), checking if a method is able to detect polyp at least in 10% of the sequence, b) Mean Processing Time per frame (MPT), c) Mean Number of False Alarms per frame (MNFP), number of false alarms that can disturb the physician and d) Reaction Time (RT), representing the delay between first appearance of a polyp in the sequence and the first correct detection provided by the method.

Results: Table 1 shows the influence of local features on the overall performance and how the combination of both types of features can lead to an overall improvement in Recall and RT, which we interpret as local descriptors complementing each other.

Method	PDR	MPT	MNFP	Prec	Rec	F1	RT
Texture (Local Binary Patterns [3])	100%	162 ms	0.7	29.88%	34.96%	32.22%	45.9 [1.8 sec]
Shape (Haar features [5])	100%	21 ms	0.6	39.14%	42.56%	40.78%	27.3 [1.1 sec]
Combination	100%	185 ms	1.0	30.72%	51.00%	38.34%	17.4 [0.7 sec]

Conclusion: Work presented in this abstract shows how a real-time still-frame-based polyp detection method can be successfully adapted to video analysis. Clinical usability metrics along with a new fully annotated video database were introduced to completely assess method performance. Results show methodology potential regarding clinical deployment as it detects all different polyps with a small RT. Results show that the sole use of shape features allows to meet real-time constraints but that a combination with a computationally efficient texture descriptor might improve frame-based performance.

Introduction: The use of Narrow Band Imaging (NBI) technology for in vivo histological prediction of colorectal polyps presents high accuracy in Referral Centers, particularly for diminutive polyps, which could be managed by the “resect and discard” strategy and, for sigmoid and rectum polyps, the “diagnose and disregard” strategy. However, the applicability of this practice in Community Hospitals still needs to be determined.

Aims & Methods: We aimed to determine the accuracy of NBI in predicting histology, according to NICE and WASP classifications, in a Center without previous NBI experience. This was a prospective study including patients submitted to colonoscopy between June 2016 and July 2017. Polyps characteristics: location, size, morphology (Paris Classification), NICE/WASP classification (hyperplastic, sessile serrated, adenoma, invasive carcinoma) and degree of confidence (low: <90% vs. high ≥ 90%). Comparison between NBI classification and histology SPSS 23.

Results: 163 polyps included (71 patients); mean polyp dimension of 6.1 mm (61.3% ≤ 5 mm); 91.4% sessile polyps; 62.6% on the left colon. Polyps classification according to NICE/WASP vs. histology: hyperplastic 49.7vs 42.9%; sessile serrated polyps 4.9vs 9.8%; adenoma 44.2 vs. 43.6%; carcinoma 1.2 vs. 0%; inflammatory reaction on histology – 3.7%. Adenoma diagnosis using NICE/WASP classification presents an accuracy, sensitivity, specificity, positive predictive value and negative predictive value of 80.9%, 78.1%, 84.2%, 85% and 77.1%, respectively. For left polyps ≤ 5 mm (n = 61) the accuracy and negative predictive value were of 81.2% and 82.3%, respectively, with 79.4% high confidence classifications. Multivariate analysis showed that high confidence prediction and ≥ 3 polyps/exam had a significant association with correct NBI classification (p < 0.05).

Conclusion: NBI utilization by inexperienced endoscopists presented moderate acuity in histological prediction. Despite promising results, acuity and confidence levels were lower than the thresholds recommended in guidelines (≥ 90%). These results justify implementing additional training and monitoring.

Introduction: Cold forceps polypectomy (CFP) is commonly used to remove diminutive colorectal polyps (≤ 5 mm). In addition, jumbo biopsy forceps are superior to standard forceps for removing colorectal polyps. However, problems remain for CFP with regard to residual adenomatous tissue on histological evaluation after a complete endoscopic cold forceps polyp resection.

Aims & Methods: The aim of this study was to evaluate the efficacy and safety of jumbo forceps biopsy using narrow-band imaging endoscopy in patients with diminutive polyps. In addition, we evaluated the factors related to one-bite resection. This is a multicenter, prospective, single-arm observational study conducted at 11 institutes of the National Hospital Organization between January 2015 and September 2016. Patients aged 20 to 75 years with diminutive polyps were enrolled in this study. When lesions were found, we used magnification endoscopy with narrow-band imaging (NBI) in all the cases. CFP was performed until no polyps were visible under magnified endoscopy with NBI. We evaluated the patients' characteristics, clinicopathological features of the polyps, adverse events, and complete resection rates of the lesions. Additionally, we studied the factors of one-bite resection using Cox's regression model.

Results: A total of 503 patients were prospectively assessed, and 1015 polyps were resected. The median age of the patients was 65 years. The patients comprised 329 men (65%) and 174 women (35%). The polyp morphologies were 0-Is lesions in 886 cases (87.2%), 0-IIa lesions in 65 (6.4%), 0-Isp lesions in 63 (6.2%), and 0-Ip lesion in 1 (0.1%). Polyps were most often resected in the ascending colon (289 lesions) or transverse colon (262 lesions). Of all the polyps, 88% (896 lesions) were adenomas, 10% (100 lesions) were hyperplastic, and 0.3% were adenocarcinomas. The mean procedure and treatment times were 26.5 and 20.4 min, respectively. The complete resection rate was 99.3%. The rate of one-bite polypectomy was 71.8%, which included rates of 100%, 91.5%, 81.8%, 56.9%, and 40.5% for lesions 1, 2, 3, 4, and 5 mm in diameter, respectively. Delayed bleeding that required endoscopic hemostasis occurred in only one case, but no other adverse events occurred. The most important factor related to one-bite polypectomy was polyp size (≤ 3 mm; OR: 5.58), followed by macroscopic type of polyps (non-IIa; OR: 1.95).

Conclusion: In this large-scale multicenter prospective study, 99.3% of all diminutive polyps were completely resected by using jumbo forceps biopsy and magnified endoscopy with NBI. In addition, we were able to do one-bite polypectomy for more smaller polyps (≤ 3 mm). Jumbo forceps biopsy appears to be adequate for resecting diminutive polyps if no residual tissue is visible by using magnified endoscopy with NBI.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0225 PERIOPERATIVE MANAGEMENT OF ORAL ANTICOAGULANTS WITHOUT HEPARIN BRIDGING THERAPY FOR PATIENTS UNDERGOING ENDOSCOPIC SURGERY: A PILOT STUDY

S. Ono¹, M. Kato², M. Kato³, K. Matsuda³, M. Tsuda³, S. Abiko⁴, S. Miyamoto³, K. Yamamoto³, T. Kudo³, Y. Shimizu¹, N. Sakamoto³

Introduction: Heparin bridging therapy (HBT) is recommended for patients administered anticoagulants who have a high thrombotic risk and who undergo a high bleeding-risk procedure such as endoscopic submucosal dissection (ESD) or endoscopic mucosal resection (EMR)^{1, 2)}. However, HBT is actually related to a high frequency of delayed bleeding^{3, 4)}.

Aims & Methods: Our aim is to analyze bleeding and coagulation markers in the management of anticoagulants without HBT during the perioperative periods of ESD and EMR. Patients who underwent ESD or EMR and received warfarin or a direct oral anticoagulant (DOAC) during the period from January 2013 to March 2017 were analyzed. Generally, administration of warfarin was continued within the therapeutic range of the international normalized ratio (INR) during the perioperative periods and DOACs were not administered on the day of the

procedure. HBT was conducted only for patients who had a hypercoagulable condition. The rates of delayed bleeding in patients who received warfarin and patients who received DOACs were compared, and coagulation molecular markers including soluble fibrin (SF), thrombin-antithrombin complex (TAT), prothrombin fragment 1 + 2 (F1 + 2) and D-dimer (DD) were compared before and after the procedures in 13 patients who received DOACs.

Results: Among the patients who underwent ESD or EMR during the study period, 51 patients received warfarin and 49 received DOACs. Delayed bleeding occurred in 6 patients (11.8%) in the warfarin group and in 8 patients (16.3%) in the DOAC group, and there was no significant difference. Only one patient with continued administration of antiplatelet agents had delayed bleeding among the patients in whom administration of warfarin was continued within the therapeutic range (5.3%, 1/19). Six (15%) of the 40 patients in the DOAC group for whom the DOAC was not administered only on the day of the procedure had delayed bleeding, and 23.8% (5/21) of the patients who received HBT had delayed bleeding. No thrombotic events occurred from one month after the procedures. One patient in whom the DOAC was not administered on the day of the procedure became positive for TAT, F1 + 2 and DD after EMR and had a hypercoagulable condition.

Conclusion: For perioperative management of anticoagulants in patients undergoing ESD or EMR, continuous use of warfarin within the therapeutic range is better than HBT. However, DOACs should be carefully managed with attention to hemorrhagic risk and coagulable condition.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal cancers are generally recognized to develop from "polyps". This "adenoma-carcinoma sequence" theory has been in the mainstream of development of colorectal cancers. But recently the existence of many depressed-type cancers has been revealed, which are considered to emerge directly from normal epithelium, not through the adenomatous stage. This theory is called "de novo" pathway. Now, it is possible to presume the histology of colorectal lesions using magnifying endoscopy (pit pattern classification) and endocytoscopy (EC classification). We can observe not only the structural atypia but also the cellular atypia in living colorectal lesions.

Aims & Methods: The aim is to clarify the endoscopic characteristics of depressed-type colorectal neoplasms, demonstrating the validity of pit pattern diagnosis and EC classification. A total of 29,030 colorectal neoplasms excluding advanced cancers were resected endoscopically or surgically in our unit from April 2001 to December 2016. Of these, 17,761 lesions were low-grade dysplasia, 2922 were high-grade dysplasia and 1077 were submucosally invasive (T1) carcinomas. According to the developmental morphology classification, they were divided into 3 types: depressed, flat and protruded-type. We investigated the rate of T1 carcinomas and the characteristics of depressed-type neoplasms concerning pit pattern and EC classification.

Results: The rate of T1 carcinomas in depressed-type lesions reached to 62.0%, meanwhile that in flat-type and protruded-type lesions was 3.3% and 2.8%, respectively. Within less than 5 mm in diameter, that was 10.6%, 0% and 0.04%, respectively. Most (93.0% and 93.1%) of the flat-type and protruded-type lesions showed type I/III or IV pit pattern corresponding to adenomas, whereas 91.3% of the depressed-type lesions were characterized by type I/II, VI or VN pit patterns correspondings to carcinomas. As for endocytoscopy, most of the flat- and protruded-type lesions showed EC2 corresponding to adenomas. In contrast, the depressed-type lesions were observed as EC3a (38.9%) and EC3b (58.0%) corresponding to invasive carcinomas.

Conclusion: This study revealed the diagnostic characteristics of depressed-type lesions. They show typically type I/II, VI or VN pit patterns in magnifying

endoscopy and type EC3a or EC3b in endocytoscopy. These lesions tend to invade the submucosal layer even when they are small. Therefore, it is important to consider deeply and examine the developmental morphology of colorectal neoplasms.

Introduction: It remains unknown if colonic lesions detection rates as quality indicators of the colonoscopy, behave in the same way in relation to colonoscopy indication.

Aims & Methods: The aim of this study was to evaluate the adenoma detection rate (ADR), serrated polyp detection rate (SDR), advanced adenoma detection rate (AADR) and colorectal cancer detection rate (CRCDR) depending on the colonoscopy indication. A total of 6912 colonoscopies have been prospectively included in the QUALISCOPIA project, an observational, multicenter and prospective study, developed in 12 centers in Spain. The ADR, SDR, AADR and CRCDR have been calculated. These data were analysed according to the colonoscopy indication adjusted by sex, age, cecal intubation, adequate cleansing (Boston scale score of 2–3 in all segments) and sedation use.

Results: The results can be seen in table 1. In colonoscopies performed due to positive fecal immunochemical test (FIT+), the ADR was 54.0% ($p < 0.001$, aOR 3.0, 95%CI 2.6–3.4). In those performed because of post-polypectomy surveillance, was 49.3% ($p < 0.001$, aOR 2.2, 95%CI 1.9–2.5), and those due to direct screening, the ADR was 31.6% ($p < 0.005$, aOR 1.4, 95%CI 1.1–1.7) compared to 28% in patients with gastrointestinal symptoms. Regarding the serrated polyps, in procedures performed due to FIT+, the SDR was 1.9% ($p = 0.094$, aOR 1.5, 95%CI 0.9–2.5), 4.2% in surveillance colonoscopies ($p < 0.001$, aOR 3.4, 95%CI 2.2–5.3), and 3.3% in direct screening ($p < 0.001$, aOR 2.8, 95%CI 1.6–5.0), compared to 1.2% of patients with digestive symptoms. Moreover, the AADR in colonoscopies performed due to FIT+ was 36.8% ($p < 0.001$, aOR 3.9, 95%CI 3.3–4.6), compared to 23.1% in surveillance colonoscopies ($p < 0.001$, aOR 1.8, 95%CI 1.5–2.2), and 14.9% in direct screening ($p = 0.023$, aOR 1.3, 95%CI 1.1–1.8). However, the SDR was 12.8% in patients with digestive symptoms. Finally, the CRCDR was 5.8% in patients with gastrointestinal symptoms ($p < 0.001$, aOR 11.6, 95%CI 4.7–28.7), 4.8% in those with FIT+ ($p < 0.001$, aOR 13.4, 95%CI 5.4–33.2), and 1.8% in direct screening ($p = 0.005$, aOR 5.1, 95%CI 1.6–15.6), compared to 0.5% in post-polypectomy surveillance.

TABLE 1: DETECTION RATES BY INDICATION

ADR	% (n)	OR (95%CI)	p-value ¹	aOR ² (95% CI)	p-value ¹
Post-polypectomy surveillance	49.3 (629/1275)	2.5 (2.2–2.9)	<0.001	2.2 (1.9–2.5)	<0.001
FIT+	54.0 (928/1718)	3.0 (2.7–3.4)	<0.001	3.0 (2.6–3.4)	0.001
Direct screening	31.6 (174/550)	1.2 (1.0–1.5)	0.085	1.4 (1.1–1.7)	0.005
Digestive symptoms	28.0 (793/2832)	1.0		1.0	
SDR					
Post-polypectomy surveillance	4.2 (53/1275)	3.5 (2.6–5.3)	<0.001	3.4 (2.2–5.3)	<0.001
FIT+	1.9 (32/1718)	1.5 (0.9–2.5)	0.091	1.5 (0.9–2.5)	0.094
Direct screening	3.3 (18/550)	2.7 (1.5–4.8)	<0.001	2.8 (1.6–5.0)	0.001
Digestive symptoms	1.2 (35/2832)	1.0		1.0	
AAADR					
Post-polypectomy surveillance	23.1 (294/1275)	2.0 (1.7–2.4)	<0.001	1.8 (1.5–2.2)	<0.001
FIT+	36.8 (632/1718)	4.0 (3.4–4.6)	<0.001	3.9 (3.3–4.6)	<0.001
Direct screening	14.9 (82/550)	1.2 (0.9–1.5)	0.177	1.3 (1.1–1.8)	0.023
Digestive symptoms	12.8 (362/2832)	1.0		1.0	
CRCDR					
Digestive symptoms	5.8 (165/2832)	13.1 (5.8–29.6)	<0.001	11.6 (4.7–28.7)	<0.001

(continued)

TABLE 1 Continued

ADR	% (n)	OR (95%CI)	p-value ¹	aOR ² (95% CI)	p-value ¹
FIT+	4.8 (83/1718)	10.7 (4.7–24.7)	0.001	13.4 (5.4–33.2)	<0.001
Direct screening	1.8 (10/550)	3.9 (1.4–10.8)	0.009	5.1 (1.6–15.6)	0.005
Post-polypectomy surveillance	0.5 (6/1275)	1.0		1.0	

¹p-value: significance level; ²aOR: adjusted Odds Ratio

Conclusion: The indication of colonoscopy has a very important influence on the different quality indicators such as detection rates of lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0228 THERAPEUTIC ERCP USING A SHORT SINGLE-BALLOON ENTEROSCOPE IN PATIENTS WITH SURGICALLY ALTERED ANATOMY

K. Masu, K. Ito, T. Ohira, S. Koshita, Y. Kanno, T. Ogawa
Gastroenterology, Sendai City Medical Center, Sendai/Japan

Contact E-mail Address: k-masu@openhp.or.jp

Introduction: Recently, we have performed therapeutic ERCP using a newly developed short single-balloon enteroscope (sSBE) (working length of 152 cm, working channel of 3.2 mm) in patients with surgically altered anatomy.

Aims & Methods: We aimed to evaluate the usefulness and safety of sSBE for therapeutic ERCP in patients with surgically altered anatomy. One hundred four patients with surgically altered anatomy who underwent therapeutic ERCP using a sSBE between August 2011 and February 2017 were included in this study. Patient anatomy consisted of Roux-en-Y anastomosis (R-Y) (n = 82), hepaticojejunostomy (HJ) (n = 11), subtotal stomach-preserving pancreaticoduodenectomy (SSPPD) (n = 11). The indications for ERCP were choledocholithiasis (68: R-Y cases), malignant biliary strictures (20: R-Y 14, HJ 7, SSPPD 4), intrahepatic stones (9: HJ 7, SSPPD 2), and anastomotic stenosis (7: SSPPD 5, HJ 2). The success rate of reaching the target site, the technical success rate, and the adverse event rate were retrospectively evaluated.

Results: The success rate of reaching the target site was 91% (95/104), and the overall technical success rate was 79% (80/104). Biliary interventions included 64 stone extraction (R-Y 58, HJ 5, SSPPD 1), and 12 metallic biliary stent placement (R-Y 7, HJ 1, SSPPD 4). Of 17 unsuccessful cases, nine with choledocholithiasis underwent surgical operation (R-Y 6, HJ 2, SSPPD 1) and EUS-guided drainage was successfully performed in six with anastomotic stenosis (SSPPD 3, R-Y 2, HJ 1). The remaining two with malignant bile duct stricture (R-Y) underwent PTCD. The adverse event rate was 10% (10: cholangitis 4, mild pancreatitis 3, perforation 2, aspiration pneumonitis 1). The two perforation cases required urgent operation but remaining eight cases were managed conservatively.

Conclusion: Therapeutic ERCP using a sSBE in patients with surgically altered anatomy was considered to be safe and effective.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0229 USEFULNESS OF SPYGLASS PERORAL CHOLANGIOSCOPY FOR THE DIAGNOSIS AND TREATMENT OF BILE-DUCT DISORDERS: EXPERIENCE FROM A LARGE-VOLUME CENTER

X. Tang, D. Zhang, C. Xu, X. Zhang
Department Of Gastroenterology, Hangzhou First People's Hospital, Nanjing Medical University, Hangzhou/China

Contact E-mail Address: solitude5834@hotmail.com

Introduction: SpyGlass single-operator peroral cholangioscopy (SOC) has been designed to overcome some limitations of conventional cholangioscopy, and demonstrated improved diagnostic and therapeutic abilities of complex pancreaticobiliary disease.

Aims & Methods: To assess the clinical efficacy and safety of the SpyGlass system for diagnosis and treatment of bile-duct disorders in a large-volume center. All patients undergoing SOC in our department between January 2013 and May 2016 were retrospectively identified from a prospectively collected database. The baseline characteristics, including age, gender, presenting symptoms, indication and others were recorded. Procedure-related parameters of SOC for detecting malignant lesions and the stone clearance rate were calculated.

Results: During the study period, a total of 68 patients underwent 78 SOC procedures: 26 (38.2%) with indeterminate strictures, 7 (10.3%) with indeterminate filling defects, 31 (45.6%) with difficult bile stones, and 4 (5.9%) with cystic lesions. SpyGlass was technically successful in 63 of 68 patients (92.6%). The mean total SpyGlass procedure time was 12 min. In patients with indeterminate biliary strictures, 6 cases of definite diagnosis (stones, varices) was made by SOC evaluation. Twenty patients underwent SOC-directed biopsy, and samples were adequate for histological diagnosis in 17 patients (85%). The preliminary accuracy of SpyGlass-directed biopsy to diagnose malignancy were 76%. For the patients with biliary stone, SpyGlass-guided holmium laser lithotripsy or electrohydraulic lithotripsy succeeded in 15 of 15 patients (100%). There were 6 procedure-related adverse events occurred (8.8%), and resolved uneventfully.

Conclusion: SpyGlass cholangioscopy system can be safe and useful for definite diagnosis with high accuracy in patients with indeterminate biliary lesions, and successfully guided stone therapy. Further prospective multicenter trials of the system are warranted in the future.

P0230 DIAGNOSTIC AND THERAPEUTIC ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) IN INFANT AND CHILDREN: A LARGE RETROSPECTIVE STUDY

X. Tang, D. Zhang, C. Xu, X. Zhang
Department Of Gastroenterology, Hangzhou First People's Hospital, Nanjing Medical University, Hangzhou/China

Contact E-mail Address: solitude5834@hotmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is increasingly being used in the diagnosis and management of biliary and pancreatic disorders in pediatric patients.

Aims & Methods: To evaluate the indications, success rate, diagnostic and therapeutic yields, and complications of ERCP performed in Chinese children. A retrospective study was conducted in an academic, tertiary care, medical center, in which all children undergoing ERCP between 2005 to 2016 were identified from endoscopy databases. Data on demographics, indication, ERCP findings, ERCP interventions performed and complications were collected.

Results: A total of 288 children (mean age 9.3 years, range 1 month to 18 years) underwent 312 ERCP procedures. General anesthesia and sedation were performed in 48% and 52% of procedures, respectively. Indications for ERCP were common bile duct obstructions (n=153, 54.2%), recurrent or chronic pancreatitis (n=64, 22.2%) and others. ERCP was successfully performed in 267 of 288 cases (92.7%). The most common ERCP findings was choledocholithiasis (n=146, 50.7%). A therapeutic intervention was performed in 70.8% patients (n=204), including sphincterotomy (n=97), stone extraction (n=55), and stent insertion (n=52). Complications occurred for only 13 patients (4.5%), including 12 cases of post-ERCP pancreatitis and 1 case of bleeding. No severe pancreatitis, or perforation was noted.

Conclusion: Diagnostic and therapeutic ERCP is effective and safe in the children population, with the high rates of technical success and low rates of complication.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0231 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH SURGICALLY ALTERED GASTROINTESTINAL ANATOMY: 11 YEARS' EXPERIENCE AT A LARGE CENTER IN CHINA

X. Tang, D. Zhang, C. Xu, X. Zhang
Department Of Gastroenterology, Hangzhou First People's Hospital, Nanjing Medical University, Hangzhou/China

Contact E-mail Address: solitude5834@hotmail.com

Introduction: It is technically challenging to perform endoscopic retrograde cholangiopancreatography (ERCP) in patients with surgically altered gastrointestinal anatomy.

Aims & Methods: The aims of this study were to investigate the yield, efficacy and safety of ERCP in surgically altered anatomy patients at a single tertiary-care center with a high volume of endoscopy. All patients with altered surgical anatomy who underwent ERCP at our center from September 2005 to July 2016 were retrospectively reviewed. Data regarding to patients baseline characteristics, procedure-related details and adverse events was recorded and analyzed.

Results: A total of 304 procedures were performed in 236 patients, including 108 cases (45.8%) with Billroth II gastrectomy, 45 cases (19.1%) with Billroth I gastrectomy, 52 cases (22.0%) with hepaticoduodenostomy, 18 cases (7.6%) with esophagogastrotomy and 13 cases (5.5%) with Roux-en-Y reconstruction. The most common indication was cholelithiasis (58.1%, 137/236). The overall technique success rate of reaching the papilla was 90.8% (276/304), including 91.3% (126/138) for Billroth II gastrectomy, 94.5% (52/55) for Billroth I gastrectomy, 89.9% (71/79) for hepaticoduodenostomy, 100% (19/19) for esophagogastrotomy and 61.5% (8/13) for Roux-en-Y reconstruction. The clinical success rate was 88.2% (268/304). Therapeutic interventions were performed in 194 patients successfully, including stone extraction (n=146), sphincterotomy (n=44), stent placement (n=57), papillary balloon dilatation (n=27) and mechanical lithotripsy (n=25). The adverse event rate was 7.2% (17/236). Mild pancreatitis occurred in 3% (7/236) of cases, perforation occurred in 2.5% (6/236) of cases, and asymptomatic hyperamylasemia occurred in 1.7% (4/236) of cases.

Conclusion: ERCP can be performed in surgically altered anatomy patients with a high success rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0232 IMPACT OF HIGH DEFINITION, NEAR FOCUS-IMAGING AND SYDNEY RECURRENCE TOOL (SERT) AFTER COLORECTAL ENDOSCOPIC MUCOSAL RESECTION: A PROPENSITY SCORE ANALYSIS

Contact E-mail Address: danielaguerrerotres@gmail.com

Introduction: Risk factors for colorectal adenoma recurrence after Endoscopic Mucosal Resection (EMR) such as size ≥ 20 mm, high grade dysplasia, use of argon plasma coagulation (APC) and intraprocedural bleeding (IPB), have been well documented in literature. However, it is unknown if the latest generation dual-focus (DF) colonoscopes ability to visualize subtle residual neoplasia, has improved the rate of complete EMR.

Aims & Methods: We aimed to assess the efficacy of the newer 190 colonoscopes versus standard 180 colonoscopes for complete resection of lateral spreading lesions (LSL) ≥ 20 mm. A secondary aim was to identify risk factors for recurrence and the applicability of the Sydney EMR recurrence tool (SERT score) in our cohort.

This was a single-center retrospective study of patients who underwent EMR with 180 or 190 colonoscope series from 2010 to 2016. Lesions ≥ 20 mm resected in a piecemeal fashion and patients with a surveillance colonoscopy after index EMR were included. A propensity score approach with inverse probability weighting (IPW) was used to control potential confounders affecting adenoma recurrence. Each lesion was graded according to SERT score and associations with recurrence were analyzed.

Results: 291 patients met inclusion criteria for the study. The rate of adenoma recurrence at the EMR site was 23.3% for the 180 colonoscope cases and 25.2% for the 190 colonoscope cases. Odds ratio (OR) for recurrence with 190 series was 1.06 (p=0.85). Adenoma size (p=0.002) and concomitant need for supplemental APC (p<0.001) were risk factors for recurrence. SERT > 0 lesions had a higher risk of recurrence during follow-up (OR 1.71; 95% CI 1.00-2.92; p=0.048) and a higher cumulative incidence for recurrence. Conversely, SERT=0 lesions reached a plateau for recurrence after 12 and 18 months in Kaplan Meier curves. Odds ratio estimates for 190 colonoscope effect on adenoma recurrence at different stages of adjustment.

Model	Odds Ratio	Lower 95% CI	Upper 95% CI	P-value
Unadjusted all-subject (en-bloc and piecemeal)	1.58	0.94	2.65	0.08
Unadjusted-piecemeal resection only	1.11	0.64	1.92	0.71
IPW adjustment-piecemeal resection	1.06	0.60	1.86	0.85

Cumulative incidence of recurrence at SC1 by SERT score in 291 lesions.

Months	N-events [SERT = 0]	Event rate,% [SERT = 0]	N-events [SERT > 0]	Event rate,% [SERT > 0]
6	26	16.4%	21	21.9%
12	34	23.3%	32	37.6%
18	34	23.3%	35	43.6%
24	35	25.4%	36	47.1%
36	36	27.5%	37	51.5%

CI: Confidence intervals; IPW: Inverse probability weighting; SERT: Sydney EMR recurrence tool; SC1: First surveillance colonoscopy.

Conclusion: In this study, recurrence was significantly associated with adenoma size and complementary use of APC for EMR. The use of the latest generation DF colonoscopes (CF-HQ190L/I) did not measurably affect adenoma recurrence at the EMR site during first surveillance colonoscopy (SC1). Lesions with SERT > 0 were associated with higher recurrence rates. In our cohort, SERT=0 lesions that remain negative for recurrence at 18 months, may return to routine surveillance.

Introduction: Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) is a potentially serious complication, and some risk factors for PEP have been reported in general ERCP in previous studies. Emergency ERCP is different from normal state ERCP, and the risk factors for PEP in emergency ERCP are not clear.

Aims & Methods: This study aimed to identify the incidence and risk factors for PEP in emergency ERCP. We performed a prospective study of 2078 cases undergoing diagnostic and therapeutic ERCP at five Japanese institutions between April 2015 and May 2016. Exclusion criteria were active pancreatitis, choledochojunostomy, inability to approach a papilla, and inspection aimed at only the pancreatic duct (PD). Emergency ERCP indicated unscheduled inspections performed within and outside duty hours in this study. PEP was considered when two of the following three conditions were met: (1) serum amylase level more than three times the upper limit of the normal range in each institution, (2) continuous abdominal pain for over 24 hours, and (3) presence of pancreatitis findings on computed tomography. The first study involved comparison of the incidence of PEP and its characteristics between emergency and elective ERCP. The second study involved determining the predictive risk factors for PEP in emergency ERCP using univariate and multivariate analyses.

Results: A total of 1677 cases were enrolled in this study. <Study 1> PEP developed in 20 of 429 cases (4.7%) from the emergency group and in 101 of 1248 cases (8.1%) from the elective group. The incidence of PEP was significantly lower in the emergency group than in the elective group (odds ratio [OR]: 0.56, 95% confidence interval [CI]: 0.32–0.92, $P=0.017$). Endoscopic sphincterotomy, stone removal, papillary balloon dilatation, and intraductal ultrasound sonography were performed significantly more often in the elective group than in the emergency group ($P < 0.001$). Placement of a biliary stent was significantly more common in the emergency group than in the elective group. In addition, the procedure time was significantly longer ($P < 0.001$) and the number of endoscopists who had more than five years of experience was significantly higher ($P=0.04$) in the elective group than in the emergency group. <Study 2> Cases with no naïve papilla ($n=181$) were excluded from the analysis of risk factors for PEP because no PEP was observed in these cases. Only cases with naïve papilla ($n=248$) were analyzed. Univariate analysis showed that contrast injection into the PD (OR: 4.20, 95%CI: 1.64–10.80, $P=0.0028$), more than four cannulation attempts (OR: 2.85, 95%CI: 1.00–8.09, $P < 0.05$) increased and placement of a biliary stent (OR: 0.028, 95%CI: 0.11–0.88, $P=0.028$) decreased the risk of PEP in emergency ERCP. Multivariate analysis showed that contrast injection into the PD (OR: 4.51, 95%CI: 1.64–12.40, $P=0.0035$) increased the risk of PEP in emergency ERCP.

Conclusion: The incidence of PEP was lower in emergency ERCP than in elective ERCP, and it was largely unaffected by the endoscopist's experience and the procedure time. This may be associated with a tendency to avoid invasive procedures in emergency cases, and it is considered that only placement of a biliary stent contributes to a decrease in the development of PEP. Close attention should be paid for contrast injection into the PD, particularly when attempt of cannulation for naïve papilla are required.

P0234 WALLED-OFF NECROSIS (WON): OUTCOMES OF AN ALGORITHMIC APPROACH TO NECROSECTOMY

J.Y. Bang, U. Navaneethan, M. Hasan, R. Hawes, S. Varadarajulu

Center For Interventional Endoscopy, Florida Hospital, Orlando/United States of America/FL

Contact E-mail Address: jrbang213@gmail.com

Introduction: Endoscopic necrosectomy (EN) in walled-off necrosis (WON) is a labor intensive, high-risk, non-standardized technique that is associated with significant morbidity and mortality.

Aims & Methods: We aimed to compare the clinical outcomes of patients with WON treated by conventional EN versus an algorithmic approach that is tailored to the extent and location of WON.

This observational study included 45 consecutive patients with WON who had suboptimal treatment response to EUS-guided transluminal drainage and subsequently underwent necrosectomy. The conventional technique using a diagnostic or therapeutic gastroscope involved removal of necrotic debris using any 15–20mm polypectomy snare, 7.5mm rat tooth or tripod grasping forceps and retrieval nets. Normal saline was used for intra-procedural irrigation and lavage of the necrotic cavity. The algorithmic technique, using a cap-fitted therapeutic gastroscope, was tailored to the extent and location of the WON: While WON extending to the flanks and more proximate (<20cm) to the abdominal wall were treated by percutaneous necrosectomy, those in close proximity to the stomach and without extension to the flanks were treated by transluminal EN. Adherent debris were removed using 15–25mm round, braided-wire snares and non-adherent debris were removed using 15–30mm oval snares. A large 14.9mm diameter, rat tooth forceps were used for debridement when the necrotic debris were not amenable to snaring. The necrotic cavity was evacuated by sucking the debris within the gastroscope cap using snares and/or forceps. In order to avoid frothing that obscures

visibility, intra-procedural lavage of the necrotic cavity was performed using normal saline mixed with 120mg gentamicin and irrigation with hydrogen peroxide was reserved for sterilizing the cavity at the end of the procedure. The primary outcome measure was to compare the treatment success and number of reinterventions performed between the two groups. Treatment failure was defined as death from underlying disease or need for open surgical necrosectomy.

Results: Of the 45 WON patients, 23 were treated using conventional techniques and 22 using the algorithmic approach. Treatment success was significantly higher for patients treated using the algorithmic approach, 100 vs. 69.6%, $p=0.009$. Of the 7 patients who had treatment failure in the conventional technique cohort, 6 required open necrosectomy and 1 died of multi-organ failure. The median number of reinterventions required to achieve treatment success was significantly lower for the algorithmic approach, 1 (IQR = 1–1) vs. 2 (IQR = 1–2), $p=0.003$. Multivariable logistic regression analysis revealed that the algorithmic approach was the only variable associated with treatment success (OR = 60.4, $p=0.02$) when adjusted for patient demographics, lab parameters and disease/WON characteristics.

Conclusion: A structured, algorithmic approach to endoscopic necrosectomy results in successful treatment outcomes.

P0235 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN THE MANAGEMENT OF PANCREAS DIVISUM ASSOCIATED WITH RECURRENT ACUTE PANCREATITIS IN CHILDREN: EXPERIENCE FROM A SINGLE CENTER IN CHINA

G. Cui, J. Yang, X. Tang, J. Yang, X. Zhang

Gastroenterology And Hepatology, Hangzhou First People's Hospital, Hangzhou/China

Contact E-mail Address: zxf837@tom.com

Introduction: Pancreas divisum (PD) is the most common congenital anomaly of the pancreas. Most PD individuals are asymptomatic, but a few may present symptoms in the form of recurrent acute pancreatitis (RAP), chronic pancreatitis (CP) or pancreatic-type pain. It is imperative to treat PD associated with RAP as early as possible to prevent it from developing CP. Unfortunately, to date, most PD-related studies have been concentrated on adults. Researches of PD in children is rare.

Aims & Methods: To evaluate the safety and efficacy of endoscopic retrograde cholangiopancreatography (ERCP) for the treatment of pancreas divisum (PD) associated with recurrent acute pancreatitis (RAP) in children. We retrospectively analyzed patients of PD associated with RAP who were younger than 18 years old from January 2011 to December 2015 in our center. All the patients were diagnosed and treated with ERCP. Patients of complete PD associated with RAP underwent endoscopic minor sphincterotomy combined with dorsal duct stenting (ESCS). Patients of incomplete PD underwent bi-papilla endoscopic sphincterotomy combined with dorsal duct stenting (Bi-ESCS). ERCP-related data, complications and other relevant data were collected. Long time follow up was conducted after removal of the last dorsal duct stent, and then to observe children's recovery, as well as their weight, growth and intelligence.

Results: A total of 227 pediatric ERCPs were performed for 117 pediatric patients during this period. Of which 24 were PD cases. The endoscopic detection rate of PD was 20.5%. Of the 24 patients, 12 were PD associated with RAP, among which 10 were complete PD and 2 were incomplete PD. A total of 21 therapeutic ERCPs were performed for these cases. All procedures were successful with 100% (21/21) of cannulation rate of the minor papilla. The mean interval of changing pancreatic dorsal duct stent is 3 months (from 2 to 6 months). ERCP-related complications were mild with a rate of 9.5% (2/21). One was acute mild pancreatitis and the other was hyperamylasemia, both of which were managed conservatively. During follow up from 15 to 74 months (mean 33.9 months), all patients had pain relief with a relief rate of 100%, of which 10 were asymptomatic with no longer onset of acute pancreatitis. During follow-up, MRCP or CT scan showed no more dilation of dorsal ducts in all children and all presented normal in weight, growth and intelligence.

Conclusion: The techniques of ESCS and Bi-ESCS under ERCP are safe and effective methods to manage PD associated with RAP in pediatric patients. It seems very vital for such children to undergo endoscopic interventions as early as possible in order to avoid developing CP.

Introduction: Endoscopic biliary stenting is the treatment of choice in presence of malignant biliary obstruction (MBO), especially if palliative treatment. The role of endoscopic biliary sphincterotomy (EBS) before stent insertion is not clearly defined. The primary outcome of our meta-analysis was to assess the technical success of biliary (plastic or metal) stent insertion. Secondary outcomes included early complications within 30 days from ERCP and late complications which (from 30 days since ERCP).

Aims & Methods: We performed a literature search by using PubMed, SCOPUS, Google Scholar and the Cochrane Central Register of Clinical Trials (up to February 2017) to identify full-text studies evaluating the efficacy and safety of stent positioning, with and without EBS, in patients with MBO not suitable to surgery.

Results: 14 papers were assessed via full text for eligibility. 8 articles were excluded leaving 6 prospective studies (total of 711 patients). **Technical success:** The overall rate of biliary stent insertion was not significantly different: 384/392 patients (98%) in the no-EBS group versus 331/339 (97.6%) in the EBS arm (OR: 1.05; 95%CI: 0.42–2.63). **Early complications:** The overall early AEs developed in 43/392 (11%) of patients without EBS versus 68/339 (20.1%) of patients who received EBS, with a significantly difference (OR: 0.55; 95%CI: 0.33–0.92). Post-ERCP pancreatitis (PEP) was no significantly different in the two groups: 24/392 (6.1%) in no-EBS group versus 17/339 (5%) in EBS group (OR: 1.33; 95%CI: 0.68–2.59). The bleeding was significantly different in patients without EBS: 0/351 of patients in no-EBS group versus 15/298 (5%) in the EBS group (OR: 0.12; 95% CI: 0.03–0.45). The rate of duodenal perforation was not significantly different: 1/320 (0.3%) in no-EBS versus 4/260 (1.5%) in EBS (OR: 0.52; 95%CI: 0.09–2.88). Early cholangitis was significantly lower in patients who didn't receive EBS: 13/392 (3.3%) patients in no-EBS group vs 25/339 (7.4%) subjects in the EBS group (OR: 0.38; 95%CI: 0.17–0.83). Early mortality rate was 0% in both groups. **Late complications:** No significantly difference occurred in the overall late adverse events in the two groups: 50/251 patients (19.9%) in no-EBS group vs 38/201 subjects (18.9%) in the EBS group (OR: 0.93; 95%CI: 0.56–1.53). No significantly differences in stent occlusion (11.6% patients in no-EBS vs 11.4% in EBS - OR: 0.90; 95%CI: 0.4–2.0). No significantly differences in stent migration (4% in no-EBS group vs 5.5% - OR: 0.81; 95%CI: 0.29–2.25). No significantly differences in late cholangitis (2.6% in no EBS vs 0% in EBS group - OR: 1.83; 95%CI: 0.17–19.85). Long-term mortality was not significantly different (2.5% in no-EBS group and 2.9% in the EBS arm - OR: 1.18; 95%CI: 0.22–6.29).

Conclusion: Our meta-analysis showed no significantly differences in technical success and in PEP. In consideration of the significantly increase of the overall AEs in the EBS group, and in particularly of the bleeding and cholangitis, the EBS seems not to be recommended in patients not suitable to surgery undergone biliary stenting.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0237 ENDOSCOPIC PANCREATIC SPHINCTEROTOMY COMBINED WITH PANCREATIC DUCT STENT CAN EFFECTIVELY PREVENT RECURRENCE OF ACUTE RECURRENT PANCREATITIS CAUSED BY BILIARY MICROLITHIASIS — A SINGLE-CENTER STUDY FROM BEIJING, CHINA

Y. Huang, X. Yan, W. Liu, Y. Zhang, W. Yao, K. Li
Gastroenterology And Hepatology, Peking University Third Hospital, Beijing/China

Introduction: Acute recurrent pancreatitis (ARP) refers to a clinical entity characterized by episodes of acute pancreatitis which occurs on more than one occasion. Biliary microlithiasis plays an important role in the etiology of ARP. Bile sludge may induce acute pancreatitis as a consequence of transient papillary edema that can obstruct the pancreatic juice flow. The established treatments of microlithiasis with ARP include endoscopic sphincterotomy (EST) and empirical cholecystectomy. However, EST may increase the morbidity of biliary reflux or cholelithiasis recurrence. We hypothesized that endoscopic pancreatic sphincterotomy (EPS) can save the function of biliary sphincter and prevent the recurrence of ARP.

Aims & Methods: The aim of the study is to evaluate the effectiveness of EPS combined pancreatic duct stent for preventing ARP caused by biliary microlithiasis. 67 patients with ARP from 2005 to 2016 were diagnosed as biliary microlithiasis by endoscopic retrograde cholangiopancreatography (ERCP), bile microscopy or intraductal ultrasonography (IDUS). The whole was divided into two groups according to endoscopic therapy by EST or EPS with pancreatic stent. Rate of pancreatitis recurrence, early complication of post ERCP pancreatitis (PEP), and late complications (3 months after treatment) which included cholangitis, cholecystitis or cholelithiasis were compared between the two groups.

Results: (1) 38 and 29 patients were included in EST and EPS group, respectively. The mean age and follow-up duration of EST and EPS were 48.4±15.1yrs, 45.7±36.5months and 45.6±15.2yrs, 24.1±26.3months, respectively. (vary from 2months to 115months). (2) The mean episodes of ARP in EST and EPS group before endoscopic therapy were 3.9±3.3 times and 7.9±11.8 times. (3) Four patients in EST group and 6 patients in EPS group suffered PEP after the

endoscopic therapy ($P=0.418$). (4) 15 patients in EST group and 3 in EPS group suffered recurrent pancreatitis. The efficiency in EST group and EPS group is 68.4% and 89.6% respectively ($P=0.039$). (5) The incidence of late complications is 18.4% in EST group and 10.3% in EPS group ($P=0.567$).

Conclusion: EPS combined with pancreatic stent is a promising strategy to prevent recurrence of ARP due to biliary microlithiasis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Periapillary diverticulum (PAD) is frequently asymptomatic, usually encountered in patients undergoing endoscopic retrograde cholangiopancreatography(ERCP).

Aims & Methods: The aim of this study was to investigate the association of PAD with bile duct stones, biliary cannulation success and different types of PAD.

A total of 1164 ERCP procedures were performed in 833 patients in a single center by single operator from January 2012 to October 2016 after excluding post liver transplant, emergency procedures. Out of 1164 ERCP procedure 49 patients were encountered with PAD, they were compared with 635 controls without PAD in terms of age, sex, CBD cannulation success and complications of ERCP.

BASELINE CHARACTERISTICS AND COMPARISON OF FINDINGS

	PAD GROUP (n = 49)	NON-PAD GROUP P-VALUE (n = 635)	P-VALUE
Age(mean ± SD)	59.10 ± 15.16	52.74 ± 17.94	<0.05
Sex (male/female)	21/28	315/320	NOT SIGNIFICANT
Patients with bile duct stones (n = number of patients) %	35 (71.4%)	210 (33.1%)	<0.05
CBD cannulation (easy/difficult) n = number of patients %	35/14 (75.5%)	263/72 (82.3%)	<0.05
Complications(bleeding/pancreatitis/perforation)%	2%/2%/2%	0.1%/0.1%/0.1%	<0.05

Results: PAD identified in 49 (4.2%) cases, PAD type I (inside the diverticulum) was found in 7 pts (14.3%), Type II (at edge/brim) in 34 pts (69.4%), Type III (adjacent/near diverticulum) in 8 pts (16.3%). Patients with PAD had mean age 59.10 years (range 18 to 84 years) 17 were <50 yrs while 32 >50yrs, compared to controls mean age 52.74 yrs (range 12 to 95 yrs) 230 were <50 yrs while remaining more than 50yrs. P-value (<0.5). PAD predominantly occurred in females 28/49 cases.

Patients with PAD had increased prevalence of gallstone/biliary stone disease compared with controls, 71.4%vs 33.1 ($p < 0.01$) compared with controls. Easy cannulation of CBD without difficulty (PRECUT/Pancreatic cannulation/stenting) was more frequent in patients controls (82.3%) compared to PAD group (75.5%) $p < 0.05$. However, CBD clearance was same in both groups >90% (p value not significant) Incidence of complications in PAD group bleeding (2%), Pancreatitis (2%) and one small retroduodenal perforation (2%) all managed conservatively. In without PAD group bleeding 0.6%, pancreatitis 0.7% and no perforation.

Conclusion: PAD is seen with advanced age, predominantly in female and frequently associated with bile duct stones. In this case control study PAD did not appear to be a barrier for successful ERCP with acceptable complication rates.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0239 COMPARISON OF DIGITAL VS FIBEROPTIC CHOLANGIOSCOPY IN PATIENTS REQUIRING EVALUATION OF BILE DUCT DISEASE OR TREATMENT OF BILIARY STONES

I. D. Dimas, E. Vardas, M. Fragakaki, A. Mpitouli, E. Voudoukis, A. Theodoropoulou, G. Paspatis

Department Of Gastroenterology, Venizeleion General Hospital, Heraklion/Greece

Contact E-mail Address: gpaspatis@gmail.com

Introduction: Since the emergence of the fiberoptic single-operator cholangioscopy, the sensitivity for detecting bile duct lesions has been increased and the management of difficult stones is facilitated, establishing its superiority over standard endoscopic retrograde cholangio-pancreatography and often altering the clinical management. Digital cholangioscopes provide higher-resolution imaging of the pancreatobiliary tract compared with the fiberoptic instruments.

Aims & Methods: The aim of the present study was to assess the frequency of digital cholangioscopy (DC) to alter the diagnosis and clinical management of bile duct disease compared with fiberoptic cholangioscopy (FC). A retrospective review of 68 cases needing cholangioscopy, and which were performed in our department, was conducted. Patients enrolled exhibited stenosis of the biliary tract (67.6%), stones (20.6%), primary sclerosing cholangitis (PSC 4.4%) or other rare cause for cholangioscopy (e.g. stent migration, guidewire passage). All patients underwent endoscopic retrograde cholangiography (ERC) before cholangioscopy. Aim of cholangioscopy was to confirm ERC diagnosis, obtain adequate biopsy specimens for histological evaluation and remove biliary stones. From 5/2009 to 8/2015 all cholangioscopies were performed with the fiberoptic scope. From 9/2015 to 3/2017 all cholangioscopies were performed with the digital scope.

Results: 30 women and 38 men with a mean age of 61 years underwent cholangioscopy. Fiberoptic cholangioscope was used in 39 cases and digital cholangioscope was performed in 29 cases respectively. Cholangioscopy-guided biopsies for malignancy were obtained in 11 and 15 cases respectively. In only one case of FC (9.1%) biopsy confirmed the endoscopic diagnosis, in contrast with 10 cases of DC-guided biopsies (66.7%) confirming the diagnosis. In 13 patients who underwent DC (44.8%) the initial diagnosis and clinical management was altered after cholangioscopy (e.g. cancer diagnosis, successful EHL lithotripsy), in contrast with 11 cases of FC (28.2%). Moreover it was unanimously felt by our staff that DC was an easier procedure compared to FC.

Conclusion: Our data suggest that DC has overcome the impediment of fiberoptic technology, providing increased sensitivity and specificity for visual impression diagnosis of malignancy and successful therapy of biliary stones. Moreover DC has the ability to alter more often the initial ERC diagnosis or management compared to FC and provides a new sophisticated and easy to use equipment.

Introduction: Tokyo Guidelines 2013 (TG13) have been used worldwide to assess the diagnostic criteria and severity grading of acute cholangitis. Acute cholangitis is a life-threatening disease, and the emergency biliary drainage procedure is necessary for moderate or severe cases, according to TG13. In recent years, with an aging society, necessity to perform endoscopic retrograde cholangiopancreatography (ERCP) in elderly patients are increasing. However, few studies have examined the efficacy and safety of emergency ERCP in super-elderly patients with severe cases.

Aims & Methods: In this study, we examined the efficacy and safety of emergency ERCP in super-elderly patients with moderate to severe acute cholangitis, according to TG13. We performed 178 emergency ERCP procedures in 132 patients during 3 years (June 2014–December 2016). We determined patients ≥ 90 years as “super-elderly” and those < 90 years as “non-super-elderly”. Evaluation criteria included comorbidities, oral administration of anticoagulants, cause of cholangitis, ERCP procedure (examination time, endoscopic biliary sphincterotomy (EST)/pre-cut papillotomy, treatment success rate, presence or absence of peripapillary diverticula and papilla after EST, sedation dosage), ERCP-related complications (bleeding, perforation, post-ERCP pancreatitis, post-ERCP pneumonia, death within 30 days after ERCP procedure), and anesthesia-related complications (blood pressure decrease, pulse reduction, respiratory depression).

Results: We examined 69 males (52.3%) and 63 females (47.7%). Women accounted for a larger proportion in the super-elderly group (71% vs 40%). The average age was 92.5 years (range, 90–97) in the super-elderly group and 77.9 years (range, 50–89) in the non-super-elderly group. The super-elderly group comprised 54 ERCP procedures (moderate, 32; severe, 22) against 124 ERCP procedures (moderate, 104; severe, 20) in non-super-elderly group, and severe cases observed in the super-elderly group were statistically significant ($p < 0.001$). Regarding comorbidities, chronic heart and renal failure were statistically dominant in the super-elderly group. However, no difference was seen in the presence of other diseases and receiving anticoagulant medication between the two groups. The causes of acute cholangitis were common in both groups with common bile duct stone (46% vs 46%), followed by malignant obstruction (9% vs 12%) and benign stenosis (0% vs 5%), but no difference was found. Regarding the ERCP procedure, the examination time was longer in the super-elderly group (37.5 ± 28.1 min vs 29.2 ± 24.0 min, $p = 0.044$), but there was no difference in the procedure success rate (93% vs 97%, $p = 0.249$) and the presence of peripapillary diverticula. The patients were sedated using midazolam (MDZ) plus pentazocine (PTZ). The amount of anesthetic used was less in the super-elderly group (MDZ: 2.2 vs 3.3 mg, $p < 0.001$, PTZ: 3.1 vs 5.4 mg, $p = 0.005$). Regarding (i) ERCP-related and (ii) anesthesia-related complications, these were higher in the super-elderly group [(i) 15% vs 9%, $p = 0.293$, (ii) 17% vs 7%, $p = 0.0504$]. Every patient with complication improved with conservative treatment, and no intravascular or surgical treatment was required.

Conclusion: Acute cholangitis in super-elderly patients was more likely to become severe and the complications were higher than that in non-super-elderly patients. When performing an emergency ERCP procedure in super-elderly patients, we should particularly pay attention to developing complications in patients with moderate or higher acute cholangitis, according to TG13.

Introduction: Dysplasia may persist at the termination of the common bile duct (CBD) after endoscopic ampullectomy. Radiofrequency ablation (RFA) could be an interesting alternative to surgery to reduce the risk of invasive cancer with less morbi-mortality.

Aims & Methods: The aim of the study was to evaluate the efficacy and morbidity of endo-biliary RF for the treatment of residual endo-biliary dysplastic lesions after endoscopic ampullectomy. A prospective open-label multicenter study

included 20 patients with low-grade dysplasia (DBG) or high grade (DHG) lesions in the CBD, confirmed by a double anatomopathological lecture, in relation to a residual adenomatous bud after endoscopic ampullectomy for ampullary adenoma. The lesions should extend to a maximum length of 20 mm in the CBD. Endoscopic retrograde cholangio-pancreatotomy (ERCP) was performed under general anesthesia with the HabibTM EndoHPB probe (EMcision, UK) (effect 8, power 10Watts, 30 s). Biliary \pm pancreatic stent were placed at the end of the procedure. The primary endpoint was the rate of residual neoplasia (eg, DBG, DHG or invasive carcinoma) at 1 year after treatment. Secondary endpoints were: 1) residual neoplasia at 6 months after treatment; 2) rate of surgery at 12 months; 3) adverse events.

Results: The mean age (\pm SD) was 67 years (\pm 11), with 12 men and 8 women. RFA was performed on average (\pm SD) 1.9 years (\pm 3.5) after ampullectomy. The mean resected ampullary adenoma size (\pm SD) was 24.9 mm (\pm 10.2), and 7 patients had adjacent duodenal mucosectomy at the time of ampullectomy. The histology of the resected ampullary adenoma was DBG for 7 patients, DHG for 12 patients, and in situ carcinoma for 1 patient. Lateral margins were healthy for 13 patients. CBD recurrence was diagnosed predominantly on ERCP and/or endoscopic ultrasonography surveillance procedures with an estimated mean infiltration height (\pm SD) of 11.2 mm (\pm 4.5). The passage of the RFA probe was judged to be easy in 100% of cases with visibility of the radio-paque markers judged satisfactory to very satisfactory in 80% of the cases. All patients included had RFA without any technical problems. All patients had biliary stent (4 SEMS 10 mm, 16 plastic stents 10 French) implanted following RFA and 5 (25%) had a pancreatic stent. The residual rate of DBG, DHG, invasive carcinoma at 6 months and at 12 months after treatment were 25% (5/20, DBG, carcinoma) and 45% (9/20, DBG, carcinoma) respectively. The adverse events were as follows: 4 benign pancreatitis all medically treated, 2 patients had angiocholitis requiring biliary stent replacement, 1 patient had an episode of unexplained spontaneously resolved abdominal pain (normal CT scan, colonoscopy and biological tests). At M12, one patient presented with a biliary scar stricture resolved by dilation and a calibration biliary stent.

Conclusion: Endobiliary RFA performed on residual endo-biliary dysplastic buds after ampullectomy is an alternative to surgery, with a rate 55% dysplasia eradication at 12 months after a single RFA session. Regular monitoring of these patients is still necessary considering recurrence rate. Multiple RFA sessions may be proposed in case of incomplete results.

Introduction: Simulation-based training has become an important pillar in competence-based learning in medicine, especially in training novice endoscopists. Several simulators have been validated and implemented in training curricula pertaining gastrointestinal endoscopy. Surprisingly, limited data are available on simulators in ERCP training, despite the fact that ERCP seems to be an ideal platform for simulator-based training due to its technical complexity. The available simulators are difficult to implement in training settings due to the lack of realism or use of live animals or ex-vivo components. Recently, the Boškoski-Costamagna ERCP Trainer was validated as a very realistic training model by our study group. A novel mechanical papilla has been designed allowing to train (precut) sphincterotomy. The mechanical papilla is inserted into the simulator. A specific alloy allows for electrical conduction and cutting of the material using standard sphincterotomes and needle knives.

Aims & Methods: The aim of our study was to determine the expert validity of this cutting papilla and its didactic value for training sphincterotomy, as judged by experts. Expert participants with more than 2500 ERCPs lifetime were invited to perform a sphincterotomy and fill out a questionnaire on the realism of the sphincterotomy procedure and its didactic value.

Results: A total of 40 ERCP experts were included. All experts were men, originating from 16 different countries with a mean age of 49.6 years (range 37–65). Thirty-seven participants were gastroenterologists (92.5%), 3 participants were surgeons (7.5%). The mean number of years of endoscopic experience was 20.9 (range 10–40). Experts' opinion on realism of performing a sphincterotomy was rated 6.98 on a ten-point Likert scale, resemblance of the performed maneuvers 7.60 and tactile feedback 6.78. When asked if the cutting was perceived as expected, experts rated 6.35 and the cutting result was rated 7.30 on a ten-point scale. The potential as a training tool of the cutting papilla in training novices was rated 3.93 on a four-point scale, and there was a high agreement among the experts to include the papilla in the training of novices (3.93 on a four-point scale).

Conclusion: This is the first mechanical papilla available for training sphincterotomy on the Boškoski-Costamagna ERCP Trainer and demonstrates good expert validity. ERCP experts highly agree on the didactic value and added value of this papilla in the training curriculum of novice endoscopists.

P0243 MEDICO-LEGAL CLAIMS IN GASTROINTESTINAL ENDOSCOPY: DOES PROCEDURE RISK RELATE TO SUCCESSFUL OUTCOMES?

S. Budihal, J. F Mayberry

Digestive Diseases Centre, University Hospitals Leicester, GB/United Kingdom

Contact E-mail Address: shivbudihal@yahoo.co.uk

Introduction: Complications in endoscopy can lead to adverse clinical events. The likelihood of developing a complication depends on the degree of risk associated with a certain procedure. It is generally noted that riskier the procedure larger is the chance for a complication and higher the likelihood for medico legal issues. This is relevant as in the event of the risk materialising, patients make seek legal redress. The aim of this study was to investigate the degree of success of medico legal claims based on the nature of the endoscopic procedure and the outcome of the claims.

Aims & Methods: The National Health Service Litigation Authority (NHS LA) database in U.K. was searched using a Freedom of Information request (F/2405) to investigate endoscopic claims notified to the NHS LA between 2010/11 and 2014/15. The terms "Gastroscopy", "Sigmoidoscopy", "Colonoscopy", "PEG" and "ERCP" were used to search the database. They were then analysed for procedure type, characteristics and outcomes. StatsDirect statistical software was used for statistical analysis.

OUTCOME OF ENDOSCOPY CLAIMS

PROCEDURE	OPEN	SUCCESSFUL	UNSUCCESSFUL
Gastroscopy	6	10	7
PEG	12	19	12
Sigmoidoscopy	17	13	5
ERCP	22	26	24
Colonoscopy	50	40	28

Results: A total of 291 claims were notified to the NHS LA during this period. 107 (36.7%) of claims still remain 'open'. Analysing outcomes by procedures reveals a success rate of 44%, 44%, 37%, 36% and 34% (rounded up to the nearest whole figure) for Gastroscopy, PEG, Sigmoidoscopy, ERCP and Colonoscopy claims respectively. There is no statistical difference between the proportions comparing Gastroscopy and Colonoscopy (StatsDirect software used)

Conclusion: A significant number of claims remain open leading to concern and worry among endoscopists. The impact on practitioners after a successful claim is unknown and merits further investigation. Procedures considered as dangerous like ERCP and Colonoscopy have the least successful claims. It is imperative that clinicians remain vigilant. Performing Gastroscopy is dangerous and so is undertaking a Percutaneous Endoscopic Gastrostomy. Endoscopists should tighten their approach to all procedures.

P0244 VISUALIZATION OF INTRA-AMPULLARY CHOLEDOCHOCELE WITH CONTRAST MEDIUM FOR EVALUATING TECHNICAL DIFFICULTY IN ERCP

N. Nishino

Gastroenterology Center, Southern Tohoku Hospital, Koriyama/Japan

Contact E-mail Address: nishinon@tim.hi-ho.ne.jp

Introduction: Choleldochocele has been rarely recognized. We focus on intra-ampullary choleldochocele (IAC). We had experienced some cases with IAC as refractory access to bile duct (BD). IAC has small cyst within ampulla regulated by Oddi's sphincter, so the BD axis has changed via IAC. The cases with IAC would require a high technical skill for axis alignment or alternative strategy such as infundibulotomy or precut. We propose advantage of conventional ERCP (cERCP) with contrast medium, which provides images of IAC and leads to evaluate the difficulties in cannulation.

Aims & Methods: This study aims to recognize the morphology of intra-ampullary bifurcation of bile duct (BD) and pancreatic duct (PD). Its variation allows the elucidation of the reason for difficulties in cannulation. The current study is a retrospective consecutive case study that is conducted in a single facility, with a study period of 8 years. Our strategy for ERCP was carried out with the contrast medium injected via a catheter, but without guide wire (GW) seeking. Intra-ampullary bifurcation was particularly visualized with the contrast medium, and X-ray images were magnified sequentially 5–10 times each. The eligibility criteria were: it must be naive papilla and both of BD and PD must be visualized. The following factors were evaluated: ampulla shape, number of orifices, angle of intra-ampullary bifurcation and presence of IAC. The Location, size and shape of IAC were observed. The requirement of GW placement on PD to access BD were evaluated. The shapes of the ampulla were divided into three groups: long nose (L/N), meaning a long protrusion, Dome (D), meaning a hemisphere and flat (F). The IAC location were classified into BD (Ab), PD (Ap) and common channel (Ac). The choleldochocele shapes were divided into three groups: spindle (Sp), sphere (Sh) and oval (Ov). IAC was also recognized on magnetic resonance cholangiopancreatography (MRCP). We analyzed our results of image database with descriptive epidemiology.

Results: There were cases of 1223 naive papilla out of 2226 cases in total. The success rate to access BD with naive papillae was 97.7% (1195/1223) and overall post-ERCP pancreatitis (PEP) was 1.3% (29/2226). The eligible patients were 908 (505 male and 403 female), among whom IAC was identified in 6.0% (54/908). The prevalence of IAC in the L/N, D and F types were 8.9% (48/542), 1.2% (4/339) and 7.4% (2/27), respectively. IAC was significantly higher in the L/N ($p < 0.01$) and F ($p < 0.05$) types than in the D type. The choledochocoele shapes of Sp, Sh and Ov were 59.3%, 13.0%, 27.8%, respectively. The average size was 8.1 mm (3.7–18.3) in diameter. The location of IAC in Ac and Ab were 63.0% and 37.0%. The IAC in Ab was found with L/N shape only. Patients of 53.7% (29/54) required GW placement on PD to access BD. IAC was alternatively seen on MRCP in 10% (3/30).

Conclusion: Choledochocoele is rarely seen on even cERCP, in addition the visualization of IAC has been rarely reported. IAC could be actually visualized with prudent contrast medium injection. Our results showed miscellaneous variations in the intra-ampullary images. IAC would require refractory pursuit of the axis alignment due to its unexpected pathway within ampulla to access BD. Moreover 6.0% prevalence of IAC should not be ignored. IAC can be one of the factor of refractory cannulation. cERCP with focus on ampulla could the difficulty in cannulation. On the other hand, WGC would not do. The previous randomized control trials showed no difference to access to BD between WGC and cERCP. However, both procedures still remained cases with refractory cannulation. It has been reported that refractory cannulation might cause PEP1). Therefore careful attention should be paid while passing through IAC to avoid PEP. According to ampulla shapes, especially of L/N and F, cERCP would be recommended to identify the presence of IAC. It will be a warrant strategy to choose.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Most appropriate endotherapy of biliary anastomotic strictures (AS) remains to be defined.

Aims & Methods: Aim is to retrospectively report the endotherapy for duct-to-duct AS in 2013, procedure related complications and medium-term outcome results in Italy. A questionnaire was sent to the Endoscopy Units working with Italian Liver Transplantation Centers (BASALT study group).

Results: At present sixteen of the 19 Units (84%) returned the questionnaire. Complete endotherapy data and follow-up are available for 182 pts. One-hundred and two patients have been treated with plastic multistenting (PM), 27 with fully covered SEMS and 53 with single stenting (SS). Radiological success was achieved in 144 pts (79%), i.e. 86% of PM, 89% of fully covered SEMS and 60% of SS ($p < 0.01$ vs PM). Recurrence occurred in 31 pts, i.e. 21% of pts in whom radiological success was achieved: 11% of PM ($p < 0.0001$ vs SEMS and $p < 0.05$ vs SS), 41% of fully covered SEMS and 17% of SS. After failure of first-line endotherapy (36) or recurrence (31), patients were re-treated with endotherapy (75%), surgery (21%) or percutaneous balloon dilation (3%); one patient dropped out because of death unrelated to endotherapy. Second-line endotherapy was PM for 26%, fully covered SEMS for 52% and SS for 22% of pts and radiological success was achieved in 82% of them (in 86%, 89%, and 60% with PM, SEMS and SS respectively). Procedure-related complications occurred in 7.8% (51/656), i.e. 2.6% pancreatitis (1 severe leading to death), 4.1% cholangitis and 0.9% bleeding. Overall clinical success was achieved in 83% after a median f-up of 25 mos and no need of surgery in 92% of patients.

Conclusion: Endotherapy is confirmed as the preferred first-line and rescue option for AS. Progressive plastic multi-stenting is most frequently used. Single stenting has suboptimal results and should be abandoned. Use of SEMS is effective, but recurrences seem to be frequent, although a larger patients' sample needs to be evaluated.

Introduction: EUS-guided Cysto-Enterostomy (EUCE), technique indicated for drainage of symptomatic pancreatic pseudocysts and other peri-enteric fluid collections, requires specific skills for which dedicated models are needed. Based on a compact EASIE model (Erlangen Active Simulator for Interventional Endoscopy) we developed two ex-vivo porcine models of retrogastric cysts and evaluated learning performance within the frame of a structured training program.

Aims & Methods: The first model was made of porcine colon (i.e. "natural cyst"), and second one was made with an ostomy bag (i.e. "artificial cyst"). All procedures were achieved with EUS scope under fluoroscopy. Both models were evaluated prospectively over a 2-days session involving 14 students and 5 experts.

Results: "Natural cyst" and "artificial cyst" were prepared respectively within 10 and 16.5 minutes ($p = 0.78$). More than 10 EUCE procedures were done in each model. Model grading (analogic scale) showed no significant difference for primary endpoint of global satisfaction ($p = 0.06$). Regarding secondary endpoints, difference was not significant for overall impression of realism ($p = 0.75$) whereas it was significant favoring "artificial cyst" in terms of ability to teach procedural steps ($p = 0.01$) and ease of puncture ($p = 0.03$) because of less elasticity. Moreover, experts considered ability to improve students' proficiency superior with "artificial cyst" ($p = 0.008$).

Conclusion: Both "artificial and natural cysts" are efficient for EUCE training in terms of global satisfaction. However, the "artificial cyst" model appears to make procedure easier and better to teach procedural steps improving students' proficiency. Larger applications of this model are needed to validate as a standard of training.

Introduction: Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) is an established procedure for obtaining a pathological specimen. However, detailed techniques of EUS-FNA vary substantially across medical centers. There is a need to establish more efficient method for better diagnostic accuracy and adequate sample. In the present study, we investigated the suction method for collecting specimens by EUS-FNA.

Aims & Methods: The aim of our study was to compare conventional suction using a 20 mL syringe and capillary suction during EUS-FNA. Patients who referred to EUS-FNA for solid mass lesion were prospectively enrolled. We performed EUS-FNA with two needle passes and applied each pass of different techniques which were randomly allocated. The diagnostic accuracy, the quantity of samples (0–5.5 represents sufficient material for adequate for histological interpretation and a high-quality sample), the degree of contamination, and the amount of blood (0–2.2 represents significant amount of blood) were compared between conventional suction and capillary suction. Further analysis was carried out in the patients with pancreatic cancer. For patients with negative EUS-FNA, surgical specimen evaluation, results of other diagnostic investigations and/or long term clinical follow-up (6 months) were used to establish the definitive diagnosis.

Results: During the study period, 96 patients underwent EUS-FNA were enrolled and 7 patients were excluded due to loss of follow-up. Finally 89 patients (averaged 68.5 y/o, M:F=47:42) were analyzed. There were 60 pancreatic lesions (42 pancreatic cancer, 6 neuroendocrine tumor, etc.), 17 lymph adenopathy, 6 sub-mucosal lesions, 6 other lesions biopsied, with a mean diameter of 28 ± 3 mm. Although there was no significant difference in the diagnostic accuracy (86.5% vs. 79.8%, $p=0.32$), the quantity of samples (3.64 vs. 3.43, $p=0.21$) and the degree of contamination, the samples obtained by conventional suction contained more blood compared to those obtained by capillary suction (0.17 vs. 0.02, $p < 0.05$). Moreover, conventional suction showed favorable diagnostic accuracy (83.3% vs. 69.0%, $p=0.20$) and significantly higher quality of samples (3.38 vs. 2.74, $p < 0.05$) than capillary suction, in the patients with pancreatic cancer.

Conclusion: Capillary suction was effective in the EUS-FNA sampling and associated with less contamination with blood, but conventional suction is recommended in case of fibrotic pancreatic cancer for obtaining high-quality sample.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0248 A PROSPECTIVE COMPARISON OF EUS-GUIDED TISSUE ACQUISITION USING A 25G-GAUGE CORE BIOPSY NEEDLE WITHOUT AND WITH A STYLET FOR INTRAABDOMINAL SOLID MASS LESIONS

J. Kim, M.J. Yang, J.C. Hwang, B.M. Yoo

Dept. Of Gastroenterology, Ajou University Hospital, Suwon/Korea, Republic of

Contact E-mail Address: jinhkim@ajou.ac.kr

Introduction: The effectiveness of endoscopic ultrasound (EUS) guided tissue acquisition using a 25G-gauge core biopsy needle without and with a stylet has never been compared.

Aims & Methods: The aims of this study were to evaluate the feasibility, safety, and diagnostic yield for malignancy of the 25-gauge core biopsy needle without (S-) a stylet and to compare its performance with that of the 25-gauge core biopsy needle with (S+) a stylet. This study was a single-center randomized clinical trial. From March 2013 to January 2016, a total of 114 patients (57 in a S- group and 57 in a S+ group) with solid lesions were included. S- or S+ EUS guided tissue acquisition was performed using a 25-gauge core biopsy needle without an on-site cytopathologist.

Results: There were no significant differences in technical success (100% vs. 100%, $P=1.000$), the mean number of needle passes (6.8 vs. 7.0, $P=0.556$), or complication (0% vs. 3.5%, $P=0.496$) between the S- group and the S+ group. The S- and S+ groups exhibited comparable outcomes with respect to cytologic diagnostic yield (91.2% vs. 93.0%, $P=1.000$), histologic diagnostic yield (87.7% vs. 86.0%, $P=1.000$), and needle malfunction (7% vs. 0%, $P=0.118$). The procedure time was significantly shorter in the S- group than in the S+ group (32.4 vs. 39.7 min, $P < 0.001$).

Conclusion: EUS guided tissue acquisition using a 25G-gauge core biopsy needle without a stylet did not decrease the diagnostic yield for malignancy and is associated with shorter procedure time.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0249 DIAGNOSTIC EFFICACY OF ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE ASPIRATION FOR A PANCREATIC MASS USING THE CELL BLOCK METHOD WITHOUT RAPID ON-SITE CYTOLOGY

K. Masu¹, K. Ito¹, Y. Noda¹, S. Koshita¹, Y. Kanno¹, T. Ogawa¹, T. Sawai²

Introduction: Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) has been shown to be efficient for diagnosis of pancreatic masses. Only with

the smear method, however, its diagnostic efficacy may vary greatly depending on the level of proficiency of the cytopathologists. On the other hand, the cell block (CB) method allows cytological and/or histological evaluation with hematoxylin and eosin (HE) staining and with immunostaining for serial sections if necessary.

Aims & Methods: The aim of this study was to evaluate the diagnostic efficacy of EUS-FNA for a pancreatic mass using the CB method without rapid on-site cytology retrospectively. A total of 206 patients with pancreatic masses (head: 87, body: 86, tail: 33) who underwent EUS-FNA using a GF-UL240P or GF-UCT260 (Olympus Medical Systems, Ltd., Tokyo, Japan) between June 2005 and November 2016 were included in this study. The needles used were 22/25G needles. At least two passes were made during the procedure (mean 3.0 ± 0.9 passes). Adequate specimens were regarded to be those in which whitish fragments were macroscopically achieved. The samples were immediately fixed in 10% formalin and processed by the cell block method using sodium alginate. Rapid on-site cytology was not performed. All samples were stained by hematoxyline and eosin, periodic acid Schiff and Alcian-blue, and immunohistochemical stainings if necessary. Class IIb, IV, and V were defined as malignant. The final diagnosis was based on histological findings of surgically resected specimen, image diagnosis and clinical course for more than six months.

Results: The final diagnosis was malignancy in 184 patients (pancreatic ductal cancer (PDC), 171; neuroendocrine tumor (NET), 9; malignant lymphoma, 2; metastasis of malignant melanoma, 1; solid pseudopapillary neoplasm, 1), and benignancy in 23 patients (autoimmune pancreatitis (AIP), 11; chronic pancreatitis, 7; organizing pancreatic pseudocyst, 4; IPMN, 1). Adequate tissue sampling was successfully achieved in 97% (199/206). Of 199 patients with successful tissue sampling, sensitivity, specificity and accuracy for malignancy were 98% (175/179), 95% (19/20) and 97% (194/199). The diagnostic accuracy of PDC only by HE and PAS-AB staining was 76% (129/170) (Class V 91; IV 36; IIb 2), but by adding immunohistochemical staining, the accuracy of PDC was 98% (167/170) (Class V 112; IV 50; IIb 5). In the cases of highly suspicious NET, all samples were stained by chromogranin A or synaptophysin and the diagnostic accuracy of NET was 100% (6/6). No procedure-related complications occurred.

Conclusion: EUS-FNA of a pancreatic mass with the CB method without rapid on-site cytology showed high accuracy for definitive diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0250 A COMPARATIVE STUDY BETWEEN EUS-GUIDED BILIARY DRAINAGE AND PERCUTANEOUS BILIARY DRAINAGE IN PATIENTS WITH MALIGNANT BILIARY OBSTRUCTION AND FAILED ERCP

L. Lu, J. Yang, H. Jin, X. Tang, J. Yang, X. Zhang

Department Of Gastroenterology, Hangzhou First People's Hospital, Hangzhou/China

Contact E-mail Address: zacharylu@126.com

Introduction: Patients with malignant biliary obstruction conventionally undergo percutaneous transhepatic biliary drainage (PTBD) after failed endoscopic retrograde cholangiopancreatography (ERCP) (1). While PTBD is effective, it is associated with significant morbidity, such as bile leakage, bleeding, and pneumothorax, and involves uncomfortable external drainage (2). Endoscopic ultrasound-guided biliary drainage (EUS-BD) is a minimally invasive endoscopic option increasingly offered as an alternative to PTBD for malignant biliary obstruction after failed ERCP (3). Although a recent meta-analysis reported better clinical efficacy and superior safety of EUS-BD when compared to PTBD, data from mainland China is sporadic (4).

Aims & Methods: We aimed to compare efficacy and safety of EUS-BD to PTBD in patients with malignant biliary obstruction after failed ERCP at a single tertiary referral center from mainland China. From November 2011 through December 2015, consecutive patients undergoing EUS-BD or PTBD for malignant biliary obstruction after failed ERCP were included. Demographical, biochemical, and outcome data were registered for each group. The primary outcomes included technical success rate and incidence of complications, the second outcomes were clinical success rates and re-intervention rate.

Results: A total of 93 patients (mean age 68 ± 13.5 years, 49 males) were included, 33 in the EUS-BD group and 60 in the PTBD group. Both groups were similar in terms of age, gender, baseline bilirubin and functional status. Technical success was achieved in 32 (97%) of 33 patients in the EUS-BD group and in 57 (95%) of 60 patients ($p > 0.05$) in the PTBD group. The clinical success (jaundice relief: reduction in serum bilirubin by 50% within the first month) was achieved in all patients with technical success (32/32, 100% EUS-BD vs. 57/57, 100% PTBD). Procedure-related complication rates were higher in the PTBD group (18/57, 31.6%: 5 bleeding, 5 catheter site infection, 4 bile leaks, 2 cholangitis, and 2 tube malposition) than in the EUS-BD group (3/32, 9.4%: 2 bleeding and 1 cholangitis) ($p=0.018$). Rate of re-intervention appeared to be lower in the EUS-BD group (2/32, 6.3%: 2 stent occlusion) than in the PTBD group (17/57, 29.8%: 6 stent occlusion, 5 catheter site infection, 4 bile leaks, and 2 tube malposition) ($p=0.009$).

Conclusion: Despite similar high technical and clinical success rates compared with PTBD, EUS-BD was associated with reduced rate of complications and required fewer re-interventions. EUS-BD seems a better alternative than PTBD for malignant biliary obstruction after failed ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0251 A PROSPECTIVE COMPARATIVE STUDY OF EFFICACY OF EUS GUIDED FNA VERSUS ERCP GUIDED BRUSH CYTOLOGY IN ATTAINMENT OF HISTOPATHOLOGY OF DISTAL CBD MASSES

P.N. Desai, M. Kabrawala

Endoscopy, Surat Institute Of Digestive Sciences, Surat/India

Contact E-mail Address: drp_desai@hotmail.com

Introduction: Distal CBD masses have always been a diagnostic dilemma. They are difficult to diagnose with any modality used. Brush cytology under ERCP guidance was used uptill now and also intraductal biopsies were used. The yield was hardly around 60% using all together. We started doing EUS localization of these difficult to identify distal CBD masses and took FNA from them. We devised a protocol to see the results of EUS FNA and brush cytology in the diagnosis of these masses.

Aims & Methods: We aimed to study the efficacy of EUS guided FNA for attaining tissue from distal CBD masses and comparing it to ERCP guided brush cytology from the same masses. 56 cases with distal bile duct mass with obstructive jaundice in the last 3 years were taken for the study. The protocol we followed First - EUS was done using a linear echoendoscope, mass identified and FNA performed with a 25 G needle making 2 to 5 passes and material sent for cytology. Same patients subjected to ERCP. A wide papillotomy was performed and over the wire cytology brush was used and brush cytology was obtained. Two passes were made and material taken on a slide and sent for cytology after wet fixation.

Results: Total number of cases 56 Age (range) 57.2 ± 13.6 Male to Female 40: 16 Total Serum Bilirubin 90 mg/dl) 5.9 ± 6.4 Mean size of the mass 12 mm (7 mm to 30 mm). Mean Number of passes with FNA needle 2.5 (2 to 5 passes). Mean number of passes with cytology brush 2 (2to 5). Positive diagnosis obtained with FNA 47 (83.9%). Positive Diagnosis obtained by brush 34 (60.7%)

Diagnosis in Positive Cases

	FNA (47)	Brush Cytology (34)
Malignancy	38 (80.8%)	23 (67.6%)
Suspicious Of Malignancy	5 (10.6%)	7 (20.5%)
Benign	4 (8.5%)	4 (8.5%)

With EUS the tumors were sometimes difficult to locate and identify. But giving some time and instilling water in duodenum were useful techniques to identify the masses. Only a 25 G needle was used as the FNA had to be taken almost always from the duodenum and with difficult angles. But we succeeded in taking FNA from all cases.

Conclusion: EUS FNA is a very effective method for diagnosis of distal bile duct masses with a certain diagnosis in almost 81% and a suspicious diagnosis in around 11% cases. Its efficacy is better than ERCP guided brush cytology. Even small masses are amenable to FNA using EUS guidance. Male over 57 years with jaundice and distal bile duct obstruction has a very likelihood of have a distal CBD cholangio carcinoma.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0252 RANDOMIZED TRIAL COMPARING THE LUMEN-APPOSING METAL STENTS (LAMS) AND PLASTIC STENTS FOR EUS-GUIDED DRAINAGE OF WALLED-OFF NECROSIS (WON)

J.Y. Bang, M. Hasan, U. Navaneethan, R. Hawes, S. Varadarajulu
Center For Interventional Endoscopy, Florida Hospital, Orlando/United States of America/FL

Contact E-mail Address: jybang213@gmail.com

Introduction: Although lumen-apposing metal stents (LAMS) are being increasingly used for drainage of walled-off necrosis (WON), their advantage over plastic stents is unclear.

Aims & Methods: We aimed to compare the efficacy of LAMS and plastic stents for drainage of WON.

Symptomatic patients with WON (>20% necrosis) were randomized to undergo transmural drainage using LAMS (Hot AXIOS, 15 mm × 10 mm) or two double pigtail plastic stents (7Fr × 4 cm). Reintervention in persistently symptomatic patients included additional stent placement, percutaneous drainage and/or endoscopic necrosectomy. Treatment success was defined as symptom relief in conjunction with resolution of WON on CT at 6-week follow-up. Main outcome measure was to compare the no. of reinterventions. Secondary outcome measures were to compare treatment success, procedural duration, resolution of systemic inflammatory response syndrome (SIRS), clinical and stent-related adverse events, readmissions and length of hospital stay. Sample size to detect a difference of 1 in the no. of reinterventions performed at 90% power was calculated at 58 patients.

Results: 60 patients were randomized to LAMS (n=31) or plastic stent (n=29) placement. While there was no significant difference in the no. of reinterventions (median 1 [IQR 1–2] for both stent types, p=0.78), the procedural duration was significantly shorter (15 vs. 42.5 mins, p<0.001) and stent-related adverse event rate was significantly higher with LAMS placement (32.3 vs. 6.9%, p=0.02). At an interim audit, significant adverse events (delayed bleeding [n=3], buried stent [n=2], biliary stricture [n=3]) were observed in the LAMS cohort after 3 weeks post-intervention. This necessitated an amendment to the study protocol whereby a CT scan was obtained at 3 weeks followed by LAMS removal if the WON had resolved. After protocol amendment, no difference in stent-related adverse events was observed between the cohorts (LAMS 6.5 vs. plastic 6.9%, p=0.99). Also, there was no significant difference in treatment success, SIRS resolution, clinical adverse events, readmissions or length of hospital stay between the cohorts (Table).

		Metal (n = 31)	Plastic (n = 29)	p-value
Procedure duration (mins):	Median [IQR]	15 (8–25)	42.5 (21–55)	<0.001
Resolution of pre-intervention SIRS (%):		44.4	69.2	0.38
Length of hospital stay (days):	Median [IQR]	3 (0–5)	3.5 (2–11)	0.16
Treatment success (%):		96.3	88.0	0.34
Adverse events (%):	Overall	41.9	20.7	0.10
	Stent-related	32.3	6.9	0.02
	Other	9.7	13.8	0.70
No. of reinterventions (n):	Median [IQR]	1 (1–2)	1 (1–2)	0.78
Readmissions (%):		29.0	34.5	0.78

Conclusion: Except for shorter procedural duration, there was no significant difference in treatment outcomes between patients treated with LAMS or plastic stents. Given the faster resolution of WON, to minimize adverse events, patients undergoing LAMS placement should undergo post-intervention imaging at 3 weeks followed by stent removal if the WON has resolved.

P0253 TRANS AORTIC ENDOSCOPIC ULTRASOUND GUIDED FNA IN THE DIAGNOSIS OF LUNG CANCERS AND MEDIASTINAL LYMPH NODES

P. Somani, M. Sharma

Department Of Gastroenterology, Jaswant Rai Speciality Hospital, Meerut/India

Contact E-mail Address: dr_piyushsomani@yahoo.co.in

Introduction: Obtaining a tissue diagnosis from a lung tumour or a mediastinal lymph node located lateral to the aorta (para-aortal) is a diagnostic challenge because of the interposition of the aorta. Invasive surgical procedures like mediastinotomy, thoracotomy, or video-assisted thoracic surgery is required for the diagnosis of these lesions. Lymph node stations immediately anterior to the aortic arch and lateral to the descending aorta are difficult to access. Lymph nodes on the “far-side” of major blood vessels can be visualized by endoscopic ultrasound(EUS), however Fine needle aspiration(FNA) is avoided due to concern for bleeding complications. Tumours and mediastinal lymph nodes located in the para-aortic region can easily be visualized by esophageal EUS, because the aorta provides an excellent medium to transfer ultrasound waves.

Aims & Methods: We aimed to evaluate the feasibility, yield, and safety of EUS-guided transaortic FNA of lung tumours and para-aortic lymph nodes.

We undertook a retrospective case series of 12 consecutive patients with suspected lung cancer or tuberculosis who underwent transaortic FNA during a study period of 7 years. In all cases, the para-aortic lesion was the only site suspicious for malignancy/tuberculosis (other lesion/lymph node if present were negative). Based on CT/PET imaging, a transesophageal FNA performed through the aorta was considered as the only option to diagnose or stage these patients by means of a minimally invasive procedure. Seven patients had left-sided lung mass (mean size 30 mm). Four were located in left lower lobe and three in left upper lobe. Four patients had enlarged para-aortic lymph node (mean size 18 mm, range 8–22 mm), suspicious for IASLC stations 5 (n=1) and 6 (n=3). One patient had anterior mediastinum mass. EUS was performed with a linear echoendoscope. All aspirates were obtained under real-time US guided FNA by using a 22/25-gauge needle. A single real-time FNA of the lung mass or lymph node was performed. The para-aortic area was observed on EUS for 5 minutes to assess for immediate procedure-related complications.

Results: The final diagnosis was known in 11 patients (5 non-small-cell lung carcinoma [NSCLC], 2 small-cell lung carcinoma [SCLC], 3 tuberculosis and one thymolipoma). EUS-FNA established diagnosis in 9 of 12 patients (75%) (4 NSCLC, 1 SCLC, 3 tuberculosis and 1 thymolipoma). One aspirate revealed reactive nodal tissue, and one demonstrated nonrepresentative material. One procedure was abandoned due to complication. Three patients in whom diagnosis was not established by transaortic FNA underwent subsequent surgical staging (1 thoracotomy, 1 mediastinotomy, and 1 VATS), and malignancy was found in 2 of the 3 patients. Trans aortic FNA was found to be safe. In one patient, EUS images after FNA were suspicious for a small para-aortic hematoma. This patient recovered without any adverse event.

Conclusion: This case series demonstrates the feasibility and probable safety of single EUS guided transaortic aspiration in para-aortic lesions. The diagnostic yield is 75 percent. Clearly, further study and very careful selection by expert EUS operators is needed before this procedure can be routinely recommended. Advantages of this procedure includes day care procedure, less invasive than surgical procedures, low cost, good diagnostic yield and can be performed in poor surgical candidate. Limitations includes single centre study, require EUS expertise, more data is required. At present, Transaortic FNA should only be performed in the absence of alternative minimally invasive diagnostic procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0254 ULTRASOUND-GUIDED ENDOSCOPIC TRANSGASTRIC DRAINAGE OF PANCREATIC FLUID COLLECTIONS

M. Silva¹, S. Lopes¹, A. Peixoto¹, F. Vilas-Boas¹, P. Moutinho-Ribeiro¹, G. Macedo²

Introduction: Ultrasound-guided endoscopic transgastric drainage (EUSTD) of pancreatic fluid collections (PFCs) by using double-pigtail plastic stents (DPPS) requires placement of multiple stents and can be restricted by inadequate drainage and leakage risk. Recently, the use of fully covered self-expanding metal stents (FCSEMSs) has been reported as an effective alternative.

Aims & Methods: We aimed to evaluate the successful placement of stents, the complete resolution of PFCs at 6-months, adverse events, and recurrence of EUSTD of PFCs using DPPS and FCSEMSs.

This was a single-centre retrospective study (2012–2016) on 67 patients with symptomatic/infected PFCs, who underwent EUSTD. PFCs were drained using DPPS and FCSEMSs (Hanarostent BCF and Hot AXIOS system).

Results: We included 42 cases of pancreatic pseudocysts (PP), and 25 walled-off necrosis (WON), drained using FCSEMSs in 51% of cases. The remaining cases (49%) were drained using DPPS exclusively. Eighteen (27%) patients had a prior failed drainage attempt. Median follow-up time was 88 weeks (IQR: 42–140); 19 patients were lost to follow-up (6 deaths during follow-up). The median size of lesions was 92 mm (IQR: 74–120). The overall technical success rate was 78% (74% for PP and 84% for WON; $p > 0.05$). Six patients required additional drainage with a different modality (surgery/percutaneous drainage) and 8 cases required another EUSTD attempt. Complete resolution of PFCs with DPPS was lower compared with those that underwent drainage with FCSEMSs (58% vs. 84%; $p < 0.05$). Complete resolution of PP was lower than in the cases of WON (65% vs. 79%; $p > 0.05$). Procedure-related adverse events were noted in 18% of cases of the DPPS group and 21% in the FCSEMS group ($p > 0.05$); overall 1 procedure-related death was registered (massive bleeding after a FCSEMS placement). Recurrence occurred in 27% cases of PP and in none of WON ($p > 0.05$); the recurrence was higher in the DPPS group than in the FCSEMS group (43% vs. 13%; $p > 0.05$).

Conclusion: EUSTD of PFCs using FCSEMSs improves clinical outcomes with similar adverse event rates compared with the cases drained with DPPS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Histological examinations and immunohistochemical stains (IHC) are necessary for the differential diagnosis of gastrointestinal subepithelial lesions (SELs). Endoscopic ultrasound-guided fine needle biopsy (EUS-FNB) is the primary modality in the diagnosis of SELs, but still has limited accuracy. A new 20 gauge (G) biopsy needle with a core-trap technology (EchoTip ProCore®, Cook Medical) has been developed with a large core size and enhanced flexibility.

Aims & Methods: The aim of this multicenter study was to determine the feasibility, efficacy and safety of EUS-FNB with the new 20G needle in diagnosing SELs. Data retrieved from a prospectively collected database at five medical centers were analyzed and all consecutive patients with SELs undergoing EUS-FNB with the 20G needle were included in the present study. The reference standards for the final diagnosis were histology on surgical specimen or clinical follow-up.

Results: A total of 50 SELs in 50 patients (22 males, mean age 61.5 ± 14.8 years) were included. The mean lesion size was 43.1 ± 17.5 mm. The lesion locations were esophagus (n=1), stomach (n=37), distal duodenum (n=5), rectum (n=6), and colon (n=1). The procedure was technically feasible in all patients. Mean number of passes required to reach a diagnosis was 2.2 (range 1–4). Definitive diagnosis with full histological assessment including IHC was obtained in 88% (44/50) of the patients. Diagnosis of EUS-FNB showed 36 (72%) malignant SELs (32 GISTs, 1 metastasis from breast cancer, 1 leiomyosarcoma, 1 carcinoid, 1 SEL-like adenocarcinoma), 8 (16%) benign SELs (3 leiomyomas, 4 schwannomas, and 1 lipoma), and 6 (12%) indeterminate SELs. Considering malignant vs. benign lesions, the sensitivity, specificity, PPV, and NPV were 85% (95%CI 70.2–94.3), 100% (95%CI 58.7–100%), 100% (95%CI 85.1–100%), and 62.5 (95%CI 27.7–84.8), respectively. No major complications requiring additional care have been observed.

Conclusion: In this multicenter study, we found that EUS-FNB with the new 20G core needle is an effective and safe method for the diagnosis of SELs with a high rate of producing adequate histological material and high diagnostic accuracy even from difficult-to-approach anatomical locations. Comparative studies with different needle sizes are awaited.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic ultrasonography (EUS)-guided ethanol ablation for pancreatic cystic lesions (PCLs) is a recently introduced treatment option for PCLs. The aim of this study was to compare the clinical outcomes of EUS-guided ethanol ablation with those of the natural course of PCLs.

Aims & Methods: We performed retrospective study of patients with PCLs divided in two groups: EUS-guided ethanol ablation group (n=118, performed between June 2006 to August 2015) and natural course group (n=458, diagnosed between January 1993 to August 2015). The propensity score-matching analysis

between the two groups was applied in order to minimize the effect of selection bias. The primary outcome was the rate of significant reduction in size (<20% of initial size). The secondary outcomes were the rate of significant growth in size (>10 mm), complete remission rate, and surgical resection rate.

Results: In a propensity matched analysis of 88 pairs, the mean initial cystic size of EUS-guided ethanol ablation group and natural course group was 23.72 ± 10.99 , 23.16 ± 13.15 mm and the mean follow-up duration was 75.45 ± 38.12 , 82.12 ± 59.06 months respectively. Significant reduction in size was detected in 53 (60.2%) of the EUS-guided ethanol ablation group and 17 (19.3%) of the natural course group ($p < 0.001$). Significant growth in size was detected in 6 (8.9%) of ablation group and 11 (12.5%) of natural course group. ($p = 0.202$). Seven patients (7.95%) underwent surgical resection in the EUS-guided ethanol ablation group and 17 patients (19.3%) in the natural course group ($p = 0.028$) during follow-up. Overall 28.8% patients (34 of 118) who underwent EUS-guided ethanol ablation had achieved the complete remission.

Conclusion: PCLs that underwent EUS-guided ethanol ablation can be seen the likelihood of getting clinical benefits such as reduction of the cystic size, the chance for surgical resection in comparison to the natural course of them. It is also expected to achieve a certain level of complete remission for PCLs.

Introduction: Histological tissue comprising tumor and desmoplastic stroma is required for molecular profile-based personalized chemotherapy in pancreatic cancer. Recently, a three-plane symmetric needle with Franseen geometry and a Fork-tip biopsy needle have been developed for histological tissue procurement.

Aims & Methods: We aimed to compare tissue acquisition between the 22G Franseen and 22G Fork-tip needles in patients undergoing EUS-guided sampling of pancreatic masses.

Patients with pancreatic masses were randomized to undergo EUS-guided sampling using the 22G Franseen and 22G Fork-tip needles. Two dedicated passes were first performed using both needles in individual patients for cell block. Subsequent passes were then performed for rapid onsite evaluation (ROSE) using both needles alternately until a diagnosis was established. The main outcome measures were to compare total tissue volume and presence of desmoplastic stroma in pancreatic cancer. Secondary outcome measures were to compare rates of diagnostic cell block and diagnostic adequacy at ROSE.

Results: In 50 patients randomized to undergo EUS-guided sampling, the diagnosis was pancreatic cancer in 43, neuroendocrine tumor in 2, lymphoma in 1 and chronic pancreatitis in 4 patients. There was no significant difference in total tissue area (median 6.1 mm^2 [IQR 3.5–10.5] vs. 8.2 mm^2 [IQR 4.0–13.0], $p = 0.53$), presence of desmoplastic stroma in tumor (100 vs. 83.3%, $p = 0.23$), rates of diagnostic cell block (96.0 vs. 92.0%, $p = 0.68$) and diagnostic adequacy at ROSE (94.0 vs. 98.0%, $p = 0.62$) between the Franseen and Fork-tip needles, respectively.

Conclusion: Both the Franseen and Fork-tip needles appear equally effective in yielding histological tissue. By virtue of their ability to yield a diagnostic cell block in greater than 90% of patients, the new generation FNB needles may obviate the need for ROSE during EUS-guided tissue sampling.

Introduction: To evaluate the success rate of double-balloon endoscopic retrograde cholangiography (DBERC) to reach the anastomosis in patients with surgically altered gastrointestinal anatomy.

Aims & Methods: We review 346 patients with surgically altered anatomy who underwent DBERC from April, 2002 to December, 2016 (47 patients with biliary atresia(BA) after living donor liver transplantation (LDLT), 33 with LDLT without BA, 45 with biliary resection and choledochojejunostomy, 111 with gastric resection and Roux-en-Y bypass, 48 with gastric resection and Billroth-IIremnant, 18 with pylorus-preserving pancreatoduodenectomy, and 42 others). We evaluate the success rate according to the type of gastrointestinal anastomosis, age, and age at surgery.

Results: The success rate for reaching the biliary anastomosis (or papilla of Vater) in all 346 patients (66y.o (3–91)) was 83%. The rate in 47 patients with BA after

LDLT (12y.o (3–39)) was 57%. In the remaining 299 patients the rate was 87%. The success rate of reaching the biliary anastomosis in patients with BA after LDLT was significantly lower than other patients ($p < 0.01$). There was no significant difference between the success rate in the patients over or under 13 years at the time of ERCP (50% vs 56%, $p = 0.70$). The success rate was lower in patients who underwent initial surgery as an infant (Kasai hepatopuertoenterostomy) than in those past infancy (54% vs 88%, $p < 0.01$). When reaching the biliary anastomosis is successful, the success rate of cannulation in the patients after LDLT is high (92%).

Conclusion: The success rate for reaching the biliary anastomosis in patients with BA after LDLT is significantly lower than other patients. The age at the time of ERCP did not affect the success rate of reaching the biliary anastomosis, but the success rate was lower in patients who underwent their initial surgery as infants.

Introduction: Liver tumors such as hepatocellular carcinoma and liver metastases sometimes occur in positions in which treatment using percutaneous radiofrequency ablation (RFA) is difficult, such as the caudate lobe and surface of the left lobe. EUS-guided RFA (EUS-RFA) can offer an alternative treatment by accessing these tumors through the stomach or duodenum. To the best of our knowledge, only one report has described EUS-RFA of the liver in an animal model, using a 19-gauge EUS-FNA needle with an umbrella-shaped array at the needle.

Aims & Methods: We examined whether a novel 19-gauge RFA needle can be introduced to ablate the liver in a porcine model under EUS guidance. Two pigs were used in this study. All procedures were carried out under general anesthesia. EUSRA™ 19-gauge needles and a VIVA combo™ generator (TaeWoong Medical, Gimpo city, Korea) were used for the procedures. Three kinds of RFA needles (10-, 15-mm, and 20-mm exposed tips) were used. After the echoendoscope was advanced to the stomach, the RFA needle was inserted into the surface of the left lobe. EUS-RFA was performed at 5–40 W for 2–6 min in general mode. In each pig, three RFA needles with 10-, 15-, or 20-mm exposed tips were serially used for insertion and ablation. Subsequently, the RFA needle with the 10-mm exposed tip was used in the quadrate lobe of the gallbladder through the bulb of the duodenum.

Results: All procedures were technically successful. After the procedure, the liver of the pig was removed, and visible RFA effect were evaluated macroscopically. Histology with hematoxylin and eosin (HE) staining showed coagulative necrosis in the ablated area, corresponding with the macroscopic ablated area.

Conclusion: In this experimental study, EUS-RFA could be performed technically not only in the surface of the left lobe, but also in the adjacent to the gallbladder of the porcine liver. Further studies are required to confirm the efficacy and safety.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Small bowel varices (SBV) occur as a consequence of portal hypertension and may result in life-threatening mid-gut bleeding. First line management usually involves radiological intervention (RI) (e.g. TIPSS, stenting of occluded mesenteric veins +/- embolisation of culprit varices). In cases where RI is impossible, management options become very limited.

Aims & Methods: This case series evaluated the usefulness of DBE facilitated cyanoacrylate injection of SBV. Retrospective review of DBE facilitated cyanoacrylate injection of SBV at our institution (December 2015 to August 2016). Demographic, clinical, endoscopic and radiological findings, interventions and follow-up data were analysed.

Results: Seven DBEs were performed in 5 patients (3 women, median age: 73-years). Four patients had previous surgery (hemi-hepatectomy (n = 2); SB resection (n = 2)); one patient had a history of intra-abdominal sepsis in childhood causing portal vein thrombosis. No radiological or surgical options were deemed feasible in any case. SBV were diagnosed at capsule endoscopy and triple phase CT mesenteric angiography. At DBE, a total of 10 nests of SBV were identified

and injected with cyanoacrylate glue. There were no haemorrhagic or embolic complications but 1 patient developed an infection of a congenital urachal cyst, which was treated successfully with antibiotics. All patients underwent DBEs via the anterograde route and 1 patient required bi-directional DBE for treatment of both proximal and distal SBV and another patient required a 2nd anterograde DBE for treatment of further patent proximal SBV. At 30-day follow-up post-therapy, only 1 patient had experienced a mild recurrence of mid-gut bleeding.

Conclusion: Cyanoacrylate injection therapy of SBV at DBE appears to be a safe and effective management strategy for this condition when other first-line options are not feasible.

Introduction: The development of balloon endoscopy and capsule endoscopy has made observation of the small intestine possible in clinical practice. The usefulness of magnifying endoscopy has already been reported in observing the pharynx, esophagus, stomach and colon. A single-balloon enteroscopy (SBE) with 80x magnification has been recently developed.

Aims & Methods: The aim of this pilot study was to assess the efficacy of narrow-band imaging (NBI) magnifying findings for evaluating the severity of inflammation in small intestinal Crohn's disease (CD). The study was conducted in Showa University Northern Yokohama Hospital. We included CD patients who underwent enteroscopy with magnification from September 2013 to February 2015. NBI images and a biopsy specimen were obtained from small intestinal mucosa for CD patients with use of SBE (Y-0007, Olympus, Tokyo). Magnifying NBI was performed, and the images were evaluated by assessing visibility, increased vascularization, and the increased caliber of capillaries into three grades as follows: Normal, Visible and Irregular. Normal was indicative of inactive disease, while Visible and Irregular were indicative of acute inflammation in our study. The outcome measures included the diagnostic ability of magnifying NBI findings to distinguish active CD from inactive CD on the basis of histological activity.

Results: Twenty-four patients were enrolled. There was a correlation between magnifying NBI findings and the histological assessment (Spearman's $|r| = 0.549$). The sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of magnifying NBI findings for diagnosing acute inflammation were 88.2%, 71.4%, 88.2%, 71.4%, and 83.3%, respectively.

Conclusion: The NBI magnifying findings in the small intestinal mucosa had a correlation with histological inflammation and could help in distinguishing between active and inactive CD.

Introduction: Double balloon enteroscopy (DBE) has revolutionised the diagnosis and treatment of small intestinal conditions. However, even in expert hands, deep small bowel (SB) insertion can be challenging, especially in patients with a history of abdominopelvic surgery. Moreover, if the findings at DBE are not amenable to endoscopic therapy, a further surgical procedure is usually required to provide definite treatment. Laparoscopic-assisted DBE (LA-DBE) using a standard multi-port technique has previously only been reported in a small series of 3 patients with Peutz-Jeghers Syndrome (PJS) ¹.

Aims & Methods: This case series reports the development of LA-DBE using single-incision laparoscopic surgery (SILS) applied to a wide range of clinical indications. Retrospective review of LA-DBE procedures performed in a single tertiary centre over a 6 year period. Demographics, indication, findings, diagnosis and therapeutic interventions were recorded. Completion, complication rates and hospital length of stay were also captured.

Results: 17 procedures were performed over 6 years in 17 patients who had failed standard DBE. Mean (range) age was 40 (17-73) and 41% of patients were male. The enteroscopic approach was oral in 13/17 patients and rectal in 4/17. Laparoscopic approach was standard (multiport) in the first 4 cases, SILS was then used in all subsequent patients (13/17). The mean (range) procedure time

was 147 (84-210) mins. Indications were PJS (n=10), suspected submucosal/polypoid lesion at small bowel imaging (n=5) and obscure gastrointestinal bleed (OGIB) with vascular abnormalities seen at capsule endoscopy (n=2). In 15/17 procedures the target pathology was reached using laparoscopic assistance only and 1/17 was converted to intraoperative enteroscopy (IOE). In 1/17 the suggested pathology at magnetic resonance enterography (MRE) was not identified. Therapy was applied in 15/17 (88%) cases. 7 underwent endoscopic therapy of which 6 polypectomy and 1 ablation with argon plasma coagulation (APC). 4 required limited SB resection and 4 underwent both endoscopic polypectomy and small bowel resection for a second polyp that could not be removed endoscopically. A total number of 57 polyps were removed with the largest measuring 40mm. The range of length of surgically resected SB was 4-17cm. Diagnoses were PJS polyps (n=9), neuroendocrine tumour (NET) (n=2), PJS polyps and NET (n=1), transmural arteriovenous malformation (n=1), angioectasia (n=1), inflammatory polyp (n=1), leiomyoma (n=1), Meckel's diverticulum (n=1). Median length of stay post procedure was 2 (1-19) days. 8/17 patients were discharged at 24 hours. 3/17 patients developed complications: 1 post procedure ileus, 1 pelvic collection that was managed with antibiotics and 1 patient that was readmitted 8 days post procedure with subacute SB obstruction which resolved with conservative management.

Conclusion: LA-DBE appears to be a safe, effective and minimally invasive procedure that can be applied for the management of a wide range of small bowel pathology. A SILS approach allows all therapeutic modalities to be available as needed during the procedure, including conversion to IOE, laparoscopic small bowel resection and laparotomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0263 GASTRIC EMPTYING IN CROHN'S DISEASE - EVALUATION BY SMALL BOWEL CAPSULE ENDOSCOPY

A.M. Singeap¹, A. Trifan¹, S. Chiriac¹, I. Gîrleanu¹, T. Cuciureanu¹, C. Stanciu²

¹Gastroenterology, "Grigore T. Popa" University of Medicine and Pharmacy, Iasi/Romania

²Institute of Gastroenterology and Hepatology, Iasi/Romania

Contact E-mail Address: anamaria.singeap@yahoo.com

Introduction: The complex relationship between inflammatory bowel disease (IBD) and motility disorders of the digestive tract is a complex area of study, so far incompletely elucidated. The association between Crohn's disease and gastric emptying time modification has been relatively less studied. However, there is no single standardized method to study gastric emptying, one particular investigation that could bring direct information in this field being the small bowel capsule endoscopy (SBCE).

Aims & Methods: We aimed to study gastric emptying by small bowel capsule endoscopy in patients with suspected and confirmed Crohn's disease. We evaluated gastric passage time showed by SBCE in patients with small bowel Crohn's disease, compared to patients without IBD, investigated by SBCE (PillCam), following recognized indications, in the Institute of Gastroenterology and Hepatology of Iasi, tertiary center in North-East of Romania.

Results: 144 SBCE studies were included, 24 were cases of suspected and confirmed Crohn's disease. The mean time of gastric passage in patients with Crohn's disease was 51 ± 21.9 minutes, longer than in patients without inflammatory bowel disease, in which the mean gastric passage time was 24 ± 16.6 minutes.

Conclusion: Gastric passage time, evaluated by SBCE, is prolonged in patients with Crohn's disease compared to patients without IBD, suggesting a relationship between chronic inflammation and gastric motor disorders. Globally, the values correlated with those considered as physiological by other exploration methods. SBCE studies may provide additional data on gastric motility (and in general gut motor disorders), with special usefulness in some individual cases, as: particular symptoms or variations in the bioavailability of small bowel-released drugs.

P0264 META-ANALYSIS SHOWS THAT PURGATIVE PREPARATION INCREASES SMALL BOWEL VIDEO CAPSULE ENDOSCOPY DIAGNOSTIC YIELD AND IMPROVES THE QUALITY OF SMALL BOWEL MUCOSA VISUALIZATION

P. Gkolfakis, G. Tziatzios, G. D. Dimitriadis, K. Triantafyllou

^{2nd Dept Of Internal Medicine And Research Institute, National and Kapodistrian University of Athens, Medical School, Athens/Greece}

Contact E-mail Address: ktriant@med.uoa.gr

Introduction: The value of purgative preparation (PP) before small bowel video capsule endoscopy (VCE) remains controversial and it has been recently challenged.

Aims & Methods: The aim of this meta-analysis was to examine the effect of PP on small bowel VCE outcomes. We performed literature searches in MEDLINE and Cochrane Library to identify randomized-controlled trials (RCTs) evaluating the effect of small bowel preparation -purgative (PEG, sodium phosphate,

others) vs. clear liquids diet- on VCE outcomes. Examination's diagnostic yield (DY) was meta-analysis primary end point; small bowel visualization quality (VQ), VCE completion rate (CR), gastric (GTT) and small bowel (SBTT) transit times comprised the secondary endpoints. Study outcomes effect sizes were calculated using RevMan 5.3 software fixed or random effect model, as appropriate, and they are presented as OR[95%CI] or mean difference[95%CI], respectively. Heterogeneity was measured using the I^2 statistics. Publication bias was assessed by Funnel plots inspection and the quality of the meta-analyzed studies was assessed using the Jadad criteria.

Results: We identified 9 eligible RCTs with 12 sets of data, including 1029 subjects. They were low risk of bias trials and no publication bias was detected. As compared to clear liquids diet, PBP significantly increased small bowel VCE DY (1.44 [1.14–1.83], $I^2=39\%$). However, a sensitivity analysis that excluded studies with sodium phosphate preparation (abandoned nowadays) and PBPs different (not widely used) than PEG showed no benefit of PEG preparation over clear liquids (1.31 [0.79–2.17], $I^2=54\%$). VQ significantly improved after PBP (2.05 [1.49–2.82], $I^2=45\%$), without any significant effect on VCE CR (0.98 [0.73–1.33], $I^2=0\%$) and GTT (-1.21 [-7.21–4.79] min, $I^2=94\%$). On the contrary, VCE SBTT was statistically lower by -15.06 [-25.52–-6.61] min ($I^2=90\%$) after PBP.

Conclusion: In comparison to clear liquids diet, PBP increases small bowel VCE DY and improves VQ without affecting exam's CR. However, the positive effect of PBP on VCE DY is mainly derived from two relative small, old (2004 and 2009) RCTs and disappears if only PEG preparation studies are meta-analyzed.

P0265 INTER-OBSERVER AGREEMENT IN BROTZ CLEANING SCALES FOR CAPSULE ENDOSCOPY

M. Sousa, R. Pinho, A. Ponte, J. Silva, J. Rodrigues, J. C. Silva, A. Rodrigues, L. Proença, J. Carvalho
Gastroenterology, Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia/Portugal

Contact E-mail Address: mafalda_m_p_sousa@hotmail.com

Introduction: The diagnostic yield of capsule endoscopy (CE) depends on the adequate visualization of the mucosa. As with colonoscopy, cleaning scales should be described in the report in order to better interpret results. In 2009, Brotz et al proposed and validated 3 different cleansing scales in 40 patients.

Aims & Methods: A hundred CE videos (Mirocam®) were reviewed by 2 authors at a fixed frame rate of 100 frames per second in quadruple view (Miroview Client). The CE were evaluated according to Brotz scales: (1) Overall adequacy assessment (adequate/inadequate) (2) Qualitative scale (excellent, good, fair, poor) and (3) Quantitative scale (0–10 score, graded from 0–2 visualization of the mucosa, fluids, bubbles, bile and luminosity). The aim of this study was to evaluate the inter-observer variability of this cleaning scales. The kappa coefficient was used to calculate the inter-observer agreement in overall adequacy assessment and the intra-class correlation coefficient was used to evaluate the concordance of the qualitative and quantitative scales.

Results: In overall adequacy assessment, the quality of bowel preparation was classified as adequate by observer 1 in 67% and by observer 2 in 73%, with an inter-observer kappa index of 0.76 ($p < 0.001$) suggesting strong agreement. In the qualitative scale, most of the bowel preparations were considered reasonable (40% observer 1 vs 36% observer 2), with an intra-class coefficient of 0.89 ($p < 0.001$). In the quantitative scale, the mean score of the two observers was 6.5 and 6.7, resulting in an intra-class agreement of 0.78 ($p < 0.001$).

Conclusion: The optimization of quality of bowel preparation and the diagnostic yield of the CE requires, first, a well-validated cleaning scale. Brotz's rating scales have strong inter-observer agreement. The qualitative scale is easier to apply and has better inter-observer agreement, so the authors propose that it should be used routinely in the CE report.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Capsule endoscopy (CE) is the prime mode of investigation for small bowel (SB) pathology. However, as an entirely visual medium it depends

heavily on image quality. The definition of optimal image quality remains unstandardised between studies and poses significant limitations to the quality of study reporting. As yet, there is no widely-accepted or integrated method for scoring SB cleanliness during CE reporting. This pilot study aims to quantify the image properties contributing to adequate visualisation quality in CE images.

Aims & Methods: Five clear images of SB pathology were obtained using MiroCam® (Intromedic, South Korea), image resolution 320×320 pixels(px): P1 and P2 angioectasias, ulcer, aphtha and polyp. Each image was processed using GIMP2 image editing software (www.gimp.org) for 3 parameters: (1) opacity (opacity filter matched in colour to commonly-seen SB contents, 10–90% in 10% increments), (2) blur (Gaussian blur, radius 1–10px), (3) contrast (-50% to 50% in 10% increments). Gaussian blur was used to simulate the effects of rapid capsule movement as well as to affect image definition. A set of 5 original and 190 edited images was obtained. A web-based survey was created using Google Forms and 9 expert CE readers were asked to indicate whether each image was adequate or not for diagnosis. The order of images was randomised for each reader. For each type of pathology, we determined the threshold of image quality which was deemed adequate for diagnosis.

Results: For image opacity, both angioectasias and the polypoid lesion were adequately visualised below 40% opacity whereas the threshold was lower for both the ulcer and aphtha (10% opacity). Increasing blur radius significantly impacted the acceptability of images for reaching a diagnosis with confidence; for most images, blur radius 3px was the threshold for adequate visualisation but even 1px of blur radius decreased the visualisation quality of the aphtha image. The aphtha image was also affected the most by decreased contrast; conversely the ulcer was deemed more inadequately visualised with higher contrast. The other images were generally adequately visualised at $\pm 10\%$ contrast. Results are detailed in the table below.

Percentages of respondents finding each image adequate

Image parameter	P2 Angioectasia	P1 Angioectasia	Ulcer	Aphtha	Polypoid lesion
Original image	100%	100%	100%	88.9%	100%
Opacity					
10% opacity	100%	100%	100%	77.8%	100%
20% opacity	100%	100%	88.9%	77.8%	100%

2px	100%	100%	100%	77.8%	100%
3px	100%	100%	100%	77.8%	100%
4px	77.8%	100%	100%	77.8%	77.8%
5px	33.3%	66.7%	100%	22.2%	44.4%
6px	33.3%	55.6%	88.9%	33.3%	11.1%
7px	22.2%	22.2%	55.6%	25%	0%
8px	11.1%	22.2%	33.3%	0%	0%
9px	22.2%	0%	33.3%	11.1%	0%
10px	0%	0%	33.3%	0%	0%
Contrast					
-50%	66.7%	77.8%	66.7%	0%	88.9%
-40%	100%	85.7%	55.6%	11.1%	100%
-30%	100%	100%	88.9%	11.1%	100%
-20%	100%	100%	88.9%	22.2%	100%
-10%	100%	100%	100%	44.4%	100%
+10%	88.9%	100%	100%	88.9%	100%
+20%	100%	100%	75%	100%	77.8%
+30%	100%	100%	62.5%	88.9%	66.7%
+40%	100%	100%	66.7%	88.9%	66.7%
+50%	66.7%	55.6%	11.1%	88.9%	66.7%

Conclusion: This pilot study shows that image quality is a defining factor in accurate diagnosis in CE. Image quality is commonly affected by the opacity of luminal fluid/residue, and the quality of imaging delivered by the CE system. More subtle mucosal lesions such as apthae are affected more by decreased contrast. Interestingly, a relatively high level of image opacity can be tolerated by CE readers whereas blurriness seems to have a greater effect on visualisation quality and reviewer confidence in the diagnosis. The effects of these aspects in combination merit further investigation.

Introduction: Inflammatory bowel diseases (IBDs) are chronic inflammatory diseases that may affect the whole gastrointestinal (GI) tract, mainly the small bowel and colon. Endoscopic evaluation of these parts is essential to assess disease extent and severity. The small bowel colon capsule endoscopy (SBC-CE) system is a new system composed of a two-headed capsule with a panoramic field of view and adaptive frame rate, customized for complete coverage of IBD lesions in the entire bowel, data recorder and new disease specific software, allowing assessment and follow-up over time of disease severity and extent.

Aims & Methods: The aim was to evaluate SBC-CE system functionality in suspected or established IBD (Crohn's disease [CD] and Ulcerative Colitis [UC]) patients. This was a prospective 5 center feasibility study assessing the performance of the new capsule and software. Subjects enrolled into the study ingested the new capsule after standard bowel preparation plus boosts. Contraindications for its use included obstruction, dysphagia or swallowing disorders, pacemakers etc. GI patency was assured using the patency capsule. The primary endpoint was successful procedure in terms of video creation and report generation in accordance to the video reading methodology. Secondary endpoints were subjective coverage of SBC, subjective duration of total and segmental reading time, over all video quality and occurrence/severity of adverse events. **Results:** 68 patients were screened, of which 54 were enrolled and 49 ingested the capsule (14 patency failure, 5 withdrew consent). Mean age was 40.1 years, 51% were males. 69% of patients had established CD, 10% UC and 21% suspected CD. The disease was active in 62% of known IBD patients. One patient who underwent extensive colon resection was excluded from all colon analyses. Overall cleansing was regarded good or excellent in 96% of patients. All 49 videos met the primary endpoint, i.e. video was created and report generated with all included information and in accordance to the video reading methodology. All capsules reached the rectum/toilet with no retention, most while photographing. Gastroenterologists were satisfied with small bowel coverage 6.6 ± 0.6 (mean \pm standard deviation) and colon coverage of 6.0 ± 1.2 in a scale of 1–7 (unconfident to confident), image quality 6.1 ± 0.8 (1–7, poor to excellent), and subjective video reading time 3.9 ± 1.4 (1–7, very short to very long). There were 4 patients with small interferences related to video continuity (gaps).

Conclusion: The new SBC capsule is a friendly, minimally invasive capsule allowing complete evaluation of the entire gut of IBD patients. The system may be used to assess disease severity and extent and for follow up of IBD patients.

P0268 THE UTILITY OF A NOVEL TRANSPAPILLARY DILATION TECHNIQUE WITH A DIATHERMIC CATHETER FOR SEVERE MAIN PANCREATIC DUCT STRICTURE DUE TO CHRONIC PANCREATITIS

S. Kato, M. Kuwatani, R. Sugiura, I. Sano, K. Kawakubo, N. Sakamoto
Gastroenterology And Hepatology, Hokkaido University Hospital, Sapporo/Japan

Contact E-mail Address: shinchan1231@gmail.com

Introduction: Transpapillary dilation for severe main pancreatic duct (MPD) stricture is sometime difficult and diathermic dilation is now getting attention as a salvage technique for severe stricture; however its efficacy and safety remains unclear.

Aims & Methods: To evaluate the efficacy and safety of a novel transpapillary dilation technique with a diathermic catheter for severe MPD stricture due to chronic pancreatitis. Between April 2011 and March 2017, 143 patients with chronic pancreatitis underwent endoscopic transpapillary stent placement for MPD. MPD dilatation was indicated in 18 patients, and diathermic dilation was required in nine patients. We evaluated (1) the patients' characteristics, (2) procedure characteristics, (3) clinical outcomes, (4) adverse events.

Results: (1) Six patients were men and three were women (mean age, 50.1 years). Alcohol 8, unknown 1. The strictures were in the head of pancreas: 8, body: 1.

The mean length of stricture was 20.2 mm (range, 10–30.8). The mean MPD diameter on the distal side of stricture was 6.2 mm (range, 3–12.7). Five patients (55.6%) among them had no former procedure for MPD including stenting. (2) A wire-guided 6Fr diathermic catheter with 30 W power was used for all cases. All cases underwent diathermic dilation as salvage procedure subsequent to conventional dilation. One to 7 diathermy procedures (mean 2.9) were required to pass through each stricture. (3) Passage of the diathermic catheter and stent placement was successful in all patients (100%). After diathermy and stent placement, 8 (88.9%) showed improvement of clinical symptoms (abdominal pain). Recurrence of stricture was observed in 2 patients (22.2%). One of them needed diathermic dilatation again. (4) Two adverse events (22.2%) were observed and both of them were mild pancreatitis. Multiple diathermy procedures (6 times and 4 times, respectively) and relatively long duration of total diathermy (39 sec. and 25 sec. respectively) were observed in cases with pancreatitis.

Conclusion: Transpapillary diathermic dilation is a relatively safe and effective salvage procedure for severe MPD stricture due to chronic pancreatitis. However, care should be taken in cases that require multiple times and long duration diathermy procedures because of a risk of pancreatitis.

P0269 CLINICAL OUTCOMES OF BILIARY DRAINAGE DURING NEOADJUVANT CHEMOTHERAPY/CHEMORADIO THERAPY IN MULTICENTER PANCREATIC CANCER STUDIES: METAL STENT VERSUS PLASTIC STENT

M. Kuwatani, T. Nakamura, T. Hayashi, Y. Kimura, M. Ono, K. Yamakita, T. Goto, K. Takahashi, M. Motoya, H. Maguchi, S. Hirano, N. Sakamoto

Hokkaido Pancreatic Cancer Study Group (HOPS), Sapporo/Japan

Introduction: It is controversial whether preoperative biliary drainage is necessary or not in patients with pancreatic head cancer. Meanwhile, some reports indicated the necessity of biliary drainage in the case of severe jaundice and neoadjuvant chemotherapy/chemoradiotherapy (NAC/NACRT).^(1, 2)

Aims & Methods: We aimed to clarify clinical outcomes of biliary drainage with metal stent (MS) or plastic stent (PS) during neoadjuvant chemotherapy/chemoradiotherapy in patients with pancreatic cancer who underwent subsequent pancreatoduodenectomy. Patients and methods: From Oct. 2013 to Apr. 2016, 96 patients with pancreatic cancer were registered to NAC (S-1 [80 mg/m², twice daily], 2 cycles) or NACRT (a total dose of 50.4 Gy in 28 fractions and S-1 [80 mg/m², twice daily on radiation day alone] for 1 month and subsequent chemotherapy with gemcitabine for 3 cycles) studies conducted by Hokkaido Pancreatic Cancer Study Group (HOPS) (UMIN000013031/UMIN000012293). Of them 29 patients who underwent biliary drainage with a MS or PS before NAC/NACRT and subsequent pancreatoduodenectomy were analyzed. Examination items were 1) patient characteristics, 2) preoperative recurrent biliary obstruction (RBO: stent obstruction, migration, tumor ingrowth/overgrowth) occurrence rate, 3) NAC/NACRT delay or discontinuation rate, 4) surgical time, volume of hemorrhage, and postsurgical adverse event rate.

Results: 1) The median of age was 67 years (50–83); M/F ratio was 13/16. The distribution of pathological stages (based on the General Rules for the Study of Pancreatic Cancer by the Japan Pancreas Society, 6th edition) included 2 patients with stage I, 1 with II, 13 with III and 13 with IV disease. NAC and NACRT were performed for 14 and 15 patients, respectively. MS and PS were used in 17 and 12 patients, respectively. The distribution of used MS and PS diameters included 17 patients with 10 mm, 9 with 7F, 2 with 8.5F and 1 with 10F. 2) RBO occurred in 5.9% of patients in the MS group and 83.3% in the PS group with a significant difference ($p < 0.0001$). The RBO included the following conditions: stent obstruction, 1 patient in the MS group and 8 in the PS group; stent migration, 0 in the MS group and 2 in the PS group. 3) NAC/NACRT delay was observed in 35% of patients in the MS group and 50% in the PS group. NAC/NACRT discontinuation was observed in 12% of patients in the MS group and 17% in the PS group. There were no significant differences between both groups in rates of delay and discontinuation of the neoadjuvant therapies. 4) The operative time of the MS group was significantly longer than that of the PS group (610 min vs 495 min, $p = 0.036$), while blood losses (870 ml, the MS group vs. 658 ml, the PS group) and postoperative morbidity rates (35%, the MS group vs. 33%, the PS group) of both groups were not significantly different.

Conclusion: MS is better than PS from the viewpoint of the prevention of RBO. Meanwhile, MS was similar to PS in the postoperative outcome. For standardization of biliary stenting during NAC/NACRT, further large-scale and prospective studies are needed.

P0270 OUTCOME OF ENDOSCOPIC REINTERVENTION FOR MALIGNANT HILAR OBSTRUCTION TREATED BY STENT-IN-STENT DEPLOYMENT

D.H. Kang, H.W. Kim, C.W. Choi, S.J. Kim, J.S. Lee, C.W. Yeo, H.S. Nam, S.H. Choi, J.H. Ko, B.J. Kwon, D.G. Ryu

Introduction: Endoscopic biliary decompression is widely used for advanced hilar cholangiocarcinoma. Bilateral stenting has become more feasible with more experienced endoscopists and the development of new devices. However, stent dysfunction develops in 3% to 45% because of tumor ingrowth, overgrowth, or debris as disease progresses. Endoscopic reintervention is difficult and complex with worsening bile duct strictures. The present study aimed to evaluate a suitable reintervention procedure for stent malfunction after stent-in-stent (SIS) deployment for malignant hilar obstruction.

Aims & Methods: From September 2009 to June 2016, a total of 52 patients who underwent endoscopic bilateral stenting at Pusan National University Yangsan Hospital were enrolled in this study. Among them, 20 patients who underwent reintervention due to stent malfunction were analyzed. Reintervention was performed endoscopically or percutaneously. Technical and functional success rates were evaluated retrospectively.

Results: Technical and functional success rates of endoscopic reintervention were 83% (10/12) and 80% (8/10), respectively. Endoscopic bilateral and unilateral reintervention success rates were 75% (6/8) and 100% (4/4), respectively. Functional success was observed in 8 out of 10 patients (80%) who achieved technical success. For bilateral reintervention, either plastic or plastic and metal stents were used. PTBD was performed in 8 patients because of duodenal stenosis (2 patients) and poor conditions.

Conclusion: Endoscopic reintervention could be considered in the case of stent malfunction and fair patient conditions after SIS placement for malignant hilar obstruction. Decisions regarding bilateral or unilateral drainage and types of stents should depend on the conditions of the disease and the patient.

Introduction: Endoscopic ultrasound-guided biliary drainage (EUS-BD) has been regarded as an effective alternative in cases of endoscopic retrograde cholangiopancreatography (ERCP) failure or inaccessible papilla. However, EUS-BD for right intrahepatic duct obstruction (EUS-BDR) remains challenging, although recent studies showed promising result. The aim of current study was to evaluate the feasibility and long-term outcomes of EUS-BD with transmurally covered metal stents for right intrahepatic duct obstruction.

Aims Methods: In this single-center, retrospective study, a total of 24 consecutive patients who underwent EUS-BDR after failed ERCP were enrolled. The patients consisted of 12 cases of benign strictures and 12 cases of malignant strictures. The biliary stents used in this study was covered metal stent with antimigration properties (fully covered metal with anchoring flaps or partially covered metal stent with anchoring flaps). The technical success rate, clinical success rate and adverse events were evaluated.

Results: The target bile duct was right anterior in 6 patients and right posterior segmental duct in 18 patients. Among them, percutaneous transhepatic biliary drainage assisted EUS-BDR was performed in three patients. The technical and clinical success rate was 95.8% (23/24) and 95.6% (22/23). Mean diameter of right intrahepatic duct was 6.5 (4–30) mm. A fully covered metal stent was used in 22 patients and partial covered stent in 2 patients. Early adverse events developed after EUS-BDR in 2 patients (1 case of cholangitis and 1 case of liver abscess in patients with malignant biliary stricture). Late adverse event that stent occlusion was observed in 5 patients. Neither proximal peritoneal stent migration nor spontaneous distal stent migration was observed during follow-up periods. The stent patency duration was 275.2 (147.8–402.7) days. During follow-up period, stent revision via fistula tract was successful and additional percutaneous biliary drainage for right intrahepatic duct obstruction was not required in all patients who achieved clinical success.

Conclusion: EUS-BD using transmurally covered metal stent with antimigration properties for right intrahepatic duct obstruction may be technically feasible, effective and relatively safe for both benign and malignant biliary strictures by expert hands. Furthermore, the route of hepaticoduodenostomy created by covered metal stent was durable and endoscopically easily managed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0272 UTILITY OF EUS-GUIDED HEPATICOGASTROSTOMY WITH ANTEGRADE STENTING FOR MALIGNANT BILIARY OBSTRUCTION OF ERCP INABILITY

H. Imai, M. Takenaka, M. Kudo
Gastroenterology And Hepatology, Kindai University, Osakasayama/Japan

Contact E-mail Address: codenamenengan1023@gmail.com

Introduction: Recently, EUS-guided biliary drainage (EUS-BD) techniques such as EUS-guided choledochoduodenostomy (CDS), hepaticogastrostomy (HGS) antegrade stenting (AGS) and rendezvous stenting (RVS) are useful for biliary drainage methods after unsuccessful ERCP. Among these procedures, CDS and RVS require the echoendoscope reaching duodenum. Therefore, HGS or AGS are indicated in cases with inaccessible duodenum. However, HGS is associated with a higher risk of adverse events, compared with the other methods. When the stent dysfunction occurs, re-intervention is more difficult after AGS alone than after HGS or CDS. Thus, we started to add AGS during HGS in a single session from Sep. 2011.

Aims & Methods: The aim of this study to assess the efficacy and safety of HGS combined with AGS for malignant biliary stricture-induced obstructive jaundice. Between Jan. 2006 and Dec. 2014, ERCP was attempted in patients with obstructive jaundice, which was successful in 641 patients and impossible in 154 patients (101 cases due to post-surgical altered anatomy or duodenal stenosis, 53 cases due to difficult cannulation). A total of 145 patients received EUS-BD; HGS and HGS with AGS were attempted in 42 (Group A; from Jan 2006 to Aug 2011) and 37 patients (Group B; from Sep 2011 to Dec. 2014), respectively. The assessed outcomes were the technical and functional success rates, adverse events rate, re-intervention rate, procedure time, overall patient survival time, and time to stent dysfunction or patient death. In Group A, technical success of HGS was defined as successful stent deployment between the left hepatic bile duct and the stomach. In Group B, technical success of HGS with AGS was defined as successful stent deployment at bile duct stricture (AGS) in addition to success of HGS. Functional success for obstructive jaundice was defined as a decrease in bilirubin levels to <40% of the pretreatment value within 2 weeks. The incidence rate of adverse events such as peritonitis, bile leakage, bleeding, stent migration, and stent occlusion was assessed. The re-intervention was defined as any endoscopic, surgical, or percutaneous procedure that was required to improve symptoms after placement of the stent. Time to stent dysfunction or patient death was defined as the time from stent deployment to biliary re-intervention due to stent dysfunction or the time from stent deployment to patient death. Groups A and B were compared in terms of the technical success, clinical success, and adverse events outcomes, the procedure time, the overall patient survival and time to stent dysfunction or patient death. For subgroup analysis in patients who underwent chemotherapy the Groups A and B were compared in the overall patient survival, time to stent dysfunction or patient death and adverse events rate.

Results: Technical success rate of Group A was significantly higher than Group B (97.6 vs 83.8%, $p=0.03$). The two groups were comparable for the functional success rate (90.2% vs 90.3%), although the rate of adverse events tended to be higher in Group A than in Group B (26.1% vs 13.5%, $p=0.10$). The re-intervention rate tended to be higher in Group A than in Group B (16.7% vs 8.1%, $P=0.25$). Groups A and B did not differ significantly in terms of median overall patient survival (75 days vs. 61 days, $P=0.70$), and median time to stent dysfunction or patient death (68 vs 63 days, $P=0.08$). In patients who underwent chemotherapy, there were no difference in the overall patient survival time (121 vs 157 days, $p=0.08$) between the two groups although the time to stent dysfunction or patient death was significantly shorter in Group A than in Group B (71 vs 95 days, $p=0.02$).

Conclusion: Technical success rate of HGS with AGS was lower than HGS, although HGS with AGS is superior to HGS in terms of stent patency in patients receiving chemotherapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0273 EUS-GUIDED GALLBLADDER DRAINAGE REDUCES LATE ADVERSE EVENT AND NEED FOR RE-INTERVENTION COMPARED WITH PERCUTANEOUS CHOLECYSTOSTOMY IN PATIENTS WHO ARE NOT ELIGIBLE FOR SURGERY

D.H. Cho, S.S. Lee, D. Oh, T.J. Song, D.H. Park, D.W. Seo, S.K. Lee, M. Kim
Gastroenterology, Asan Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: dhcho81@daum.net

Introduction: Endoscopic ultrasound guided transmurally gall-bladder drainage (EUS-GBD) with covered metal stent has become increasingly used to treat patients with acute cholecystitis who are not a candidate for surgical treatment. However, there are limited data comparing long-term outcomes of EUS-GBD with covered metal stent and conventional percutaneous cholecystostomy.

Aims & Methods: This is a single-center, retrospective study comparing long-term outcomes of EUS-GBD and percutaneous cholecystostomy in patients who are not suitable for cholecystectomy. Data about the patient who underwent EUS-GBD for acute cholecystitis is obtained from prospective collected EUS database of our institute. In percutaneous cholecystostomy group, electrical medical record of patients who underwent percutaneous cholecystostomy was reviewed and analyzed. Demographics and procedure related outcomes including early, late adverse events and need for re-intervention in each group was compared.

Results: A total of 181 patients (74 in EUS-GBD group and 107 in percutaneous cholecystostomy group) were enrolled in this study. The cause of cholecystitis and ASA class were similar in both groups. The technical/clinical success rate was 100%/98.6% in EUS-GBD group and 99.1%/97.2% in percutaneous cholecystostomy group ($P=0.591$ and 0.646) respectively. Early adverse event rate was also similar between two groups (6.8% in EUS-GBD group vs. 15.0% in percutaneous cholecystostomy group, $P=0.103$). However, late adverse events including migration of stent or dislodgement of drainage tube, stent or tube occlusion, tract inflammation around percutaneous tube, bile leakage and recurrence of cholecystitis was more frequently observed in percutaneous cholecystostomy group (5/74 in EUS-GBD group and 21/107 in percutaneous cholecystostomy group, $P=0.017$). Percutaneous cholecystostomy tube was indwelled for

median 20 days (14.0–45.2) after the procedure. A total of 7 patients in EUS-GBD group received re-intervention for adverse events and all of them were conducted successfully. The patients who underwent percutaneous cholecystostomy more frequently received re-intervention for adverse event or recurrence of cholecystitis after removal of cholecystostomy. (7/74 vs. 23/106, $P=0.041$).

Conclusion: EUS-GBD and percutaneous cholecystostomy were both effective interventions to urgent drainage for acute cholecystitis. However, EUS-GBD might be beneficial than percutaneous cholecystostomy in long term management for the patients with acute cholecystitis who are not suitable for cholecystectomy.

P0274 ENDOSCOPIC TREATMENT OF ANASTOMOTIC BILIARY STRICTURES IN PATIENTS WITH LIVING DONOR LIVER TRANSPLANTATION: MULTIPLE PLASTIC STENTS VS FULLY COVERED SELF-EXPANDABLE METALLIC STENTS

A.T. Eminler, E. Parlak, A. S. Koksall, B. Toka, M. I. Uslan
Gastroenterology, Sakarya University, Sakarya/Turkey

Contact E-mail Address: drerkanparlak@gmail.com

Introduction: The “fully covered self-expandable metallic stents”(fcSEMSs) were found to be non-inferior to multiple plastic stents (MPSS) for the treatment of anastomotic biliary strictures after orthotopic liver transplantation (OLT). However, there is scarce data about their efficacy in the treatment of anastomotic biliary strictures after living donor liver transplantation (LDLT). We aimed to compare the efficacy of fcSEMS and MPSS for the treatment of anastomotic biliary strictures after LDLT.

Aims & Methods: We retrospectively analyzed the data of LDLT patients with duct-to-duct anastomotic biliary strictures who underwent endoscopic treatment at our center within the last 3 years. FcSEMSs were inserted in 23 patients (13 men, mean age: 53 ± 10 years) (Group-1). Thirty-two patients (23 men, mean age: 51 ± 9 years) were managed with MPSS insertion (Group-2). In Group-1, secondary branch ducts were prophylactically drained with insertion of plastic stent(s) in order to prevent the development of cholangitis due to their occlusion. FcSEMS and plastic stent(s) were left in place for 2 months. In Group-2, maximum number of plastic stents were inserted and replaced every 3 months. Patients with a follow-up duration of at least 3 months after stenting were included to the study. Primary end-points were the number of endoscopic procedures and the time required for stricture resolution. The secondary end-point was the recurrence rate of the stricture.

Results: FcSEMSs were successfully deployed in all cases. The diameter of the Fc-SEMSs were 10 mm in 22 patients and 8 mm in 1 patient. The length of the Fc-SEMSs were 8 cm in 13 patients, 10 cm in 8, and 6 cm in 2 patients. Secondary branch ducts were prophylactically drained with a single plastic stent in 12 patients, 2 plastic stents in 8 patients, and 3 plastic stents in 3 patients. The median number of endoscopic procedures was 2 (2–4) in Group-1 and 4 (2–9) in Group-2 ($p < 0.001$). The time required for stricture resolution was shorter in Group-1 (65.7 ± 18.2 days) than in Group-2 (240.1 ± 183.4 days) ($p < 0.001$). The recurrence rates were similar in Group-1 (17.4%) and Group-2 (15.6%) ($p=0.57$) after a follow-up period of 515 ± 290 and 378 ± 86 days, respectively.

Conclusion: FcSEMS insertion is an effective method for the treatment of anastomotic biliary strictures after LDLT, with a less number of endoscopic sessions and a shorter stenting duration required for the resolution compared to MPSS.

Introduction: Colorectal stenting is a minimally invasive, reliable and effective intervention in patients with malignant colonic obstruction, associated with a low complication rate and mortality compared with traditional surgical treatment. One of the actual problems associated with colorectal stenting is the recurrence of symptoms of obstruction. The most common cause is migration of covered stents and ingrown of uncovered stents^{1, 2, 3}. The aim of our study was to compare the results of the use of stents of a new design, the development of which was aimed at preventing these complications.

Aims & Methods: We aimed to evaluate the results of the use of stents of the new design (double uncovered and dual coated colorectal stents). Between December 2012 and April 2017, 77 patients with colonic malignant obstruction were implanted 78 stents (39 bare, 39 covered EGIS Colorectal stent, S&G Biotech Inc., South Korea). A double uncovered stent has a two-layer structure created by crossing two stents, resulting in a smaller cell size. Such a design theoretically can prevent migration and reduce tumor ingrowth. The covered stent is coated with a silicone membrane between two layers of a metal mesh with distal, uncoated ends of 5 mm each. The role of the membrane is to prevent the ingrowth of the tumor, localization and uncoated edges prevent the migration of the stent. All interventions are performed by one operator using endoscopic and radiological control. Groups of patients using coated and uncovered stents were comparable in terms of sex, age, duration of symptoms of obstruction, and stenosis localization. The reasons for the obstruction were primary tumors of the

colon 97.4%. The localization of the tumor is most common in the sigmoid colon - 54% patients. Palliative care was provided to 43(55.8%) patients, «bridge to surgery» – 34 (44.7%) patients.

Results: Clinical success was achieved in 74 (96.1%) patients. In two cases, when using covered stents, the symptoms of obstruction could not be regressed, the patients were operated. In one case, 18 hours after stenting with an uncovered stent, was diagnosed perforation due to obstructive colitis. The average stay in hospital after the intervention was 3 days; the difference between the groups was statistically insignificant. 30 day mortality was 5.2%, the difference was statistically insignificant. Complications were detected in 3 patients in the group of bare stents and in 1 patient in the group of covered stents, the difference was statistically insignificant. One patient with the carcinoma of a sigmoid colon with invasion in anterior abdominal wall noted the appearance of subcutaneous emphysema without pneumoperitoneum, in 3 (3.8%) patients the occlusion of the stents. The reasons for obstruction of the stents were occlusion by the obstruction from stool (fibers) on the 83rd day (the endoscopic recanalization was performed) and tumor overgrowth by 165 days (endoscopic «stent-in-stent» placement). In one patient, the cause of occlusion is unknown, operated in another hospital 34 days after stenting - a transversostomy was performed, died on the 4th day after the operation.

Conclusion: Double bare and double covered colorectal stents were feasibility and efficacy for relieving malignant colorectal obstruction. Reobstruction was rare complication and not different in both groups stent groups. Necessary to continue to research for the accumulation of material from other centers.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic therapy has been emerged as alternative treatment to bariatric surgery for reducing weight. We developed a new endoscopic gastrointestinal (GI) bypass stent and designed a preclinical study to assess the safety in a porcine model.

Aims & Methods: The aim of this study is to investigate the feasibility of our GI bypass device in animal. Before animal study, we performed an experimental study for durability test under simulated intestinal fluid flow. And next, we performed an animal study with 10 Yorkshire pigs. The stents were placed on pylorus with fixation by clippings or on duodenal bulb without fixation. Follow up endoscopy was done per one week after implantation. After they were sacrificed, gastric, duodenal, and jejunal tissues were harvested and examined for histologic assessment of any device or procedure-related effects.

Results: Our new GI bypass stent showed a good durability in simulated solution flow. No breakage or migration of stent occurred under continuous water flow in simulation system setting. In animal study, the mean starting weight was 30.1 ± 1.5 kg. Delivery of the implant took an average of 19.8 min (range, 11–32 min) in pylorus stent group and 11.2 min (range, 6–18 min) in duodenal bulb stent group. It required an average clipping time of 10.8 min (range, 8–14 min). Followed for stent migration after implantation, the mean patency duration was 1.5 ± 0.7 weeks. One pig was died due to small bowel perforation and peritonitis after stenting. In histologic finding, there were moderate degree of mucosal erosions, but no definite ulceration on pylorus and duodenum.

Conclusion: New GI bypass stent has a good physicochemical properties in simulated intestinal system. In animal, all stents were successfully deployed but migration at short term follow-up were shown in this study. Proper fixation method such as endoscopic suture machine and modification of stent would be required.

Introduction: Dysphagia may occur due to benign pharyngo-esophageal strictures, often requiring repeated dilations. The aim of the study was to access long-term efficacy of pharyngo-esophageal dilations due to anastomotic or post-radiation strictures.

Aims & Methods: Retrospective study of patients suffering of dysphagia due to radiation (Group I) or anastomotic (Group II) induced pharyngo-esophageal benign strictures submitted to endoscopic dilation between January 2013 and December 2015. The long-term efficacy (after a minimum follow-up of 12 months) was prospectively assessed by telephone interview by: a) dysphagia improvement or b) resolution (grade 0 or 1 of Mellow-Pinkas scale), c) absence of further dilations and d) absence of PEG. Additional therapy (PEG or prosthesis placement, electroincision or surgery) was considered inefficiency criteria and these patients were excluded from the interview. Post-procedure complications were registered. Efficacy predictive factors were assessed.

Results: Forty-eight patients (296 dilations) were evaluated (median of 4 dilations/patient): 85% were male, mean age of 62 years-old, 60% belonging in Group I. The median interval between dilations was of 5 weeks. Pre-dilation dysphagia Mellow-Pinkas score and luminal calibre were 3 ± 1 and 7 ± 2 , 8 mm, respectively. Twenty-eight patients (out of 30 live patients non-submitted to additional therapies) answered to the interview: a) 96% had improved, b) 60% had resolved dysphagia, c) 75% didn't need further dilations, d) 89% without PEG, with a combined efficacy of 58, 3%. Nine patients required additional therapy (6 PEGs, 2 prosthesis, 1 electroincision). Overall, 17 (out 21 with previous PEG) were able to resume feeding per os. Fifteen and 29% presented Kochman criteria for refractory and recurrent strictures, respectively. There were two post-procedure complications (<1%): one deep laceration and one pharyngo-esophageal fistula. Overall mortality was of 20% (10 patients died of non related procedure causes). Mean follow-up was 29, 2 ± 11 , 2 months. Number of dilations and initial lumen calibre were significant predictors of combined efficacy in the univariate analysis; radic strictures predicted a greater final dysphagia in the uni- and multivariate analysis; recurrent/refractory stenosis didn't significantly predict global efficacy.

Conclusion: Our dilation programme presents relevant benefit to these patients and a low rate of complications. Patients with post-radiation strictures presented a worse prognosis. Even though retrospective we present the longest follow-up and focusing not only in objective measures but also in patient perception of relief.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Current guidelines favour the use of bleeding stents over balloon tamponade for refractory esophageal variceal bleeding (EVV). However, data on the efficacy of and outcomes after the placement of an SX-ELLA “Danis-Stent” are limited.

Aims & Methods: Retrospective multicenter study including cirrhotic patients receiving Danis-Stents for massive/refractory EVV at 4 tertiary care centers in Vienna (Medical University of Vienna, Krankenhaus Rudolfstiftung, Wilhelminenspital and Krankenhaus Hietzing). Rates of bleeding control (5 days), bleeding-related mortality (6 weeks) and overall mortality were assessed.

Results: Among 35 patients, 13 patients had an unsuccessful endoscopic band ligation (EBL) prior to Danis-Stent placement. Danis-Stent controlled EVV in 80% (28/35) of patients. In the remaining uncontrolled bleeders (n=7), 3 patients had subsequent EBL, while in 3 patients the stent had to be replaced and 1 patient received a Linton-tube. Among these patients with initial Danis-Stent failure, 4 died of uncontrollable EVV, 2 experienced early bleeding-related mortality, and only 1 patient achieved a successful long-term bleeding control. In total, early-rebleeding within 6 weeks occurred in 14.3% (including n=1 while Danis-Stent was still in place and n=5 after Danis-Stent was removed): 3 underwent EBL, 1 received a subsequent Danis-Stent, and 1 patient was treated with a Sengstaken tube. Moreover, among n=14 patients without early rebleeding within 6 weeks, only n=3 (21.4%) showed rebleeding later during follow-up: n=2 patients were treated with a Sengstaken-Tube (both experienced bleeding-related death) and n=1 had another Danis-Stent placed (successful bleeding control). Only n=11 (31.4%) patients did not experience any rebleeding after Danis-Stent removal, while n=8 patients died with the Danis-Stent in situ. Notably, no “early-TIPS” was performed in this study, but 4 (11.4%) received an elective TIPS during follow-up. N=6 patients (17.1%) died due to uncontrolled bleeding (≤ 5 days) and n=10 died within 6 weeks (bleeding-related mortality: 28.6%). Overall, n=22/35 (62.9%) patients died. The median survival was 10.5 (IQR82) days after Danis-Stent placement. Median Danis-Stents dwell time was 5 (range: 0–13) days. The most common adverse events were stent dislocations (n=13; 37.1%), while ulcers/necrosis of the esophageal mucosa were seen in only 4 (11.4%) patients.

Conclusion: Danis-Stent controlled refractory/massive EVV in 80% of patients but bleeding-related mortality was as high as 45%. While stent dislocations are frequent, ulcers/necrosis of the esophagus were rare with a dwell time of 5 days. The implementation of an early-TIPS strategy might improve the overall outcome after Danis-Stent placement.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0279 A NOVEL METHOD WITH SELF-EXPANDABLE METALLIC STENT FASTENED WITH CLIP AND LOOP FOR THE TREATMENT OF ANASTOMOTIC STRICTURE AFTER SUBTOTAL GASTRECTOMY

J.K. Kang, S.G. Lim, K.M. Lee, S.J. Shin, B.M. Yoo, J. Kim, C. Noh

Introduction: Benign anastomotic strictures are common adverse events of gastrointestinal tract surgery. And, they are difficult to be managed conservatively. The first choices of treatment of anastomotic strictures are balloon dilatation and bougienage. But, they are requiring repeated sessions. Self-expandable metallic stent (SEMS) placement has continuous expanding effect for a long period. But, It has problem of frequent stent migration, because of slow stent expanding, 2–3 days. Therefore the new method to inhibit stent migration is needed for more successful management of anastomotic stenosis.

Aims & Methods: The aim of this study was to evaluate the clinical feasibility of new method to inhibit stent migration in postoperative anastomotic stricture. From May 2013 until February 2015, patients with benign anastomotic stricture after subtotal gastrectomy were enrolled at a single tertiary referral hospital, prospectively. The Niti-S ComVi pyloric stents (Taewoong Medical, Korea), double-layered covered, were inserted. We made two nylon thread loops at the proximal bared section of the stents. After stent placement, stent fastening with loop and clip method was performed. Patients’ symptoms and oral intake were assessed once or twice a week with a clinical check-up or telephone interview. After two weeks, the loop and stent removals were done.

Results: In all patients, stents were successfully inserted and patency were confirmed (technical success rate, 100%). The obstructive symptoms were subsided in 12 of 13 patients (clinical success rate, 92.3%). Stent migration was found in a follow-up endoscopy on 14 days (1 of 13, 7.7%). Anastomotic stenosis occurred in two patients 14 and 20 days after stent removal. However, obstructive symptoms were relieved by stent reinsertion.

Conclusion: The new method with fastening the stent with loop and clip can reduce the risk of stent migration.

Our fastening method can be feasible and useful technique for postoperative anastomotic stricture after subtotal gastrectomy.

A large-scale prospective research is needed to validate the clinical effectiveness of our method and to determine the appropriateness.

Introduction: The optimum management of refractory or recurrent oesophageal strictures (RBES) despite repeated attempts at dilatation is controversial¹. An accepted method includes temporary stent placement. Most commonly temporary fully covered self-expanding metal stents (FC-SEMS) are used but these require removal some 8–12 weeks later. Oesophageal biodegradable stents (EBS) have the advantage that they do not require removal. However, there is a lack of good-quality evidence in support of their use^{2,3}. We aimed to review the safety and efficacy of a large series of single and multiple EBS insertions for benign RBES in a single tertiary referral centre.

Aims & Methods: A retrospective review of insertion of EBS (SX-ELLA) between April 2008 and October 2016 was conducted. Patients with one or more EBS insertion for benign RBES were included and clinical data extracted from the hospital database. 30 day safety and efficacy for all stent insertions and 12 month efficacy and median time to further intervention (MTFI) for first stents were analysed using the Stata package.

Results: 20 patients (13 m, 7 f; age 44–93; Charlson index range 2–8, median 4) with 37 stents were included. Stricture aetiologies included peptic (55%), radiotherapy (20%), post-surgical (20%) and post EMR (5%). Dysphagia score ranged from 2–4 (median 3). The total median number of dilatations prior to first EBS was 6 (range 0–17). 15 (75%) patients had previously had a FC-SEMS placed with subsequent recurrence of symptoms. 30-day technical success and symptom improvement was 100%. 30-day adverse events included 4 (11%) stent migrations and 12 (32%) with significant pain, 3 patients requiring in-patient pain control (<3 days). There were no significant bleeds or perforations. 12 months following first EBS insertion 18 (90%) required further endoscopic intervention due to recurrent symptoms; 5 (25%) had further dilatation, 9 (45%) had either a FC-SEMS (2 patients) or a further EBS (7 patients), 3 (15%) had NG tube insertion and 1 (5%) patient died of unrelated illness. 2 (10%) were symptom free after one stent at 12 m. MTFI was 139 days (range 75–517) and was not dependent on aetiology (peptic vs. non-peptic; 135 vs. 127 days, $p=0.54$). There was a significant reduction in median number of interventions in the 12 m following EBS insertion compared to the preceding 12 m (2 vs. 7 respectively, $p=0.0003$). 7 (35%) patients received multiple EBS (range of stent insertions 2–9). 3 of these (43%) have subsequently required no further intervention, 3 (43%) continue to receive intermittent EBS, inserted on a symptomatic basis, 1 (14%) patient continues to receive treatment for RBES, but has declined further EBS after 2 EBS resulted in discomfort.

Conclusion: Use of EBS for RBES in our centre was safe and well tolerated but there was short-lived pain in a significant number. In this highly selected cohort of difficult strictures, EBS led to short-term benefit in all patients but sustained benefit in only 10%. However, there was a significant reduction in intervention frequency 12 m after stent insertion and repeated EBS insertion appears a reasonable strategy for the most resistant strictures. The role of EBS earlier in the treatment pathway for RBES needs exploring in future studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Fully covered self-expanding metallic stents (SEMS) have an established role in the palliation of oesophageal strictures, particularly in those with malignancy. SEMS are advantageous as they reduce the rate of tumour ingrowth, in doing so reduce the need for repeated endoscopic interventions in a cohort of

patients with severe comorbidity. A drawback to SEMS include their ability to migrate distally, with some studies estimating the rate at around 20%^(1–3). We report a single-centre, retrospective cohort study on the use of SEMS, and aimed to establish risk factors for stent migration.

Aims & Methods: Case note review was undertaken retrospectively on all patients who had fully covered SEMS inserted at a high-volume tertiary oesophageal cancer centre between Jul 13 to Feb 17. All SEMS were placed under fluoroscopic guidance by experienced endoscopists. Stent migration was confirmed endoscopically or radiologically and was defined as displacement of the stent into the stomach or distal to the baseline stenosis with subsequent loss of the recanalised lumen. Shapiro-Wilks testing showed non-normal distribution of data. Non-parametric testing by logistic regression was therefore performed.

Results: 188 stents were inserted to palliate malignant strictures, 75% in males. We observed a migration rate of 20% (39) in our cohort. We observed a significant association between predilation (within 7 days of the stent procedure) and subsequent stent migration (31% in dilated vs 13% in undilated [OR 2.89 CI: 1.33–6.30, ($p=0.005$)]. This also met Bonferroni-corrected significance. We demonstrate a trend towards shorter strictures being associated with an increased risk of migration [OR 1.14 CI: 1.122–1.164 ($p=0.052$)]. There were no significant associations between migration and whether patients received previous chemo-radiotherapy, or whether the stent crossed the GOJ.

Conclusion: Endoscopic placement of SEMS is a safe and effective procedure in the management of malignant dysphagia with a low risk of complications. Predilation of lesions within 7 days of SEMS insertion carries a risk of subsequent stent slippage – suggesting that a cautious approach to dilation may be prudent. Further, larger studies may demonstrate an association with shorter strictures and migration. The migration rate at our centre is consistent with those found in other studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0282 COMBINED RESECTION IN ESOPHAGEAL CANCER: MYTH OR REALITY

D. Rusanov¹, K. Pavelets¹, M. Antipova¹, M. Protchenkov¹, M. Pavelets¹, U. Drozd¹, A. Sokolova¹, G. Florovsky¹
¹Faculty Surgery Named After Prof. A.A. Rusanov, Saint-Petersburg State Pediatric Medical University, Saint-Petersburg/Russian Federation

Contact E-mail Address: Rusanov.vergeltung@yandex.ru

Introduction: Esophagus cancer is one of the 10 most common malignant diseases of the digestive tract and ranks 7th in the structure of mortality. The indicators of 5-year survival, at the present stage, rarely overcome the threshold of 15–20% in the I–III stage of the disease. Most patients are considered inoperable by the time of admission to hospital due to the spread of the tumor process. Local-regional spread of the tumor is the reason for refusing to perform radical surgical intervention. Taking into account the data for the last 10 years, only 1.6% of patients had different types of combined and surgical treatment. According to various authors, chemoradiotherapy is offered as an alternative to surgical intervention in locally advanced forms of esophageal cancer. In addition, there is no consensus between “western” and “eastern” authors about the issues of lymphodissection in esophageal cancer. Thus, for the optimal primary staging of esophageal carcinoma and planning of surgical treatment, the surgeon needs a preoperative, spatial picture of the prevalence of the tumor process in patients suffering from esophageal cancer.

Aims & Methods: To analyze the probation of tumor using computer 3D-model of mediastinum and long-term results of treatment. Describes the experience of treatment of 190 patients with esophageal cancer from 2010 to 2015. Of them to 52 (27.3%) performed CT, to 37 (19.5%) EUS. Besides, CT to 101 (53.1%) and MRI 7 (0.1%) with subsequent 3D-modeling. I group- 123 (64.7%) patients, performed surgical treatment based on resection of thoracic part of esophagus, fundamental part of stomach and two-field lymphodissection. To 15 (7.9%) performed combined operations. The data obtained were compared with intraoperative findings and pathological examination. II group- 67 patients (35.3%), used palliative treatments: 31 (16.3%) - esophageal stenting, 26 (13.7%) - argon-tumor recanalization, 10 (5.3%) - argon-tumor recanalization with esophageal stenting.

Results: On data of all 59 (100%) 3D-models, were estimated, localization and length of esophageal tumor, it's relationship with the structures of the mediastinum, severity of intraabdominal and intrathoracic lymphadenopathy. In most cases, according to the data 3D- model, as well as intraoperative, met defeat of middle and lower esophagus. Severity of involvement of mediastinal structures rated at 48 patients (81.4%). At 35 (59.3%) and 37 (62.7%) cases amared fiber mediastinum, at 5 (8.5%) patients - invasion to the main bronchi, At 13 (22.0%) and 11 (18.6%) combination of anatomical structures of mediastinum defeat.

Severity of intrathoracic and intraabdominal lymphadenopathy: mediastinal lymphadenopathy marked at 19 (32.2%) and 20 (33.9%) patients, combined of 38 (64.4%) and 35 (59.3%). At pre-operated staging mostly met advanced form of cancer: T4N1 at 16 (27.1%), T4N2 at 23 (38.9%). Sensitivity in staging of tumor 89.8%. Long-term results: 1-year survival at I group 96.1%, 3-year is 42.3%, 5-year 19.6%; at II group 1-year survival 6.45%.

Conclusion: The use of 3D-modeling performed using MRI, spiral CT and EUS, allows to planning the optimal surgery and lymph node for locally common form of esophageal cancer, and improve the results of survival. The scope of surgical intervention is advisable to plan taking into account the constructed 3D-models, which helps to solve the problem of the possibility of surgical intervention in esophageal cancer.

P0283 INFLUENCE OF CONTINUOUS ADMINISTRATION OF LOW-DOSE ASPIRIN FOR INTRAOPERATIVE BLEEDING ON GASTRIC ENDOSCOPIC GASTRIC DISSECTION: A PROPENSITY SCORE MATCHING ANALYSIS

Y. Horikawa, N. Mimori, H. Mizutani, Y. Kato, S. Fushimi, S. Okubo, S. Sato
Gastroenterology, Hiraka General Hospital Dept. of Gastroenterology, Yokote/Japan

Contact E-mail Address: horikawa_01@me.com

Introduction: Endoscopic submucosal dissection (ESD) was a promising method for the resection of superficial gastric neoplasms. The patient with antithrombotic agents has increased for first or secondary prevention of cardiovascular or cerebral disease. Continuous administration of low-dose aspirin (LDA) during ESD was recommended in American, British and Japanese guidelines. However, the influence of this drug for the hemostasis condition during ESD procedure is still unclear. Therefore, we performed this study for addressing intraoperative bleeding risk without cessation of LDA.

Aims & Methods: In this retrospective study, we assessed the hemostasis condition during ESD that were treated for superficial gastric lesions between January 2014 and March 2017. Patients with antithrombotic therapy by LDA (n=42) and those with no antithrombotic therapy (n=187; Control) were compared using propensity score matching. Primary outcome was frequency of intraoperative major bleeding. Secondary outcomes included procedure time, Hb reduction rate, En bloc resection rate, and adverse events rate.

Results: The propensity score analysis yielded 39 matched pairs. Adjusted comparison between the two groups showed similar with regards to major bleeding, median [range] (times): 1.0 [0.0–4.0] vs. 1.0 [0.0–4.0], $p=0.621$. Procedure time was prolonged in Aspirin group by 16.7% without significant differences. Other aspects were the same in both groups with low incidence of adverse events; perforation (0%), thromboembolism (0%).

Conclusion: This study indicated the feasibility of gastric ESD with continuous administration of LDA including little intraoperative bleeding and adverse events.

P0284 WEEKDAY OF CANCER SURGERY IN RELATION TO PROGNOSIS

P. Lagergren, F. Mattsson, J. Lagergren
Department Of Molecular Medicine And Surgery, Karolinska Institutet, Stockholm/Sweden

Contact E-mail Address: pernilla.lagergren@ki.se

Introduction: Later weekday of surgery seems to reduce the prognosis in oesophageal cancer, while any such influence on other cancer sites is unknown. This study aimed to test whether weekday of surgery influences prognosis following commonly performed cancer operations.

Aims & Methods: This nationwide Swedish population-based cohort study from 1997–2014 analysed weekday of elective surgery for 10 major cancer groups in relation to disease-specific and all-cause mortality. Cox regression provided hazard ratios with 95% confidence intervals (CI) adjusted for the covariates age, sex, comorbidity, hospital volume, calendar year, and tumour stage.

Results: Included were 228,927 patients. Later weekday of surgery (Thursdays and even more so Fridays) was associated with increased mortality rates for gastrointestinal cancers. The adjusted hazard ratios for disease-specific mortality comparing surgery on Friday with Monday were 1.57 (95% CI 1.31–1.88) for oesophago-gastric cancer, 1.49 (95% CI 1.17–1.88) for liver-pancreatic-biliary cancer, and 1.53 (95% CI 1.44–1.63) for colorectal cancer. Excluding mortality during the initial 90 days of surgery made little change to these findings, and the all-cause mortality was similar to the disease-specific mortality. The associations were similar in analyses stratified for covariates. No consistent associations were found between weekday of surgery and prognosis for cancer of the head-and-neck, lung, thyroid, breast, kidney-bladder, prostate, or ovary-uterus.

Conclusion: Later weekday of surgery (Thursday-Friday) seems to negatively influence the prognosis for cancer of the gastrointestinal tract, indicating a need for re-scheduling of these operations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0285 IMPACT OF POSTOPERATIVE COMPLICATIONS AND PERIOPERATIVE ONCOLOGICAL TREATMENTS FOR GASTRIC CANCER PATIENTS AFTER GASTRECTOMY

Contact E-mail Address: satoki_k@hotmail.com

Introduction: Recently, multidisciplinary treatments such as perioperative chemo/radio treatments have been introduced to improve their prognosis in gastric cancer surgery. Besides that, the postoperative severe complications are thought to be the poor prognostic factor. Present study assessed the prognostic impacts of severe postoperative complications and perioperative oncological treatments in gastric cancer patients.

Aims & Methods: Consequent gastric cancer patients who underwent curative gastrectomy in Karolinska University Hospital between 2006 and 2016 were enrolled. Patients' characteristics, surgical data, postoperative courses and prognosis were examined retrospectively. Complications were evaluated according to Clavien-Dindo classification. The significance of postoperative severe complications and perioperative oncological treatment for overall survival (OS) was evaluated by the Cox proportional hazard model.

Results: Hundred-sixty-nine patients were examined in this study. 89 (52.7%) and 66 (39.1%) patients had neoadjuvant and adjuvant treatment, 85 (50.3%) and 84 (49.7%) underwent distal and total gastrectomy, respectively. 24 (14.2%), 16 (9.5%) and 5 (3.0%) were diagnosed as grade III, IV, V complications. The prognosis of the patients with grade III or higher complication was significantly worse (3-year OS: 66.6% vs 47.3%, $P=0.001$). Subgroup analysis by pathological stage showed that the prognosis of pStage III/IV patients with postoperative grade III or higher complication was significantly poorer than the patients without grade III or higher complications (3-year OS: 45.3% vs 7.5%, $P<0.001$). For the patients who had either neoadjuvant or adjuvant treatment, however, no obvious prognostic worsening were seen by the existence of complications (3-year OS: 66.5% vs 52.9%, $P=0.13$). Multivariate analysis identified that severe complication was independent risk factor for OS (hazard ratio 1.82; 95% confidence interval 1.08–3.05), especially in pStage III/IV gastric cancer (hazard ratio 3.00; 95% confidence interval 1.53–5.86).

Conclusion: Postoperative severe complications had considerable impact on the OS, especially for pStage III/IV gastric cancer patients. Perioperative oncological treatment may be able to prevent the prognosis from deteriorating due to postoperative complications.

Introduction: Duodenal papillary tumor as rare gastrointestinal neoplasm is essential for curative therapy due to its malignant potential. Endoscopic papillectomy to the treatment of duodenal papillary tumor has developed and is accepted as an alternative approach to surgery in select cases. Endoscopic papillectomy as a relatively difficult endoscopic technique mainly performed by experienced endoscopists. Moreover, the indications and standard endoscopic procedures for endoscopic papillectomy have not been established.

Aims & Methods: We aimed to investigate the clinical value of endoscopic papillectomy for duodenal papillary tumor based on the endoscopic and clinical characteristics. Between 2006 and 2017, seventy-five patients with duodenal papillary tumor under endoscopic papillectomy in the gastrointestinal endoscopic center of Chinese PLA General Hospital were included. These patients were diagnosed of duodenal papillary tumor by the clinical manifestation, laboratory tests, CT, MRCP, endoscopy, EUS, ERCP along with biopsies and histopathologic tests. During the detailed clinical assessment combined with patients' wishes, endoscopic papillectomy and followed ERCP procedures were performed successfully, and the clinical data of these patients were retrospectively summarized.

Results: 75 patients (50 males and 25 females) with a median age of 58.6 yrs (range 27 to 82 yrs) were evaluated. The main clinical symptoms were predominated by abdominal pain followed by cholestasis and cholangitis, but nine cases with no abdominal symptoms. Endoscopic papillectomy was technically feasible in all these patients, and was mainly performed by four experienced endoscopists. The majority of excised tumors were exogenous (90.7%, 68/75), and the tumor size ranged between 8 and 55 mm. The final histopathological diagnosis included adenoma (37.3%, 28/75), adenoma with high-grade intraepithelial neoplasia (18.7%, 14/75), adenoma with low-grade intraepithelial neoplasia (26.7%, 20/75), adenoma combined with local carcinoma (16%, 12/75), and neuroendocrine tumor (1.3%, 1/75). En bloc resection was achieved in 53 cases (70.7%) and the piecemeal resection was performed in 22 cases (29.3%). After endoscopic papillectomy, the ERCP procedures were performed in 70 cases (93.3%). The prophylactic pancreatic duct stent was placed in 30 cases (40%) for preventing pancreatitis, the biliary plastic stent or nasobiliary drainage tube in 16% (12/75), the combined of both in 17.3% (13/75), and no stent placement in 26.7% (20/75). Moreover, intraoperative hemostasis was performed in 47 cases (62.7%), including pure endoscopic clip placement, followed by injection therapy, thermal therapy or in combination. Regarding to the postoperative adverse events,

hemorrhage was identified in 11 patients (14.6%) but mainly cured by endoscopic hemostasis, followed by pancreatitis (9.3%, 7/75) but cured with medical treatment.

Conclusion: Endoscopic papillectomy can be considered as a feasible and reasonable treatment option for suitable patients with tumors of duodenal papilla.

Introduction: Prophylactic surgery of familial adenomatous polyposis (FAP) ranges from total colectomy with ileorectal anastomosis (IRA) to proctocolectomy with ileoanal anastomosis and J pouch (IAA). Rectal preservation is based on studies that did not include systematic endoscopic treatment that we perform. The objective was to compare IRA to IAA in terms of oncological safety and quality-of-life.

Aims & Methods: Between January 1965 and November 2015, all consecutive patients who underwent prophylactic surgery for FAP with aggressive endoscopic follow up in our unit: systematic endoscopic treatment of adenomas (argon, mucosectomy), were prospectively included. MYH-related polyposis and patients who underwent abominoperineal resection were excluded from analysis.

Results: 296 patients were included: 92 proctocolectomy with IAA (31.1%), 197 total colectomies with IRA (66.5%), and 7 abdominoperineal resections (2.4%). Mean (SD) number of preoperative rectal adenomas was 24.7 (33.9) in the IRA group vs. 52.8 (27.8) in the IAA group ($p=0.0001$). Rectal cancer prevalence was 3.1% ($n=9$). Mean (SD) follow-up was 16.6 (11.9) years, during which the mean (SD) number of lower endoscopies was 3.4 (2.5) in the IRA group vs. 3.4 (2.5) in the IAA group ($p=0.91$); mean (SD) number of treated adenomas was 17.8 (20.8) and 12.9 (18.8), respectively ($p=0.06$); secondary cancer incidence was 6.1% vs. 1.1% ($p=0.06$). The 15-year recurrence-free and overall survival (IR vs. IAA) were respectively 99.5% vs. 100% ($p=0.09$) and 98.9% vs. 98.8% ($p=0.82$).

Conclusion: Combination of aggressive endoscopic treatment and extended rectal preservation appears to be a safe alternative to ileoanal anastomosis and J pouch.

P0288 ANAL PROBLEMS DURING PREGNANCY AND POSTPARTUM: A PROSPECTIVE COHORT STUDY

K. Ferdinande, Y. Dorreman, K. Roelens, W. Ceelen, D. De Looze
University of Ghent, Ghent/Belgium

Contact E-mail Address: kymentie.ferdinande@ugent.be

Introduction: Many pregnant women have anal symptoms during pregnancy and postpartum. The most common proctological problems reported are haemorrhoids, anal fissures and anal incontinence. Literature about this problem is scarce.

Aims & Methods: The aim of this study is to determine the prevalence of anal problems and constipation during the second and third trimester of pregnancy, in the immediate postpartum and up to three months after childbirth. We also want to identify the risk factors for the development of anal symptoms. This is a prospective cohort study. Women between their 19th and 25th week of pregnancy are included. High-risk pregnancy and non-Dutch speaking are exclusion criteria. Ninety-four women were followed with a symptom questionnaire in the second and third trimester, in the immediate postpartum (within 3 days) and three months postpartum. Descriptive data were obtained from the patient files. A specific proctological diagnosis was presumed on the basis of combined symptoms (rectal bleeding, anal pain and swelling). Constipation was defined by the Rome III criteria. Statistical analysis was performed with SPSS and risk factors were identified using multivariate analysis with binary logistic regression.

Results: Sixty-eight percent of the women developed anal symptoms during the whole study period. Anal symptoms occurred in 50% of the women during pregnancy, in 56.2% in the immediate postpartum and in 62.9% during the three months postpartum. The most prevalent symptom was anal pain. Constipation was reported by 60.7% during the whole study period. Most prevalent diagnoses were: hemorrhoidal thrombosis (immediate postpartum), hemorrhoidal prolapse (3rd trimester and immediate postpartum) and anal fissure (not episode-related). Anal incontinence was only reported in 2% during the postpartum. Multivariate analysis identified constipation and a history of anal problems as significant risk factors for the development of anal complaints prepartum and postpartum.

Conclusion: Two-thirds of pregnant women deal with anal symptoms during pregnancy or postpartum, especially hemorrhoidal complications and anal fissure. This high prevalence emphasises the clinical importance of this problem. The most important risk factor is constipation. Therefore, prevention of constipation in pregnant women is recommended.

Introduction: Diverticulitis is a common gastrointestinal disease in developed countries, especially among elders. It is classified into five stages according to the severity of the inflammation with stage 5 involving peritonitis as a consequence of perforation and organ dysfunction with 30-day-mortality reaching 32%. This indicates that acute diverticulitis is an emergency case requiring rapid management. However, the surgical interventions of diverticulitis vary according to its grade and severity, there is a controversy about the preferable and suitable of these different surgical procedures for each grade or complication.

Aims & Methods: We aimed to systematically review and meta-analyze randomized controlled trials (RCTs) comparing outcomes and complications between different surgical approaches for acute diverticulitis and its complications. Nine electronic databases, including PubMed, Scopus, Google Scholar, ISI Web of science, WHO Global health library (GHL), POPLINE, Virtual health library (VHL), NYAM (New York Academy of Medicine), and SIGLE (System for information on grey literature in Europe), were searched for RCTs comparing different surgical procedures for different grades of diverticulitis. Out of 1738 articles, we included 14 studies with 1076 patients. The primarily assessed outcomes were post-surgical mortality rate besides short- and long-term post-surgical major and minor complications. The risk of bias was assessed using the Cochrane Collaboration tool. The pooled risk ratio (RR) and 95% confidence interval (CI) were calculated in the meta-analysis using the RevMan platform. The protocol was registered in PROSPERO (CRD42015032290).

Results: Outcome data were analyzed from five RCTs comparing laparoscopic sigmoid resection (LSR) ($n=247$) versus open sigmoid resection (OSR) ($n=237$) for treatment of acute complicated diverticulitis with minimal heterogeneity. For short-term outcomes, there was no significant difference in postoperative overall morbidity (RR=0.89, 95% CI [0.61–1.31]; $P=0.56$), all major postoperative morbidity (RR=0.79, 95% CI [0.12–5.07]; $P=0.80$), and all minor postoperative complications (RR=0.98, 95% CI [0.62–1.57]; $P=0.94$). Similarly, there was no difference between the two procedures regarding the long-term postoperative overall morbidity (RR=0.83, 95% CI [0.57–1.21]; $P=0.34$), all major morbidity (RR=0.78, 95% CI [0.46–1.31], $P=0.34$), and mortality (RR=0.95, 95% CI [0.04–24.59]; $P=0.98$). In other four RCTs compared laparoscopic lavage with resection (sigmoidectomy) for treatment of perforated diverticulitis with peritonitis, the postoperative mortality rate was non-significant in both short-term (RR=1.55, 95% CI [0.79–3.04]; $P=0.21$) and long-term (RR=0.67, 95% CI [0.29–1.58]; $P=0.36$) follow up. Interestingly, the short-term reoperation rate and long-term presence of intra-abdominal abscesses were significantly higher in LL group (RR=1.74, 95% CI [1.01–3.02], $P=0.05$) and (RR=2.47, 95% CI [1.03–5.92]; $P=0.04$) respectively. The remaining five RCTs compared between different procedures, like primary anastomosis versus non-restorative resection, RP-LASR versus NRP-LASR, and primary versus secondary resection, for different situations and reviewed qualitatively.

Conclusion: The superiority of LSR over OSR was non-significant in the treatment of acute symptomatic diverticulitis regarding postoperative complications, operational time, and cost. However, the cosmetic aspect still gives LSR more advantage. Regarding perforated diverticulitis with purulent peritonitis, our results showed that LL is as safe as resection (either Hartmann's operation or sigmoidectomy with primary anastomosis) regarding short- and long-term postoperative outcomes especially in long-term, hospital stay, and operational duration. Hence, LL is feasible and can act as definitive treatment. Further RCTs are still needed to make a decision regarding these and other procedures.

Introduction: There has been enormous progress in diagnosing and treatment of colorectal cancer (CRC), however a great number of patients is nevertheless diagnosed in advanced disease stages. It is of great importance to develop non-invasive, inexpensive, prognostic, diagnostic, and treatment predicting biomarkers in early diagnostics of CRC considering its incidence worldwide. There are studies suggesting that the systemic inflammation play an important role in CRC tumor stage development, which can be reflected by the levels of neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR).

Aims & Methods: This study was designed to investigate the efficiency of preoperative NLR, PLR as a tool for the assessment of synchronous lymph nodes

and liver metastases in newly diagnosed patients with CRC. Three hundred patients with I-IV stage CRC undergoing surgical resection were included in this cross sectional study. Complete blood counts with automated differential counts were performed preoperatively. The NLR was calculated by dividing the absolute neutrophil count by the absolute lymphocyte count; also PLR was calculated by dividing the absolute platelet count by the absolute lymphocyte count. The diagnostic performance of NLR and was estimated by ROC curve.

Results: Our results suggest that there was high statistically significant difference between NLR ($p=0.003$), PLR ($p=0.002$) and tumor stages (I to IV). ROC curve analysis showed high diagnostic efficacy of NLR (AUC 0.774, 95%CI=0.683–0.790) and PLR (AUC 0.698, 95%CI=0.663–0.742) for synchronous lymph node and liver metastases. Also combination of NLR and PLR improved diagnostic efficacy (AUC 0.841, 95%CI=0.811–0.863) for synchronous liver and lymph node metastases.

Conclusion: Our results suggest that NLR and PLR could be useful diagnostic CRC biomarkers, and could have potential use in early recognition of different stages of CRC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Diagnosis of appendicitis is still clinically challenge where resource is limited. The purpose of this study is to develop and externally validate Ramathibodi Appendicitis Score (RAMA-AS) in aiding diagnosis appendicitis.

Aims & Methods: Two-phase cross-sectional study (i.e., derive and validation) was conducted at Ramathibodi Hospital (for derive), Thammasat University Hospital and Chaiyaphum Hospital (for validation). Patients with abdominal pain and suspected of having appendicitis were enrolled. Multiple logistic regression was applied to develop parsimonious model. Calibration and discrimination performances were assessed. In addition, our RAMA-AS was compared with Alvarado's score performances using ROC curve analysis. The study was conducted and reported according to Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis Or Diagnosis (TRIPOD) statement.

Results: The RAMA-AS consisted of 3 domains 7 predictors including symptoms (i.e. progression of pain, aggravation of pain, and migration of pain), signs (i.e. fever and rebound tenderness), and laboratory (i.e. white blood cell count (WBC) and neutrophil). The model fitted well with data and it performed better discriminate than the Alvarado score with C-statistic of 0.842 (95% CI: 0.804, 0.881) versus 0.760 (0.710, 0.810). Internal validation by bootstrap yielded Sommer's D of 0.686 (0.608, 0.763) and C-statistics of 0.848 (0.846, 0.849). The C-statistics of two external validations were 0.853 (0.791, 0.915) and 0.813 (0.736, 0.892) with fair calibrations.

Risk group	Sensitivity	Specificity	LR+	LR-	Post-positive test odds
Very low	100	0	1	0	61.8
Low	89.75 (85.25–93.26)	54.97 (46.67–63.06)	1.98 (1.65–2.37)	0.19 (0.13–0.28)	76.00 (73.00–79.00)
Moderate	64.08 (57.73–70.09)	88.08 (81.82–92.78)	5.25 (3.39–8.13)	0.41 (0.34–0.49)	89.00 (85.00–93.00)
High	37.96 (31.86–44.36)	95.36 (90.68–98.12)	8.36 (3.96–18.00)	0.65 (0.59–0.72)	93.00 (86.00–97.00)

Conclusion: RAMA-AS is a useful tool for diagnosis of appendicitis. It has good discrimination performance and good calibration performance after revision.

Practitioners should be encouraged to use the score in clinical practice in order to conforming diagnosis and choosing the patient who should undergo imaging or surgical management.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Haemorrhoidectomy in ulcerative colitis (UC) have been considered to be potentially dangerous, but the evidence is poor.

Aims & Methods: A study was conducted to ascertain the safety of haemorrhoidectomy in patients with UC. Retrospective review of 44 UC patients from 2004 to 2014. Patient demographics and clinical characteristics (anorectal symptoms, prior non operative haemorrhoidal therapy, whether proven UC preoperatively (BD) and unproven preoperatively (AD), whether to use azathioprine, presence of other perianal disease, and activity, anatomic location of UC) were recorded. Postoperative complications, and differences between BD and AD were analysed. **Results:** The patients were 29 males (65.9%), median age 44 (range, 19–72) years. Predominant symptoms were bleeding and prolapse (n=24; 54.5%), prolapse only (n=6; 13.6%), bleeding only (n=14; 31.8%). 17 patients (BD, 38.6%) were diagnosed with UC prior to surgery. 4 patients (9.1%) had azathioprine therapy before surgery. There was no other perianal disease. Disease was limited to the rectum (n=33; 75%), left-sided (n=9; 20.5%), and extended to right-sided (n=2; 4.5%). During follow-up, there were no complications such as sepsis, anal stenosis, abscess and fistula formation, and recurrence. There was no difference in complications and other clinical characteristics between BD and AD. There was no difference in complications according to disease extent ($p=0.158$).

Conclusion: Our data suggest that haemorrhoidectomy may be performed safely in UC patients.

P0293 EARLY VERSUS DELAYED CLOSURE OF TEMPORARY LOOP ILEOSTOMY AFTER COLORECTAL SURGERIES: A PROSPECTIVE RANDOMIZED STUDY

S. Gavini, V. Vutukuru, D. Annareddy, C. Chandramalteeswaran, V. Dasari, N. Pagadala

Gi Surgery, SVIMS, Tirupathi/India

Contact E-mail Address: srkgavini@gmail.com

Introduction: Temporary loop ileostomies are commonly performed to protect a distal anastomosis in colorectal surgeries. Although they have been shown to reduce the number of leaks requiring surgery, they remain a source of complications and have an adverse effect on the quality of life. A few non-randomized studies have shown the feasibility of early stoma closure.

Aims & Methods: To compare the outcomes of early and delayed closure of temporary loop ileostomy in terms of operative parameters, morbidity, mortality, and quality of life. The study was conducted from May 2014 to September 2015. Following creation of loop ileostomy after colorectal surgeries, distal loop contrast study was done on POD 7. Patients who had no leak were randomized to either early closure (8–13 days) or delayed closure (after 6 weeks) group. Patient demographics, operative parameters, morbidity, mortality and quality of life data were recorded in both groups.

Results: There were 24 patients in each group. Both groups were comparable in terms of demographic data except for age, which was significantly higher ($p=0.012$) in the early closure group. Incidence of stoma related complications ($p=0.01$) and Pittman ostomy complication severity index ($p < 0.01$) were significantly higher in the delayed group. Operative time ($p=0.033$) and Surgeons assessment score ($p=0.0012$) for the stoma closure surgery were significantly lower for the early closure group. There was no significant difference in the duration of hospital stay and the incidence of postoperative complications in the two groups. Quality of life as calculated by the Ostomy Adjustment Index score (OAI 23) was better in the early closure group ($p=0.014$).

Conclusion: Early closure of a temporary loop ileostomy is feasible with the advantages of decreased stoma related morbidity, operative difficulties without increased morbidity and mortality when compared with conventional delayed ileostomy closure.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0294 FULL-SCALE INTRODUCTION OF RADICAL LAPAROSCOPIC SURGERY FOR INGUINAL HERNIA EMPLOYING THE TRANSABDOMINAL PREPERITONEAL (TAPP) REPAIR AND EARLY OUTCOMES

T. Saito, T. Sano, S. Komatsu, T. Arikawa, S. Ishiguro, K. Komaya
Gastroenterological Surgery, Aichi Medical University, nagakute/Japan

Contact E-mail Address: tsaito0726@gmail.com

Introduction: Ger reported the first laparoscopic hernia repair in 1982 by approximating the internal ring with stainless steel clips. The laparoscopic trans-abdominal preperitoneal (TAPP) repair was a revolutionary concept in hernia surgery and was introduced by Arregui and Dion in the early 1990s. Institutions performing radical laparoscopic surgery for inguinal hernia have been rapidly increasing since the NHI point was amended in Japan. However, in the 12th JAPAN SOCIETY FOR ENDOSCOPIC SURGERY questionnaire survey, the recurrence rate after surgery employing the TAPP method was reported to be 4%, posing a problem regarding the thoughtless introduction of the TAPP method. Our hospital performed surgery employing the TAPP method only occasionally until April 2015, but treatment of inguinal hernia was integrated, the indication was established in May 2015, and laparoscopic surgery employing the TAPP method has been performed for the indicated cases. In this study, we investigated the current state of inguinal hernia treatment at our hospital. Surgical indication of inguinal hernia in our department is as follows. Symptomatic inguinal hernia is treated using the TAPP method when there is only one POSSUM score-based risk factor. When 2 or more risk factors are present or the patient has undergone surgery of the prostate, the anterior approach is employed (the UHS and Mesh Plug methods for internal and external inguinal hernia, respectively). Treatment under local anesthesia is prioritized for patients aged 90 years or older and patients with PS2 or higher. Arrangement in operating room is that the operator and assistant stand on the left and right sides of the patient, respectively, an anesthesiologist stands at the patient's head, and a nurse stands caudal to the assistant.

Aims & Methods: In this study, we investigated the current state of inguinal hernia treatment at our hospital. The subjects were 120 patients who underwent radical surgery for inguinal hernia before and after the full-scale introduction of the TAPP method (early period: October 2014-April 2015 (7 months), late period: May 2015-November 2015 (7 months), 47 and 73 patients were treated in the early and late periods, respectively). Changes in the surgical procedure, complications, and duration of hospital stay were investigated in 120 patients.

Results: The median age was 70 years old (19–91 years old). There were 114 male and 6 female patients, with a total of 132 lesions (unilateral in 108 (right: 60, left: 48) and bilateral in 12). The hernia classification (Japanese Hernia Society) was 1, 2, 3, 4, rec in 91, 37, 0, 3, and 1 lesions. Surgery was performed under local anesthesia in 43, lumbar anesthesia in 1, and general anesthesia in 76. A laparoscope was used in 70 and not used in 50. TAPP, mesh plug, and UHS and others were used in 58, 54, 17, 3 lesions. There was no change for both the Early period and the Late Period about the median operative time (Early period: 93 minutes, Late period: 102 minutes). Early Period was 4 days (4–24), Late Period was 3 days (3–9) for median duration of hospital stay. In Early period, complications which required treatment (Clavien Dindo Grade3 or higher) were intestinal obstruction and recurrence in one each. In Late period, the recurrence and complications of Clavien Dindo Grade3 or higher did not occur.

Conclusion: No severe complication or recurrence has occurred since integrating treatment for inguinal hernia and introduction of the TAPP method. Application after carefully deciding the indication may be important for laparoscopic surgery for inguinal hernia. A randomized prospective exploratory study on analgesic methods for laparoscopic radical surgery for inguinal hernia aiming at introducing day surgery (approved by the Ethics Committee) is being performed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0295 EFFECTIVENESS OF PURE LAPAROSCOPIC LEFT COLECTOMY WITH PRIMARY ANASTOMOSIS AND LOOP ILEOSTOMY FOR THE TREATMENT OF COMPLICATED HINCHEY 3 DIVERTICULITIS

F. Roscio, A. De Luca, I. Scandroglio
Galmarini Hospital, ASST Sette Laghi, Tradate/Italy

Contact E-mail Address: francesco_roscio@yahoo.it

Introduction: To evaluate the effectiveness of laparoscopic left colectomy with primary anastomosis and loop ileostomy in the treatment of complicated acute diverticulitis with diffuse purulent peritonitis (Hinchey 3), also considering the lack of evidence about this topic due to the difficulty of carrying out comparative trials with the laparoscopic washing/drainage technique.

Aims & Methods: A consecutive unselected series of 44 patients undergone emergency surgery for acute complicated Hinchey 3 diverticulitis from January 2012 to December 2016 was retrospectively evaluate. All patients were treated by pure

laparoscopic left colectomy with primary colorectal anastomosis and temporary loop ileostomy. All the procedures were performed by the same surgeons (IS, ADL, FR). Perioperative care plan, operative steps and surgical instrumentations were standardized. We collected patients-, surgery- and hospital stay-related data, as well as short-term outcomes. Complications were classified using the Clavien–Dindo classification system (CDCS).

Results: There were 31 men (70.4%) and 13 women (29.6%) with a mean age of 57.8 ± 11.9 years. The mean body mass index was 28.3 ± 3.1 kg/m². No conversion to open surgery was registered. The mean operative time and estimated blood loss were 184.3 ± 32.7 minutes and 81.2 ± 72.7 ml respectively. All the specimens showed diverticulitis with peridiverticulitis. Length of hospital stay was 7.8 ± 2.8 days and we have not recorded any readmissions in patients discharged within 60 days after surgery. The rates of postoperative complications were 6.8% and 2.3% for grades 3 and 5 according to the CDCS respectively.

Conclusion: Laparoscopic left colectomy with primary anastomosis and loop ileostomy seems to be a good technique that resulted in encouraging short-term outcomes. In expert hands it represents an effective technique for the treatment of acute diverticulitis complicated by diffuse purulent peritonitis.

P0296 LAPAROSCOPIC COMPLETE LATERAL LYMPH NODE DISSECTION FOR LOW RECTAL CANCER

T. Kinoshita, K. Komori, T. Oshiro, A. Ouchi, Y. Shimizu
Gastroenterological Surgery, Aichi Cancer Center Hospital, NAGOYA/Japan

Contact E-mail Address: t-kinoshita@aichi-cc.jp

Introduction: Total mesorectal excision (TME) with lateral pelvic lymph node dissection (LLND) is a standard procedure for low rectal cancer in Japan. However, ME alone is the international standard surgical procedure for rectal cancer. Complete LLND is difficult because of the narrow visual field in the pelvic cavity and the complicated anatomical structure and invasive procedure which needs longer operative time and greater blood loss. Herein we introduce laparoscopic LLND as our new procedure securing equivalent range of lymph node dissection and report the clinical outcomes.

Aims & Methods: After laparoscopic ME, first, the external iliac artery was exposed and the external iliac nodes were completely removed from inguinal ligament. Obturator nodes were completely dissected while preserving the obturator nerve, resecting the obturator artery and vein, and confirming lateral pelvic wall, bladder wall and sciatic nerve. Subsequently, proximal internal iliac nodes were removed and superior vesical artery was separated. Distal internal iliac nodes from the coccygeal muscle (Alcock's canal) were completely dissected while preserving the superior vesical artery and the pelvic plexus, and transecting several inferior vesical arteries. Finally, bilateral hypogastric nerves were separated to be preserved. Common iliac nodes were dissected; aortic bifurcation nodes and presacral nodes were also dissected by exposing the aortic bifurcation and the pelvic surface of the sacrum.

Results: Between 2015 and 2016, we performed laparoscopic ME with LLND for 10 patients with cT2 or deeper low rectal cancer. The median operative time was 502 min (420–679 min), and the median blood loss was 90 ml (5–500 ml). Postoperative complications developed in 4 (40%) patients, and the most frequent one was temporary urination disorder in 2 (20%) patients. The median number of harvested lateral lymph node was 20 (14–23). So far there are no recurrent cases.

Conclusion: Our laparoscopic LLND provides good visual field and reduces an amount of operative bleeding and results in favorable clinical outcomes.

Introduction: Natural orifice transluminal endoscopic surgery (NOTES) proposed advantages should be established by comparison with standard procedures. Using a single side transluminal access, the feasibility of performing advanced surgical procedures is still limited, especially for a single endoscope. We used the ANUBIS-system for sigmoid resection with a transgastric access to the abdominal cavity assisted by colonoscopy and one trocar.

Aims & Methods: The experimental study was conducted in a porcine model in general anesthesia. After operation in an acute model, we started the study with 5 pigs in a survival model. Using Anubisscope, a transgastric access was reached by needle-knife incision and balloon dilatation. CO₂ peritoneum was achieved by insufflation via a working channel. By steering the colonoscope, the colon was maneuvered endoluminally and the colic mesentery was exposed. Bowel-close mesocolic preparation was performed with a coagulating hook-knife with simultaneously assistance by a grasper via the Anubisscope. Both instruments have the possibility of two-directional movements. The access angle for preparation and visualisation could be altered during the procedure by manoeuvring the colonoscope and the movements of the flexible endoscopic instruments. To prepare anastomosis, circular stapler anvil was introduced transluminally and penetration of the colon wall was carried out. Subsequently, proximal resection of the sigmoid colon was performed using a linear stapler inserted through a trocar at the left

lower abdomen. The bowel extraction was performed by invagination transrectally. After extracorporeal distal linear stapling of the sigmoid, the colorectal anastomosis was completed by applying a circular stapling device transrectally, assisted by a transcutaneous inserted grasper. Function testing was performed by the colonoscope. Gastric access closure was performed by OTSC clip.

Results: The procedure was successful in all animals with operation time ranging from 4.5 to 6 hours. After weight gain in all cases, the animals were sacrificed after postoperative day 42 and the workup showed competent anastomotic healing with a stenosis and consecutive prestenotic dilatation in one case. These animal had a small peritoneal abscess beside the anastomosis. Gastric closure was healed and the OTSC clip still in situ in all animals. In one case we used two OTSC clips for gastric closure, there were severe adhesions with two perigastric abscesses.

Conclusion: The use of an operating platform like the Anubisscope has the advantage of flexible preparation in opposite position of the instruments. The disadvantages are the only two degrees of freedom of the flexible instruments and the rotation-like movements. Flexible colonoscopy provided a fixed reference frame that enabled preparation and dissection. For resection and anastomosis an additional transcutaneous access was necessary.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0298 ASCITES, COMPLEX ADNEXAL MASSES AND RAISED CA-125 IN POST-MENOPAUSAL WOMEN: OVARIAN CANCER OR TUBERCULOSIS?

S. Jarda¹, H. Kchir², N. Maamouri¹, H. Chaabouni¹, N. Ben Mami¹

Introduction: Peritoneal tuberculosis (TB) and advanced ovarian cancer, two conditions with different management and prognosis, have many similarities: ascites, complex adnexal mass, peritoneal deposits, and raised CA-125 level. Symptoms such as weight loss, reduced appetite, and dull abdominal pain are also common to these two entities.

Aims & Methods: The aim of this study was to analyze patients' characteristics, laboratory investigations, radiological and surgical findings in post-menopausal women with pelvic TB who were diagnosed after laparotomy or laparoscopy for suspected ovarian cancer. We report twenty-one cases of pelvic-peritoneal TB in post-menopausal women who presented with features mimicking ovarian malignancy from 2004 to 2014 in a Tunisian center.

Results: The mean age was 59.8 (46-87 years). Three patients have personal or family history of TB. All women presented with abdominal pain and distension of varying duration of 1 month to 6 months. Eleven patients had reduced appetite and weight loss, and four women gave a history of low-grade fever. A CT scan showed the presence of solid-cystic adnexal masses ranging from 3 cm to 12 cm in 100% and ascites in 90.4%. Ascitic fluid analysis was done in 19 patients which showed a lymphocytic predominant pattern, and absence of malignant cells. Ascitic fluid cultures were negative in all. CA-125 was elevated in all and ranged between 185 and 1300 IU/ml. CA-125 >600 IU/L was found in three women. Quantiferon-TB Gold (QFT-G) performed in 3 patients was positive in two. A laparoscopic evaluation with biopsies was performed in 16 patients and an exploratory laparotomy in 4 women for suspected ovarian cancer. Intraoperative findings of tubercles on the pelvic organs and peritoneal surfaces suggested TB in 18 patients. In two, TB was not suspected intraoperatively. The diagnosis of TB was confirmed by histopathology in 95.2%. Response to therapeutic trial of anti-tubercular drugs was the basis of diagnosis in one case because of a high anesthetic risk.

Conclusion: It is a diagnostic challenge to differentiate pelvic-peritoneal TB from ovarian cancer which has entirely different management and prognosis. Ascitic fluid showing lymphocytic predominance and no malignant cells and positive(QFT-G) are pointers to obtain a histopathological diagnosis by laparoscopic biopsy or frozen section at laparotomy.

P0299 INSULINLIKE GROWTH FACTOR IGF-I AND INFLAMMATORY RESPONSE IN THE COLONIC MUCOSA IN ULCERATIVE COLITIS

V. Pavlenko, F. Urusova, G. Eseneeva, A. Pavlenko, N. Korablina
Stavropol State Medical University, Stavropol/Russian Federation

Contact E-mail Address: pavlenkovv@yandex.ru

Introduction: Peptide growth factors including the IGF family are expressed in the intestine and modulate proliferative activity of the intestinal epithelium in ulcerative colitis (UC) and Crohn's disease (CD). At the same time, IL-8 is one of the main triggers behind the immunoinflammatory process in the colonic mucosa (CM) in UC, and its level may be of prognostic value in determining the illness course.

Aims & Methods: The aim of the study was to identify the role that IGF-I plays in colonic inflammation in 35 patients with different clinical (Rahmivich index) and endoscopic (Mayo index) activity of UC. The treatment was administered in view of the severity of UC. 20 healthy volunteers were the control group. IGF-I levels in peripheral blood were determined by ELISA (Mediagnost, Germany). The results were expressed as nmol/l. The spontaneous and E. Coli LPS-induced synthesis of IL-8 in rectal bioptic samples were studied via ELISA. The results

were expressed as picograms per 1 mg of wet tissue (pg/mg). The severity of the inflammation in the CM was studied by the method of Avtandilov G.G. counting with inflammatory infiltrate (in %) in the lamina propria. The study implied investigating the cellular composition of the inflammatory infiltrate in the lamina propria. Depending on the density of the inflammatory infiltrate, the patients were divided into two groups: Group 1 revealed a weak inflammatory response ($20.2 \pm 0.8\%$), while Group 2 demonstrated prominent infiltration intensity ($39.0 \pm 2.09\%$, $P < 0.05$ to Group 1). Statistical processing was performed using the SPSS 13.0 software.

Results: It has been shown that in acute UC stages the amount of IGF-I in the blood plasma decreased (15.16 ± 1.35 nmol/l ($p < 0.05$ to control)), while spontaneous production of IL-8 chemokine in rectal bioptic samples went up (300.0 ± 6.0 pg/ml, $P < 0.05$). In case of the LPS stimulation the production of IL-8 in the CM went up more than 2 times (750.0 ± 7.0 pg/mg, $P < 0.05$). There was significant inverse correlation (rs) detected between the IGF-I levels in the blood plasma, on one hand, and indicators of the UC clinical, endoscopic activity and the intensity of the inflammatory infiltrate in the CM, on the other. Direct relationship was found between the levels of spontaneous and stimulated production of the IL-8 chemokine and the density of the inflammatory infiltrate in the CM of patients with active UC. Through the period of the clinical remission development (an average of 8 weeks) the IGF-I levels increased up to 94.125 ± 28.18 nmol/l ($P < 0.05$), yet have not reached the control value ($P < 0.05$ to control). Induction of the clinical remission was associated with a decrease to the level of the control values for spontaneous and LPS-induced IL-8 production, regardless of UC activity.

Conclusion: The intensity of the inflammatory process in the CM depends on the level of IL-8 produced by respective cells. Evidently, IL-8 has a capacity of inhibiting the production of IGF-I at the peak of inflammation (acute UC). Increased synthesis of IGF-I and reduced IL-8 in remission facilitates regeneration of the damaged mucosa.

P0300 REGULATORY B CELLS CONTRIBUTE TO THE ALLEVIATION OF COLITIS INDUCED BY DEXTRAN SULPHATE SODIUM AFTER H.PYLORI INFECTION

X. Li¹, N. Wang¹, Q. Xue¹, J. Tan¹, J. Wang¹

¹Department Of Gastroenterology, Peking University, People's Hospital, Beijing/China

Contact E-mail Address: lixialjay@163.com

Introduction: Epidemiological studies have showed that there was an inverse association between *Helicobacter pylori* (*H.pylori*) infection and the incidence of inflammatory bowel disease (IBD). Our previous research indicated that the regulatory immune responses induced by *H.pylori* infection were not limited to gastric mucosa, IL-10-producing Breg cells and Foxp3⁺Treg cells expanded in spleen and mesenteric lymph nodes (MLN), the balance of intestinal mucosal immunity was influenced to a skewed regulatory immune response.

Aims & Methods: A murine model with *H.pylori* infection and acute and chronic colitis induced by dextran sulphate sodium (DSS) was established to explore the function of the Breg cells in the effect of *H.pylori* infection on acute and chronic colitis induced by DSS. A C57BL/6 mice model of acute and chronic colitis was induced by 3% DSS with or without *H.pylori* infection in advance, the colitis performances were assessed by disease active index (DAI), colon length and colonic histological inflammatory scores. The CD19⁺IL-10⁺Breg cells and CD4⁺CD25⁺Foxp3⁺Treg cells in blood, spleen, MLN, PP and gastrointestinal mucosa were measured by flow cytometry, immunohistochemistry and immunofluorescence. The anti- and pro-inflammatory cytokines were also detected at mRNA level by real-time PCR.

Results: Compared with the DSS treated acute colitis group, *H.pylori*/DSS co-treated acute colitis group: (1) DAI and colonic histological scores reduced (9.25 ± 4.42 vs 16.00 ± 2.00 , $P = 0.025$) and colon length shortened less (6.56 ± 0.63 vs 5.40 ± 0.54 , $P < 0.001$). (2) The percentages of CD19⁺IL-10⁺Breg cells detected by flow cytometry expanded in different tissues: blood: 5.05 ± 0.68 vs 2.89 ± 0.55 , $P = 0.001$; spleen: 4.32 ± 0.56 vs 3.17 ± 0.20 , $P = 0.05$; MLN: 5.89 ± 0.54 vs 4.94 ± 0.65 , $P = 0.047$; PP: 6.95 ± 1.67 vs 5.39 ± 0.88 , $P = 0.005$; respectively. (3) The percentages of CD4⁺CD25⁺Foxp3⁺Treg cells expanded in different tissues: spleen: 13.50 ± 1.37 vs 10.73 ± 1.13 , $P = 0.008$; MLN: 17.50 ± 0.82 vs 14.87 ± 1.53 , $P = 0.001$; PP: 12.70 ± 3.24 vs 8.58 ± 1.71 , $P = 0.028$. The numbers of Foxp3⁺ cells per HPF in colonic mucosa: 3.44 ± 0.40 vs 2.58 ± 0.34 , $P = 0.004$. (4) mRNA expression in colonic mucosa: IL-10 ($P = 0.001$) mRNA relative expression upregulated and IFN- γ ($P = 0.048$) mRNA relative expression downregulated significantly. Compared with DSS treated chronic colitis group, *H.pylori*/DSS co-treated chronic colitis group: (1) DAI and colonic histological scores reduced (9.00 ± 1.73 vs 14.67 ± 1.53 , $P = 0.001$), and colon length shortened less (6.82 ± 0.41 vs 5.98 ± 0.15 , $P = 0.001$). (2) The percentages of CD19⁺IL-10⁺Breg cells expanded which were consisted with the acute colitis groups: spleen: 7.05 ± 0.28 vs 5.39 ± 0.72 , $P = 0.024$; MLN: 4.78 ± 0.73 vs 3.02 ± 0.83 , $P = 0.047$; PP: 7.14 ± 1.04 vs 4.34 ± 1.03 , $P = 0.005$; respectively. (3) The percentages of CD4⁺CD25⁺Foxp3⁺Treg cells decreased dramatically in different tissues: blood: 4.66 ± 0.22 vs 7.37 ± 0.87 , $P < 0.001$; spleen: 9.07 ± 2.88 vs 13.10 ± 1.19 , $P = 0.018$; PP: 7.33 ± 1.07 vs 12.80 ± 0.96 , $P < 0.001$; The numbers of Foxp3⁺ cells per HPF in colonic mucosa: 3.66 ± 0.99 vs 4.08 ± 0.56 , $P = 0.392$. (4) mRNA expression in colonic mucosa: IL-10 ($P = 0.023$), Foxp3 ($P = 0.000$) mRNA relative expression upregulated significantly, and IFN- γ ($P = 0.001$), TNF- α ($P = 0.005$), IL-17A ($P = 0.019$) and IL-23 ($P = 0.000$) mRNA relative expression downregulated significantly.

Conclusion: (1) *H. pylori* infection can alleviate the acute and chronic colitis induced by DSS. (2) CD19⁺IL-10⁺Breg cells and CD4⁺CD25⁺Foxp3⁺Treg cells expanded significantly in *H. pylori*/DSS co-treated acute colitis mice. (3) CD19⁺IL-10⁺Breg cells expanded while CD4⁺CD25⁺Foxp3⁺Treg cells reduced significantly in *H. pylori*/DSS co-treated chronic colitis mice. The potential protective effect of *H. pylori* infection on acute and chronic colitis induced by DSS may through the expansion and function of CD19⁺IL-10⁺Breg cells.

P0301 FUNGAL COMPOSITION AND FUNGI-BACTERIA CORRELATION IN IBD PATIENTS WITH DIFFERENT TREATMENT STRATEGIES

J. Xu¹, Z. Wu¹, Y. Song¹, N. Wu², F. Zhang¹, H. X. Ren¹, N. Chen¹, Y. L. Liu¹
¹Department Of Gastroenterology, Peking University People's Hospital, Beijing/China

²Institute Of Clinical Molecular Biology & Central Laboratory, Peking University People's Hospital, Beijing/China

Contact E-mail Address: jerry1989@hsc.pku.edu.cn

Introduction: The microbial dysbiosis plays a pivotal role in the pathogenesis of inflammatory bowel disease (IBD), however, the role of fungal microbiota in IBD was unclear. The aim of our study was to clarify the gut fungal composition in IBD patients with different treatment strategies.

Aims & Methods: 73 IBD patients were divided into three groups, Untreatment (n=21), Antiinflammation (n=43) and Immunosuppression (n=9). Antiinflammation was defined as treatment with 5-aminosalicylic acid (5-ASA)/salazosulfapyridine (SASP) and Immunosuppression as treatment with Glucocorticoid (GC), azathioprine (AZA), biologics and thalidomine. Noninflamed and inflamed mucosae were acquired for 16S and ITS sequencing to investigate the bacterial and fungal composition. Inflamed mucosa was used for RNA extraction and real-time PCR to detect the expression of IBD-associated biomarkers, such as TNF- α , IL-17A, MCP-1, etc. Analysis of Spearman's correlation was performed to estimate the fungi-bacteria and microbiota-biomarkers correlation.

Results: Compared with noninflamed mucosa, lower diversity and evenness were observed in inflamed mucosa in all IBD patients, but no significance in noninflamed (or inflamed) mucosa of different treatment strategies. Beta diversity showed a treatment-dependent clustering in inflamed mucosa. Fungal microbiota was constituted by fungi from Ascomycota, Basidiomycota and Zygomycota phyla. There was a higher proportion of Zygomycota in inflamed mucosa than noninflamed mucosa in untreated IBD patients, and Antiinflammation and Immunosuppression didn't significantly alter its abundance. *Mortierella* from Zygomycota was the richest fungi in both inflamed and noninflamed mucosae of all patients. To analyze the effects of treatment strategies on fungal microbiota in IBD patients, we found Immunosuppression decreased abundance of Ascomycota in both noninflamed and inflamed mucosae, while antiinflammation increased Ascomycota in noninflamed mucosa but decreased it in inflamed mucosa. Both Antiinflammation and Immunosuppression increased Zygomycota in inflamed mucosa, but not in noninflamed mucosa. Fungi-bacteria correlation analysis showed a weak correlation in noninflamed mucosa of untreated IBD patients, and Antiinflammation and Immunosuppression didn't significantly alter fungi-bacteria correlation patterns in noninflamed mucosa. However, after Immunosuppression, fungi including *Candida*, *Chaetomium*, *Cladosporium* and *Cryptococcus* were positively correlated to bacteria such as *Coprococcus* and *Lachnospira*. Furthermore, *Mortierella* was negatively correlated with *Blautia* and *Lachnospira* in inflamed mucosa of immunosuppression. In analysis of bacteria-biomarkers correlation, we found bacteria such as Clostridiales, Lachnospiraceae, Parabacteroides, *Blautia*, *Coprococcus*, *Roseburia*, *Faecalibacterium*, *Ruminococcus* and *Megamonas* were significantly correlated to several biomarkers (such as IFN- γ , IL-10, IL-17A, IL-22, TNF- α , etc). Notably, there were different correlation patterns in different treatment strategies, especially, IL-17A was extensively correlated to bacteria such as *Enterococcus*, *Coprococcus*, *Faecalibacterium* and *Klebsiella* in inflamed mucosa of Immunosuppression, but only correlated to *Faecalibacterium* in inflamed mucosa of Antiinflammation. Additionally, we found a weak fungi-biomarkers correlation in IBD patients, but fungi such as *Asterotremella* and *Verticillium* were correlated to biomarkers such as IL-17A, IL-22, IL-8 and MCP-1, and treatment altered microbiota-biomarkers correlation patterns.

Conclusion: Treatment strategies affect fungal composition. To some extent, immunosuppression may aggravate gut fungal dysbiosis in IBD patients, but antiinflammation partially ameliorate it. The bacteria-fungi and microbiota-biomarkers correlation displayed a treatment-specific feature, and treatments change these correlation patterns. Additionally, IL-17A tended to be the main mediator for bacteria to induce inflammation in IBD.

Introduction: MMP9 is involved in the degradation of the extracellular matrix and its expression is elevated in the inflamed tissue of patients with ulcerative

colitis (UC) [1–3]. Pre-clinical models of colitis demonstrate a therapeutic benefit of anti-MMP9 in preventing and ameliorating colitis [4]. Andecaliximab (previously GS-5745) is a high-affinity IgG4 monoclonal antibody against human Matrix Metalloproteinase 9 (MMP9). In a 36-day Phase 1b study in UC, andecaliximab demonstrated clinical efficacy relative to placebo treatment [5]. Here we describe bacterial microbiota analysis of stool samples collected during the Phase 1b study of andecaliximab in UC.

Aims & Methods: The objective of this study is to examine changes to the bacterial microbiota pre- and post-andecaliximab treatment and relative to therapeutic response. Stool was collected prior to treatment (Baseline) and at the end of the study (Day 36). Clinical response was defined as a Mayo score reduction ≥ 3 point and $\geq 30\%$ reduction from baseline score; accompanying decrease in rectal bleeding sub-score of ≥ 1 or an absolute rectal bleeding sub-score of 0 or 1. DNA was extracted from fecal samples using a modified CTAB method and 16S rRNA amplicon sequencing was performed on 59 samples (27 paired and 5 unpaired samples). Alpha diversity, beta diversity (calculated in QIIME), and taxonomic differences were examined between placebo and andecaliximab-treated patients and between responders and non-responders.

Results: Compared to placebo-treated patients, those who received andecaliximab trended towards decreased alpha diversity ($p=0.06$) at 36 days post-treatment. These changes in alpha diversity were not dose related. At Day 36, a trend towards a significant difference in community beta-diversity was observed between the andecaliximab-treated group relative to placebo ($p=0.07$). Andecaliximab treatment was also associated with differences in bacterial taxonomy relative to placebo ($p=0.07$). Specifically, the genera *Clostridia* and *Akkermansia* represented some of the top organisms enriched post andecaliximab treatment relative to placebo. Andecaliximab treatment exhibited a non-significant expansion of *Akkermansia* from Baseline to Day 36 ($p=0.15$). Amongst andecaliximab-treated patients, responders exhibited a trend of increased relative abundance of *Akkermansia muciniphila* ($p=0.08$).

Conclusion: *Akkermansia muciniphila* is the most consistently enriched organism for subjects treated with andecaliximab who respond to treatment. The presence of *Akkermansia muciniphila* at Baseline and/or an increase in *Akkermansia* relative abundance may be associated with response to andecaliximab. Analysis of a larger study population would be required to verify these observations. Recent Phase 2 studies of andecaliximab in UC and Crohn's disease failed to demonstrate clinical efficacy. Therefore these microbiome results are unlikely to be pursued in relation to andecaliximab treatment effects, but may be beneficial as a reference for future trials in inflammatory bowel disease.

Introduction: Crohn's Disease (CD) and Ulcerative Colitis (UC) are Inflammatory Bowel Diseases (IBD) with a complex etiology, including an immune response against microbial and autologous antigens and an imbalance between pro-inflammatory and anti-inflammatory mediators. Different approaches have been used to study the pattern of cytokines in IBD and few data are available on cytokines production in different intestinal compartments. Laser Capture Microdissection (LCM) is a powerful tool for the isolation of specific tissue compartments (1).

Aims & Methods: This work was designed to investigate the pattern of cytokines that regulate the mucosal immune response occurring in different intestinal compartments of IBD patients, using LCM technology (1). Frozen sections of colonic biopsies were obtained from 5 patients with active CD, 5 patients with active UC and 5 controls. None of the patients with CD or UC had been ever undergone medical therapy. Epithelium (EP) and lamina propria (LP) were isolated by LCM, RNAs from EP and LP samples were extracted and, after a reverse transcription, RNA levels of TNF- α , IFN- γ , IL-17, IL-10 and TGF- β were determined by quantitative PCR, using glyceraldehyde 3-phosphate dehydrogenase (GAPDH) as reference gene.

Results: We observed a significant increase in gene expression level of IL-17 in the lamina propria of UC patients respect to CD and controls ($p < 0.05$). TNF- α , IFN- γ , IL-10 and TGF- β levels were significantly higher in the LP of CD as compared to UC and controls ($p < 0.05$). All the cytokines investigated were not significantly up-regulated in the surface EP of both CD and UC patients, when compared to controls.

Conclusion: Our data show that the LP compartment play a key role in the mucosal immune response in IBD patients. In particular, CD seems to be prominently an innate immune response-mediated disease, which is characterized by an increased production of IFN- γ and TNF- α . On the opposite, UC seems to be prominently a CD4 lymphocyte-mediated disease, which is characterized by an increased production of IL-17. Concomitantly with the pro-inflammatory response, high amounts of the anti-inflammatory cytokines IL-10 and TGF- β are also produced in CD compared to UC patients, suggesting that in UC patients the immune-regulatory mechanisms could be impaired. This work underlines the importance of LCM as a valuable tool to determine potential inflammatory components involved in IBD pathogenesis.

Introduction: The gut microbiota play important roles in the development of the ulcerative colitis (UC). Enough evidence has proven the role of intestinal bacterial microbiota in UC pathogenesis. However, the role of intestinal fungal microbiota in UC pathogenesis has not been fully demonstrated.

Aims & Methods: Fungal microbiota from the descending colon mucosal samples of 14 active UC patients and 15 healthy subjects (HS) were analyzed by high-throughput sequencing method. The expressions of pro-inflammatory cytokines (IL-1 β , TNF- α , INF- γ , IL-6, IL-17A, and IF-23) in intestinal mucosal tissues were examined. The Baron and Mayo scores of UC patients were evaluated, and the correlations between intestinal fungal composition and intestinal inflammatory status were analyzed.

Results: The number of fungi decreased significantly in inflamed mucosal tissue compared to HS counterpart while the shannon diversity did not show significant differences. Fifteen major genera were examined, among which *Wickerhamomyces*, unidentified genus of *Saccharomycetales*, *Aspergillus*, *Sterigmatomyces*, and *Candida* showed increasing trends, whereas *Exophiala*, *Alternaria*, *Emericella*, *Epicoecum*, *Acremonium*, *Trametes*, and *Penicillium* showed decreasing trends in UC patients compared to HS. The pro-inflammatory cytokines (IL-1 β , TNF- α , INF- γ , IL-6, IL-17A, and IF-23) were up-regulated in the UC patients. The genera *Wickerhamomyces*, *Sterigmatomyces*, and *Penicillium* were positively correlated with the expression of several pro-inflammatory cytokines in the colonic mucosa, whereas *Nigrospora* was negatively correlated. *Nigrospora* and *Sterigmatomyces* were positively correlated with the Baron and/or Mayo score.

Conclusion: The fungal microbiota in the colonic mucosa of UC patients was different from that of the HS. Alterations in gut fungal composition might be associated with mucosal inflammation and pathogenesis of UC. Further studies are needed to define the fungal composition in detail and identify the role of different fungi in the gut, and determine the mechanism of the host-fungal interaction underlying the development of UC.

Introduction: STAT6 plays a crucial role in M2a macrophage polarization in vitro and these cells mediate mucosal healing in an acute model of TNBS-colitis

through the expression of Wnt ligands (Mucosal Immunology, 2016). We have recently reported that STAT6 deficiency favours fibrosis in a murine model of TNBS colitis (P031, ECCO 2016).

Aims & Methods: We aim to characterize here the functional relevance of the macrophage phenotype in fibrosis development. WT or STAT6 (-/-) mice were given TNBs (0.5, 0.5, 0.75, 0.75, 1, and 1 mg, intrarectally) or saline weekly and they were sacrificed 3, 5 or 7 weeks after the first TNBs administration. The percentage of CD206, CD16, and CD86 positive cells was analyzed by flow cytometry in F4/80+ macrophages isolated from the intestinal mucosa. The mRNA expression of Wnt ligands was evaluated in F4/80+ CD16+ macrophages isolated from the mucosa, 7 weeks after the first TNBs administration and results are expressed as fold induction vs vehicle-treated mice. The mRNA expression of CD16 and fibrosis markers were evaluated in the colonic mucosa. Data are expressed as Mean \pm SEM with $n \geq 8$ in all groups. In all cases results were expressed as fold induction vs vehicle (* $p < 0.05$ vs TNBS WT) and correlations between data were analyzed using Pearson's correlation coefficient (* $p < 0.05$).

Results: TNBs increased the percentage of CD206 positive macrophages in the mucosa of TNBS-WT animals while it failed to do that in TNBS-STAT6 (-/-) mice. The percentage of CD16 positive macrophages increased in a time-dependent manner only in the mucosa of STAT6 (-/-)-TNBS-treated mice. The percentage of CD86+ cells was similar between TNBS-WT and TNBS-STAT6 (-/-) mice. In CD16+ macrophages isolated from TNBS-STAT6 (-/-) mice the mRNA expression of canonical and non-canonical Wnt ligands was significantly increased compared with cells isolated from TNBS-WT mice (Table). A positive and significant correlation between CD16 and Vimentin ($p = 0.0088^*$, $r = 0.51$), α -SMA ($p = 0.0044^*$, $r = 0.55$) and MMP2 ($p = 0.0002^*$, $r = 0.67$) was detected in TNBS-STAT6 (-/-) mice but not in WT animals.

Table

	2B	5A	6	7B	10A
WT	1, 6 \pm 0, 2	2, 1 \pm 0, 5	1, 2 \pm 0, 1	2, 7 \pm 0, 6	3, 3 \pm 0, 8
STAT6 (-/-)	1, 9 \pm 0, 4	6, 4 \pm 0, 6*	2, 7 \pm 0, 4*	15, 3 \pm 2, 2*	2, 9 \pm 1, 0

Conclusion: The expression of Wnt ligands from CD16 positive cells, which are accumulated in the mucosa, may be involved in murine intestinal fibrosis

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Although the etiology of ulcerative colitis (UC) has yet to be characterized, it is increasingly accepted that the cause of UC might well be related to commensal enteric bacteria in a genetically susceptible patient. Anti-inflammatory drugs and immune system suppressors are usually prescribed for UC treatment, and we previously demonstrated that triple antibiotic combination therapy with oral amoxicillin (1500 mg/day), tetracycline (1500 mg/day) or fosfomycin (3000 mg/day), and metronidazole (750 mg/day) (ATM/AFM), for two weeks, induces remission in more than 27% of patients with active UC including those with steroid-refractory or dependent disease, suggesting ATM/AFM to possibly be effective for achieving UC remission.

Aims & Methods: Thirty-two patients with UC given ATM/AFM therapy for two weeks on average were enrolled in this study. The clinical conditions of these UC patients were evaluated by Mayo score. Fecal samples were obtained prior to, after therapy and at three months after treatment completion. Gut microbiota were compared employing metagenomic analysis of fecal samples.

Results: Of the 32 patients, 17 and eight, respectively, experienced complete and partial remission over three months in response to ATM/AFM therapy, whereas ATM/AFM showed no efficacy in seven patients. The metagenomic analysis revealed abundant human DNA to correlate positively with the disease activity indicated by the Mayo score. Furthermore, dramatic gut microbiota changes were observed at an early stage, i.e. just two weeks after starting ATM/AFM therapy. Comparison of the metagenomic data suggested that the dysbiosis

before treatment in the active stage to possibly be associated with increased populations of *Bacteroides*, *Parabacteroides*, *Rickenella*, *Clostridium*, *Flavonifractor*, *Pelagibacter*, *Bordetella*, *Massilia* and *Piscirickettsia* species. In responders after treatment, populations of *Bifidobacterium* and *Lactobacillus* species were significantly increased. In this study, there was an especially strong negative correlation between *Bacteroides* and *Bifidobacterium* both before and after treatment.

Conclusion: These results suggested metagenomic analysis results to be associated with a remarkable change in gut microbiota after antibiotic combination treatment. In responders, remission is associated with increases in *Bifidobacterium* and *Lactobacillus* species and a decrease in *Bacteroides*.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Classically, enteroendocrine cells (EEC) are renowned for regulating gastrointestinal motility, secretion, and insulin levels by release of peptide hormones. Yet, via receptors and transporters, EEC are capable of sensing the lamina propria and luminal environment, including the microbiota, and also mediate immune-related signals. In particular, the L-cell-derived incretin hormone glucagon-like peptide 1 (GLP-1) is increasingly recognized to exert direct effects on immune cells and to orchestrate a metabolic-inflammatory response. In inflammatory bowel disease (IBD), a role for EEC in disease pathogenesis is indicated by a risk-associated SNP and autoantibodies affecting EEC function as well as general disease symptoms like insulin resistance and altered intestinal motility. However, the total number of studies investigating EEC number and function in IBD and mouse models of intestinal inflammation is limited and results are conflicting.

Aims & Methods: To characterize alterations in GLP-1-expressing EEC numbers under intestinal inflammatory conditions, immunostainings for GLP-1 and ChgA as well as mRNA expression analysis was performed in intestinal tissue samples. Mouse models of intestinal inflammation used include genetic models, *Il-10*^{-/-} mice (colitis), an adoptive transfer model, *Rag2*^{-/-} mice reconstituted with CD4⁺ T cells (colitis), chemically (DSS)-induced colitis and an infection model (*Citrobacter rodentium*).

Results: Numbers of GLP-1⁺ and ChgA⁺ cells were consistently reduced in all mouse models of intestinal inflammation. These changes were confined to the site of active inflammation. Neither absence of mature B and T cells in *Rag2*^{-/-} mice alone was associated with reduced numbers of EEC, nor adoptive transfer of CD4⁺ T cells per se, since transfer of non-colitogenic CD4⁺ CD25⁺ T cells did not lead to changes in ChgA⁺ cell numbers in the colon. The reduction of GLP-1⁺ and ChgA⁺ cells observed by immunohistochemistry was reflected by diminished levels of *Gcg* and *Chga* mRNA expression, whereby mRNA levels of the L-cell derived-hormone *Ppy* remained unaltered.

Conclusion: To our knowledge, this work provides the first comprehensive study of GLP-1⁺ and ChgA⁺ cell numbers in different mouse models of intestinal inflammation. A reduction of GLP-1-expressing EEC seems to be a general feature of small as well as large intestinal inflammation. Further research will clarify if these alterations represent a consequence or causatively contribute to intestinal inflammation and elucidate the functional consequences on immune responses.

Introduction: Neutrophil extracellular traps (NETs) are fibrous structures released by activated neutrophils upon stimulation. NETs consist of chromatin and cytoplasmic proteins, which are released extracellularly during a process called NETosis. Tissue factor (TF) is the main in-vivo initiator of coagulation and is expressed on NETs in a plethora of neutrophil-mediated thromboinflammatory conditions [1–3]. Ulcerative colitis (UC) is characterized by infiltration of neutrophils into the affected mucosa and increased risk of thromboembolic events; however the mechanism behind the thrombophilic state of UC has not been clearly elucidated yet [4, 5].

Aims & Methods: We aimed to investigate for the first time the role of neutrophils/NETs through TF expression in the pathophysiology of UC. Neutrophils, sera and colon biopsies were obtained from 10 naïve patients with active UC (6 male and 4 female, mean age 34.6 ± 19.1 years, mean Mayo score 8.5 ± 1.4) and from 10 naïve patients suffered from active Crohn disease (CD) (7 male, 3 female, mean age 34.2 ± 18.5, CDAI > 220). Additionally, 10 sex- and age-matched healthy subjects, were served as control subjects (5 male, 5 female, mean age 38.5 ± 12.5). Ex-vivo findings regarding peripheral blood neutrophils and colonic tissue specimens were verified using appropriate in-vitro stimulations of control neutrophils with corresponding sera and intestinal tissue-conditioned media, respectively. Identification and quantification of NETs were performed with immunofluorescence confocal microscopy (ICM), flow cytometry and MPO/DNA complex ELISA. The expression of TF on neutrophils/NETs was determined using ICM, qRT-PCR and western blot analysis. The bioactivity of TF on NETs was assessed by measuring thrombin-antithrombin complex levels with ELISA.

Results: Neutrophils from patients with active UC are characterized by increased NET formation in both the peripheral blood and affected colonic mucosa, compared to CD. Furthermore, NETs in UC are decorated with functionally active TF and the amount of TF-bearing NETs was reduced from the inflamed to normal colon. In-vitro stimulations of controls neutrophils with sera or intestinal tissue-conditioned media corroborated the findings obtained ex-vivo.

Conclusion: NETs expressing bioactive TF may be involved in the induction of intestinal inflammation and systemic thrombosis in UC probably constituting a novel candidate diagnostic and/or therapeutic target.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The intestinal epithelium is a multicellular interface that is completely renewed every 3–5 days. Pluripotent stem cells reside at the crypt bottom giving rise to transient amplifying cells and subsequently differentiated intestinal epithelial cells (IEC) of all subtypes. Phases of cellular and functional transitions are characterized by distinct metabolic identities, reflected by changes in mitochondrial activity. Alterations in mitochondrial function and mitochondrial unfolded protein response (MT-UPR) activation are associated with various chronic pathologies including inflammatory bowel diseases (IBD) and cancer. We have previously shown that MT-UPR and mitochondrial function itself is involved in the regulation of cell cycle progression and intestinal stemness. Here, we present evidence that impaired mitochondrial proteostasis is sufficient to drive differentiation of *Lgr5*⁺ stem cells (ISC) into Paneth cells.

Aims & Methods: To depict the impact of imbalances in mitochondrial proteostasis on ISC, we used mice with a tamoxifen-inducible ISC or IEC-specific conditional knockout allele for the mitochondrial chaperone Hsp60 and the mitochondrial protease ClpP. Molecular consequences of the gene deletions in the different models were further characterized ex vivo using intestinal organoid culture. In situ hybridization, IHC and combinations of both as well as IF were performed to illustrate alterations of IEC subtypes. Readouts were complemented by mRNA expression analysis and biochemical approaches.

Results: ClpP-knockout as well as chemical inhibition of the respiratory chain in intestinal organoids led to diminished *Lgr5* expression confirming our results from IEC and ISC specific Hsp60-deletion. In vivo, the ISC-specific loss of HSP60 resulted in a transient drop in *Lgr5*⁺ cells with *Lgr5* expression being reduced from day 2 after end of tamoxifen treatment and signals reappearing from day 4. Cells positive for the stem cell markers *Olfm4* and *Hopx* expanded at day 2, indicating reserve stem cell populations compensating for the *Lgr5*⁺ ISC loss. Minimal numbers of *Lgr5*⁺ stem cells at day 2 were further paralleled by increased numbers of *Lgr5*⁺, *Lyz*⁺ Paneth cells and no signs of enhanced cell death, indicating differentiation of ISC into Paneth cells. *Lgr5*⁺, *Lyz*⁺ Paneth cells displayed a premature phenotype with diffuse *Lyz* staining in the cytoplasm.

Abstract No:P0310

BILE ACIDS						
375.28/10.79	Faecal	UV	Decreased	0.0046	Lithocholic acid	Secondary bile acid from bacterial metabolism of chenodeoxycholic acid
375.28/10.81	Serum	UV	Decreased	0.0041	Lithocholic acid	
391.28/10.35	Serum	UV	Decreased	0.0072	Deoxycholic acid	Secondary bile acid from metabolism of cholic acid
407.28/8.33	Serum	UV	Decreased	0.0045	Cholic acid	Primary bile acid
432.314/9.91	Serum	UV	Decreased	0.0230	Glycolithocholic acid	Sulphur ester of lithocholic acid
373.272/10.17	Serum	MV	Decreased	0.0007	5-Cholenic Acid-3B-ol	
391.283/10.34	Serum	MV	Decreased	0.0018	Deoxycholic acid	

Concomitantly, these cells were positive for the WNT ligand WNT10A and autophagy/mitophagy-associated LC3, suggesting autoregulatory mechanisms for the maintenance of the stem cell niche and mitochondria-associated functional alterations, respectively.

Conclusion: Our results indicate that mitochondrial function not only reflects IEC phenotypic changes but seems to be the driving force in differentiation processes. Mitochondrial function might therefore represent a key player at the edge of intestinal tissue homeostasis and repair/healing processes in the context of diseases.

Introduction: Previous studies have shown differences in disease phenotype of ulcerative colitis (UC) in South Asian (SA) migrants compared to Caucasians with pan-colonic phenotype predominant.¹ The gut microbiota differs in Caucasian and SA patients with UC² however, there is limited evidence on how this translates to the metabolome.

Aims & Methods: We aimed to examine the metabolic profile in a newly diagnosed cohort of UC patients recruited from St. Marks Hospital, London, UK. Patients were stratified by ethnicity (SA, Caucasian, Other), treatment (None, 5-ASA, Azathioprine and Steroids) and disease duration. Healthy controls (HC) were recruited locally among the staff at St. Marks Hospital. Biofluids (urine, faeces and serum) were collected at diagnosis (time point 1; months 0–3) and 2 further time points over one year (time point 2: months 4–8, time point 3: months 9–12). Metabonomics approach was applied using two different UPLC-MS profiling methods; for small metabolites (hydrophilic liquid chromatography, HILIC) and for bile acids (BA) platforms. Univariate (UV) and multivariate (MV) data analysis was implemented to build models using principle component analysis (PCA) and orthogonal partial least squares -discriminant analysis (OPLS-DA) to find metabolites that were expressed in significantly different amounts between the two populations, time points (1 vs 3) and treatment groups.

Results: Fifty patients with UC of SA and Caucasian backgrounds were recruited. A total of 309 samples were collected. Sample collection was completed for all time points for 18 SA (11 UC and 7 HC) and 21 Caucasians (9 UC and 12 HC). There was no significant difference between SA and Caucasian at time points 1, 2 and 3 and treatment groups. Significant differences were observed between HC vs. disease, SA HC vs. Caucasian HC and SA UC vs. Caucasian UC. For the UC cohort, robust models were obtained by OPLS-DA between SAs and Caucasians; Faecal HILIC (R^2Y 0.869, Q^2Y 0.451, $p < 0.0003$) and urine HILIC (R^2Y 0.783, Q^2Y 0.526, $p < 0.0001$) and serum BA (R^2Y 0.702, Q^2Y

0.517, $p < 0.0001$) and faecal BA (R^2Y 0.832, Q^2Y 0.395, $p < 0.0001$). Combined analysis revealed 1611 significant features (faecal HILIC 60, urine HILIC 189, serum BA 489 and faecal BA 873). The assigned features are shown in Table 1. Faecal HILIC showed significantly higher essential amino acids (Adenine, L-phenylalanine, L-tryptophan) levels on UV and higher 1-leucylproline and creatinine levels on MV analysis for SAs. Urine HILIC showed lower creatine, L-phenylalanine and hippuric acid levels. Serum primary (Cholic and chenodeoxycholic acid) and secondary bile acids (BA modified by the gut) were significantly reduced in SAs. Table 1: Significant metabolites in OPLS-DA model between South Asian (SA) and Caucasians with UC. *compound is increased or decreased in SA compared with Caucasians respectively

Conclusion: This study highlights the promise of UPLC-MS profiling to differentiate between SA and Caucasian groups. There are several possible reasons but two important factors are differing microbial metabolism and diet between the two groups. We are conducting further studies incorporating dietary data and 16S microbial analysis in this cohort. In combination with matching disease extent (left-sided vs colonic disease) may help to identify possible explanations for the different disease phenotype in this group.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Patients with active inflammatory bowel disease have elevated myeloid lineage leucocytes¹ including the CD14+CD16+DR++ phenotype known as proinflammatory monocytes, and a major source of tumour necrosis factor- α .² Accordingly selective depletion of myeloid leucocytes by granulocyte/monocyte apheresis (GMA) is expected to promote remission or enhance drug efficacy. However, studies in ulcerative colitis (UC) patients have reported contrasting efficacy outcomes, ranging from an 85%³ to statistically insignificant level.⁴ Patients' baseline demographic features may guide to selecting responder patients.

Aims & Methods: In a retrospective and single-centre setting we aimed to understand if patients' baseline clinical and endoscopic features were relevant guide for identifying likely responders and non-responders to adsorptive GMA. The subjects were 145 consecutive UC patients who had undergone GMA with the Adacolumn as remission induction therapy between 2012 and 2016. Seventy-three patients were steroid naive, 70 were steroid dependent, and 2 patients were steroid refractory. Patients had received up to an 11 GMA sessions over 10 weeks. At entry and week 12, patients were clinically and endoscopically evaluated, allowing each patient to serve as her or his own control. Clinical activity index (CAI) ≤ 4 was defined as remission. Biopsies from endoscopically detectable inflamed large intestinal mucosa were processed to see the impact of GMA on leucocytes within the mucosal tissue.

Results: At entry, the average CAI was 12.8, range 10–17. Ninety-three patients (64.1%) had responded to GMA, 52 of 73 steroid naive (71.2%), 40 of 70 steroid dependent (57.1%), and 1 of the 2 steroid refractory cases. On average remission was sustained for 8.6 months in steroid naive patients and for 10.4 months in steroid dependent subgroup. Observations on mucosal tissue biopsies showed that infiltrating leucocytes were mostly neutrophils and monocytes. There was a marked reduction of infiltrating leucocytes in responder patients. Patients with extensive deep UC lesions together with loss of the mucosal tissue at the lesions were non-responders. Patients with the first UC episode were identified as the best responders (100%), followed by steroid naive patients. Additionally, a short duration of active UC prior to GMA marked a patient as a likely responder. Further, all patients who achieved remission were steroid free at week 12.

Conclusion: First-episode and steroid-naïve cases who responded well to GMA attained a favourable long-term clinical course. Additionally, GMA was more effective if applied immediately after a relapse than after a lag time. In general, GMA is favoured by patients for its safety profile and for being a non-drug remission induction therapy. Patients with extensive deep ulcers, with long duration of UC refractory to multiple pharmacologicals are unlikely to benefit from GMA. In therapeutic settings, knowing baseline clinical and endoscopic features, which may identify GMA responder patients should guide to stop futile use of medical resources.

Introduction: Much research has demonstrated that tolerogenic dendritic cell (DC) with the capacity to induce regulatory T cells (Treg) play an important role in maintaining immune tolerance and has been proposed for treatment of inflammatory bowel disease (IBD). In this study, we report on the use of glial-derived neurotrophic factor (GDNF) produced by Enteric glial cells (EGCs) as a new approach to induce tolerogenic DCs with capacity to generate Treg, to restore immune tolerance in vivo, and to ameliorated experimental colitis.

Aims & Methods: DCs were generated from rat bone marrow (BMDC) in the absence (DC_{Control}) or presence of GDNF (DC_{GDNF}) and additionally stimulated with LPS to induce maturation (mDC). The expression of major histocompatibility complex II (MHC-II), CD40, CD80, and CD86 was determined by flow cytometry. Levels of IFN- γ , interleukin-4 (IL-4), and IL-10 in the culture supernatants were determined by ELISA. The location of GDNF receptor- $\alpha 1$ (GFR- $\alpha 1$) in DCs was detected by immuno-fluorescence staining. The expression of GFR- $\alpha 1$ and ERK1/ERK2 in DCs was tested by Western Blot. SD rats were fed with 5% Dextran Sulphate Sodium (DSS) to induce experimental colitis, the therapeutic action of DC_{GDNF} were examined. Diverse clinical signs of the disease including weight loss, diarrhea, colitis, histopathology were evaluated, and the mechanisms involved in the potential therapeutic effect of DC_{GDNF}, such as inflammatory cytokines and chemokines (IL-4, IFN- γ , TNF- α , IL-1 β , IL-17), the generation of IL-10-secreting Treg (Treg1), and the level of Treg1/Th2, Treg1/Th17 were investigated.

Results: GFR- $\alpha 1$ was expressed in BMDC, and the expression of ERK1/ERK2 were significantly up-regulated after treatment with GDNF. DC_{GDNF} did not up-regulate MHC-II, CD40, CD80, CD86, and produced very low levels of proinflammatory cytokines (IFN- γ , IL-4) but secreted significant levels of the anti-inflammatory cytokine IL-10 after LPS stimulation, as compared with DC_{Control}. CD4 T cells primed with DC_{GDNF} resulted in weak proliferation and exhibited a Tr1-like phenotype, which characterized by IL-10, whereas DC_{Control} induced a strong proliferation, exhibited a phenotype characterized by IFN- γ , IL-4. DC_{GDNF} injection significantly ameliorated body weight loss, diarrhea, and colonic histopathologic injury in rat, and DC_{GDNF} injection strikingly reduced the production of inflammatory factors such as IL-4, IFN- γ , TNF- α , IL-1 β , and IL-17, generated Treg1 with suppressive capacity on autoreactive T cells, and demonstrated a higher level of Treg1/Th2, Treg1/Th17.

Conclusion: GDNF could induce tolerogenic DCs through ERK1/ERK2 signal pathway, and DC_{GDNF} could alleviate the severity of DSS induced colitis in rats. The mechanism may be related to down-regulation of inflammatory and immune response, generating Treg1 and restoring immune tolerance.

Introduction: Alterations in short chain fatty acid (SCFA) metabolism have been reported in inflammatory bowel disease (IBD). Among SCFA, butyrate has been described as a potent communicator to the immune system eliciting an anti-inflammatory response and other positive effects to human health¹. A reduction of faecal butyrate levels has been reported in IBD but results have been conflicting or discrepant because of small study numbers and failure to distinguish disease type, activity or other variables such as diet. Microbiota is receiving increasing attention as a key environmental factor influencing IBD², and butyryl-CoA:acetate CoA-transferase (BCoAT) is considered the main enzyme involved in butyrate synthesis by gut microbiota³.

Aims & Methods: We performed a comparative assessment of the capacity of the microbiota for butyrate synthesis by quantifying BCoAT gene content in stool from patients with Crohn's disease (CD; n = 71), ulcerative colitis (UC; n = 58) and controls (n = 75), and determined whether it was related to disease activity, inflammation, microbial diversity and composition and/or dietary habits. BCoAT gene content was quantified by qPCR⁴. Disease activity was assessed clinically and faecal calprotectin concentration measured as biomarker of inflammation in the gut. Microbial composition was determined by sequencing 16S rRNA gene. Dietary data were collected using an established food frequency questionnaire.

Results: Reduced butyrate-synthetic capacity was found in patients with active and inactive CD (p < 0.001 and p < 0.01, respectively), but only in active UC (p < 0.05). In patients with CD, low BCoAT gene content (below 9.5 log10 copies BCoAT/g) was associated with active disease, increased inflammation, lower microbial diversity, greater microbiota compositional change and decreased butyrogenic taxa, while no major changes were observed between patients with UC grouped according to BCoAT gene levels. Reduced BCoAT gene content in patients with CD was, in part, linked with lower intake of certain foods containing fibre (vegetables, fruits, high-fibre cereals, brown/wholemeal bread and nuts).

Conclusion: Reduced butyrate-synthetic capacity by the microbiota is more evident in CD than UC and may relate to reduced fibre intake. The results suggest that simple replacement of butyrate per se may be therapeutically inadequate, whereas manipulation of microbial synthesis perhaps by dietary means may be more appropriate and profitable for patients with CD.

Introduction: Antibiotics sometimes have an influence on colitis negatively. Although it is well known that dysbiosis is one of the major disturbances to the gut environment, the molecular mechanisms underlying the pathogenesis remains unclear.

Aims & Methods: We aimed to clarify how antibiotics affect the gut microbiota and the pathology of colitis. Mice were gavaged with ampicillin (ABPC), vancomycin (VCM), metronidazole, neomycin, or a combination of ABPC and VCM (A-V) for three consecutive days. Colitis was assessed by fecal occult blood test (FOBT) and mRNA level of cytokines. Metabolites and short chain fatty acid (SCFA) in the feces were measured by a chromatography-tandem mass spectrometry. Fecal microbiota was characterized by 16rRNA sequencing. In the glutamine (Gln) treatment exam, the mice were given 30 mg/mL of Gln in drinking water ad lib for six days, and additionally gavaged A-V for the last three days. *In vitro* experiments, mouse colon carcinoma cell line CMT93 and macrophage cell line RAW267.4 were stimulated by butyric acid.

Results: ABPC and VCM, but not other antibiotics, resulted in FOBT-positive in some cases. All A-V treated mice were FOBT-positive and IL-6, IL-12p40 and MIP-1a were significantly increased. The caecums were enlarged and dun-colored in the A-V mice. Moreover, Gln metabolites and SCFA including butyric acid were decreased and family S24-7 and order Clostridiales were less abundant in the feces of A-V mice. Interestingly, Gln treatment improved the antibiotics-induced colitis. Butyric acid reduced mRNA expression of pro-inflammatory cytokines in RAW267.4 and induced expression of antimicrobial peptides (secretory leukocyte protease inhibitor and lactoferrin) in CMT93.

Conclusion: A-V treatment induced mild colitis with reduced abundance of family S24-7 and order Clostridiales, which might disturb Gln and SCFA metabolisms.

Introduction: Inflammatory bowel disease (IBD) is a group of gastrointestinal tract diseases consisting mainly of Crohn's Disease (CD) and Ulcerative Colitis (UC). Various etiological factors contribute to the pathogenesis of IBD, including modulation of microbiota, epithelial barrier disruption, genetics and environmental factors. Currently, the treatment of IBD comprises several groups of drugs the choice of which is made based on disease activity and extent. The treatment options include: analogs of 5-aminosalicylic acids, glucocorticoids and other immunosuppressive drugs such as azathioprine. Biological therapy with anti-tumor necrosis factor alpha (TNF α) are considered when conventional therapy fails. In portion of patients surgical approach is necessary. Therefore novel pharmacological targets are sought in order to improve the remission rate and avoid the disabling procedures. G protein-coupled receptor 18 (GPR18) belongs to the endogenous cannabinoid system which already earned its place in the pathogenesis of IBD. GPR18 was found to be implicated in protection against bacterial infection and organ injury. Reports indicate that it may also be connected to the obesity/diabetes-related inflammation. As we lack data regarding its association with intestinal inflammation we attempted to shed some light on this phenomenon.

Aims & Methods: The aim of the study was to assess the anti-inflammatory and anti-nociceptive actions of GPR18 in the intestinal inflammation. The anti-inflammatory activity of GPR18 agonist PSB-KK-1415 and antagonist PSB-CB5 (1–5 mg/kg, i.c., once daily) was characterized in two mouse models of colitis, induced by 2, 4, 6-trinitrobenzenesulfonic acid (TNBS) and dextran sulfate sodium (DSS). The extent of inflammation was evaluated based on the macroscopic score, microscopic score, quantification of myeloperoxidase (MPO) activity and alpha (TNF α) in colonic tissue. The expression of GPR18 gene in colonic samples from patients with IBD was quantified using real-time RT PCR and Western blot analysis. GPR 18 was localized in human colonic samples using immunohistochemistry methods.

Results: The results of our study with lower doses of GPR18 ligands in the semi-chronic TNBS model of colitis showed a non-significant decrease in macroscopic score, ulcer score and a significant decrease in MPO activity ($p < 0.05$) in mice injected with PSB-KK-1415 compared with TNBS-treated mice. PSB-CB5 increased inflammation indices. Study in the mouse model of TNBS-induced colitis with higher dose of PSB-KK-1415 presented a pronounced reduction in

the indices after treatment with the agonist. We also showed that GPR18 is expressed in the colon of patients with IBD.

Conclusion: We demonstrated potential ability of the GPR18 agonist PSB-KK-1415 to alleviate inflammation in the mouse models of colitis and showed that GPR18 is expressed in the human colon. We conclude that GPR18 is another receptor of the endogenous cannabinoid system family which may be implicated in the pathogenesis of IBD and intestinal inflammation overall.

P0316 THE MECHANISM OF PROTECTIVE ROLE OF D3 DOPAMINE RECEPTORS IN PATHOGENESIS OF ULCERATIVE COLITIS

A. Prysiachniuk, T. Dovbychuk, Y. Holota, I. Varenjuk, L. Garmanchuk, G. Tolstanova

Taras Shevchenko National University of Kyiv, ESC 'Institute of Biology and Medicine', Kyiv/Ukraine

Introduction: Our previous study showed that activation of D3 dopamine receptors (D3R) had the beneficial effect in experimental colitis treatment while the mechanism of this effect is unclear [1]. The disruption of surface colon mucosa layer with subsequent activation of local immune response by the bacterial infiltration into the inner layer of the mucosa are the key pathogenic mechanisms of ulcerative colitis progression and perpetuation. We found the localization of D3R on the Goblet cells in colonic mucosa [2].

Aims & Methods: In present study we tested the hypothesis that activation of D3R improves colonic mucus secretion during experimental colitis. Study was done on male Wistar rats (180–230). Experimental colitis was induced by 6% iodoacetamide (IA) (0, 1 ml, enema). Selective D3R agonist 7-OH-DPAT (0.02 mg/100 g, s.c.) was injected 0, 5 h prior to IA enema. Rats were euthanized 0, 5 and 2 h after IA enema. During the autopsy 7 cm colon from the anus has been removed. Surface mucus layer was separated from epithelial cells with N-acetyl-L-cysteine and glycoproteins were measured by periodic acid/Schiff (PAS) staining or by the reaction with Folin reagent. The content of hexose, fucose and hexosamine were determined by standard biochemical assays. Morphometric analysis was performed to evaluate the histological changes of colonic epithelial and Goblet cells. Oxidative metabolism and arginase activity (analyzed by colorimetric method) in peritoneal macrophages were investigated.

Results: Pre-treatment with 7-OH-DPAT did not affect the glycoprotein levels in normal mucosa, but significantly increased total levels of glycoprotein (1, 6-fold, $p < 0.05$) and hexose (1, 1-fold, $p < 0.05$) during IA-colitis. Furthermore, 7-OH-DPAT significantly increased functional reserve of peritoneal macrophages in 0, 5 h (1, 6-fold, $p < 0.05$) and in 2 h (1, 3-fold, $p < 0.05$) after IA enema. Pre-treatment with 7-OH-DPAT decreased the mucosal layer thickness 1, 1-fold ($p < 0.05$), crypt depth 1, 1-fold ($p < 0.05$) and Goblet cell intersection area 1, 2-fold ($p < 0.05$) after IA enema.

Conclusion: Pre-treatment with D3R-agonist increased levels of mucus secretion and activated natural immune response by macrophage activation during experimental colitis, which could indicate about the protective role of D3R.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0317 INFLAMMATION AT DISTAL ILEOCAECAL RESECTION MARGINS INCREASE THE RISK OF POSTOPERATIVE CROHN'S RECURRENCE

K. Wasmann¹, J. Van Amesfoort¹, L. Koens², W.A. Bemelman¹, C.J. Buskens¹

¹Surgery, Academic Medical Centre, Amsterdam/Netherlands

²Pathology, Academic Medical Center, Amsterdam/Netherlands

Contact E-mail Address: k.a.wasmann@amc.nl

Introduction: Guidelines advise limited resection for Crohn's terminal ileitis, as previous literature did not demonstrate clinical benefit from more extensive resections. Recently, some cohort studies identified positive resection margin as an independent risk factor for postoperative Crohn's recurrence. But it is difficult to draw clinical conclusions, as non-uniform pathological definitions have been used. The aim of this study was to assess the incidence of non-radical resections by a validated pathological score, and correlate pathological findings to clinical outcome.

Aims & Methods: H&E stained slides from proximal (ileum) and distal (colon) resection sites were scored according to the modified Geboes score from all consecutive patients undergoing primary ileocaecal resection between January 2002 and September 2009. Endpoints were clinical recurrence (defined as recurrent disease activity demonstrated by endoscopy or MRI) requiring upscaling medical treatment or surgical recurrence.

Results: Of 104 ileocaecal resections, 30 (29%) and 15 (14%) had inflammation at the proximal and distal resection margins, respectively. After a median follow-up of 8.6 years, clinical recurrence was seen in 57%, and surgical recurrence in 26%. A significantly increased recurrence rate was seen in patients with active inflammation at the distal resection margin whereas recurrence rates were comparable for inflammation at the proximal site and radical resections (87%, 61%, and 50% resp., $p < 0.001$). Active inflammation at the distal resection margin (HR: 3.189 (1.635–6.220); $p = 0.001$) and smoking (HR: 2.502 (1.331–4.703); $p = 0.004$) were the only independent predictors for clinical recurrence. The incidence of surgical recurrence was too small to perform statistics.

Conclusion: Inflammation at the distal (colon) resection margin, and not the proximal ileum, after ileocaecal resection was associated with significantly increased risk of clinical recurrence. This unexpected finding suggests that radicality does not play a role in correctly diagnosed terminal ileitis (L1 disease), while it is of crucial importance to exclude colonic activity (L3 disease). As this different phenotype is unlikely to benefit from more extensive surgery, pathological finding of positive distal resection margin should be regarded as a risk factor, warranting prophylactic drugs or close monitoring.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0318 APPLICATION OF NEW SINGLE NUCLEOTIDE POLYMORPHISMS TO THE IDENTIFICATION OF ADHERENT-INVASIVE *E. COLI* (AIEC)

C. Camprubi-Font, M. Lopez-Siles, M. Ferrer-Guixeras, L. Niubo-Carulla, C. Abellà-Ametller, L.J. Garcia-Gil, M. Martínez-Medina
Biological Department, Universitat de Girona, Girona/Spain

Contact E-mail Address: c.camprubi4@gmail.com

Introduction: The genetic basis that constitutes an adherent-invasive *Escherichia coli* (AIEC), a pathotype associated with Crohn's disease, still needs to be deciphered. Obtaining new molecular tools for AIEC identification would be of great significance, as current techniques based on phenotypic screening of cultured bacteria are time consuming (1).

Aims & Methods: Our aims were: (i) to search for genetic elements putatively involved in the AIEC phenotype in order to find specific signature sequences and (ii) to determine the distribution of these elements to assess their usefulness in AIEC identification. AIEC-specific sequences were identified through comparative genomics of three *E. coli* strain pairs (from different phylogroups) displaying different AIEC phenotype but identical pulsotype. Paired-end libraries of Illumina HiSeq and PacBio of the six strains' genomes were combined de novo and assembled by SPAdes. Differences in gene content between pairs were accomplished with OrthoVenn. Harvest was performed to compare strain pairs against an AIEC reference genome (UM146). Only non-synonymous single nucleotide polymorphisms (SNPs) in coding regions were selected. We performed Sanger sequencing to confirm the presence of SNPs and to evaluate the distribution of the SNPs in a collection of 22 AIEC and 29 non-AIEC isolates. Nucleotides for each SNP were analysed taking into account AIEC phenotype, adhesion and invasion indices by χ^2 test or Kruskal-Wallis test, as required. Binary logistic regression was applied to assess the usefulness of particular variants for AIEC screening. Isogenic mutants were generated with a PCR product using the method previously described(2, 3) to assess the effect of the novel candidate genes in AIEC phenotype. In this collection, point mutations or prevalence of previously AIEC-associated genes has also been examined.

Results: A total yield of 5209 gene clusters was obtained, 3327 of which were common for the six strains and none was found to be common in the three AIEC strains, not even exclusively in two of them. Comparative genomics identified 18 SNPs between the strains of the D-phylogroup pair, 17 in the B2-pair and 30 in the B1-pair that met the selection criteria. Of those, 24 SNPs (found in 13 genes) were confirmed and further analysed in the strain collection. Three of the SNPs-encompassing genes were related with adhesion/invasion and two with stress

tolerance. Three SNPs resulted in differential nucleotide distribution between AIEC and non-AIEC strains ($p < 0.016$). These SNPs also presented association with adhesion and invasion strain capacities ($p < 0.006$). Interestingly, one of these polymorphisms can predict the AIEC phenotype with a 71% of specificity ($p = 0.008$). No differences according to pathotype were reported in the prevalence of previously AIEC-related genes, nor in point mutations frequency.

Conclusion: Our study corroborates the absence of AIEC-specific genetic markers widely distributed across all AIEC strains. Nonetheless, three SNPs putatively involved with the AIEC phenotype have been described and one of them could be applied in AIEC screening.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0319 LIPOSOMAL FORMULATION AS A NEW DRUG DELIVERY SYSTEM FOR CROHN'S DISEASE - VALIDATION IN THE MOUSE MODEL OF TNBS-INDUCED COLITIS

J. B. Krajewska, P. Pietruszka, D. Tomczyk, J. Fichna
Department Of Biochemistry, Medical University of Lodz, Lodz/Poland

Contact E-mail Address: julia.krajewska@stud.umed.lodz.pl

Introduction: Crohn's Disease (CD), one of the two main types of inflammatory bowel disease (IBD), constitutes a significant healthcare burden, especially in the developed societies. Current methods of treatment are only partially effective and/or associated with major adverse effects. New therapeutic solutions are required to ameliorate the effects of medical therapy, reducing complications and improving patients' quality of life.

Aims & Methods: The objective of the study was to assess the effectiveness of delivery of anti-inflammatory drugs encapsulated in the liposomal formulation. Liposomes were prepared using thin-lipid hydration method. 0.9% sodium chloride was used as a solvent. The hydration solutions contained an aminosalicylate mesalazine (5-ASA), two recently validated plant-derived anti-inflammatories with low bioavailability, chlorogenic acid (CGA) and berberine, and pure solvent as negative control. Colitis was induced in male BALB/c mice by a single intracolonic (i.c.) administration of 2, 4, 6-trinitrobenzene sulphonic acid (TNBS) on Day 0. Liposomal suspensions containing 5-ASA (5 mg/kg), CGA (20 mg/kg), berberine (5 mg/kg) and the solvent were administered i.c. twice daily from Day 3 to Day 6. Mice were sacrificed on Day 7 and colonic damage was evaluated.

Results: The macroscopic scoring system included the evaluation of the colon length and bowel thickness as well as the presence of ulcers, haemorrhage, faecal blood and diarrhea. Additionally, tissue myeloperoxidase (MPO) activity was determined and body weight was measured. The obtained results indicate that the best anti-inflammatory effect was obtained when liposomal suspension with berberine was used, while the treatment with 5-ASA was less effective. Surprisingly, CGA administration caused a detrimental effect as demonstrated by higher macroscopic score and increased MPO activity.

Conclusion: Drug-loaded liposomes may enhance the penetration of active compounds through the gut wall and therefore allow for increased bioavailability and effectiveness of the treatment at lower doses. We also showed that plant-derived compounds with low bioavailability, such as berberine and CGA, provide a new direction in the search of anti-inflammatory substances. However, increased bioavailability of anti-inflammatories due to liposomal formulation may result in adverse effects.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0320 EPIDEMIOLOGY OF MICROSCOPIC COLITIS IN NOTTINGHAM: A CONTEMPORARY COHORT STUDY

N. R. Lewis¹, T. Archer¹, P. Kaye²

¹Gastroenterology, Nottingham University Hospitals NHS Trust, Nottingham/United Kingdom

²Histopathology, Nottingham University Hospitals NHS Trust, Nottingham/United Kingdom

Contact E-mail Address: nina.lewis@nuh.nhs.uk

Introduction: Diarrhoea is a common indication for colonoscopy. International guidelines recommend colonic biopsies should be routinely taken at lower GI endoscopy in patients with diarrhoea [1, 2] to look for microscopic colitis. The epidemiology of contemporary microscopic colitis is largely unknown with published data based on an earlier time period pre-2001 and in small retrospective case series. We have systematically collected a large and contemporary cohort of patients with incident microscopic colitis to help further our understanding of this disease.

Aims & Methods: Colonic biopsies demonstrating microscopic colitis between 2005–2016 were identified from electronic pathology records. GI endoscopy procedures taking place during this time period were identified from an electronic database. Incidence rates were calculated using the total population for Nottinghamshire derived from UK mid-year population estimates [3]. Poisson regression models were used to determine rate ratios.

Results: 843 people were diagnosed with microscopic colitis of which 60.7% were female (n = 512). The mean age at diagnosis was 65.0 (95%CI 64.0, 65.9) years. 57.5% (n = 485) had collagenous colitis and 42.5% had lymphocytic colitis. The

incidence rate of microscopic colitis appeared to increase with time (Table). The incidence rate of microscopic colitis in 2016 was twice of that observed in 2009 (incidence rate ratio 1.86; 95%CI 1.41, 2.46). There was a strong, independent graded association between the incidence of microscopic colitis and the number of lower GI endoscopy procedures undertaken ($p=0.03$).

Year	N microscopic colitis	Incidence per 100, 000	Incidence rate ratio [95%CI]	N lower GI endoscopy
2005	3	0.39		
2006	4	0.52		
2007	5	0.65		
2008	23	2.96		
2009	76	9.74	1.0	
2010	74	9.44	0.97 [0.71, 1.34]	
2011	94	11.95	1.22 [0.91, 1.66]	
2012	104	13.16	1.35 [1.01, 1.82]	10124
2013	89	11.18	1.15 [0.84, 1.56]	10100
2014	118	14.72	1.51 [1.13, 2.01]	11026
2015	104	12.91	1.32 [1.01, 1.78]	13225
2016	147	18.15	1.86 [1.41, 2.46]	13031

Conclusion: Microscopic colitis diagnosis is becoming more common. It is unclear whether microscopic colitis itself is increasing or greater numbers of lower GI endoscopy are being undertaken causing an ascertainment bias. Further work is required to explore environmental exposures such as drugs associated with microscopic colitis and to observe its natural history.

Introduction: Data on extra-intestinal manifestations (EIM) and their impact on disease course of ulcerative colitis (UC) in population-based cohorts are scarce, particularly in paediatric- and elderly-onset UC patients.

Aims & Methods: The aims of this population-based study were to assess 1) the occurrence of EIM in paediatric- and elderly-onset UC; and 2) their impact on long-term disease outcome. Paediatric-onset (<17 years at diagnosis) and elderly-onset UC patients (>60 years) from a French prospective population-based Registry (EPIMAD) were included. Data on EIM and other clinical factors at diagnosis and at maximal follow-up were collected.

Results: 158 paediatric- and 470 elderly-onset patients were included (median age at diagnosis 14.5 and 68.8 years; median follow-up 11.2 and 6.2 years, respectively). EIM occurred in 8.9% of childhood- and 3% of elderly-onset patients at diagnosis and in 16.7% and 2.2% of individuals during follow-up ($p < 0.01$). The most frequent EIM was joint involvement (15.8% of paediatric-onset and 2.6% of elderly-onset). Presence of EIM at diagnosis was associated with more severe disease course (need for immunosuppressive or biologic therapy or colectomy) in both paediatric- and elderly-onset UC (HR = 2.0, 95%CI: 1.0-4.2 and HR = 2.8, 0.9-7.9). Extensive colitis was another independent risk factor in both age groups.

Conclusion: Elderly-onset UC patients had lower risk of EIM either at diagnosis or during follow-up than paediatric-onset individuals. EIM at diagnosis predicted more severe disease outcome including need for immunosuppressive or biologic therapy or surgery in both paediatric- and elderly-onset UC.

Introduction: Data on long-term natural history of microscopic colitis (MC), including collagenous (CC) and lymphocytic colitis (LC) are lacking.

Aims & Methods: All new cases of MC diagnosed in the Somme area, France between January 1st, 2005 and December 31st, 2007 were prospectively included. Colonic biopsies from all patients were reviewed by a group of 4 expert gastrointestinal pathologists to assess the diagnosis of CC or LC. Demographic and clinical data were retrospectively collected from diagnosis to February 31st, 2017.

Results: One hundred and thirty cases of MC, 87 CC and 43 LC, were included (median age at diagnosis 70 and 48 years, respectively). The median follow-up was 9.6 years (Q1 = 7.6; Q3 = 10.6). By the end of follow-up, 37 patients (28%) relapsed after a median time of 3.9 years (1.2; 5) since diagnosis, without significant difference between CC and LC (30% vs 26%, $p=0.47$). Twenty patients (15%) were hospitalized for a disease flare and 32 (25%) presented with another autoimmune disease. Budesonide was the most widely used treatment ($n=74$, 59%), followed by 5-aminosalicylic acid ($n=31$, 25%). Median duration of budesonide treatment was 92 days (70; 168) and no adverse event to budesonide were reported. Sixteen patients (22%) developed steroid-dependency and 4 (5%) were corticosteroid-resistant. Only one patient was treated by immunosuppressants (azathioprine). No colorectal cancer was reported during follow-up. Any of the death ($n=25$) observed during follow-up were linked to MC. In multivariate analysis, age at diagnosis (HR 1.03; 95%CI, 1.00-1.06; $p=0.02$) and budesonide exposure (HR 0.40; 95%CI, 0.18-0.90; $p=0.03$) were significantly associated with relapse.

Conclusion: This population-based study showed that after diagnosis, two third of patients with MC observed long term clinical remission. Age at diagnosis and budesonide exposure were associated with a risk of relapse.

Introduction: It has been demonstrated in many chronic conditions, including inflammatory bowel disease (IBD), that better patients' knowledge about pathology and treatment improves the course and management of disease. The aim of this study was to develop an updated self-questionnaire to assess patients' level of knowledge of IBD.

Aims & Methods: The IBD-INFO included 3 parts: an original part (Q1), and 2 parts from the translation of the pre-existing questionnaires Crohn's and Colitis Knowledge score (CCKNOW) (Q2) and Crohn's and Colitis Pregnancy Knowledge score (CCPKNOW) (Q3). The reliability and discriminatory ability of the questionnaire were validated with 3 groups of non-IBD volunteers with various theoretical knowledge levels. The final questionnaire (64 validated questions) was then tested on 364 in- and out- IBD patients from 4 French university hospitals. The score for each part of the questionnaire was calculated and factors associated with low scores were identified by uni- and multivariate logistic regression analyses.

Results: The scores obtained by the 3 non-IBD volunteer groups differed significantly ($p < 0.0001$) and the IBD-INFO questionnaire showed excellent internal reliability and consistency ($\alpha = 0.98$). The median total score obtained by the IBD patients was 27/64 [0-59], and scores for Q1, Q2 and Q3 were, respectively, 10/23

[0–21], 11/24 [0–23] and 4/17 [0–16]. In multivariate analysis, lack of a university degree, not being a member of a patient association, not receiving anti-TNF α treatment, duration of IBD ≤ 3 years, male sex and age > 38 years and were independent risk factors of poor IBD-INFO knowledge score. The areas of knowledge least mastered were vaccination, IBD-related cancers, treatments and pregnancy.

Conclusion: Using the IBD-INFO, an updated self-administered questionnaire built to assess IBD patients' knowledge, several risk factors have been highlighted that allow better targeting of patients and areas requiring an improvement in the level of information.

Introduction: Inflammatory bowel diseases (IBDs), comprising Crohn's disease (CD) and Ulcerative colitis (UC), are characterized by chronic remittent intestinal inflammation and carry the risk for extraintestinal manifestations including primary sclerosing cholangitis (PSC). Available data on the impact of PSC on the disease course in IBD patients is conflicting. Therefore, we assessed the impact of coincidental PSC on the disease course in a large IBD patient cohort.

Aims & Methods: In total 1814 patients with histologically confirmed IBD were evaluated. Medical records from 705 UC and 1022 CD patients as well as from 77 UC-PSC and 10 CD-PSC patients were assessed. Data were evaluated using standard statistical methods. In matched-pair analyses, IBD patients with and without PSC were matched at the ratio of 3:1 by sex, disease entity, age at diagnosis, time from diagnosis to first presentation, and duration of follow-up. Time to event analysis was performed using survival analytic methods including Kaplan-Meier method and Log-rank test.

Results: PSC was diagnosed in 77 and 10 patients out of 781 UC (9.8%) and 1033 CD patients (1.0%), respectively. Age at UC onset was significantly lower in UC-PSC patients than in patients without PSC (23.3 vs. 29.3 years; $p < 0.001$). Extensive disease manifestation was observed in 46% of UC patients, whereas pancolitis was more frequently diagnosed in UC-PSC patients (75%, $p < 0.001$). Concerning CD, all patients with coincident PSC showed colonic involvement, while only 69% of the CD patients without PSC had colonic manifestation ($p = 0.044$). Interestingly, IBD patients without PSC presented more frequently with active disease, as compared to IBD-PSC patients (1.1/year vs. 0.7/year; $p = 0.055$). Conveniently, average disease activity assessed by complete Mayo score, was significantly higher in UC patients with acute flare as compared to UC-PSC patients (7.3 vs. 6.2; $p < 0.001$). Investigation of the average disease activity in 5-year-intervals in UC patients revealed a stronger disease activity in UC patients without PSC especially within the first 10 years after UC onset. Furthermore, biological therapy including vedolizumab and anti-TNF antibodies was initiated more frequently (35% vs. 22%, $p = 0.043$) and earlier (20.4 vs. 28.6 years after onset, $p = 0.087$) in UC without PSC than in those with coincident PSC. Colorectal high grade intraepithelial neoplasia (HGIEN) and CRC were detected in 25 IBD patients without PSC and in 7 IBD-PSC (4 UC and 3 CD) patients (1.45% vs. 8.05%). Of note, in IBD-PSC patients, HGIEN/CRC occurred significantly earlier than in IBD patients without PSC (20-year-risk: 9.6% vs. 5.6%; $p = 0.003$).

Conclusion: In our large cohort study, IBD patients with coincident PSC showed a distinct disease course with less relapse, lower disease activity, but earlier disease onset and higher risk for extensive disease manifestation as well as increased risk for colorectal dysplasia development.

Introduction: The EpiCom-cohort is a European prospective population-based cohort of unselected, uniformly diagnosed patients with inflammatory bowel disease (IBD) diagnosed in 2010 in centres from Western and Eastern European countries. The cohort aims at describing differences in occurrence, treatment strategies, disease course and prognosis within Europe.

Aims & Methods: Patients were followed each 3rd month for the first year after diagnosis and then according to the treating physician for the 2–5th year of follow-up. Clinical data on surgery, hospitalizations and medical treatment incl. biological therapy were captured prospectively throughout the follow-up period and entered in a validated web-based database. The aim of the study was to investigate differences in disease outcome and the use of biologicals between Eastern and Western Europe, from diagnosis and during the first 5 years of follow-up. Associations between outcomes and multiple covariates were analysed by Cox regression analyses.

Results: A total of 1289 patients aged 15 years or older from 29 centres in 13 Western and 8 Eastern European countries were followed prospectively of whom 717 (56%) had ulcerative colitis (UC), 488 (38%) had Crohn's disease (CD), and 84 (6%) had IBD unclassified (IBDU). Crude annual rates for CD and UC patients regarding surgery, biological treatment and hospitalization are shown in Table 1. Significantly more CD patients in Western Europe received biological therapy ($p < 0.05$), while surgery and hospitalization rates did not differ between the regions ($p > 0.05$). In UC, surgery rates did not differ between the regions, while hospitalization rates were higher in Western Europe ($p < 0.05$). Cox regression analysis showed that in CD stricturing (B2) or penetrating disease (B3) and progressing from luminal disease to B2/B3 increased while early (< 6 months from diagnosis) treatment with immunosuppressives reduced the risk of surgery and hospitalization. In UC, progressing to extensive colitis increased the risk of colectomy while females, extensive disease, need for prednisolone at diagnosis, and progressing to extensive colitis carried the highest risk for hospitalization. The cumulative probability of CD patients receiving treatment with 5-ASA was 90% in Eastern Europe and 56% in Western Europe, 69% and 75% for prednisolone, 54% and 66% for immunomodulators, respectively. For UC patients the cumulative probability of receiving treatment with 5-ASA within the first year of disease was 100% in Eastern Europe and 91% in Western Europe, 44% and 52% for prednisolone, 27% and 30% for immunomodulators, respectively.

Conclusion: In an era of early and aggressive immunological therapy, surgery and hospitalization rates for CD and surgery rates for UC patients were similar in Eastern and Western Europe. Overall, surgery and hospitalization rates were comparable to population-based cohorts from the past decade and pre-biological era. This similar disease course was in spite of more early and aggressive treatment with biologics and immunomodulators, with significantly more CD and UC patients in Western Europe receiving biologics.

Disclosure of Interest: All authors have declared no conflicts of interest.

Abstract No: P0325**Table 1:** Crude rates for surgery, biological therapy and hospitalization after 1 and 5 years follow-up in the EpiCom-cohort

		Biological therapy			Surgery			Hospitalization		
		1 year	3 years	5 years	1 year	3 years	5 years	1 year	3 years	5 years
Crohn's disease	Eastern Europe	4 (5%)	6 (7%)	12 (14%)	12 (14%)	16 (19%)	18 (21%)	22 (26%)	26 (31%)	26 (33%)
	Western Europe	80 (20%)	110 (27%)	132 (33%)	50 (12%)	70 (17%)	89 (22%)	91 (23%)	122 (30%)	147 (36%)
Ulcerative colitis	Eastern Europe	1 (1%)	6 (5%)	10 (8%)	2 (2%)	2 (2%)	3 (2%)	8 (6%)	16 (13%)	21 (17%)
	Western Europe	28 (5%)	53 (9%)	70 (12%)	21 (4%)	33 (6%)	40 (7%)	85 (14%)	124 (21%)	142 (24%)

P0326 OPIATE USE IN INFLAMMATORY BOWEL DISEASE. PRESCRIPTION TRENDS AND MORTALITY IN AN ENGLISH PRIMARY CARE COHORT FROM 1990–2014

N. Burr¹, C. Smith¹, R. West¹, M. A. Hull¹, V. Subramanian¹

¹Gastroenterology, Leeds Teaching Hospitals NHS Trust, Leeds/United Kingdom

Contact E-mail Address: nick.burr@nhs.net

Introduction: Chronic abdominal pain is a common symptom in inflammatory bowel disease (IBD). Pain management is complicated by clinically important gastrointestinal side effects of many of the available analgesics, particularly opiates. Opiate prescribing for cancer and non-cancer pain has increased dramatically in recent years but there is a paucity of data on prescription trends for individuals with IBD. The only population-based study is from Canada where 5% of subjects with IBD became heavy opiate users after 10 years of diagnosis and there was a strong association between heavy opiate use and mortality (OR 2.91, 95% CI 1.58–5.02). In this study we explore trends in the prescription of opiate medications and assess the association between opiate prescription and mortality in English primary care cohort of patients with IBD.

Aims & Methods: We used the English primary care database ResearchOne for this study which holds records from approximately 6 million individuals (>10% of the total population). We extracted relevant clinical codes and prescription data on all patients with IBD, and separated out those with ulcerative colitis (UC) and Crohn's disease (CD). We created 4 categories of opiate medication use, namely: any opiate medication, codeine only, tramadol, and strong opiates. We defined 3 groups of prescription density as none/infrequent users, moderate and heavy users as <1, 1–3 and >3 prescriptions per calendar year respectively. We examined the trend in opiate prescriptions for all IBD patients in 4 year blocks from 1990–2014 using χ^2 for trend as a significance. Separate trends were produced for each of our opiate classes. We calculated a propensity score estimating the conditional probability of being prescribed an opiate medication based on pre-defined characteristics which may influence the prescription of opiates. All-cause mortality in opiate users and non-users was compared in a propensity score matched, Cox proportional hazards regression analysis to produced hazard ratios (HR) and 95% confidence intervals (CI). All analyses were performed for each opiate medication class in CD and UC patients.

Results: We included 3517 patients with CD and 5349 with UC. Opiate prescriptions increased from 10% in 1990 to 30% in 2014 (χ^2 for trend $p < 0.005$). There was a similar, significant increase for codeine (χ^2 for trend, $p = 0.008$), tramadol ($p < 0.005$) and strong opiates ($p < 0.005$) when analyzed separately. Table 1 shows the association between opiate use and all-cause mortality in patients with IBD. Any opiate use in patients with UC was associated with increased mortality (HR 1.67, 95% CI 1.25–2.23). The strongest associations were for heavy users of strong opiates in patients with CD (HR 2.18, 95% CI 1.20–3.95) and UC (HR 3.30, 95% CI 1.77–6.18). There was no associations for prescriptions of tramadol at any prescription density in CD or UC.

Table 1: – The association between opiate prescriptions and all-cause mortality in patients with inflammatory bowel disease in the English primary care database Research One. Propensity score matched, Cox proportional hazards regression analysis.

	Crohn's disease Hazard ratio (95% CI)	Ulcerative colitis Hazard ratio (95% CI)
Any opiate medication		
None/infrequent use (<1 prescription per year)	1	1
Moderate use (1–3 prescriptions per year)	0.94 (0.64–1.39)	0.83 (0.56–1.21)
Heavy use (>3 prescriptions per calendar year)	1.15 (0.85–1.55)	1.67 (1.25–2.23)
Codeine only		

(continued)

Table 1 Continued

	Crohn's disease Hazard ratio (95% CI)	Ulcerative colitis Hazard ratio (95% CI)
Tramadol alone or in combination with codeine		
None/infrequent use (<1 prescription per year)	1	1
Moderate use (1–3 prescriptions per year)	1.66 (0.89–3.09)	0.72 (0.35–1.47)
Heavy use (>3 prescriptions per calendar year)	0.70 (0.35–1.39)	1.83 (1.10–3.05)
Strong opiates		
None/infrequent use (<1 prescription per year)	1	1
Moderate use (1–3 prescriptions per year)	0.69 (0.27–1.72)	0.50 (0.19–1.36)
Heavy use (>3 prescriptions per calendar year)	0.79 (0.35–1.81)	1.39 (0.66–2.94)
Strong opiates versus weak opiates		
None/infrequent use (<1 prescription per year)	1	1
Moderate use (1–3 prescriptions per year)	1.34 (0.67–2.70)	2.44 (1.16–5.15)
Heavy use (>3 prescriptions per calendar year)	2.18 (1.20–3.95)	3.30 (1.77–6.18)
Strong opiates versus weak opiates		
None/infrequent use (<1 prescription per year)	1	1
Moderate use (1–3 prescriptions per year)	1.36 (0.69–2.69)	1.81 (0.91–3.62)
Heavy use (>3 prescriptions per calendar year)	2.04 (1.14–3.65)	2.47 (1.41–4.33)

Conclusion: Our study is the largest population based study of opiate use in patients with IBD. We have shown a significant increase in the prescription of opiates since 1990, with 30% being prescribed an opiate medication between 2010 and 2014. Prescriptions of codeine in UC and strong opiates in both CD and UC were associated with increased all-cause mortality. There appears to be a dose association as heavy users of strong opiates had the largest association with mortality. Observational studies are not proof of causality and there may be residual confounding. A dose response is a strong indicator that opiates could be responsible for the associations seen, which is consistent with other studies investigating opiates used for non-cancer pain in chronic disease. Randomised controlled trials would be unethical and not feasible to investigate this potential effect so population-based observational studies may provide the best estimate. Opiate prescriptions are increasing worldwide for chronic non-cancer pain, and individuals with IBD can now be included. Clinicians managing pain in individuals with IBD should consider the potential implications of prescribing, or continuing with opiate prescriptions as they are a marker for increased mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0327 PATIENTS WITH INFLAMMATORY BOWEL DISEASE HAVE AN INCREASED RISK OF PERIODONTITIS CORRELATED WITH DISEASE ACTIVITY

Introduction: We aimed to: (1) evaluate the prevalence of periodontitis in patients with inflammatory bowel disease (IBD), (2) assess the impact of IBD activity and IBD therapy on parodontal outcomes.

Aims & Methods: In a prospective 6-months study, dental examination was performed in 54 patients with IBD and in 19 healthy controls. IBD related variables were prospectively collected, as well as markers for periodontitis including gingival bleeding (BOP index, marker of periodontal inflammation), gingival recession (REC index, marker of cumulative periodontal destructions) and probing depth (PPD as a marker of the severity of the disease). Additional dental examination was proposed 3 months after to all patients diagnosed with periodontitis.

Results: Among the 54 included patients, 44 had Crohn disease (81%) and 31 were women (55%). At the time of dental examination, median age was 33 years (Q1 = 26; Q3 = 41), 20 (36%) were smokers and the median IBD duration was 8.4 years (3.4–16.3). Eleven (20%) were treated by corticosteroids, 27 (49%) by anti-TNF, 6 (10%) by other biologics and 8 had no IBD treatment. IBD was significantly associated with periodontitis (81% vs 27%; Odds Ratio 2.9, 95%CI 1.3–6.2). Mild, moderate and severe periodontitis were respectively observed in 34 (63%), 8 (15%) and 3 (5%) IBD patients. As compared to healthy controls, IBD patients had significant increase of BOP index ($p = 0.008$), probing depth ($p = 0.03$), and REC index ($p = 0.01$). Patients with active IBD (Harvey Bradshaw > 4 or Mayo Score > 1) had a significant increase of BOP index ($p = 0.007$) as compared to patients with inactive disease. A significant correlation between BOP and Harvey-Bradshaw index was observed ($r = 0.44$, $p = 0.0018$). Anti-TNF therapy was significantly associated with lower BOP index ($p = 0.02$). All patients with diagnosis of periodontitis were treated by periodontal debridement and subgingival irrigation with povidone-iodine which led to a significant decrease of BOP index three months after diagnosis.

Conclusion: Inflammatory bowel diseases were associated with an increase risk of periodontitis. Gingival inflammation was correlated to disease activity and anti-TNF therapy was associated with a lower risk of active parodontal disease.

Contact E-mail Address: isiddique@hsc.edu.kw

Introduction: Crohn's disease is a chronic, immune mediated inflammatory condition which affects the gastrointestinal tract. NOD2/Card15 mutations have been linked to an increased risk of Crohn's disease and to some of its phenotypes. This study aimed to determine the presence of the above mutations in Arab patients suffering from Crohn's disease in Kuwait.

Aims & Methods: Blood samples were obtained from 103 Arab patients with Crohn's disease and 100 Arab control subjects. The genomic DNA was isolated from the samples using Qiagen DNA Blood mini kit. The isolated DNA were used in Polymerase Chain Reaction (PCR) using four sets of primers specific for each mutation in the NOD2/Card15 (rs2066842, SNP5, Exon 802C > T; rs2066844, SNP8, Exon4 2104C > T; rs2066845, SNP12, Exon 8 2722G > C; and, rs2066847, SNP13, Exon11 3020insC). The PCR-amplified DNA were sequenced using ABI 3130xl Genetic analyzer, and specific mutations were detected by using the sequence analysis software.

Results: Table 1 shows the results of all homozygous and heterozygous mutations found in the patients and control subjects. The mutation in rs2066842 (SNP5, Exon4 802C > T) was detected in the NOD2/Card15 sequence of 17 (16.5%) Arab patients with Crohn's disease compared to 32 (32.0%) normal controls ($p < 0.05$). This difference was statistically significant if the mutation was heterozygous ($p < 0.05$) but not in homozygous. The mutation in rs2066845 (SNP12, Exon 8 2722G > C) was found in 24 (23.3%) patients and 10 (10.0%) controls ($p < 0.05$). This difference was statistically significant if the mutation was homozygous ($p < 0.05$) but not in heterozygous. The mutation in rs2066844 (SNP8, Exon4 2104C > T) was found only in one patient and no controls and rs2066847 (SNP13, Exon11 3020insC) was not detected in any of the patients or controls. Table 1. Mutations in SNP5, SNP8, SNP12 and SNP13 of the NOD2/Card15 gene in Arab patients with Crohn's disease and control subjects.

Conclusion: This study suggests that mutation in rs2066845 (SNP12, Exon 8 2722G > C) occurs more frequently in Arab patients with Crohn's disease compared to controls, but the disease is associated only with the homozygous mutation. Mutation in rs2066842 (SNP5, Exon4 802C > T) occurs more frequently in controls compared to patients and the heterozygous mutation appears to have a protective effect against Crohn's disease in the Arab population. Mutations in

rs2066844 (SNP8, Exon4 2104C > T) and rs2066847 (SNP13, Exon11 3020insC) are not seen in this population.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There is limited data on genetics of inflammatory bowel disease (IBD) in populations where the condition is emerging, especially from South Asia.

Aims & Methods: A case [histologically confirmed ulcerative colitis (UC) and Crohn disease (CD) of ≥ 1 year duration] control [unrelated, healthy, gender matched] study was conducted at four major gastroenterology centres in Sri Lanka. Phenotypic data (type, location, severity, treatment types, response to treatment and complications) of cases were obtained. Cases and controls were genotyped for 16 selected variants with known IBD disease associations in Western and East Asian populations [IL12B:rs1045431, IL23R:rs11805303, ARPC2:rs12612347, IRGM:rs13361189, IL26/IL22:rs1558744, CDH1:rs1728785, IL10:rs3024505, FCGR2A:rs3737240, PTGER4:rs4613763, IL17REL/PIM3:rs5771069, HNF4A:rs6017342, STAT3:rs744166, SMURF1:rs7809799, LAMB1:rs886774, HLA DRB5, DQA1, DRB1, DRA:rs9268853, MST1, UBA7, APEH:rs9822268]. Genotypes of all variants were in Hardy-Weinberg Equilibrium. ($P > 10^{-3}$). To account for multiple hypothesis testing associations that had a p-value of < 0.003 were considered significant.

Results: There were 411 (males = 49.6%) cases [UC-258 (62.8%), males-47.7%), CD-153 (37.2%), males-50.3%] and 465 (males-50.5%) controls. The following variants were associated with corresponding phenotypes: IL23R:rs11805303 with IBD (all cases) ($p = 0.001$); IL12B:rs1045431 with upper gastrointestinal (UGI) CD ($p = 0.001$); IL17REL/PIM3:rs5771069 with relapsing IBD ($p = 0.003$); MST1, UBA7, APEH:rs9822268 with maintained remission ($p < 0.001$); IL17REL/PIM3:rs5771069 with disease complications in all cases ($p = 0.001$); HLA-DRB5, DQA1, DRB1:rs9268853 with immunomodulator use in all cases ($p = 0.001$). Two variants showed a non-significant trend toward s association-PTGER4:rs4613763 with ileal CD ($p = 0.005$); IL17REL/PIM3:rs5771069 with treatment-refractory IBD (all cases) ($p = 0.005$).

Conclusion: This first study, confirms the association of genetic variants of IBD previously reported in other populations, with clinical, prognostic and treatment phenotypes of IBD in a Sri Lankan (South Asian) population.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: lariwar@mail.ru

Introduction: Among the numerous genetic factors associated with ulcerative colitis (UC), an increasing attention has been paid to the polymorphisms of the vitamin D receptor gene (*VDR*) associated with disorders of innate and adaptive immunity, as well as the barrier function of the intestinal epithelium. However, the results of studies on the prevalence, clinical, diagnostic and prognostic significance of polymorphisms of the *VDR* gene in different populations are ambiguous and contradictory. In particular, associations of Bsm I polymorphism of the *VDR* gene with UC in the Chinese population and in the Jewish Ashkenazi has been found, while in the Irish population, with a sufficient prevalence of Bsm I polymorphism, this association is absent [1–3]. In the Russian Federation, there is no data on the prevalence, clinical, diagnostic and prognostic significance of Bsm I polymorphism of the *VDR* gene with UC. These circumstances determined the purpose and objectives of this study.

Aims & Methods: The purpose is to assess the clinical, diagnostic and prognostic significance of the Bsm I polymorphism of the *VDR* gene (rs1544410) at UC among the residents of the Kemerovo region of the Russian Federation. The study included 76 patients with UC and 85 controls. Genotyping was performed by PCR method ("SNP-express" reagents, Lytech Co. Ltd., Russia) with electrophoretic detection of amplification products. Statistical analysis was performed using the χ^2 and Mann-Whitney tests. In the presence of statistically significant differences ($p < 0.05$), odds ratios (OR) with 95% confidence interval (CI) were calculated.

Results: It was found that the frequency of the allele B polymorphism of the *VDR* Bsm I gene was higher among patients with UC than in the control group (44% vs. 26%, $p = 0.02$), which increases the risk of this pathology by 2.2% (95% CI: 1.2–4.1). In the case of carriers of the B/B genotype, the risk of developing UC increased up to 3.5 times in comparison with the control group (21% vs. 7%, $p = 0.02$, 95% CI: 1.4–8.6), whereas in b/b genotype the risk of UC decreased (33% and 54%, respectively, $p = 0.02$, OR = 0.4, 95% CI: 0.2–0.7). Significant differences between carriage of the B allele Bsm I polymorphism and the features of the clinical course of the UC have not been established. However, it has been shown that in carriers of allele B, the clinical implementation of UC develops significantly later than in patients with the b/b genotype (43 and 28.5 years, respectively, $p = 0.04$).

Conclusion: For the carriers of the B allele Bsm I polymorphism of the *VDR* gene is a predictor of a high risk of ulcerative colitis with an increase in the age of diagnosis. Genotype b/b Bsm I polymorphism of the *VDR* gene has a protective effect in the development of ulcerative colitis among the residents of the Kemerovo region of the Russian Federation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Having a family history for inflammatory bowel disease (IBD) is the only known risk factor for disease development. Indeed, up to 30% of IBD patients report at least 1 first-degree relative with IBD, and siblings carry the

highest risk. Recent data have shown that genetic and serological markers may predict IBD development. However, there are only few studies evaluating a genetically well-characterized population and at high risk for disease, such as siblings and twins. Therefore, aim of this study was to evaluate genetic and serological findings as markers of disease susceptibility in healthy siblings and twins of children with IBD.

Aims & Methods: This is the first phase of a prospective, longitudinal, multi-center, case-control study. Serum was collected from 80 siblings and twins of children with IBD and 77 healthy controls with no family history for IBD. Genotyping (TagmanMGB) for variants of ATG16L1 (SNP rs2241880), STAT3 (SNP rs744166), ECM1 (SNP rs3737240), NKX2-3 (SNP rs10883365), was performed. Serological titers of anti-Saccharomyces cerevisiae (ASCA IgG and ASCA IgA), perinuclear anti-neutrophil cytoplasmic antibodies (pANCA), anti-outer membrane porin C antibody (anti-OmpC), and antibacterial flagellin antibody (anti-CBir1), were determined by specific enzyme-linked immunosorbent assay (ELISA).

Results: Fifty-nine out of 80 cases (74%) and 50/77 controls (65%) were positive for at least 1 of the serum autoantibodies ($p = 0.29$); a combination of any 4 of them was found in 3 cases (4%) and no controls ($p = 0.28$). No significant difference was shown for any of the studied autoantibodies between cases and controls. Homozygosity for any susceptibility gene variant was found in 60 out of 80 cases (75%) and in 52/77 controls (67.5%) ($p = 0.37$), with no significant association between family history and genotype status. No combination of gene variants significantly differed between cases and controls.

Conclusion: Our preliminary results argue against a role of commonly recognized genetic polymorphisms and microbial antibodies as markers of disease susceptibility in siblings of children with IBD. However, data from larger and prospective studies, possibly including microbial characterization, are warranted before drawing definite conclusions.

P0332 ROLE OF DNMT3A IN INTESTINAL EPITHELIAL CELLS

A. Fazio, J. Kuiper, A. Sinha, R. Sheibani-Tezerji, P. Rosenstiel

Institute of Clinical Molecular Biology, Kiel/Germany

Contact E-mail Address: a.fazio@ikmb.uni-kiel.de

Introduction: DNA methylation is an important epigenetic modification mechanism of gene expression. Several studies have shown an association of impaired methylation with inflammatory bowel diseases (IBD) pathogenesis. DNMT3A and DNMT3B are two of the three members of the family of *de novo* DNA methyltransferases. Variants in these proteins are responsible for the establishment of *de novo* genomic DNA methylation patterns and are involved in the normal development as well as in many diseases. However, it is unknown if DNMT3A may play a role during the mechanism involved in this abnormal methylation pattern and consequently the development of diseases.

Aims & Methods: To assess the function of DNMT3A in intestinal epithelial cells (IECs), human Caco-2 colonic carcinoma cells were transfected with siRNA targeting DNMT3A, DNMT3B and DNMT3L. Gene expression analysis and DNA methylation analysis using qRT-PCR, RNA sequencing and 850k methylation chip assay were performed. For long-term experiments, we used a CRISPR/Cas9 genome editing to delete DNMT3A gene in Caco-2 cells. DNMT3A knockout Caco-2 cells were grown in a 3D-Matrigel culture system and after 2 weeks, spheroids cells were stained for actin/nuclei and subjected to confocal microscopy analysis.

Results: From the RNA sequencing data, approximately 1000 genes were found to be differentially expressed between cells lacking DNMT3A and controls. The KEGG pathway analysis identifies differentially regulated genes associated with several functional categories comprising extracellular matrix receptor interaction, focal adhesion and MAPK signalling pathway. In contrast, we observed no difference in DNA methylation between the groups. Furthermore, loss of DNMT3A induces abnormal spheroids formation by reducing spheroids diameter and defect in actin organization and lumen formation. Thus, the observed morphological phenotype may be linked to the differentially regulated genes involved in the previous analysed pathways.

Conclusion: Rapidly inactivation of DNMT3A in IECs promotes changes in gene expression, but does not change global DNA methylation. The absence of DNMT3A induces abnormal/defective spheroids formation in 3D culture system. Hence, our data provide a preliminary overview of DNMT3A in intestinal epithelial cells and its potential role in maintaining intestinal homeostasis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0333 ORMDL PROTEINS: CRITICAL REGULATORS OF FINE-TUNING OF THE UNFOLDED PROTEIN RESPONSE IN INTESTINAL INFLAMMATION

M. Jentzsch, M. Falk-Paulsen, A. Luzius, S. T. Stengel, J. Kuiper, B. Messner, F. Tran, K. Aden, P. Rosenstiel

Institute Of Clinical Molecular Biology, Christian-Albrechts-University and University Hospital Schleswig-Holstein, Kiel/Germany

Contact E-mail Address: s.stengel@ikmb.uni-kiel.de

Introduction: The endoplasmic reticulum (ER) plays a crucial role in maintaining cellular homeostasis by coordinating the processing and folding of secretory and membrane proteins. The accumulation of unfolded or misfolded proteins induces ER stress. The unfolded protein response (UPR) aims at restoring ER function and is comprised of three signaling branches via inositol-requiring enzyme 1

(IRE1), double-stranded RNA-dependent protein kinase (PKR)-like ER kinase (PERK) and activating transcription factor 6 α (ATF6 α). Defects in the ER stress response have been shown to predispose to chronic inflammatory bowel disease (IBD). Genome-wide association studies identified disease susceptibility loci in or adjacent to several UPR related genes including *XBPI* and *ORMDL3*.

Aims & Methods: The objective of this study was to determine the function of ORMDL3 in UPR signaling to gain insights into the molecular mechanisms promoting chronic intestinal inflammation. Using molecular cell biology approaches, we studied the effect of ORMDL3 on ATF6 α , PERK and IRE1 signaling. The role of ORMDL3 in intestinal inflammation was determined *in vivo* in both an acute and chronic DSS-colitis model using *Ormdl3*-deficient mice.

Results: Our *in vitro* studies demonstrate that ORMDL3 facilitates ER stress-induced ATF6 α activation. Overexpression of ORMDL3 resulted in increased cleavage of ATF6 α and augmented ERSE promoter activity. Mechanistically, we show that ORMDL3 colocalizes and directly interacts with ATF6 α . Furthermore, ORMDL3 overexpression induced the PERK pathway by elevating p-eIF2 α and CHOP protein levels. In contrast, we observed an inhibition of IRE1 signaling exerted by ORMDL proteins as shown by reduced XBPI splicing and decreased UPR promoter activity. *Ormdl3*-deficient mice showed an increased susceptibility to acute DSS-induced colitis compared to their wild-type littermates, as indicated by a more severe body weight loss and higher disease activity indices (DAI). In contrast, *Ormdl3*-deficiency was observed to be beneficial in the course of chronic colitis: compared to their wild-type littermates, *Ormdl3*^{-/-} mice showed less body weight loss and an improved survival rate.

Conclusion: This study demonstrates for the first time the modulatory functions of ORMDL proteins as regulators of all three UPR signaling pathways. Additionally, our *in vivo* studies suggest that ORMDL proteins constitute a precise fine-tuning mechanism of the UPR determining cell fate decisions in response to ER stress.

P0334 THE USE OF LÉMANN SCORE TO EVALUATE THE DAMAGE TO THE DIGESTIVE TRACT CAUSED BY CROHN'S DISEASE IN AN EGYPTIAN COHORT

H. M. Saad¹, O. E. Salem¹, M. A. Salem¹, M. E. Ibrahim², S. M. El Kady¹

¹Internal Medicine, Alexandria University, Alexandria/Egypt

²Radiology, Alexandria University, Alexandria/Egypt

Contact E-mail Address: hussienmahmoud7@hotmail.com

Introduction: Several studies have assessed Crohn's disease (CD) according to disease activity using clinical, laboratory & radiological activity indexes; but few have analyzed the damage the disease bring about on the GI tract. Lémann score was designed to develop a comprehensive assessment of the structural bowel damage, including stricturing lesions, penetrating lesions (fistulas and abscesses), and surgical resection. ⁽¹⁾

Aims & Methods: To calculate Lémann score in a cohort of Egyptian patients to determine its ability to assess the structural damage caused by CD in Egyptian population. Lémann score was calculated using specific computer software based on the original paper by Pariente. B et al ⁽¹⁾ in a cohort of Egyptian patients with CD followed from April 2013 - August 2015. The temporal relation between Lémann score and disease duration was also assessed.

Results: A total of 100 Egyptian patients with CD were enrolled, 69% males and 31% females. Median age was 32 years, 36% were smokers. The clinical presentation varied between abdominal pain occurring in 90% followed by 69% with chronic diarrhea, 52% with weight loss. Few patients (26%) presented with extraintestinal manifestations. According to ECCO classification of disease severity 73% of our patients had mild disease, 17% had moderate disease, 10% had severe disease. According to Montreal classification, 25% of patients were A1, 55% A2, 20% A3, 79% L1, 9% L2 & 12% L3, 63% B1, 7% B2, 26% B3, & only 4% had perianal disease. According to CDAI, 83% were in clinical remission, 11% mild "CDAI 150-220", 4% moderate "220-450", 2% severe "CDAI > 450" disease activity. When assessing structural damage of upper GIT, 4% had stricturing lesions, 2% grade 1 & 2% grade 2 lesions. The small bowel showed stricturing lesions in 65%: 39% grade 1, 23% grade 2, 3% grade 3 lesions. 25% of patients had grade 3 penetrating lesions, 5% had surgery which was resection in all the cases. As regards the assessment of stricturing lesion in the colon/rectum, the cecum showed stricturing lesions in 3%, 2% grade 2 and 1% grade 3 lesions; ascending colon showed stricturing lesions in 20%, with 7% grade 1 lesions, 11% grade 2 & 2% grade 3 lesions; transverse colon showed stricturing lesions in 1%; sigmoid colon showed stricturing lesions in 2%; rectum showed stricturing lesions in 1; while in only 1% whole colon showed grade 1 stricturing lesions affecting the 6 segments. In addition, 12% had grade 3 penetrating lesions while 9% had history of surgery mainly intestinal resection. In the anal canal, only 3% of patients had grade 3 penetrating lesions. The mean Lémann score was 4.02 \pm 4.19 & the median was 2. Increased median Lémann score was statistically positively correlated with disease duration of ≤ 2 years & > 2 - < 10 years and ≥ 10 years respectively. ($r_s = 0.343$ & $p < 0.001$) (KW = 9.235(0.010)). The current study showed that affection of the GI tract was (5%, 92%, 41%, and 3% with upper tract, small bowel, colon/rectum, & anus CD location, respectively). There is an increase in median Lémann score with increase in disease duration (global test $p < 0.001$): 0.60, 2.50, 6.40 for disease duration of ≤ 2 years & > 2 - < 10 years and ≥ 10 years respectively. These results are in concordance with what was published by Pariente B et al. ⁽¹⁾

Conclusion: Crohn's disease affection pattern in our Egyptian Cohort is mainly in the small bowel (92%) followed by the colon (41%) with the upper GI and the anal canal representing only 5% and 3% respectively. Lémann score designed by

and derived from the linear mixed model showed a good fit with the investigator organ damage evaluations in Egyptian population with CD. Lémann score could strongly assess the damage to the digestive tract caused by CD in a cohort of Egyptian patients. Despite calculating Lémann score in Egyptian cohort reflects the same positive trend with western cohort but with relatively smaller figures could reflect that Egypt is a young population for CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Biosimilar infliximab CT-P13 received EMA approval in June 2013 for all indications of the originator product and its use is mandatory in all anti-TNF naïve IBD patients in Hungary since May 2014.

Aims & Methods: In the present study we aimed to prospectively evaluate the immunogenicity profile of the biosimilar infliximab and predictors of TDM in IBD during the first year of therapy in a nationwide, multicentre cohort. Demographic data were collected and a harmonized monitoring strategy was applied. Clinical and biochemical activity were evaluated at weeks 14, 30 and 54. Routine therapeutic drug monitoring (TDM) was applied. Trough level (TL) and anti-drug antibody (ADA) concentration were measured by ELISA (LT-005, TheraDiag, France) at baseline and at 2, 6, 14, 30 and 54 weeks right before anti-TNF administration during the induction treatment.

Results: 353 consecutive IBD patients (209 CD patients and 144 UC patients) were included in the present cohort. 23.4% of CD patients and 19.4% of UC patients had received previous anti-TNF therapy. None of the patients had received infliximab within 12 months prior to initiation of the biosimilar infliximab. 60/51% of CD/UC patients received concomitant immunosuppressives at baseline. Mean TLs were 18.9, 17.3, 7.4, 4.3 and 5.3 μ g/ml at weeks 2, 6, 14, 30 and 54 in CD and 19.1, 11.8, 5.0, 3.9 and 4.5 μ g/ml UC. Previous anti-TNF therapy was associated with lower early TL-s in both CD (week 2, 14, and 30, $p < 0.05$) and UC (week 2 and 6, $p = 0.03$). ADA positivity rates were 4.3%, 12.0%, 20.9% and 28.6% in naïve patients at weeks 0, 14, 30 and 54 (total = 266, 312, 290 and 210). ADA positivity at week 14 was associated with lower TLs in all CD (week 2, 14 and 30, $p < 0.007$ for all) and UC (week 6, 14 and 30, $p < 0.001$ for all) patients. Concomitant IS use prevented ADA formation in anti-TNF-naïve patients (week 14, 30 and 54, $p = 0.01$, 0.02 and 0.004) in CD but not in UC and did not affect clinical remission or response rates. 32 (8.9%) patients had infusion reactions during induction or maintenance treatment, of which 16 patients had received previous infliximab treatment.

Conclusion: Drug TLs and ADAs in IBD patients until week 54 were in line with results reported for the originator in previous studies. Patients with previous exposure to anti-TNFs had lower early TL coupled with ADA positivity and were more likely to develop infusion reactions. Concomitant IS use prevented ADA development in anti-TNF naïve patients.

Introduction: The most relevant scope of serologic antibodies in Crohn's disease [CD] is to stratify the risk of complicated disease course. Significance of distinct antibody classes and their characterisation was rarely considered. We aimed to address these concerns.

Aims & Methods: Sera of 266 well-characterized CD patients (m/f:112/154, median age: 25 yrs, B1:80.1%, P1:18.0%) and 155 controls were assayed for traditional anti-microbial antibodies (ASCA IgA/IgG, anti-OMP IgA). Endotoxin core IgA (EndoCAB) and a panel of non-specific immunoglobulin A (IgA) antibodies (IgA1, IgA2 and secretory [s] IgA) were also assessed by ELISA. An observational follow-up study [median, 143 months] was conducted to assess possible associations between serologic antibodies and the development of various complications and subsequent surgical interventions. A novel flow cytometry test system was established for characterisation of IgA type ASCA to reveal possible origin of the antibody.

Results: A total of 65.7% and 46.2% of the CD patients were positive for ASCA IgA/IgG and anti-OMP antibodies. Both ASCA types occurred equally. EndoCAB IgA positivity was more frequent (15.4% vs. 5.4%, $p < 0.01$) and sIgA levels were increased [median, 51 vs. 29 µg/ml, $p < 0.001$] in CD compared to controls. They were also associated with presence of IgA type anti-microbial antibodies. Contrary, ratio of IgA2/A1 in CD corresponded with the value of the controls. In Kaplan-Meier analysis, development of internal penetrating and/or stenosing (IP/S) complications and resective surgery (SR) was significantly associated with IgA type ($p_{\text{LogRank}} < 0.001$ and $p_{\text{LogRank}} = 0.025$ respectively), while development of perianal penetration (PP) with IgG type ASCA ($p_{\text{LogRank}} = 0.008$). Performance OMP IgA was equal to ASCA IgA, however sIgA not. Anti-microbial antibodies remained independent predictors in multivariate Cox-regression analysis comprising relevant clinical factors.

Summary of multivariate Cox regression analysis for the association of serologic antibodies with complicated disease course

HR [95% CI]; p	IP/S in B1 pts	SR in B1 pts	PP in P0 pts
ASCA IgA	2.92 [1.85–4.62]; <0.001	1.77 [1.09–2.87]; 0.021	
ASCA IgG			2.77 [0.36–5.63]; 0.005
ASCA IgA/IgG	1.76 [1.09–2.87]; 0.022	1.45 [0.86–2.45]; 0.163	2.07 [0.98–4.39]; 0.057
Omp IgA	1.66 [1.09–2.54]; 0.019	2.08 [1.28–3.38]; 0.003	1.13 [0.63–2.01]; 0.692
sIgA	1.54 [0.97–2.44]; 0.066	1.37 [0.82–2.28]; 0.23	1.25 [0.67–2.34]; 0.475
Endocab IgA	2.60 [1.62–4.17]; <0.001	1.66 [0.96–2.87]; 0.071	0.74 [0.33–1.68]; 0.475

Without uncoupling of Ig antibody classes yielded clearly inferior performance. ASCA IgA subtyping assays revealed marked increase in the proportion of IgA2 subtype (29%) and presence of the secretory component (89% of total ASCA IgA) concurrently.

Conclusion: Consideration of antibody classes is an important novel parameter in serology-based prediction in CD. Involvement of gut mucosal immune system is in center of IgA type antibody formation reflecting sustained exposure and dys-regulated immunoresponse to bacterial constituents.

Introduction: Achievement of endoscopic healing is a key treatment goal in patients with Crohn's disease (CD). We previously reported that magnetic resonance enterography (MRE) could exactly assess small bowel (SB) active lesions such as ulcers using balloon assisted enteroscopy (BAE) reference [1, 2].

Aims & Methods: We aimed to evaluate whether MRE could predict patient prognosis in prospective observational study. From July 2012 to December 2015, 139 CD patients in clinical and serological remission were followed up

after BAE and MRE procedure. Two endoscopists performed BAE and assessed the endoscopic findings, while two radiologists assessed the MRE findings. Both the endoscopists and radiologists were blinded to the patient's clinical presentation and results of other studies. We used Simple Endoscopic Score for CD (SES-CD) for endoscopic evaluation and Magnetic Resonance Index of Activity (MaRIA) for MR evaluation. Endoscopic healing was defined as the absence of ulcerative disease (SES-CDa < 5). Primary endpoints were clinical relapse and serological relapse. The relationship between endoscopic SB lesions and endpoints was evaluated. Moreover, whether MRE findings could predict patient outcomes was assessed.

Results: The median duration of follow-up was 27 months (range, 12–48). Clinical and serological relapse occurred in 30 (21.6%) and 62 (44.6%) patients, respectively. SB endoscopic healing (SES-CDa < 5) was achieved in 76 (54.7%) patients. Multiple regression analysis of BAE findings showed that the absence of SB endoscopic healing (ulcerative disease; SES-CDa ≥ 5) was an independent risk factor for clinical relapse (Hazard ratio [HR] = 4.78; 95% CI: 1.94–11.80; $P = 0.001$) and serological relapse (HR = 2.84; 95% CI: 1.63–4.95; $P < 0.001$). On Kaplan–Meier analysis, patients who did not achieve endoscopic healing were at a significant risk of worse outcomes (clinical relapse, $P < 0.001$; serological relapse, $P < 0.001$). MR ulcer healing (MaRIA score < 11) showed a high sensitivity (82.5%; 95% confidence intervals [CIs]: 74.9%–88.2%) and specificity (85.5%; 95% CIs: 79.2%–90.2%) for endoscopic healing. On Cox's proportional hazards analysis, MRE findings of ulcer healing were associated with a low risk of clinical relapse (Hazard Ratio [HR]: 0.24; 95% CIs: 0.111–0.54%; $P = 0.001$) and serological relapse (HR: 0.47; 95% CIs: 0.29%–0.78%; $P = 0.003$).

Conclusion: The absence of endoscopic healing (ulcerative disease) were seen in a considerable number of CD patients who were in clinical-serological remission, and these lesions were at risk factor for worse prognosis. MRE could evaluate SB endoscopic healing with a high diagnostic accuracy and could predict patient outcomes.

Introduction: In Crohn's disease (CD), accurate evaluation of location and small bowel involvement are necessary at the time of diagnosis for prognostic concern and planning of treatment strategy. Since Double Balloon Endoscopy (DBE) enables us to examine deep small bowel either oral or anal it could be of great utility in the management of Crohn's disease patients.

Aims & Methods: We aimed to evaluate the diagnostic yield and therapeutic impact of DBE on small bowel CD. The medical records of 180 CD patients, from October 2009 to April 2015, were retrospectively analysed. Patients were included if they had known CD based on clinical, colonoscopic and histological findings and had been subjected to DBE. If one patient underwent more than one DBE examination only the first evaluation was considered. The primary end point of our study was to evaluate small bowel involvement that is beyond the reach of conventional colonoscopy. The secondary endpoints were to determine the impact of DBE findings on management strategy of CD. The diagnostic yield of DBE in small bowel CD was determined. In addition, the changes in medical treatment, endoscopic intervention and surgical procedures, within three months after DBE, were analysed.

Results: Among 180 patients with CD, 90 patients underwent 168 DBE examinations and were included. The mean age of included patients was 40 ± 13.6 years. They were 63 males and 27 females. Eighty-two (91%) patients with established CD underwent DBE for evaluation of small bowel involvement and 8 (9%) patients underwent DBE because of suspicion of CD and had been newly diagnosed. The overall diagnostic yield of DBE was 69%. DBE revealed small bowel involvement proximal to the terminal ileum in 40 (64.5%) patients; of them 17 (42.5%) patients had isolated small bowel CD. Within 3 months after DBE examination the management strategy of CD changed in 47 (52.2%) patients, based on DBE findings. The medical treatment escalated in 20 (32%) patients, and decreased in 7 (11%). Fourteen (24%) patients underwent DBE-assisted balloon dilatation, and 6 (9.6%) patients underwent CD-related surgery.

Conclusion: DBE is able to detect small bowel involvement in a significant proportion of CD patients. The DBE findings modified the management strategy in at least one half of CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Therapeutic adherence is crucial in the management of patients with inflammatory bowel disease (IBD). Poor adherence may lead to suboptimal control of the disease, decreased quality of life and increased health care costs.

Aims & Methods: 1) To evaluate the prevalence of non-adherence to treatment in Spanish patients with IBD and 2) To identify factors associated with low, medium and high adherence. We performed a cross-sectional study that included consecutive patients with IBD attending our adult IBD clinic in a three-month period. Consenting patients completed a survey performed by two researchers not involved in the care in our patients. Activity was assessed with Harvey-Bradshaw index in Crohn's disease (CD) and Partial Mayo Score in Ulcerative colitis (UC). Anxiety and depression were estimated by the Goldberg Anxiety and Depression Scale and modified Morisky Medication Adherence Scale (MMAS-8) was used to assess adherence (<6, 6–7 and 8 points indicate low, medium and high adherence, respectively). In statistical analyses, Chi-square and Student's t-test were used for side by side comparisons and logistic regression for multivariate analysis.

Results: A total of 181 patients were evaluated. The median age was 47±16 years; 98 (54.1%) were males and 32 (17.7%) were active smokers. 82 (45.3%) patients had CD and 99 (54.7%) had UC. The mean disease duration was 10.21±8.59 years. Most patients were in remission (87.8%). In relation to the treatment, 35.9% were taking mesalazine, 2.8% steroids, 29.3% immunomodulators and 30.4% biologics. The oral route was the most frequent (52.5%), following by rectal route (17.1%) and subcutaneous or intravenous (30.4%). Based on MMAS-8, almost half of our patients 84 (46.4%) had high adherence to IBD treatment, 56 (30.9%) had medium and 41 (22.7%) had low adherence. In relation to factors associated with adherence, univariate analyses showed that patients with high adherence were older (52.0±16.1 years vs. 42.5±14.4; p<0.001) and their disease had longer duration (12.2±9.7 years vs 8.5±7.1; p=0.004) than patients with medium/low adherence. However, smokers had a low adherence (p=0.007). Multivariate analysis confirmed that age was associated with high adherence (OR:1.04, CI95% 1.01–1.06, p=0.002) and being smoker with low adherence (OR:3.47, CI95% 1.36–8.90, p<0.01). Also, multivariate analysis showed that CD was associated with low adherence (OR:2.54, CI95% 1.11–5.79, p<0.05). Other factors as sex, anxiety, depression, quality of life, disease activity, type of drugs or administration route were no significantly associated with adherence.

Conclusion: Only active smoking and age were predictors of insufficient adherence to drugs in IBD. Efforts for reinforce adherence should be especially directed to young patients. Quitting tobacco could improve adherence.

P0340 IS THE CDMRIS USEFUL TO MONITOR PATIENTS WITH CROHN'S DISEASE BY MAGNETIC RESONANCE IMAGING?

Introduction: Magnetic resonance enterography is now recognized by the European Crohn's and Colitis Organization (ECCO) as a reference procedure to assess the intestinal involvement of Crohn's disease (CD), including extramural complications, as well as to monitor patients under treatment. A new MRI index of severity was developed in 2015 by the GETAID consortium, specifically to evaluate lesions located in the small intestine. This score, labeled CDMRIS (Crohn's disease magnetic resonance index of inflammation severity), considers, for each 20-cm small bowel segment, the intensity of relative contrast enhancement (mild-moderate or severe), deep ulceration without fistula, "comb sign", any fistula, and abscess. Although well standardized, this index has not yet been validated, either for the initial assessment of CD at diagnosis, or for monitoring patients under treatment. Its feasibility in routine practice has never been tested.

Aims & Methods: The aims of this study were to evaluate the feasibility of applying the CDMRIS score in clinical practice, to evaluate its variability after the initiation or optimization of an anti-TNF treatment, and to measure its correlation with an evaluation of clinical activity. Patients with known small bowel CD who underwent two MRI examinations at a maximal interval of 30 months were included between 2010 and 2015. Each exam was interpreted twice and the CDMRIS score was calculated on both exams in addition to classical criteria. All patients had a clinical evaluation over time, separating them in two groups: "active" and "inactive" disease.

Results: Seventy-two patients were included, with a mean CDMRIS of 3.4 at baseline, decreasing to 2.6 (p=0.052) independently of clinical disease activity. The mean interval between the two MRIs was 15.4 months, and there was a significant, larger decrease in the CDMRIS score when the interval was above 12 months. Two other radiological parameters decreased significantly: the rate of patients with a mural T2-hyperintensity (36.1% to 20.8% p=0.042), with a good clinico-radiological correlation, and mean wall thickness (5.5 to 4.4 mm, p=0.047).

Conclusion: This study demonstrated the feasibility of applying the CDMRIS in clinical practice, but sensitivity was too low to detect early changes. Accuracy for a long-term monitoring needs to be evaluated. Wall thickness and mural T2-hyperintensity emerged as two sensitive radiological factors, significantly associated with the disease activity, allowing monitoring of the short-term efficacy of biotherapies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Crohn's Disease Activity Index (CDAI) has been shown to correlate poorly with endoscopic measures of mucosal inflammation/ulceration.^{1,2} There is a movement towards using components of the CDAI, namely stool frequency (SF) and abdominal pain (AP), rather than the total score, to evaluate a patient's disease activity in registration trials. This post hoc analysis assessed the association between individual components of the CDAI with the Simple Endoscopic Score for Crohn's Disease (SES-CD) from EXTEND.

Aims & Methods: All patients randomized in the EXTEND study³ with both CDAI and SES-CD values at the time point evaluated (week 12 and week 52) were analyzed. Correlations between SES-CD and CDAI, SES-CD and individual components of CDAI, and mean changes from baseline in both SES-CD and CDAI were assessed at weeks 12 and 52 using Pearson correlation coefficient. Endoscopies were scored by a central reader. Data are reported as observed.

Results: A total of 121 patients at week 12 and 80 patients at week 52 had both CDAI and SES-CD values. Mean (SD) CDAI and SES-CD values at week 12 were at 193.8 (116.4) and 8.0 (7.4), respectively, and 132.5 (97.6) and 5.9 (6.6), respectively, at week 52. A significant, but weak correlation was observed between CDAI and SES-CD at week 12 ($r=0.31$ [$P<0.001$]) and at week 52 ($r=0.31$ [$P=0.005$]). Similar results were observed for correlations between mean changes from baseline in CDAI and SES-CD at weeks 12 ($r=0.35$ [$P<0.001$]) and 52 ($r=0.31$ [$P=0.005$]). Correlations between individual components of CDAI and SES-CD at weeks 12 and 52 are shown in the table. SF, AP, extra-intestinal manifestations, and SF + AP were significantly correlated with SES-CD at week 12; the strongest correlation was for SF ($r=0.46$) and the addition of AP to SF did not increase the correlation (Table). At week 52, SF, hematocrit, and SF + AP were significantly correlated with SES-CD. At week 12, the correlation of SES-CD with SF was similar regardless of whether the patient had disease of the ileum ($r=0.44$ [$P<0.001$] with ileal disease; $r=0.48$ [$P<0.001$] without ileal disease), while SES-CD correlated more strongly with AP in those with ileal disease ($r=0.27$ [$P=0.036$]) than those without ileal disease ($r=0.16$ [$P=0.233$]).

Table: Correlation of components of the CDAI with SES-CD

Variable	Week 12 n=121			Week 52 n=80		
	Mean (SD)	r	P-value	Mean (SD)	r	P-value
Stool frequency*	47.1 (35.2)	0.46	<0.001	33.7 (32.1)	0.35	0.002
Abdominal pain	41.0 (29.6)	0.21	0.020	21.8 (25.6)	0.06	0.597
General well-being	63.3 (50.2)	0.16	0.073	42.2 (46.7)	0.17	0.123
Extra-intestinal manifestations	14.0 (16.3)	0.22	0.017	11.5 (13.8)	0.11	0.317
Diarrhea/pain medications	3.2 (9.3)	0.01	0.927	1.9 (7.3)	0.08	0.465
Abdominal mass	0.8 (4.0)	-0.50	0.588	0.0 (0.0)	NA	NA
HCT	21.1 (21.3)	0.09	0.355	17.7 (20.6)	0.40	<0.001
Weight (kg)	3.2 (6.1)	-0.03	0.770	3.8 (7.0)	-0.07	0.568
Stool frequency + Abdominal pain	88.1 (56.6)	0.40	<0.001	55.5 (48.1)	0.26	0.018

*the number of liquid or very soft stools per day. SES-CD, Simple Endoscopic Score for Crohn's Disease. HCT, hematocrit. NA, not applicable.

Conclusion: Data from patients with moderate to severe CD and evidence of mucosal ulceration in EXTEND supported previous findings that the CDAI was only weakly correlated with SES-CD, as assessed at 12 and 52 weeks. Only SF was significantly correlated with SES-CD at both time points. At 12 weeks, the correlation of SES-CD with SF was not affected by the presence of ileal disease, while correlation with AP was stronger with ileal disease than without it.

Introduction: Crohn's disease (CD) with complications such as penetrating, structuring, and perianal disease are called complicated CD. However, no validated, inexpensive, or sensitive models for prediction of risk are available in complicated CD. We have found that a novel immunological balance, the CD8⁺CD28⁺/CD8⁺CD28⁻, consisting of CD8⁺CD28⁺ and CD8⁺CD28⁻ T cells, can predict the prognosis for patients with inflammatory bowel disease (IBD). Thus, we hypothesize that the CD8⁺CD28⁺/CD8⁺CD28⁻ balance (ratio) can predict the poor outcome for patients with complicated CD.

Aims & Methods: To test the efficiency of CD8⁺CD28⁺/CD8⁺CD28⁻ balance to predict a subsequent active stage, and to explore the correlation between the balance and the risk factors, for the newly diagnosed complicated CD. Seventeen patients with complicated CD were enrolled as the observation group, while the other 48 CD patients with no complications were enrolled as the control group. Peripheral blood samples were drawn from all the 65 newly diagnosed CD patients for CD8⁺ T cells testing through flow cytometry (FCM) when enrolling. The potential risk factors, including demographic, pathophysiological, and therapeutic factors were compared between the two groups. A 30-week follow-up was performed and the CD8⁺ T cells testing were repeated. The sensitivity and specificity of the CD8⁺ T cells' level and balance in predicting were analyzed through receiver operator characteristic (ROC) curves. The cumulative remission lasting rates (CRLRs) under the different risk factors were analyzed using the Kaplan-Meier method.

Results: I. Risk factors: compared with the control CD group, patients with complicated CD had a larger proportion in male ($P=0.001$), younger in age ($P=0.019$), lower body mass index (BMI) ($P<0.0001$), higher Crohn's disease activity index (CDAI) ($P<0.0001$), higher prescription rates in immunosuppressants ($P=0.029$) and steroids ($P=0.015$), as well as a significant higher surgical rate ($P<0.0001$). Pearson and Spearman correlation analysis showed that CD8⁺CD28⁺/CD8⁺CD28⁻ balance was associated with BMI, CDAI, steroids, and surgery (all $P<0.005$). II. Follow-up and dynamic changes of the balance: the ratios of CD8⁺CD28⁺/CD8⁺CD28⁻ reached the bottom at the 30th week and were significantly lower at the 0, 6th, 22nd, and 30th week during follow-up, in the complicated CD patients when compared to the control ones (all $P<0.05$). A shorter lasting time of remission (LTR) was found in complicated CD patients ($P=0.044$). ROC curve showed that CD8⁺CD28⁺/CD8⁺CD28⁻ ratio could accurately predict the active stage for the complicated CD patients [with area under curve (AUC) of 0.890, and 95% CI of 0.822 to 0.958], and the best sensitivity of 89.2% and specificity of 85.3% were found when the ratio was 1.03. III. Kaplan-Meier analysis: Undergoing of steroids and surgery was closely related to worse outcome for the complicated CD patients, and patients who underwent steroids and surgery had the significantly lower CD8⁺CD28⁺/CD8⁺CD28⁻ ratio and lower CRLRs (all $P<0.05$).

Conclusion: Depending on steroids and surgery stands for a more severe disease activity and thus disequilibrate the immunological balance, which could be the main reason for lower CD8⁺CD28⁺/CD8⁺CD28⁻ ratio, and this ratio can predict the active stage sensitively for patients with complicated CD. More strategies should be taken when the ratio is to be lower than 1.03.

P0343 BOWEL PREPARATION QUALITY OF NER1006 VERSUS STANDARD 2L PEG WITH ASCORBATE AS ASSESSED BY COLONOSCOPISTS AT SITE: A POST HOC ANALYSIS FROM A RANDOMISED CONTROLLED TRIAL

J. Manning¹, L. Clayton², V. Lorenzo-Zúñiga García³

¹Borders General Hospital, Melrose/United Kingdom

²Clinical Development, Norgine Ltd., Harefield, Uxbridge/United Kingdom

³Department Of Medicine, Universitat Autònoma de Barcelona, Barcelona/Spain

Contact E-mail Address: Jmanning1@nhs.net

Introduction: Successful colonoscopy requires effective bowel cleansing. NER1006 is the first 1L polyethylene glycol (PEG)-based bowel preparation, a patented combination optimised for effective bowel cleansing. The MORA study was a multicentre randomised Phase 3 clinical trial using blinded central readers to assess the cleansing efficacy of the overall colon and high-quality cleansing of the ascending colon by NER1006 vs standard 2L PEG with ascorbate (2L PEG + Asc) [1]. This post hoc analysis shows the cleansing assessment by site colonoscopists, who typically guide clinical decision-making; hence this analysis may be more relevant for clinical practice than previous analyses.

Aims & Methods: In the MORA study 849 patients (males and females, aged 18–85) were randomly assigned in a 1:1:1 ratio to receive i) NER1006 in an evening/morning split-dose (N2D), or ii) NER1006 in a morning-only dose (N1D) or iii) 2L PEG + Asc in an evening/morning split-dose. The 796 subjects who underwent a colonoscopy and were assessed by a treatment-blinded site colonoscopist were included in this analysis. Cleansing was assessed according to the Harefield Cleansing Scale [2]; following segmental scoring, cleansing of the overall colon was graded from A to D; grades A and B were judged as successful cleansing. Cleansing of the ascending colon and caecum was scored from 0 to 4; scores of 3 and 4 were judged as high-quality cleansing.

Results: The bowel preparation quality of NER1006 showed a statistically significant improvement over 2L PEG + Asc for the overall colon when both treatments were administered as an evening/morning split-dose (P = 0.003; 95% CI: 2.0–10.1%) (Table 1). NER1006 administered either as an overnight split-dose or morning-only dose produced high-quality cleansing of the ascending colon in a statistically significantly higher proportion of patients compared to 2L PEG + Asc (P < 0.001; 95% CI: 7.2–23.1% and P < 0.001; 95% CI: 7.2–23.0% respectively). The morning-only dose showed no difference compared to 2L PEG + Asc as an evening/morning split-dose for overall colon cleansing quality (P = 0.924; 95% CI: –5.1–4.6%). Table 1. A comparison of bowel cleansing efficacy as assessed by site colonoscopists between NER1006 (administered in a N1D or N2D regimen) or 2L PEG + Asc.

Conclusion: Colonoscopists assessed both dosing regimens of NER1006 as having a significantly increased rate of high-quality cleansing of the ascending colon when compared with 2L PEG + Asc; this cleansing is important in ensuring the detection of lesions in the ascending colon. When comparing similar overnight split-dose treatment regimens, NER1006 showed a significantly increased rate of overall bowel cleansing compared to 2L PEG + Asc.

²Ohio GI and Liver Institute, Cincinnati/United States of America/OH

Contact E-mail Address: rng@norgine.com

Introduction: The success of colonoscopy is dependent on efficient bowel cleansing. Inadequate bowel cleansing may decrease diagnostic sensitivity, necessitate repeat procedures and potentially delay appropriate treatment. The increasing frequency of the incidence of colorectal cancer arising in the ascending colon necessitates effective cleansing of this area; additionally these cancers are often associated with poorer prognoses. Data suggest that detection in the ascending colon is more dependent on higher grades of cleansing, perhaps due to the nature of polyps present, which may be more likely to be sessile or serrated. NER1006 is the first 1L polyethylene glycol (PEG)-based bowel preparation, a patented combination optimised for effective bowel cleansing. The NOCT study (a multicentre randomised Phase 3 clinical trial investigating bowel cleansing efficacy of NER1006 vs trisulfate solution) reported bowel preparation quality assessed by central readers.¹ This post hoc analysis shows the cleansing assessment by site colonoscopists, who typically guide clinical decision making; hence this study may be more relevant for clinical practice than previous studies.

Aims & Methods: In the NOCT study 621 patients (males and females, aged 18–85) were randomly assigned in a 1:1 ratio to receive either NER1006 or trisulfate solution, each administered as an overnight split-dose. Data from the 523 patients who underwent a colonoscopy and had a site colonoscopist assessment were used in this analysis. Colonoscopists were blinded to the preparation administered. Cleansing was assessed according to the Harefield Cleansing Scale;² following segmental scoring, cleansing of the overall colon was graded from A to D; grades A and B were judged as successful cleansing. Cleansing of the ascending colon was graded from 0 to 4; grades 3 and 4 were judged as high-quality cleansing.

Results: As Table 1 shows, the bowel preparation quality of NER1006 when assessed by site colonoscopists did not show a statistically significant difference to trisulfate for the overall colon (93% vs 94%, $P=0.681$; 95% CI: –5.1–3.3%) or ascending colon (80 vs 74%, $P=0.079$; 95% CI: –0.7–13.6%). There was, however, a numerical advantage in favour of NER1006 on the proportion of patients achieving high-quality cleansing success in the right colon.

Table 1: Successful colon cleansing rates when treated with NER1006 or trisulfate solution.

Bowel preparation	N	Patients with successful cleansing n (%)	Difference (%)	P-value	95% CI (%)
Overall colon					
NER1006	259	241 (93)	–1	0.681	–5.1–3.3
Trisulfate	264	248 (94)			
Ascending colon					
NER1006	259	208 (80)	6	0.079	–0.7–13.6
Trisulfate	264	195 (74)			

N.B. successful cleansing defined here as a Harefield Cleansing Scale grade of A or B (overall colon) or 3 or 4 (ascending colon, high quality)

Conclusion: For both preparations, site colonoscopist findings demonstrated similar very high rates of cleansing success for the overall colon (>93%) and high rates of high-quality cleansing of the ascending colon (>73%), however, statistical significance was not met in either comparison. The rates of cleansing success in the ascending colon reported by the site colonoscopists are notably higher than those previously reported by central readers.

Introduction: The efficacy of colonoscopy is dependent on the quality of bowel cleansing. NER1006 is the first 1L polyethylene glycol (PEG)-based bowel cleansing solution and is a patented combination optimised for effective bowel cleansing. The DAYB study was a European multicentre, randomised trial that tested the hypothesis that NER1006 would be non-inferior to sodium picosulfate and magnesium citrate (NaPic + MgCit) in terms of overall bowel cleansing and high-quality cleansing of the ascending colon plus caecum [1]. Bowel cleansing was assessed using the Harefield Cleansing Scale (HCS) [2]. The primary end-points of the study were assessed by video review by a central reader. Bowel cleansing on the HCS was also assessed by the site colonoscopist and this post hoc analysis assessed the cleansing grades as determined by the site colonoscopists.

Aims & Methods: In the DAYB study, 515 patients (aged 18–85, median age: 55.0 years) underwent screening, surveillance, or diagnostic colonoscopy and were randomly assigned in a 1:1 ratio to receive either NER1006 or NaPic + MgCit, each on the day before colonoscopy. In this analysis, data from 479 patients who underwent a colonoscopy and had a completed assessment by the site colonoscopist were included. Colonoscopists were blinded to the preparation administered. Cleansing was assessed according to the HCS; cleansing of each segment of the colon was scored from 0 to 4. Scores 3 and 4 of the ascending colon were judged as high-quality cleansing. Cleansing of the overall colon was graded from A to D; grades A (all segments scored 3 or 4) and B (≥ 1 segments scored 2, no sections scored 1 or 0) were judged as successful cleansing.

Results: As indicated in Table 1, in the overall colon, successful cleansing was achieved in 12% more patients who received NER1006 than who received NaPic + MgCit (73% vs 61%, $P=0.003$, 95% CI: 4.0–20.7). In the ascending colon, high-quality cleansing was achieved in 20% more patients who received

NER1006 than who received NaPic+ MgCit (34% vs 14%, $P < 0.001$, 95% CI: 12.7–27.8).

Table 1: A comparison of bowel cleansing efficacy as assessed by site colonoscopies between NER1006 and NaPic+ MgCit

Bowel preparation	N	Patients with successful cleansing n (%)	Difference (%)	P-value	95% CI
Overall colon					
NER1006	236	173 (73)	12	0.003	4.0–20.7
NaPic+ MgCit	243	148 (61)			
Ascending colon					
NER1006	236	82 (34)	20	<0.001	12.7–27.8
NaPic+ MgCit	243	35 (14)			

N.B. successful cleansing defined here as a Harefield Cleansing Scale grade of A or B (overall colon) or score of 3 or 4 (ascending colon, high quality)

Conclusion: NER1006 was shown to provide significantly better cleansing of the overall colon and high-quality cleansing of the ascending colon compared to NaPic+ MgCit, when both treatments were administered the day before colonoscopy. The cleansing efficacy rate of the comparator was within its previously reported cleansing rates for day before administration, suggesting the improvement seen with NER1006 is of clinical relevance.

Introduction: Several studies in recent decades have revealed new roles for vitamin D. For example, vitamin D plays a role in regulating skeletal muscle, as well as in cardiovascular and renal physiology, producing anticancer effects, suppressing fibrosis, and as a regulator of the immune system. In light of these new roles—especially as a regulator of the immune system and suppressor of fibrosis—vitamin D deficiency is considered to be related to disease activity and intestinal fibrosis, including that seen in Crohn's disease (CD). Several reports have demonstrated a relationship between vitamin D deficiency and CD activity according to clinical parameters such as Crohn's disease activity index (CDAI) and quality of life (QoL). However, no reports have demonstrated this relationship by using endoscopic parameters such as endoscopic activity, mucosal inflammation, and intestinal fibrostenosis.

Aims & Methods: The aim of this study was to clarify the relationship between vitamin D deficiency and CD by using endoscopic parameters, as well as clinical parameters. Of the CD patients visiting Nagoya University Hospital from May 2011 to February 2016, 82 patients were enrolled in this study. Serum 25-hydroxyvitamin D (25(OH)D) levels, disease activity, and clinical factors of the subjects were investigated prospectively. Endoscopic findings of 52 of the 82 total patients enrolled were investigated retrospectively from endoscopic records. This study design was approved by the ethics committee of Nagoya University Hospital. Clinical remission was defined as CDAI ≤ 150 . Mucosal healing was defined as a simple endoscopic score for Crohn's disease (SES-CD) ≤ 1 . Moreover, to evaluate endoscopic activity from two aspects (mucosal inflammation and fibrotic stenosis), we divided SES-CD score into endoscopic "mucosal inflammation score" and "narrowing score". No mucosal inflammation was defined as mucosal inflammation score ≤ 1 , fibrostenosis was defined as narrowing score 0. The primary endpoint of this study was the relationship between 25(OH)D and clinical activity. Secondary endpoint was the relationship between 25(OH)D and endoscopic findings, including mucosal healing, mucosal inflammation, and intestinal fibrostenosis.

Results: Mean age of the subjects was 41.11, and the male/female proportion was 64/18. The mean serum 25(OH)D level of subjects was 17.1 ng/mL, and 61 cases (74.4%) were classified as severe deficiency or deficiency. Mean serum 25(OH)D levels of the clinical remission and clinically active groups were 18.7 \pm 8.1 ng/mL and 12.4 \pm 3.6 ng/mL, respectively ($P < 0.001$). In a multivariate analysis, low levels of serum 25(OH)D and serum albumin and positive C-reactive protein

(CRP) results were correlated with clinical activity. Mean serum 25(OH)D levels of the mucosal healing and no mucosal healing groups were 24.0 \pm 9.8 ng/mL and 15.1 \pm 6.6 ng/mL, respectively, ($P < 0.001$). Mean serum 25(OH)D levels for the no mucosal inflammation and mucosal inflammation groups were 21.6 \pm 9.6 ng/mL and 14.3 \pm 5.5 ng/mL, respectively, ($P < 0.001$); and those of the no fibrostenosis and fibrostenosis groups were 20.2 \pm 8.9 ng/mL and 14.2 \pm 6.7 ng/mL, respectively, ($P < 0.001$; Mann-Whitney U test). In a multivariate analysis, low serum 25(OH)D levels were related with mucosal inflammation and intestinal fibrotic stenosis of CD ($P < 0.05$; logistic regression analysis).

Conclusion: This study demonstrated the relationship between vitamin D level and disease activity in CD patients. The disease pathology of CD consists of repetitive intestinal inflammation and intestinal fibrostenosis formed during healing of the inflammation. We consider it important to demonstrate this relationship not only using clinical parameters, but also using endoscopic parameters such as mucosal inflammation and intestinal fibrostenosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0347 PATIENT SATISFACTION WITH HOME MONITORING OF DISEASE ACTIVITY AND FECAL CALPROTECTIN IN ADULT PATIENTS WITH INFLAMMATORY BOWEL DISEASE- INTERIM ANALYSIS OF 68 PATIENTS

P. Weimers, D. Marker, D. V. Ankersen, J. Burisch, P. Munkholm

Introduction: Inflammatory Bowel Disease (IBD), mainly represented by Crohn's Disease (CD) and Ulcerative Colitis (UC), is a chronic, relapsing and remitting disease impairing patients' quality of life (QOL). To maintain a high QOL and to decrease the inflammation burden, it is important to tightly monitor the disease and promptly treat relapses when they occur. The quality of care perceived by IBD patients play an important role in the management of IBD. An eHealth web application consisting of a validated Fecal Calprotectin (FC) home testing kit (Calpro Smart™), questionnaires regarding disease activity and QOL has been developed to improve disease monitoring, patient empowerment and patient-caregiver communication.

Aims & Methods: The aim of this study was to evaluate patient satisfaction with an eHealth home monitoring solution during the participation in a one year trial. The trial includes 120 adult IBD patients which have been randomized into two groups; one performing a disease activity screening procedure every 3 months (3M) and one screening only at the patient's discretion, on demand (OD). Both groups used the web-program where they were requested to fill out a disease activity questionnaire, Harvey-Bradshaw Index (HBI) for CD or Simple Clinical Colitis Activity Index (SCCAI) for UC, and perform a home testing of FC. The results from disease activity questionnaire and FC score are combined in the web-program rendering a Total Inflammation Burden Scoring (TIBS) which is visualized to the patient in a traffic light manner for instant recommendation of individualized treatment strategies. At baseline and upon completion of the trial the patients were requested to fill out a QOL questionnaire (Short-Inflammatory Bowel Disease Questionnaire (s-IBDQ)) as well as a questionnaire regarding their overall satisfaction with the trial and the home monitoring solution.

Results: To date, 83 patients have been included, 15 patients have dropped out (7 in OD-group and 8 in 3M-group) and 68 (3M-group: n = 32, 47%; OD-group: n = 36, 53%) patients have fulfilled the first year of follow-up and were included in the analysis. The trial lived up to the expectations in n = 63, 93% (3M-group: n = 29, 91%; OD-group: n = 34, 94%) of the patients and the support given to the patients was estimated to be sufficient by n = 67, 99% (3M-group: n = 31, 97%; OD-group: n = 36, 100%). Only n = 14, 21% (3M-group: n = 6, 19%; OD-group: n = 8, 22%) of the patients experienced difficulties with the application or the home testing kit and n = 64, 94% (3M-group: n = 29, 91%; OD-group: n = 35, 97%) wanted to continue to be monitored in an eHealth setting in the future. The mean s-IBDQ scores at baseline were 58 (95% CL: 55–61) in the 3M-group and 54 (95% CL: 50–58) in the OD-group as well as 58 (95% CL: 54–62) in the 3M group and 61 (95% CL: 58–64) in the OD group at one year follow up. No difference in s-IBDQ measured QOL was found between the two groups. However, patients in the OD group had a significant increase in mean S-IBDQ score at follow up ($p = 0.04$).

Conclusion: Patients in both groups were generally satisfied by the home monitoring set up. Patients in the on-demand group also presented a significant increase in quality of life over time.

Introduction: Inflammatory bowel diseases (IBD), such as ulcerative colitis (UC) and Crohn's disease (CD), are chronic gastrointestinal diseases that are associated with protein-energy malnutrition (PEM). Although the frequency of altered body composition, such as reduced fat-free mass or skeletal muscle volume, has been shown to be high in patients with IBD, the relationships between skeletal muscle volume and the prognosis are yet to be elucidated.

Aims & Methods: We have conducted a retrospective study on 61 IBD patients who have admitted due to exacerbation of the disease. We have enrolled IBD patients who had abdominal computed tomography and assessed the nutritional indices, such as the Onodera's prognostic nutritional index (O-PNI) and controlling nutritional status (CONUT). O-PNI was calculated based on the serum albumin and total lymphocyte count, using the following equation: O-PNI = 10 × [serum albumin (g/dl) + 0.005 × total lymphocyte count (/ml)]. The L3 skeletal muscle index (SMI) which is the cross-sectional area of the skeletal muscle at the level of the third lumbar (L3) vertebra normalized by the height squared is used to identify sarcopenia.

Results: Sarcopenia defined as low SMI were observed in 44% of all IBD patients (29% in CD, 54% in UC). In UC patients, the O-PNI, CONUT, height and albumin were significantly lower than the CD patients. Spearman's rank correlation revealed that the SMI has a strong correlation to body weight and O-PNI in IBD patients. Multivariate analysis using Cox regression model demonstrated the presence of sarcopenia (P=0.022), disease type (CD or UC) (P=0.034), and C-reactive protein (P=0.047) were the significant factors predicting intestinal resection. The cumulative operation-free survival rate was significantly lower among sarcopenic patients in all IBD patients (P=0.039) and stratified analysis in CD patients (P=0.032) using Kaplan-Meier method and log-rank test.

Conclusion: The L3 skeletal muscle area can be a prognostic factor of intestinal resection in IBD, especially in CD. The results may originate from the fact that CD presents the gastrointestinal diseases which accumulate intestinal deformity.

Introduction: Crohn's Disease (CD) spans a wide range of severity, from mild to severe. To avoid under- as well as overtreatment is challenging. While factors determining bad prognosis are studied in detail, factors predicting a mild course with the chance of simple treatments are less known. Here we show first results of a prospective evaluation of a retrospectively created score (JCC 2013;7:e263) for prediction of mild CD which consists of age at diagnosis, CRP, an endoscopy score, presence of perianal lesions and complications.

Aims & Methods: This is a prospective, ongoing study performed in 12 IBD-specialized private gastroenterology practices (outpatients only) in Germany. All consecutive newly diagnosed CD patients (diagnosis ≤6 weeks) are included. At screening ileocolonoscopy with histology, investigation of the perianal area, laboratory tests including CRP are performed and CD complications (stenosis, fistula, extraintestinal manifestations or fever >38°C) evaluated to complete of the above quoted score. Patients are treated at the discretion of the physician. In case of a score indicating a good prognosis (≤2) or of mild clinical appearance mesalamin is started. In all other cases patients are treated according to guidelines. 5 year follow up is planned for all patients. If initial therapy fails, treatment

is escalated. Source data verification is performed by external monitors. Primary aim of the study is to confirm the previously identified score and to test its power to predict a mild disease course as indicated by the need of not more than mesalamin therapy. Additional analyses include the percentage of patients with a score indicating a severe disease and their characteristics at diagnosis. This interim analysis presents preliminary data.

Results: Currently, 78 patients (33 male, 45 female; age 16–72, mean 35 years) with newly diagnosed CD are enrolled. 56 CD-patients with follow up ≥8 weeks (mean 8.5 months), mean age 35 years, 35 female, 21 male, mean CRP 12.2 mg/l were included into the interim analysis. In 28 patients with a score from 0–2 step-up treatment occurred in 7%, whereas in 28 patients with a score >2, step-up rate was 43% (p=0.0043). Differences between patients with a score 0–2 and >2 were age (41 vs. 28 years, p=0.0011), CRP <2 mg/l (17/28 patients vs. 0/28, p < 0.0001), endoscopic score 1.4 vs. 2.7, p < 0.0001), perianal lesions 0/28 vs. 4/28, stenosis 1/28 vs. 6/28. There were no differences in terms of sex, fistula, extraintestinal manifestations and fever.

Conclusion: In this early analysis of a prospective study planned with a 5-year follow-up a significant proportion of patients with mild CD and simple mesalamin therapy can be identified. These initial results encourage to continue and expand this prospective long-term study on the predictability of a mild CD course.

Introduction: The Spanish Working Group on Crohn's Disease and Ulcerative Colitis (GETECCU) and other international guidelines recommend testing of latent tuberculosis infection (LTI) before anti TNF therapy by screening with tuberculin skin test (TST) and, in a potential state of anergy, double screening by TST and interferon-gamma release assays (IGRAs) or two-time tuberculin test (TST/booster). Routine repetition is not recommended.

Aims & Methods: We aimed to assess the correlation between (TST/booster) and IGRAs using QuantiFERON-TB (QFT) and the usefulness of repeating periodic (annual or biannual) screening in a population of IBD patients of Zamora (Spain). In a single cohort of IBD patients attended in the department of gastroenterology of Zamora Hospital, we implemented a questionnaire and collected TST/booster performed previously to February 2015. Afterwards, prospectively, between February 2015 to February 2017, TST and QFT were performed at the same day, and the TST/booster 7 days after. Finally we compared the results of the LTI screening performed prospectively with the screening of the retrospective cohort.

Results: A total of 404 patients were included with a mean age of 51.5 (SD 16.6), 225 (55.7%) male and 179 (44.3%) female. 227 patients (56.2%) were ulcerative colitis, 167 (41.3%) were Crohn disease and 10 (2.5%) were diagnosed of indeterminate colitis. 160 patients live in rural areas (40.6%). 60/355 (16.9%) were smokers. The prevalence of LTI and the correlation between TST/booster and QFT is shown in table 1.

Table 1: Prevalence of LTI and correlation between TST/booster and QFT.

	Prevalence of LTI	Prevalence of LTI in patients on immunomodulator treatment	Prevalence of LTI in patients on anti-TNF therapy
TST/booster or QFT (+)	130/399 (32.6%) (95% CI [27.8–37.3%])	47/239 (28.5%)	9/49 (18.4%)
TST/booster positives	116/371 (31.3%)	40/163 (24.5%)	
TST (–)/booster (+)	28/272 (10.3%)	12/135 (8.9%)	3/42 (7.1%)
QFT positives	40/264 (15.5%)	6/105 (5.7%)	0/12
TST/booster(–)/QFT (+)	12/264 (4.5%)	3/89 (0.8%)	0/11
TST/booster(+)/QFT(–)	24/370 (6.4%)	4/162 (2.4%)	3/49 (6.1%)

Prevalence of LTI in retrospective testing was of 54/246 (22.0%). Prospective testings were positive in 72/261 (27.6%). During the follow up, 30/191 (15.7%) patients who were negative for screening before 2015 were converted in positive for LTI (95% CI [10.2–21.1]).

Conclusion: The prevalence of LTI in our area is high (32.6%). The simultaneous performance of the TST/booster and QFT increases the detection of LTI. The TST/booster increases the detection of LTI even when is performed in patients without immunosuppressive treatments, in whom is not routinely recommended. The QFT is more useful in patients without immunosuppressive therapy. The repeated screening (annual or every two years) is useful in this population with high prevalence of LTI, since it may detect LTI in patients with previous negatives test (15.7%). The TST/booster is essential due to the possible false negatives of QFT when screening patients on anti-TNF therapy.

Introduction: Magnetic resonance enterography (MRE) and capsule endoscopy (CE) are prime modalities for evaluation of small bowel in patients with Crohn's disease (CD). However, detection of proximal (jejunum and proximal ileum) small bowel inflammation by MRE is challenging. Current quantitative scores such as Magnetic Resonance Index of Activity (MaRIA) do not incorporate proximal small bowel data and were validated against ileocolonoscopy. Magnetic resonance enterography global score (MEGS) was designed for quantitative evaluation of the entire digestive tract; however, it was only validated against ileocolonoscopy and its accuracy in the proximal small bowel was not assessed. CE allows for accurate assessment of the entire small bowel and is the modality of choice for evaluation of the proximal small bowel.

Aims & Methods: We aimed to compare the quantitative evaluation of the small bowel inflammation by MEGS score and the Lewis capsule endoscopy score. Patients with known quiescent small bowel (CD) for at least 3 months (CDAI < 150) were prospectively recruited and underwent magnetic resonance enterography (MRE) and capsule endoscopies (CE). MEGS score was calculated for each bowel segment and the entire small bowel. MEGS is based on the involved segment length, wall thickness, mural enhancement, mural and perimural edema and extra-intestinal findings. In addition, MARIA score was calculated for the terminal ileum. Small bowel inflammation on CE was quantified using the Lewis score (LS) (LS < 135- mucosal healing; LS ≥ 790 – moderate to severe inflammation). Proximal small bowel was defined as jejunum and duodenum on MRE and as 1st and 2nd tertiles LS on CE. Distal small bowel was defined as terminal ileum on MRE and 3rd tertile LS on CE. Fecal calprotectin (FCP) levels were measured and correlated with all scores.

Results: Fifty-two patients were included in the study. There was a strong correlation between MEGS and LS (Pearson correlation $r=0.61$, $p=0.001$) for the entire small bowel. In the proximal small bowel, the correlation was moderate (for duodenum vs LS 1st tertile and proximal ileum vs 2nd tertile LS - both $r=0.54$, $p=0.001$). In the terminal ileum, there was a strong correlation between MEGS and MaRIA score ($r=0.74$, $p=0.001$) while both MRE based scores were moderately correlated with 3rd tertile LS ($r=0.5$, $p=0.001$ for both). The correlation with FC was stronger for MEGS ($r=0.68$ $p=0.001$) than for MaRIA ($p=0.40$ $p=0.01$) or for LS ($r=0.38$, $p=0.02$).

Conclusion: MEGS score provides accurate evaluation of the small bowel in CD and is strongly correlated with FC levels; the main advantage of MEGS is the accurate quantification of proximal small bowel inflammation that is unavailable for other quantitative MRE scores.

Contact E-mail Address: ukopylov@gmail.com

Introduction: Small-bowel capsule endoscopy (CE) is a prime modality for evaluation of the small bowel. The Lewis score (LS) and the Capsule Endoscopy Crohn's Disease Activity Index (CECDAI) are validated endoscopic indices for quantification of small bowel inflammation on CE. It is unclear whether these indexes are interchangeable for evaluation of mucosal inflammation in established Crohn's disease (CD).

Aims & Methods: We aimed to prospectively compare the quantitative evaluation of the small bowel inflammation by both scores. Patients with known quiescent small bowel (CD) for at least 3 months (CDAI < 150) were prospectively recruited and underwent CE. LS was calculated using the capsule reading software (RAPID 8) and CECDAI was calculated manually, by 2 independent experienced gastroenterologists (one for each score) unaware of each other's results. Mucosal healing was defined as LS < 135; LS ≥ 790 signified moderate to severe inflammation. Fecal calprotectin (FCP) and C-reactive protein (CRP) levels were measured and correlated with the scores.

Results: Fifty patients were included in the study. There was a strong correlation between LS and CECDAI (Pearson's $r=0.67$, $p=0.001$). CECDAI < 7.2 corresponded to mucosal healing (LS < 135), while CECDAI > 11.1 corresponded to moderate to severe inflammation (LS ≥ 790) by linear regression. There was a moderate correlation between both scores and FCP levels that was somewhat stronger for CECDAI ($r=0.39$, $p=0.002$ vs $r=0.53$, $p=0.001$ for both). There was a weak correlation between LS and CRP levels ($r=0.27$, $p=0.04$) and none for CECDAI and CRP ($r=0.21$, $p=0.1$).

Conclusion: In our prospective study, CECDAI and LS strongly correlated and performed similarly for quantitative assessment of mucosal inflammation in established CD.

Disclosure of Interest: U. Kopylov: The study was supported by a generous grant by the Helmsley Charitable fund

P0353 CONCORDANCE BETWEEN TUBERCULIN SKIN TEST AND INTERFERON GAMMA RELEASE ASSAY FOR LATENT TUBERCULOSIS SCREENING IN INFLAMMATORY BOWEL DISEASE (META-ANALYSIS)

S. Alrajhi¹, P. Germain², W. Afif², M. Martel²

¹Internal Medicine, McGill University, Montreal/Canada/QC

²McGill University, Montreal/Canada/QC

Contact E-mail Address: saad.alrajhi@mail.mcgill.ca

Introduction: Screening for latent tuberculosis infection (LTBI) is mandatory prior to initiating anti-tumor necrosis factor (anti-TNF) medications. New guidelines recommend interferon-gamma release assays as first line screening method for the general population. Studies have provided conflicting evidence on the performance of interferon-gamma release assays (IGRAs), compared to tuberculin skin test (TST) in inflammatory bowel disease (IBD) patients. We assessed the concordance of these two tests in IBD patients and the effect of immunosuppression on their performance.

Aims & Methods: We performed a systematic search of MEDLINE, EMBASE and Cochrane Library databases, from 2011 to 2016, for relevant studies testing both TST and IGRA in IBD patients. The primary outcome was concordance between TST and IGRA. Secondary outcomes were effects of immunosuppressive therapy on both TST and IGRA. Immunosuppression was defined as either steroids more than 5mg for at least two weeks, thiopurine, methotrexate or cyclosporine. We used the Mantel-Haenszel method for a pooled random effects model, given heterogeneity of studies included. We also compared the fixed effects model to exclude any effect of smaller studies. Heterogeneity between studies was analysed using the statistical I^2 , Q and Tau 2 tests. The quality of included studies was evaluated using a modified QUADAS-2 method.

Results: Sixteen studies, including 2488 patients with IBD, were included for the analysis. The pooled concordance between the TST and IGRA was 85% (95% confidence interval [CI] 81%–88%, $p=0.01$). Effects of immunosuppression on both tests were reported in eight studies including 814 patients with IBD. The odds ratio of testing positive by IGRA decreased to 0.57 if immunosuppressed (95% confidence interval [CI] 0.31–1.03, $p=0.06$). The odds ratio of testing positive by TST if immunosuppressed was 1.14 (95% confidence interval [CI] 0.61–2.12, $p=0.69$). Using the fixed effect model yielded similar results, however the negative effect of immunosuppression on IGRA reached statistical significance ($p=0.06$ to 0.01).

Conclusion: While concordance was 85% between TST and IGRA, the performance of IGRA seems to be negatively affected by immunosuppression. Given the importance of detecting latent TB prior to anti-TNF initiation, using only IGRA should be avoided in immunosuppressed IBD patients.

P0354 THIOPURINE MAINTENANCE THERAPY FOR IBD: WHICH IS THE BEST METHOD TO MEASURE MEDICATION ADHERENCE?

A. Ochieng, V. George, C. Selinger

Gastroenterology, St James Hospital, Leeds/United Kingdom

Contact E-mail Address: odouri.ochieng@nhs.net

Introduction: For the majority of patients with IBD long-term therapy is required to maintain remission, yet 30–45% of patients do not adhere to their IBD medication. Medication adherence can be assessed with prescription refill rates, biological measures (metabolites, trough levels, etc) and patient self-report tools. There is currently no accepted gold standard and the feasibility and utility of different adherence assessment tools in the routine outpatient clinic setting have not been fully examined. The aim of this service improvement project was to test the acceptability of self-report tools assessing thiopurine adherence in the IBD clinic and to correlate the results with thioguanine-nucleotide (TGN) levels.

Aims & Methods: Consecutive outpatients on thiopurine maintenance therapy for IBD for >3 months were recruited from clinic. Patients self-reported adherence using a visual analogue scale (VAS), the validated Morisky adherence tool (MOR) and the validated Medication Adherence Report Scale (MARS). TGN levels were classed as complete non-adherence (<100 and MMP low), partial adherence (TGN 100–235 and MMP low) or full adherence (>235 or MMP high). Correlation analysis was performed using Pearson tests.

Results: Of 100 approached patients none refused participation and TGN levels were available for 69. These included 38 women. Diagnoses were Crohn's disease in 27, ulcerative colitis in 41 and IBD-U in 1 cases. Concomitant therapy included 5-ASA (25 cases), anti-TNF (13 cases) and Vedolizumab (2 cases). The proportion of adherent patients was according to the relevant report tool 71% (TGN), 87% (VAS), 87% (Morisky) and 77% (MARS). VAS (Pearson 0.315; $p=0.005$) and Morisky (Pearson -0.363 ; $p=0.001$) correlated moderately with TGN, but MARS (Pearson 0.09; $p=0.39$) did not. The 7 patients, who were non-adherent by TGN were detected by VAS in 3, Morisky in 6 and MARS in 3 cases. However, patients showing non-adherence according to self-report tools had normal TGN levels in 6 of 10 cases for VAS, 10 of 26 for Morisky and 4 of 15 for MARS.

Conclusion: Self-report tools provided a patient-friendly and inexpensive way of assessing adherence, but the correlation with TGN levels was only moderate. While providing a more objective assessment TGN levels are problematic for routine use in all patients. TGN require a more invasive and expensive approach. Furthermore, TGN cannot detect "white coat adherence" (patients take medication only around appointments), which is the most likely explanation for normal TGN levels in patients reporting to be poorly adherent. Neither TGN levels nor self-report tools can be seen as the gold standard at present.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0355 ROLE FOR THERAPEUTIC DRUG MONITORING IN ASSESSING SECONDARY LOSS OF RESPONSE TO MAINTENANCE ANTI-TNFA THERAPY IN INFLAMMATORY BOWEL DISEASE

Introduction: Anti-TNFA therapies have improved outcomes in patients with inflammatory bowel disease. Their use has been associated with improved clinical endpoints, reduced hospitalisation and rates of surgery. However secondary loss of response (LOR) to both infliximab (IFX) and adalimumab (ADA) is a significant problem, leading to further flares of disease, disease progression and poorer outcomes. Therapeutic drug monitoring (TDM), which involves measurement of an individual's anti-TNFA trough and antibody levels, offers the opportunity of exploring an immune basis behind LOR, and potentially adjusting doses or switching therapies to help regain clinical response.

Aims & Methods: The aim of this study was to evaluate whether TDM can help predict secondary LOR to infliximab and adalimumab and whether dose

adjustments based on this information can help patients regain clinical response. This was a prospective, single-centre study, performed from September 2015 to April 2016, at our institution. Patients with Ulcerative colitis (UC) and Crohn's disease (CD) were enrolled, if they were clinically (based on Harvey-Bradshaw (HBI) or partial Mayo scores) felt to be experiencing a secondary LOR to either infliximab or adalimumab maintenance therapy. Patients had serum biochemical markers measured, including CRP and albumin. In addition assessment of inflammation took place, with measurement of SES-CD and Mayo scores, for CD and UC respectively. Anti-TNFA trough and antibody levels were performed using standard ELISA techniques. Patients were followed for a one-year period, from their initial assessment for secondary LOR to assess outcomes.

Results: 46 patients were recruited, 40 CD with Harvey-Bradshaw Index (HBI) >4 points and 6 patients with UC with Partial Mayo Score (PMS) >2 points. Mean age for the cohort was 40.9 years, 26 (56.5%) were female, mean duration of disease was 9.8 years, 3 (8.3%) were smokers, 7 (15.2%) on immunomodulators, and 11 (23.9%) had prior anti-TNFA exposure. 17 (48.6%) were on an adalimumab maintenance dose of 40 mg every other week. Overall HBI for the group was 11.9, partial Mayo 6.5. In terms of markers of inflammation, mean SES-CD was 8.5, Mayo endoscopy score 2.7. Mean adalimumab trough level was 4.5 ug/ml, and 15/36 (42.9%) had a sub-therapeutic trough level less than 1 ug/ml. 9 patients (25.7%) had antibodies to adalimumab. Mean infliximab trough level was 8.1 ug/ml and 2/10 (20%) had sub-therapeutic trough levels, none with antibodies. Higher baseline adalimumab trough levels, were noted in patients who were well or who had functional symptoms at one-year follow-up compared to patients, who were unwell, and required change in therapy, mean trough 6.4 ug/ml (IQR 2.1–10.3) compared to 2.9 ug/ml (IQR 0.3–6.3) (p value = 0.0265 95% C.I. 0.4 to 6.5). The area under the curve [AUC] for association of ADA level at secondary LOR with a good outcome was 0.766, $p=0.037$. In addition a trough level of 3.5 ug/ml predicted clinical response at one year, following secondary LOR to adalimumab, with a sensitivity of 85.7% and a specificity of 81.8%. Similarly for infliximab higher baseline trough levels, were noted in patients who were well at one-year follow-up compared to those who required change in treatment, 16.0 ug/ml (IQR 15–16.8) versus 4.6 ug/ml (IQR 1.1–6.1), p value = 0.005 95% CI 4.5 to 18.3. The therapeutic strategy chosen for each group was: 23.9% no change in treatment, 26.1% increase anti-TNFA dose or decrease infusion interval, 19.6% switch to another anti-TNFA drug, 15.2% switch to non anti-TNFA (ustekinumab). For patients who had doses adjusted, clinical response (decrease of HBI ≥ 3 points for CD) was reached in 77.8% of patients and remission (HBI ≤ 4 for CD) in 55.6% at the end of follow-up.

Conclusion: Secondary LOR to anti-TNFA therapy has a significant impact on patient outcomes. Therapeutic drug monitoring is helpful for predicting secondary LOR and for facilitating dose adjustment or switch in therapy in a clinically guided fashion.

Contact E-mail Address: mariangela.allocca@humanitas.it

Introduction: Bowel Ultrasound (US) and Magnetic Resonance Enterography (MRE) are accurate in assessing disease activity and complications in Crohn's disease (CD) patients. The comparative accuracy of US versus MRE + Colonoscopy (CS) in assessing disease activity and complications and influencing the decision-making process in CD is unknown.

Aims & Methods: Ileocolonic CD consecutive patients seen in a tertiary referral Center (Humanitas Research Hospital, Milan, Italy) were prospectively assessed by MRE, CS and US, within 1 week. Sensitivity, specificity, accuracy, positive and negative predictive values (PPV and NPV) of US in assessing localization and extension (bowel wall thickening >3 mm), bowel wall enhancement (increase of vascularization at power Doppler), strictures (narrowing of the lumen), fistulas and abscesses, and active disease (presence of ulcers at colonoscopy) were calculated using CS in combination with MRE findings as a reference standard. Two independent blinded IBD specialists reviewed separately MRE and US findings, and were asked to decide the therapeutic strategy (continue therapy vs. optimize/change therapy). Kappa agreement between MRI and US was also investigated.

Results: Forty-one consecutive CD patients, irrespectively of disease activity and current therapy, were enrolled. Twenty-three patients had active disease as assessed by MRE and CS (56%), 20/41 (49%) had CD-related complications. Sensitivity, specificity, accuracy, PPV and NPV of US are showed in Table 1. Based on US findings alone, compared to MRE + CS, management of IBD patients (continuing or changing/optimizing therapy) was judged accurate in 85% of patients, compared to 75% managed by MRI only ($p < 0.001$). Agreement between MRE and US was 80%.

Parameter	Sensitivity %	Specificity %	Accuracy %	PPV %	NPV %
Localization + extension	80 (0.50–0.93)	94 (0.70–0.99)	85 (0.70–0.94)	95 (0.76–0.99)	75 (0.50–0.91)
Bowel wall enhancement	80 (0.58–0.94)	88 (0.65–0.98)	84 (0.69–0.94)	89 (0.66–0.98)	80 (0.56–0.94)
Strictures	76 (0.50–0.93)	79 (0.57–0.93)	78 (0.62–0.89)	72 (0.46–0.90)	82 (0.61–0.95)
Fistulas	100 (0.16–1)	97 (0.86–0.99)	97 (0.87–0.99)	66 (0.09–0.99)	100 (0.90–1)
Abscesses	100 (0.02–1)	95 (0.83–0.99)	95 (0.83–0.99)	33 (0.01–0.90)	100 (0.90–1)
Active disease	83 (0.58–0.96)	100 (0.85–1)	93 (0.80–0.98)	100 (0.78–1)	88 (0.69–0.97)

Conclusion: US was as accurate as the combination CS + MRI in assessing disease activity and complications in CD patients. Therapeutic decisions based on US findings alone were appropriate in the vast majority of CD patients. US is a non-invasive, easy-to-use tool to manage CD patients in clinical practice.

Introduction: Diagnostic delay seems to be common in inflammatory bowel disease (IBD), especially in Crohn's disease (CD). We sought to investigate the diagnostic delay in Austrian IBD patients and to identify associated risk factors as well as the impact of delayed diagnosis on the risk of intestinal surgery in CD.

Aims & Methods: In a multicentre cohort study adult patients with IBD (CD, ulcerative colitis UC, inflammatory bowel disease unclassified IBDU) attending 18 Austrian outpatient clinics were recruited between May 2014 and July 2015 to complete a multi-item questionnaire, which recorded medical and socioeconomic characteristics. Study outcome was the diagnostic delay defined as the time period from first symptom onset to diagnosis of IBD. A multivariable proportional hazard regressions model based on interval censored latency times was calculated.

Results: 1217 patients (CD 779, UC 400, IBD 21, missing 17; females 615) with a median age of 40 years (interquartile range (IQR) 31–52 years) and a median disease duration of 10 years (IQR 4–18 years) were analysed. The median diagnostic delay was 0.53 years (IQR 0.20–1.92 years) in CD and 0.28 years (IQR 0.11–0.86 years) in UC, respectively ($p < 0.001$). In the multivariable regression analysis patients with CD had a significantly longer diagnostic delay than patients with UC (HR 1.56; 95% CI 1.34–1.82; $p < 0.0001$) and a quadratic effect of age leading to higher risk of delayed diagnosis in older patients ($p < 0.0001$) was found. Diagnostic delay did not differ significantly between patients with intestinal CD-related surgery (53% of all CD patients) and those without surgery. However, in the Kaplan-Meier curve for the probability of being diagnosed after symptom onset a trend of a difference between both groups was seen after 10 months ($p = 0.13$).

Conclusion: The median diagnostic delay was longer in CD (6 months) than in UC patients (3 months) and was associated with older age at diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Enterobacteria, especially adherent and invasive *E. coli* (AIEC), are suspected to play a key role in Crohn's disease (CD). These bacteria are able to highly adhere to the ileal mucosa of CD patients through the CEACAM6 receptor (Carcinoembryonic antigen-related cell adhesion molecule 6). It has been shown that therapies targeting enterobacteria and/or AIEC could be more effective in mice overexpressing CEACAM6. In this line, the overexpression of CEACAM6 in the ileum as well as the presence of AIEC in the ileum could be potential biomarkers to select the patients who could benefit from drugs targeting the host-pathogen interaction. Unfortunately, the identification of these biomarkers is time-consuming and invasive highlighting the need for more convenient alternative.

Aims & Methods: We aimed to assess the correlation between the level of CEACAM6 in the saliva and the level of CEACAM6 in the ileum in CD patients and to define the best threshold of CEACAM6 in the saliva to detect overexpression of ileal CEACAM6. In addition, we attempted to identify non-invasive biomarkers of AIEC infection. In this prospective multicentre study (8 centers), all the patients requiring ileocolonoscopy, regardless the indication, were consecutively included between September 2015 and September 2016. Clinical and endoscopic data were collected on the day of colonoscopy. Blood samples, stool samples (before bowel cleansing), saliva and ileal biopsies from healthy and ulcerated areas were also collected. CEACAM6 from ileal biopsies and saliva were measured (duplicates) using ELISA assays. AIEC were identified using phenotypical assays.

Results: Overall, 102 patients were enrolled in the study (Table 1).

Table 1: Baseline characteristics of the 102 CD patients included in the study.

Prior intestinal resection	43 (43.4%)
Current therapies	

(continued)

5-ASA	7 (7.1%)
Corticosteroids	12 (12.4%)
Immunosuppressive therapies	33 (33.9%)
Anti-TNF agents	33 (33.9%)
Other biologics	3 (3.0%)
CDAI, mean \pm standard deviation	131 \pm 109
CRP, g/L mean \pm standard deviation	8, 1 \pm 13, 8
Fecal calprotectin, μ g/g mean \pm standard deviation	244 \pm 358

Ileal CEACAM6 level did not depend on disease severity or the site of biopsies as the median level of ileal CEACAM6 was 854.9 pg/mg [570.2; 1646] and there was no difference in healthy or ulcerated zone (756 pg/mg [487; 1617] vs 947 pg/mg [604; 1820], $p=0.86$). The median level of CEACAM6 from saliva was 3837 pg/mg [1889; 7338]. There was a positive correlation between the levels of CEACAM6 in saliva and CEACAM6 in the ileum ($\rho=0.47$; $p < 0.0001$) in both macroscopically healthy areas ($\rho=0.53$, $p < 0.0001$) and ulcerated zone ($\rho=0.39$, $p=0.0082$). Using a ROC curve, we determined the best threshold of CEACAM6 in saliva for detecting ileal CEACAM6 overexpression. Using a ROC curve (area under the curve (AUROC)=0.73), the cut-off value of 3800 pg/mg demonstrated the best performances to detect ileal CEACAM6 overexpression with substantial specificity (76.0% [54.9–90.6]) and positive predictive value (87.5% [74.8–95.3]). The number of enterobacteria was increased in CD patients with prior intestinal resection (562 [20;1674] vs. 116 [0;752] pg/mg, $p=0.03$). Interestingly, the number of enterobacteria was also increased in AIEC positive-patients (640 [184;2392] vs. 60 [0;1028] pg/mg, $p=0.004$). Using a ROC curve, we determined the best threshold of enterobacteria in the ileum to detect the presence of ileal AIEC bacteria. We found an area under the curve (AUROC) of 0.70 [0.61; 0.77]. The cut-off value of 60 cfu/biopsy demonstrated the best performances to detect the presence of ileal AIEC bacteria. The number of enterobacteria associated to ileal mucosa (cut-off value >60 cfu/biopsy) strongly predicted the presence of AIEC and then is a reliable test for AIEC screening with very high negative predictive value (94.1% [80.3–99.3]) and high sensitivity (91.7% [73.0–99.0]).

Conclusion: CEACAM6 measurement in the saliva is feasible, non time-consuming and non-invasive. It could be a reliable test to detect the overexpression of CEACAM6 in the ileum from CD patients and could then be proposed as a non-invasive biomarker to select patients who might benefit from anti-adhesive therapies. In addition, we identify that the number of enterobacteria associated to the ileum is a convenient and reliable test to screen CD patients for AIEC bacteria.

Introduction: Fibroblast growth factor 19 (FGF19) is the ileal hormone providing feedback inhibition of bile acid (BA) synthesis in the liver. BAs are actively reabsorbed in the terminal ileum by the apical sodium-dependent BA transporter (ASBT). FGF19 is produced by the ileal enterocytes in response to absorbed BAs binding and activating the nuclear BA receptor, also known as farnesoid X receptor (FXR) [1]. The FXR activation may enhance expression of anti-inflammatory genes and down-regulate pro-inflammatory genes [2]. The glucocorticoid budesonide has been shown to increase the expression of ASBT and BA absorption inducing FGF19 release [3]. Disturbances in BA enterohepatic circulation may be associated with colonic inflammation, but little is known about the mechanisms of BA dysregulation in ulcerative colitis (UC).

Aims & Methods: The aim of the study was to evaluate serum FGF19 level in patients with active and inactive phase of UC. Fasting serum FGF19 level was measured using ELISA test in 14 patients with active UC (7 F, 7 M; mean age 44), 16 UC patients in remission (10 F, 6 M; mean age 39), and 7 healthy controls (4 F, 3 M; mean age 35). Disease activity was assessed based on the clinical evaluation and fecal calprotectin level. Non-parametric statistics were used and results are expressed as median with interquartile ranges. The Mann-Whitney U test was used for the comparison of differences between the groups. Spearman's rank correlation coefficient was also calculated.

Results: Median fecal calprotectin level in UC patients with active and inactive phase of the disease amounted to 1675.1 vs 142.8 μ g/g, respectively ($p=0.004$). Median serum FGF19 level was significantly higher in UC patients in remission (median 192.6 pg/ml, range 155.1–351.2) than in UC patients with active disease (median 82.6 pg/ml, range 64.0–151.8), $p=0.004$. Median FGF19 level in healthy controls (median 151.6 pg/ml, range 121.6–216.1) was lower than in UC patients in remission and higher than that in patients with active UC, but the differences did not reach statistical significance. A negative correlation between serum FGF19 and fecal calprotectin levels was observed, but it was not statistically significant ($R = -0.328$, $p=0.077$).

Conclusion: The increased FGF19 level in UC patients in remission, compared to the patients with active UC, may be influenced by the treatment, in particular corticosteroids used to induce remission. Steroid-induced increase in FGF19 synthesis may be associated with anti-inflammatory effect. The stimulation of FGF19 release during UC remission may also have beneficial effect by the inhibition of BA synthesis and reduction of excess colonic BAs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Crohn's disease (CD) has a progressive course and often causes mucosal injury throughout the gastrointestinal tract. Mucosal healing (MH) has been proposed as a treatment goal for patients with CD. Endoscopy, computed tomography, magnetic resonance imaging, and other examinations are used to evaluate MH. However, repeated examinations require considerable effort and are highly invasive. Recently, fecal calprotectin (FC) has attracted attention as a new biomarker. The correlation between FC levels and CD activity is well established in ileocolonic or colonic CD, but few reports have described this correlation in ileal CD alone.

Aims & Methods: This study evaluated the correlation between FC levels and endoscopic activity in ileal CD. Fifteen patients with ileal CD who underwent double-balloon endoscopy (DBE) between May 2016 and February 2017 at our hospital were included in this study. The entire small intestine was examined with DBE and radiological enteroclysis. We evaluated the correlations of FC levels, C-reactive protein (CRP) levels, erythrocyte sedimentation rates (ESRs), and CD activity index (CDAI) scores with the endoscopic activity. To evaluate the endoscopic activity of the small intestine, we used Double-Balloon Endoscopic Score for CD (DES-CD), which is a modified version of the Simple Endoscopic Score for CD (SES-CD). To determine the DES-CD, the small intestine was divided into four segments (upper jejunum, lower jejunum, upper ileum, and lower ileum), and four variables were evaluated in each segment (ulcer size, extent of ulcerated surface, extent of affected surface, and stenosis) in accordance with the SES-CD. For the evaluation of mucosal injury, the partial DES-CD (pDES-CD) was calculated by excluding "stenosis" from the DES-CD. The DES-CD and DES-CD ranges were 0–46 and 0–24, respectively.

Results: Fifteen patients (11 males and four females) with a median age of 42 (range, 27–71) were assessed. No colitic lesions were observed in any of the patients. The DES-CD correlated with FC ($\gamma=0.688$, $P=0.005$) and CRP ($\gamma=0.765$, $P=0.001$) levels. In addition, the pDES-CD correlated with FC levels ($\gamma=0.803$, $P=0.001$), CRP levels ($\gamma=0.673$, $P=0.006$), and ESRs ($\gamma=0.704$, $P=0.003$). The CDAI scores did not correlate with either of the endoscopic scores.

Conclusion: In this study, the endoscopic activity in ileal CD correlated with FC levels. In addition, pDES-CD scores exhibited a stronger correlation with FC levels than did DES-CD scores. This might be because FC levels reflect mucosal injury and not stenosis. Our findings suggest that FC can be used for monitoring mucosal injuries in the small intestine and as a biomarker for evaluating MH.

Introduction: Increasingly, immunosuppressive medications such as azathioprine and biologics are being used in order to promote clinical remission in inflammatory bowel disease (IBD) patients. It has been reported that such treatments increase the risk of developing all types of skin cancer. Education of these patients is key in order to promote their awareness of their increased risk and it is vital for gastroenterologists to counsel patients on sun protection strategies on initiating therapy. We recently performed a pilot study in this group which highlighted gaps in their knowledge of the increased risk and prevention strategies. We speculate clinician's lack of knowledge was partly to blame.

Aims & Methods: Our aim was to determine Irish IBD clinicians' knowledge of the skin cancer risk and advised photoprotective behaviours in this cohort. Cross-sectional descriptive study. We invited IBD clinicians via email to fill in an anonymous online survey designed to assess knowledge of skin cancer risk and prevention methods as recommended by the "Sunsmart" guidelines, as currently gastroenterology based guidelines are lacking. In addition their grade of training and clinical experience was noted.

Results: To date, 45 Irish Gastroenterology clinicians completed the online questionnaire. Of these, fifteen (33%) were consultants, fourteen (31%) gastroenterology trainees, four (9%) general medical trainees and twelve (27%) IBD nurse specialists. Overall, clinician's knowledge of general factors associated with increased risk of skin cancer was reassuring; with all 45 (100%) knowing sun beds increased skin cancer risk and almost 100% (44, 98%) knew working outdoors incurred increased risk. 42 (93%) knew a personal history of skin cancer and previous blistering sunburn were risks; however, only 34 (79.1%) recognised family history as a risk. Regarding gender associated risk; only 67.4% (n=29) knew men were greater risk than women of non-melanoma skin cancer (NMSC). Their knowledge of specific immunosuppressant risk was suboptimal; while many (37, 82%) recognized azathioprine was a risk factor for developing NMSC, only 53% (n=24) knew anti-TNF medications were strongly associated with an increased risk of malignant melanoma. Regarding prevention strategies; the majority knew what changes to look for in a suspicious mole; 100% (n=45) knew to be suspicious of changing color and 84% (n=38) of an irregular border, but shockingly only five (11%) perform yearly skin checks on their patients on immunosuppressants. Their knowledge of preventative measures was also lacking; 37 (86%) knew patients should wear SpF 50 but almost half (47% n=20) thought it should be applied twice daily rather than two hourly (51% n=23) and only 47% (n=20) knew patients should stay in the shade from 11am-3pm. Regarding their own practice; 39 (87%) report they do emphasise the importance of sun protection in their patients; however, worryingly only 24 (55.8%) had heard of our national skin cancer prevention guidelines "Sunsmart". Of interest; while physicians had a greater understanding of patient risk factors ($p < 0.03$), nurse specialists were more likely to emphasise the need for sunprotection in clinic ($p < 0.0003$), and of physicians, trainees had a more complete knowledge of all advised preventative measures ($p < 0.03$).

Conclusion: Our study highlights IBD clinicians' suboptimal knowledge of immunosuppression risk and their lack of emphasis on preventative measures and skin examination in clinics. A targeted educational and awareness programme may address this.

P0362 HOME MONITORING OF DISEASE ACTIVITY AND FECAL CALPROTECTIN IN ADULT PATIENTS WITH INFLAMMATORY BOWEL DISEASE – INTERIM ANALYSIS OF 68 PATIENTS

D. V. Ankersen, D. Marker, P. Weimers, J. Burisch, P. Munkholm
Department Of Gastroenterology, North Zealand University Hospital, Frederikssund/Denmark

Contact E-mail Address: dorit.vedel.ankersen@regionh.dk

Introduction: Due to the chronic and progressive nature of inflammatory bowel disease (IBD) it is of significant importance to detect and treat a relapse as soon as possible in order to decrease the total inflammation burden and avoid progression of intestinal damage, and possibly improve the disease course. A validated Fecal Calprotectin (FC) home testing kit and smart phone application CalproSmart™ have been added to an existing eHealth web-application, enabling patients to monitor their disease activity using clinical scores and FC from home with results shown on their smart phone. eHealth allows for tight monitoring of disease activity, however, the frequency of an optimal screening procedure for adult IBD patients has not yet been determined.

Aims & Methods: The aim of this one-year randomized controlled trial of 120 adult IBD patients, was to determine if an eHealth screening procedure for disease activity should be implemented in clinical practice 'every 3 months, 3M' or according to patients own gut feeling, 'on demand, OD'. Both groups used the ehealth-program to tightly monitor their disease activity either OD or every 3M. Patients randomized to screen every 3M were also allowed to monitor themselves OD if they were feeling a flare was coming. The web-algorithm consists of a short disease questionnaire either Harvey-Bradshaw Index (HBI) for Crohn's disease (CD) or Simple Clinical Colitis Activity Index (SCCAI) for Ulcerative Colitis plus home monitoring of FC, which together gives a total inflammation burden scoring (TIBS). Based on longitudinal FC and disease

activity scores area under the curve (AUC) were calculated by an algorithm taking the inclusion date and the first observation 357 days after inclusion into the calculation.

Results: To date, 83 patients have been included, 15 patients have dropped out (7 in OD-group and 8 in 3M-group) and 68 (3M-group: n=32, 47%; OD-group: n=36, 53%) patients have fulfilled the first year of follow-up and were included in the analysis. There were no statistical difference between the two groups OD vs. 3M on the following indices: Active disease (FC > 600 mg/kg) at inclusion n=17, 25% (3M-group: n=6, 19%; OD-group: n=10, 29%, $p=0.26$), active disease at least once throughout the whole year: 41 patients (61%) (3M-group: n=21, 66%; OD-group: n=20, 57%, OD, $p=0.32$). Patients screened themselves with regards to FC 233 times in the OD-group and 232 times in the 3M-group. The mean no of FC home measurements pr. patient was similar in the two groups: OD 6.7 (95% CL: 5.2–8.2) vs. 3M 7.3 (95% CL:5.9–8.5), $p=0.54$. Median (range) AUC for FC and disease active scores were not significantly different in the groups (OD, 3M): 62016 (3782–541338) vs 89730 (10286–353881) $p=0.71$, 549 (0–3726) vs 610 (0–2.884) $p=0.61$.

Conclusion: In this preliminary analysis, no difference between the two screening procedures was found in regards to disease course and resource utilization. A slightly but non-significant reduction in no of FC measurements pr. patient used in OD-group relative to 3M-group could argue for an economical benefit of choosing the OD screening procedure. Long-term results are awaited.

Introduction: Ulcerative colitis (UC) and Crohn's disease (CD) represent a serious medical and socio-economic problem worldwide. The family of S100 proteins represents a total of at least 25 relatively small calcium binding proteins. S100 proteins have a broad range of functions: they play a role in the regulation of cell proliferation, differentiation, apoptosis, energy metabolism, cellular signalling, and calcium homeostasis. S100A4 (metastatin-1, calvasculin) strongly contributes to a process of metastasizing. Still, the role of S100A4 seems to be more complex as its profibrotic effect has been confirmed in the myocardium, liver parenchyme and in the intestine. Fibroblasts represent the key cell type in the pathogenesis of fibrostenosing/stricturing CD.

Aims & Methods: The aim of this prospective study was to assess serum concentration of S100A4 protein in UC and CD. Study included 118 subjects: 93 patients with CD (44 men, 49 women, aged 22–79, mean 44 ± 14), 16 patients with UC (8 men, 8 women, aged 20–74, mean 39 ± 15) and 9 controls (average risk population with normal findings on colonoscopy and with negative history of colorectal neoplasia and/or inflammatory bowel disease; 2 men, 7 women, aged 23–74, mean 52 ± 17). CD group was divided according to the Montreal classification: 20/93 (22%) patients had B1 phenotype, 19/93 (20%) B2, 20/93 (21%) B3 and 34/93 (37%) B2 + B3. Perianal involvement was present in 27/93 (29%). L1 involvement was present in 15/93 (16%), L2 in 14/93 (15%) and L3 in 64/93 (69%). Serum concentration of S100A4 protein was investigated by means of Human Protein S100-A4 ELISA kit, the quantitative sandwich enzyme immunoassay technique (purchased from My Biosource, San Diego, California, USA).

Results: Serum concentration of S100A4 protein was significantly higher in UC (mean $158.6 \pm 56.2 \mu\text{g/L}$) compared to controls (mean $104.8 \pm 40.5 \mu\text{g/L}$), $p=0.019$ and in CD (mean $154.4 \pm 52.1 \mu\text{g/L}$) compared to controls, $p=0.007$. No difference in S100A4 was revealed between UC and CD, $p>0.05$. In CD group, serum concentration of S100A4 in each subgroup (divided according to behaviour of CD) was significantly higher compared to controls, $p<0.05$. No differences in S100A4 were documented between each CD phenotypes. Serum concentration of S100A4 was significantly higher in L2 (mean $144.6 \pm 44.2 \mu\text{g/L}$) compared to controls, $p=0.041$ and in L3 (mean $163.0 \pm 52.8 \mu\text{g/L}$) compared to controls, $p=0.002$. Serum concentration of S100A4 was significantly higher in L3 (mean $163.0 \pm 52.8 \mu\text{g/L}$) compared to L1 (mean $126.9 \pm 47.6 \mu\text{g/L}$), $p=0.017$. No difference in S100A4 was observed between patients with and without perianal involvement, $p>0.05$.

Conclusion: Association of serum S100A4 protein with UC and CD was confirmed. In CD, disease behaviour did not have impact on serum concentration of S100A4 protein. In CD, higher levels of serum S100A4 were observed in patients with ileo-colonic and colonic involvement compared to those with isolated small bowel involvement.

Introduction: Hypovitaminosis D is common in Inflammatory Bowel Disease (IBD) patients. Some studies suggest that the finding may be related to severity of the disease.^{1, 2}

Aims & Methods: The aim of the study was to determine the Vitamin D (VitD) status in an Italian IBD cohort in relation to disease activity. Serum 25-hydroxyvitamin D was measured in 260 IBD outpatients, not supplemented with VitD (110 Crohn's Disease (CD) and 150 Ulcerative Colitis (UC); 145 males and 115 females; mean age 50.7 ± 15 years), and compared to those of 205 healthy blood donors, matched by sex, age (+/-2 years) and month in which the blood sample was collected. VitD levels were correlated to C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), Harvey Bradshaw Index (HBI) and Crohn's Disease Activity Index (CDAI) for CD and Mayo partial score for UC. Chi square, T test and linear correlation were used when appropriate.

Results: IBD patients were at higher risk of VitD deficiency (defined as <20 ng/ml) than controls (OR 4.5, 95%CI 2.9–6.9, p < 0.0001). Of 260 IBD patients, 156 (60%) had VitD deficiency, more often in CD than in UC (72.7% vs 48% respectively, p < 0.0001). Age <40 and ≥60 years, winter/spring season, CRP ≥0.5 mg/dl, ESR ≥20 mm/h, previous intestinal surgery and HBI ≥5 were significant risk factors for VitD deficiency. No differences were observed in relation to sex, smoking status, BMI, age at diagnosis, localization and behavior of disease, and need of steroids. There was a weak negative correlation between CRP values, HBI scores and VitD levels (R = -0.13, p = 0.037 and R = -0.26, p = 0.006 respectively).

Conclusion: VitD deficiency is significantly more common in IBD patients than in controls, more so in CD. Patients with active disease are more likely to have VitD severe deficiency than those in remission. The correlation with activity indexes should be confirmed in larger series.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Small bowel (SB) Crohn's disease (CD) strictures can comprise of both inflammatory and fibrotic elements. An accurate tool to discriminate fibrosis and inflammation would be clinically useful to guide therapy and predict response. While the magnetic resonance index of activity (MaRIA) is a validated means to assess activity, to date, no specific tool has been developed to identify fibrotic from inflammatory disease. Lesions with a dense fibrotic matrix exhibit delayed gadolinium enhancement on MRI. The role of delayed enhancement in assessment of SB CD strictures is unclear. Recent evidence suggests relative contrast enhancement (REC) of >24% on delayed MRI sequences may accurately detect fibrosis.

Aims & Methods: To determine the feasibility of MRE SB stricture assessment with early (70s) and late (7mins) phase post gadolinium imaging comparing MaRIA, RCE and biochemical activity in patients with ileal CD. We performed a retrospective review of 208 consecutive MREs with known and suspected SBCD. MRE was performed as standard with additional coronal T1 sequences 7 minutes post gadolinium administration. Demographics, MRE findings and biochemical markers were recorded. Patients with stricturing disease were further assessed. Two independent blinded Radiologists calculated RCE and MaRIA's at 70 sec and 7 min.

Results: Median age 40.5 years; male n = 83(39.9%). 117, 72 and 19 patients had known CD, suspected CD and indeterminate IBD, respectively. In total, 119(57.2%) MREs were normal. Ileitis, strictures and fistulas were found in 40(19.2%), 49(23.6%) and 1(0.5%) patients, respectively. While there was no difference in Hb between patient groups (Normal, Inflammatory and Stricturing CD); Albumin and CRP were statistically different between normal subjects and those with disease; albumin 42 g/L v 38.9 g/L in normal v stricturing disease (p < 0.0181 95%CI -0.23—0.02). CRP 8.8 mg/L v 18.3 mg/L (p < 0.003 95%CI -0.46—0.10) and v 29 mg/L (p < 0.002 95% CI -0.43—0.11) amongst normal v inflammation and strictures respectively. Neither parameter could differentiate between inflammatory and stricturing disease. 26 MREs performed with ileal CD have been further assessed; median age = 41yrs, male = 10(38%). RCE > 24% and high T2 signal intensity (SI); 6/26 (23%) and 11/26 (42.3%). REC > 24% occurred in only 1/10 with a visible stenosis. Average MaRIAs: 2/26(7.7%) < 7 mild; 3/26 (11.5%) 7–11 moderate; 21/26 (80.7%) > 11 severe. MaRIAs did not change significantly between 70 sec and 7 min. As expected T2 SI increased with MaRIAs > 11, 26 v 13 (p < 0.001, 95% CI 7.73–17.27). RCE did not correlate with MaRIA group, suggesting MaRIA is not a predictive factor for fibrosis. Consistent with MRE findings, CRP was higher in patients with MaRIA > 11(13.3 v 5.2) and lower in patients with RCE > 24% (3.9 v 14), p < 0.04 95% CI 0.37–15.71 and p < 0.01 95% CI 2.5–19.05 respectively.

Conclusion: Unlike biochemical markers, MRE may be a useful means to differentiate between inflammatory and stricturing disease. Further study is required to assess the long-term predictive value. RCE may be a useful adjunct to current MRE and help detect fibrosis in small bowel lesions and warrants further investigation.

P0366 GASTRODUODENAL INVOLVEMENT IN PATIENTS WITH CROHN'S DISEASE – UPPER ENDOSCOPY ONLY IN SYMPTOMATIC PATIENTS?

M. Sousa, L. Proença, J. Silva, A. Ponte, J. Rodrigues, J. C. Silva, J. Carvalho
Gastroenterology, Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia/Portugal

Contact E-mail Address: mafalda_m_p_sousa@hotmail.com

Introduction: The need for upper endoscopy in patients with Crohn's disease (CD) without symptoms is controversial. The aim of this study was to establish the prevalence of gastroduodenal involvement, regardless of symptoms, and its prognostic implications.

Aims & Methods: Patients from a single centre with established CD (n = 347) were retrospectively evaluated – inclusion criteria: upper endoscopy without treatment. Gastroduodenal involvement was defined by considering macroscopic (erosions, ulcers or stenosis) and microscopic criteria (focal gastritis, cryptic irregularity, erosion/ulceration and granuloma in the absence of *Helicobacter pylori* (HP) infection).

Results: We included 140 patients - phenotype: 50% inflammatory, 31% stricturing and 19% penetrating; Location: 42% ileal, 45% ileocolic and 13% colic. Upper endoscopy was performed in 19% for symptoms and in 81% for staging. Gastric macroscopic findings were detected in 49% (69/140); the most common were erosions (21%) and erythematous mucosa (18%). Biopsies were performed in 56% of patients: chronic gastritis 66%, normal 23%, granuloma 5%, focal gastritis 2% and cryptic microabscess in 2%. HP was positive in 25% of patients. In the duodenum, endoscopic lesions were observed in 33% of the patients (46/140); the most common were erosions (16%) and ulcers (9%). Biopsies were performed in 32% and the most prevalent findings were chronic non-specific inflammation 62%, ulcers 17%, granuloma 3% and erosion 3%. Applying macro/microscopic criteria, gastroduodenal involvement by CD was considered in 18% of the patients and was not correlated with the presence of symptoms, phenotype or localization of the disease. The presence of gastroduodenal involvement was a significant predictor of hospitalization (p = 0.009).

Conclusion: The prevalence of gastroduodenal involvement by CD in this sample was 18%, and a larger percentage have macro/microscopic findings that are not disease specific. The presence of symptoms does not predict gastroduodenal involvement due to CD that is associated with a worse prognosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0367 INCIDENTAL FINDINGS AT CT ENTEROGRAPHY IN PATIENTS WITH CROHN'S DISEASE: CLINICAL SIGNIFICANCE AND IMPACT ON TARGETED THERAPY

R. Morais¹, S. Lopes², I. Pita², F. Magro¹, G. Macedo²

¹Gastroenterology, Centro Hospitalar São João, Porto/Portugal

²Centro Hospitalar São João, Porto Medical School, Porto/Portugal

Introduction: CT enterography is one of the most accurate imaging methods for evaluating Crohn's disease (CD) extent and intestinal involvement.

Aims & Methods: The aim of this study was to determine the frequency and clinical impact of the incidental findings in CD patients who underwent CT enterography.

This was a retrospective study that evaluated patients with CD who underwent CT enterography between January 2012 and December 2016. Incidental findings were defined as previously unknown extraintestinal lesions. The orientation of the patients after their detection was evaluated.

Results: A total of 520 patients who underwent CT enterography were identified, with incidental findings being reported in 276 (53%). The median age was 43 (32–53) years and 53% were women. The main indication for CT enterography was CD staging (81%). A total of 531 incidental findings were detected (median of 2 [1–3] per patient). The main findings identified were hepatic nodules (n = 59), hepatic cysts (n = 55) and sacroiliitis (n = 46). The findings implicated orientation to another medical specialty in 80 patients (29%), the main ones being Urology (n = 14) and Gynecology (n = 11). The findings implied additional exams in 59 patients (21%). Five (2%) underwent subsequent surgical intervention. Clinically relevant findings were found in 38 patients (14%), including 2 renal tumors, 2 ovarian teratomas and 3 cases of primary sclerosing cholangitis. The detection of incidental findings implied a change in CD therapy in 9 patients (3%): one suspended biologic therapy, 2 suspended immunomodulator therapy and 6 initiated biologic therapy.

Conclusion: Incidental findings are relatively common in patients with CD who undergo CT enterography. A significant proportion is clinically relevant and may involve change CD therapy. A risk stratification may be important to avoid morbidity associated with unnecessary examinations to assess benign situations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0368 CLINICAL SIGNIFICANCE OF ASYMPTOMATIC CLOSTRIDIUM DIFFICILE CARRIAGE IN PATIENTS ON IMMUNOMODULATOR FOR INFLAMMATORY BOWEL DISEASE

S.T. Law, W.M. Yip, K.K. Li

Department Of Medicine And Geriatrics, Tuen Mun Hospital, Hong Kong/Hong Kong Prc

Contact E-mail Address: stl168@hotmail.com

Introduction: Clinical significance of asymptomatic *Clostridium difficile* (*C. difficile*) carriage in patients on immunomodulator for inflammatory bowel disease (IBD) is largely unknown. [1, 2]

Aims & Methods: The aim of this study was to investigate the clinical implication of asymptomatic carriage of *C. difficile* in IBD patients.

Consecutive IBD patients on immunomodulators in clinical remission for the past six months were prospectively recruited from the IBD clinic since 2013.

Those cases were excluded if they had past history of total colectomy, the dosage of their immunomodulators were titrated according to their disease activity in the past six months or the types of their immunomodulators were other than azathioprine, mercaptopurine or methotrexate.

Stool specimen for *C. difficile* cytotoxin real-time polymerase chain reaction (RT-PCR) assay was obtained to all eligible patients at the time of enrollment and every follow-up during the study period. Patients were monitored for any IBD flare-up in which if happened, an additional stool specimen for *C. difficile* cytotoxin RT-PCR assay was obtained.

The primary outcomes were the disease activity which was graded by Crohn Disease Activity Index (CDAI) in Crohn disease (CD) (graded as follows: <150: remission; 150–<220: mild-moderate; 220–<450: moderate-severe; >450: severe/fulminant) and Ulcerative colitis Disease Activity Index (UCDAI) in ulcerative colitis (UC) (graded as follows: the total index score ranges from 0–12; 0–2: remission; 3–6: mild; 7–10: moderate; >10: severe UC). The secondary outcome was proportion with *C. difficile* diarrhea which was defined in the patients with active lower gastrointestinal symptoms accompanying with positive RT-PCR assay of *C. difficile* at that instant.

Statistical inference of the variables was examined by Mann-Whitney U and χ^2 test for numerical and categorical parameters respectively

Results: Of 197 IBD patients (CD: 98 (49.75%); male: 132(67.01%); age (yrs): median 43, minimum 17, maximum 79), 9(4.57%); CD: 6 patients) patients were found to be asymptomatic carriage of *C. difficile* during the study period. The demographic features, including age, gender ratio, smoking history and the duration of IBD, of the patient group with and without asymptomatic carriage of *C. difficile* were comparable each other. Four UC patients in the non-carriage group had prior history of anti-TNF exposure in which three were treated as maintenance therapy for the active disease activity, associated axial spondyloarthritis and rectovaginal fistula while the other two patients (one from each group) had received three doses of anti-TNF as rescue therapy for severe disease flare-up.

Incidence rates of the disease flare-up were comparable (11.17 vs. 22.22%, $p = 0.313$) between the non-carriage and carriage groups in which all these flares were under-controlled by course of high-dose prednisolone.

The asymptomatic carriage group had a significant higher rate (33.33 vs. 7.45%, $p = 0.007$) and earlier onset (18.78 vs. 34.42 months, log rank $p = 0.009$; Mann-Whitney U, $p = 0.037$) in evolving into clinical *C. difficile* infection as compared with the non-carriage group.

No other serious complications, such as toxic megacolon, colonic perforation, sepsis, and death, were reported in the both groups during the study period.

Clinical characteristics of the IBD patients with and without asymptomatic carriage of *C. difficile*

	Non <i>C. difficile</i> carrier (n = 188)	<i>C. difficile</i> carrier (n = 9)	P value
Age (Yr)	43(26)	44(33)	0.788
Sex (m:f)	128:60	4:5	0.159
Smoker (n, %)	24(12.77)	1(11.11)	0.881
Year of Diagnosis (Yr)	7(9)	7(13)	0.940
Crohn disease (n, %)	92(48.94)	6(66.67)	0.298
Prior exposure of Anti-TNF (n, %)	4*(2.13)	1** (11.11)	0.095
Flare up (n, %)	21(11.17)	2(22.22)	0.313
mild/moderate/severe	16/5/0	2/0/0	0.165/0.617/ns
<i>C. difficile</i> infection (n, %)	14(7.45)	3(33.33)	0.007

Data were expressed as median(interquartile range)

*: all are UC cases and 3 for maintenance therapy with indications as follows: refractory control, spondyloarthritis, rectovaginal fistula

**: case of UC received 3 doses of anti-TNF for severe flare

Abbreviation: IBD, inflammatory bowel disease; *C. difficile*, *Clostridium difficile*; ulcerative colitis, UC; ns, non-significant

Conclusion: The incidence of asymptomatic carriage of *C. difficile* in the IBD patients on immunomodulators was not common. It did not associate with the disease flare-up but a significant portion of them could evolve subsequently into clinical infection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Due to the relapsing and highly variable nature of ulcerative colitis (UC), it would be desirable to have reliable tools for measuring parameters of disease activity in order to monitor response to therapy and to detect relapse. In Crohn's disease it has already been shown that ultrasound (US) is a useful to monitor the disease activity.¹ The hypothesis of the TRUST&UC (TRansabdominal UltraSonography of the bowel To monitor disease activity in subjects with Ulcerative Colitis) study is that transabdominal US is an easy to use, easily repeatable, and accurate diagnostic tool in the assessment of UC activity, in monitoring the disease course, and response to therapy.

Aims & Methods: TRUST&UC is a German ongoing prospective, observational multi-center study in patients with active UC. The primary objective of this study is the prospective evaluation of bowel wall US in response to therapy in order to assess its value in monitoring UC patients in routine medical practice. Clinical parameters (e.g. CRP, fecal calprotectin) and the Simple Colitis Clinical Activity Index (SCCAI) were used for routine assessment of disease activity.

Results: 176 patients with active UC have been enrolled in 37 German IBD study group (GISG) centres until February 2017. 47.2% of the patients were female, median age was 38.9 years (range 19–77) with median disease duration of 152.2 days (range -8–1017). Of all the patients with a clinical flare defined by SCCAI 90.3% showed a bowel wall thickening (BWT), and only 9.7% showed no US signals. At US examination, a BWT in the colon sigmoideum was present in 87.5% of the patients, in the colon descendens in 83.7%, in the colon transversum in 42.3% and in the colon ascendens in 18.3%. Loss of bowel wall

stratification was the case in 20.6% of the patients, mesenteric fibro-fatty proliferation in 40.0% and more than 50% had an increased signal in the color Doppler US. At baseline systemic steroids were used in 62.1%, azathioprine in 36.2%, and TNF antagonists in 40.0% of patients (N=174). All follow-up patients (N=104) displayed acute inflammatory symptoms at baseline, with at least moderate disease activity which required an introduction or escalation of treatment. After 12 weeks, the US examination showed significant improvements of the following parameters: BWT in colon sigmoideum (87.5% vs 33.7%, $p=0.034$) and colon transversum (42.3% vs 15.4%, $p=0.012$), loss of haustration (54.8% vs 33.7%, $p<0.001$), ascites (9.7% vs 2.9%, $p<0.001$), mesenteric lymphadenopathy (31.6% vs 14.3%, $p=0.005$), mesenteric fibro-fatty proliferation (40.0% vs 10.0%, $p=0.041$) and increased signal in color Doppler US (56.7% vs 23.1%, $p=0.039$). A decrease of BWT was significantly accompanied by a decrease in SCCAI (8.0 to 1.5 points, $p<0.001$). **Conclusion:** In this real-life cohort almost 90% of the patients showed a BWT, a pivotal IBD symptom and within 12 weeks selected bowel US parameters improved significantly from treatment intensification. Therefore, US examination is a useful tool to monitor disease activity and response to therapy in UC patients.

Introduction: Blocking TNF α is an important treatment option for inflammatory bowel disease (IBD). The etiology of the disorder comprises a permanent activation of immune cascades and imbalanced cytokine networks. Evidence has been put forward that alteration of the human gut microbiome may play a critical role in the pathogenesis of IBD. However, the impact of targeted cytokine blockade on dysbiosis of intestinal microbial communities is poorly understood. Here, we investigate the effect of anti-TNF α treatment on gut microbial community structures in a prospective, longitudinal study for 30 weeks. The study compares IBD as a disorder, which primarily affects the gut, with seropositive and -negative rheumatoid arthritis and ankylosing spondylitis as a rheumatic disorder (RD) as an inflammatory disease complex, which usually does not affect the intestine.

Aims & Methods: anti-TNF α naive patients suffering from IBD (n=12) or RD (n=17), subject to first-time anti-TNF α therapy were recruited for longitudinal stool sampling at baseline and 2, 6 and 30 weeks after therapy induction. Intestinal microbiota communities were studied by 16S rRNA gene (V4) sequencing. Changes in microbiota before and after therapeutic interventions were assessed in terms of alpha and beta diversity, indicator species and prediction of metabolic cooperative interactions. Samples from healthy controls (n=19) were included as a benchmark of healthy microbial profiles.

Results: Intestinal microbial diversity and cooperativity are decreased in both disease entities, IBD and RA. In IBD, anti-TNF α therapy is able to restore microbial diversity and cooperativity. More over cooperative metabolic interaction is significantly increased only in anti-TNF α responders. In RA, anti-TNF α therapy did not significantly restore microbial community structures.

Conclusion: We show that anti-TNF α treatment increases the gut microbial diversity and coupling of cross feeding metabolic interactions towards the state of healthy individuals. Assessment of metabolic interactions of intestinal microbiota may serve as a marker for clinical response in IBD patients.

P0371 SELF-MONITORING OF THE COLONIC INFLAMMATORY BOWEL DISEASE BY A RAPID HOME BASED FEACAL CALPROTECTIN TEST AND A SYMPTOM QUESTIONNAIRE

A. Puolanne¹, M.A. A. Färkkilä¹, K. Kolho²

¹Clinic Of Gastroenterology, Helsinki University Hospital, Helsinki/Finland

²Pediatric Gastroenterology, University of Helsinki Childrens Hospital, Helsinki/Finland

Contact E-mail Address: anna-maija.puolanne@hus.fi

Introduction: Faecal calprotectin (FC) is a most reliable noninvasive means to distinguish remission from active inflammation in inflammatory bowel disease (IBD). Commercially available FC tests are time-consuming, and consequently new rapid tests have been validated. As the incidence of IBD is increasing, self-monitoring and eHealth technologies have been evaluated in managing patients with this life-long disease.

Aims & Methods: The aim of this prospective study was to evaluate the feasibility and cost-effectiveness of a semi-quantitative rapid FC home test and a validated symptom questionnaire, in patients with colonic IBD. The influence of the self-monitoring to the course of the disease will also be evaluated. Between April 2015 and December 2016, 180 patients with colonic IBD (126 with UC, 47 with CD, and 7 with IBD unclassified) were included in the study and randomized in a study group and control group. Patients in the study group were instructed to perform the FC home test and fill in a symptom questionnaire every other month and with increasing of the symptoms, and sent the results to the study/IBD nurse by e-mail. The control group patients filled in the symptom questionnaire at baseline and at 12 months and with the appointment to the outpatient clinic according to normal practice. The patients were not reminded of performing the stool tests or filling in the questionnaires. The study period was 12 months, and it is still ongoing.

Results: By the end of February 2017, 134 of the 180 included patients had completed the 12 months' follow-up. In the study group, 20/91 (22%) patients had performed the stool tests and filled in the symptom scores according to the study protocol for 6 months, and 14/91(15%) patients for 12 months. In the control group, 14/89 (16%) patients had filled in the symptom score at baseline and at 12kk. There was no significant difference of the adherence between patients stratified for IBD-diagnosis, age, or sex. The satisfaction of the patients with the program as well as the reasons for the discontinuation of the study and influence of self-monitoring in the number of relapses, phone calls, e-mails, and appointments to the outpatient clinic in both groups will be evaluated.

Conclusion: The self-monitoring of IBD activity with a rapid FC home test provides an option for individualized treatment for increasing amount of IBD patients. However, in this study the adherence to the self-monitoring program was low. The patients need to be reminded of performing the stool tests and filling in the questionnaires in time. Also, the selection and education of the patients, as well as the easy accessibility of the monitoring program are crucial and need further consideration.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Although the incidence of ulcerative colitis (UC)-related colorectal cancer (CAC) is increased in cases with long duration of disease, it should also be recognized that sporadic tumors (ST) develop as older. Various studies have been conducted on CAC, but there are few clinical studies on ST merged with UC. In

this study, the clinical and endoscopic features of CAC and ST, treatment method, and prognosis are compared.

Aims & Methods: Among 261 UC patients who underwent colonoscopy (CS) and had neoplastic lesions, the clinical features, treatment and prognosis were compared between 71 patients (88 lesions) with CAC (including HGD; CAC group) and 47 patients (63 lesions) who underwent local excision (surgical or endoscopic resection) within the presence of the past/present inflammation of UC (ST group). Definition of CAC and ST was performed by conventional pathological and immunohistochemical findings.

Results: The age of UC onset (29.8 vs. 39.0) and tumor detection (45.5 vs. 57.3) in the CAC group were significantly higher than those in ST group ($p < 0.01$). The CAC group (47.1%) has a higher percentage of chronic persistent type than the ST group (2.3%), and the Mayo endoscopic score is also significantly higher ($p < 0.01$) in the CAC group (1.43) than ST group (0.38). The percentage of advanced cancer (35.2% vs. 7.9%) was higher in CAC group than ST group. In patients with intraepithelial neoplasia (IEN) or submucosal lesions, flat lesion was found in 15 lesions of CAC group and whereas no flat lesion was observed in ST group. Only one lesion in ST group could not distinguish the lesions from the surrounding mucosa without magnifying colonoscopy. In ST group who received resections, 4 patients after resections observed ectopic CAC or low-grade dysplasia during follow-up. In CAC group, 50, 5, 4 patients received total colectomy, local colectomy, ESD, respectively, whereas in ST group, 1, 7, 40, 15 patients received total colectomy, local colectomy, EMR and polypectomy, ESD, respectively. Although mortality from cancer was 11.4% (8/70 cases) in CAC group, group, no death due to cancer observed in patients whose lesions were found as IEN. On the other hand mortality from cancer was 2.1% (1/47 cases) in ST group.

Conclusion: Most sporadic lesions were endoscopically distinct and local resection was safe if inflammation was controlled. After the sporadic lesions were resected in remitting UC patients, regular surveillance colonoscopy is necessary because 8.5% (4/47) of patients was found CAC/dysplasia. Even in CAC group, prognosis is well in patients with IEN.

P0373 CAN WE PREDICT THE LACK OF RESPONSE TO CYCLOSPORINE AS SECOND LINE THERAPY IN PATIENTS WITH ACUTE SEVERE COLITIS REFRACTORY TO CORTICOSTEROIDS?

H. Aya, B.S. Aida, H. Bassem, J. Hanen, E. Nour, B.M. Imed, A. Salem, B. Ahlem, K. Mehdi, J. Ali

Gastroenterology, University Hospital Sahloul, Sousse/Tunisia

Introduction: Acute severe colitis (ASC) is a dangerous clinical condition that requires intensive intravenous (iv) corticosteroids treatment. Nevertheless, about 30–40% of patients fail to response. Intravenous cyclosporine is an effective rescue therapy in steroid-refractory patients.

Aims & Methods: The aim of our study was to identify the clinical and biological predictive factors of lack of response to cyclosporine as second-line therapy in patients with ASC refractory to IV corticosteroids.

Results: Our study included 52 females and 38 males, with a mean age of 35 years [14–70 years]. There were 34 patients with Crohn's disease and 56 diagnosed with ulcerative colitis. Among the 90 patients enrolled, 68 patients (75.5%) had a good response to cyclosporine. Eleven patients were non responders and underwent colectomy. In univariate analysis, more than 6 bloody stools per day before initiation of cyclosporine therapy, a C-Reactive Protein (CRP) greater than 45 mg/l prior to treatment, and at day 3 and 7 of treatment by cyclosporine ($p = 0.007$; 0.002 and 0.001 respectively), ESR greater than 30 mm at day 3 of treatment ($p = 0.05$), thrombocytosis at day 3 of treatment ($p = 0.05$), a Lichtiger colitis activity index scoring greater than 10 at day 3 of treatment ($p = 0.001$) and the need for blood transfusion ($p < 0.0001$) were significantly correlated with the lack of response to cyclosporine therapy. In a multiple linear regression analysis, only a CRP greater than 45 mg/l on day 7 of treatment, and the necessity of transfusion were predictive factors of no-response to cyclosporine ($p = 0.008$).

Conclusion: Cyclosporine therapy is rapidly effective in preventing surgery in patients with ASC with a response rate of 75.5%. A high CRP on day 7 of treatment with cyclosporine and the need for transfusion, predispose to poor response to intravenous cyclosporine.

Contact E-mail Address: zsuzsa.kurti@gmail.com

Introduction: Accelerated treatment strategy, including tight disease control and early aggressive therapy with immunomodulators (IM) and biological agents have become increasingly common in IBD.

Aims & Methods: The aim of the present study was to estimate the early treatment strategy and outcomes in newly diagnosed patients with Crohn's disease (CD) diagnosed between 2004–2015 in Hungary based on the administrative database of the National Health Insurance Fund (OEP). We used the administrative database of the National Health Insurance Fund (OEP), the only nationwide state-owned health insurance provider in Hungary. Newly diagnosed CD patients were identified through previously reported algorithms using the ICD-10 codes for Crohn's disease in the out-, inpatient (medical, surgical) non-primary care records and drug prescription databases between 2004–2015. Patients were stratified according to the year of diagnosis and maximum treatment step during the first 3-years after the diagnosis.

Results: A total of 6173 (male/female: 46.12%/53.87%) newly diagnosed CD patients were identified during the observational period. Maximum treatment steps did not differ in patients diagnosed before and after 2009 (5-ASA: 11.7% vs. 13.5%, steroid 31% vs. 30.5%, IM 40.4% vs. 40.2%, biologicals 16.5% vs. 15.6%). Probability of hospitalizations during the first 3-years from diagnosis was lower according to the maximal treatment step in patients diagnosed after 2009 (at 36 × 30-day period: overall 55.7% vs. 47.4% ($p = 0.000$), anti-TNF: 73% vs. 66.7% ($p = 0.103$), IS: 64.6% vs. 56.1% ($p = 0.000$), steroid: 44.2% vs. 36.8% ($p < 0.007$), 5-ASA: 32.6% vs. 26.7% ($p = 0.157$)), respectively. In contrast, surgery rates were not different according to the maximum treatment step (at 36 × 30-day period: overall 16.0% vs. 15.3% ($p = 0.672$) anti-TNF 26.7% vs. 27.2% ($p = 0.993$), IS: 24.1% vs. 22.2% ($p = 0.565$), steroid 8.1% vs. 7.9% ($p = 0.896$), 5-ASA 10% vs. 11% ($p = 0.816$)).

Conclusion: Distribution of maximal treatment steps and surgery rates was not different in patients diagnosed before and after 2009, although immunosuppressive and was commenced earlier. Of note, steroid and 5-ASA remained high after 2009. Maximal treatment steps were associated to hospitalization and surgery rates, suggesting that maximal treatment steps can be used as proxy marker of severity in CD. Hospitalization rates during the first 3-years after the diagnosis decreased in all treatment groups, suggesting a change in the patient management.

Introduction: Numerous studies have shown that mesenchymal stromal cells (MSCs) have a high potential for differentiation and immunosuppressive properties. Currently under phase I-III clinical trials evaluating the efficacy and safety of MSCs in the treatment of patients with inflammatory bowel disease - ulcerative colitis and Crohn's disease.

Aims & Methods: We aimed to compare the frequency of relapses and duration of remission for 5 years of follow up in patients with luminal Crohn's disease (CD) and the total defeat of ulcerative colitis (UC) receiving therapy with mesenchymal stromal cells (MSCs), bone marrow. We compared the frequency of relapses in patients with luminal form CD (colitis and ileocolitis), with a group of patients with UC (total lesion) receiving MSCs. A group of patients (CD) aged 22 to 56 years (Me-28) ($n = 24$) received MSC culture scheme (0-1-2 weeks, then every 26 weeks). The second group of patients with UC ($n = 26$) aged 20 to 62 years (Me-28) received the culture of MSCs in a similar way. Evaluation of the effectiveness of therapy for relapse frequency was carried out at 12, 24, 36, 48 and 60 months after initiation of therapy.

Results: Among the patients in 1st group relapse in the 12 months of observation occurred in 2/24 patients (8.3%) in 2nd group, relapse occurred in 3/26 (11.5%) (OR-0.72; 95% CI 0, 13–3, 96, $p = 0.92$). After 24 months in the group of patients (group 1) receiving MSC, relapse occurred in 5/24 (20.8%) in group 2 patients with recurrent disease in 7/26 (26.9%) (OR -0.77; 95% CI 0.13–3.96, $p = 0.92$). After 36 months in group 1 patients with a relapse of the disease in 8/24 (33.3%) in group 2 relapsed in 14/26 (53.8%) (OR-0.62; 95% CI 0.32–1.21; $p = 0.24$). After 48 months in group 1 receiving MSC, relapsed in 11/24 (45.8%) in group 2 relapsed in 18/26 (69.2%) (OR-0.6; 95% CI 0.37–0.97, $p = 0.048$). After 60 months in 1st relapse in 16/24 (66.6%) in group 2 relapsed in 22/26 (84.6%) (OR-0.63; 95% CI 0.44–0.90, $p = 0.013$).

Conclusion: MSCs transplantation longer contributes to clinical remission in patients with Crohn's disease luminal shape compared to a group of patients suffering from ulcerative colitis.

Introduction: Perianal fistulas are the most widespread and common types of fistulas in Crohn's disease (CD). They are difficult to treat, worsen the quality of life of the patient and increase the risk of bowel resection. Despite the significant effect of anti-cytokine therapy fistulous forms of CD, treatment of these patients remains a difficult task with high risk of relapse of CD. Mesenchymal stromal cells have immunomodulatory properties and a large regenerative potential, at present also used for treatment of fistulous CD and perianal fistulas of different etiologies.

Aims & Methods: We aimed compare the efficacy of combined therapy (local and systemic) mesenchymal stromal cells (MSCs) of bone marrow, infliximab (IFX) and antibiotics/immunosuppression (IS) on the rate of healing of simple perianal fistulas in Crohn's disease. 36 patients with Crohn's disease with perianal lesions were divided into three groups depending on the method of therapy. The first group of patients aged from 19 to 58 years (Me-29) (n=12) received culture of MSCs systemically via the scheme and locally: on the perimeter of the fistulous introduced 40 million MSCs - 4 point of inject and 1 ml of saline containing 10 million MSCs. Then after 4 and 8 weeks re-injected 40 million MSCs in the area of the fistula. The second group of patients with CD (n=10) aged 20 to 68 years (Me-36) were receiving anti-cytokine therapy of IFX. The 3-rd group of patients with CD (n=14) aged 20 to 62 years (Me-28) received antibiotics and is. In the dynamics evaluated the closure of the external opening of the fistula. Ano- and rectosigmoidoscopy carried out after 3, 6, 12 and 36 months from start of therapy. **Results:** After 12 weeks among patients of the 1st group simple healing of fistulas was observed in 10/12 patients (83.3%), in the 2nd group healing simple fistulas have a 8/10 (80.0%) (OR-0.83; 95% CI 0.14-4.9; p=0.72). In the 3rd group - in 5/14 patients (35.7%) (OR 0.26; 95% CI 0.07-0.97; p=0.04 in comparison with the 1st group). After 6 months in the 1st group of patients receiving MSCs, healing of simple fistulas persisted in 8/12 (66.6%) with the 2nd group - 7/10 (70.0%) (OR - 1.11; 95% CI 0.32-3.84; p=0.76). In the 3rd group - patients 4/14 (28.6%) (OR - 0.47; 95% CI 0.2-1.11; p=0.12 in comparison with the 1st group). After 12 months in the 1st group receiving MSCs, healing of simple fistulas persisted in 7/12 (58.3%), in the 2nd group - in 6/10 (60.0%) (OR - 1.25, 95% CI 0.48-3.22; p=0.69). In the 3rd group - in 2/14 patients (14.3%) (OR-0.49; 95% CI 0.24 to about 0.98; p=0.03 in comparison with the 1st group). After 36 months among the patients of the 1st group, the closure of the fistula was preserved in 5/12 patients (41.6%), in the 2nd group - 5/10 (50.0%) (OR - 1.17; 95% CI 0.53-2.55; p=0.96). In the 3rd group - in 0/14 patients (0.0%) of (OR - 0.58; 95% CI 0.36-0.94; p=0.01 in comparison with the 1st group). **Conclusion:** Combined stem cell and anti-cytokine therapy of CD with perianal lesions significantly contributes to more frequent and prolonged closure of simple fistula, compared with antibiotics/immunosuppressant.

Introduction: Mesenchymal stromal cells (MSC) are used for the treatment of chronic inflammatory and autoimmune diseases in recent years, including rheumatoid arthritis (RA) and inflammatory bowel disease (IBD). In most cases, together with the MSC, patients receiving concomitant immunosuppressive therapy. It is found that immunomodulatory drugs (azathioprine (AZA), methotrexate, 6-mercaptopurine, infliximab (IPF)), regardless of the concentration, do not affect the viability, differentiation, phenotype, and ability to inhibit proliferation of MSCs peripheral blood mononuclear cells [1]. However, studies conducted by Huang HR et al. demonstrate that IPF rendered minimal impact on the MSC proliferation, apoptosis and cell cycle, while, azathioprine inhibited cell proliferation and induced apoptosis of MSCs in vitro [2].

Aims & Methods: We aimed to evaluate the effectiveness of therapy mesenchymal stromal cells (MSCs) from the bone marrow of patients with Crohn's disease (CD) receiving azathioprine. 34 patients with inflammatory (luminal) form CD were divided into two groups. The first group of patients aged 19 to 58 years old (Me-29) (n=15) was treated with anti-inflammatory therapy with MSCs culture in combination with AZA. The second group of patients with CD (n=19) aged 23 to 60 years old (Me-31) received MSCs according to the recommended scheme without AZA. To assess the effectiveness of anti-inflammatory therapy was determined by the dynamics of the level of pro-inflammatory interleukins (IL) - TNF- α , IFN- γ and IL-1 β at 2, 6 and 12 months from the start of MSC therapy. Initial level of IFN- γ in the 1st group was 110.4 \pm 12.5 pg/ml, in the 2nd - 450.8 \pm 22.4 pg/ml (p<0.05), TNF- α in 1st group - 13.9 \pm 1.9 pg/ml, in the 2nd - 66.7 \pm 14.2 pg/ml (p<0.05), IL-1 β in 1st group - 5.7 \pm 0.28 pg/ml, in the 2nd - 9.2 \pm 0.2 pg/ml (p<0.05).

Results: After 2 months of therapy MSCs level of IFN- γ in 1st group was significantly decreased from baseline and was 86.5 \pm 9.1 pg/ml, the 2nd was 96.9 \pm 12.1 pg/ml (between groups p=0.5), TNF- α in 1st group decreased to 39.6 \pm 8.4 pg/ml, in the 2nd - 56.5 \pm 10.7 pg/ml (between groups p=0.2), IL-1 β in 1st group - 50.7 \pm 9.3 pg/ml, in the 2nd - 56.2 \pm 10.2 pg/ml (between groups p=0.7). After 6 months of therapy MSCs level of IFN- γ in 1st group decreased

and amounted to 79.4 \pm 8.5 pg/ml, in the 2nd - 80.8 \pm 7.3 pg/ml (between groups p=0.9), TNF- α in 1st group decreased to 44.9 \pm 6.3 pg/ml, in the 2nd - 49.7 \pm 10.4 pg/ml (between groups p=0.7). IL-1 β in 1st group - 45.6 \pm 7.3 pg/ml, in the 2nd - 54.2 \pm 9.2 pg/ml (between groups p=0.45). After 12 months of initiation of therapy MSCs level of IFN- γ in 1st group decreased and amounted to 90.8 \pm 6.5 pg/ml, in the 2nd - 128.8 \pm 12.3 pg/ml (between groups p=0.02), TNF- α in the 1st group - 78.9 \pm 10.5 pg/ml, in the 2nd - 116.9 \pm 13.2 pg/ml (between groups p=0.04), IL-1 β in 1st group - 68.7 \pm 8.9 pg/ml, in the 2nd - 96.9 \pm 9.6 pg/ml (between groups p=0.03)

Conclusion: After one year of observation concomitant treatment with AZA when administered MSCs significantly reduces the level of pro-inflammatory cytokines, which could have a more pronounced anti-inflammatory therapeutic effect.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0378 EFFICACY AND SAFETY OF RECTAL 5-AMINOSALICYLIC ACID VERSUS CORTICOSTEROIDS IN ACTIVE DISTAL ULCERATIVE COLITIS: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

X. Zhao, H. Zhang

Department Of Gastroenterology, Jiangsu Province Hospital and Nanjing Medical University, Nanjing/China

Contact E-mail Address: zhaoxj91718@163.com

Introduction: Ulcerative colitis (UC) is characterized by diffuse and continuous inflammation of the colon. Currently, the etiology and pathogenesis remain unclear. According to a previous epidemiological study, approximately 75% of newly diagnosed UC patients have active distal UC. Topical 5-aminosalicylic acid (5-ASA) and corticosteroids are used frequently in the treatment of active distal UC.

Aims & Methods: Our study aimed to determine the efficacy and safety of different topical drugs used to treat active distal UC. A random-effects model within a Bayesian framework was utilized to compare treatment effects and safety as odds ratios (ORs) with corresponding 95% credible intervals (CrI). The surface under the cumulative ranking area (SUCRA) and median rank (MR) with corresponding 95% CrI were calculated to rank the treatment outcomes.

Results: In the induction of clinical and endoscopic remission, most regimens showed significant advantages over placebo except topical budesonide 0.5 mg/d and hydrocortisone 100 mg/d. According to SUCRA and MR values, rectal 5-ASA 1.5 to 2.0 g/d + Beclomethasone dipropionate (BDP) 3 mg/d rendered the highest probability of being the best regimen to achieve clinical and endoscopic remission, followed by the separate use of 5-ASA 4 g/d and BDP 3 mg/d. The occurrence of adverse events was not significantly different between each treatments and placebo.

Conclusion: In conclusion, the combined use of topical 5-ASA and BDP proved to be the best choice for active distal UC and further well-designed researchers are warranted to assess its efficacy and safety.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The oral delivery of therapeutic concentrations of anti-TNF to affected mucosa of patients with inflammatory bowel disease (IBD) has remained challenging despite advances in protein engineering, the attractions of oral dosing for chronic therapies, and the acknowledged benefit of anti-TNF monoclonal antibodies in the management of IBD. As the ileum is commonly involved in Crohn's disease (CD), it is important to deliver drug there if treatment is to be effective. This is the first report of a domain antibody to TNF, V565, engineered to be resistant to intestinal proteases, delivering high concentrations of active compound in the ileal fluid following oral administration to human volunteers. The oral domain antibodies (Vorabodies) are delivered via enteric coated mini-tablets (MTs) designed to release active drug at pH 6.5.

Aims & Methods: Following prior placebo-controlled demonstration of the safety and tolerability of high single and multiple doses of V565, this open label assessment was performed to confirm the delivery of active domain antibody to the terminal ileum of human subjects. Four subjects with a terminal ileostomy were given a single oral dose of V565 and ileostomy bags were collected hourly for the first 12 hours post dose with further collections 16, 20 and 24 h post dose. Contents were analysed for V565 concentrations by competitive ELISA. In addition serial blood samples were taken for determination of V565 serum concentrations over 24 h.

Results: Four subjects with an ileostomy (3 with UC; 1 with a prior history of colonic obstruction) were given a single 1665 mg dose of V565. The dose was selected based on the prior demonstration of safety and tolerability of this dose and the likely maximum daily dose for initial clinical efficacy assessment. High concentrations of active V565 were demonstrated in the ileal fluid of all four subjects as shown in Table 1 below.

Subject	Micromolar concentration of V565 in ileal fluid							
	Hours post-dose							
	1	2	3	4	5	6	7-16	17-24
31001	–	406	306	0.8	0	0	0	0
31002	–	33	1130	792	82	13	5(ave)	0
31003	–	–	1060	496	7	0	38(ave)	0
31004	–	126	0.2	11	4	7	0	0

In addition to the V565 concentrations in ileal fluid, partially dissolved MTs were recovered from the ileostomy bags of all subjects. Each 1665 mg dose contained a total of 135 MTs. 50 MTs were recovered 2 h post dose from Subject 31001; these were not analysed for V565 as this was a post hoc analysis and the MTs were not stored in a way to enable reliable analysis. 64MTs (containing 135 mg V565) were recovered 3 h post dose from subject 31002; 78MTs (458 mg) 3 h post dose from subject 31003; and 125MTs (1260 mg) 2 h post dose from subject 31004. Overall, 66–82% of an administered dose was recovered from ileostomy bags when MT quantities were added to ileal fluid concentrations. V565 was not detected in any serum sample (LLOQ 62.5 ng/ml).

Conclusion: V565, an oral domain antibody (Vorabody) to TNF engineered to be resistant to intestinal proteases, resulted in high concentrations of active drug in ileal fluid and was not detected in serum following oral administration. In patients with no ileostomy the partially dissolved MTs seen in this study are expected to provide active V565 to lesions distal to the ileum. This profile may be beneficial for IBD and merits further investigation as a potential oral treatment.

Contact E-mail Address: dobrolyubova.ekaterina@rambler.ru

Introduction: In recent years publications of different countries paid great attention to the symptoms, that specific for the functional bowel disease in patients with UC in remission. Our aim was to determine the incidence of IBS – like disorders in UC, especially their clinical manifestations and medical therapy.

Aims & Methods: The study included 162 patients with UC a year after the last attack of the disease, that were on maintenance therapy with 5-ASA dosage of 2 gram per day for the last 12 months. Study group was dominated by women - 94 patients (58%), average the age of the subjects was 38 ± 3 years. Localization of the UC in 83% of cases revealed left-sided and 17% - subtotal lesion of the colon. All patients underwent a standard examination of the definition of the level of C-reactive protein (CRP), and faecal calprotectin (FCP), and exclude the acute intestinal clostridial infection, faecal microbiota was determined. The clinical activity of the general condition of the patient and endoscopic subscale were evaluated using the Mayo score. Quality of life of patients was calculated on a Gastrointestinal Symptom Rating Scale (GSRS), where the minimum score was 15 and the maximum 105. Evaluation of the severity of IBS symptoms was calculated using a visual - analogue scale (VAS), where 0 was the absence of clinical manifestations IBS, and 10 - the maximum clinical manifestations.

Results: Of the 162 explored patients in 122 cases (77.8%) clinical and endoscopic remission in UC was determined: a total Mayo score ≤ 2, physician's global assessment = 0, rectal bleeding = 0, endoscopic subscale = 0, the normal structure of the colon mucosa by histological study of biopsies, CRP < 5, FCP ≤ 50 mg/g, the amount of points on the scale GSRS = 15, VAS = 0. In 36 (22.2%) patients intestinal symptoms were determined: mushy stools 2–4 times per day at daytime, bloating and rumbling in the abdomen. In the clinical picture of 5 patients of these group (3.1%) there dominated loose stools 3–4 times a day, sometimes streaked with blood. The examination revealed the exacerbation of UC, left-sided lesion, moderate activity (a total Mayo score = 5, physician's global assessment = 1, rectal bleeding = 1, endoscopic subscale = 2, intense lymphoplasmacytic infiltration on histological studies of colon mucosa biopsies, CRP = 11 ± 0.9 mg/l, FCP = 250 ± 40 mg/g, quality of life GSRS lowered to 35 ± 5 points. For these patients the dose of mesalazine was increased to 3 g per day and rectal forms of mesalazine were added. In 31 (19.1%) patients in the clinical picture pain syndrome was dominated (daily abdominal pain, worse before stool, severity of pain according to VAS = 7 ± 1 points), abdominal distension (VAS = 6 ± 1 points), rumbling, frequency stool reached 2–4 times per day, sometimes with mucus, but without blood. The examination confirmed the remission of UC (total Mayo score ≤ 2, physician's global assessment = 0, rectal bleeding = 0, endoscopic subscale = 0, the minimum colitis histological study biopsies of colon mucosa, CRP = 2.5 ± 2.5 mg/l, FCP = 125.0 ± 25.0 mg/g, the level of quality of life was reduced by GSRS to 75 ± 5 points. In this group of patients showed changes in faecal microbiota: reducing the number of bifidobacteria < 107 CFU (colony-forming unit) and lactobacilli < 105 CFU per 1 g. of feces, the growth performance of opportunistic microbiota: Klebsiella > 104 CFU per 1 g. of feces, Proteus > 104 CFU per 1 g. of feces, Citrobacter > 104 CFU per 1 g. of feces, Cocciosis microflora, Escherichia coli hemolitica > 0 CFU per 1 g. of feces. Attempt to increase the dosage of 5-ASA and accession to treatment the rectal forms of mesalazine in this group of patients have not led to the disappearance of the existing symptoms. This group of patients was appointed by pathogenetic therapy of functional bowel disease: myotropic antispasmodics (mebeverin 405 mg/day), a course of rifaximin (1650 mg/day) and combination probiotics on the background maintenance therapy mesalazine 2 g/day. As a result of therapy regression of IBS - like symptoms was reached: severity of pain according to VAS = 0, bloating VAS = 0, stool frequency was 1 time per day without mucus, improved quality of life by GSRS to 15 points.

Conclusion: In 19.1% of the studied patients with UC in remission IBS-like disorders was found. In the clinical picture pain syndrome, bloating, rumbling, moderate diarrhea syndrome with mucus, a sharp decline in quality of life level GSRS were determined. The development of clinical manifestations of IBS in the target group of patients with UC is associated with persistent changes in faecal microbiota. Remission of UC with IBS-like disorders reached by the appointment of pathogenetic therapy of functional bowel disease on the background of mesalazine maintenance therapy.

Introduction: Fatigue is a common symptom in inflammatory bowel disease (IBD) and persists despite clinical remission. Acupuncture has been shown to be effective for treating fatigue in many chronic diseases. Fatigue can be

objectively evaluated by the IBD validated Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACIT-F).

Aims & Methods: The main objective was to assess the efficacy of electroacupuncture (EAc) vs. sham EAc and no treatment for treating fatigue in patients with quiescent IBD in a single-blind randomized trial. Secondary objectives were to assess changes in quality of life, depression, anxiety and sleepiness after treatment with EAc.

Methods: Fifty-two patients with quiescent IBD and severe fatigue (FACIT-F < 40) (65.3% female, mean age 42 years) were randomized to EAc vs sham acupuncture vs control group. Patients in EAc and sham EAc groups performed a total of 9 acupuncture sessions during eight weeks (2 sessions/first week and one session per week during 7 weeks). Fatigue was evaluated with IBD validated Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACIT-F). Patients also completed validated questionnaires to assess quality of life in IBD, depression, anxiety and sleepiness during and after the treatment periods.

Results: Both EAc and Sham group improved the FACIT-F score post-treatment (EAP -9.53 points, 95% CI (-12.3 to -6.75, Basal Vs 9th session $p < 0.001$); Sham -5.46 points, 95%CI (-9.7 to -2.7, Basal Vs 9th session $p = 0.003$). No significant changes were observed in control group ($p = 0.339$). We found a trend for better response in the EAP than in the sham group although the difference in FACIT-F score was not significant ($p = 0.09$). EAc also improved quality of life (-5.17 points, 95% CI (-8.2 to -2.06, Basal Vs 9th session $p = 0.003$); depression (8.9 points, 95% CI (4 to 13.8, Basal Vs 9th session $p = 0.002$), anxiety (10.6 points, 95% CI (3.6 to 17.6, Basal Vs 9th session $p = 0.006$) and sleepiness scores (1.46 points, 95% CI (0.096 to 2.83, Basal Vs 9th session $p = 0.038$). However, the differences in between EAc and sham and control groups were not significant ($p > 0.05$).

Conclusion: Both targeted and sham electroacupuncture are effective in managing fatigue in patients with quiescent IBD. NCT02733276.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Anti-TNF, such as adalimumab (ADA) and infliximab (IFX), have improved the therapeutic care of Crohn's disease (CD). However their use may be associated with loss of efficacy, adverse events and sometimes primary failure. After the first anti-TNF discontinuation, it is possible to switch to another anti-TNF. In France, three anti TNF are available in ulcerative colitis (IFX, ADA and golimumab), but only the first two are approved in CD, because golimumab has not been studied in this indication. The aim of this study was to report golimumab efficacy and safety in CD.

Aims & Methods: This national multicenter retrospective study included patients with CD from 12 French tertiary centers who received golimumab and analyzed: clinical response, duration of treatment, tolerance, reasons for discontinuation of treatment, disease phenotype, and treatments preceding and associated with golimumab. The main endpoint was the efficacy of golimumab defined by the duration of treatment before failure (need for therapeutic optimization or cessation). Predictive factors of therapeutic response were determined (log rank and Cox model), and the tolerance was evaluated.

Results: One hundred and fifteen patients with a median duration of the disease of 13.5 years received on average golimumab in 3, 6 th line of biotherapy. The overall clinical response assessed by the physician was 55.8% at the time of the

re-evaluation (on average, at 3.8 months [0.6-24] after initiation of therapy). The mean duration of treatment was 12.3 months (0.55-44). Sixty-seven percent of patients received treatment for more than 6 months and 48.7% of patients were still treated with golimumab at the end of the follow-up. At 12 months, 34.9% of patients still received golimumab without optimization. At 24 months, this figure was 19.3%. In univariate analysis, the factors associated with a longer golimumab treatment duration without stopping or optimizing were the active smoking status ($p = 0.043$), the absence of anoperineal lesions ($p = 0.012$), the presence of extra-intestinal symptoms ($p = 0.035$), the presence of a co-immunosuppression of more than 6 months ($p < 0.001$) and discontinuation of the first anti-TNF α for intolerance ($p = 0.022$). In multivariate analysis, discontinuation of the first anti-TNF α for intolerance and the presence of co-immunosuppression with thiopurine derivatives or methotrexate over 6 months were independently associated with golimumab efficacy (OR 2.16, 95% CI [1.25-3.86], $p = 0.005$ and OR 3.98, 95% CI [2.3-7.1], $p < 0.001$, respectively). Side effects led to discontinuation of treatment in 6% of patients. These were paradoxical psoriasis in three patients, paresthesia ($n = 1$), lower extremity edema ($n = 1$), injection site reaction ($n = 1$) and not reported reason for one patient.

Conclusion: After failure of the other anti-TNF agents, golimumab is well tolerated and results in sustained clinical response in one in two patients with Crohn's disease, particularly when associated with a co-immunosuppression, and if the reason for discontinuation of the first anti -TNF α was an intolerance.

P0383 BIOLOGICS AND BIOSIMILARS: WHAT MATTERS TO PHYSICIANS?

A. Molinari¹, A. Loaiza-Bonilla², D. Charles¹

¹Global Alliance for Patient Access, Washington, DC/United States of America

²Cancer Treatment Centers of America, Philadelphia, PA/United States of America/AL

Contact E-mail Address: pdavidcharles@gmail.com

Aims & Methods: The purpose of this survey was to determine physicians' familiarity and comfort level with prescribing biosimilars to patients. The survey was sent to physicians residing in the European Union and specializing in the following clinical fields: dermatology, endocrinology, gastroenterology, neurology, oncology, and rheumatology.

Introduction: Biologic medicines and their biosimilar counterparts are effective therapies for many conditions, including inflammatory bowel disease, Crohn's disease, and ulcerative colitis. The European Medicines Agency (EMA) has approved twenty-two biosimilar medicines, which are derivatives of eight original biologics, and four more biosimilar are scheduled to be reviewed this year. As the number of approved biosimilars rises, regulatory agencies must closely monitor their safety and efficacy.

Results: The majority of survey respondents specialized in endocrinology (19%) and gastroenterology (19%). Respondents were recruited almost equally from the five countries, with France being the most represented country (22%) and the UK being the least represented (18%). The majority of respondents (55%) indicated that safety and efficacy is the most important factor in determining whether a patient should be switched from a prescribed biologic therapy to its approved biosimilar. Thirty percent of respondents indicated that clinical trials related to the disease or condition being treated is the most important factor to switching. Only 12% of respondents indicated that cost to the government or insurance companies is a primary concern, and only 3% were primarily concerned with immunogenicity.

Conclusion: This survey suggests that the safety and efficacy of biosimilar medicines is of paramount importance to physicians and that physicians highly value clinical trial data for biosimilars. Given that biosimilars are structurally distinct from their original innovator biologic counterparts, the EMA should consider requiring more stringent clinical trials data for biosimilars seeking approval. Specifically, the EMA should require clinical trials for each proposed indication and should provide physicians with this data so that physicians can make informed prescribing choices for the safety of their patients.

Introduction: Oral steroids are effective in inducing remission of moderate flares of patients with either ulcerative colitis (UC) or Crohn's disease (CD). However, we know little about their efficacy in immunosuppressed patients or their possible role in reducing biologics and/or surgical needs in these patients

Abstract No: P0384

IMM > 6 MONTHS	CD 260 (65%)	UC 138 (35%)	TOTAL 392 (100%)

Appendectomy	91 (77%)	6 (5%)	97 (25%)
Extraintestinal manifestations	49 (19%)	23 (18%)	72 (19%)
Smoke habit	Smoker 84 (32%) Ex-smoker 50 (19%) Non smoker 126 (48%)	Smoker 17 (13%) Ex-smoker 12 (9%) Non smoker 103 (78%)	Smoker 101 (26%) Ex-smoker 62 (16%) Non smoker 229 (58%)
Steroids at diagnosis	200 (77%)	104 (79%)	304 (78%)
Biological before IMM	4 (2%)	0 (0%)	4 (2%)
Surgery before IMM	62 (24%)	2 (16%)	64 (16%)
Steroids post-IMM	Classical 38 (63%) Low biodisp 22 (37%)	Classical 18 (62%) Low biodisp 11 (38%)	Classical 56 (63%) Low biodisp 33 (37%)
Surgery at follow-up	13 (5)	1 (0.8%)	14 (3.5%)
Biologic at follow-up	27 (10%)	9 (7%)	35 (9%)

Aims & Methods: We aimed to determine the efficacy of systemic or low bioavailability oral steroid treatment for moderate flares of patients with at least 6 months of immunosuppressive treatment, and describe long-term follow-up. Inflammatory bowel disease (IBD) immunosuppressed patients (thiopurines or methotrexate) from our population-data registry were analyzed. For statistical analysis, Chi-square test, U Mann-Whitney test and Kaplan Meier survival analysis were used.

Results: 392 IBD patients with a median of 82 (6–271) months of immunosuppressive (IMM) treatment were identified (table 1). 89 patients (23%) (33% UC and 67% CD) needed at least one steroid treatment during follow-up (63% systemic steroid and 37% low bioavailability oral steroid) with a median time of steroid treatment of 4 (1–168) months. Average time from IMM to steroid treatment was 26 (6–207) months. In IBD patients there were no differences regarding sex, age, disease, location, perianal disease, extra intestinal manifestations, appendectomy, smoke habit, need for steroids at diagnosis and previous abdominal surgery between patients with no need of steroids and patients with steroid treatment during follow-up. In CD patients, biological treatment for perianal disease before IMM ($p=0.0039$) and fibrostenotic (B2) or fistulizing (B3) behavior ($p=0.005$; OR 2.284) were risk factors for using steroids after IMM treatment. In UC patients, no statistically significant variables were identified. 49 of these 89 steroid treatment patients (55%) needed biological treatment or surgery after a median of 13 months (0–178); 19 (21%) needed more than one steroid treatment (2–5) and just 31 patients (35%) did not need any other treatment. CD patients had higher risk ($p=0.007$; OR: 3.529) to receive biological treatment or surgery versus UC patients. Otherwise, the more months using steroids in UC patients, the greater risk for biological or surgery treatment ($p=0.009$). During follow-up, though it's not statistically significant ($p=0.078$), we observe that 75% probability of rescue treatment for UC patients is 62 months versus 36 months for CD patients.

Conclusion: 23% of IBD immunosuppressive patients needed at least one steroid treatment after 6 months of IMM. Previous biological treatment and B2-B3 behavior predicted steroid treatment in CD patients, who had 3.5 times more risk to receive biological treatment or surgery after steroid treatment using it earlier than UC patients. Just 1/3 of patients who needed steroid treatment after IMM did not need any other rescue treatment.

Introduction: PYRAMID was an international multi-center non-interventional postmarketing registry assessing long-term safety and effectiveness of adalimumab (Humira® [ADA]) as used in routine clinical practice. Patients with and without prior ADA experience were allowed to enroll. The final long-term

effectiveness of ADA is reported in adult ADA-naïve patients (those who had not received ADA before registry enrollment) with moderate to severe Crohn's disease (CD) who were treated according to the local product label.

Aims & Methods: All patients entering the registry were followed for up to 6 years. Effectiveness of ADA was measured using Physician's Global Assessment (PGA; [a composite of Harvey Bradshaw Index and rectal bleeding score]), Short Inflammatory Bowel Disease Questionnaire (SIBDQ), and 4 components of the Work Productivity and Activity Impairment (WPAI) questionnaire, including absenteeism, presenteeism, overall work impairment, and activity impairment. Effectiveness measures, captured in all patients who received at least 1 dose of ADA in the registry and had at least 1 post-enrollment measurement, were summarized descriptively by the number of observations that were not missing at each registry visit; data were reported as observed. Values at enrollment are considered as baseline values.

Results: Among 5025 patients evaluated in the registry, 2057 (40.9%) were ADA-naïve. Of these, 1199 patients (58.3%) were female; mean age 37.1 years at enrollment. Mean \pm SD ADA exposure for the ADA-naïve subgroup during the registry was 1118.5 ± 842.3 days. A total of 1082 patients (52.6%) had prior exposure to at least 1 anti-TNF/biologic; 853 (41.5%) and 831 patients (40.4%) used immunomodulators and corticosteroids, respectively, at enrollment. Mean change from baseline in effectiveness measures for patients with CD is shown in the table. Mean PGA score and SIBDQ as well as WPAI domains improved in ADA-naïve patients from enrollment to 1 year and were sustained for up to 6 years (table). No new safety signals were identified in the registry.

Conclusion: At 1 year after entering the international postmarketing registry of ADA use in routine clinical practice, clinically meaningful improvements in disease activity, work productivity, and activity impairment were achieved in ADA-naïve patients with moderately to severely active CD. These improvements were maintained for up to 6 years of the registry among the patients who remained in the study.

Introduction: Adalimumab (ADA) has been shown to improve clinical outcomes and health-related quality of life (HRQoL) significantly in patients (pts) with ulcerative colitis (UC) in a clinical practice setting.¹ Evidence is limited about benefits of ADA among UC pts with different characteristics.

Aims & Methods: The aim was to examine clinical and HRQoL effects of ADA in pts with UC based on disease severity and prior use of tumour necrosis factor inhibitor (TNFI). InspirADA details have been presented.¹ Pts received ADA 160/80 mg at week (wk) 0/2 followed by ADA 40 mg eow at wks 4 through 26. Pts who did not respond to ADA by wk 8 were to discontinue. Pts who lost response at or after wk 8 could escalate to ADA 40 mg weekly. UC pts were categorized into subgroups based on physician global assessment (PGA) of disease severity (moderate [baseline PGA = 2] vs severe [baseline PGA = 3]) and previous TNFI use (naïve vs experienced). Proportions of pts with Simple Clinical Colitis Activity Index (SCCAI) response (defined as a decrease of ≥ 2 points vs baseline) and remission (defined as an SCCAI ≤ 2) were calculated for each cohort at wks 2, 8 and 26. Change from baseline in HRQoL outcomes was calculated, including Short Inflammatory Bowel Disease Questionnaire (SIBDQ), European Quality of Life-5 Dimensions-5 Level (EQ-5D-5L), Treatment Satisfaction Questionnaire for Medication (TSQM) and Work Productivity and Activity Impairment (WPAI). Missing data were imputed using nonresponder imputation for response/remission and last observation carried forward for all other outcomes. Comparisons of remission rate (using logistic regression) and HRQoL outcomes (using linear regression) were conducted in moderate vs severe UC and in TNFI naïve vs experienced cohorts.

Results: Among pts with moderate UC (n = 386) and severe UC (n = 74), SCCAI response rates were 74.6% vs 74.3%, 80.1% vs 71.6%, and 67.1% vs 64.9% at wk 2, 8, 26, respectively. Although remission rates were similar between moderate and severe pts at wk 26 (49.5% vs 40.5%, p = 0.16), ADA provided greater disease control for moderate pts at wk 2 (29.8% vs 9.5%, odds ratio [OR] 4.1, 95% confidence interval [CI] 1.8-9.1; p < 0.001) and wk 8 (52.3% vs 31.1%, OR 2.4, 95% CI 1.4-4.4; p = 0.01) compared to severe pts (table). The rate of dose escalation (ADA 40 mg weekly) was 28.0% in moderate and 28.4% in severe UC pts. HRQoL outcomes were similar between the moderate and severe cohorts. Among pts who were naïve (n = 389) and those experienced to TNFIs (n = 72), response rates were 74.0% vs 76.4%, 79.2% vs 75.0%, and 66.3% vs 68.1% at wk 2, 8, 26, respectively. No significant difference was observed in remission rates for naïve vs experienced pts at wk 2 (28.0% vs 19.4%, p = 0.43) and wk 26 (49.4% vs 41.7%, p = 0.39), but naïve pts showed a significantly higher remission rate than those experienced to TNFIs at wk 8 (52.2% vs 31.9%, OR 2.1, 95% CI: 1.2-3.7; p < 0.001). The rate of dose escalation was 26.5% in naïve pts vs 36.1% in experienced pts (p = 0.09). In general, HRQoL outcomes were similar between naïve and experienced TNFI pts.

Table: Remission rate by disease severity and previous use of TNFIs

Remission rate, n (%)	Moderate UC (n = 386)	Severe UC (n = 74)	Odds ratio (95%CI)*	P value
Wk 2	115 (29.8%)	7 (9.5%)	4.06 (1.81-9.12)	<0.001
Wk 8	202 (52.3%)	23 (31.1%)	2.43 (1.43-4.40)	0.001
Wk 26	191 (49.5%)	30 (40.5%)	1.44 (0.87-2.38)	0.16

(continued)

Table Continued

Remission rate, n (%)	Moderate UC (n = 386)	Severe UC (n = 74)	Odds ratio (95%CI)*	P value
Remission rate, n (%)	Naïve to TNFIs (n = 389)	Experienced to TNFIs (n = 72)	Adjusted odds ratio (95%CI)*	P value
Wk 2	109 (28.0%)	14 (19.4%)	1.30 (0.68-2.51)	0.43
Wk 8	203 (52.2%)	23 (31.9%)	2.09 (1.19-3.65)	0.01
Wk 26	192 (49.4%)	30 (41.7%)	1.26 (0.75-2.11)	0.38

*Comparison between naïve and experienced groups was adjusted for baseline SCCAI. Because baseline SCCAI is highly correlated with PGA, adjustment for baseline SCCAI in moderate and severe UC pts defined by PGA was not performed.

Conclusion: ADA treatment achieved clinically relevant rates of SCCAI response and remission even in pts who had severe UC and those who were more treatment-refractory (experienced to TNFIs), in clinical practice. In addition, ADA was associated with greater disease control in the induction period for pts with moderate than severe UC and for naïve pts than those experienced to TNFIs.

Introduction: Treatment with intravenous (IV) CT-P13, a biosimilar infliximab (INX) licensed for use in 80 countries, is highly effective and well tolerated. To increase treatment modalities with CT-P13 for patients, a new subcutaneous (SC) formulation was developed.

Aims & Methods: This phase I and open label study, conducted at a single site in Korea, was designed to evaluate safety and pharmacokinetics (PK) of SC administration of CT-P13 in healthy subjects. In a single dose escalation study, 38 subjects received either SC injection or IV infusion of CT-P13 on Day 0 and were followed for 12 weeks (20 subjects in 3 different dosages of SC; 18 subjects in 2 different dosages of IV). After reviewing safety data observed for 48 hours, the next cohort was conducted subsequently from low dose to high dose. The PK profile of SC and IV formulation was evaluated by measuring the AUC_{0-last}, C_{max}, T_{max} and T_{1/2}.

Results: A total of 38 male subjects with median age of 23 years (range 19, 30 years) had no treatment-emergent serious adverse events or systemic hypersensitivity reaction. In SC cohort, two subjects experienced mild injection site reactions, and both have resolved without any treatment. Mean AUC_{0-last} and C_{max} ranged from 5016.4 to 14253.6 h*ug/mL and 10.0 to 23.1 ug/mL, respectively, after a single SC injection of CT-P13. SC CT-P13 formulation was absorbed slower into the systemic circulation (median T_{max} ranging from 7.0 to 7.1 days) in comparison with IV formulation (median T_{max} ranging from 2.2 to 3.2 hours) but the drug elimination measured by half-life (T_{1/2}) was similar (mean range 11.3 to 13.7 days vs. 11.7 to 12.2 days) between SC and IV formulations, respectively. Bioavailability of CT-P13 SC was approximately 60.6%, when comparing across all CT-P13 SC cohorts to CT-P13 IV cohorts.

Conclusion: PK profiles after a single SC injection were linear by dose levels. SC administration of CT-P13 is feasible in terms of bioavailability and safety profiles.

Introduction: Biological therapy has been highly effective for inflammatory bowel disease (IBD). In addition to anti-tumour necrosis factor (anti-TNF) drugs, a gut-selective anti-integrin biologic, vedolizumab (VDZ), has been approved since 2014. However, the real-world comparative effectiveness of VDZ and anti-TNF has not been fully investigated.

Aims & Methods: This study aimed to evaluate all-cause and IBD-related healthcare utilisation in IBD patients (pts) newly treated with VDZ and anti-TNFs. Crohn's disease (CD) and ulcerative colitis (UC) pts ≥ 18 years old with ≥ 2 claims for VDZ or ≥ 2 claims for anti-TNF from 20/5/2014 to 31/12/2016 were identified from a large, de-identified administrative claims database in the US (Truven MarketScan® Commercial and Medicare Supplemental Databases). The date of the first VDZ/anti-TNF claim was defined as index date. New VDZ/anti-TNF treatment was defined as no claims for these agents in the 1 year before index date. All pts had ≥ 12 -month continuous enrolment prior to and ≥ 6 -month following index date. All-cause and IBD-related healthcare utilisation including hospitalisation, emergency department (ED) visits and outpatient visits during 6 months post-index were examined for the IBD cohort overall, as well as in CD and UC cohorts. Multivariable logistic regression was employed to estimate the odds ratio (OR) for hospitalisation and ED visits, while Poisson regression was used to examine the rate ratio (RR) for outpatient visits with VDZ compared to anti-TNF use, controlling for demographic characteristics, index year, baseline Charlson comorbidity index (CCI) and baseline hospitalisation and ED visits 1 year prior to index date. In sensitivity analyses, outpatient visits related to infusion administration for VDZ or anti-TNF were excluded to examine the RR associated with outpatient visits that were not related to the visits for infusion procedure.

Results: A total of 652 and 6974 IBD pts newly treated with VDZ and anti-TNF were identified, respectively (mean age [year]: 45 VDZ vs 42 anti-TNF; male: 47% vs 48%). VDZ pts had a higher CCI than anti-TNF pts (0.7 vs 0.5). During the 6 month follow-up, compared to anti-TNF, use of VDZ had significantly higher rates of all-cause hospitalisation (16.3% vs 13.1%, OR 1.30, 95% confidence interval [CI] 1.03–1.64), all-cause outpatient visits (mean visits 45.1 vs 31.0, RR 1.39, 95%CI 1.32–1.37) and IBD-related outpatient visits (mean visits 28.1 vs 17.5, RR 1.60, 95%CI 1.51–1.69). A sensitivity analysis excluding outpatient visits related to infusion administration showed similar results for IBD-related outpatient visits (RR 1.53, 95%CI 1.44–1.62). In pts with CD, the magnitude of risk of IBD-related hospitalisation was even higher (OR 1.67, 95%CI 1.17–2.38), but no significant difference in IBD-related hospitalisation (OR 0.57, 95%CI 0.30–1.06) was observed in pts with UC. The difference in IBD-related ED visits between VDZ and anti-TNF pts was not significant in CD (OR 1.32, 95%CI 0.96–1.82) or UC (OR 0.72, 95%CI 0.40–1.29). However, the rates of outpatient visits were consistently higher in VDZ vs anti-TNF across CD (RR 1.82, 95%CI 1.69–1.96) and UC cohorts (RR 1.29, 95%CI 1.18–1.42). The results were similar in the sensitivity analyses when infusion-related visits were excluded.

Conclusion: In this real-world setting, VDZ treatment was shown to be associated with higher all-cause hospitalisations and outpatient services compared to anti-TNF for pts with IBD. A higher risk of IBD-related hospitalisation associated with VDZ use was observed in CD but not UC pts. Outpatient visit rates were consistently higher for VDZ users, regardless of taking into account the infusion-related visits for biologics. These results should be interpreted with caution as disease activity was not fully accounted for in this claims data analysis.

P0389 SAFETY OF ANTI-TNF TREATMENT IN ELDERLY PATIENTS WITH INFLAMMATORY BOWEL DISEASE

L. Maia, P. Lago, Á. Rodrigues, M.S. Rodrigues, C. Caetano, D. Ferreira, M. Rocha, I. Pedrito

Gastroenterology, Centro Hospitalar do Porto, Porto/Portugal

Contact E-mail Address: luism Maia.gastro@gmail.com

Introduction: Due to population ageing and improved survival, the percentage of elderly patients with inflammatory bowel disease (IBD) is increasing. The safety

of tumour necrosis factor antagonists (anti-TNF) treatment in this populations is ill-studied.

Aims & Methods: To assess the main adverse events (AE) of this therapy in the elderly population in comparison with the younger patients, we performed a retrospective cohort study of patients with IBD that initiated treatment with anti-TNF between 2003 and 2014, with follow-up until December 2016. Demographic, clinical and medication data were collected. AE (infectious including opportunistic, malignancy, dermatologic, neurologic, cardiac and vascular, hepatic, infusion reactions and others) occurring during anti-TNF treatment in elderly and younger patients were analysed and both groups were compared. The severe AE definitions from Food and Drug Administration (FDA) and European Medicines Agency (EMA) were used.

Results: Of the 219 patients (55.3% women; average disease duration 13.60 \pm 7.74 years), 25 were more than 65 years-old (elderly group, mean age 70.0 years vs. younger group, mean age 41.77 years). Infliximab was used in 174 patients (on average 1585 days) and adalimumab in 93 (on average 1379 days), with a total 1106 years of anti-TNF exposure. In the elderly, azathioprine was used less frequently (68.0 vs. 95.4%, $p=0.000$). There were 46 severe AE overall, including 18 cancers and 16 opportunistic infections (5 tuberculosis). Malignancy (20.0% vs. 6.7%, $p=0.039$) and cardiovascular events (16.0 vs. 4.1%, $p=0.036$) occurred more frequently in the elderly, whereas dermatologic AE were more common in the younger group (4.0 vs. 19.1%, $p=0.044$). The total number of severe AE (24.0 vs. 20.1%, $p=0.794$) including death (4.0 vs. 2.6%, $p=0.521$) was not significantly different between groups.

Conclusion: Despite being at higher risk of malignancy and cardiovascular events, the total number of severe adverse events was not significantly increased in elderly patients. Particular attention to malignancy surveillance and treatment of cardiovascular comorbidities is advised in this population.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Over the past twenty years, the introduction of biological agents into clinical practice has radically improved outcomes in patients with inflammatory bowel disease (IBD), Crohn's disease (CD) and ulcerative colitis (UC). Tumor necrosis factor (TNF) antagonists, such as infliximab, act by preventing TNF from binding to its receptor, neutralizing its activity and alleviating mucosal inflammation. However, biological agents are much more expensive than traditional treatments, and the high cost of these drugs in the treatment of IBD imposes a considerable burden on the national healthcare system. As a result, interest in biosimilars has grown as biosimilar agents are highly similar in terms of quality, efficacy, and safety to already licensed biologics but are associated with lower development costs. CT-P13 (Remsuma® and Inflectra®) is a biosimilar of infliximab (Remicade®), which is its reference product (RP). Both CT-P13 and infliximab RP are chimeric IgG1 monoclonal antibodies produced in cell lines derived from the same cell type of murine hybridoma. CT-P13 was authorized by the EMA in 2013 for several indications, including IBD, based on two pivotal clinical trials in patients with rheumatoid arthritis (RA) and ankylosing spondylitis (AS). However, a number of observational studies of CT-P13 in clinical practice in both anti-TNF-naïve patients and those who have been switched from infliximab RP have been published with good results.

Aims & Methods: We aimed to assess the effectiveness and safety of switching to CT-P13 from infliximab reference product (RP) in patients with inflammatory bowel disease. This was a prospective single-center observational study in patients with moderate to severe Crohn's disease (CD) and ulcerative colitis (UC). All patients were switched from infliximab RP (Remicade®) to CT-P13 treatment and followed for up to 12 months. The efficacy endpoint was the change in clinical response assessed at 3-monthly intervals, according to the Harvey-Bradshaw (HB) score and partial Mayo score for patients with CD and UC, respectively. C-reactive protein (CRP) was also measured. The Cochrane's Q and Friedman tests were used to analyze the change in clinical scores and CRP. Adverse events were monitored and recorded throughout the study.

Results: A total of 98 patients with inflammatory bowel disease (67 CD/31 UC) were included. 83.6% (56/67) of patients with CD were in remission at the time of the switch and 62.7% were in remission at 12 months. The HB score showed a significant change at 12 months ($P=0.007$) but no significant change was observed in median CRP at this timepoint ($P=0.364$). 80.6% (25/31) of patients with UC were in remission at the time of the switch and 65.3% (18/28) were in remission at 12 months. No significant changes in the median partial Mayo score ($P=0.058$) or CRP ($P=0.329$) were observed at 12 months. Serious adverse events related to medication were reported in 11 (11.2%) patients. In this group, six patients discontinued treatment because of these AEs.

Conclusion: Switching from infliximab RP to CT-P13 is efficacious and well tolerated in patients with CD or UC for up to 12 months.

P0391 CLINICAL RESPONSE TO VEDOLIZUMAB IN IBD PATIENTS IS ASSOCIATED WITH THE CONCOMITANT USE OF IMMUNOMODULATORS

I. Parisi, R. Vega, L. Whitley, S. Bloom, S. McCartney
Gi Medicine, University College London Hospitals, London/United Kingdom

Contact E-mail Address: ioannaparis@hotmail.com

Introduction: The role of biologics in medical management of inflammatory bowel disease (IBD) has been established since anti-TNF agents invaded the market several years ago. Vedolizumab, an anti-integrin gut-selective molecule, is a more recent biologic treatment which has been approved for the management of both Crohn's disease and ulcerative colitis. Its efficacy in inducing and maintaining remission was shown in GEMINI studies, although a good percentage of the trial participants had previously failed anti-TNFs. We conducted this study in order to describe outcomes in a real-life cohort of IBD patients who were treated with Vedolizumab, consisting both of previously anti-TNF exposed but also anti-TNF naïve patients. Multivariate analysis searched for factors associated with response to treatment.

Aims & Methods: All patients with IBD who received at least three doses of Vedolizumab in UCLH since the drug was officially licensed in the UK were included in the study. Demographics, clinical and endoscopic response rates were recorded and analysis was conducted in the whole cohort and in the subgroups of Crohn's and UC patients separately. Univariate analysis and logistic regression were conducted in order to identify important associations with clinical response.

Results: 59 patients with IBD were treated with vedolizumab from May 2015 to October 2016. 28 (47%) had Crohn's disease and the majority ($n=43$, 73%) had mainly colonic inflammation (12 colonic Crohn's, 29 UC, 2 IBDU). Median time from diagnosis to Vedolizumab initiation was 8 years. 17 (29%) were anti-TNF naïve (all UC) and 28 (67%) had previously failed both Infliximab and Adalimumab. 36 (61%) were on a concomitant immunomodulator (IM), either a thiopurine or methotrexate. 41 (70%) patients had a clinical response to Vedolizumab based on a reduction of Harvey-Bradshaw index (HBI) from baseline ≥ 3 points for Crohn's patients or a reduction of partial Mayo score ≥ 2 points for UC patients. The rates of response were similar in Crohn's and UC patients while there was no difference in response according to gender, previous anti-TNF exposure, disease duration or location of inflammation. Patients on no concomitant IM were less likely to respond to Vedolizumab (Odds ratio 0.26, 95%CI 0.07–0.91, $p=0.036$). 11(18.6%) patients experienced adverse events while treated with Vedolizumab, five of which were related to active IBD. There were two minor allergic reactions and two mild infections.

Conclusion: Clinical response to Vedolizumab was observed in two-thirds of our IBD patients, similarly in Crohn's disease and ulcerative colitis. Concomitant IM were the only factor which was importantly associated with a higher response rate. Overall there were no serious adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Anti-TNF α therapies have helped improved response rates, reduced complication rates, and quality of life for patients with inflammatory bowel disease (IBD). However primary loss of response (LOR) is still a big concern. Therapeutic drug monitoring (TDM) potentially offers the opportunity of adjusting doses of anti-TNF α in a treat to target fashion. The end of anti-TNF α induction therapy is a key time point in the management of IBD. TDM is a useful method to help explore an immune basis behind LOR. In addition anti-TNF α trough and antibody levels, are a significant predictor of future likelihood of clinical response and mucosal healing.

Aims & Methods: The aim of this study was to explore the relationship between infliximab (IFX) and adalimumab (ADA) trough and antibody levels with clinical response rates, at the end of anti-TNF α induction therapy. This was a prospective, single-centre study. Patients were recruited from the gastroenterology department at our centre, from July 2015 to August 2016. Inclusion criteria were all patients older than 17 years old with IBD who started treatment with anti-TNF α drugs, either infliximab or adalimumab, during the study period. Patient demographics, medication and clinical history were collected from the electronic hospital information system. Baseline clinical disease activity indexes were performed (Harvey-Bradshaw Index for Crohn's disease (CD), and partial Mayo scores for Ulcerative colitis (UC)). Clinical response was defined as reduction in HBI ≤ 3 or reduction in partial Mayo score ≤ 4 and $< 30\%$ from baseline. Anti-TNF α trough and antibody levels were measured using standard ELISA techniques. Blood was taken just prior to their first maintenance infusion. Only patients who completed induction therapy were included. Standard induction were regimens used, 5 mg/kg week 0, 2 and 6 and 160 mg, 80, mg and 40 mg every other week.

Results: 35 patients were recruited; 23 CD, 12 UC. 18 patients were treated with ADA, 17 with IFX. Mean age was 40.3 years, 22 (62.9%) were female, 12 (34.3%) were on thiopurines and 9 (25.7%) had prior anti-TNF α exposure. Overall response rate was 51.4% (n=18), 33.3% (n=6) for ADA, and 70.6% (n=12) for IFX. Overall trough levels were 12.5 ug/ml for IFX, and 4.4 ug/ml for ADA, 71.4% had therapeutic trough levels > 1 ug/ml. There was a clear link between higher anti-TNF α trough levels at the end of induction with clinical response rates. For infliximab, mean trough levels in responders was 16.4 ug/ml (IQR 8.4–22.7) versus 5.3 ug/ml (0.5–8.8) for non-responders (p value 0.026 95% CI: 1.50–20.7). The area under the curve [AUC] for association of IFX level at end of induction with clinical response was 0.864, p=0.0001. In addition a trough level of 4.8 ug/ml predicted clinical response at end of induction, with a sensitivity of 90.91% and a specificity of 67%. Similarly there was a link between higher ADA levels with clinical response, though not statistically significant (Responders mean trough 6.6 ug/ml (IQR 4.9–8.7) versus non-responders 3.0 ug/ml (IQR 0.1–2.7) p value 0.135 95% CI 1.24–8.43). Antibody formation occurred in 6 patients (17.1%). Of the patients who had primary non-response, 18/35 (51.4%) had doses of anti-TNF α escalated, 7/17 (41.1%) for infliximab, and 11/18 (61.1%) for adalimumab. 4 patients required surgical intervention, including 1 colectomy.

Conclusion: Higher trough levels at the end of anti-TNF α induction are associated with improved response rates. Ongoing work will define optimal targets at this key timeframe.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Lymphocytic colitis (LC) is a common cause of chronic, non-bloody diarrhea. Budesonide appears to be effective based on small studies. Mesalazine has been proposed as a treatment option but no placebo-controlled trials have been reported. Thus, we performed a placebo-controlled, multicenter study to evaluate budesonide and mesalazine as induction treatments for lymphocytic colitis.

Aims & Methods: Patients with active lymphocytic colitis were randomly assigned to either budesonide 9 mg once daily or mesalazine 3 g once daily, or placebo for 8 weeks in a double-blind, double-dummy design. The primary endpoint was clinical remission defined by the Hjortswang-Criteria (1). Secondary endpoints included histopathology and safety.

Results: Based on an interim analysis the trial was stopped in accordance with the pre-specified adaptive design. The final analysis included 57 patients (19 per group). Most patients were of female gender (72%) and mean age was 59 years. The proportion of patients in clinical remission at week 8 was significantly higher in the budesonide group than in the placebo group (intention-to-treat (ITT) 79% vs 42%; p=0.01). The difference in clinical remission at week 8 between mesalazine (63%) and placebo failed statistical significance (p=0.09). The proportion of patients with histological remission at week 8 was higher with budesonide (68%) than with mesalazine (26%; p=0.02) and placebo (21%; p=0.008). The rate of adverse events did not differ among groups.

Conclusion: Oral budesonide 9 mg once daily is highly effective and safe for induction of clinical and histological remission in lymphocytic colitis, while oral mesalazine 3 g once daily was only numerically, but not statistically significant better than placebo.

Introduction: A pregnant woman with ulcerative colitis (UC), compared with age-matched controls, is at higher risk of adverse outcomes including spontaneous abortion, preterm birth and low birth weight.^{1, 2} Tofacitinib is an oral, small molecule Janus kinase inhibitor that is being investigated for UC. Tofacitinib has been shown to be foetocidal and teratogenic in both rats and rabbits at exposures 146 times and 13 times, respectively, the human dose of 5 mg twice daily (BID). There are no adequate and well-controlled studies of tofacitinib in pregnant women.

Aims & Methods: We report the pregnancy outcomes from three randomised, placebo-controlled studies (OCTAVE Induction 1, NCT01465763; OCTAVE Induction 2, NCT01458951; OCTAVE Sustain, NCT01458574) and one ongoing open-label extension study (OCTAVE long-term study, NCT01470612) of tofacitinib monotherapy in patients (pts) with moderate to severe UC.^{3, 4} Pregnancy outcomes following maternal or paternal exposure to tofacitinib 5 or 10 mg BID were identified from Pfizer's internal safety database up to 23 March, 2017, and categorised as: healthy newborn, medical termination, foetal death, congenital malformation, spontaneous abortion or pending/lost to follow-up. Trial protocols required use of highly effective contraception for females of childbearing potential, and study drug to be discontinued in any female pts who became pregnant.

Results: A total of 1139 unique pts (incl. placebo) enrolled in the UC OCTAVE trials, of whom 296 were females of childbearing age. There were a total of 25 pregnancies reported with exposure to tofacitinib. Of these, 11 were cases of maternal exposure, all during the 1st trimester, including: 2 (18.2%) spontaneous abortions (5 mg BID, n=1; 10 mg BID, n=1), 2 (18.2%) medical terminations (both 10 mg BID), 4 (36.4%) healthy newborns (all on 10 mg BID) and 3 (27.3%) cases lost to follow up (all on 10 mg BID). Out of the 14 cases of paternal exposure, 11 (78.6%) were healthy newborns (5 mg BID, n=2; 10 mg BID, n=9) and 3 (21.4%) were pending/lost to follow-up (5 mg BID, n=1; 10 mg BID, n=2). Overall, there were no cases of foetal death or congenital malformation.

Table: Summary of pregnancy outcomes in the OCTAVE programme

	Foetal death	Congenital malformation	Spontaneous abortion	Healthy newborn	Medical termination	Pending/lost to follow-up
Maternal exposure (n=11)						
Tofacitinib 5 mg BID	0	0	1	0	0	0
Tofacitinib 10 mg BID	0	0	1	4	2 [†]	3
Paternal exposure (n=14)						
Tofacitinib 5 mg BID	0	0	0	2	0	1
Tofacitinib 10 mg BID	0	0	0	9	0	2

†Case 1: the subject decided to terminate pregnancy based on potential risks of tofacitinib; Case 2: reason unknown;

BID, twice daily.

Conclusion: Based on the limited data and follow up available, pregnancy and newborn outcomes among pts with UC with prenatal (maternal/paternal) exposure to tofacitinib appear to be similar to those reported for the UC population, as well as those previously reported in pts with RA and PsO.⁵ Larger, long-term follow-up studies are needed to examine safety of tofacitinib during pregnancy.

Introduction: Granulocyte and monocyte adsorptive apheresis (GMA) has been shown to be effective and safe in patients with inflammatory bowel disease (IBD). We report an interim analysis of a post-marketing surveillance study of granulocyte and monocyte adsorptive apheresis using Adacolumn® for patients with inflammatory bowel disease who have special situations (PARTICULAR).

Aims & Methods: The aim of the PARTICULAR study was to assess the safety and efficacy of GMA treatment in patients with IBD who have special situations. This study was an interim analysis of the multi-centre observational study conducted at 80 institutions in Japan. Data were collected from patients with ulcerative colitis (UC) or Crohn's disease (CD) who received GMA between November 2013 and September 2016. Patients who had at least one special situation were included in the study. GMA was performed using Adacolumn® (JIMRO, Takasaki, Japan). Each patient received up to a maximum of 11 GMA sessions. Safety assessments were performed on all patients in this study. All adverse

events (AEs) during the study period were recorded. AEs for which the causality of GMA could not be ruled out were defined as side effects (SEs). Feasibility problems (FPs) included blood withdrawal difficulty, venous pressure elevation, coagulation in the apheresis system and venous access difficulty. The safety of GMA was investigated in the following six special situation subgroups: the elderly (≥ 65 years), concomitant treatment with multiple immunosuppressants, retreatment with GMA, anaemia (haemoglobin < 10 g/dl), paediatric (≤ 18 years) and other groups. We also compared AEs, SEs and FPs between the subgroups with/without each special situation by univariate analysis. The efficacy of GMA was also assessed in patients with UC. Patients with a partial UC disease activity index score (pUC-DAI) of < 3 , those with missing pUC-DAI scores and those receiving concomitant treatment with infliximab, adalimumab, tacrolimus or cyclosporine were excluded from efficacy assessment. pUC-DAI scores were calculated at baseline and then after the final GMA session or when GMA therapy had to be discontinued because of AEs or FPs. Remission was defined as a pUC-DAI score of ≤ 2 with no individual sub-score exceeding 1 point. Patients who received additional treatment by the final GMA session, including steroids, infliximab, adalimumab, tacrolimus and cyclosporine, were considered non-responders to GMA.

Results: This study included 363 patients (304 UC, 59 CD). Among these patients, SEs, AEs and FPs were observed in 3.0%, 10.7% and 16.3% of the patients, respectively. There were 105, 112, 103, 89, 43 and 39 patients in the elderly, concomitant treatment with multiple immunosuppressants, retreatment with GMA, anaemia, paediatric and other groups, respectively. The incidence of AEs was significantly higher in patients on multiple concomitant immunosuppressants compared with those not receiving them. Likewise, the incidence of AEs was significantly higher in patients of the anaemia group compared with patients with haemoglobin of ≥ 10 g/dl. The incidence of FPs was significantly lower in patients of the retreatment with GMA group than in those who received GMA for initial treatment (Table 1). The efficacy of GMA was assessed in 209 UC patients. The numbers of patients administered prednisolone, infliximab, adalimumab, tacrolimus and cyclosporine were 24, 6, 3, 6 and 1, respectively, and these patients were considered to be non-responders to GMA. The mean pUC-DAI score significantly decreased from 6.2 at baseline to 3.4 after the final GMA session ($P < 0.001$) and the remission rate at the final GMA session was 43.5%.

Conclusion: This multi-centre observational study showed that GMA has an acceptable safety profile in IBD patients and sufficient effectiveness in UC patients who have special situations. However, care should be taken when GMA is used in patients with anaemia or those who have received concomitant treatment with multiple immunosuppressants.

Introduction: People with Inflammatory Bowel Disease (IBD) commonly experience mental health issues (MHIs) such as anxiety and depression. MHIs reduce quality of life and are associated with poor medication adherence and worse disease course. However, psychological support is not routinely provided to people with IBD. There are scant prospective, systematically gathered data on MHIs in IBD, despite solid evidence of the value of psychological input for people with other chronic diseases.

Aims & Methods: The current study is investigating: the prevalence of MHIs in an IBD cohort; the acceptability and uptake of psychological screening; the acceptability and uptake of psychological support and treatment; whether MHIs correlate with higher healthcare utilisation; and potential benefits of integrated psychological care to patients' mental health, physical health, and/or healthcare utilisation. Potential participants were prospectively recruited from the IBD service of a large tertiary hospital in South Australia via post and in-person at scheduled/routine outpatient appointments. Data were collected at two time-points – at baseline screening and at 12 month follow-up. Mental health, medication adherence, and quality of life were measured by questionnaires: the Hospital Anxiety and Depression Scale (HADS), the Kessler 6 Scale of General Psychological Distress (K6), the Morisky Medication Adherence Scale (MMAS-8), and the Assessment of Quality of Life measure (AQoL-8D). Demographic and healthcare utilisation data were collected by electronic,

Table1: Safety profile of GMA in each group

	AEs (No. of patients) P value	SEs (No. of patients) P value	FPs (No. of patients) P value
All subjects (n = 363)	10.7 % (n = 39)	3.0 % (n = 11)	16.3 % (n = 59)
Elderly (n = 105)	9.5 % (n = 10) p = 0.6284*	0% (n = 0) p = 0.0690**	17.1% (n = 18) p = 0.7650*
Multiple immunosuppressants (n = 112)	17.0% (n = 19) p = 0.0134*	5.4 % (n = 6) p = 0.1011**	19.6 % (n = 22) p = 0.2685*
Retreatment (n = 103)	9.7 % (n = 10) p = 0.6859*	2.9 % (n = 3) p = 1.0000**	8.7 % (n = 9) p = 0.0172**
Anaemia (n = 89)	18.0 % (n = 16) p = 0.0158*	4.5% (n = 4) p = 0.4743*	21.4% (n = 19) p = 0.1548*

Others (n = 39)	2.6%(n = 1) p = 0.1001**	0%(n = 0) p = 0.6159**	15.4%(n = 6) p = 1.0000**

GMA; Granulocyte monocyte adsorptive apheresis *Chi-squared test **Fisher's exact tests AEs; Adverse events SEs; Side effects FPs; Feasibility problems

state-wide hospital records. Psychological support was offered where scores on HADS and/or K6 indicated likely need.

Results: 500 patients were approached during the 12-month screening phase; 50.6% were male, 70.8% had Crohn's disease, mean age of 40 years, mean disease duration of 11 years, 43% in clinical remission, and 9.8% current smokers (Australia's average 13.3%). Of these 500, 67% participated in psychological screening, 38% scored within the clinical range, and 17% accepted psychological support. Gender was a significant predictor of participation in psychological screening: women were 62% more likely to participate than men. Analgesics and/or mental health medication increased the likelihood of scoring within the clinical range nearly fivefold (analgesic use $OR = 5.32$, $p = .030$; psych $OR = 6.04$, $p = .001$). Significant predictors of accepting psychological treatment included older age ($OR = 1.03$, $p = .041$), anxiety ($OR = 1.09$, $p = .045$), general distress ($OR = 1.11$, $p = .003$) and lower quality of life ($OR = .93$, $p = .042$). At baseline, anxiety and depression were both negatively correlated with medication adherence (anxiety $r = -.323$, $p = .000$, depression $r = -.200$, $p = .000$) and overall quality of life (anxiety $r = -.708$, $p = .000$; depression $r = -.787$, $p = .000$). Depression and general distress were related to overall healthcare utilisation (depression $r = .131$, $p = .018$, general distress $r = .124$, $p = .026$). Anxiety was not related to overall healthcare utilisation, but was positively correlated with numbers of emergency department presentations ($r = .124$, $p = .024$), outpatient appointments ($r = .119$, $p = .030$), and appointment cancellations ($r = .155$, $p = .005$). Currently, approximately half of the twelve month follow-up data has been collected. Preliminary analysis shows improvements for patients' mental health, quality of life and medication adherence (see table below).

Table1: Outcomes of psychological support

Variable	Screening (Mean)	SD	Follow-Up (Mean)	SD	t value	p value	Eta ²
Anxiety	12	3.6	9	4.1	4.87	.000***	0.36
Depression	8.8	3.9	6.4	5.0	4.34	.000***	0.30
Distress	18.2	4.8	13.9	5.1	7.47	.000***	0.56
Mental QoL	51.1	15.9	60.6	18.5	-4.91	.000***	0.39
Physical QoL	72.5	14.9	75.0	17.7	-1.50	.142	0.06
Total QoL	57.6	14.6	65.1	17.4	-4.39	.000***	0.34
Medication adherence	5.1	2.0	5.7	2.2	-2.03	.049*	0.09

* $p < .05$, ** $p < .01$, *** $p < .001$

Conclusion: Psychological issues are prevalent in patients with IBD and associated with lower quality of life and reduced medication adherence. Women are more likely to participate in psychological screening, and in general the screening approach was widely accepted. In addition, high proportions of patients reported clinical levels of distress (irrespective of their IBD activity) and went on to accept psychological intervention. All of which demonstrates a widespread need for support in this cohort. Furthermore, preliminary data of treatment outcomes are promising. At study completion we will be better able to clarify the extent to which patients with IBD benefit from this new integrated approach.

P0397 LONG-TERM EFFICACY, SAFETY, AND IMMUNOGENICITY DATA FROM A PHASE III CONFIRMATORY STUDY COMPARING GP2017, A PROPOSED BIOSIMILAR, WITH REFERENCE ADALIMUMAB

A. Blauvelt¹, J. Lacour², J. F. Fowler³, E. Schuck⁴, J. Jauch-Lembach⁴, A. Balfour⁴, C. L. Leonardi⁵

Introduction: Demonstration of biosimilarity is based on the evaluation of physicochemical, biological, preclinical, and clinical data. Based on this totality of evidence, a biosimilar may be approved for use in the same indications for which the reference medicine is approved without conducting a clinical trial in each indication. A prerequisite for this extrapolation is clinical confirmation of

biosimilarity in a patient population sensitive enough to detect potential differences in efficacy, safety, or immunogenicity between the proposed biosimilar and the reference medicine. GP2017, a proposed biosimilar to adalimumab, was investigated in patients with chronic plaque psoriasis.

Aims & Methods: To evaluate long-term efficacy, safety, and immunogenicity in patients continuously treated with either GP2017 or reference adalimumab from initial randomization to Week 51. Eligible patients with moderate-to-severe chronic plaque psoriasis were randomized to receive an initial dose of 80mg subcutaneous GP 2017 or reference adalimumab, followed by 40mg every other week, starting one week after the initial dose, up to Week 17. At Week 17, patients with $\geq 50\%$ improvement in Psoriasis Area and Severity Index (PASI 50) at Week 16 were re-randomized in a 2:1 ratio to either remain on their initial study treatment or undergo a sequence of three treatment switches between GP 2017 and reference adalimumab until Week 35. Thereafter, patients were returned to their originally randomized treatment up to Week 51.

Results: From randomization to Week 51, 168 and 171 patients received continuous treatment with GP 2017 or reference adalimumab, respectively. In the per-protocol analysis set, PASI 75 response rates for continual GP2017/reference adalimumab at Weeks 17 and 51 were 75.2%/67.8% and 84.5%/79.6% respectively. Investigator's global assessment (IGA) response rates (IGA score of 0 [clear] or 1 [almost clear] and ≥ 2 point improvement from baseline) were also similar between the continual GP2017/reference adalimumab groups, increasing over time and remaining stable from Week 17 (60.0%/53.9%) to Week 51 (59.8%/55.1%). There were no clinically relevant differences between the continual GP2017/reference adalimumab groups in the frequency of adverse events (AEs) (61.3%/64.9%), treatment-related AEs (17.9%/18.7%), serious AEs (3.0%/8.8%), or AEs leading to discontinuation of study drug (4.8%/7.0%). Infections/infestations were the most commonly reported AEs, with nasopharyngitis most frequently reported by 8.9%/10.5% of patients treated with continual GP2017/reference adalimumab. Between Weeks 1 and 51, binding antidrug antibodies were detected in 38.8%/45.3% of patients treated with continual GP2017/reference adalimumab, 88.7%/84.7% of which were neutralizing.

Conclusion: Efficacy was similar and sustained in patients with psoriasis continuously treated with GP 2017 or reference adalimumab for up to 51 weeks. Safety profiles and immunogenicity were generally similar in both groups. Clinical data add to the totality of evidence suggesting GP 2017 could be used as a biosimilar for the treatment of the same indications for which reference adalimumab is approved, including inflammatory bowel disease.

Introduction: Granulocyte-monocyte apheresis (GMA) can be employed for the treatment of inflammatory bowel disease (IBD), especially for ulcerative colitis (UC). The usual treatment schedule is a weekly session for 5 weeks processing 1800 ml in 60 minutes. It has been described that different factors of the disease and the technique can improve the response to this treatment.

Aims & Methods: We performed a retrospective study of all patients treated with GMA (Adacolumn) in 3 IBD Units in Spain. The clinical and analytical data were assessed before and 1 month after the end of the GMA. The Ethics Committee of Euskadi approved the study protocol. The aim of our study was to evaluate the presence of clinical, analytical of technique-related factors associated to a better response to GMA.

Results: A total of 105 patients were included [51 female (49%), age 35.7 (SD 16.5)]. Ninety-three had UC (50% extensive, 45% left-sided), 10 Crohn's disease (90% ileocolonic) and 2 IBD-U. Mayo score at baseline was 3.5 (SD 4.6) and Harvey – Bradshaw was 10.1 (SD 3.8). The Mayo endoscopic subscore was 1 (16%), 2 (56%) or 3 (27%). Almost all patients (97%) have been previously treated with steroids and 42% were exposed to biologics. At baseline, 85% were on steroids, 38% thiopurines and 18% biologics. None of the previous or concomitant treatments were associated with a better response to GMA. Fifty-six subjects received weekly sessions for 5 weeks processing 1800 ml/session in 60 minutes. Forty patients received an intensive GMA regimen: biweekly sessions with a mean of 8 sessions (SD 2.6), processing 3886 ml/session (SD 1729) and lasting 91 minutes (SD 24). The intensive group showed a slightly higher response rate to GMA as compared with those in the standard regimen (response rate 67% vs 55%, $p=0.28$). Those subjects treated with > 5 sessions showed higher remission (24% vs 13%) and response rates (47% vs 24%) as compared to < 5 sessions ($p=0.004$). A mean duration of > 60 min/session also showed better results in terms of remission (22% vs 16%) and response (45% vs 27%) when compared to < 60 min/session ($p=0.04$). There was also a trend towards higher remission rates in those with higher processed blood volume. Thirty-nine percent were able to wean off steroids completely one month after GMA. We observed a decrease in the mean platelet volume and the platelet to lymphocyte ratio after GMA in those cases who did not respond.

Conclusion: GMA showed its clinical efficacy in this clinical practice study. Increasing the number of sessions or its length were associated with a better response to GMA. The mean platelet volume and the platelet to lymphocyte ratio could help to predict the response.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Circulating and mucosal concentrations of matrix-metalloproteinase-9 (MMP-9) are upregulated in patients with ulcerative colitis (UC) and correlate with disease activity. Selective inhibition or deletion of MMP-9 reduced disease severity in murine models of colitis. Accordingly, MMP-9 has been proposed as a biomarker for disease activity and/or as a treatment target in UC. Andecaliximab (GS-5745) is a monoclonal antibody that selectively binds and inhibits MMP-9. A Phase 1 dose-ranging study of andecaliximab was conducted in UC patients, demonstrating clinical response and remission. We conducted a phase 2 study to further evaluate the safety and efficacy of andecaliximab in subjects with UC.

Aims & Methods: This was a double-blind, randomized, placebo-controlled 8-week induction study in adult subjects with UC with moderate to severe disease activity; defined as an endoscopic score ≥ 2 , rectal bleeding score ≥ 1 , stool frequency score ≥ 1 and physician global assessment of 2 or 3 (using the Mayo score). Subjects were required to have an inadequate response to, or loss of response or intolerance to at least 1 of the following treatments in the last 5 years: corticosteroids, immunomodulators, TNF-alpha antagonist or vedolizumab. Subjects were randomized 1:1 to receive subcutaneous (SC) injections of: placebo, 150 mg andecaliximab every 2 weeks (Q2W) or 150 mg andecaliximab weekly (QW). Centrally-read sigmoidoscopies/colonoscopies were performed at

baseline and week 8. The primary outcome was EBS clinical remission, defined as an Endoscopic subscore of ≤ 1 , rectal Bleeding subscore of 0, and ≥ 1 point decrease in Stool frequency from baseline to achieve a subscore of 0 or 1.

Results: A total of 165 subjects from 23 countries were enrolled. The percentage (confidence intervals) of subjects achieving EBS clinical remission was similar between subjects treated with andecaliximab Q2W, andecaliximab QW and placebo: 7.4% (2.1–17.9%), 1.8% (0–9.6%) and 7.3% (2.0–17.6%), respectively. Confidence intervals overlap for all groups and no single EBS component subscore appears to have driven the results. No concerning imbalances occurred between the treatments groups (Table 1).

	150 mg Q2W N = 54	150 mg QW N = 56	Placebo N = 55
Mayo Clinical Score, mean (SD)	9 (1.3)	9 (1.3)	9 (1.3)
TNF-alpha experienced	53.7%	55.4%	54.5%
Corticosteroid use at baseline	37%	39.3%	30.9%

The frequency of adverse events (AEs) was similar in the andecaliximab Q2W, andecaliximab QW and placebo groups: 53.7%, 58.9% and 60%, respectively. Common AEs included anemia, abdominal pain and nausea. Three AEs led to discontinuation in the andecaliximab QW group compared to one each in the andecaliximab Q2W and placebo groups. Two serious AEs occurred in the andecaliximab QW group (anemia and angina pectoris) compared to one in placebo. Frequency of arthralgia and musculoskeletal pain was similar between andecaliximab and placebo groups.

Conclusion: SC 150 mg andecaliximab was well tolerated; however, neither dosing regimen demonstrated a treatment effect in subjects with UC.

Introduction: Elevated levels of matrix-metalloproteinase-9 (MMP-9) and its degradation products are detected in patients with active Crohn's disease (CD). Selective inhibition of MMP-9 reduced fibrosis in a murine model of intestinal fibrosis, suggesting that MMP-9 may contribute to intestinal complications in CD. Accordingly, MMP-9 has been proposed as a therapeutic target for CD. Andecaliximab (GS-5745) is a monoclonal antibody that selectively binds and inhibits MMP-9. It was found to be safe in a phase 1 dose-ranging study in UC subjects, where it showed clinical response and remission compared to placebo. The aim of this phase 2 study was to evaluate the safety and efficacy of andecaliximab in subjects with moderately to severely active CD.

Aims & Methods: This was a double-blind, randomized, placebo-controlled 8 week induction study in adult CD subjects with moderate to severe disease activity (defined as: CDAI total score 220–450, weighted PRO2 score ≥ 11 [standard CDAI weightings: abdominal pain 0–3 x7 plus mean number of daily stools x2] and SES-CD total score ≥ 6 [or ≥ 4 score if disease limited to ileum and/or right colon or ulcer presence and size score ≥ 2]). Subjects were required to have an inadequate response, or loss of response or intolerance to at least 1 of the following treatments in the last 5 years: corticosteroids, immunomodulators, TNF-alpha antagonist or vedolizumab. Subjects were randomized 1:2:2 to receive subcutaneous (SC) injections of: placebo, 150 mg andecaliximab every 2 weeks (Q2W), 150 mg andecaliximab weekly (QW) or 300 mg andecaliximab QW. Centrally-read colonoscopies were performed at baseline and week 8. Co-primary outcomes were clinical response (PRO2 score of ≤ 8 at week 8) and endoscopic response (SES-CD decrease of $\geq 50\%$ from baseline at week 8).

Results: A total of 187 subjects were enrolled from 13 countries. No concerning baseline imbalances occurred between the treatment groups, overall: 17.6% of subjects had evidence of fistula at screening, mean (SD) disease duration was 12 (9.5) years, 84.5% of subjects had previous exposure to TNF-alpha antagonist and 44.4% of subjects were taking oral corticosteroids at baseline. The

Abstract No: P0400

Number (%) of Subjects Achieving [confident intervals]	150 mg Q2W N = 53	150 mg QW N = 53	300 mg QW N = 53	placebo N = 28
PRO2 score of ≤ 8	9 (17.0%) [8.1–29.8]	7 (13.2%) [5.5–25.3]	6 (11.3%) [4.3–23.0]	4 (14.3%) [4.0–32.7]
$\geq 50\%$ decrease in SES-CD	6 (11.3%) [4.3–23.0]	7 (13.2%) [5.5–25.3]	4 (7.5%) [2.1–18.2]	3 (10.7%) [2.3–28.2]
CDAI ≤ 150	11 (20.8%) [10.8–34.1]	9 (17.0%) [8.1–29.8]	6 (11.3%) [4.3–23.0]	6 (21.4%) [8.3–41.0]

The frequency of adverse events (AEs) was similar between the treatment groups: placebo (67.9%), 150 mg Q2W (60.4%), 150 mg QW (62.3%), 300 mg QW (69.8%). Common AEs included abdominal pain, nausea, fatigue, anemia and pyrexia. One AE led to study discontinuation in the placebo group (3.6%) compared to 2 in the 150 mg QW group (3.8%) and 4 in the 300 mg QW group (7.5%). Three serious AEs occurred in the placebo group (10.7%) compared to 1 in the 150 mg Q2W group (1.9%), 6 in the 150 mg QW group (11.3%) and 8 in the 300 mg QW group (15.1%). Frequency of arthralgia and musculoskeletal pain was similar or lower in andecaliximab groups compared to placebo.

percentage of subjects achieving clinical response/remission and endoscopic response was similar between treatment groups (Table 1).

Conclusion: SC andecaliximab was well tolerated; however, none of the treatment regimens demonstrated a treatment effect in subjects with CD.

P0401 TUBERCULIN SKIN TEST CONVERSION RATE IN INFLAMMATORY BOWEL DISEASE PATIENTS RECEIVING ANTI-TNF ALPHA AGENTS

M. Fragkaki, A. Mpitouli, I. Dimas, G. Paspatis, K. Karmiris
Gastroenterology, Venizeleion General Hospital, Heraklion/Greece

Contact E-mail Address: gpaspatis@gmail.com

Aims & Methods: Few data exist regarding the kinetics of this test during therapy. Therefore, our study investigated the conversion rate of PPD-TST in IBD patients under anti-TNF α treatment. Anti-TNF α -treated IBD patients followed up in our centre with a baseline PPD-TST underwent a second one during therapy. Those with a positive PPD-TST either at baseline or during therapy ($d > 10$ mm in naïve and $d > 5$ mm in those exposed to immunomodulators [IMS]) received 300 mg isoniazid orally for 9 months.

Introduction: Anti-TNF α therapy increases the risk of tuberculosis (TB) (re-)activation in inflammatory bowel disease (IBD) patients. Purified protein derivative tuberculin skin test (PPD-TST) is considered a pre-requisite at baseline.

Results: Sixty-eight IBD patients have currently been enrolled (males: 51.47%, Crohn's disease: 82.35%). Median age at IBD diagnosis was 33.1 years [IQR: 20.3, range: 16.7–66.7]. Median duration of IBD was 7.7 months [IQR: 9.8, range: 1.4–32.7]. Nine patients (13.23%) had a positive PPD-TST at baseline, 48 patients have undergone a 2nd PPD-TST (median time between the 1st and 2nd PPD-TST: 44.26 months [IQR: 42.8, range: 6.3–190.1]). Twenty patients were under combination therapy with an IMS at the 2nd PPD-TST. Six patients with a positive baseline PPD-TST remained positive (in 5 patients the diameter was decreased & in one increased 7 mm). Out of the remaining 42 patients with a negative baseline PPD-TST, eight (19%) exhibited a positive 2nd PPD TST; three of them were receiving infliximab for less than 3 years and five of them adalimumab (2 for less and 3 for more than 3 years). Only 2/8 were under combination therapy. There was no case of active tuberculosis during the study. All patients with a PPD-TST conversion received anti-tuberculous treatment.

Conclusion: A positive PPD-TST followed by anti-TB treatment before the initiation of anti-TNF α in IBD patients was not associated with an increased rate of TB infection during therapy. One-fifth of the patients with a negative baseline PPD-TST demonstrated a conversion but without any undesirable consequence if so treated. Therefore, the kinetic of PPD-TST in IBD patients under anti-TNF α treatment should be monitored.

Introduction: Adalimumab and anti-adalimumab-antibodies (AAA) levels have been associated with clinical outcome of Crohn's disease (CD). Nevertheless, because adalimumab is usually self-injected at home, prospective serial-sampling studies are scarce. Thus, data on the temporal evolution of adalimumab immunogenicity is still limited, and the validity of comparisons of adalimumab versus infliximab immunogenicity remains questionable.

Aims & Methods: Our aim was to assess trends in adalimumab and AAA levels over time and their clinical implications. CD patients starting adalimumab therapy were followed prospectively in three participating medical centers in Israel, by establishing a program for home-visits by physicians at induction and every 3 months, or in case of relapse. At each home visit, patients' clinical activity scores were determined and blood tests obtained for CRP, drug and AAA trough levels. AAA levels were determined by a drug-tolerant assay. A comparison with temporal evolution of infliximab immunogenicity in a previously reported cohort using the same assay and methodology was additionally performed.

Results: 102 CD patients starting adalimumab were prospectively followed. Fourteen (14%) experienced primary non-response and 20 (20%) lost response to adalimumab therapy during maintenance. Thirty-three (32%) developed AAA, which were more common among those previously exposed to adalimumab ($p = 0.002$) but were not affected by co-treatment with immunomodulators or not ($p = 0.28$). AAA developed as early as week 2 in 18/33 (55%) of AAA positive patients (7/18 with history of interrupted therapy), and in 26/33 (79%) within week 14. Patients with week 2 AAA had 34% of primary non-response compared to 9% in patients without early AAA (OR = 4.8, $p = 0.009$). In 92.6% of cases, AAA preceded loss-of-response or occurred simultaneously (median interval - 4 weeks). As compared to antibodies-to-infliximab (ATI), AAA formation rate over time was significantly lower ($p = 0.01$, log rank test), and some patients developed AAA even after one year of therapy. Transient AAA were much less common than transient ATI (7% vs 32%, $p < 0.0001$), and 85% of AAA events were associated with loss of response compared with 58% rate for ATI ($p = 0.01$).

Conclusion: AAA formation often occurs earlier than appreciated, and associates with primary non-response to adalimumab induction. Overall rate of immunogenicity is lower for adalimumab compared to infliximab. However, once they occur, AAA are more specific than ATI.

Introduction: Golimumab (GLB) has been the last anti-TNF agent authorized for the treatment of Ulcerative Colitis (UC). Results from registry trial (PURSUIT) documented a clinical response in 51% of patients after 6 weeks

of GLB with 47–49% of patients maintaining the effect after one year. Due to its relatively recent use there are still few real-life data on clinical outcomes of patients receiving golimumab in the routinely activities. In our region GLB became available starting July 2015.

Aims & Methods: Aim of this study has been to prospectively evaluate the efficacy and safety of golimumab for the treatment of UC in the real-life setting of our referral centre. 13 patients (7 male, 4 female) with moderate-to-severe UC were enrolled in the study from June 2015 to December 2016. Patients received an induction dose of GLB 200 mg s.c. at baseline, 100 mg at week 2 and then a monthly dose of 50 mg or 100 mg for a body weight < or > 80 kg, respectively, with no optimization allowed. Partial Mayo score was computed at baseline and every 2 weeks for the first 6 weeks of therapy, then every 4 weeks throughout the maintenance period. Follow-up is still ongoing. Primary end point has been the clinical response at the end of the induction phase (intended as the reduction of Partial Mayo score >30% and >3 points vs baseline) and in the maintenance period, the secondary end point being the steroid-free clinical remission (Partial Mayo score <2 with all subscores <1) at the end of the induction phase and throughout the maintenance phase. Complete follow-up is available for all patients at week 30, with 4 patients reaching the week 54 of monitoring.

Results: At the time of GLB starting, localization of the disease according to Montreal classification was left-sides colitis (E2) in 70%, pancolitis (E3) in 23% and proctitis (E1) in 7% of patients. Ten patients (77%) were anti-TNF naïve, 3 patients (23%) had already received one anti-TNF in the past. Clinical response was obtained in 6/13 (46%) at week 6 and in 2 further patients at week 10, for a total of 8/13 (62%). Three patients resulted in complete clinical steroid-free remission after 6 weeks. At week 30, 5 patients still showed a clinical response (38%), one of them (7%) resulted in complete steroid-free remission. Among the 4 patients reaching week 54, 2 experienced a flare of disease whereas 2 were still in remission (16%); the last patient is in remission at week 42, potentially accounting for a total of 3/13 patients in remission after one year (23%). No differences were found between naïve and non-naïve patients. No significant adverse events were reported in the study period.

Conclusion: Our real-life data seem to suggest that Golimumab, as compared to registry trials, is able to induce a better initial clinical response but shows a higher secondary loss of response in the long term. Whether this really reflects a lower efficacy of GLB or could depend on the unavailability of dose optimization, not allowed in the Italian prescription rules for GLB, needs to be evaluated.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The Observational Postmarketing Ulcerative colitis Study (OPUS) registry was conducted to collect long-term (5 years) real-world clinical practice safety data in patients with moderate to severe ulcerative colitis (UC) treated with originator infliximab and to compare this safety profile to that of UC patients treated with standard therapies.

Aims & Methods: The OPUS registry was a prospective, non-randomized, observational study that followed patients with UC (in routine practice in 14 European countries) who were enrolled to receive treatment with either originator infliximab or standard therapy (defined as initiation or dose-increase of corticosteroids and/or immunosuppressants), as determined by their treating physician. Adverse events (AEs) were recorded during the 5-year follow-up period; at any time during the 5 years of observation, the patient's therapy could be changed to any other UC therapy, based on the physician's clinical judgment. Frequency of events was evaluated in nine pre-specified categories (serious infection, infusion-related reaction, fatality, worsening or new case of congestive heart failure (CHF), central and peripheral demyelinating neurological disorder, hematologic condition, malignancy/lymphoproliferative disorder, autoimmune disorder, or hepatobiliary event). Multivariable Cox proportional hazards (PH) models assessed time-to-first AE for the originator infliximab and standard therapy groups, using an intent-to-treat approach, in eight of the pre-specified categories (infusion-related reactions were not compared between originator infliximab and standard [i.e., generally oral] therapies); p-values were not adjusted for multiple comparisons. Safety data were collected every 6 months.

Results: Data for 2239 patients were available: 1180 patients enrolled to standard therapy (including 296 patients who switched to originator infliximab during follow-up) and 1059 patients enrolled to originator infliximab. Patients who received originator infliximab, standard therapy, or who were switched to originator infliximab during follow-up on standard therapy, were followed for medians of 59.4, 50.6, and 49.8 months, respectively. However, median exposure to

infliximab was 19.8 and 15.9 months in the originator infliximab and switched-to-originator infliximab groups, respectively. Patients enrolled in the originator infliximab group, compared with the standard therapy group, had more severe disease at baseline, based on partial Mayo score (PMS): 46.0% of patients in the originator infliximab group had severe disease (PMS of 7–9 [out of 9]), compared with 30.5% in the standard therapy group. In time-to-event analyses adjusting for risk factors/confounders, enrollment into the originator infliximab group was associated with a higher risk of serious infection (hazard ratio = 2.08, 95% confidence interval [CI] 1.42, 3.06; p < 0.001) compared with enrollment into the standard therapy group (Table). No notable risk differences between groups were identified for hematologic condition, autoimmune disorder, malignancy/lymphoproliferative disorder, hepatobiliary event, and fatality (Table). Because of very low incidence of AEs in the categories of CHF and demyelinating disorder (€0.3% in each group), meaningful multivariable time-to-event analyses could not be performed for these categories.

Conclusion: Data from 5-year safety follow-up of patients with moderate to severe UC in this non-randomized registry population demonstrate that, compared with the standard therapy group, the patients enrolled to receive originator infliximab had an increased risk of serious infection. This finding is consistent with the previously established safety profile for originator infliximab in the treatment of UC. In this large registry, the originator infliximab group, compared with the standard therapy group, did not have a significantly increased risk of a hematologic condition, autoimmune disorder, malignancy/lymphoproliferative disorder, hepatobiliary event, CHF, demyelinating disorder, or fatality. No new safety concerns were observed with originator infliximab in the OPUS registry.

Introduction: Several oral mesalazine utilise pH-dependent release coating to optimise mucosal delivery of active drug. Little data currently exist on concurrent intestinal pH and transit times in patients with UC to predict likely efficacy-based delivery profiles. No studies have accounted for acute variations in dietary fibre intake, which might affect regional transit and pH profiles.

Aims & Methods: This study aimed to (1) to examine regional luminal pH and transit after acute changes in fibre intake in quiescent UC patients; and (2) deduce delivery of topically-acting drugs using published pharmacokinetic (PK) data. In this randomised, double-blind study, patients with UC in clinical remission (partial Mayo Score ≤1 + faecal calprotectin <150 µg/g) without recent antibiotic (including sulfasalazine), probiotic or fibre use were recruited. After a 7-day run-in, subjects were supplied with study meals containing high (13 g oligosaccharides and resistant starch) (HF) or low (<1 g) fermentable fibre (LF) over a 12-h period prior to the ingestion of a pH-motility capsule (Smart Pill). Telemetric recordings were made for 5 days or until the capsule had been excreted. After a ≥3-day washout period, they crossed-over to the other dietary arm and pH-motility test. Small and large intestinal pH profiles were defined as the length in time (h) of different intraluminal pH ranges – pH <6, ≥6 to <7 and ≥7 and compared between diets. Using published PK of pH-dependent coated mesalazine preparations, the patterns of dissolution in UC patients were estimated.

Results: In 15 patients (aged 24–72 y; 9 males – 5 extensive, 5 distal and 5 proctitis), acute HF intake significantly increased median (IQR) time for colonic pH < 6 [HF: 4.5 (2.4–10.2) vs LF: 0.9 (0.2–3.1) h; p = 0.004, Wilcoxon], tended to increase colonic pH ≥ 6 to < 7 [HF 7.5 (6.3–13.5) vs LF: 7.1 (3.4–15.2) h] and had no impact on colonic pH ≥ 7 [HF: 4.8 (2.1–8.1) vs LF: 1.2 (1.0–11.4)]. Table 1 summarises hypothetical dissolution profiles for pH-coated mesalazine in patients with UC. Considerable variations across release mechanisms were evident, but, despite alterations in pH and transit, the patterns were not affected by diet for Eudragit L alone or with slow release mechanisms. Only minor differences were found for Eudragit S and MMX.

Conclusion: Current delivery mechanisms for mesalazine lead to a proportion of quiescent UC patients having incomplete release and suboptimal regional

	Pre-specified Category of Adverse Event					
	Serious Infection	Hematologic Condition	Autoimmune Disorder	Malignancy/Lympho-proliferative Disorder	Hepatobiliary Event	Fatality

Introduction: Golimumab (GLM) is a subcutaneously administered anti-tumor necrosis factor (anti-TNF) antibody that is approved for the treatment of moderate to severe ulcerative colitis (UC). We investigated the association between systemic exposure (area under the curve (AUC)) of GLM during induction therapy and endoscopic response in moderate-severe UC.

Aims & Methods: In this prospective observational trial, patients with moderate to severe UC (Mayo endoscopy score ≥ 2) received induction treatment with GLM 200 mg SQ (at week 0) and 100 mg (at week 2) followed by 50 or 100 mg at week 6, in patients with a bodyweight of less or more than 80 kg, respectively. Serum GLM concentrations were measured at day 0, 4, 7, 14, 18, 28, 42 and 56, as well as anti-GLM antibody levels, C-reactive protein (CRP) and albumin serum concentrations. Serum GLM concentrations were measured with an enzyme-linked immunoassay and anti-GLM antibody levels were measured with a drug-sensitive antigen binding test, both developed by Sanquin laboratories. Endoscopic response was defined as ≥ 1 point reduction in endoscopic Mayo score at week 8–10 compared to baseline. AUCs were calculated using nonlinear mixed effect modelling (NONMEM®) and were compared using the non-parametric Mann-Whitney U test. Correlation analysis was performed using Pearson's correlation coefficient. A receiver-operating characteristic (ROC) curve reported the predictive performance of GLM serum trough levels at week 2 and 6 for endoscopic response.

Results: A total of 20 patients were enrolled of which 19 patients underwent an endoscopy at baseline and 8–10 weeks after start of treatment. Median age (interquartile range) was 46 years [36–57], median baseline CRP serum concentration was 4.5 mg/L [1.1–13.7] and median baseline albumin serum concentration was 44 g/L [40–45]. None of the patients developed antibodies against GLM during induction treatment. After the induction phase, 12 out of 19 patients (63%) achieved an endoscopic response. Median AUC at week 2 and 6 was higher in endoscopic responders compared to non-responders. Median GLM trough concentrations at week 2 and 6 were higher in endoscopic responders compared to non-responders (Table 1). Correlations between GLM trough concentrations and AUCs at week 2 (Pearson correlation coefficient: 0.86, $P < .0001$) and week 6 (Pearson correlation coefficient: 0.81, $P < .0001$) were statistically significant. Despite a low area under the ROC-curve (AUROC), a GLM serum trough concentration ≥ 6.6 mg/L at week 2 (AUROC: 0.68, 95% CI: 0.43–0.927, sensitivity: 75%, specificity: 57%) was associated with endoscopic response after the induction phase. At week 6, a GLM serum trough

concentration ≥ 3.3 mg/L (AUROC: 0.75, 95% CI: 0.526–0.974, sensitivity: 67%, specificity: 71%) was associated with endoscopic response after the induction phase.

Table 1: Median golimumab trough concentrations and AUCs at week 2 and 6

	Endoscopic responders median [IQR]	Endoscopic non-responders median [IQR]	P-value
AUC (mg/L/day), week 2	134 [102–170]	94 [80–169]	.48
AUC (mg/L/day), week 6	333 [250–476]	212 [206–417]	.21
Serum trough concentration (mg/L), week 2	9.1 [6.1–10]	6.1 [5.2–9.0]	.20
Serum trough concentration (mg/L), week 6	3.8 [2.6–6.0]	2.4 [1.1–3.8]	.08

Conclusion: Serum trough concentrations of GLM and AUCs at week 2 and 6 were higher in endoscopic responders compared to patients without an endoscopic response. A significant correlation was found between GLM trough concentrations and AUC. A GLM trough level ≥ 3.3 mg/L at week 6 is associated with improved endoscopic outcomes.

Introduction: Tofacitinib is an oral, small molecule Janus kinase inhibitor being investigated for moderately to severely active ulcerative colitis (UC). We performed a systematic literature review (SLR) and network meta-analysis (NMA) to compare the efficacy and safety of tofacitinib to available tumour necrosis factor inhibitors (TNFi) and integrin receptor antagonists for induction therapy of adults with moderately to severely active UC.

Aims & Methods: Using indexing and free-text terms, searches were conducted in the EMBASE, MEDLINE, CENTRAL, DARE and CINAHL databases to identify RCTs published as of January 2015. Proceedings of relevant conferences from 2012–2014 were also reviewed. Comparators of interest were infliximab, golimumab, adalimumab and vedolizumab. Two reviewers independently assessed studies for inclusion, and extracted and validated the study/patient data. Fixed- and random-effects Bayesian NMAs were conducted to compare efficacy outcomes and rates of adverse events (AEs) at 6–12 weeks in the overall population (TNFi-naïve or exposed) and by prior TNFi exposure.

Abstract No: P0405**Table 1:** Hypothetical dissolution profiles UC patients (n = 15)

Dissolution characteristics	Eudragit L	Eudragit L with slow release	Eudragit S	Multi-matrix (MMX)
<i>Hypothetical complete dissolution</i>	<i>pH ≥ 6 for 1 h</i>	<i>pH ≥ 6 for 4–5 h</i>	<i>pH ≥ 7 for 2–4 h</i>	<i>pH ≥ 7 for 6 h</i>
Complete in small intestine	67%	100%	HF 25%; LF 19%	HF 0%; LF 13%
Complete dissolution	100%	HF 97; LF 100%	HF 80; LF 87%	HF 53; LF 67%

Results: Twelve induction trials were identified from the SLR (ACT 1 & 2, EUCALYPTUS, GEMINI-I, PURSUIT SC, TOFACITINIB PHASE 2, Feagan 2005, ¹ Probert 2003, ² UC-SUCCESS, ULTRA 1, ULTRA 2, Suzuki 2014³) and included in the NMA. Unpublished data from tofacitinib Phase 3 induction trials (OCTAVE 1 & 2) were also used in the analysis. Fixed-effects NMA showed that tofacitinib 10 mg twice daily (BID) is associated with a higher rate of mucosal healing vs adalimumab 160/80/40 mg in the overall population (odds ratio [OR] 1.82 [95% credible interval (CrI) 1.06, 3.14]), and vs vedolizumab 300 mg (OR 3.71 [95% CrI 1.37, 10.64]) and etrolizumab 300 mg (OR 12.09 [95% CrI 1.68, 122.73]) in TNFi-exposed patients. A higher rate of clinical remission was seen with tofacitinib 10 mg BID vs adalimumab in TNFi-exposed patients (OR 11.93 [95% CrI 1.84, 154.78]). AE rates were similar between tofacitinib 10 mg BID and comparators in the overall and TNFi-naïve populations when analysed individually, but tofacitinib 10 mg BID was found to be associated with a higher rate of disaggregated AEs (“any AE”) than etrolizumab 300 mg in the overall population (OR 2.78 [95% CrI 1.08, 7.41]). There were no statistically conclusive differences in the rates of specific AEs between tofacitinib 10 mg BID and comparators.

Conclusion: This NMA suggests that tofacitinib may be more effective as induction therapy in moderately to severely active UC than adalimumab and vedolizumab in TNFi-exposed patients, and is associated with a higher rate of mucosal healing than adalimumab in the overall population. Rates of specific safety events were similar between tofacitinib and other treatments.

Introduction: Patients with inflammatory bowel disease (IBD) experience higher rates of *C. difficile* infection (CDI) than the overall population, often lack typical risk factors, and frequently experience severe and recurrent episodes. MODIFY I/II were global trials of the efficacy and safety of bezlotoxumab (bezlo: a human monoclonal antibody against *C. difficile* toxin B), in which bezlo was superior to placebo at preventing CDI recurrence (rCDI) in participants with primary or recurrent CDI given antibacterial drug treatment for CDI. Participants with IBD

could be enrolled if, in the opinion of the investigator, symptoms were more likely due to CDI than IBD.

Aims & Methods: The objective of this post-hoc subgroup analysis was to summarize CDI-related outcomes, including initial clinical cure and rCDI, through 12 weeks in participants with IBD enrolled in the MODIFY trials. CDI-related outcomes through 12 weeks in the subset of IBD participants enrolled in the MODIFY trials included: initial clinical cure (no diarrhea during the 2 consecutive days following completion of ≤14 days of an antibacterial drug treatment for CDI); and rCDI (new episode of diarrhea associated with a positive stool test for toxigenic *C. difficile* in participants who had achieved initial clinical cure). For this post-hoc analysis, participants randomized to bezlo or actoxumab + bezlo were pooled and are referred to as the “bezlo” group and participants randomized to placebo or actoxumab were pooled and are referred to as the “no bezlo” group.

Results: Overall, 2559 participants were included in the mITT population; 1554 participants were randomized to a bezlo group and 1005 were randomized to a no bezlo group. There were 44 participants with IBD: 23 (52.3%) had ulcerative colitis; 18 (40.9%) had Crohn’s disease; and 3 (6.8%) had non-characterized IBD. Compared with participants without IBD, participants with IBD tended to be younger, were more often treated as outpatients, were more often immunocompromised, and a smaller percentage had severe CDI. Among IBD participants, a higher proportion had initial clinical cure in the no bezlo group compared with the bezlo group and there was a higher proportion of participants with rCDI in the no bezlo group compared with the bezlo group. In IBD participants who did not receive bezlo, most of the recurrences (5 of 7) occurred within 4 weeks after study infusion, while most of the recurrences among participants who received bezlo occurred after week 4 (3 of 4).

Conclusion: Participants with IBD and CDI enrolled in the MODIFY trials were younger, more likely to be diagnosed with CDI as an outpatient, to be immunocompromised, and to develop rCDI compared with non-IBD participants. Bezlo yielded a 27.2% absolute reduction (50% relative reduction) in the incidence of rCDI in participants with IBD. The efficacy of bezlo in preventing rCDI may extend to patients with IBD, but additional data are needed due to the limited cohort size.

	IBD n=44	No IBD n = 2515

P0409 SIMILAR TRIAL - EFFICACY OF INFLIXIMAB-BIOSIMILAR COMPARED TO INFLIXIMAB-BIOLOGICAL IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE IN REMISSION - A RANDOMIZED, CONTROLLED, DOUBLE BLIND, PHASE 4 NONINFERIORITY TRIAL

Introduction: Crohn's disease (CD) and ulcerative colitis (UC) are the main entities of inflammatory bowel disease (IBD). For most patients, medical treatment is sufficient to keep the disease in remission. In both diseases tumor necrosis factor- α (TNF- α) inhibitors, such as Infliximab (IFX), are a major component in inducing and maintaining remission in more refractory patients. Recently IFX-biosimilars have been introduced for the treatment of IBD, these are less expensive than IFX-biologicals. Efficacy of IFX-biosimilar and IFX-biological have been compared for ankylosing spondylitis and rheumatoid arthritis showing no difference between efficacy and safety. So far, no double blind randomized clinical trial has been published that compared IBD patients who used IFX-biological or IFX-biosimilar. Cohort studies in IBD patients showed switching from IFX-biologicals to IFX-biosimilar had no impact on short-term clinical outcomes. The aim of this study was to examine non-inferiority in safety and efficacy of IFX-biosimilar compared with IFX-biologicals and to evaluate adverse effects and pharmacokinetics.

Aims & Methods: We randomized patients with CD or UC in clinical and biochemical remission to either switch to IFX-biosimilar or to continue using IFX-biological. Randomization was performed in a 2:1 ratio (65% to IFX-biosimilar). Patients in both arms received 4 to 6 doses of 5 mg/kg to 10 mg/kg during the 30-week study period. Patients eligible for inclusion had to be in clinical remission (HBI < 5 and MAYO < 2) and have a fecal calprotectin < 250 mg/g. The primary endpoint was number of patients in remission at week 30. We measured C-reactive protein [CRP], fecal calprotectin [FCP], infliximab trough level [TL] and anti-drug antibodies [ADAs]. Patients were asked to fill in SIBDQ and Mayo or HBI questionnaires three times during the study period. Adverse events (AE) and serious adverse events (SAE) that patients experienced were documented.

Results: So far, we included 47 patients from 6 secondary Dutch Teaching hospitals. 35 patients had CD and 12 had UC. 27 patients were female, 20 were male. Mean age at inclusion was 42 years. 21 patients have finished the 30-week follow-up. 15 received IFX-biosimilar, 6 IFX-biological. One patient experienced relapse of IBD, this patient received IFX-biosimilar. 2 patients experienced a SAE, none were related to the study drug.

Conclusion: This is the first double blind randomized clinical trial that compares treatment of IBD with IFX-biological or IFX-biosimilar. The preliminary results show that switching from IFX-biological to IFX-biosimilar is feasible and safe.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0411 ENCAPSULATED FECAL MICROBIOTA TRANSFER IN PATIENTS WITH CHRONIC, ANTIBIOTIC-REFRACTORY POUCHITIS

A. Steube¹, M. Vital², A. Sturm³, C. Buening⁴, A. Stallmach¹, D. Pieper²

Introduction: We analyzed the success of fecal microbiota transfer (FMT) via encapsulated or endoscopic jejunal application to 14 patients with chronic, antibiotic refractory pouchitis.

Aims & Methods: FMT was performed either via encapsulated cryopreserved microbiota or via endoscopic jejunal application to 14 patients. Stool samples for FMT preparation derived from three unrelated healthy donors. Patients were treated by FMT every 4 weeks according to the individual therapeutic outcome. Stool samples before FMT and during follow-up were subjected to microbial community structure analysis through high throughput sequencing of the V1-2 regions of the 16S rRNA (1), clinical response and mucosal inflammation was assessed by fecal calprotectin (FCP) levels.

Results: Clinical response occurred in 7 of 14 patients after two to four FMTs. 4 patients showed clinical worsening and 3 patients showed no improvement. FCP dropped in responders from 536 mg/kg stool (med.; min-max: 116-3000) to 150 mg/kg (191-1409), whereas in patients with flare FCP values increased from 1005 mg/kg (529-1579) to 1450 mg/kg (1221-1778). Microbiota analysis of 10 patients and two donors revealed a significantly lower diversity in pouchitis patients compared to healthy donors as assessed by the total phylotype number, the Shannon diversity and Pielou's evenness. In patients showing response, typically a significant increase in diversity was observed. This increase in diversity was due to the successful establishment of the donor microbiota as assessed by the analysis of sample-similarity matrices constructed using the Bray-Curtis algorithm and a detailed analysis of the taxonomic composition. The encapsulated

fecal microbiota was as effective as the endoscopic jejunal application in its competence to restructure the patients microbiota. However, an increase in the diversity and an overall restructuring of the microbiota into a composition resembling the donor not necessarily correlated with clinical outcome and clinical worsening was observed during three FMTs where the established microbiome structure resembled that of the healthy donor in diversity and composition. Interestingly, a high abundance of Ruminococcaceae was associated with remission in a recent study on ulcerative colitis (2). However, two patients showed worsening here despite a high increase in the relative abundance of Ruminococcaceae after FMT.

Conclusion: Fecal microbiome transfer in patients with chronic pouchitis is a promising therapeutic option and donor microbiomes could successfully be transferred via capsules or via jejunoscopes delivering fresh stool filtrate. However, a simple increase in microbial diversity and successful establishment of members of the butyrate producing Lachnospiraceae and Ruminococcaceae families is not sufficient for a successful outcome of FMT.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Mucosal healing (MH) has been established as co-primary treatment target in Crohn's disease, predominantly defined by the absence of ulceration. However, even in patients with MH, inflammation may persist on histologic examination¹. Filgotinib (FIL), a selective inhibitor of JAK1 that blocks cytokine signaling through inhibition of STAT phosphorylation, has recently shown efficacy in a double-blind, placebo (PBO)-controlled Phase 2 study in CD (FITZROY²). Effects of filgotinib versus placebo have been demonstrated on centrally read endoscopy and histopathology assessments after a 10-week induction treatment.

Aims & Methods: In this post hoc analysis, we explored the correlation between histologic and endoscopic disease activity at baseline (BL) and following FIL induction therapy by comparison of total ileal Global Histology Activity Score (IGHAS)/colonic GHAS (CGHAS) score or IGHAS/CGHAS activity subscores (a; activity items: presence of epithelial damage, polymorphonuclear leukocytes in lamina propria, neutrophils in epithelium, erosion or ulceration, granuloma³.) versus total ileal Simplified Endoscopic Score for CD (ISES-CD)/colonic SES-CD (CSES-CD) score or ISES-CD/CSES-CD ulcer subscores (u; sum of size and % affected surface). CD patients were randomized 3:1 to receive 200 mg FIL or PBO QD for 10 weeks². Intestinal biopsies were collected at BL and Week 10 (W10) from the most affected areas of each predefined bowel segment (ileum, ascending, transverse, descending, sigmoid colon and rectum). Biopsies were formalin fixed and paraffin embedded. The mean changes from baseline for each treatment group were compared to zero using a one-sample t-test.

Results: Baseline values were comparable across treatment groups, although CGHAS and CSES-CD were numerically higher in the PBO group (Table 1). Following 10 weeks of treatment with FIL 200 mg, histologic measures of colonic mucosal inflammation (CGHAS and aCGHAS) were significantly improved and were coupled with macroscopic changes in both CSES-CD and uCSES-CD. Changes in histology score for ileal segments were numerically greater after FIL treatment versus placebo. Histology total and subscores were significantly associated with total and endoscopic ulcer subscores at both time points, and more pronounced when looking into the colonic segments versus the ileal segments (IGHAS v ISES-CD: Corr = .062, p < 0.001; Corr = .065, p < 0.001; BL and W10 respectively)(aIGHAS v uISES-CD: Corr = 0.53, p < 0.001;

Abstract No: P0412

	Mean (SD)	IGHAS		CGHAS		ISES-CD		CSES-CD	
		PBO	FIL	PBO	FIL	PBO	FIL	PBO	FIL
Total Score	Baseline	4.10 (3.94)	3.94 (3.74)	21.10 (19.26)	14.69 (12.25)	4.13 (3.32)	4.41 (3.53)	11.91 (8.31)	9.63 (8.04)
	ΔW10	0.24 (3.66)	-0.37 (3.69)	-0.81 (14.72)	-4.83(11.07)	-0.30 (1.72)	-0.18 (2.27)	-2.09 (6.62)	-2.68 (4.90)
	N	21	52	21	52	23	76	23	76
Subscore*	Baseline	2.57 (2.56)	2.27 (2.67)	13.76 (13.05)	9.33 (8.47)	2.39 (1.90)	2.55 (2.07)	7.22 (5.23)	6.09 (5.34)
	ΔW10	0.10 (2.84)	-0.23 (2.95)	-0.86 (10.79)	-3.48 (8.28)	0.00 (0.95)	-0.21 (1.51)	-1.70 (4.37)	-1.76 (3.64)
	N	21	52	21	52	23	76	23	76

Only subjects with non-missing data for all segments at BL and W10 were included in the calculation;*Subscore for GHAS data is activity subscore and for SES-CD data is ulcer subscore; bolded texts indicate p-value <0.05 from t-test

Corr = 0.43, $p < 0.001$; BL and W10 respectively) (CGHAS v CSES-CD: Corr = 0.80, $p < 0.001$; Corr = 0.77, $p < 0.001$; BL and W10 respectively) (aCGHAS v uCSES-CD: Corr = 0.77, $p < 0.001$; Corr = 0.70, $p < 0.001$; BL and W10 respectively).

Conclusion: Improvements in endoscopic severity induced by filgotinib are paralleled by reductions of histologic scores. In line with previous findings from anti-TNF therapies^{4, 5} colonic mucosa is more prone to improve than ileal disease. Spontaneous reductions of histologic activity under placebo were not observed.

Introduction: Ustekinumab (UST) has been shown to induce and maintain clinical response and remission in moderate to severe Crohn's disease (CD) in 2

induction [(UNITI-1 (anti-TNF failures) and UNITI-2 (anti-TNF non-failures) and 1 maintenance (IM-UNITI)] randomized, placebo controlled Phase 3 trials. We evaluated the efficacy (response and remission) for all patients who received an intravenous (IV) induction dose of approximately 6 mg/kg, including responders (CDAI decrease ≥ 100) and non-responders, 8 weeks after the first UST maintenance dose of 90 mg subcutaneous (SC), i.e. 16 weeks from the IV induction dose.

Aims & Methods: Patients achieving clinical response 8 wks after a single IV induction dose were randomized to SC placebo (PBO), UST 90 mg every 12 weeks (q12w) or every 8 weeks (q8w). UST patients not in clinical response 8 weeks after the IV induction dose were given UST 90 mg SC and if in clinical response 8 weeks later were continued on 90 mg SC q8w dosing. A total of 458 patients were exposed to an IV induction dose of 6 mg/kg (UNITI-1, N = 249 and in UNITI-2, N = 209) with a response rate at week 8 of 37.8% and 57.9% vs. PBO response rate of 20.2% and 32.1% respectively. The remission rate at week 8 in UNITI-1 and UNITI-2 was 20.9% and 40.7 vs. PBO of 7.3% and 19.6% respectively. For this evaluation, the response and remission status of the entire population exposed to an IV induction dose of 6 mg/kg of UST was evaluated 8 weeks after the first subcutaneous maintenance dose of UST. All patients who received 6 mg/kg IV UST induction were included, including responders randomized to SC PBO (who did not receive SC UST at week 8).

Results: Of the 219 patients not in clinical response in UNITI 1&2, 37.6% and 60.5% respectively were in clinical response 8 weeks after the first maintenance UST dose (90 mg SC). Evaluating all patients exposed to 6 mg/kg IV UST induction, response rates 8 weeks after the first subcutaneous injection (16 weeks after the IV induction dose) for UNITI1&2 are 47.4% and 73.7% respectively (see table for response and remission rate). Similar assessments were calculated in the sub-population who were anti-TNF naive upon enrolment into UNITI-2.

Response rates and Remission rates for all patients 16 weeks after induction of 6 mg/kg IV UST

Study	IV UST (n)	% Clinical Response	%Clinical Remission
UNITI-1	249	47.4	24.1
UNITI-2	209	73.7	55.5
UNITI-2 TNF Naive	144	72.9	60.4

Conclusion: These numbers at week 16 are expected to reflect real-world experience in patients who receive the induction dose and one additional maintenance dose 8 weeks later. The resulting rates of response and remission are higher than previously reported in the induction studies across all populations (anti-TNF non-failures and anti-TNF failures). About 73% of anti-TNF non-failures attain clinical response and over half are in remission. The data support the clinical rationale for providing at least one SC maintenance dose of ustekinumab irrespective of clinical response 8 weeks after IV induction.

Introduction: Biologics such as infliximab (IFX) (an anti-TNF) and vedolizumab (VDZ) (anti-integrin) are treatment options for patients with moderate-to-severely active inflammatory bowel disease (IBD), who have failed conventional therapy.

Aims & Methods: Our aim was to compare time to treatment discontinuation, flares, and hospitalisations among patients with IBD initiating VDZ versus IFX who were biologic-naïve. All patients with IBD (ulcerative colitis or Crohn's disease [CD]) who initiated biologic treatment with VDZ or IFX between 01/05/2014 and 22/02/2016 were identified in the US Explorys Universe database; the first infusion was deemed the index date. Analyses focused on patients who: (1) successfully completed induction therapy (≥ 3 infusions within 98 days of index date); (2) were ≥ 18 years of age at index; (3) had ≥ 365 days of medical history prior to index ("baseline"); and (4) had 365 days of follow-up after the index date. VDZ initiators were matched to IFX initiators (1:3) using propensity scores. Kaplan-Meier Method was used to compare median time to discontinuation of VDZ and IFX during follow-up, defined as the first of either: no receipt of biologic ≤ 90 days of previous infusion, or switch to another biologic. Similar method was also used to compare median time to IBD-related hospitalisations, surgeries, and flares (defined as use of intravenous steroids), respectively. Interquartile range (IQR) was also calculated.

Results: 105 VDZ initiators were matched to 315 IFX initiators. Baseline characteristics of both cohorts are described in Table 1. CD accounted for ~60% of patients in each cohort. In the baseline period, ~70% of patients in both cohorts had received corticosteroids; 20% of VDZ vs. 38% of IFX initiators received an immunosuppressive therapy. Median time since diagnosis was 2.4 years for VDZ initiators and 1.9 years for IFX initiators. Median time to treatment discontinuation was 244 (IQR for VDZ: 194–307 and IFX: 190–300) days in both cohorts. Median time to first IBD-related hospitalisation was 153 (IQR: 78–209) days for VDZ initiators vs. 98 (IQR: 45–168) days for IFX initiators. For IBD-related flares, median time was 111 (IQR: 40–226) days for VDZ initiators vs. 93 (IQR: 35–182) days for IFX initiators.

Table 1. Baseline characteristics of propensity-score matched IBD patients initiating therapy with vedolizumab or infliximab

	Vedolizumab (N = 105)	Infliximab (N = 315)	p-value
Mean (SD) age, years	46 (16.0)	44 (16.8)	0.297
Female, %	52.4	52.7	>0.999
Caucasian, %	89.5	84.1	0.180
Insurance type, %			0.202
Medicaid	6.7	11.1	
Medicare	23.8	14.3	
Private	63.8	65.7	
Other	5.7	8.9	
Patients with Crohn's Disease, %	60.0	60.9	
Mean (SD) time from diagnosis, years	3.6 (3.5)	3.1 (3.6)	0.667
Comorbidities, %			
Congestive heart failure	3.8	2.9	0.745
Rheumatic disease	5.7	2.9	0.221
Mild liver disease	11.4	10.2	0.715
Malignancies	6.7	4.1	0.295
IBD-related measures (during the baseline period), %			
Surgery	5.7	7.3	0.663
Hospitalisations	37.1	32.7	0.407
Corticosteroids	70.5	71.1	0.902
Immunosuppressives	20.02121	37.8	0.001

Conclusion: Among biologic-naïve IBD patients, there was a trend toward prolonged median times to first IBD-related hospitalization or first flare with VDZ compared to IFX. The median time to discontinuation was comparable between the therapies. Future studies should examine comparative effectiveness outcomes in a larger cohort over a longer follow-up period.

Introduction: Cancer development has been linked to oxidative stress by increasing DNA mutations or inducing DNA damage, genome instability and cell proliferation. Interestingly, reactive oxygen species (ROS) seem to modulate antigen presentation, a crucial event in the immune surveillance mechanisms¹. We recently showed that expression of the co-stimulatory molecule CD80 on epithelial cells has a critical role during the immune surveillance process occurring in colon carcinogenesis². Remarkably, ROS have been involved in the transcriptional regulation of CD80 gene expression³; in addition, oxidative DNA damage was directly correlated to CD80 expression in colon mucosa dysplasia⁴.

Aims & Methods: Therefore, the aim of this work was to examine the role of ROS on CD80 expression in colonic epithelial cells using an *in vitro* and an *in vivo* model of colonic carcinogenesis. A mouse colorectal cancer cell line, CT26, was used to quantify the expression of CD80 in response to pro-oxidant (such as Antimycin A and H₂O₂) and antioxidant (N-acetyl cysteine) stimuli in presence or absence of pharmacological inhibitors of p38MAPK (SB203580 and BIRB 796) and NF-κB (JSH-23). C57BL/6 mice (wild type, WT) received azoxymethane (AOM) i.p. at a dose of 10mg/kg body weight weekly for 6 weeks to induce colorectal cancer (CRC) and then sacrificed four months after the first AOM injection to perform flow cytometry analysis on colonocytes and mucosal lymphocytes. Mice were also randomized to received 5mM N-acetyl cysteine (NAC) in drinking water (pH 7) *ad libitum* after AOM treatment.

Results: In CT26 cells ROS-generating agents (Antimycin A and H₂O₂) caused a significant CD80 up-regulation at mRNA (p=0.01) and protein level (p < 0.001). H₂O₂-induced CD80 up-regulation in colonic epithelial cells was significantly inhibited by N-acetyl cysteine (p < 0.001) and by p38MAPK (p=0.001) but not by NF-κB pharmacological inhibition. *In vivo* administration of N-acetylcysteine significantly reduced AOM-induced CD80, MHC-I and MHC-II up-regulation in colonic epithelial cells (p < 0.001, p < 0.001 and p < 0.001, respectively). Moreover, CD8+CD28+, CD8+CD69+, CD4+CD25+ T cells rate in colonic mucosa was significantly lower in AOM-NAC mice than AOM mice (p=0.08, p=0.03 and p=0.01, respectively).

Conclusion: All in all, our data support the hypothesis that oxidative stress promote the antigen presenting function of colonic epithelial cells by inducing CD80 in the early stages of colonic carcinogenesis. ROS-mediated CD80 up-regulation in colonic epithelial cells relies on the p38MAPK pathway *in vitro*.

Introduction: Altered immune activity and gut microbiota alterations are proposed to be important factors in the pathophysiology of irritable bowel syndrome (IBS), but the relevance for symptoms is unclear.

Aims & Methods: We aimed to determine if colonic antimicrobial gene expression profiles differ between IBS and healthy subjects and if potential alterations are linked to immune activity or gut microbiota composition. The expression of 84 key antimicrobial genes in sigmoid colon biopsies from patients with IBS, defined as being either immuno-active or immuno-norm based on systemic and mucosal cytokine profiles (Bennet et. al *Am J Gastro*, 2016), and healthy subjects was assessed by Human Antibacterial Response RT² Profiler PCR Array. Targeted 16S rRNA pyrosequencing was performed on faecal microbiota. To identify discrimination profiles based on multiple variables between IBS patients and healthy subjects, orthogonal partial least squares discriminant analysis (OPLS-DA) with a cut off for Variable Importance for the Projection >0.7 was performed.

Results:

Table 1: Differences in mucosal antimicrobial mRNA expression between IBS (Immuno-active and Immuno-norm) and healthy subjects.

Gene (2Δ Ct)	IBS (n = 31) v Healthy (n = 16)	Immuno-active (n = 16) v Healthy	Immuno-norm (n = 15) v Healthy	Immuno-active v Immuno-norm

Data presented as p-values (Mann-Whitney t-test) ‘-’ = non significant. We included 31 IBS patients (16 females, median age 32 (25–44) years) and 16 healthy subjects (8 females, median age 27(24–30) years). An OPLS-DA model demonstrated that the antimicrobial profiles differed between IBS and healthy subjects ($R^2 = 0.54$, $Q^2 = 0.16$). The mucosal mRNA expression of 14 antimicrobial genes was downregulated, while one gene was upregulated in IBS patients compared to healthy subjects (Table 1). Antimicrobial profiles did not differ between IBS patients subtyped according to their predominant bowel habit ($R^2 = 0.16$, $Q^2 = -0.02$). An OPLS-DA model showed discrimination between immuno-active (n = 16) and immuno-norm (n = 15) IBS patients based on their mucosal antimicrobial profiles ($R^2 = 0.91$, $Q^2 = 0.61$). This finding was corroborated by four antimicrobial genes being altered between the two IBS groups (Table 1). Adding healthy subjects to the model revealed three differing antimicrobial profiles for each respective group ($R^2 = 0.44$, $Q^2 = 0.30$). Compared to healthy subjects, 19 genes in the immuno-active and immuno-norm IBS groups were differently expressed ($p < 0.05$, Table 1). Only one of the antimicrobial genes differently expressed between IBS patients and healthy subjects was associated with faecal microbiota in immuno-norm IBS patients (Conserved Helix-Loop-Helix Ubiquitous Kinase (CHUK) with *Anaerovorax* $r = -0.76$, $p < 0.01$). In the immuno-active IBS group 11 associations were identified, including TNF

Receptor Superfamily Member 1A (TNFRSF1A) with *Bifidobacterium* ($r = -0.80$, $p < 0.01$).

Conclusion: The intestinal antimicrobial gene profiles differ between subsets of IBS patients and healthy subjects. An altered ability to recognise microbiota associated with immune activity and the relative abundance of gut bacteria may play a role in the complex pathophysiology of IBS.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0417 THE EXPOSURE OF ANTIBIOTICS IS ASSOCIATED WITH INCREASED RISK OF COLORECTAL CANCER- A SYSTEMATIC REVIEW AND META-ANALYSIS

X. He¹, W. Wu², Y. Ding³, L. Sun¹

¹Department Of Gastroenterology, Sir Run Run Shaw Hospital, Zhejiang University, Hangzhou/China

Introduction: Recently, accumulating evidence suggested that the dysbiosis of the intestinal microbiota was associated with increased risk of colorectal cancer and might play a significant role in the colorectal carcinogenesis [1–2]. Many environmental factors (e.g. diet and lifestyle) that altered the gut microbiota had been reported in the development of colorectal cancer[3]. Antibiotics are able to shift the gut microbiota by altering bacterial composition and functions. The overuse of antibiotics has been associated with several adverse effects, such as severe infections, obesity, inflammatory bowel disease. Similarly, it is plausible to hypotheses that overuse of antibiotic might be linked to CRC by altering the colonic microbiota. However, the relationship between antibiotic and CRC was unclear and studies regarding this topic were limited [4–7].

Aims & Methods: To evaluate the association between use of antibiotic and the risk of developing colorectal cancer, a systematic literature search was conducted using PubMed, EMBASE, Web of science and Cochrane library to identify related studies published before October 2016. Two independent investigators screened and extracted data from included articles. A random-effects model was adopted to calculate overall odds ratio (OR) and 95% confidence interval (CI).

Results: From initial search, we identified four case-control studies and finally included in the meta-analysis. Compared with no/low use of antibiotics, high prescriptions of antibiotics were significantly associated with an excess cancer risk (OR = 1.11, 95%CI 1.01–1.21). There was a significant heterogeneity across studies ($I^2 = 62.1\%$, $P = 0.048$). Longer duration of antibiotics was also significantly linked to increased risk of CRC (OR = 1.14, 95%CI 1.03–1.25) with no significant heterogeneity ($I^2 = 39.6\%$, $P = 0.191$). There was no evidence of significant publication bias among this meta-analysis.

Conclusion: Higher prescriptions and longer duration exposure of antibiotics were associated with increased risk of developing colorectal cancer. Further studies are needed to verify our results and explore underlying mechanisms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Internal biliary drainage has been confirmed better than external biliary drainage in alleviating the damage of intestinal mucosa barrier caused by obstructive jaundice, but the relevant mechanism is still unclear.

Aims & Methods: We aimed to investigate the effect of internal and external drainage of obstructive jaundice rats on intestinal mucosal barrier function with special reference of intestinal immune-related index expression. Sixty male Sprague-Dawley rats were randomly assigned to four groups: OJ, sham operation (SH), internal biliary drainage (ID) and external biliary drainage (ED). All animals underwent surgical ligation of the bile duct, except SH was produced by separating common bile duct locally but not dividing on day 1. Then ED and ID were reoperated on day 8 for biliary drainage procedure. Blood from inferior vena cava were collected for the test of DAO and sIgA activities by the method of ELASA. The terminal ileum specimens of each groups were collected for observation of the morphological changes with haematoxylin-eosin (HE) staining. The expression of IgA mRNA, pIgR mRNA, GP-BAR1mRNA, RD-5mRNA were measured by reverse transcription polymerase chain reaction (RT-PCR). GP-BAR1 of the ileum mucosa was analyzed by Western blot.

Results: After bile duct ligation, the injuries of the intestinal mucosa were obvious in OJ group with thinner mucosa, sparser villi, destruction of the epithelial integrity and accompanied by inflammatory cell infiltration. The mucosal lesions evaluated by Chiu's method was 2.158 ± 0.579 , while the impaired intestinal mucosa have different degrees of recovery and ID group was more similar to SH group in intestinal mucosal morphology. The levels of the DAO in OJ group were increased more dramatically than that in SH, ID and ED groups while sIgA were decreased ($p < 0.01$), and the activities of the DAO, sIgA in ID group were similar to the level of SH group ($p > 0.05$), different to the level of ED group ($p < 0.01$). The changes of the plasma DAO and sIgA activities were significantly correlated with the conditions of intestinal mucosa ($P < 0.01$). The expression of RD-5 mRNA in OJ group were decreased significantly than that in SH, ID and ED groups while GP-BAR1 mRNA, IgA mRNA, pIgR mRNA were increased ($p < 0.01$). Interestingly enough, after external bile drainage, there is no improvement in IgA mRNA and pIgR mRNA ($P > 0.05$). But in ID, the relative expression of IgA mRNA and pIgR mRNA reduced markedly ($P < 0.01$). while the mRNA expression of GP-BAR1 and RD-5 mRNA in ED group was changed less than that in ID which were more similar to SH group. The protein expression of GP-BAR1 was increased significantly in the intestinal mucosal of OJ group, which was higher than that of in SH group ($P < 0.01$). After internal and external biliary drainage to alleviate OJ respectively, the GP-BAR1 expression was decreased significantly in ID group, similar with SH group (ID vs OJ, $P < 0.01$; ID vs SH, $P > 0.05$), and lower than that of in ED group ($P > 0.05$). **Conclusion:** The differential expression of IgA mRNA, pIgR mRNA, GP-BAR1 mRNA, RD-5 mRNA and activities of DAO and sIgA in OJ, ID, ED and SH reflect internal biliary drainage better than external biliary drainage. There may be a regulatory mechanism between GP-BAR1 and intestinal immune-related index, which thus appears to be a key factor in maintaining function of intestinal mucosa barrier.

P0419 COMPARATIVE EFFECT OF XYLOGLYCAN ASSOCIATIONS WITH COMPOUNDS FROM ANIMAL OR ALGAE ORIGIN ON LPS-INDUCED ENTERITIS IN RATS

H. Eutamene, C. Harkat, V. Theodorou

Unité De Neuro-gastroentérologie & Nutrition, Toxalim UMR 1331 INRA/UPS/INPT-EI-Purpan, Toulouse/France

Contact E-mail Address: helene.eutamene@inra.fr

Introduction: Xyloglucan (XG) is a film-forming agent exhibiting protective effects against diarrhea linked to infectious gastroenteritis in humans; further in animal models, xyloglucan efficacy against cholera-toxin-induced diarrhea was timely prolonged when this mucoprotectant agent is associated with gelatin from animal origin. The use of compounds from animal source in galenic formulations is nowadays questionable.

Aims & Methods: Thus, in this study, we aimed at comparing the efficacy of XG associated with gelatin vs XG associated with gelose a moiety from algae origin on LPS-induced enteritis in rats. Since LPS-induced enteritis is characterized by increased intestinal epithelial permeability and mucosal inflammation, the efficacy of xyloglucan associations was evaluated by measurement of these two parameters. Male Wistar rats (200–225 g) were orally treated with either XG (10 mg/kg) + gelatin (25 mg/kg) or XG (10 mg/kg) + gelose (25 mg/kg) or XG (10 mg/kg) + gelose (50 mg/kg) or vehicle (NaCl 0.9%) 3 h before intraperitoneal (IP) administration of LPS from *E. coli* (1 mg/kg). Six hours later after LPS administration, the animals were sacrificed and strips of jejunum were collected in order to evaluate (i) intestinal epithelial paracellular permeability to FITC-dextran 4Kd in Ussing chambers and (ii) mucosal inflammatory response by myeloperoxidase (MPO) activity measurement.

Results: Compared with control, LPS administration induced a significant increase ($p < 0.05$) of intestinal paracellular permeability (53.0 ± 4.9 vs 181.6 ± 21.1 pmol/cm² respectively) associated with jejunal mucosal inflammation (302.1 ± 9.5 vs 655.6 ± 108.9 U MPO/g protein, respectively). XG (10 mg/kg) + gelose at the lowest dose (25 mg/kg) failed to reverse the intestinal hyperpermeability and mucosal inflammation induced by LPS. In contrast, XG (10 mg/kg) + gelatin (25 mg/kg) and XG (10 mg/kg) + gelose at 50 mg/kg significantly ($p < 0.01$) and equally prevented LPS-induced hyperpermeability (34.8 ± 2.8 , 38.7 ± 3.9 vs 181.6 ± 21.1 pmol/cm² respectively) and jejunal inflammation (277.0 ± 32.2 ; 286.2 ± 28.8 vs 655.6 ± 108.9 U MPO/g protein respectively).

Conclusion: This study shows that oral treatment with xyloglucan associated with gelose at 50 mg/kg has similar protective effects on LPS-induced enteritis in rats than xyloglucan associated with gelatin. These data demonstrate that algae is an effective and safe substitute for replacing compounds from animal origin in xyloglucan mucoprotectant formulations.

Introduction: The old age is one of the most important risk factors for recurrent *C. difficile* Infection (CDI). However, risk factors among the elderly patients are largely unknown.

Aims & Methods: The purpose of this study was to investigate risk factors associated with recurrent CDI in the elderly. Patients 65 years of age or older with positive CDI toxin test between January 2005 and December 2016, who received either oral metronidazole or oral vancomycin therapy were included. Recurrent CDI was defined as another positive laboratory result for *C. difficile* toxin between 15 days and 90 days after initial positive diagnostic test. Clinical charts of relevant factors in 633 patients with positive CDI toxin tests were reviewed. Continuous variables were tested via Student's t-test, and categorical data was analyzed via Chi-Square test. All variables with $P < 0.1$ in the univariate analysis were included in the multivariable logistic regression analysis.

Results: The overall mean age was 77.0 ± 7.0 years. In 96 (15.2%) of 633 patients, *C. difficile* toxin was detected again after the initial test. The length of hospital stay was longer in recurrent CDI group than in non-recurrent group (80.54 ± 89.44 vs. 43.81 ± 65.42 , $P < .001$). Patients with eGFR < 60 ml/min/1.73 m² were at higher risk for the development of recurrent CDI than those with normal renal function (OR 1.844; 95% CI, 1.139–2.985, $P = .013$). There were no significant differences on mean age (77.21 ± 6.65 in recurrent CDI group vs. 77.01 ± 7.04 in non-recurrent CDI group, $P = .799$) and proton pump inhibitor therapy (OR 1.277; 95% CI, 0.825 to 1.977, $P = .272$) between both groups. Renal function and length of hospital stay were significantly associated with recurrence of CDI.

Conclusion: In this study, impaired renal function and prolonged hospitalization were related to the increased risk of recurrent CDI.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cytomegalovirus (CMV) colitis in adults is mostly described in immunocompromised patients (solid organ or hematopoietic stem cell transplant recipients, patients with human immunodeficiency virus (HIV) infection, use of

immunosuppressive drugs, including steroid or chemotherapeutic agents), and often has poorer outcome than in children. Besides, it was also frequently presented in patients with known or subsequent new diagnosis inflammatory bowel disease [1, 2]. However, there are only case reports and few case series with limited patients (below 15 cases) among immunocompetent individuals without steroid use or inflammatory bowel disease [3–5]. The largest meta-analysis study of cytomegalovirus colitis in immunocompetent hosts included 44 patients and noted advanced age, male gender, presence of immune-modulating comorbidities and need of surgical intervention negatively influencing survival in 2005 [6]. The case number of CMV colitis in immunocompetent patients seemed increasing in our hospital these years. There was no single study showing comprehensive clinical characteristics, identifying the independent factors of in-hospital mortality and comparing the differences between immunocompetent and compromised patients with CMV colitis. Therefore, we tried to clarify the issue in this study.

Aims & Methods: We enrolled 42 immunocompetent patients and 27 immuno-

compromised patients with CMV colitis diagnosed by immunohistochemistry stain between April 2002 and December 2016 in Linkou Chang Gung Memorial Hospital, a 3383-bed tertiary medical center and referral center in Taiwan. We analyzed the risk factors of in-hospital mortality and overall survival. Furthermore, we compared the clinical differences between immunocompetent and immunocompromised patients with CMV colitis.

Results: Early diagnosis (before 9 days) was independent predictor of in-hospital mortality in CMV colitis patients. ICU admission ($P = 0.010$), requisite days of diagnosis ≥ 9 days after admission ($P = 0.018$), shock ($P = 0.001$), respiratory failure ($P = 0.033$), hemoglobin < 10 g/dL ($P = 0.002$), Creatinine ≥ 1.37 mg/dL ($P = 0.004$) and CRP ≥ 59 mg/dL ($P = 0.011$) negatively impacted on overall survival. There were older and more comorbidities in immunocompetent group. However, the in-hospital mortality rate and overall survival rate was similar to immunocompromised group. Besides, *Clostridium difficile* infection or steroid use didn't affect in-hospital mortality rate and overall survival rate neither. Melena was first and most common symptom in immunocompetent group, but diarrhea in the other.

Analysis of the clinical factors associated with in-hospital mortality in all patients

Characteristic	Odd ratio	95%CI	P-value

Introduction: *Clostridium difficile* infection (CDI) is one of the most common hospital-acquired infections. Faecal microbiota transplantation (FMT) is used for complicated recurrent CDI treatment; however, to date no data on the efficacy of this method in Eastern Europe have been published.

Aims & Methods: The aim of this study was to assess effectiveness of FMT for recurrent CDI therapy in the hospital of Lithuanian University of Health Sciences (LUHS KK, Kaunas, Lithuania). Clinical data of patients who were treated for recurrent (>2 times) CDI using FMT in the Department of Gastroenterology of LUHS KK during 2015–2016, were analyzed. All patients were monitored for disease relapse for six months. Clinical data, the use of antibiotics and immunosuppressive drugs were included in analysis. Statistical analysis was performed using statistical software package SPSS version 17.

Results: FMT was used for 18 patients with recurrent CDI. The mean age of patient was 60.4 ± 8.4 years. The patients were treated with antibiotics 14.8 days on average before manifestation of CDI. FMT procedure was performed using naso-enteral tube. After the first procedure, the positive clinical effect was observed in 15 patients with a cure rate of 83.3%. FMT procedure was repeated for two out of the three patients without positive effect (one patient refused repetitive FMT). Normal stool habits were restored in both patients leading to the increase of cure rate to 94.4% (17 out of 18 patients). Seventeen patients that were successfully treated with one or two FMT procedures in the short term also remained asymptomatic (100 %) at 6 months of follow up. All patients without positive effect of first FMT procedure were on immunosuppressive drugs (3/3;

100%), as compared to only one patient in the group with positive effect (1/15; 7.1%), p = 0.028.

Conclusion: FMT is an effective therapy for recurrent CDI infection both in short and long term follow-up. Effectiveness of primary FMT treatment could be associated with the use of immunosuppressive drugs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0423 A RANDOMISED CONTROLLED TRIAL OF RIFAXIMIN TO PREVENT RELAPSE OF CLOSTRIDIUM DIFFICILE ASSOCIATED DIARRHOEA AFTER RESOLUTION WITH STANDARD THERAPY

Introduction: *Clostridium difficile* associated diarrhoea (CDAD) is a common nosocomial infection. The most commonly prescribed treatments, metronidazole and vancomycin, have a primary cure rate of 90% but 1 in 4 cases suffer a relapse in the following months. A disrupted microbiota is thought to increase the risk of relapse. Rifaximin is a non-absorbable antibiotic that suppresses *C. difficile* proliferation. In a trial of 68 patients Garey et al. found that a course of rifaximin after standard therapy reduced relapse rate though not significantly¹.

Aims & Methods: We aimed to further investigate the efficacy of rifaximin to prevent CDAD relapse in a parallel group, randomised, placebo controlled trial in 23 hospitals in England. **Population:** age ≥ 18 with resolution of CDAD after treatment with metronidazole or vancomycin, defined as cessation of diarrhoea for ≥ 2 days. CDAD diagnosis required evidence of toxin production or pseudomembranes at endoscopy. Exclusion criteria were pregnancy or breast feeding; life expectancy < 4 weeks; unable to take intervention (hypersensitivity or swallowing disorder); > 5 days elapsed since treatment. Randomisation was stratified by hospital using a remote, internet-based system. Participants, clinicians and researchers were blind to allocation. **Intervention:** Rifaximin 1200 mg daily for two weeks then 600 mg daily for two weeks, in three divided doses. **Comparator:** identical placebo. **Primary Outcome:** relapse ≤ 12 weeks after treatment initiation, defined as diarrhoea (≥ 3 type 6 or 7 stools per day) for 2 days with evidence of toxin production. **Sample size:** The planned sample size was 180 to detect a difference in relapse of 20% (30% placebo, 10% rifaximin) with 80% power, allowing for loss to follow-up of 20%. EudraCT 2012-003205-10; www.clinicaltrials.gov NCT01670149; ISRCTN 65163992

Results: Recruitment occurred December 2012–March 2016. Of 2157 patients screened, 151 were eligible, willing and randomised before funding limits were reached (74 placebo, 77 rifaximin). Primary outcome data were available on 130. Mean age was 71.9 (SD 15.3).

36% were in-patients at start of intervention. 13% had a prior recorded episode of CDAD. 26% were using proton pump inhibitors prior to CDAD diagnosis, with a higher rate of use in the rifaximin group (32% vs. 20%). 18/61 (29.5%) on placebo relapsed within 12 weeks compared to 11/69 (15.9%) on rifaximin, a difference between groups of −13.7% (95% CI −28.1% to 0.7%, p = 0.06). The risk ratio was 0.54 (95% CI 0.28 to 1.05, p = 0.07). During 6-month safety follow up 9 participants died in each group (12%). Adverse event rates were similar between groups.

Conclusion: CDAD relapse rate was 13.7% lower than on placebo. The confidence interval means that lack of effect remains possible but the estimated effect size is similar to Garey's trial¹ with meta-analysis of the trials showing a statistically significant effect. The effect size is similar to that reported for fidaxomicin at 40 days², or for bezlotoxumab at 3 months³. Age and mortality rate were higher in our trial which may reflect greater similarity to the population at risk. Comparative trials of the effectiveness and cost effectiveness of alternative treatment strategies should follow.

Disclosure of Interest: R. Spiller: Trial funded through National Institute for Health Research RfPB grant PB-PG-0110-21041. Norgine Pharmaceuticals Ltd supplied product and comparator free of cost.

All other authors have declared no conflicts of interest.

P0424 A SYSTEMATIC REVIEW AND META-ANALYSIS OF IN-HOSPITAL DELAY BEFORE SURGERY AS A RISK FACTOR FOR COMPLICATIONS IN PATIENTS WITH ACUTE APPENDICITIS

S. Van Dijk¹, A. Van Dijk¹, M.G.w. Dijkgraaf², M.A. Boermeester³

Introduction: The traditional fear that every acute appendicitis will eventually perforate leads to prompt surgery, but this fear may be outdated. In-hospital delay of surgery for acute appendicitis has been subject of a large number of studies. However, consensus about the consequences of delaying appendectomy is lacking, which is reflected in variety or absence of recommendations in guidelines.

Aims & Methods: The aim of this study was to assess in-hospital delay of surgery as potential risk factor for complicated appendicitis and complications in patients with acute appendicitis. PubMed and EMBASE were searched from 1990 to July 2016. Outcome measures of interest were complicated appendicitis, surgical site infections and postoperative morbidity. All studies reporting surgically treated patients with one of these outcome measures in two or more predefined time intervals were included. Adjusted odds ratios were pooled using forest plots if possible. All unadjusted data was pooled using generalized linear mixed models.

Results: Forty-five studies with 152,314 patients were included. Pooled adjusted odds ratios revealed no significantly higher risk for complicated appendicitis when delaying appendectomy for 6 to 12 hours or 13 to 24 hours; odds ratio 1.07 (95% CI 0.98–1.17) and 1.09 (95% CI 0.95–1.24), respectively. For a delay of more than 24 hours, insufficient adjusted data was available for meta-analysis. Pooled unadjusted data showed a decreased risk for complicated appendicitis when appendectomy was delayed for 24 to 48 hours, however statistical uncertainty in this interval increased considerably compared to the first 24 hours.

Conclusion: Delaying appendectomy for up to 24 hours after admission did not result in higher rates of complicated appendicitis, surgical site infections or morbidity. When prompt surgery is hampered by logistic or personal reasons, delaying appendectomy up to 24 hours is an acceptable alternative for patients with no preoperative signs of complicated appendicitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0425 VANCOMYCIN FOLLOWED BY FECAL MICROBIOTA TRANSPLANTATION VERSUS VANCOMYCIN FOR INITIAL CLOSTRIDIUM DIFFICILE INFECTION: AN OPEN-LABEL RANDOMISED CONTROLLED TRIAL

Introduction: Fecal microbiota transplantation (FMT) is effective for the treatment of recurrent *Clostridium difficile* infection (CDI) but its role as an initial therapy for patients with CDI has not been studied.

Aims & Methods: We assessed the efficacy of FMT in patients with an initial episode of CDI compared with standard vancomycin regimen. In a single center, open-label, randomised study, we assigned 30 patients with an initial episode of CDI to receive either: oral vancomycin (500 mg four times daily) followed by FMT consisting of a single infusion of donor feces through a nasoduodenal tube; or a standard oral vancomycin regimen (500 mg four times daily for 10 days). The primary end point was resolution of diarrhea associated with CDI without relapse within 10 weeks after initiation of therapy. Secondary outcomes included 30-day and 6-month mortality, 30-day colectomy rates, length of hospital stay, adverse effects and alteration of fecal microbiota after FMT using metagenomic sequencing.

Results: Baseline characteristics including age, gender and co-morbidities were comparable between the vancomycin and FMT arm. 60% and 47% of subjects in the vancomycin and FMT arm, respectively, had severe CDI. Resolution of *C. difficile* infection occurred in 10 of 15 patients (66.7%) receiving vancomycin and 11 of 15 patients (73.3%) receiving FMT ($p=1.00$). Two deaths occurred in the vancomycin group and none in the FMT group within 30 days. Nine (60%) and three deaths (20%) occurred in the vancomycin and FMT arms, respectively, within 6 months. None of the patients had a colectomy. Median length of hospital did not differ between both arms (13 vs 15 days; $p=0.95$). No serious adverse events attributed to FMT were observed. A restoration of healthy control enriched bacteria in recipients was observed after FMT, with a decrease in abundance of CDI-enriched bacteria. FMT, but not vancomycin treatment, resulted in marked virome alterations.

Conclusion: In this pilot randomised controlled trial, FMT was not superior to vancomycin in patients with an initial episode of CDI. 30-day and 6-month mortality was higher in the vancomycin arm. A restoration of healthy control enriched bacteria in recipients was observed after FMT, with a decrease in abundance of CDI-enriched bacteria (Clinical Trial registry, NCT02570477; Funded by the Hong Kong Society of Gastroenterology Society).

Introduction: Tuberculosis (TB) carries significant morbidity globally and in Europe: it is most commonly pulmonary but it can also affect the gastrointestinal (GI) tract (6% of total cases in UK). Abdominal tuberculosis (A-TB) is a rare disease which can also present an unique diagnostic challenge, mimicking various GI diseases leading to late diagnosis and treatment. There is limited clinical data on its presentation and clinical features in Europe - in the UK it is registered via regional Public Health registries.

Aims & Methods: We reviewed a 10-year cumulative regional TB database in an university teaching hospital covering an urban multi-ethnic population to report clinical details of A-TB and results on this unusual condition. A clinical review of patients diagnosed for A-TB between 2006 to 2016 in a single tertiary centre in South Birmingham covering a multi-ethnic urban population of ~750,000 was conducted. A central surveillance database managed by Respiratory Physicians and Public Health England were used to identify patients with A-TB. We reviewed clinical data from electronic records including radiology, chemical pathology, histopathology, endoscopy databases, surgical notes and letters.

Results: Of 41 patients [M=22(54%); mean age 42y (SD±17y)] identified with A-TB, 41% (17) were Pakistani, 15% (6) were other Asian, 19% (8) were Afro-Caribbean. Thirty-three (80%) were residents of economically deprived areas which were among the 10% of most deprived constituencies in the UK. The most frequently reported symptoms were abdominal pain (n=23; 56%), weight loss (n=17; 41%), fever (n=10; 24%) & vomiting (n=9; 22%). Twelve (29%) patients were first seen in a surgical clinic and 9 (22%) in a medical gastroenterology clinic. A-TB was confirmed on tissue biopsy in 22 (54%), of which two were diagnosed post-bowel resection. Seventeen (41%) patients had positive cultures with full drug sensitivity and 5 (12%) patients had polymerase chain reaction (PCR) tests. Eight patients (20%) had concurrent pulmonary TB. Thirty seven patients (90%) received full, successful treatment for A-TB.

Conclusion: Asian ethnicity and low socioeconomic status appear to be risk factors for A-TB in a single UK tertiary center. Histological diagnosis at endoscopic or surgical biopsy is a reliable diagnostic tool for confirming TB. Both gastroenterologists and surgeons need to consider A-TB in their differentials, as once diagnosed, most are successfully treated.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: *Clostridium difficile* infection represents a major burden in Europe and North America. However, data on its disease epidemiology remain sparse in Asia. This study aims to investigate the burden, risk factors and clinical outcomes of *C. difficile* infection in Hong Kong, using a large territory-wide population database.

Aims & Methods: This is a population-based study conducted from 1 January 2006 to 31 December 2014, and included all in-patient *C. difficile* infections in public hospitals in Hong Kong. Cases were identified from a territory-wide electronic database, and were defined as the isolation of *C. difficile*, or positive test for either toxin or molecular assay from the fecal specimens. The disease incidence, mortality, risk factors and clinical outcomes were analyzed.

Results: A total of 15,753 cases were identified, including 14,402 (91.4%) health-care-associated and 817 (5.1%) community-associated infections. The crude incidence increased from 16.21 in 2006 to 49.36 in 2014 per 100,000 population ($P_{trend} < 0.001$), representing an over 30% increase annually. This rise was

notably contributed by elderly patients, of which the incidence has increased by three-fold over the period. Recurrence at 60 days increased from 5.7% in 2006 to 9.1% in 2014 ($P_{trend} < 0.001$). The increased use of proton-pump inhibitors accounted for 58.8% of the surge.

Conclusion: The incidence of *C. difficile* infection has increased more than three-fold, and was associated with an increased disease recurrence and use of proton-pump inhibitors. Our results suggest need for further surveillance in Asia which harbors over half of the world's population.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Post-polypectomy bleeding (PPB) is the most common complication following polypectomy, especially in cases with large pedunculated polyps. Although the clip application before snare polypectomy may decrease PPB, there were few prospective randomized studies to confirm the efficacy of prophylactic clip. This present study was conducted to investigate whether prophylactic clip application for large pedunculated colorectal polyps could decrease PPB and to evaluate associated risk factors of PPB.

Aims & Methods: We enrolled 137 pedunculated polyps (≥ 1 cm in size) in 116 patients. The polyps were randomized into the two groups with or without prophylactic clips application. Immediate PPB was defined as bleeding that continued for over 30 seconds from the polypectomy site and graded from grade 1 to 4, and delayed bleeding was defined as a history of hematochezia from the day of procedure to the day of first visit of outpatient clinic.

Results: Sixty-seven polyps were included in the clip group and 70 polyps in the control group respectively. Immediate PPB occurred in 6 cases (9.0%) of the clip group and 22 cases (31.4%) of the control group ($P=0.001$). The occurrence of immediate PPB of grade 3–4 which needed endoscopic treatment was lower in the clip group than in the control group (4.5% vs. 20.0%, $P=0.008$). However, that of grade 1–2 was not different in both groups (4.5% vs. 11.4%, $P=0.208$). Delayed bleeding occurred in five polyps in both groups ($P=0.943$). The prophylactic clip application was a significant factor for lowering immediate PPB in the univariate (OR 0.215, 95% CI 0.081–0.571, $P=0.002$) and multivariate analysis (OR 0.210, 95% CI 0.074–0.591, $P=0.003$). In addition, polyp size ≥ 20 mm and stalk diameter ≥ 4 mm were significant risk factors of immediate PPB compared with polyp size 10–19 mm and stalk diameter 1–3 mm.

Conclusion: The prophylactic clip application in large pedunculated polyps ≥ 1 cm is effective in reducing immediate PPB. Polyp size and stalk diameter are associated with PPB.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Heparin replacement (HR) during periprocedural periods is described in various guidelines as the recommended method while discontinuing warfarin. However, the rate of post-colonic polypectomy bleeding in patients undergoing HR has been reported to be as high as 20%. As an alternative method to HR, colonic polypectomy without discontinuation of warfarin may be feasible, however there is still insufficient evidence. The aim of this study was to assess the safety of colonic polypectomy/endoscopic mucosal resection (EMR) without discontinuation of warfarin during periprocedural periods.

Aims & Methods: This is a prospective multicenter single-arm exploratory study in Japan. Patients who received warfarin for the purpose of prevention of thrombosis were prospectively enrolled and underwent colonic polypectomy or EMR without discontinuation of warfarin. Conventional clip closure of the resection site was performed in all cases and oral diet was resumed 2 days after the procedure. The primary outcome was post-polypectomy/EMR bleeding that was confirmed by emergency endoscopy or a decrease in the hemoglobin level of > 2 g/dl with hematochezia even if the bleeding site was not identified.

Results: Between January 2015 and November 2016, a total of 30 consecutive patients (M/F: 26/4, 69.9 ± 8.0 years) were enrolled in this study after written informed consent was obtained. A total of 81 lesions (tumor diameter: 5.4 ± 2.9 mm, adenoma 70, others 10, lost lesion 1, number of prophylactic clipplings 4.9 ± 2.2) were treated by polypectomy/EMR. Four patients experienced post-polypectomy/EMR bleeding (4/30: 13.3%) in 3–11 days after the procedure although no cases required blood transfusion. In 3 of these bleeding cases, a single responsible site was identified by emergency endoscopy. Therefore, the confirmed rate of post-polypectomy/EMR bleeding based on the number of resected lesions was 3.9% (3/76), but may range to 9.9% (8/81). There were no other adverse events.

Conclusion: The rate of post-colonic polypectomy/EMR bleeding in patients without discontinuation of warfarin single therapy was comparable to that in patients undergoing HR. Colonic polypectomy/EMR without discontinuation of warfarin is feasible and may reduce the hospitalization associated with HR.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0430 EFFECTS OF HEPARIN BRIDGING THERAPY ON POST-POLYPECTOMY BLEEDING AND THROMBOEMBOLIC RISKS IN PATIENT UNDERGOING COLONOSCOPIC POLYPECTOMY

Introduction: Warfarin and direct oral anticoagulants (DOACs) rivaroxaban, apixaban, dabigatran and edoxaban are approved for stroke prevention in patients with atrial fibrillation (AF). The Japan Gastrointestinal Endoscopy Society guidelines recommend that anticoagulants should be discontinued at a low thromboembolic risk, or replaced by heparin bridging therapy at a high thromboembolic risk, for colonoscopic polypectomy. However, safety and efficacy of heparin bridging therapy for colonoscopic polypectomy remains scarce.

Aims & Methods: The aim of the present study was to evaluate the risk of post-polypectomy bleeding (PPC) in patients who take anticoagulants. We retrospectively collected data of patients who underwent colonoscopic polypectomy between January 2014 and February 2017 at Nagoya City University Hospital. Polyp characteristics (number of polyps removed per patient, size, morphology) and patient characteristics (age, sex, comorbidities, medication) was analyzed.

Results: A total of 1007 patients underwent colonoscopic polypectomy. 67 patients were in the anticoagulants group and 808 patients were in the normal group (taking no antiplatelet agents and anticoagulants). The incidence of PPC was significantly higher in the anticoagulants group than in the normal group

(2.98% vs 1.49%, respectively). No patients experienced recurrent bleeding and a blood transfusion. The mean age (71.3 ± 8.2 years) and male (82.1%) in the anticoagulants group were higher than those in the normal group (67.7 ± 11.2 years and 64.1%). There was no difference between the groups in size of polyp and morphology. In the anticoagulants group, 34 patients received heparin bridging therapy (warfarin 30, warfarin + antiplatelet 3, rivaroxaban 1) and 33 patients discontinued anticoagulants (warfarin 8, warfarin + antiplatelet 1, rivaroxaban 10, apixaban 8, dabigatran 4, edoxaban 2). The incidence of PPC was no difference between two groups (1, 1 patient, respectively). There was no difference between the groups in age, sex, size of polyp and morphology. Recurrent bleeding didn't occur. In the discontinued group, 1 patient developed acute myocardial infarction in next day after colonoscopic polypectomy.

Conclusion: Patients taking anticoagulants have an increased risk of PPB compared with the control, even if the anticoagulants are discontinued. Heparin-bridge therapy might be responsible for increased PPB in patients taking anticoagulants.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0431 ARTERIOSCLEROSIS IS A SIGNIFICANT CONTRIBUTOR TO COLON DIVERTICULUM RECURRENT BLEEDING

Introduction: Intermittent bleeding from colon diverticulum has a significant clinical impact with some cases experiencing recurrent bleeding episodes for several years. No report has directly evaluated the association between arteriosclerosis and diverticulum bleeding recurrence.

Aims & Methods: We sought to assess the degree of arteriosclerosis in cases with diverticulum bleeding as well as the patients' clinical characteristics. We conducted a retrospective cohort study in a group of 79 consecutive patients with colon diverticulum bleeding (51 men) who underwent both colonoscopy and computed tomography (CT) between August 2007 and March 2014. The mean age of the patient population was 69.5 years (range 29–91 years) and mean (\pm standard deviation) follow-up time was 6.2 (± 2.0) years (range 3.1–9.7 years). Patients were divided into two groups: the recurrent bleeding episode group and the single bleeding episode group. Recurrent bleeding episodes were defined as bleeding intervals of > 1 month. Cases that underwent successful therapy during the initial bleeding episode were excluded. We compared Agatston scores (total calcium score) between the two groups of patients to assess the degree of arteriosclerosis. A calcified lesion was defined as an area of at least 2 connected pixels with > 120 Hounsfield units (HU) on the unenhanced CT scan. Aortic mural calcified area \times cofactor (1:120–199HU, 2:200–299HU, 3:300–399HU, 4: > 400 HU) was determined. The sums of the scores for every calcified speck were calculated across all lesions in a slice from the level of the diaphragm to the aortiliac bifurcation to obtain the total calcium score. Moreover, the relationship between recurrent bleeding episodes and the patients' clinical characteristics, including age, sex, smoking habit, comorbidities (hypertension, cerebro-cardiovascular disease, diabetes mellitus, hyperlipidaemia, chronic liver disease, chronic kidney disease, and chronic obstructive pulmonary disease), internal medicine (antithrombotic drug, non-steroidal anti-inflammatory drug, and proton pump inhibitor), shock vital on hospitalization, and transfusion need, was determined.

Results: Overall, 39 (49%) cases had recurrent bleeding episode and 40 (51%) had single bleeding episode. The cumulative recurrent bleeding rate in the recurrent bleeding episode group was 33% and 59% at 1 and 3 years, respectively. Agatston scores in the recurrent bleeding episode group were significantly higher than those in the single bleeding episode group (5902 ± 7187 vs 2912 ± 4687 , $P = 0.031$). Clinical characteristics associated with recurrent bleeding episodes were cerebro-cardiovascular disease ($P = 0.0044$), chronic kidney disease ($P = 0.031$), and antithrombotic drug ($P = 0.048$) in univariate analysis. Subsequent multivariate analysis determined that cerebro-cardiovascular disease was an independent contributor to recurrent bleeding episode (OR: 5.48; 95%CI: 1.11–40.7).

Conclusion: Arteriosclerosis along with cerebro-cardiovascular disease may be a significant contributing factor for colon diverticulum recurrent bleeding.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0432 EARLY VERSUS STANDARD COLONOSCOPY – A RANDOMIZED CONTROLLED TRIAL IN PATIENTS WITH ACUTE LOWER GASTRO-INTESTINAL BLEEDING: RESULTS OF THE BLEED STUDY

I. Van Rongen¹, B. Thomassen², L. Perk¹

¹Gastroenterology, Haaglanden MC, The Hague/Netherlands

²Landsteiner Institute, Haaglanden Medical Centre, The Hague/Netherlands

Contact E-mail Address: inge.van.rongen@gmail.com

Introduction: The incidence of acute lower gastro-intestinal bleeding (LGIB) is estimated at 21 adults per 100,000 person years and is increasing with the ageing of the population [1]. Diagnostic management of LGIB has been extensively debated in recent literature, especially whether colonoscopy within 24 hours of presentation is feasible and safe [2–4].

Aims & Methods: The aim of our study was to examine differences in length of hospital stay in patients with LGIB receiving either early colonoscopy (within 24 hours of presentation) or standard colonoscopy (within 1–3 days).

We performed a single-centre, non-blinded randomized controlled trial, including patients presenting at the emergency department with acute hematochezia and excluding patients with an upper bleeding source. Primary outcome was the length of hospital stay. Secondary outcomes included yield of colonoscopy, blood transfusion requirements, recurrent bleedings, complications, diagnostic and therapeutic interventions related to complications and 30-day mortality. The follow-up period was one month.

Results: In total, 132 patients were randomized: 63 for early colonoscopy and 69 for standard colonoscopy. Baseline characteristics of both groups were comparable. In the intention-to-treat (ITT) analysis, the length of hospital stay was significantly lower in patients that underwent an early colonoscopy, compared to the standard colonoscopy group: median 2.0 days [IQR 2.0–4.0] vs. median 3.0 days [IQR 2.0–4.0] ($p = 0.009$). Recurrent bleedings and hospital re-admissions were significantly more frequent in the early colonoscopy group: 13% vs. 3% ($p = 0.04$) and 11% vs. 2% ($p = 0.02$) respectively. The reason for more recurrent bleedings could not be established, although use of anti-thrombotic therapy might be a factor. No difference was observed regarding the number of patients diagnosed with either a confirmed active bleeding or presumptive bleeding source. In both groups, blood transfusion rate was similar and thirty-day mortality was zero.

Conclusion: In patients with LGIB, early colonoscopy reduces the length of hospital stay compared to standard colonoscopy. However, more recurrent bleedings are observed and no improvement of diagnostic yield could be established.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Direct oral anticoagulants (DOAC) are now popularly used as anticoagulation for atrial fibrillation and deep vein thrombosis, as well as Warfarin. But, direct comparison of DOAC and warfarin in the patients with gastrointestinal bleeding was little reported.

Aims & Methods: We retrospectively analyzed 18 on DOAC and 60 cases on Warfarin of the patients with gastrointestinal bleeding from January 2011 to March 2017 on the basis of single-center experience in Japan. We analyzed concentrated red cell (CRC) and fresh frozen plasma (FFP) transfusion rate, re-bleeding rate during hospitalization, the duration from bleeding to endoscopy, from endoscopy to discharge and from bleeding to discharge in both group. In DOAC group, each 6 patients took Dabigatran, Rivaroxaban and Apixaban.

	DOAC (N = 18)	Warfarin (N = 60)	p value
Male sex, n (%)	15 (83.3%)	41 (68.3%)	0.20
Age, years	74.0 \pm 2.2	74.4 \pm 1.2	0.87
Anti-platelet therapy, n (%)	8 (47.1%)	22 (36.7%)	0.44
Lower gastrointestinal bleeding, n (%)	12 (66.7%)	29 (48.3%)	0.17
Bleeding after endoscopic procedure, n (%)	11 (61.1%)	22 (36.7%)	0.07
Hemoglobin, g/dl	11.1 \pm 0.7	9.6 \pm 0.4	0.06
PT-INR	1.51 \pm 0.36	2.50 \pm 0.19	0.02
Fresh frozen plasma transfusion, n (%)	3 (16.7%)	20 (33.3%)	0.16
Concentrated red cell transfusion, n (%)	9 (50.0%)	32 (53.3%)	0.80
Re-bleeding during hospitalization, n (%)	1 (5.6%)	12 (20.0%)	0.11

(continued)

Continued

	DOAC (N = 18)	Warfarin (N = 60)	p value
The duration from bleeding to endoscopy, days	0.8 ± 0.5	1.2 ± 0.2	0.52
The duration from endoscopy to discharge, days	9.0 ± 5.5	23.0 ± 3.0	0.03
The duration from bleeding to discharge, days	9.8 ± 5.4	24.2 ± 3.0	0.02
Thrombotic embolism during hospitalization, n (%)	0 (0.0%)	1 (1.7%)	0.47

Results: Patient characteristics such as sex, age, anti-platelet therapy, location of bleeding and bleeding after endoscopic procedure had no significant difference in both groups. Upper gastrointestinal bleeding occurred 6 (33.3%) of DOAC group and 31 (51.7%) of Warfarin group. Hemoglobin tended to be lower (11.1 ± 0.7 g/dl vs 9.6 ± 0.4 g/dl, $p=0.06$) and international normalized ratio of prothrombin time (PT-INR) was significantly prolonged in Warfarin group (1.51 ± 0.36 vs 2.50 ± 0.20, $p=0.02$). CRC transfusion rate had no significant difference in both group, but FFP tended to be transfused at high rate in Warfarin group (16.7% vs 33.3%, $p=0.16$). Re-bleeding rate during hospitalization had no significant difference in both group, but tended to be higher in Warfarin group (5.6% vs 20.0%, $p=0.11$). The duration from bleeding to endoscopy had no significant difference in both group (0.8 ± 0.5 days vs 1.2 ± 0.2 days, $p=0.52$), but the duration from endoscopy to discharge was significantly longer in Warfarin group (9.0 ± 5.5 days vs 23.0 ± 3.0 days, $p=0.03$). Also, the duration from bleeding to discharge was significantly longer in Warfarin group (9.8 ± 5.4 days vs 24.2 ± 3.0 days, $p=0.02$). Thrombotic embolism during hospitalization occurred only 1 (1.7%) of Warfarin group.

Conclusion: The duration of hospitalization was significantly shorter in DOAC group of the patients with gastrointestinal bleeding, and the rate of FFP transfusion and re-bleeding tended to be lower in DOAC group. This study showed that DOAC may be more superior to Warfarin as anticoagulation for atrial fibrillation and deep vein thrombosis at the quality of life (QOL) in the patients with gastrointestinal bleeding.

Introduction: In Korea, colorectal cancer is the most common cancer among old aged women over 65 years old. The incidence of colorectal cancer, in particular, is dramatically increasing due to environmental factors such as the westernized eating habits. Furthermore, due to advances in medicine, the survival rate of those with advanced colon cancer is increasing. An increased risk of malignant tumors associated with colorectal cancer has been suggested recently, but adequate studies have not been conducted. The purpose of the study is to determine whether ovarian cancer is more common in the patients diagnosed with colorectal cancer than in the general population. If a woman diagnosed with colorectal cancer indeed has a high incidence of ovarian cancer, a screening test can be performed on high-risk patients.

Aims & Methods: This is a retrospective cohort study using data registered in the National Health Insurance Corporation as a cancer diagnostic code since 2007. In Korea, once cancer is diagnosed, this information is recorded by the National Health Insurance Corporation with a relevant code, and this system provides every patient's data for medical research purposes. The colorectal cancer group includes patients newly enrolled with the corresponding diagnostic code (ICD-10 code C18, C19, and C20). The 56,682 colorectal cancer patients and 288,119 sex- and age- matched general population was collected. Propensity score methods were used to facilitate the creation of comparison group that is similar. Each cancer patient was matched to five individuals in the unexposed cohort. All data was followed up by a new diagnostic code of ovarian cancer (ICD-10 code C56) was given. After adjusting for sex, age, smoking, drinking, exercise and comorbidities (diabetes mellitus, hypertension, and hyperlipidemia), further analysis was performed. The hazard ratios and 95% confidence intervals were calculated via Cox proportional hazards regression models. Statistical analysis will be performed with SPSS version 24.0. When $P < 0.05$, the result was defined as statistically significant.

Results: Patients with colorectal cancer were followed up for an average of 4.4 years until the occurrence of ovarian cancer. During the follow-up period, 338 out of 56,682 (0.60%) colorectal cancer patients and 258 out of 288,119 (0.09%) people in the general population were diagnosed with ovarian cancer. Ovarian cancer was more common in the colorectal cancer group than the general population [Hazard ratio (HR) 7.13, 95% Confidence interval (CI) = 5.06–10.05]. The additional analysis was conducted only for those who had medical checkup data within one year (14, 190 patients in colorectal cancer group, 71,933 people in the control group). Even though the subjects in this group were adjusted for several factors (age, sex, smoking, drinking, exercise, diabetes, hypertension, and hyperlipidemia), the incidence of ovarian cancer was also higher in colorectal cancer group [HR 7.12, 95% CI = 5.05–10.04]. Colorectal cancer patients had a higher risk of ovarian cancer across all age groups including patients under the age of 55 years [HR 10.69, 95% CI = 6.26–18.26] and patients older than 55 years [HR 5.17, 95% CI = 3.26–8.19].

Conclusion: In conclusion, data from the National Health Insurance Corporation revealed that the incidence of ovarian cancer in colorectal cancer patients was higher than that of the general population. In woman diagnosed with colorectal

cancer, the screening test should be done to monitoring the occurrence of ovarian cancer. Further research is necessary to determine the interactive association between the development of ovarian cancer and colorectal cancer, and large prospective studies are needed.

Introduction: Colonoscopy is an imperfect tool. Several publications confirm colorectal cancer may manifest after a negative colonoscopy(1–3). The term “interval cancer” has often been used for cancers appearing after a negative colonoscopy. However, this is primarily a screening term(1). Post-colonoscopy colorectal cancer (PCCRC) is a broader term for cancers detected after a negative colonoscopy in any setting, including screening(2). Although there is overlap between these two terms, they are not synonymous. PCCRC can be thought of as the overarching term. PCCRCs can be subcategorized into interval cancers (identified prior to the next recommended screening or surveillance procedure) and non-interval cancers (identified at or after a recommended screening or surveillance interval, or where no subsequent screening or surveillance interval was recommended, up to 10 years following the colonoscopy).

Aims & Methods: The goal of this consensus process was to provide a framework for the terminology, identification, analysis and reporting of cancers appearing after a negative colonoscopy or computed tomographic colonography (post-colonoscopy/post-imaging colorectal cancers- PCCRC/PICRC respectively). We based our methodology on The Appraisal of Guidelines for Research and Evaluation (AGREE II) tool(4). An international multidisciplinary team (gastroenterologists, pathologists, epidemiologists, a radiologist and a patient representative) were summoned by the World Endoscopy Organisation (WEO); the final panel consisted of 20 voting members. The following topics were addressed by 2 working groups (WGs):

1. Aetiology WG

- Terminology of aetiology categories
- Risk factors/potential explanations of PCCRC
- How to ascribe potential explanations
- Minimal colonoscopy, histology and radiology datasets to examine PCCRC
- Molecular tests to be performed to examine PCCRC
- Prevention of PCCRC in high-risk groups

2. Performance WG

- PCCRC calculation & reporting
- PCCRC monitoring
- PCCRC papers peer-review
- Post-imaging CRC A literature search was performed in MEDLINE and Cochrane using terms “colorectal cancer AND interval cancer”, “healthcare quality assurance AND colorectal cancer” and “healthcare quality assurance AND colorectal cancer AND interval cancer”. The final output consisted of 391 articles. Proposed statements were subjected to anonymous voting via e-correspondence. Each statement was scored on an scale of 1 (strongly agree) to

5 (strongly disagree). A modified Delphi process was followed; consensus required at least 80% agreement. In areas of continuing disagreement, a recommendation for or against a particular statement required both >50% of participants in favour and <20% preferring the comparator. Failure to meet this resulted in no recommendation. The GRADE system for rating evidence and strength of recommendations was applied to final statements.

Results: The final output consists of 21 statements providing guidance on key aspects of PCCRC/PICRC, namely definitions, terminology, qualitative review/aetiology attribution and quantitative assessment of cases. A Root-Cause Analysis checklist as well as a PCCRC/PICRC manuscript peer-review checklist were also developed.

Conclusion: This is the first consensus aiming to standardise terminology around PCCRC. Each previous study defined PCCRC differently, making its use for benchmarking purposes impossible. This consensus presents a methodology for analysis of causation of PCCRC/PICRC and defines its potential role as a key quality indicator, providing recommendations for future investigators, policy makers, services and patients.

Introduction: Colorectal cancer (CRC) is still the third most common malignancies in the US according to Colorectal Cancer Statistics, 2017[1]. During past decades, the incidence and mortality of CRC among individuals aged over 50 years are declining significantly, while the rate of CRC in the young is sharply on the rise curiously [2–3]. Escalating rate of young-onset CRC, coupled with increased survival rate, would definitely lead to accumulation of young survivors considerably. There is a growing study reporting the risk of second primary cancers (SPCs) in certain cancer survivors, including CRC. Several population-based studies revealed that patients with a history of CRC were at high risk of SPCs than the general population [4–6]. However, to the best of our knowledge, very little is known regarding the risk and sites of SPCs following prior diagnosis of CRC in the young (aged ≤ 50).

Aims & Methods: To address this important gap, we aimed to quantify the relative risk of SPCs after a diagnosis of CRC in the young CRC survivors. We conducted this retrospective study by utilizing the Surveillance, Epidemiology, and End Results (SEER) database and identified primary CRC patients with subsequent cancers between 1973 and 2013. We excluded cases with less than 6-months latency restriction. Standardized incidence ratios (SIR) and absolute excess risk (AER) were calculated to assess the relative risk for SPCs. SIRs for subgroup analysis were further stratified by gender, race, calendar year, latency period, SEER stage, cancer subsite, radiotherapy. All statistical tests were performed by SEER*Stat version 8.3 and a P value <0.05 was considered statistically significant. Our study was approved by the review board of Zhejiang Institute of Gastroenterology, Sir Run Run Shaw Hospital, China.

Results: Among 340,992 CRC patients, there were 44,472 survivors who developed 51,084 SPCs during the follow-up, including 3283 young (young aged ≤ 50) and 41,189 (old > 50) old survivors. The SIR of all sites significantly decreased with increased age. Compared with the general population, SIRs of all solid tumors and hematological disease were significantly increased in the young. There was significant 43% risk of SPCs in young survivors (SIR=1.43, 95%CI=1.39–1.48, AER=33.85) and slight increases in old survivors (SIR=1.02, 95%CI=1.01–1.03, AER=4.20). For young survivors, small

intestine (SIR=8.36), colon (SIR=3.77), rectum (SIR=3.56), bile ducts (SIR=3.70) were the most common sites. This trend was persisted regardless of other factors, such as gender, race, calendar year, stage, subsites, radiation, latency. For young patients with second cancers, 36.4% died of their initial cancer, but 44.6% died of their second primary malignancy.

Conclusion: Excess risk of developing a second malignancy existed in young-onset CRC survivors and this trend was consistent among different subgroups. About 44.6% young patients died of their SPCs. We hope our results may provide some implication for future surveillance and prevention strategies for young CRC survivors.

P0438 INCIDENCE OF FECAL OCCULT BLOOD TEST INTERVAL CANCERS IN COLORECTAL CANCER SCREENING; A SYSTEMATIC REVIEW AND META-ANALYSIS

E. Wieten¹, E. Schreuders¹, E.J. Grobbee¹, D. Nieboer², I. Lansdorp-Vogelaar², M.J. Bruno¹, E.J. Kuipers¹, M.C.w. Spaander¹

Contact E-mail Address: e.wieten@erasmusmc.nl

Introduction: Worldwide, many organized colorectal cancer (CRC) screening programs use non-invasive fecal occult blood tests (FOBTs). Although the interval colorectal cancer (iCRC) rate is an important performance indicator of a screening program, data on iCRC after negative FOBTs are limited.

Aims & Methods: In this systematic review and meta-analysis we compared the incidence of iCRCs following a negative fecal immunochemical test (FIT) or guaiac fecal occult blood test (gFOBT). Second, we assessed if screening-related or patient-related factors are associated with FOBT iCRCs. Ovid Medline, Embase, The Cochrane Library, the Science Citation Index, PubMed publisher and Google scholar were searched up to May, 2016. All studies reporting on the incidence of FIT or gFOBT iCRCs in average CRC screening populations were included, without language restrictions. Main outcome was pooled incidence rate of iCRCs per 100,000 person-years (p-y). FOBT iCRC was according to international standards defined as cancer that developed after a negative FOBT and before the next FOBT was due. Pooled incidence rates were obtained by fitting random effect poisson regression models. The between-study heterogeneity of effect-size was quantified using the I².

Results: We identified 5,873 records, of which 413 full-text articles were assessed for eligibility and 30 studies were included in both qualitative and quantitative syntheses. Meta-analyses comprised data of 5,252,563 screening participants, in which 14,030 screen-detected CRCs and 5398 FOBT iCRCs were documented. Pooled incidence rates of iCRC following FIT and gFOBT were 20 (95%CI 14–28; I²=94%) and 40 (95%CI 26–61; I²=93%) per 100,000 p-y, respectively. The pooled incidence rate ratio of FIT iCRC compared to gFOBT iCRC was 0.50 (95%CI 0.30–0.84, n=30 studies). For every FIT iCRC, three CRCs were found with FIT, while for gFOBT the ratio between iCRC and screen-detected CRC was 1:1.3, Table 1. No significant differences were found between the relative risk of FOBT iCRC in the second and third screening round compared to the first, with 1.03 (95%CI 0.94–1.13) and 1.08 (95%CI 0.93–1.22), respectively. Incidence rate ratio of FOBT iCRC was 1.2 (95%CI 0.8–1.7) for males relative to females and 5.0 (95%CI 1.2–21) for screenees aged ≥60 relative to <60 years.

Table 1: Baseline data of 30 studies included in quantitative meta-analyses displayed per test type

	Screening participants n = 5, 252, 563	Screen-detected CRCs n = 14, 030	FOBT iCRCs n = 5, 398	Ratio screen-detected CRC to FOBT iCRCs
FIT n, (%)	4,774,516 (91)	12,172 (87)	4003 (80)	3.0
gFOBT n, (%)	478,047 (9)	1858 (13)	1395 (20)	1.3

Conclusion: This is the first study to report on the pooled incidence of FIT and gFOBT iCRC in screening setting. The incidence rate of iCRC after a negative

FOBT is two-fold higher in gFOBT than in FIT, which supports the use of FIT over gFOBT as screening stool test. However, for every three FIT-detected CRCs, still one CRC is missed, which highlights the importance to adequately inform screeners about the risk of developing a colorectal carcinoma after a negative FIT.

⁴Skåne University Hospital Malmö, Department of Gastroenterology and Hepatology, Malmö/Sweden

Contact E-mail Address: anna.forsberg@ki.se

Introduction: Age and family history of colorectal cancer (CRC) are the strongest risk factors for CRC. Obesity, commonly assessed based on body mass index (BMI), is associated with an increased risk for CRC in men but the association is weaker in women and differs between studies. We investigated which of the following body composition measures: BMI, waist circumference (WC), waist-hip ratio (WHR), weight-height-ratio (WHtR), weight-hip-height ratio (WHHR), A Body Shape Index (ABSI) and percent body fat that best predict the development of CRC in men and women.

Aims & Methods: We used data from Malmö Diet and Cancer cohort in Sweden, including 16,840 women and 10,903 men (mean age, 58.1 years at baseline), followed for a median of 19.8 years. We identified cases with CRC until the end of 2014 using national Swedish registers. Hazard ratios (HR) for CRC, colonic cancer (CC) and rectal cancer (RC) per one standard deviation increase in each body composition measure respectively were calculated using Cox regression models, stratified by sex and adjusted for age, alcohol consumption, smoking, education and physical activity. Likelihood ratio tests and C-statistics were calculated to identify the anthropometric measure that improves the null model the most.

Results: Incident CRC occurred in 880 individuals (477 women) during follow-up. All body composition measures apart from WHHR significantly predicted CRC in men and waist circumference (WC) was the best predictor based on C-statistics and LR-test (HR per standard deviation [SD] increment, 1.19; 95% CI, 1.08–1.31, LR-test $p < .001$, C-statistics 0.6278). The association between WC and CRC was only found in men with a BMI above 25. All body composition measures apart from WHHR and percent body fat significantly predicted CC in men, again WC was the best predictor (HR 1.25; 95% CI, 1.11–1.42, LR-test $p < .001$, C-statistics 0.6444). ABSI was the only measure significantly associated with risk for RC in men (HR, 1.24; 95% CI, 1.05–1.47). In women neither of the measures was significantly associated with an increased risk for CRC, CC nor RC.

Conclusion: In this Swedish population-based cohort study on well-characterized participants, body composition measures predicted CRC in men but not in women after adjusting for age, education and health behaviors. WC was the best predictor of CRC and CC in men and the association was only significant in overweight/obese men in stratified analyses. Gender difference in the interplay between sex and metabolic hormones in the adipose tissue may explain the lack of associations in women.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0440 TH17 CELLS INDUCE EPITHELIAL-MESENCHYMAL TRANSITION VIA IL-17/PI3K/AKT/SNAIL PATHWAY IN COLORECTAL CANCER

Q. Li¹, X. Xu², P. Zhou²

¹Endoscopy Center, Zhongshan Hospital, Fudan University, Zhongshan Hospital, Fudan University, Shanghai/China

²Endoscopy Center, Zhongshan Hospital, Fudan University, Shanghai/China

Contact E-mail Address: liquanlin321@126.com

Introduction: T helper 17 (Th17) cells participate in the progression of various cancers. Both tumor-promoting and tumor-suppressing effect have been reported. The role of Th17 cells in colorectal cancer (CRC) remains controversial and the specific mechanism of how Th17 cells affect the development of CRC remains to be explored.

Aims & Methods: The study aimed to clarify the role of Th17 cells in CRC and identify the underlying molecular mechanisms. The percentage of Th17 cells and

IL-17 expression were evaluated via flow cytometry, enzyme-linked immunosorbent assay, and immunohistochemistry in tissue samples and peripheral blood. Effects and underlying molecular mechanisms of IL-17 cells on epithelial-mesenchymal transition (EMT) process were explored in vitro using IL-17 transfection and in nude mice by implanting IL-17 overexpressed CRC cells. To detect the direct role of Th17 cells on EMT process, SW480 cells were co-cultured with Th17 cells via transwell system. Cancer signaling phospho antibody microarray was used to explore the potential signaling pathway. The clinical significance of Th17 cells was investigated in tissue microarrays containing CRC tissues from 90 patients following surgery using immunohistochemistry.

Results: A higher percentage of Th17 cells and serum IL-17 level were found in CRC patients than healthy controls, and Th17 cells presented a gradual upward trend in normal epithelium-adenoma-carcinoma sequence. The overexpression of IL-17 significantly promoted tumor proliferation and invasion, and inhibited apoptosis in vitro and in vivo. IL-17 overexpression reduced the expression of E-cadherin and induced the expression of Snail, β -catenin, and Vimentin in both SW480 cells and tumor xenografts, suggesting that IL-17 could induce the EMT process in CRC. When co-cultured SW480 cells with Th17 cells, we found Th17 cells could directly promote the EMT process of tumor cells. Furthermore, using cancer signaling phospho antibody microarray, we found that PI3K/AKT/Snail signaling pathway played a key role in the regulation of EMT. EMT process could be reversed by LY294002 and IL-17 mAb intervention, suggesting that IL-17/PI3K/AKT/Snail pathway played a vital role in Th17 cells-induced EMT in CRC. Supporting these findings, in human CRC tissues, immunostaining indicated that the percentage of Th17 cells was significantly associated with E-cadherin expression and AKT phosphorylation. The clinical significance of Th17 cells was authenticated by revealing that the combination of intratumoral Th17 cells and E-cadherin served as a better prognosticator for postoperative tumor recurrence than either marker alone.

Conclusion: Th17 cells promote EMT process and facilitate tumor progression via activating IL-17/PI3K/AKT/Snail signaling pathway in CRC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0441 MICRORNA EXPRESSION PROFILE IN RECTAL CANCER

J. Král¹, V. Rusnakova², L. Langerova², V. Korenkova², P. Vodicka³, J. Spicak¹, J. Slysokova³

¹Dept. Of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

²Institute of Biotechnology AS CR, v.v.i., Prague/Czech Republic

³Department Of The Molecular Biology Of Cancer, Institute of Experimental Medicine AS CR, v.v.i., Prague/Czech Republic

Contact E-mail Address: jan.kral@centrum.cz

Introduction: Colorectal cancer (CRC) remains the second most common cancer in women and third in men worldwide, with more than 1.3 million patients diagnosed every year (1–3). Still more than 50% of patients are diagnosed with advanced disease (stage III and IV), which has worse prognosis and survival. There is a need for new biomarkers for early diagnostics, predicting patient's treatment response and follow-up. Recent data suggest that microRNAs (miRNAs) might be utilized as these biomarkers (4, 5).

Aims & Methods: We focused on specifying differences in expression profile between rectal tumor and adjacent healthy mucosa. Individual miRNA levels were analyzed in relation to patient's treatment response and post-treatment survival, in order to identify miRNAs with possible role of predictive and prognostic markers in rectal cancer. At first, we screened 20 pairs of rectal tumors and healthy surrounding mucosae for the expression levels of 2555 microRNAs using 3D-Gene TORAY microarray system. We have identified 71 candidate miRNAs with different expression profile in tumor and healthy tissue. These 71 miRNAs were further explored and verified in larger cohort of 101 rectal tumors and 105 colon tumors compared to matched healthy tissues by qPCR (Fluidigm BioMark). Results were analyzed in relation to different clinico-pathological characteristics of tumors, to individual patient's treatment response and overall or disease-free survival.

Results: We confirmed 18 miRNAs to be differently expressed in rectal tumors as compared to healthy mucosa. This expression profile was observed in tumors resected prior to neoadjuvant therapy, but not in those that were neoadjuvantly treated. Only 2 miRNAs were dysregulated irrespectively on neoadjuvant therapy. We have further investigated whether this signature is specific for rectal cancer, or is observed also in colon cancer. We have found that 14 out of 18 miRNAs were indeed commonly dysregulated in whole CRC, and 4 miRNAs were dysregulated in rectal tumor only. In order to identify miRNAs with any association to treatment, we have analyzed miRNA expression profile of rectal tumors in relation to patient's treatment response and their long-term survival. Thirteen miRNAs were differently expressed between tumors that responded to therapy and those that relapsed.

Conclusion: We have identified miRNA expression patterns specific for rectal cancer and identified miRNA candidates that might be used as a predictive and prognostic marker in patient's follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0442 MUSCARINIC-3 RECEPTOR TARGETED MIRNAS ARE INVOLVED IN BILE ACID-INDUCED PROLIFERATION ON H508 COLON CANCER CELL LINE

F. Tekin, C. Aktan, N. Oruc, O. Ozutemiz

Gastroenterology, Ege University Medical School, Izmir/Turkey

Contact E-mail Address: drtekinfatih@gmail.com

Introduction: Studies with the colon cancer cell lines which express muscarinic-3 (M3) receptors showed that taurine conjugates of lithocholic acid, but not other bile acids, bind to M3 receptors, and stimulate an increase in cell proliferation. On the other hand, many microRNAs (miRNAs) are involved in colon carcinogenesis. However, the interaction of bile acid-M3 receptors and miRNAs and their potential effects in colon carcinogenesis remains to be elucidated.

Aims & Methods: For the first time in the literature, we examined the possible role of M3 receptor-targeted miRNAs on two human colon cancer cell lines: H508, which expresses M3 receptors, and SNU-C4, which does not. Cell proliferation for 6 days after sodium taurothiocholate (ST) and atropine (A) treatment was analysed by WST-1 method. Expression of M3 receptor gene at mRNA level was analysed by qPCR, and at protein level by Western Blot method. Apoptotic experiments were analysed by Annexin V assay. MiRNAs which possibly targeted M3 receptors were identified by in silico analyses. The methods were repeated three times, and the average values were calculated.

Results: When compared to SNU-C4 cells, M3 receptor gene expression was found to be increased 70-fold on H508 cells. After a 6-day incubation, maximum H508 cell proliferation (300%) was achieved on 5th day with a dose of 300 µM ST, inhibited by a dose of 1 µM A. In contrast, the SNU-C4 cells showed no significant change in cellular proliferation. Treatment of H508 cells with ST caused a decrease (2.53-fold) of M3 receptor gene expression, however, no change of M3 receptor at protein level was seen. No changes in apoptosis on both colon cancer cell lines were observed. Of 25 M3 receptor-targeted miRNAs, expression levels altered in 9; 6 of them were up-regulated (hsa-miR-129-5p, hsa-miR-30c-5p, hsa-miR-224-5p, hsa-miR-30b-5p, hsa-miR-522-3p, hsa-miR-124b) and 3 of them (hsa-miR-30e-5p, hsa-miR-147b, hsa-miR-885-3p) were down-regulated on H508 cells ($p < 0.05$).

Conclusion: ST interact with M3 receptors which modulate colon cancer cell proliferation on H508 cells. M3 receptor-targeted miRNAs are involved in ST induced proliferation. Whether the use of ursodeoxycholic acid, selective anti-miRNAs, anti-cholinergic agents or other approaches to blocking potential interactions of bile acids/salts with neoplastic colonic epithelium may be a useful adjunct to colon cancer prevention or treatment remains to be determined.

Introduction: Dyslipidaemia and statin use have been associated to colorectal cancer (CRC), but prospective studies have shown controversial results. Dyslipidaemia has been thought to have an important role in inflammatory pathways, oxidative stress and insulin resistance, which could contribute to the pathogenesis of cancer. However, findings from prospective studies that have examined the association between serum dyslipidaemia (low density lipoprotein cholesterol (LDL), HDL or TG) and colorectal neoplasia have been inconsistent. [1–4] It is unknown whether lipids and lipoproteins cause cancer or are intermediate or correlated factors within carcinogenic pathways. Epidemiological studies could be confounded by 3-Hydroxy-3-methylglutaryl-coenzyme A reductase inhibitors (statins) use, which might also have a protective effect to CRC. It is unclear whether it is statin use or dyslipidaemia that prompted statin use, which may be associated with CRC. Indeed, a large number of epidemiological studies have examined the effect of statins on colorectal cancer risk, with often inconsistent results.[5–6] A Mendelian randomization approach could help to establish a causal relationship between dyslipidaemia and CRC.

Aims & Methods: We aimed at determining whether dyslipidaemia is causally linked to CRC risk and to explore association of statins with CRC. A case-control study was performed including 1336 CRC cases and 2744 controls (MCC-Spain) between 2008 and 2013. Subjects were administered an epidemiological questionnaire that included lifetime regular use of prescription drugs. Also, subjects were genotyped with an exome array supplemented with 5000 custom SNPs. We applied the Mendelian randomization approach. The array included 136 SNPs previously shown to be associated with blood lipids levels in GWAS, that were used to build three genetic lipid scores, as the count of risk alleles. The scores were specific for low density lipoprotein cholesterol (LDL), high density lipoprotein cholesterol (HDL) or triglycerides (TG). We tested the association on regular statin use and the genetic lipid scores with logistic regression models, adjusted for potential confounders.

Results: The LDL genetic risk score was significantly associated with statin consumption (OR = 1.07, 95%CI 1.05–1.10, $p = 4.4 \times 10^{-11}$). The dyslipidaemia genetic risk score was not significantly associated with CRC for either of the target lipids studied. Cases had the same average alleles as controls in all the lipid traits. Statin use was a borderline significant protective factor for CRC (multivariate adjusted OR = 0.83; 95%CI 0.69–1.00, $p = 0.049$).

Conclusion: Using the Mendelian randomization approach, our study does not support the hypothesis that lipid levels are associated with the risk of CRC. This study does not rule out, however, a possible protective effect of statins in CRC by a mechanism unrelated to lipid levels.

Introduction: Long non-coding RNAs (lncRNAs) contribute to different cancers including colorectal cancer (CRC) through influencing cancer-related processes such as cell proliferation, apoptosis, and invasion. Previous studies have shown altered LINC00152 expression in CRC, but the detailed mechanism of its effects during colorectal carcinogenesis and cancer progression is not well studied.

Aims & Methods: We aimed to study the effects of LINC00152 to the cell cycle regulation and promoter DNA methylation of several CRC-associated tumor suppressor genes in colon cancer cells. We also analyzed the expression and promoter DNA methylation of LINC00152 and of its regulated molecules in human colonic tissue samples. LINC00152 were silenced in SW480 colon carcinoma cells using Stealth siRNAs. Cells were harvested 48 or 72 hours after transfection. Flow cytometric cell cycle analysis was performed using propidium-iodide DNA staining. Cyclin D1 protein expression was detected using flow cytometry after labeling with anti-cyclin D1 antibody. The effect of LINC00152 silencing to DNA methylation levels of SFRP1, SFRP2, SDC2 and PRIMA1 tumor suppressor gene promoters was studied using MethyLight technology. Promoter methylation and expression of the above molecules were also studied on human colonic tissue samples.

Results: LINC00152 expression was successfully silenced in SW480 cells with 93–98% efficiency. Silencing of LINC00152 suppressed cell growth, induced apoptosis and decreased cyclin D1 protein expression. LINC00152 knockdown did not affect the promoter methylation status of SFRP1, SDC2 and PRIMA1 genes, while reduced the DNA methylation level of SFRP2 promoter. Remarkable hypomethylation of LINC00152 promoter was detected in CRC compared to normal samples ($p < 0.01$), which correlated with increased expression ($R = 0.90$). SFRP2 promoter hypermethylation and decreased expression were measured in CRC and adenoma tissues compared to normal samples ($p < 0.05$).

Conclusion: Our results support that LINC00152 lncRNA can contribute to CRC development by facilitating cell proliferation through upregulation of cyclin D1 cell cycle progression gene and by affecting promoter methylation of SFRP2 tumor suppressor gene. On human tissue level, similar signaling pathway alterations were detected in CRC.

Introduction: Colonoscopy surveillance of polyps is based on their size, number and pathological features. The role of their genetic profile to predict advanced metachronous lesions (AML) remains unknown.

Aims & Methods: To study the relation between genetic profile of polyps and both risk of AMLs and time to develop them in surveillance. 308 patients with colonic polyps were consecutively enrolled between 2007 and 2009 for this cohort study, and followed up to 2014. Variables as age, sex, smoking, weight, number of colonoscopies and number and characteristics of polyps were collected. 995 polyps were analyzed for somatic mutations on BRAF and KRAS genes using allelic discrimination by real-time PCR and direct DNA sequencing, respectively. High level of methylation on CpG islands (CIMP-H) was also tested using MS-MLPA. AML was defined by a size higher than 9 mm, high-grade dysplasia or villous component in adenomatous lesions. Regarding serrated lesions, AML was defined by a size higher than 9 mm, any grade of dysplasia and proximal location. Risk of developing AML for individual genetic markers was studied using Chi-square tests and logistic regression for univariate and multivariate analysis, respectively. Log-rank test with Kaplan Meier survival curves for univariate analysis and Cox-regression model for multivariate analysis were also performed. As logistic as Cox regression were adjusted by sex, age, familial colorectal cancer, smoking and features of AML in first colonoscopy. P value of 0.05 was considered significant.

Results: Patients were followed up for a median of 26 months (range 63). 21% of polyps in first colonoscopy were CIMP-H. KRAS and BRAF mutations accounted for 25% and 17% of polyps, respectively. In univariate analysis, KRAS-mutated polyps were related to higher risk of AML in surveillance (52% KRAS-mutated polyps vs 31% non-mutated; $RR = 1.8$, 95% CI 1.2–2.9; $p = 0.01$). Similar results were obtained regarding CIMP-H (77% CIMP-H

polyps vs 38% non-CIMP; $RR = 3.7$, 95% CI 1.3–10.3; $p = 0.005$) but no association was found with BRAF-mutated ones. Logistic regression showed CIMP-H as the unique genetic marker of risk for AML (OR 11.41, 95% CI 2.04–63.70; $p = 0.006$). Regarding time to develop AML, shorter intervals were found related to CIMP-H (median of 31 vs 48 months in non-CIMP-H; $p = 0.002$) and KRAS-mutations (median of 36 vs 49 months in non-mutated; $p = 0.029$) in univariate analysis. There were no significant results concerning BRAF status. Multivariate analysis highlighted CIMP-H as the unique independent marker associated to shorter time to develop AML (HR 4.01, 95% CI 1.36–10.46; $p = 0.01$).

Conclusion: Presence of CIMP-H in polyps associates higher risk of subsequent AML and shorter interval to their development. Genetic profile of polyps emerges as useful tool for colonoscopy surveillance.

Introduction: Colorectal cancer (CRC) frequently harbours concomitant mutations in KRAS and APC that promote carcinogenesis. Epigenetic dysregulation plays essential roles in the tumorigenicity of KRAS mutant CRC. Our preliminary data demonstrated that simultaneous KRAS gain-of-function mutations in APC-null CRC cells induced the hypermethylation of DNA and histones, an effect driven by metabolic rewiring of glutamine metabolism. We recently unveiled that glutamine metabolism in KRAS-mutant CRC could be rewired by the mitochondrial glutamate transporter, SLC25A22, a synthetic lethal gene in KRAS-mutant CRC in vitro and in vivo. In this study, we investigate the potential role of SLC25A22-mediated glutaminolysis in regulating DNA and histone methylation in CRC, its underlying mechanisms, and the association of SLC25A22 with epigenetic dysregulation in human CRC cohorts.

Aims & Methods: We aim to 1) evaluate the impact of mutant KRAS on DNA and histone methylation in CRC; 2) examine the role of SLC25A22 in DNA and histone methylation in KRAS-mutant CRC; 3) elucidate the underlying mechanisms that underlies SLC25A22-mediated epigenetic dysregulation; and 4) investigate the clinical association between SLC25A22 and epigenetic dysregulation in CRC patients. DNA methylation was determined by the Illumina 860K methylation array and Methyl Light qMSP assays. Histone methylation was determined by Histone H3 Modification Multiplex Assay Kit and Western blot. U-13C5-Glutamine metabolic labelling and analysis of glutamine metabolism via the TCA cycle was determined by liquid chromatography-mass spectrometry analysis. In clinical samples, SLC25A22 mRNA and protein expression was determined and their correlation with CpG Island Methylator Phenotype (CIMP) status and histone methylation mark (H3K36me2) was evaluated.

Results: Using three pairs of isogenic cell lines harbouring wild-type and mutant KRAS (DKS8(WT) vs DLD1(mutant); HKE3(WT) vs HCT116(mutant); ICT(WT) vs ICT-KRAS(mutant)), we demonstrated that significant DNA and histone H3 hypermethylation in cell lines expressing mutant KRAS. DNA hypermethylation was associated with the up-regulation of 5-hmC, indicating suppressed DNA demethylation in KRAS mutant CRC cell lines. Metabolomic analysis revealed that KRAS mutation modified glutaminolysis via TCA cycle leading to high succinate and fumarate to α -ketoglutarate (α KG) ratio, which was to be pivotal in suppressing the enzymatic activity of dioxygenases such as DNA and histone demethylases, thereby leading to aberrant methylation. Interestingly, simultaneous APC-loss and KRAS activating mutations synergistically up-regulated the expression of SLC25A22, a key regulator of glutamine metabolism via the TCA cycle. CRISPR-Cas9 mediated knockout of SLC25A22 suppressed glutaminolysis in KRAS-mutant CRC cell lines, which in turn, reduced the ratio of succinate and fumarate to α -ketoglutarate. The impact of SLC25A22 knockout on glutamine metabolism had a profound effect on epigenetic regulation, as DNA methylation profiling revealed that SLC25A22 knockout increased 5-hmC levels and decreased DNA hypermethylation in KRAS-mutant CRC cell lines. Moreover, histone H3 methylation was reduced at multiple histone marks after the knockout of SLC25A22. These data implied that SLC25A22 inhibited DNA and histone demethylases by promoting the production of succinate and fumarate. Indeed, succinate supplementation reversed the effect of SLC25A22 knockout on DNA and histone methylation in KRAS-mutant CRC cell lines. In addition, succinate restored cell growth in SLC25A22 knockout cell lines, suggesting that epigenetic dysregulation was closely associated with tumorigenicity. In human CRC, SLC25A22 expression was positively associated with CIMP ($P < 0.0001$) and histone H3K36me2 methylation status ($P < 0.0001$).

Conclusion: SLC25A22 promotes the tumorigenicity of KRAS mutant CRC by driving aberrant DNA and histone hypermethylation, an effect mediated by increased production of TCA cycle intermediates succinate and fumarate, which inhibits DNA and histone demethylases. SLC25A22 is correlated with CIMP and histone hypermethylation in CRC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0447 FOLLISTATIN-LIKE PROTEIN 1 SUSTAINS COLON CANCER CELL GROWTH AND SURVIVAL

G. Bevivino¹, V. De Simone¹, R. Izzo¹, M. Di Giovangiulio¹, S. Sedda¹, E. Franzè¹, A. Rizzo¹, P. Rossi², C. Stolfi¹, G. Monteleone¹

Introduction: Follistatin-like protein 1 (FSTL1) is a secreted glycoprotein, widely expressed in human tissues, which plays key functions in the regulation of cell survival, proliferation, differentiation and migration. Moreover, deregulated expression of FSTL1 has been described in malignancies but its contribution to carcinogenesis remains controversial.

Aims & Methods: We here investigated the expression and role of FSTL1 in sporadic colorectal cancer (CRC). FSTL1 was evaluated in human CRC samples and cell lines by immunohistochemistry, Western blotting and real-time PCR. Cell proliferation and survival and cell cycle were evaluated in human CRC cell lines (i.e., HCT-116, DLD-1) treated with a specific FSTL1 antisense (AS) or control oligonucleotide by flow-cytometry. By Western blotting, we assessed expression of proteins involved in cell cycle progression, poly ADP-ribose polymerase (PARP), caspase-9 and active caspase-3. Moreover, the effect of FSTL1 knockdown on cell death was evaluated in cells cultured in the presence or absence of the pan-caspase inhibitor Q-VD-OPH by flow-cytometry.

Results: FSTL1 was significantly increased in both epithelial and lamina propria compartments of human CRC specimens as compared to controls. In CRC cell lines, FSTL1 knockdown caused accumulation of cells in G1 phase of the cell cycle and reduced CRC cell proliferation. FSTL1-deficient CRC cells had reduced levels of proteins involved in late G1 cell cycle phase, such as phosphorylated retinoblastoma protein (pRb), E2F-1, cyclin E and cyclin-dependent kinase-2 (Cdk2), with no modification of early G1 phase proteins (i.e. cyclin D). Treatment of CRC cells with FSTL1 AS increased the percentages of apoptotic cells and this effect was associated with activation of PARP, caspase-9 and caspase-3. Pre-incubation of HCT-116 and DLD-1 cells with Q-VD-OPH abolished the FSTL1 AS-induced cell death and reduced PARP and caspase activation, thus indicating that FSTL1 silencing induces CRC cell death through a caspase-dependent mechanism.

Conclusion: Our data indicate that FSTL1 is over-expressed in CRC cells and suggest a role for this protein in promoting intestinal tumorigenesis.

Introduction: In sporadic colon cancer, TP53 mutation is well known to occur in the late phase of colon carcinogenesis as adenoma-carcinoma sequence. Although numerous reports about clinical information of the patients with colon cancer have suggested that TP53 mutation might be related to various malignant potentials, direct effect of TP53 mutation on malignant potential in colon cancer is still unknown. Notably, there is no report about a relationship between TP53 mutation and cancer stemness. We therefore aimed to assess the function of TP53 mutation in colon cancer cells, by using recently established lentiviral CRISPR Cas9 system.

Aims & Methods: Two types of TP53 mutation were generated in LS174T cells, which are derived from human colon adenocarcinoma with wild-type TP53 (WT-TP53), by using lentiviral CRISPR Cas9 system. The guide RNAs were designed to bind exon3 or exon 10 of TP53, respectively. TP53 mutation in LS174T was confirmed by direct sequencing. The expression of TP53 protein was assessed by immunohistochemistry. Loss of function of TP53 was assessed by Nutlin-resistance and the expression of TP53 target genes. Malignant potentials of TP53-mutated cells were assessed by MTS Assay, 3D sphere formation assay and cell migration assay for cell proliferation, cancer stemness and cell migration, respectively. Chemo-resistance was also assessed by the treatment with 5-FU and L-OHP.

Results: We first selected LS174T cells with WT-TP53 because TP53 gene has already been mutated in almost colon cancer cell lines. We then successfully established 2 types of TP53 mutation in LS174T cells due to high effectiveness of gene-mutating by lentiviral system. Mutation in exon3 (TP53Ex3) and exon10 (TP53Ex10) of TP53 created the shorter form of TP53 (TP53Ex3; 55a.a. and TP53Ex10; 377a.a., respectively) compared to WT-TP53 (393a.a.). Mutant TP53 (TP53Ex10) is strongly expressed in nuclei as often shown in colon cancer region, whereas both WT-TP53 and mutant TP53 (TP53Ex3) are not

expressed in LS174T cells. In contrast, both TP53 mutants (TP53Ex3 and TP53Ex10) showed Nutlin-resistance and the down-regulation of TP53 target genes, suggesting that both mutants induced loss of function of TP53. We then assessed the effect of both TP53 mutants on various malignant potentials, resulting equally in accelerated cell growth, enhanced invasiveness and the resistance against 5-FU treatment compared to WT-TP53. Moreover, both mutants showed more frequent formation of 3D sphere and more expression of Lgr5 than WT-TP53, suggesting the promotion of cancer stemness by TP53 mutation even after being adenocarcinoma.

Conclusion: We for the first time showed the direct effect of TP53 mutation on malignant potential in colon cancer cells. Loss of function of TP53 induced by not only TP53Ex10 but also TP53Ex3 mutation, might promote malignant potentials including cancer stemness at the late phase of carcinogenesis. In general, nuclear accumulation of TP53 protein in cancer region is represented as TP53 mutation. However, negative staining of TP53 might also be careful for TP53 mutation to estimate malignant potential in colon cancer, since N-terminal mutation of TP53 in colon cancer has already been reported.

Introduction: Endogenous opioid system is involved in the maintenance of the intestinal homeostasis. Recently, we proved that stimulation of opioid receptors using P-317 – a novel cyclic morphiceptin analog with mu- and kappa- opioid receptor affinity, resulted in alleviation of acute phase of experimental colitis (induced by dextran sodium sulfate [DSS]) in mice. Chronic inflammation is associated with increased risk of colitis-associated colorectal cancer. Stimulation of opioid receptors produces different effects on cancer progression depending on the cancer type and stage of disease.

Aims & Methods: The aim of our studies was to characterize the role of the endogenous opioid system in pathogenesis and treatment of colitis-associated colorectal cancer using P-317. Colitis-associated colorectal cancer was induced by a single intraperitoneal injection of azoxymethane [AOM] (10mg/kg) and subsequent addition of DSS (1.5% w/v) into drinking water (week 2, 6, 9). From week 3, P-317 was injected intraperitoneally at the dose of 0.1mg/kg twice per week and the body weight and clinical score (rectal bleeding, stool consistency) were assessed. After 14 weeks, the macroscopic colon damage score was assessed and the samples were collected and used for biochemical, molecular and histological studies.

Results: A significant difference in colorectal tumor development was observed between vehicle- and P-317-treated mice. P-317 significantly decreased total number of colonic tumors as well as colon thickness and width after 14 weeks of disease induction. Myeloperoxidase activity, a marker of neutrophil infiltration, was inhibited by P-317 injections. Hematoxylin and eosin staining confirmed anti-tumor activity of P-317 as indicated by histological score connecting the following features: muscle thickness, damage of the intestinal wall, immune cell infiltration, invasion depth, crypt hyperplasia and disruption. The expression of IL-1β and TNF-α at mRNA level was decreased in P-317-treated mice as compared to vehicle-treated group.

Conclusion: P-317 may become an important pharmacological tool to study the factors that determine the development of inflammatory bowel disease and to define the role of the endogenous opioid system in chronic colitis and colorectal cancer.

Introduction: Colorectal cancer (CRC) is the third most common type of cancer in the world, and its incidence continues to rise^[1, 2]. The probability of recurrence and subsequent death due to colorectal cancer is associated with its stage^[1, 2]. Because of its insidious onset, the diagnosis of CRC is usually delayed. However, serological markers can be a relatively easier and cheaper alternative to colonoscopy for screening an average risk population^[1]. Several recent studies have shown that high-motility group box 1 (HMGB1) plays a critical role in tumorigenesis, disease progression and metastasis by activation of cancer cells, promotion of tumor angiogenesis, suggesting that HMGB1 may be useful as a new biomarker of cancer^[1, 2, 3, 4]. Studies have shown that HMGB1 is over-expressed in various types of cancers, include CRC, and those cases with higher expression of HMGB1 are associated with lymphatic metastasis, distant metastasis and poor prognosis^[5]. Several reports have demonstrated that HMGB1 is

secreted by cancer cells may be involved in occurrence of tumor metastasis [6, 7]. In a study by Luo et al, the authors found that HMGB1 secreted by the primary tumors had an apoptotic effect on the Kupffer cells which promoted development of liver [6, 7]. Furthermore, some researchers showed that increased levels of c-IAP2 and pERK, the downstream effector molecules of HMGB1 are found in tumors [8]. The current studies suggest that HMGB1 may be useful for diagnosis and treatment of CRC. However, whether HMGB1 has any role in the development of CRC metastasis is not clear. In this study, we investigated the effects of HMGB1 on CRC, and the possible underlying mechanisms were examined.

Aims & Methods: To investigate the relationship between high-mobility group B1 (HMGB1) and colorectal cancer (CRC) and the probable underlying pathogenic mechanism. In this prospective study, patients with CRC undergoing primary surgery and healthy subjects (control group) were included from July 2013 to December 2014. Serum HMGB1 concentration was determined using ELISA and HMGB1 mRNA expression was detected by RT-PCR method. Immunohistochemical analysis was performed to determine HMGB1, pERK and c-IAP2 protein expressions in the cancer tissues.

Results: 144 patients with CRC and 50 healthy subjects underwent serum HMGB1 testing. Resected specimens of 50 patients were used for HMGB1 mRNA and protein expression analysis. Serum HMGB1 levels in CRC patients were higher than that of the control group (8.42 vs. 1.79 µg/L, $p < 0.05$). Preoperative serum HMGB1 concentrations were significantly higher than the postoperative values (8.42 \pm 5.67 vs 1.64 \pm 1.89 µg/L, $p < 0.05$). Serum HMGB1 levels in CRC patients with distant metastasis were significantly higher (13.32 \pm 6.12 vs 7.37 \pm 5.17 µg/L, $p < 0.05$). HMGB1 mRNA and protein expression in CRC tissues was significantly higher than in the adjacent normal mucosa. HMGB1 protein expression positively correlated with the lymph node metastasis. There was positive correlation between HMGB1 and c-IAP2 ($r = 0.457$, $P < 0.05$), HMGB1 and pERK ($r = 0.461$, $P < 0.05$) as well as pERK and c-IAP2 ($r = 0.399$, $P < 0.05$).

Conclusion: HMGB1 expression in CRC correlates with distant and lymph nodal metastasis. It may inhibit apoptosis by inducing activation of pERK and cIAP2.

Introduction: Colorectal cancer (CRC) is often diagnosed at an intermediate or late stage with poor prognosis. Hence, there is an urgent need for new biomarkers for the early detection of colorectal cancer. The aim of the work was to investigate the lipidomic profile of serum, red blood cells (RBCs), the serum metabolomic profile from patients with CRC to identify the stage of the disease and the presence of metastasis of various localizations.

Aims & Methods: Sera, RBCs from 64 patients (52 \pm 7 years old) with colorectal adenocarcinoma were analyzed by 1H NMR spectroscopy, gas chromatography. The metabolomics, lipidomic profiles generated from each platform were compared between the following groups: locoregional CRC (N = 28 –with T2 n = 12, with T3 n = 16); liver-only metastases (N = 19); and extrahepatic metastases (N = 17). The control group consisted of 26 healthy people.

Results: Complex of serum metabolites as myristic acid, palmitic amide, oleamide, hexadecanedioic, octadecanoic, eicosatrienoic acids, LPC(18:2), LPC(20:4), LPC(22:6), LPC(16:0) contributed to the differentiation of the early CRC patients from healthy controls (AUC of 0.97), while lysophosphatidylcholine (18:0, 16:0), lysophosphatidic acid (18:0, 16:0), phosphatidylcholine (34:1) were significantly increased with the CRC progression, which allowed us to distinguish early stages from late ones (AUC of 0.82). The erythrocyte increased levels of stearic ($p = 0.03$), oleic acid ($p = 0.02$) and decreased total phospholipid fraction ($p < 0.05$), arachidonic, eicosapentaenoic, docosahexaenoic acids

($p < 0.01$), polyunsaturated:saturated fatty acid ratio ($p < 0.001$) occurred in cancer patients. The linoleic acid proportion in the RBCs phospholipid fraction was lower in patients with CRC ($p = 0.02$), but no changes were found in the serum phospholipid fraction. Changes in fatty acid composition may affect different aspects of cell structure and function, including proliferation. By ¹H NMR spectroscopy 55 metabolites were detected, with 25 found to be differentially abundant in the initial data filtering process ($p < 0.30$). The serum metabolomic profile associated with locoregional CRC was distinct from that associated with liver-only metastases, based on 1H NMR spectroscopy ($p = 4.43 \times 10^{-7}$). Similarly, the serum metabolomic profile differed significantly between patients with liver-only metastases and with extrahepatic metastases ($p = 0.04$). So, we revealed that isoleucine and 2-oxoglutarate were more abundant in sera from patients with extrahepatic metastases, while methionine and fumarate were more abundant in liver-only metastases.

Conclusion: Investigation of blood serum and erythrocyte metabolites should be considered as promising for verification of colorectal cancer, the detection of metastases of various localizations.

Introduction: Accumulating data indicate that some microRNAs (miRNAs or miRs) function as tumor suppressors or oncogenes in cancer development. We previously reported that certain miRNAs (miR-143, -145, -7, and -34a) were differently expressed in samples of tumors and paired non-tumorous samples taken from the same patients with colorectal tumors, and there was a relation close to adenoma-carcinoma sequence for these miRNAs expression.

Aims & Methods: In this study, we focus on the miRNA expression profiles of multiple colorectal adenomas comparing between sporadic colorectal adenoma and familial adenomatous polyposis (FAP). We examined the miRNA expression profiles (miRs-143, -145, -7, and -34a) and morphological appearance of 102 sporadic colorectal adenomas (SA), 27 tumors of multiple colorectal adenoma (over 10 adenomas/one patient, MA), 21 tumors of FAP and 114 sporadic cancer (SC).

Results: The expression levels of miRs-143 and -145 were reduced in all tumors compared with the paired non-tumorous samples in the same patient. Especially, these miRNAs were significantly reduced in MA ($P = 0.042$ and $P = 0.004$) and FAP ($P = 0.027$ and $P = 0.022$) compared with SA. The expression levels of miR-7 were significantly up-regulated in cancers compared with adenomas ($P < 0.001$). The expression levels of miR-34a were significantly down-regulated in CA ($P < 0.001$), MA ($P < 0.001$), and FAP ($P = 0.006$) compared with SA.

Conclusion: These findings suggest that the malignant potential of MA and FAP was higher than SA, therefore MA needs strict follow-up like FAP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0453 UTILITY OF MEAN PLATELET VOLUME, PLATELETCRIT, PLATELET-LYMPHOCYTE RATIO AND NEUTROPHIL-LYMPHOCYTE RATIO IN THE DIFFERENTIATION OF COLON CANCER AND COLONIC POLYPS IN OLDER PATIENTS

F. Karakaya, Ç. Kalkan, I. Soykan

Gastroenterology, Ankara University, Ankara/Turkey

Contact E-mail Address: mfkarakaya@yahoo.com

Introduction: Colorectal carcinoma (CRC) is an important cause of mortality and morbidity and mostly encountered in anemic and non-anemic elderly symptomatic patients, irrespective of the iron status. There is a close association between increased mean platelet volume (MPV) and the presence of many solid tumors such as hepatocellular carcinoma, pancreatic carcinoma, lung cancer, endometrial cancer and gastric cancer. Neutrophil/lymphocyte ratio (NLR) and platelet/lymphocyte ratio (PLR) are markers of systemic inflammatory response and their elevation is closely some studies to be associated with progression of colorectal carcinoma. Although colonoscopic examination is the standart way of colorectal cancer screening, screening for patients between 75 and 85 years of age should be tailored on the basis of the presence of coexisting conditions because the risk of serious complications from colonoscopy also increase with age.

Aims & Methods: The aim of this study was to investigate whether MPV, plateletcrit, PLR and NLR may have a role in the discrimination of CRC and colonic polyps in older patients. 418 patients aged > 65 years with colorectal carcinoma (n=93) (Group I) and colonic polyps (n = 325) (Group II) were included into the study. Also 601 (Group III) patients aged > 65 years with normal colonoscopic findings served as a control group. All study subjects were investigated by using MPV, plateletcrit, PLR and NLR in order to establish sensitivity and specificity for predicting colorectal carcinoma and colonic polyps for each parameter studied.

Results: MPV, PCT, NLR and PLR were significantly higher in Group III compared to Groups II&III. However, only MPV was significantly higher in Group II compared to group I (8.6 ± 1.1 vs 8.2 ± 1 , $p < 0.001$). The cut-off value of MPV in predicting CRC from patients with normal colonoscopic findings was 9.15 fL with a sensitivity and specificity of 80% and 91% respectively ($r = 0.892$). MPV and PCT were also significantly higher in patients with neoplastic polyps compared to patients with non-neoplastic polyps (MPV: 8.7 ± 1.1 vs 8 ± 1 , $p < 0.001$ and PCT: 0.23 ± 0.07 vs 0.19 ± 0.05 , $p = 0.003$).

Conclusion: MPV and PCT may have a role as useful and simple markers in the distinction of patients with colorectal cancer from patients with normal colonoscopic findings. In the clinical settings, these simple markers may be useful in selecting older patients for colonoscopic examination.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0454 IMPROVING THE SELECTION OF COMPLETE RESPONDERS FOR WATCHFUL WAITING AFTER CHEMORADIO THERAPY FOR RECTAL CANCER: WHAT CAN WE LEARN FROM THE 'MISSED' PATHOLOGIC COMPLETE RESPONDERS AFTER SURGERY?

Introduction: Rectal cancer patients with clinical evidence of a complete response after chemoradiotherapy may be selected for watchful waiting instead of surgical resection (although currently mainly within the scope of clinical trials). The clinical selection of potential candidates for watchful waiting to date is mainly done using a combination of imaging (MRI) and endoscopy. However, it is known that with this strategy up to 29% of complete responders may still be missed¹. Failure to identify complete responders will deny these patients the option of watchful waiting as a result of which they will receive potentially unnecessary surgery. Investigating the reasons why some complete responders are missed with current selection tools can help to further optimize our selection strategy and help improve the identification of potential candidates for watchful waiting in the future.

Aims & Methods: Aim of this study was to assess what can be learned from operated ('missed') pathologic complete responders by re-evaluating their post-CRT appearance on imaging and endoscopy.

Patients with a pathologic complete response (pCR) after CRT and surgery were retrospectively selected from our hospital's database (2005–2015). The MRIs (including diffusion weighted images) + endoscopic images performed post-CRT were re-evaluated by a team consisting of an expert radiologist and expert surgeon. The MRI morphology (signal abnormalities, diffusion restriction, volume, shape, aspect of lymph nodes) was assessed on T2-weighted MRI and diffusion-weighted MRI (DWI). On endoscopy the aspect of the scar (normal/teleangiectatic, ulcer, polypoid) was assessed. Additionally, the likelihood for a complete response was re-scored by the expert team according to updated selection criteria and classified as (1) residual tumour or (2) (near) CR.

Results: 41 patients with ypT0 after surgery were identified: 9/41 (22%) had ypT0N+ disease, 32 (78%) were true complete responders (ypT0N0). Upon re-assessment by the expert team, 20/32 ypT0N0 patients (63%) were still deemed to have residual tumour (non-cCR group), the remaining 12 (37%) were deemed to be possible clinical complete responders (cCR-group). In the non-cCR group (vs. the non-CR group) patients more often showed heterogeneous signal on T2W-MRI (75%vs.25%, $p = 0.01$), massive/spicular fibrosis (90%vs.58%, $p = 0.07$) and residual high signal on DWI (58%vs.27%, $p = 0.11$). On endoscopy the majority of patients still had mucosal abnormalities (see Table 1). Eight ypN0 patients were still overstaged as being yN+ at re-assessment, mainly based on irregular nodal morphology.

Table 1: Endoscopic features of patients with 'missed' complete response (pCR after surgery)

Feature	Present in (%) of patients
Gross residual tumour	33%
Polypoid tissue	38%
Ulcer with irregular border	29%
Flat ulcer	25%
White scar (with teleangiectasia)	33%

Conclusion: Main reasons for missing a complete response after CRT are heterogeneous T2W-MRI signal, massive/spicular fibrosis, residual diffusion-signal,

ycN+ disease and residual mucosal abnormalities at endoscopy. Knowledge about these features may serve as a teaching reference to help improve the selection of patients for watchful waiting in the future.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0455 RADIOMICS AS A NOVEL TOOL FOR PRE-TREATMENT RESPONSE PREDICTION IN RECTAL CANCER

J. J.m. Van Griethuysen¹, S. Trebeschi¹, D.M. Lambregts², M. Lahaye², F. Bakers³, R.f.a. Vliegen⁴, E. Voest², G.L. Beets⁵, R. G.h. Beets-Tan¹, H. J.w.l. Aerts⁶

Introduction: In patients with locally advanced rectal cancer (LARC) that show a very good response to neoadjuvant treatment, organ-preserving treatments such as watchful waiting may be a good alternative to surgical resection and can improve functional outcome and quality of life. If we can predict upfront (i.e. before onset of CRT) how patients will respond to treatment this may create opportunities to further personalize and optimize the neoadjuvant treatment to enhance the chance of a good response, thereby ultimately offering more patients the chance of organ preservation. A promising new tool in this regard is 'Radiomics'. Radiomics refers to a collection of analytical methods to convert images into high dimensional data via a set of quantitative descriptors called "features". These features have the potential to uncover disease characteristics that cannot be detected by means of conventional (visual) imaging evaluation.

Aims & Methods: We aimed to assess the Radiomics signature¹ of patients with LARC and evaluate its potential value for pre-treatment prediction of the response to neoadjuvant chemoradiotherapy.

We retrospectively assessed the primary staging MRIs (1.5T) of 124 LARC patients treated with CRT. The standard MRI protocol included T2-weighted (T2W) and diffusion-weighted imaging (DWI) sequences, as well as quantitative apparent diffusion coefficient (ADC) maps derived from the DWI scans. For each patient, the whole volume of the rectal tumour was delineated on pre-treatment MRI: [1] by 2 expert pelvic radiologists, [2] using a semi-automatic (region growing) software algorithm, and [3] by manual adjustment of the semi-automatic delineations by two non-expert readers, adding up to 5 delineations per tumor/patient in total. Radiomics signatures were extracted from the images for each of the five delineations (3802 features in total). Features showing both sufficient stability (ICC ≥ 0.75) as well as reproducible performance (Wilcoxon test, False Detection Rate (FDR) 10%) across different readers/delineations were selected to test their performance in predicting response to CRT by means of receiver operator characteristics (ROC) curve analysis. The main outcome was complete tumour regression (yT0) versus residual tumour (yT1-4) using histology and/or long-term FU as the standard of reference.

Results: Out of 3802 initially identified Radiomics features, 1853 proved stable across different readers/delineations. For the four manual delineations $\pm 300/3802$ features per reader remained significantly performant after FDR correction. However, these features did not sustain after FDR correction for the fully automated segmentation. A final subset of 266 features remained stable and performant across all five readers/delineations. These features resulted in a mean AUC of 0.67 (range 0.64–0.73) to predict a complete response and a mean ICC of 0.81 (range 0.75–0.95). Best results were obtained for textural features measuring the heterogeneity of the tumor on DWI (all top 20 features). In contrast, more 'common' radiological features such as volume showed inferior performance (highest rating 56). Results derived from delineations performed by the two expert radiologists and non-expert readers resulted in comparable diagnostic performance.

Conclusion: 1) Various Radiomics features extracted from pre-treatment MRI correlate to neoadjuvant treatment response and may be used as imaging biomarkers to predict the response to chemoradiotherapy in rectal cancer.

2) Best results are obtained for textural features (representing tumour heterogeneity) derived from diffusion-weighted MR sequences

3) Features extracted from semi-automated (software generated) delineations show inferior performance compared to features extracted from manual delineations, emphasizing the need for adequate tumour delineation. Interestingly, however, delineations from expert and non-expert readers rendered similar good results, suggesting that the selected features are robust and do not necessarily require highly expert input.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0456 CORRELATION OF ELECTRICAL AND VISCOELASTIC PARAMETERS OF ERYTHROCYTES WITH FATTY ACID COMPOSITION OF THEIR MEMBRANES AND SERUM IN PATIENTS WITH COLORECTAL CANCER

I. Prudnikova

Institution of Internal and Preventive Medicine, Federal State Budgetary and Scientific Institution, Novosibirsk, Novosibirsk/Russian Federation

Contact E-mail Address: dr.prudnikova@mail.ru

Introduction: An analysis of the efficient implementation of the guidelines for screening colorectal cancer (CRC) in patients with first diagnosed CRC (according to the archival case histories of the two medical institutions in Novosibirsk) was performed in 2013–2016, and leading reasons of late CRC diagnostics were identified.

Aims & Methods: We aimed to investigate the correlation of the electrical and viscoelastic parameters of erythrocytes with the fatty acid composition of their membranes and blood serum in patients with colorectal cancer (CRC) of different stages. 46 patients (median age of 53+9 years old) with CRC of various localizations and stages and 16 conditionally healthy patients were examined. Electrical and viscoelastic parameters of erythrocytes have been studied by dielectrophoresis. Fatty acid composition of erythrocyte membranes and serum has been studied using GC/MS system triple quad Agilent 7000B (USA).

Results: Erythrocytes of patients with CRC were characterized by increasing the proportion of deformed cells with reduced strain amplitude and surface charge (low levels of cell velocity to electrodes and dipole moment) ($p < 0.001–0.05$). Metastasis was associated with an increase in the cell electrical conductivity, a sharp decrease of polarizability, and an increase in the tendency to hemolysis ($p < 0.0001–0.03$). Saturated fatty acids prevailed in composition of erythrocyte membranes in patients with CRC; omega 6/omega 3 fatty acid index was decreased, while the level of linoleic acid was significantly increased as related to oleic acid in serum of the patients with CRC compared to the healthy people ($p < 0.01–0.04$). The observed shifts correlated with a disease stage ($r = 0.64$; $p = 0.04$). The erythrocyte strain amplitude was associated with the level of unsaturated fatty acids in erythrocyte membranes ($r = 0.58$; $p < 0.05$), as well as with summarized viscosity ($r = -0.47$; $p = 0.03$) and rigidity ($r = -0.41$; $p < 0.05$). While the level of hemolysis of erythrocytes and their tendency to aggregate correlated with the level of lysofractions of fatty acids ($r = 0.54$, $p = 0.04$; $r = 0.42$, $p < 0.05$). The surface charge of erythrocytes more closely correlated to the level (C16:2 and C18:1) in the blood serum ($r = -0.42$; $p = 0.04$). There was a shift of the crossover frequency to the high-frequency range ($p = 0.03$), a decrease of the cell capacity ($p < 0.01$), and a decrease of polarizability at high frequencies (106, 0.5 × 106 Hz) ($p = 0.02–0.05$), as well as a decrease of C18:3, C20:2, C20:3, C20:5 and C22:6 levels in erythrocyte membranes (but not in blood serum) ($p < 0.01$) at the initial stages of CRC.

Conclusion: Revealing changes in the parameters of erythrocytes and fatty acid composition in blood serum associated with a stage of the disease can be promising for diagnostics and the case follow-up of patients with CRC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0457 CLINICOPATHOLOGICAL STUDY OF LATERALLY SPREADING TUMORS OF THE COLORECTUM

M. Iwabuchi, M. Sugimura, S. Toda, K. Ukai
Gastroenterology, Sendai Medical Center, Sendai/Japan

Contact E-mail Address: s7856@snh.go.jp

Introduction: Laterally spreading tumors (LSTs) of the colorectum are classified into the following four subtypes according to their morphology: granular homogeneous type (LST-GH), granular nodular mixed type (LST-GM), non-granular flat-elevated type (LST-NGF), and non-granular pseudo-depressed type (LST-NGPD). Clinical features of each subtype of LSTs have not been fully evaluated.

Aims & Methods: The aim of this study was to clarify the clinicopathological features of colorectal LSTs focusing on their subtypes. We reviewed clinical charts and surgical pathology files of 5352 endoscopically resected specimens during January 2007 and December 2016 at our institution. A total of 422 LSTs were detected. We examined the clinical features (mean age, male to female ratio, size, location, Incidence of concomitant carcinoma) according to their subtypes.

Results: Of these 422 lesions, a total of 151 (35.8%) were LST-GH, 34 (8.1%) LST-GM, 209 (49.5%) LST-NGF, and 28 (6.6%) LST-NGPD. Mean age of patients with each subtype was 68.3 years old for LST-GH, 67.1 for LST-GM, 67.9 for LST-NGF, and 67.2 for LST-NGPD. Male to female ratio (M/F) was 1.21 for LST-GH, 2.05 for LST-GM, 1.95 for LST-NGF, and 1.65 for LST-NGPD. Mean size of LST-GH (21.2 mm) and LST-GM (25.8 mm) were significantly larger than that of LST-NGF (17.0 mm) and LST-NGPD (15.1 mm). All subtypes were located predominantly in the proximal colon. Incidences of concomitant carcinomas in LST-GH, LST-GM, LST-NGF, and LST-NGPD were 19.2% (29 out of 151), 55.9% (19 out of 34), 16.3% (34 out of 209), and 57.1% (16 out of 28), respectively. Incidences of concomitant submucosal carcinomas in LST-GH, LST-GM, LST-NGF, and LST-NGPD were 0% (0 out of 151), 14.7% (5 out of 34), 1.0% (2 out of 209), and 25.0% (7 out of 28), respectively.

Conclusion: Each subtype of LSTs has distinct clinical features. LST-GM and LST-NGPD have higher malignant potentials than other subtypes. Especially LST-NGPD has the highest risk of invasive carcinoma regardless of its size. Therefore we should carefully detect these lesions and choose appropriate treatment according to the subtypes.

P0458 POST-INVESTIGATION COLORECTAL CANCER RATES INCLUDING POST COLONOSCOPY COLORECTAL CANCER RATES IN A DISTRICT GENERAL HOSPITAL: THE POOLE EXPERIENCE MARCH 2015 TO FEBRUARY 2017

S.D. Parry, T. Deacy, E. J. Williams

Dept. Of Gastroenterology, Poole Hospital NHS, Poole Dorset/United Kingdom

Contact E-mail Address: sally.parry@poole.nhs.uk

Introduction: Post-colonoscopy colorectal cancer (PC-CRC) rates are proposed as a quality indicator of a colonoscopy service. Extrapolating the data is challenging but important to assess local practise and to compare with recent published National Data. We aimed to calculate the PC-CRC and the post CT (Colonoscopy + abdomen) CRC rate at Poole Hospital using the number of colonoscopies or CT scans done within 3 years of a CRC diagnosis as the denominator for post-investigation PI -CRC calculations as outlined in a previous study¹.

Aims & Methods: Retrospective audit of all patients diagnosed with CRC during a two year period 1st March 2015–28th February 2017 inclusive identified via the Somerset Cancer registry database for Poole Hospital using Crystal software. Previous colonoscopy and CT Colonoscopy (CTC) or CT abdomen results in the 3 years preceding the diagnostic investigations were reviewed across two neighbouring hospitals sharing the same electronic patient records. If patients had multiple surveillance colonoscopies the latest was counted as false negative as in previous studies¹.

Results: 416 patients were identified, 67 were excluded (39 non adenocarcinoma, 3 out of area, 12 patients where earlier decision was best supportive care, 6 patients diagnosed at laparotomy, 2 patients with abnormal PET scans and 6 with incomplete datasets). 348 patients were included for analysis. Colorectal cancer was diagnosed by colonoscopy in 200 patients and by CTC or CT abdomen in 148 cases. In the colonoscopy diagnosed group, 55 were via Bowel Cancer Screening Programme (BCSP), 138 via the symptomatic service and 7 from the surveillance programme. In the BCSP group 1 patient had a preceding colonoscopy within the previous 3 years (6–36 months)¹. In the symptomatic service groups there were 7 preceding colonoscopies and in the surveillance group there were 5 preceding (“false negative”) colonoscopies within the previous 3 years. The overall PC-CRC rate was 6.5 (+3.6, -2.2) % (90% confidence interval). In the CT diagnosed group, 1 patient from the BCSP group, 10 patients from the symptomatic service and 4 from the surveillance group underwent CT scans within the preceding 6–36 months. All but one of these 15 patients had undergone preceding CT abdomen scans with one elderly patient from the symptomatic group having undergone a prior CT colonoscopy. The post CT-CRC rate was 10.2 (+5.0, -3.2) % and the overall combined post investigation colorectal cancer (PI-CRC) rates during this two year period was 8.0 (+2.8, -2.0) %.

Conclusion: Our findings offer the opportunity for further review of individual cases at local governance level and within the limitations of data collection (NHS hospital records reviewed) our estimated PC-CRC rate of 6.5% compares favourably to the published National PC-CRC rate of 8.6% between 2001–2007¹. However, we question the validity of a post CT-CRC rate as a true quality indicator as a CT abdomen scan is a non-colon dedicated study. In addition, the method of calculating PI -CRC rates needs ratification as well as more robust IT systems to capture and analyse the data if it is indeed a measure that is to become part of endoscopic quality assurance. Finally our numbers are small and methods suitable for retrospective observational population based studies may not transfer to assessing quality indicators at a local level.

P0459 RISK OF DETECTION OF GASTROINTESTINAL NEOPLASMS AND DEATH IN SYMPTOMATIC PATIENTS WITH A POSITIVE FECAL IMMUNOCHEMICAL TEST WITHOUT COLORECTAL CANCER

N. Pin, M.J. Iglesias, D. Remedios, P. Vega, J. Cubiella

Servicio De Aparato Digestivo, Complejo Hospitalario Universitario de Ourense, Ourense/Spain

Contact E-mail Address: noel.pin.vieito@sergas.es

Introduction: The fecal immunochemical test (FIT) has a high diagnostic accuracy for the detection of colorectal cancer (CRC) in symptomatic patients. However, we do not know the risk of other gastrointestinal neoplasms associated with a false positive test.

Aims & Methods: To calculate the risk of detection of gastrointestinal tract tumors (GITT) and death in symptomatic patients with a positive FIT determination and without a CRC in a complete colonoscopy with an adequate bowel preparation. We designed a prospective cohort study with follow-up. Patients from the COLONPREDICT study with complete colonoscopy without CRC were included. Two cohorts were defined: FIT positive and negative according to the $\geq 20\mu\text{g}$ hemoglobin/g of feces threshold. We performed a descriptive analysis of the GITT detected during follow-up and mortality. We estimated the differences in the risk of GITT detection and mortality between the two cohorts by logistic regression and proportional hazards after adjusting for age, sex, and significant colonic lesions (CSL) detection at baseline colonoscopy.

Results: We included 1061 patients without CRC and a complete baseline colonoscopy; 320 (30.2%) with a positive FIT and 741 with a negative FIT. The median follow-up was of 36.0 ± 8.9 months with no difference between both groups ($p=0.2$). There were significant differences regarding age (67.5 ± 12.7 years vs 64.8 ± 13.5 years, $p=0.04$) and sex (45.9% vs 52.0% females, $p=0.04$) between both cohorts. We detected a GITT in 14 (4.4%) patients with a positive FIT: 5 CRC, 6 gastric, one esophageal, 1 small intestinal lymphoma and one patient with a CRC and a small intestine adenocarcinoma; and in 12 (1.6%) with a negative FIT: 4 CCR, 4 gastric, 2 small intestine adenocarcinoma, one esophageal, and one patient with a gastric and a CRC. Patients with a positive FIT had a non-significant increase in the risk of GITT detection (OR 2.1, 95% CI 0.9–4.8) after adjusting for age, sex and SCL. The overall risk of death in both groups was 8.8% and 6.7%, respectively, with no significant differences between both groups in the survival analysis (HR 1.3, 95% CI 0.8–2.1). However, the risk of death due to a GITT was 3.1% (10 deaths) in the positive FIT group and 0.8% (6 deaths) in the negative FIT group, with a significant difference after adjusting for age, sex and SCL (HR 3.2 95% CI 1.2–8.9).

Conclusion: Symptomatic patients with a positive FIT and complete colonoscopy without CRC are at increased risk of death due to GITT regardless of age, sex or the presence of SCL.

Introduction: Emergency surgery is a standard treatment for colorectal cancer (CRC) with acute colorectal obstruction (ACO). Transanal colorectal tube (TCT) placement is an alternative endoscopic treatment for ACO; however, the oncological outcomes of TCT placement for the curative treatment of CRC remain unknown.

Aims & Methods: Data were retrospectively reviewed from patients with distal stage II/III CRC who underwent surgery between January 2007 and December 2011 at two Japanese affiliate hospitals with an interexchange of endoscopists and surgeons. One hospital conducted emergency surgery and the other performed TCT placement as the standard treatment for CRC with ACO. To analyze the efficacy of TCT placement, we compared long-term outcomes for stage II/III CRC with ACO among patients in the two institutions.

Results: In total, 764 patients with distal stage II/III CRC were identified for this study. Among the 764 patients, 690 did not have ACO (non-ACO group), and 74 had ACO (ACO group). In the non-ACO group, we confirmed that the surgical quality was equivalent between the two institutions, with no significant differences in overall survival (OS) ($P=0.271$) or disease-free survival (DFS) ($P=0.184$). Among the 74 patients with ACO, 27 underwent emergency surgery (surgery group) and 47 underwent TCT placement (TCT group). The rate of primary resection/anastomosis was higher in the TCT group than in the surgery

group (91.5% vs. 22.2%; $P < 0.001$). No significant differences were noted between the two groups in OS (surgery vs. TCT: 5-year OS, 65.9% vs. 58.1%; $P=0.452$) or DFS (surgery vs. TCT: 5-year DFS, 47.6% vs. 43.1%; $P=0.755$). Subset analysis also showed no significant differences in OS and DFS between patients with stage II and stage III CRC.

Conclusion: TCT placement can achieve similar long-term outcomes to those of emergency surgery, with a high rate of primary resection and anastomosis for distal stage II/III CRC with ACO.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Self-expandable metallic stent placement for malignant colorectal obstruction has been widely used; however, factors affecting the technical difficulty of stenting remain unclear.

Aims & Methods: The aim of this study was to clarify the factors associated with the technical difficulty of stenting for malignant colorectal obstruction. We established the Colonic Stent Procedure Research Group to provide instructions on how to safely perform stent placement, and then, we conducted this prospective, single-arm, observational, multicenter clinical trial between October 2013 and May 2014 in Japan. Thirty-two facilities participated in this study. A double-wire woven uncovered stent was placed by using a standard through-the-scope colonoscopic placement technique in each patient. Stent deployment time was defined as the time from reaching a lesion with a colonoscope to finish stenting. Technically difficult cases of stenting were defined as those that had a longer than 75% deployment time. We examined the clinical data and extracted factors associated with the technical difficulty of stenting by using univariate and multivariate analyses.

Results: A total of 205 consecutive patients were enrolled in this study. Nine patients including 3 patients with technical failure of stenting, 5 patients with non-stenting and 1 patient with stenting for benign lesion were excluded. The remaining all 196 patients were succeeded in stenting. Of these, 100 were men (51%), and the median age was 72 years old (interquartile range (IQR), 62–82 years old). One hundred eleven patients (57%) underwent stenting as a bridge to surgery, and 85 (43%) underwent stenting for palliation. The technical and clinical success rates were 98.5% and 97.0%, respectively. None of the patients experienced colorectal perforation. The median total procedure time in the cohort with technical success was 30 minutes (IQR, 18–42 minutes). The median deployment time was 21 minutes (IQR, 11–31 minutes). Forty-nine patients with a deployment time longer than 31 minutes were regarded as technically difficult cases of stenting. The following were identified as independent factors of the technical difficulty in stent placement: presence of ascites (odds ratio, 2.483; 95% confidence interval [95%CI], 1.17–5.29; $p=0.02$), placement of >1 stent (odds ratio, 4.80; 95%CI, 1.10–21.1; $p=0.04$).

Conclusion: This study demonstrated the high technical and clinical success rate of double-wire woven uncovered stent placement for malignant colorectal obstruction. Clinicians should perform this procedure carefully in patients with presence of ascites.

P0462 PROGNOSIS AND CLINICOPATHOLOGICAL FACTORS OF PATIENTS WHO SELECTED THE FOLLOW-UP OPTION AMONG HIGH-RISK T1 COLORECTAL CANCER PATIENTS AFTER ENDOSCOPIC RESECTION BASED ON JAPANESE CLINICAL PRACTICE GUIDELINE: A RETROSPECTIVE OBSERVATIONAL STUDY

Introduction: Colorectal cancer is the third most common cancer in the world and the fourth leading cause of cancer death¹. Treatment strategy for colorectal cancer is selected considering clinical stages. T1 colorectal cancer (T1CRC) can be treated with endoscopic resection. If patients have pathological risk factors such as deep submucosal invasion, budding, poor mucin pathological features and lymphovascular invasion, they considered to be at high risk of lymph node metastasis based on the indication of Japanese Society for Cancer of the Colon and Rectum guideline². In such cases, the selection of subsequent option is important and has been frequently decided by clinicians' customs and preferences. However, it is not clear whether these risk factors adequately predict patients' prognosis in the clinical practice.

Aims & Methods: This research aims at revealing the prognosis and clinicopathological features of pathologically high-risk T1CRC patients (the high-risk group) with and without additional surgery; followed up by computed tomography, ultrasound, endoscopy, and tumor marker (CEA: carcinoembryonic antigen). 1. To evaluate the difference of overall survival (OS), cancer specific survival (CSS) and recurrent-free survival (RFS) between the patient performed additional colectomy with lymph node dissection (AS) and the patient followed up without additional surgery (FU). 2. To reveal what clinicopathological factors are considered in the selection of subsequent option, whether AS or FU, in the high-risk group. We retrieved the clinical data of 162 patients who had diagnosed and treated as T1 colorectal cancer at Kyoto University Hospital (Kyoto, Japan) between February 2005 and February 2015. Treatment strategy after diagnosed as "high-risk" and clinicopathological features, presence or absence of recurrence and the final state as of February 2017. We used the Kaplan-Meier product limit method and the Log-rank test to compare OS, CSS, and RFS between AS and FU groups. In clinical setting, based on the guideline indication, the clinician offered subsequent options and described their risks and benefits, and the patient expresses his or her preferences and values. Factors considered through selecting treatment strategy were extracted from informed consent and provider's note of electronic medical records.

Results: Among 162 T1CRC patients, 78 cases were treated with endoscopic resection for the first time. Of them, 46 patients had at least one pathological risk factor (high-risk patients). Among 46 high-risk patients, 22 patients were carefully followed up (FU), 20 patients were performed additional surgery with lymph node dissection (AS). Four patients treated with additional radiation therapy were excluded. Median survival time was 39 (FU) and 62 (AS), respectively. No difference was detected in OS (p value = 0.99), CSS (p value = 0.44) and RFS (p value = 0.81) between FU and AS groups. From provider's notes in electronic medical records, factors considered in selection of FU were extracted as follows: Patient's values and preferences 8, sole presence of "depth" risk factor 7, possible intensive surgery due to T1CRC located in the lower rectum 3, other advanced malignancy 1, and perioperative risks; advanced age 5, past history of abdominal surgery or radiation 2 and severe comorbidities 12 (chronic heart failure 4, chronic kidney disease 2, connective tissue disease 2, lung disease 1 etc). Together with absence of significant difference of prognosis in this study and the burden of surgery, the subsequent option should be selected through shared decision making between the clinician and the patient³.

Conclusion: Among high-risk group after endoscopic resection of T1CRC, no significant difference in OS, CSS nor RFS are detected between FU and AS groups. Factors considered in selecting FU were patient values and preferences, sole presence of "depth" risk factor and severe comorbidity including perioperative risk. Shared decision making should be achieved subsequent option in the high-risk group.

P0463 LONG-TERM OUTCOMES AFTER TREATMENT FOR T1 CARCINOMA OF LATERALLY SPREADING TUMORS: A MULTICENTER RETROSPECTIVE STUDY OF HIROSHIMA GI ENDOSCOPY RESEARCH GROUP

K. Yamashita, S. Tanaka, S. Oka, S. Nagata, T. Kuwai, A. Furudoi, T. Tamura, M. Kunihiro, H. Okanobu, K. Nakadoi, H. Kanao, M. Higashiyama, Y. Tamaru, F. Shimamoto, K. Chayama

Introduction: Laterally spreading tumors (LSTs) are defined as colorectal tumors defined by their characteristic laterally spreading growth pattern larger than 10 mm in size. LSTs are divided into 4 four subtypes based on different surface morphologies morphology [LST-granular (G)/homogeneous: LST-G-H and nodular mixed: LST-G-M, LST-nongranular (NG)/flat elevated: LST-NG-F and pseudodepressed: LST-NG-PD]. The aim of this study was to analyze the long-term outcomes, including recurrence, 5-year disease-free survival (DFS), 5-year disease-specific survival (DSS), and 5-year overall survival rates (OS) after treatment of T1 LSTs carcinoma.

Aims & Methods: We examined 169 patients with T1 LSTs carcinoma of LSTs treated between January 1992 and December 2008 at the Hiroshima GI Endoscopy Research Group (Hiroshima University Hospital and 9 nine affiliated hospitals) with a mean follow-up period of ≥ 5 years. 62 Sixty-two patients who were diagnosed with curable T1 LST carcinoma of LSTs after en bloc endoscopic resection (ER), according to the Japanese Society for Cancer of the Colon and Rectum (JSCCR) criteria, were defined as e-curable patients. One hundred seven patients who did not meet the criteria were defined as non-e-curable patients. According to the clinical and pathological diagnosis of LSTs, patients' backgrounds, and lesion location, the treatments were selected from among the following: ER alone (excluded histological incomplete resection), ER and an additional surgical resection with lymph node (LN) dissection, and surgical resection with LN dissection alone.

Results: Tumor size in Group A was significantly larger (A: 36.6 ± 22.6 mm vs B: 21.6 ± 7.2 mm vs C: 24.6 ± 7.6 mm, $p < 0.01$) than in the other two groups. The adenomatous component was more frequent in Group A than in the other two groups. The rates of LN metastasis in Groups A, B, and C were 10% (5/49), 20% (3/15), and 5% (1/21), respectively. There were no recurrences among the 62 e-curable patients. On the other hand, five recurrences (5%) were found in non-e-curable patients, and they were all in Group A. They consisted of local recurrence (one patient who also had lung metastasis), LN metastasis (two patients), lung metastasis (three patients), and liver metastasis (one patient who also had LN metastasis). There were no significant differences in DSS between Group A and Group B + C (LST-NG). However, OS was 93% in Group A, which was significantly lower than that (96%) in Group B + C ($p < 0.05$). DFS in Group A was 90%, which was significantly lower than that (100%) in Group B + C ($p < 0.05$). The prognosis of patients with non-e-curable disease after ER alone showed no significant differences in OS, DFS, and DSS between Group A and Group B + C. The prognosis of patients with non-e-curable disease after surgical resection showed no significant differences in DFS or DSS. However, OS in Group A was 94%, which was significantly lower than that (97%) in Group B + C ($p < 0.05$).

Conclusion: Long-term outcomes supported the JSCCR criteria for e-curable patients after ER for T1 LSTs. All recurrences occurred in patients with T1 LST-G-M carcinoma. OS and DFS in the LST-G-M group were significantly shorter than in the LST-NG group.

The non-e-curable patients were divided into 3 groups: Group A (61 patients were non-e-curable patients diagnosed with LST-G-M), Group B (23 patients were non-e-curable patients diagnosed with LST-NG-F), and Group C (23 patients were non-e-curable patients diagnosed with LST-NG-PD). There were no patients diagnosed with T1 LST-G-H carcinoma of LST-G-H.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cholangiocarcinoma and pancreatic adenocarcinoma account for over 190,000 new clinical cases of pancreatobiliary malignancy worldwide annually. For palliation of obstructive jaundice in these patients, plastic or self-expanding metal stent (SEMS) are placed. However, re-occlusion rates for currently available stents range as high as 36% for uncovered metal stents, 25% for covered metal stents and 52% for plastic stents. Tissue ingrowth accounts for up to 76% of occlusions of bare metal stents.^{1, 2, 3, 4} Stent occlusion can result in recurrent obstruction and typically requires endoscopic re-intervention. Therefore there is a real clinical need to reduce tissue ingrowth and improve biliary stent patency rates.

Aims & Methods: In this study we developed and tested a controlled-release paclitaxel-eluting SEMS designed to prevent tissue hyperplasia and stent occlusion. A 4 cm length uncovered, laser-cut nitinol stent was coated with a polymer matrix allowing slow release of paclitaxel. Naïve Yucatan swine were assigned to one of three stent groups: bare control (n = 3, no polymer), standard dose paclitaxel (n = 6, 149.4 µg paclitaxel) and challenge dose (n = 3, 538.0 µg paclitaxel). Two stents were endoscopically implanted in each swine from its assigned group, one in the intrahepatic/hilar region and a second in the common bile duct placed proximal to the papilla. Stents were assessed for migration via digital radiographs for the first 2 weeks and then monthly via endoscopy using SpyGlassTM DS cholangioscopy and cholangiography with a targeted 6 month study endpoint.

Results: At 30 days post-implant, no significant tissue reaction to any stent was observed. However, all animals displayed mild biofilm formation and increased intraductal mucus production. Substantial dilation of the common bile duct was observed in 5/11 animals with no apparent relationship between drug coating and duct dilation. At 60 days post-implant, moderate mucus and biofilm formation was observed within the stent, however in only 3 animals biliary ductal dilation persisted and the majority of stents were fully apposed to the duct wall. Although some animals displayed minimal tissue hyperplasia at the proximal end of the stents, no tissue overgrowth or stent embedding was observed in any animal. Up to 60 days post-implant, no persistent clinical symptoms were observed in any animal. Stents in one standard dose animal migrated out of the bile duct between days 15 and 30, this animal is not included in patency results reported. At both 30 and 60 day timepoints, no apparent differences in outcome were observed among the three study groups.

Conclusion: At this mid-study follow-up, paclitaxel-eluting stents appear to be safe for use in naïve tissue and do not negatively impact function of the biliary system, even at challenge condition doses. Although the cause of bile duct dilation observed in all stent groups has not been conclusively identified, we hypothesize the cause may be distal stent impaction and intermittent (clinically insignificant) obstruction of the papilla and/or stent, resulting in retained mucus and bile. Bile duct dilation, in turn, has reduced the opportunity for tissue overgrowth in all stent groups, which was expected to occur in the bare stent control group by 60 days post-implant⁵. Given the observed 60% reduction in number of dilated ducts between days 30 and 60, we expect increased rate of apposition. Ongoing efforts include continued follow-up for an additional 120 days, and in a second cohort, determination of in vivo drug release rates in the bile duct over a 30 day period. Future cholangioscopic and histopathological assessment of these swine will further clarify the safety and effectiveness of paclitaxel stent coatings to mediate bile duct tissue ingrowth.

Introduction: Meta-analyses and guidelines recommend that deep submucosal invasion (> 1 mm) in malignant colonic polyps is an important risk factor for residual malignant disease. However, the existing data are based on small retrospective studies with marked heterogeneity.

Aims & Methods: The aim of this study is to test the correlation between the submucosal invasion depth and the rate of residual malignant disease in complete endoscopic mucosal resection (EMR) of malignant colonic sessile polyps. The secondary outcomes include risk factors such as: lymphovascular invasion, tumor differentiation, resection margin status and the presence of tumor budding. A retrospective review of the endoscopy charts for the period 2000–2016 was conducted. All patients enrolled exhibited a malignant colonic sessile polyp which was endoscopically completely resected. Histological findings of the polyps were also recorded. Thorough computed or magnetic scanning was performed in all patients before deciding on further management. All patients were advised for the option of surgical treatment or endoscopic follow-up.

Results: 51 patients with confirmed adenocarcinoma in sessile colonic polyps undergoing endoscopic mucosal resection (EMR) were retrospectively included in this study. A total of 33 (64.7%) patients underwent subsequent surgery after EMR, and 18 (35.3%) chose endoscopic follow up. The histological characteristics are shown in Table 1. In 44 (86.3%) patients the submucosal invasion was > 1 mm. Residual malignant disease was identified in the surgical pathological specimen of only one patient. With a median follow-up of 25.12 months (IQR: 31.5; range 1.84–144.92), no local recurrences or lymph node metastasis were identified. 49 were alive without evidence of disease and 2 died of other causes (without evidence of disease at last follow-up). The data regarding the other risk factors are presented in Table 1.

Table 1: Histological characteristics of the patients

Factors	Total (N = 51), n (%)	EMR only, (n = 18), n (%)	EMR + Surgery, (n = 33), n (%)
Submucosal invasion	7 (13.7)	2 (11.1)	5 (15.2)
≤ 1 mm > 1 mm	44 (86.3)	16 (88.9)	28 (84.8)
Resection margin status (mm) median (IQR; range)	1 (2; 0–7)	1 (1; 0–4)	0, 8 (1.55; 0–7)
Lymphovascular invasion	7 (13.7)	0	7 (21.2)
Tumor differentiation:	14 (27.5)	6 (33.3)	8 (24.2)
well-differentiated;	28 (54.9)	9 (50)	19 (57.6)
moderate-differentiated;	9 (17.6)	3 (16.7)	6 (18.2)
poor-differentiated			
Tumor budding	9 (17.6)	4 (26.7)	5 (15.2)

Conclusion: Our data suggest that even in cases with submucosal invasion > 1 mm and the presence of other high-risk features (lymphovascular invasion, tumour budding), complete EMR in malignant colonic sessile polyps supported by the histological findings predicts for a good clinical outcome.

P0466 IMPACT OF EVALUATION OF PRECISION CHEMOTHERAPY FOR COLORECTAL CANCER (CRC) BASED ON COLLAGEN GEL DROPLET-EMBEDDED DRUG SENSITIVITY TEST (CD-DST)

T. Ochiai¹, K. Nishimura¹, T. Watanabe¹, M. Kitajima¹, A. Nakatani¹, K. Nagayasu¹, N. Sakuyama¹, T. Sato¹, K. Kishine¹, Y. Abe¹, C. Hara¹, K. Fujiwara¹, I. Nagaoka²

Introduction: The leucovorin (FOL) and fluorouracil (5-FU) plus oxaliplatin (I-OHP; FOLFOX) or FOL and 5-FU plus irinotecan (SN-38; FOLFIRI) are widely used as first-line chemotherapy in the treatment of advanced CRC. However, second-line chemotherapy must be abandoned in certain cases due to disease progression, adverse effects or high medical cost in clinical setting. First-line chemotherapy is usually administered over a long period of time. In addition, the response rate of the first-line chemotherapy is typically higher than the second-lines. Therefore, the most effective regimen should be selected as first-line chemotherapy. We have reported that individualization of first-line treatment (FOLFOX/FOLFIRI/Dual/Poor responder) was possible using CD-DST and individualized first-line therapy with the CD-DST may improve the prognosis of patients with unresectable CRC (UEGW: 2014; P1538, 2015; P1681, 2016; P0929).

Aims & Methods: In this prospective study, we evaluated the overall survival (OS) of appropriate first-line chemotherapy group and inappropriate first-line chemotherapy group based on CD-DST. Moreover, we evaluated additional effects of EGFR (Cetuximab; Cmax, Panitumumab; Pmax) to FOLFOX/FOLFIRI using CD-DST. Between Mar. 2008 and Aug. 2016, we obtained tumor specimens from 131 CRC patients without preoperative chemotherapy. Informed consent for measurement of individual chemosensitivity was obtained from all patients in writing. Approval for the present study was obtained from the Tobu Chiiki Hospital Institutional Review Board (No: 02.03.29. #1). The growth inhibition rate (IR%) was determined by CD-DST. The regimens were as follow: FOLFOX, FOLFIRI, Cmax, Pmax, and FOLFOX/FOLFIRI + Cmax. The incubation conditions were as follow: FOLFOX; 5-FU and L-OHP (6.0 and 3.0 µg/ml, respectively) for 24h. FOLFIRI; 5-FU and SN-38 (6.0 and 0.2 µg/ml, respectively) for 24h. Cmax; Cmax 250 µg/ml for 144h. Pmax; Pmax 200 µg/ml for 144h. FOLFOX + Cmax; Cmax 250 µg/ml for 120h after FOLFOX/FOLFIRI incubation process. The cumulative distribution of IR values under each condition was evaluated on the basis that the clinical response to FOLFOX and FOLFIRI is equivalent (approximately 50%). The OS between the group treated with appropriate first-line chemotherapy and the group treated with inappropriate first-line chemotherapy were evaluated Kaplan-Meier method. Additional effects of Cmax to FOLFOX/FOLFIRI were also evaluated. **Results:** There was strongly relationship between the IR% of the FOLFOX and FOLFIRI regimen ($R^2=0.7415$). The median of the IR% with the FOLFOX and FOLFIRI regimen were 58.6 and 69.1, respectively. FOLFOX responder, FOLFIRI responder, dual responder, and poor responder were 8, 10, 53, and 60, respectively. There were 42 unresectable CRC patients with chemotherapy. The median survival time of appropriate first-line chemotherapy group (n: 28) and inappropriate first-line chemotherapy group (n: 14) were 1128 and 506 days, respectively ($P=0.01$). There was positive relationship between the IR% of Cmax and that of Pmax ($R^2=0.468$). Additional rates (%) of Cmax to FOLFOX between poor responder and other responder were 19.81 and 5.46, respectively ($P=0.020$). Additional rates of Cmax to FOLFIRI between poor responder and other responder were 16.50 and -1.29, respectively ($P=0.005$). There was significantly more additional effect of Cmax to FOLFOX/FOLFIRI in poor responder than in other responders.

Conclusion: Administration of the recommended first-line regimen using CD-DST for unresectable CRC patient is important for improvement in the further prognosis. Moreover, especially in poor responder, Cmax should be administered to FOLFOX/FOLFIRI regimen.

Introduction: The standard treatment for locally advanced low rectal adenocarcinoma (ADC) is to conduct surgical resection after neoadjuvant chemoradiotherapy (CRT). In the wait-and-see (W&S) strategy, those who achieve clinical complete response (cCR) after CRT undergo regular clinical, radiologic and endoscopic surveillance, with surgery being reserved for tumor "regrowth".

Aims & Methods: To evaluate the impact of a W&S strategy for low rectal ADC, regarding overall and disease-free survival. Single-center prospective observational study. All patients with low rectal (up to 6 cm from the anal verge) ADC, stage I to III, discussed in a multidisciplinary colorectal cancer clinic since the implementation of the W&S strategy (11/2014–11/2016) were evaluated. Demographic data, post-CRT evaluation and decision, recurrence rates, "regrowth" and mortality were analyzed.

Results: 56 patients were evaluated [54% males; mean age at diagnosis 64, 4 years (34–90)], of which 53 had already completed CRT. Stage III prevailed (79%) in the initial evaluation. From the 53 patients who completed CRT, 77% were clinically reevaluated and submitted to pelvic MRI and sigmoidoscopy, after a mean of 6.7 weeks. 17% (7/41) displayed cCR and entered W&S surveillance program. In this subgroup, with a maximum follow-up of 25 months, there was only one (14%) "regrowth", which was clinically detected and then confirmed by the other surveillance methods. This patient underwent a R0 low anterior resection and there were no complications. There were no distant recurrences or deaths. In the subgroup of patients with no cCR: pathologic complete response was observed in 20%; there was one lymphatic recurrence; the overall survival was 95.2%.

Conclusion: Preliminary results of our series confirm that the W&S strategy is associated with overall and disease-free survival not inferior to those of the traditional approach, favoring its implementation.

Introduction: Patients after surgical resection of colorectal invasive cancer and those after endoscopic resections of colorectal adenoma and intramucosal cancer, both of them have the risk of metachronous advanced neoplasia during follow-up. The present study aimed to compare the risk of metachronous neoplasia during a long-term follow-up between patients with colorectal invasive cancer resected by surgery and those having colorectal adenoma and intramucosal cancer resected at initial colonoscopy.

Aims & Methods: A total of 1078 patients were colonoscopically followed-up during a long-term period in our hospital. They were divided into group A, B, and C as follows; 445 in group A (mean age 64.7 yr, M:F=2.37:1) with low-grade adenoma colonoscopically resected at baseline, 245 in group B (66.1 yr, 2.31:1) with high-grade adenoma or intramucosal cancer colonoscopically resected at baseline, 388 in group C (65.1 yr, 1.54:1) with invasive cancer resected by surgery at baseline. During follow-up colonoscopies detected metachronous neoplasms were resected and pathologically evaluated into non-index lesion (low-grade adenoma) or index lesion (high-grade adenoma or cancer). The cumulative incidences of metachronous colorectal neoplasms were compared with each other group by Logrank test.

Results: Median follow-up periods and frequencies of colonoscopy were 64.3 months and 3.7 times in group A, 52.0 months and 3.5 times in group B, and 74.6 months and 3.9 times in group C, respectively. The cumulative incidences of metachronous non-index lesion were 24.5% (109 patients with 289 low-grade adenomas) in group A, 26.1% (64 with 184) in group B, and 19.3% (75 with 229) in group C, respectively. The prevalence of metachronous non-index lesion was lower in group C compared to that in group A ($p=0.07$), and group B ($p < 0.05$). The cumulative incidences of metachronous index lesion were 7.0% (31 patients with 34 high-grade adenomas or cancers) in group A, 6.9% (17 with 17) in group B, and 12.3% (48 with 55) in group C, respectively. The prevalence of metachronous index lesion was higher in group C compared to that in group A ($p < 0.05$) and group B ($p < 0.05$). The cumulative incidences of metachronous invasive cancer were 0.9% (4 patients with 4 invasive cancers) in group A, 1.2% (3 with 3) in group B, and 3.6% (14 with 14) in group C, disclosing highest prevalence in group C ($p < 0.05$). Logrank test revealed that the cumulative incidence of non-index lesion was lowest in group C, and statistical significances were observed between group A and C ($p < 0.01$), and between group B and C ($p < 0.001$). Logrank test also revealed that the cumulative incidence of index lesion was highest in group C, but no significant differences were observed compared to those in group A and B.

Conclusion: Significant higher prevalence of metachronous index lesion including invasive cancer and, in contrast, significant lower prevalence of metachronous non-index lesion were observed in patients after resections of colorectal invasive cancer compared to those after endoscopic resections of colorectal adenoma and intramucosal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0469 LONG-TERM COLONOSCOPIC SURVEILLANCE BETWEEN PATIENTS WITH UNRESECTED DIMINUTIVE POLYPS AND THOSE WITH COLORECTAL ADENOMAS > 5MM IN SIZE RESECTED AT INITIAL COLONOSCOPY

S. Kimura¹, M. Tanaka²

¹Gastroenterology And Endoscopy, Aomori Rousai Hospital, Hachinohe/Japan

Contact E-mail Address: saint4road@gmail.com

Introduction: A long-term risk of colorectal advanced neoplasia among patients having diminutive polyps at initial colonoscopy has been unknown. The present study aimed to compare the risk of metachronous advanced neoplasia during follow-up between patients with untreated diminutive colorectal polyps and those with small or large adenoma resected at baseline colonoscopy.

Aims & Methods: A total of 1595 patients were colonoscopically followed-up during a long-term period in our hospital. They were divided into group A, B, and C as follows; 581 in group A (mean age 65.0 + -8.9 yr, M:F=411:170) with colorectal adenoma more than 5 mm in size resected at baseline, 495 in group B (65.2 + -9.6 yr, 328:167) with diminutive polyps left untreated at baseline, and 519 in group C (62.5 + -10.7 yr, 255:264) with no polyps at baseline. During follow-up colonoscopies detected metachronous neoplasms more than 5 mm in diameter were resected and pathologically evaluated into non-index lesion (low-grade adenoma) or index lesion (high-grade adenoma or cancer). The cumulative

incidences of metachronous colorectal neoplasms were compared with each other group by Logrank test.

Results: Median follow-up periods and frequencies of colonoscopy were 61.9 months and 3.6 times in group A, 61.6 months and 3.4 times in group B, and 72.3 months and 2.7 times in group C, respectively. The cumulative incidences of metachronous non-index lesion were 24.1% (140 patients with 375 low-grade adenomas) in group A, 14.7% (73 with 168) in group B, and 6.6% (34 with 56) in group C, respectively. The prevalence of metachronous non-index lesion was highest in group A followed by those in group B and C, with significant differences between group A and B ($p < 0.0005$), and B and C ($p < 0.0001$). The cumulative incidences of metachronous index lesion were 7.2% (42 patients with 45 high-grade adenomas or cancers) in group A, 5.1% (25 with 27) in group B, and 2.3% (12 with 13) in group C, respectively. The prevalence of metachronous index lesion was highest in group A followed by those in group B and C, and significant difference was observed between group A and C ($p < 0.001$), and B and C ($p < 0.05$). The cumulative incidences of metachronous invasive cancer were 1.0% (6 patients with 6 invasive cancers) in group A, 1.4% (7 with 7) in group B, and 0.2% (1 with 1) in group C with no significant difference. Logrank test revealed that the cumulative incidence of non-index lesion was highest in group A, and statistical significances were observed between group A and B ($p < 0.0001$), and between group B and C ($p < 0.0001$). Logrank test also revealed that the cumulative incidence of index lesion was highest in group A, and statistical significances were observed between group A and B ($p < 0.05$), and between group B and C ($p < 0.005$).

Conclusion: The results of a long-term colonoscopic follow-up disclosed a significantly higher prevalence of metachronous advanced neoplasms in patients with adenoma >5 mm in size resected at baseline compared to those with diminutive polyps left untreated at baseline. Persons with no polyps at baseline colonoscopy were at very low risk of advanced neoplasia within five years during follow-up.

P0470 A NEW SCORING MODEL FOR PREDICTING ADVANCED COLORECTAL NEOPLASIA IN ASYMPTOMATIC SCREENING POPULATION AND COMPARISON WITH THE MODIFIED ASIA-PACIFIC COLORECTAL SCREENING SCORE

M. Sekiguchi¹, T. Matsuda¹, Y. Kakugawa², M. Matsumoto², Y. Saito²

²Endoscopy Division, National Cancer Center Hospital, Tokyo/Japan

Contact E-mail Address: masekigu@ncc.go.jp

Introduction: Colorectal cancer (CRC) is still a major cause of death even in countries with a CRC screening program, indicating the need for improved screening methods. Risk-stratification of populations is one strategy that might satisfy this requirement. Currently, in the Asia-Pacific region, the use of the modified Asia-Pacific Colorectal Screening (APCS) score [age 50–59: 1 point, age ≥ 60 : 2, male sex: 1, presence of a first-degree relative (FDR) with CRC: 1, current or past smoker: 1, body mass index (BMI) ≥ 23 kg/m²: 1] has been proposed for risk-stratification.^{1–4} However, further validation studies are required to appraise its usefulness, and considering the reported limited discriminatory capability of the score for advanced colorectal neoplasia (ACN),⁴ the development of a more useful scoring model is expected.

Aims & Methods: The aim of this study was primarily to develop and validate a new scoring model for predicting ACN in asymptomatic screening populations that is more useful than the APCS score. We externally validated the APCS score in a Japanese screening population and compared its discriminatory capability with that of our new scoring model. Data were reviewed from 5218 consecutive asymptomatic screened individuals who underwent colonoscopy for their first time at the Cancer Screening Center, National Cancer Center Hospital, Tokyo between February 2004 and March 2013. Multivariate logistic regression was used to investigate the associations between clinical variables and the presence of ACN in the subjects, and then a new scoring model was developed based on these associations. Scores were weighted according to the beta coefficient obtained from the logistic regression model. Thereafter, the discriminatory capability of the new model was assessed using the c-statistics in the development set. Performance of the new model was internally validated using bootstrapping with 1000 replicates. The discriminatory capability of the modified APCS score in the 5218 subjects was also assessed using the c-statistics. The value obtained was compared with that of the new scoring model using the DeLong test, and this comparison was also performed in the 1000 bootstrapped replicates.

Results: A total of 225 individuals (4.3% of 5218 subjects) had ACN ($n = 257$), including 116 proximal lesions (45.1%) and 76 lesions with flat-type morphology (29.6%). An 8-point scoring model to predict ACN was developed by using five identified independent risk factors for ACN as scoring items. These included sex (male: 1 point, female: 0), age (40–49 years: 0, 50–59: 2, 60–69: 3, > 70 : 3.5), CRC family history (presence of ≥ 2 FDRs with CRC: 2, others: 0), BMI (≤ 22.5 : 0, > 22.5 : 0.5) and smoking (≤ 18.5 pack-years: 0, > 18.5 : 1). Presence of one FDR with CRC was not detected as an independent risk factor for ACN and was not assigned any score. Using the scoring model, the proportion of subjects with ACN increased with the order of scores. The proportions were 1.6% (34/2172), 5.3% (127/2419) and 10.2% (64/627) in the groups with scores of < 3 , ≥ 3 and ≥ 5 , respectively. The c-statistic of the score in the development set was 0.70 (95% CI, 0.67–0.73) and this was the same in the internal validation set. The value of the modified APCS score was 0.68 (95% CI, 0.65–0.71). The c-statistics of the new score were significantly higher than those of the modified APCS score, both in the 5,218 subjects ($P = 0.03$) and in 1,000 bootstrapped replicates ($P = 0.03$).

Conclusion: An 8-point scoring model to predict ACN in asymptomatic screening population that might have a higher discriminatory capability than the modified APCS score was developed and internally validated in this study. Our simple scoring model could stratify the screened population into low-, moderate-, and high-risk groups. Of the detected ACN, a substantial number were proximal or flat; therefore, primary screening with total colonoscopy may be advisable for high-risk individuals.

Introduction: Previous studies have shown that increase of threshold for first rectal sensation can be a predictor of fecal incontinence. However, significance of percentage range of rectoanal inhibitory reflex (%RAIR) in development of this disease remains unknown.

Aims & Methods: To determine association between %RAIR and threshold for first rectal sensation in healthy adults and its significance in development of fecal incontinence. 26 asymptomatic healthy volunteers (18 women, 8 men) median age was 35.03 years (19–59) were studied. We performed them a high-resolution anorectal manometry (HRAM) using a 20 channels silicone water-perfused catheter (Solar GI, MMS, Netherlands). The following HRAM parameters were analyzed: threshold for RAIR and %RAIR (automatically calculated as the ratio of the amplitude of the relaxation of the anal sphincter (AS) to the basal pressure AS $\times 100\%$), threshold for first rectal sensation (RS) and for desire to defecate. The statistical analyses were performed using Statistica for Windows 6.0 (StatSoft Inc.).

Results: Threshold for RAIR and %RAIR were 22.3 ml (10.0; 30.0), 74.4% (38; 99.5) respectively. Threshold for first RS was 30, 07 ml (11.1; 58.3) and desire to defecate – 65.12 ml (33.5; 182.0). Threshold for RAIR was not associated with threshold for first RS ($r = -0.07$) and for desire to defecate ($r = 0.02$). %RAIR was weak positively correlated with threshold for first RS ($r = 0.26$) and was not associated with threshold for desire to defecate ($r = -0.03$).

Conclusion: Threshold for RAIR and %RAIR are not associated with first rectal sensation. So, these parameters of RAIR cannot be predictors of fecal incontinence.

P0472 AVOIDANT COPING AND SOMATIZATION PARTLY EXPLAIN THE RELATIONSHIP BETWEEN NEUROTICISM AND GASTROINTESTINAL SYMPTOM BURDEN

M.P. P. Jones¹, A. P. Beath², A. Ejova², P. Mahoney², J. M. Koch²

¹Psychology, Macquarie University, North Ryde/Australia

²Psychology, Macquarie University, North Ryde/Australia/NSW

Contact E-mail Address: mike.jones@mq.edu.au

Introduction: Trait neuroticism has been consistently found to be associated with more severe functional gastrointestinal (GI) symptoms (1). One explanation for this is that high neuroticism predisposes individuals towards avoidant coping by leading them to view negatively-valenced situations as catastrophic (2) and, therefore, unsolvable (3). Avoidant coping, in turn, increases the risk of developing GI discomfort because over-reliance on “flight” strategies in stressful situations overstimulates the sympathetic nervous system at the expense of parasympathetic activity necessary for digestion (4). Evidence for this proposed chain of associations comes largely from studies that have observed relationships between each pair of the chain’s components: neuroticism and avoidant coping (e.g., 3), and avoidant coping and higher GI symptom burden (e.g., 1). Across two studies, this paper integrates these findings, while also exploring the role of somatisation. Somatisation is consistently observed in people suffering from functional GI Conditions (e.g., 1) and refers to a subtype of avoidant coping - the expression of psychological stress through complaints about bodily symptoms (6). Should evidence emerge that somatisation is an intermediary between avoidant coping and GI symptom burden in the relationship between neuroticism, coping styles and GI symptom burden, the dominant explanation for how avoidant coping and GI symptoms are connected would need to be expanded to

predict that somatisation has deleterious consequences for GI conditions - possibly because it encourages reduced physical activity (7).

Aims & Methods: In Study 1, 147 undergraduate students completed measures of neuroticism, 14 coping styles (including avoidant styles such as denial and disengagement), somatisation and GI symptom burden. In Study 2, where participants were undergraduates and hospital outpatients (pooled N=250), the variables investigated in Study 1 were measured alongside hypochondriasis, which was included to measure the aspect of somatisation that involves worry independently of any actual physical symptoms. Statistical analysis was based on path modeling. It involved fitting a model to test *a priori* hypothesised indirect relationships between neuroticism and GI symptom severity via the selected coping styles and somatisation. Direct effects were also estimated, meaning that the path analysis provided information regarding the significance of any indirect effects once a range of direct effects were accounted for. Only six coping styles found to correlate with both neuroticism and GI symptom severity were included (see Results table). Coping styles were assumed to covary, and the model in Study 2 assumed a covariance relationship between somatisation and hypochondriasis.

	Study 1 direct effects on row variables	Study 1 indirect effects on symptom burden via row variables	Study 2 direct effects on row variables	Study 2 indirect effects on symptom burden via row variables
Self-distraction	.33(.07)***	n.s.	.22(.07)***	n.s.
Denial	.24(.07)***	n.s.	.28(.05)***	n.s.
Venting	.36(.07)***	n.s.	.32(.06)***	n.s.
Substance-use	.40(.07)***	n.s.	.19(.06)**	n.s.
Disengagement	.52(.06)***	n.s.	.55(.06)***	n.s.
Self-blame	.53(.06)***	n.s.	.62(.04)***	n.s.
Somatisation	.42(.09)***	.16(.05)**	.40(.07)***	.17(.04)***
Hypochondriasis	Not applicable	Not applicable	.30(.08)***	.08(.03)**
Symptom burden	n.s.	Not applicable	n.s.	Not applicable
Substance-use and somatisation	Not applicable	.03(.02)*	Not applicable	n.s.
Disengagement and somatisation	Not applicable	.04(.02)*	Not applicable	n.s.
Self-blame and somatisation	Not applicable	-.05(.02)*	Not applicable	n.s.
Denial and somatisation	Not applicable	n.s.	Not applicable	.02(.01)*
Denial and hypochondriasis	Not applicable	Not applicable	Not applicable	.02(.01)*

Results: Significant standardised path model coefficients involving neuroticism across the two studies. In Study 1, neuroticism exerted indirect effects on symptom burden through substance-use-based coping and somatisation, as well as through disengagement-based coping and somatisation. In Study 2, neuroticism affected GI symptom burden through denial-based coping and somatisation, as well as through denial-based coping and hypochondriasis. An indirect effect of neuroticism through self-blame and somatisation, with the two intermediary variables relating negatively to each other, was observed in Study 1. (Note: *** $p < .001$, ** $p < .01$, * $p < .05$. n.s. denotes non-significant coefficients).

Conclusion: Somatisation and hypochondriasis were found to be intermediaries in the relationship between neuroticism, avoidant coping (through substance-use, disengagement and denial) and GI symptom burden. Two interpretations of the findings are: (1) avoidant coping can stimulate somatisation, leading to reduced physical activity, which can interfere with digestion; and (2) GI symptoms are among the wide range of functional somatic symptoms that can arise from avoidant coping. These findings open new avenues for multidisciplinary treatment of FGIDs.

P0473 POTENTIAL REGULATORY EFFECTS OF CORTICOTROPIN-RELEASING FACTOR ON TIGHT JUNCTION-RELATED INTESTINAL EPITHELIAL PERMEABILITY ARE PARTIALLY MEDIATED THROUGH CK8 UPREGULATION

Y. Hu¹, B. Lv¹

¹Gastroenterology, First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou/China

Contact E-mail Address: jiuyueqingxuan@163.com

Introduction: This study aimed to investigate the regulatory effects of corticotropin-releasing factor (CRF) on the permeability of human intestinal epithelial cells through CK8-mediated tight junction.

Aims & Methods: The expression of CRFR1 and CRFR2 on HT29 cell surfaces were detected by immunofluorescence, RT-PCR, and Western blotting. After treatment with 100 nM CRF for 72 h, the transmission of FITC-labeled Dextran was measured by using a transwell chamber; the structural changes of tight junctions were observed under transmission electron microscopy; the expression of CK8, F-actin and tight junction proteins ZO-1, claudin-1, and occludin were detected by immunoblotting and immunofluorescence. The activity of RhoA was detected by immunoprecipitation. Furthermore, effects of CRF on intestinal epithelial permeability were examined in CK8-silenced HT29 cells, which were constructed by shRNA interference.

Results: CRF treatment increased FITC-labeled Dextran permeability, caused opening of tight junctions, induced increased fluorescence intensity of CK8 and decreased intensity of ZO-1, claudin-1, and occludin, together with structural disruption. The expression of F-actin, occludin, claudin-1, and ZO-1 were downregulated. RhoA activity peaked at 30 min after CRF treatment. The increased permeability and the downregulation of claudin-1 and occludin induced by CRF treatment were not blocked by CK8 silencing. Nevertheless, CK8 silencing blocked the effects of CRF with regard to decrease in the expression of F-actin and ZO-1 and increase in RhoA activity.

Conclusion: CRF may increase intestinal epithelial permeability by upregulating CK8 expression, activating the RhoA signaling pathway, promoting intestinal epithelial actin remodeling, and decreasing the expression of the tight junction protein ZO-1. Other CK8-independent pathways may lead to decreased expression of claudin-1 and occludin, which also contributes to increased intestinal epithelial permeability.

Introduction: Diarrhea-predominant irritable bowel syndrome (D-IBS) is a chronic functional gastrointestinal disease. Its clinical manifestations are characterized by diarrhea and abdominal pain or discomfort in the absence of a demonstrable pathology. The diagnosis of D-IBS is based on symptom assessment and the Rome III Diagnostic Criteria. According to an epidemiological study, D-IBS mainly affects young adults of 20-40 years old, and the quality of their lives is seriously affected. The pathogenesis of D-IBS has not been fully clarified. Consequently, the usual treatment of the disease in Western medicine involves symptomatic therapy, which is unsatisfactory for patients while simultaneously increasing the use of health-care resources. Because traditional Chinese medicine (TCM) can significantly improve patients' symptoms and quality of life, increasing numbers of patients have begun to seek treatment with TCM. A series of randomized, double-blind, placebo-controlled trials had shown that TongXie-YaoFang(TXYF) formula can significantly improve the clinical symptoms, such as diarrhea and abdominal pain or discomfort, of patients with D-IBS and improve the quality of their lives. However, the specific mechanism of it has not been completely elaborated. The purpose of this paper is to observe the regulating effects of TXYF-formula on colonic epithelial secretion via relevant ion channels.

Aims & Methods: We aimed to investigate the pharmacological effect of TongXie-YaoFang (TXYF) formula, a Chinese herbal formula, on Diarrhea-predominant irritable bowel syndrome (D-IBS) rats. In a neonatal maternal separation plus restraint stress(NMS+RS) model of D-IBS, male Sprague Dawley rats were randomly divided into two groups (NMS+RS group and TXYF-formula group) with no handlings were used as controls (NH group). Starting from postnatal day 60, rats in TXYF-formula group were administered TXYF-formula (4.92 g/100 g bodyweight) orally twice a day for 14 consecutive days while NH group and NMS+RS group were given distilled water. Using short-circuit current technology, we observed 5-HT-induced changes of current across ion channels, such as cystic fibrosis transmembrane conductance regulator (CFTR) Cl⁻ channel, epithelial Na⁺ channel (ENaC), Ca²⁺-dependent Cl⁻ channel (CACC), Na⁺-K⁺-2Cl⁻ co-transporter (NKCC), and Na⁺-HCO₃⁻ co-transporter (NBC), in the colonic epithelium of three groups after exposure to drugs and specific blockers with a Power Lab System (AD Instruments International).

Results: Under basal conditions, the changes of short-circuit current (I_{sc}, mA/cm²) induced by 5-HT were similar in NH group and TXYF-formula group, and both higher than NMS+RS group (70.86 ± 12.32mA/cm², 67.67 ± 11.68mA/cm² VS 38.8 ± 7.25mA/cm², P < 0.01, respectively). When CACC was blocked by DIDS, 5-HT-induced I_{sc} was smaller in NMS+RS group than in NH group and TXYF-formula group, respectively (48.41 ± 13.15mA/cm² VS 74.62 ± 10.73mA/cm², 69.22 ± 11.7mA/cm², P < 0.05, respectively). The similar result could be obtained when ENaC was blocked by Amiloride (44.69 ± 12.58mA/cm² VS 62.05 ± 11.26mA/cm², 62.11 ± 12.01mA/cm², P < 0.05, respectively). However, when CFTR Cl⁻ channel was blocked by DPC, 5-HT-induced I_{sc} did not significantly differ in three groups (42.28 ± 10.61mA/cm² VS 51.48 ± 6.56mA/cm² VS 47.75 ± 7.99mA/cm², P > 0.05, respectively). The similar results could also be obtained in three groups when NBC and NKCC were respectively blocked by their blockers.

Conclusion: TXYF-formula can regulate the Cl⁻ and HCO₃⁻ secretion of colonic mucosa via CFTR Cl⁻ channel, Cl⁻/HCO₃⁻ exchanger, NBC and NKCC co-transporters.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Stressful life events may trigger the symptoms of irritable bowel syndrome (IBS). Preclinical chronic stress models have been developed in animals to mimic changes in visceral sensitivity in response to gut wall distension seen in IBS patients. In the rat, chronic passive water avoidance stress (WAS) is associated with hypersensitivity to colorectal distension. Diosmectite, a purified silicate clay, is an adsorbent widely used for the treatment of several gastrointestinal diseases, mainly diarrhoea but also the functional abdominal pain experienced in chronic IBS. However, the effect of diosmectite treatment on IBS visceral hypersensitivity has never been investigated.

Aims & Methods: The aims of the present study were to evaluate the effect of diosmectite on gut transit time and visceral hypersensitivity induced by WAS in rats. Wistar rats (175–200 g) (n = 9–10) were randomized to one of four groups: diosmectite (500 mg/kg), diosmectite (500 mg/kg, WAS procedure), water (0.5 ml/rat) or water (0.5 ml/rat, WAS procedure). Treatment was for 5 days, with the WAS procedure conducted once daily. The test apparatus consisted of a Plexiglas tank with a block affixed to the center of the floor. The tank was filled with fresh room temperature water to within 1 cm of the top of the block. Rats were placed on the block for a period of 1 h every day. For both conditions (basal and after WAS), intestinal transit was evaluated by fecal output measurement. Visceral sensitivity in response to colorectal distension (CRD) was assessed both in basal conditions and 30 min after the last WAS session.

Results: Under basal conditions, chronic oral treatment with diosmectite did not modify visceral sensitivity in response to CRD (20 ± 2 vs. 23 ± 1 cramps/5 min for vehicle at 0.8 mL; 20 ± 4 vs. 24 ± 2 for vehicle at 1.2 mL; $p = 0.97$ and $p = 0.75$ respectively) or intestinal transit in comparison with control group ($p = 0.33$). WAS treatment significantly increased the number of abdominal contractions at both 0.8 and 1.2 ml of CRD vs vehicle values (30.1 ± 2.5 vs. 19.78 ± 2.8 at 0.8 mL [$p < 0.05$]; 34.4 ± 2.4 vs. 23.2 ± 1.1 at 1.2 mL [$p < 0.05$]). One hour after the beginning of the last WAS session a significant increase of the fecal output in comparison with vehicle non-stressed rat (6.3 ± 1.1 vs. 0.3 ± 0.3 ; $p < 0.05$) was observed. Chronic administration of diosmectite significantly ($p < 0.05$) reduced the number of abdominal contractions (a visceral sensitivity index) induced by WAS: the number of abdominal contractions at 0.8 and 1.2 ml of CRD in comparison with vehicle was (30 ± 3 vs. 24 ± 2 contractions at 0.8 mL; 34 ± 2 vs. 27 ± 2 contractions at 1.2 mL). Diosmectite also tended to improve stress-induced intestinal transit acceleration (6.3 ± 1.1 vs. 4.9 ± 1.2 number of feces for 1 h; $p = 0.38$).

Conclusion: For the first time, these data illustrate in wistar rat, that diosmectite treatment is able to suppress WAS-induced visceral hypersensitivity to colorectal distension. This study adds relevant evidence to the use of diosmectite treatment in the management of IBS.

Introduction: We have recently shown that postprandial sensations correlate with changes in circulating metabolites after a meal ingestion; however this phenomenon was demonstrated with a meal load up to the level of tolerance which involved an unpleasant fullness sensation.

Aims & Methods: In the present study we aimed to evaluate the relation between the hedonic and the metabolomic responses to a palatable meal. Healthy men (n = 32; 18–44 yrs range) were evaluated after a 5 h fast. Perception measurements and blood samples were taken before and 20 minutes after ingestion of a palatable probe meal (juice and warm ham and cheese sandwich, total 300 ml, 440 kcal). Homeostatic (satiety, desire of eating a food of choice and abdominal fullness) and hedonic sensations (digestive well-being and mood) were measured

by 10 cm analogical scales. NMR spectroscopy was performed to determine plasmatic Low Molecular Weight Metabolites (LMWM) and to characterize lipoprotein profiles (number of particles, lipid content and size of the main three lipoprotein classes (VLDL, LDL and HDL)).

Results: Meal ingestion induced a pleasant sensation involving mild fullness (2.7 ± 0.4 score increment; $p < 0.001$ vs baseline) and an increase in digestive well-being and mood (3.1 ± 0.3 and 2.0 ± 0.3 score increment respectively; $p < 0.001$ vs baseline). Distinctive changes in the spectrum of circulating metabolites induced by meal ingestion were detected. A non-supervised PCA model of the metabolomic response correctly discriminated between the pre and postprandial state. The main variables determining the differences were glucose, triglycerides, number of VLDL, HDL and LDL particles, alanine, isoleucine, acetate, formate, creatine and lactate. The increase in the sensation of fullness correlated with the levels of glucose, alanine and lactate ($R = 0.44$; $p = 0.011$ and $R = 0.37$; $p = 0.036$ and $R = 0.44$; $p = 0.008$ respectively). Desire of eating a food of choice decreased after meal ingestion and correlated with the increase in HDL-triglycerides ($R = 0.35$; $p = 0.047$). The increase in the concentration of VLDL-triglycerides correlated with the increase in sensation of digestive wellbeing ($R = 0.36$; $p = 0.044$).

Conclusion: Homeostatic and hedonic sensations in response to a pleasant meal correlate with changes in circulating metabolites. Metabolomic changes in the response to a meal could serve as objective biomarkers of the postprandial experience.

P0477 NEGATIVE EFFECTS OF BIFIDOBACTERIUM BIFIDUS ON THE RAT WITH COLONIC VISCERAL HYPERSENSITIVITY INDUCED BY ACETIC ACID PERFUSION

X. Wang, W. Zhang, K. Wang, L. Zhang, Q. Sun, L. Duan

Department Of Gastroenterology, Peking University Third Hospital, Beijing/China

Contact E-mail Address: 15035126210@163.com

Introduction: Bifidobacterium with appropriate doses has been suggested to reduce the visceral hypersensitivity in IBS. But different treatment effects have been reported. The negative effect of Bifidobacterium has been rarely studied and reported.

Aims & Methods: We aimed to study the effects of gavage administration with *Bifidobacterium bifidus* for two weeks on the visceral hypersensitivity of rats. Colonic visceral hypersensitivity (CVH) was induced by colonic injection of 0.5% acetic acid (AA) in 10-day old rats while control (NS) induced with 0.9% normal saline. The abdominal withdrawal reflexes (AWR), induced by colorectal distention (CRD), was used to quantify the level of colonic sensitivity in adult rats. The CVH rats in 42-day old were treated by gavage administration with *Bifidobacterium bifidus* (1×10^9 CFU/day) for two weeks (CVH-Bifi). Other CVH rats were treated with 0.9% NaCl (CVH-NS). A group of control with normal sensitivity was treated with sham gavage (Con-sham). In day 56th, another AWR was assessed, and the hippocampus and prefrontal cortex (PFC) were separated and used to analyze the c-fos, NMDAR 2A, NMDAR2B with western-blot.

Results: After two-week gavage, the CVH-Bifi presented lower volume than that of CVH-NS in CRD, though without statistical difference (2.35 ± 0.28 vs. 2.40 ± 0.64 , $p = 0.11$). No significant difference was found between CVH-Bifi and Con-sham as well. In hippocampus, c-fos of CVH-Bifi was higher than that of Con-sham (0.77 ± 0.23 vs. 0.31 ± 0.08 , $p = 0.032$) and CVH-NS (0.77 ± 0.23 vs. 0.48 ± 0.10 , $p = 0.171$). The NMDAR2A of CVH-Bifi was higher than that of Con-sham (1.04 ± 0.22 vs. 0.51 ± 0.16 , $p = 0.055$). In PFC, the NMDAR2A in CVH-Bifi was significantly higher than that of CVH-NS (0.63 ± 0.14 vs. 0.21 ± 0.05 , $p = 0.004$) and Con-sham (0.63 ± 0.14 vs. 0.20 ± 0.07 , $p = 0.011$).

Conclusion: We reported the negative effects of *Bifidobacterium bifidus* gavage, which induced higher activation of c-fos and higher expression of NMDAR 2A in hippocampus and PFC. The roles of *Bifidobacterium bifidus* and its metabolites on visceral sensitivity needs further study to clarify.

Introduction: DA-9701, a newly developed prokinetic agent formulated with Pharbitis Semen and Corydalis Tuber, has been shown to effectively treat functional dyspepsia. Recently, it has also been suspected to improve gastrointestinal motor function.

Aims & Methods: The aims of this study were to assess the effect of DA-9701 on colonic transit time (CTT) and symptoms of functional constipation. We prospectively enrolled 33 patients with functional constipation based on the Rome III criteria. The patients received 30 mg DA-9701 three times a day for 24 days. CTT was estimated initially and at the end of treatment. We also analyzed symptoms such as spontaneous bowel movements (SBMs), straining, stool form, feeling of incomplete emptying and anorectal blockage, abdominal discomfort and pain, overall defecation satisfaction, and incidence of adverse events.

Results: Twenty-seven patients completed the study. DA-9701 was associated with a significantly reduced CTT from 34.9 ± 17.6 to 23.7 ± 19.1 hours ($P=0.001$). Segmental CTT also significantly decreased after treatment (right CTT: from 14.0 ± 8.2 to 7.5 ± 7.4 hours, $P < 0.001$; rectosigmoid transit time: from 14.2 ± 11.9 to 9.5 ± 10.9 hours, $P=0.021$). In addition, all constipation-related subjective symptoms, including SBM frequency, significantly improved compared to those before treatment. Serious adverse events did not occur.

Conclusion: DA-9701 accelerates colonic transit and safely improves symptoms in patients with functional constipation. Therefore, we suggest that this novel agent could help to treat patients with this condition.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0483 INDEPENDENT VALIDATION OF THE ROME IV CRITERIA FOR IRRITABLE BOWEL SYNDROME REVEALS THEIR MODEST PERFORMANCE AND RESTRICTIVE NATURE

O. Craig¹, C. Black¹, L. Houghton², A.C. Ford¹

¹Leeds Gastroenterology Institute, St. James's University Hospital, Leeds/United Kingdom

²Leeds Institute Of Biomedical & Clinical Sciences, St. James's University Hospital, Leeds/United Kingdom

Contact E-mail Address: ofcraig@gmail.com

Introduction: Previous symptom-based criteria to diagnose irritable bowel syndrome (IBS) performed only modestly. The Rome IV criteria are the current gold-standard, and dispensed with the symptom of abdominal discomfort, as well as making slight modifications to the symptom frequency threshold and associated symptoms required for a diagnosis of IBS. Epidemiological surveys suggest that these modifications reduce the overall prevalence of IBS in the community, but the effect on their performance in referral populations is uncertain, as independent validation studies are lacking.

Aims & Methods: We collected complete symptom data from consecutive, unselected patients referred to secondary care with lower GI symptoms, and seen in a specialist IBS clinic. All participants completed the validated Rome IV questionnaire for IBS, and underwent investigation to the level deemed appropriate by two clinicians with considerable experience in diagnosing and managing IBS. The final clinical diagnosis, after a limited panel of investigations, was recorded. Coeliac disease was excluded in all individuals, via serological testing. The reference standard used to define the presence of true IBS was a physician's clinical diagnosis of IBS, after appropriate limited investigation to exclude relevant organic disease. Sensitivity, specificity, and positive and negative likelihood ratios (LRs) were calculated for the Rome IV criteria.

Results: We recruited 104 adults referred with lower GI symptoms (81 (77.9%) female, mean age 35.8 years (range 16 to 77 years)). Among 91 individuals with IBS according to the reference standard, 72 met the Rome IV criteria (sensitivity = 79.1%), and 19 did not. There were 13 individuals who did not have IBS according to the reference standard, of whom 11 did not meet Rome IV criteria (specificity = 84.6%). The other two individuals who met Rome IV criteria, but who did not have IBS after appropriate investigation to exclude relevant organic disease, both had bile acid diarrhoea. Positive and negative LRs for the Rome IV criteria were 5.14 and 0.25 respectively. Among the 19 patients who had IBS according to the reference standard, but who did not meet the Rome IV criteria for IBS, seven (36.8%) did not meet the minimum symptom duration of 6 months, six (31.6%) did not meet the minimum pain frequency threshold of once per week, and six (31.6%) did not report two or more of pain in relation to defaecation, pain in association with a change in stool frequency, or pain in association with a change in stool form.

Conclusion: The Rome IV criteria performed modestly in a specialist IBS clinic. One-in-five patients felt to have IBS according to an experienced clinician, and after limited investigation to exclude relevant organic disease, did not meet the Rome IV criteria, suggesting they may be too restrictive for use in clinical practice.

Introduction: No studies have investigated how commonly individuals meeting the new Rome IV IBS criteria seek medical care for their bowel symptoms, or what factors determine medical consultation.

Aims & Methods: We aimed to characterize health care-seeking behaviour in Rome IV IBS subjects in a large multi-national population sample. Data was retrieved from a large Internet survey. The survey was completed by 6300 individuals distributed equally between United States, United Kingdom and Canada. Equal sex, age and education distribution across the countries was ensured by use of quota-based sampling. The survey included questions on demographics, the Rome IV diagnostic questionnaire, the Patient Health Questionnaire (PHQ-12), the 8-item Short Form (SF-8) quality of life (QOL) questionnaire, health care utilization and past gastrointestinal (GI) disease diagnoses by doctors. Respondents with an organic GI disease were excluded from the IBS population. IBS consulters were defined as individuals meeting Rome IV IBS criteria who had visited a doctor for GI symptoms.

Results: 6300 individuals completed the survey, 369 were excluded due to inconsistent responses, leaving 5931 (49.2% female; mean age 47.4 ± 17.1 years) to be included for analysis (1949 US, 1994 UK, 1988 Canada). After excluding 36 individuals due to lower GI organic disease, 305 subjects (5.1%; 66% female; mean-age 44.7 ± 14.5 years) fulfilled diagnostic criteria for IBS. From these, 195 (64%) had consulted a doctor for GI problems. IBS consulters had equal sex distribution (63.6% vs. 69% female ($p=0.4$)) and somatization scores ($p=0.8$) compared to non-consulters, but were older (mean age 47.1 ± 14.8 vs. 40.5 ± 13.1 years), more concerned about their bowel function ($p < 0.001$), more frequently bloated ($p=0.01$), and experienced greater impact on social activities ($p=0.008$). The distribution of the most bothersome symptom was similar ($p=0.38$), and abdominal pain was the predominant symptom in both groups. See table for details. The frequency of doctor visits for non-GI health issues did not differ ($p=0.15$), but IBS consulters had undergone more abdominal surgery ($p=0.04$). IBS consulters also reported higher consumption of GI related ($p < 0.001$), prescribed pain ($p < 0.001$), and anti-depressive medications ($p=0.03$), but had similar consumption of anxiety ($p=0.11$) and over the counter pain medications ($p=0.34$) as non-consulters. See table for details.

	IBS consulters	IBS non-consulters	p-value
GI symptoms			
<i>Most bothersome symptom</i>	75 (38.5)	48 (43.6)	
Abdominal pain Loose stools/high frequency	48 (24.6)	22 (20.0)	
Hard stools/low frequency Bloating None of the above	40 (20.5)	16 (14.5)	
Frequency	24 (12.3)	20 (18.2)	
Abdominal pain >3 times/week	8 (4.1)	4 (3.6)	
Bloating >3 times/month	72 (36.9)	31 (28.2)	
Concern of bowel function Not at all	158 (81.0)	74 (67.3)	
Somewhat Very	12 (6.2)	25 (22.7)	
Somatization			
PHQ-12 score 7 or above	106 (54.4)	70 (63.3)	
Quality of life			
<i>Overall estimation of health past 4 weeks (SF-8).</i>	77 (39.5)	15 (13.6)	
Very poor/poor Fair/good Very good/excellent	59 (30.3)	31 (28.2)	0, 5
	118 (60.5)	64 (58.2)	
	18 (9.2)	15 (13.6)	
<i>Bodily pain past 4 weeks (SF-8).</i> None/very mild	22 (11.3)	19 (17.3)	0.35
Mild/moderate Severe/very severe	110 (56.4)	58 (52.7)	
	63 (32.3)	33 (30.0)	
<i>Limitation in social activities due to physical health or emotional problems past 4 weeks (SF-8).</i> Not at all	24 (12.3)	29 (26.4)	0.008
Very little/somewhat	98 (50.3)	46 (41.8)	
	73 (37.4)	35 (31.8)	

(continued)

Continued			
	IBS consulters	IBS non-consulters	p-value
Quite a lot/could do no social activity			
Frequency of doctor visits			
At least one visit/year	159 (81.5)	82 (74.5)	0.19
Medication use			
For GI related issues	146 (74.9)	48 (56.4)	<0.001
For pain, over the counter	69 (35.4)	45 (40.0)	0.34
For pain, prescribed by doctor	92 (47.2)	30 (27.3)	<0.001
For depression	77 (39.5)	30 (27.3)	0.03
For anxiety	65 (33.3)	27 (24.5)	0.11
Surgery			
Cholecystectomy	38 (19.5)	14 (12.7)	0.13
Appendectomy	30 (15.4)	8 (7.3)	0.06
Hysterectomy Other abdominal surgery	26 (13.3)	5 (4.5)	0.03
	41 (21.0)	12 (10.9)	0.04

Conclusion: Among individuals who meet Rome IV criteria for IBS in the general population, those who are older, have more frequent bloating, have greater concern about their bowel function, and who are more socially affected by their bowel symptoms, are more likely to consult doctors about their bowel symptoms. In contrast, IBS consulters and non-consulters do not differ in their abdominal pain severity or extra intestinal symptom burden. [Support: The Rome Foundation].

Introduction: Non-urgent referrals to specialist gastroenterology exceed capacity, resulting in long waiting lists and poor patient outcomes. New models of care are needed to translate specialist knowledge of functional gastrointestinal disorders (FGID) into primary care practice.

Aims & Methods: This study aimed to evaluate the safety and performance of an algorithm-based approach to the diagnosis and management of FGID. Consecutive patients triaged to the 'routine waitlist' of an Australian public hospital Gastroenterology Department over 2 years, with non-specific GI symptoms (no alarms) were randomised to waitlist control or intervention (2:1). Intervention patients were screened for alarms and abnormal blood/stool tests without an in-person consultation, to exclude organic disease (full blood count, C-reactive protein, biochemistry, thyroid function tests, iron studies, coeliac serology, +/- H. pylori serology, +/- faecal calprotectin and elastase) and classified according to the Rome III criteria. Information from patients with clinical alarms was reviewed by a gastroenterologist (GE) and, where judged appropriate, a prompt GE appointment offered. Elsewhere patients received a letter stating FGID diagnosis and management options. Referrals were analysed for quality according to current triage practices.

Results: 89 intervention patients (61% female, mean 42, [SD 14] y) and 21 control (75% female, mean 42, [SD 16] y) patients completed intake. 35 intervention patients warranted prompt GE review after active screening. Organic disease was diagnosed in 10 (diagnosed: 19 FGID, 2 IBD, 1 neoplasm, 1 pancreatic insufficiency, 1 reflux oesophagitis, iron deficiency 1, 7 did not attend), and 4 had additional clinically significant findings (polyps, iron deficiency). 45 were diagnosed with a FGID (9 had another non-urgent diagnosis). At follow up (mean 2.7 yrs [SD 0.5yrs] post-referral), none of the 45 patients diagnosed with FGID had received a gastroenterology consult based on the original referral (six received a specialist appointment via duplicate referrals within the system). Confirmation of diagnoses at follow-up was received by patients and/or referring doctors in 42/45 cases (three no longer contactable). The majority of patients (37/42, 88%) had received no alternate diagnosis to account for their gastrointestinal symptoms since the study. Whilst two had additional diagnoses (FGID plus diverticulitis, FGID plus prostatitis), and two – incidental yet clinically significant findings (FGID plus polyps).

Conclusion: The quality of referrals of patients with clinically suspected FGIDs was insufficient to allow the safe triage of patients according to urgency, with a third warranting more urgent review. Organic disease was diagnosed in a significant proportion of patients who would otherwise were unlikely to have been seen in tertiary care. Use of this specialist-independent diagnostic algorithm in primary or tertiary care may facilitate more timely and accurate diagnosis of organic gastrointestinal disease, and improve patient care.

P0486 SCOTTISH GUT MOTILITY DISORDER CLINIC: REVIEW OF ACTIVITY OVER 1-YEAR PERIOD

F. Moroni¹, M. P. Eugenicos²

¹University of Edinburgh, Edinburgh/United Kingdom

²Gastroenterology, Western General Hospital, Edinburgh/United Kingdom

Contact E-mail Address: francesca.moroni@nhs.net

Introduction: IBS is common worldwide. In UK it exceeds the 20% of the population¹. Burden of Irritable Bowel Syndrome (IBS) on UK healthcare has been estimated around 1800£per patient per year². NICE guideline³ IBS provides a systematic approach to symptoms and therapies available to GPs and general gastroenterologists. This creates a good asset to minimize referrals to tertiary centres and address costs.

Aims & Methods: We retrospectively reviewed, via electronic records, all the patients seen at the Scottish Gut Motility Disorder Clinic between January and December 2016 included, focusing on original referral, diagnosis and treatment to evaluate the need for specialist input.

Results: In 2016, 378 patients attended the Motility Clinic; total of 459 visits; 333 females. Mean age was 51.4 (age range: 16 to 95 years). 60% of referrals originated via secondary care (40% GI, 50% Surgery, 10% other disciplines). The commonest reason for referral was IBS (40%); IBS-Constipation (58%), IBS-Diarrhoea (21%) or IBS-MixType (21%). 16% were referred with faecal incontinence and 37% with chronic constipation. 35% of patient didn't receive any therapy at time of referral. 44% were prescribed treatment but not followed up for assessment of successful response to therapy prior to referral to the specialist clinic. In 28% of patients the diagnosis changed following Motility clinic assessment. Diagnosis at clinic is based on ROMEIII questionnaire, depression and anxiety score, thorough history taking and physical examination (including per rectum exam), ad hoc psychiatry input and referral to specialist investigation. In 30% of patients referred with chronic constipation the diagnosis was changed to IBS-Constipation, 8% changed from IBS-D to IBS-M, 8% referred with faecal incontinence had Obstructive Defecation Syndrome, 6% referred as IBS-M were diagnosed with IBS-C, 5% referred as IBS-D were diagnosed as IBS-M, 3% referred with IBS-D had bile acid malabsorption. 56% of patients underwent specialist investigations including anorectal physiology (70%).33% of patients attending the Specialist clinic received 1st -line therapy and life style advice, albeit 57% of them, who received 2nd -line treatment, having failed 1st-line management.

Conclusion: The above data indicate the need for education and expansion of resources available in primary care to optimise patients' management. Furthermore, it highlights the necessity for the introduction of a formal Neurogastroenterology curriculum in the general Gastroenterology training.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Irritable bowel syndrome (IBS) affects 5–15% of adults in the general population, and is characterized by chronic recurrent abdominal pain and discomfort and associated with altered bowel habits. The pathophysiology of IBS is complex and not fully understood. Hence, treatment is often based on symptomatology rather than underlying physiological aberrancies.

Aims & Methods: The aim of this study was to compare the expression of membrane transporters in mucosal biopsies of healthy subjects, IBS patients and post-infectious (PI)-IBS patients. Mucosal biopsies were obtained from the unprepared sigmoid colon in 18 IBS patients, 9 PI-IBS patients and 10 healthy subjects. Total RNA was isolated and prepared for gene expression analyses using quantitative reverse-transcription polymerase chain reaction (qRT-PCR). We compared the expression of genes encoding membrane-spanning transporters, using GAPDH as a reference gene, and by using the comparative $2^{-\Delta\Delta C_t}$ method.

Results: Colonic expression of SLC7A5 and SLC3A2 (together comprising the amino acid transporter LAT1 + 4F2hc) was significantly lower in IBS patients, but not in PI-IBS patients, compared to healthy controls ($P < 0.001$). The expression of SLC7A8 (LAT2) tended to be lower in IBS patients compared to controls ($P = 0.06$). Mucosal gene expression of the short chain fatty acid transporter SMCT1 (SLC5A8) was lower in both IBS-patients and PI-IBS patients compared to healthy subjects ($P < 0.01$).

Conclusion: The amino acid transporters LAT1 and LAT2 appeared to be affected in IBS patients, but not in PI-IBS patients, compared to healthy subjects, suggesting a possible alteration in amino acids transport in this patient group. Furthermore, our results suggest a lower uptake of short chain fatty acids in both IBS- and PI-IBS patients. Altered expression of these transporters may be involved in the pathophysiology of IBS as well as being a potential biomarker of this aberration, and therefore deserves further study in IBS.

P0488 DIVERTICULITIS IN THE SIGMOID COLON HAS THE HIGHEST RISK FOR INTESTINAL COMPLICATION OF COLONIC DIVERTICULITIS IN JAPANESE PATIENTS

H. Takayama, Y. Shimodate, A. Doi, N. Nishimura, H. Mouri, K. Matsueda, H. Yamamoto, M. Mizuno

Gastroenterology And Hepatology, Kurashiki Central Hospital, Kurashiki/Japan

Contact E-mail Address: hi7.takayama@gmail.com

Introduction: Most colonic diverticulitis can be conservatively treated, but some need surgical intervention due to intestinal complications. Risk factors associated with complications of diverticulitis have been reported mainly from Western countries, but few from Asian countries including Japan.

Aims & Methods: In this study, we aimed to determine risk factors for complications of colonic diverticulitis in Japan. Two hundreds and eighty-two patients with acute diverticulitis who were hospitalized from November 2011 to November 2016 in our hospital were studied. Diagnosis of diverticulitis was based on symptoms, physical examination, blood tests, and results of computed tomography. We retrospectively collected data of medical history, examinations, and therapy. Risk factors associated with complications were analyzed by using logistic regression.

Results: Of the 282 patients, 183 (64.9%) patients had right-sided diverticulitis, and 70 (24%) had complications; perforation ($n = 53$), fistula ($n = 8$), abscess ($n = 5$) and stenosis ($n = 4$). The rate of complication was highest in sigmoid colon (88.6%) when compared with other locations; ascending colon (10%), transverse colon (1.4%), and descending colon (0%). Multivariate analysis identified the location of sigmoid colon (odds ratio 62.2, 95% confidence interval 21.8–178.0) as a significant independent factor for complications of diverticulitis. Among 70 patients with complicated diverticulitis, 55 (78.6%) patients underwent emergent surgery; most of them (54 patients, 98.2%) were with diverticulitis in the sigmoid colon.

Table. Risk factors associated with complications of colonic diverticulitis (univariate and multivariate analysis)

Factor		Univariate		Multivariate	
		Odds ratio (95%CI)	p-value	Odds ratio (95%CI)	p-value
Age	Per 10-year increment	NA		1.37 (0.99–1.89)	0.055

Introduction: Colonic diverticulosis is one of the most common gastroenterological disorders. Though diverticulosis is typically benign, many individuals develop diverticular disease (DD). DD is thought to stem from a complex interaction of environmental, dietary and genetic factors; however, the exact pathogenesis remains unknown.

Aims & Methods: The aim of our present study was to determine the role of genetic variation within genes encoding for collagens of the connective tissue in the development of diverticulosis. Genetic polymorphisms COL3A1 (rs3134646, rs1800255) and COL1A1 (rs1800012) were genotyped in 422 patients with diverticulosis and 285 controls of Caucasian descent using TaqMan assays.

Results: All genotype distributions did not deviate from the Hardy-Weinberg equilibrium. Overall, rs3134646, rs1800255 and rs1800012 were associated with diverticulosis. After multivariate logistic regression analysis, they were not linked with the risk of developing colonic diverticulosis in general; when selectively analyzing genders, the minor allele (AA) in rs3134646 remained significantly associated with diverticulosis in men ($p = 0.037$).

Conclusion: Our study shows that a variant of COL3A1 rs3134646 is associated with risk of developing colonic diverticulosis in Caucasian men, while COL3A1 rs1800255 and COL1A1 rs1800012 were not associated with this condition in our cohort of patients after adjusting for confounding factors.

Introduction: Although symptoms occur in only 20% of patients harbouring diverticula, Diverticular Disease (DD) of the colon DD represents the 8th disease as burden in USA. Several treatment are currently advised in managing those patients, but their impact on the burden of the disease is unknown. The recent DICA endoscopic classification has been developed and validated for the classification of DD, founding that treatment of DICA 1 and DICA 3 patients did not impact significantly in terms of acute diverticulitis occurrence/recurrence and surgery occurrence. Our aim was to assess the impact of using DICA classification on the burden of DD in Italy.

Aims & Methods: We assessed retrospectively the overall and the cost/year of treatments (mesalazine and/or rifaximin, or any other treatment, including probiotics, fibers, systemic antibiotics and spasmolytics) in DICA 1, DICA 2 and DICA 3 population. Analysis of diverticulosis prevalence was estimated according to data population provided by Italian Institute of Statistics (ISTAT). Cost of treatments were calculated according to data on drugs' consumption collected during the DICA study.

Results: According to 2015 ISTAT population data, we estimated that >8 million of Italian people >60 years may have diverticulosis. According to our enrolled population, we estimated that about 75% of diverticular population are on DICA 1, about 30% on DICA 2, and about 13% on DICA 3. According to the drugs' consumption recorded during our study, we estimated that overall about 679 million of euros could be spent in Italy in treating those patients. In particular, >387 million of euros are spent in DICA 1 population, >203 million of euros in DICA 2 population, and >88 million of euros in DICA 3 population. Considering that medical treatments did not show any significant advantage when treating DICA 1 and DICA 3 people in terms of prevention of acute diverticulitis occurrence/recurrence and surgery occurrence, we can estimate that >475 million of euros could be spent in Italy without any significant benefit for DD population.

Conclusion: DD has a significant burden for National Health System in Italy. DICA endoscopic classification may have a significant impact of this burden, helping to select DD people who effectively need treatments in terms of prevention of acute diverticulitis occurrence/recurrence and surgery occurrence.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Symptomatic Uncomplicated Diverticular Disease (SUDD) affects about 20% of patients having diverticulosis. However, SUDD natural history is not completely understood yet. Our aim was to assess the outcome of a cohort of SUDD patients during a 13-year follow-up.

Aims & Methods: 185 patients suffering from SUDD were enrolled during 2000–2002, and followed-up until 2015. Symptoms assessed were abdominal pain, meteorism, bowel movement/day, and each of them was scored from 0 (min) to 3 (max), with a sum ranging from 0 (min) to 12 (max). Also Visual Analogic Scale (VAS) was provided in order to assess patients' quality of life. Patients were treated according to physician convenience (rifaximin, mesalazine, probiotics, spasmolytics) only when symptoms occurred during the follow-up. Follow-up visit was performed every 6 months or whenever patients consider it necessary.

Results: During the observational period, 47 patients were lost to follow-up. Among them, 9 deceased for causes not related to diverticular disease. Acute diverticulitis occurred in 14 patients (7.56% of the overall population); 6 patients (3.24% of the overall population) underwent to surgery, and 2 patients (1.08% of the overall population) deceased for peritonitis. The mean symptoms' score was 7.5 at baseline, ranged between 6.6 and 9 during the follow-up, and was 8.4 at the

end of the observation. VAS score was 4 at baseline, ranged between 4 and 9 during the follow-up, and was 4.5 at the end of observation.

Conclusion: SUDD is a clinical entity that, although benign, significantly affects quality of life of patients. Acute diverticulitis may occur in those patients, sometimes needs of surgical treatment, and may cause mortal complications, although not frequent.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Fecal microbiota and metabolome may be altered in patients with Symptomatic Uncomplicated Diverticular Disease (SUDD). In particular, we found that *Akkermansia muciniphila* species were significantly increased in SUDD patients when compared with asymptomatic diverticulosis and healthy people, as well as PLS-DA analysis of NMR-based fecal metabolomics showed significant discrimination between HC and AD patient. Our aim was to assess the effect of current treatments for SUDD on fecal microbiota and fecal metabolic profiling in those patients.

Aims & Methods: Thirteen consecutive female patients, living in the same district and suffering from SUDD, were studied. Patients were treated with a 2-week course of 30g/day fiber supplementation (3 patients), 1.6 grams/day of mesalazine (3 patients), 900 billion/day of probiotic mixture VSL#3 (currently available in Europe as VivoMixx[®], 3 patients), and 800 mg/day of rifaximin (4 patients). Stool samples were collected at entry (T0), at the end of the 2-week course of treatment (T1), and after 30 (T2) and therefore after 60 days at the end of the therapeutic course (T3). Real-time PCR was used to quantify targeted microorganisms. High-resolution proton nuclear magnetic resonance (NMR) spectroscopy associated to Multivariate Analysis with partial least square discriminant analysis (PLS-DA) were applied on the metabolite data set.

Results: The overall bacterial quantity did not differ before and after treatment ($p=0.449$). The overall amount of *Akkermansia muciniphila* species was significantly reduced at T1 ($p=0.017$) and T2 ($p=0.026$), while at T3 it became similar to that of T0 ($p=0.09$). The amount of *Lactobacilli* group was increased in all groups but not significantly at T1 and T2, while at T3 it became similar to that of T0. All treatments showed the same results except for probiotic group, who had higher and persistent amount of *Lactobacilli* up to T3. PLS-DA analysis of NMR-based fecal metabolomics showed significant changes at T1 and T2, while at T3 it became similar to that of T0. All treatment were showed the same behaviour in influencing fecal metabolome except for rifaximin group, in which we did not find any metabolic change neither at the end of treatment nor during the washout period.

Conclusion: This preliminary study confirms that *Akkermansia muciniphila* may play a pathogenic role in the occurrence of SUDD. We found also that current treatments for SUDD patients are able to influence metabolic activity in those patients except for rifaximin.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Natural history of colonic diverticulosis and diverticular disease (DD) is poorly known, and available data derived mostly from retrospective cohort studies.

Aims & Methods: Aim of this study was to assess, in a cohort of patients with colonic diverticula, the incidence of new cases of symptomatic uncomplicated diverticular disease (SUDD) and diverticulitis, and recurrence of diverticulitis after 1-year of follow-up. GRIMAD (Italian Diverticular Disease Group) promoted the creation of REMAD (Register of Diverticular Disease) a prospective, 5-years, no-profit, cohort study involving 47 Italian centers. Each center enrolled at least 20 consecutive patients during a period of two months. Inclusion criteria were: informed consent; age ≥ 18 years and endoscopic/radiological-confirmed colonic diverticula. Outpatient/telephone visits were scheduled every 6 months. The clinical data (patients' characteristics and habits, characteristics of DD, comorbidities and therapies) collected by participating centers were reported on an electronic Case Report Form managed by CD Pharma, Milan. At entry, patients were categorized according to the following criteria: i) diverticulosis (presence of diverticula in the absence of abdominal symptoms); ii) SUDD (recurrent abdominal symptoms as abdominal pain and/or changes in bowel habit, in the absence of overt inflammation); iii) PD (patients who experienced at least one episode of acute diverticulitis in the past). Patients were allowed to continue their therapy for DD, if any. Logistic regression was performed to identify patients' features associated with new occurrence of SUDD and diverticulitis.

Results: Overall, at baseline 1217 [556 (45.7%) female, median years 67 (28–95), BMI 25.6Kg/m² (16.2–43.4)] patients were enrolled: 707 (58.1%), 300 (24.7%), and 210 (17.3%) with diverticulosis, SUDD, and PD, respectively. At 12 months, 922 patients (53.1%, 29.8%, and 17.1% with diverticulosis, SUDD, and PD) were followed, and 27.4% of patients were lost at follow-up. In the 12 months follow-up, 33 (6%) and 4 (0.7%) of diverticulosis patients developed SUDD and acute diverticulitis, respectively; 4 (1.6%) of SUDD patients developed acute diverticulitis, and in 14 (9.4%) of PD patients a new episode of acute diverticulitis occurred. Overall, only 3 patients developed a complication, without need of surgery. One year of follow-up logistic regression, showed that only female gender was associated with subjects who changed subgroup from diverticulosis to SUDD (OR 2.26, 95%CI 0.97–5.22). No specific features associated with recurrence of diverticulitis could be identified.

Conclusion: These preliminary data suggested that, during an observation period of one year, progression from diverticulosis to SUDD occurred in less than a tenth of patients, and was associated with female gender. Overall incidence of diverticulitis was very low (2.3%), whereas recurrent diverticulitis was not uncommon. This observational study suggested, that although the vast majority of patients did not show progression of disease, in those who progressed one in ten tended to relapse during follow-up.

Introduction: In the vast majority of patients colonic diverticula remain asymptomatic (diverticulosis), while about 20% develop recurrent abdominal symptoms (symptomatic uncomplicated diverticular disease, SUDD) or complications (diverticulitis), with subsequent impact on quality of life (QoL). To date, clinical features associated with each subgroup are not fully understood.

Aims & Methods: Aim of this study was to assess, in a cohort of patients with colonic diverticula, the clinical features and QoL scores associated with each subgroup of patients. GRIMAD (Italian Diverticular Disease Group) promoted the creation of REMAD [(Register of Diverticular Disease (DD)) a 5-years prospective, no-profit, cohort study involving 47 Italian centres. Each centre enrolled at least 20 consecutive patients during a period of 2 months. Inclusion criteria were: informed consent; age ≥ 18 years; endoscopic/radiological-confirmed colonic diverticula. The clinical data [patients' characteristics and habits, characteristics of DD, treatment, and QoL (SF-12 questionnaire with evaluation of physical and mental component summary scores (RPCS12 and RMCS12)] collected by participating centres were reported on an electronic Case Report Form managed by CD Pharma, Milan. At entry, patients were categorized into subgroups according to the following criteria: i) diverticulosis (presence of diverticula in the absence of abdominal symptoms); ii) SUDD (recurrent abdominal symptoms as abdominal pain and/or changes in bowel habit, in the absence of overt inflammation); iii) PD (patients who experienced at least one episode of acute diverticulitis in the past). Patients were allowed to continue their therapy for DD, if any. T test was used to compare QoL scores. Logistic regression was performed to identify patients' features associated with the presence of subtypes of DD. A p value <0.05 was considered statistically significant.

Results: 1217 patients were enrolled. Characteristics of each subgroup of patients are reported in the table.

N(%)	Diverticulosis n=707 (58.1)	SUDD n=300 (24.7)	PD n=210 (17.3)	OR (95% CI)
Female	276 (39)	174 (58)	106 (50.5)	*2.18 (1.60–2.95) #2.06 (1.43–2.98)
Age years median (range)	67 (34–93)	67 (37–90)	65 (28–95)	#2.33 (1.53–3.57)
BMI Kg/m ² median (range)	25.6 (16.2–40.8)	26 (18–41)	25.3 (16.6–43.4)	ns
Family history for DD	129 (18.2)	65 (21.7)	60 (28.6)	#1.73 (1.15–2.60)
Gastrointestinal (GI) comorbidities	224 (31.7)	134 (44.6)	69 (32.8)	*1.65 (1.21–2.25)
Charlson Index >3	108(15.3)	41(13.6)	26(12.3)	ns
RPCS12 (mean)	48.5	46.1	47.0	p value *0.0002; # 0.0302
RMCS12 (mean)	48.2	45.0	45.9	* <0.0001; #0.0048

*diverticulosis vs SUDD; #diverticulosis vs PD; ns: not significant

Conclusion: These data showed that, with respect to diverticulosis, female gender and presence of GI comorbidities are associated with SUDD, whereas younger age, family history for DD and female gender are associated with PD. Furthermore, patients with diverticulosis have higher physical and mental scores compared both to patients with SUDD and PD, suggesting that SUDD and PD reduced QoL of the affected patients.

Introduction: Patients with symptomatic uncomplicated diverticular disease (SUDD) and those with diverticulitis share similar clinical patterns characterized by abdominal pain or changes of bowel habits. In clinical practice, differential diagnosis between the two conditions may be useful in the diagnostic approach and therapeutic management.

Aims & Methods: Our aim was to assess the features of abdominal pain in patients with SUDD and previous diverticulitis (PD). GRIMAD (Italian Diverticular Disease Group) promoted the creation of REMAD (Registry of Diverticular Disease), a prospective, 5-years, no-profit, cohort study involving 47 Italian centers. All patients were enrolled during a 2 months-period. At entry, patients were categorized according to the following criteria: i) diverticulosis (presence of diverticula in the absence of abdominal symptoms); ii) SUDD (recurrent abdominal symptoms in the absence of overt inflammation); iii) PD (patients who experienced at least one episode of acute diverticulitis). Patients who fulfilled criteria for diagnosis of SUDD and PD were asked to fill in two questionnaires assessing features of short pain (<24h) and long-acting pain (>24h) in the last 6 months. Both questionnaires assessed patterns of pain, including severity (evaluated by means of a 10-cm VAS), localization, association with clinical parameters (fever, confinement to bed, medical consultation, antibiotic therapy and hospital admission). Data were expressed as percentages and means \pm standard deviations. P < 0.05 was considered significant.

Results: 1217 [556 (45.7%) female, age 66.1 \pm 9.9y] consecutive patients were enrolled in the study. 300 (24.7%) and 210 (17.3%) fulfilled criteria for SUDD and PD, respectively. Among them, 223 patients with SUDD (74.3%) and 154 patients with PD (73.3%) accepted to fill in short-lasting pain questionnaire, whereas 156 patients with SUDD (52.0%) and 140 patients with PD (66.6%)

filled in long-lasting pain questionnaire. Abdominal pain lasting <24h was reported by 192/223 patients with SUDD (86.1%) and 119/154 with PD (77.3%)($p=0.026$). Symptom severity score was higher in PD group than in SUDD group, but this difference was not statistically significant (5.5 ± 2.4 vs 5.1 ± 2.2 cm; $p=0.130$). Patients with PD had short-lived pain located more frequently in left lower abdomen (50.6% vs 39.9%; $p=0.002$), whereas abdominal diffuse pain was more prevalent in patients with SUDD (29.6% vs 20.8%; $p=0.058$). Pain lasting >24h was more prevalent in PD group compared to SUDD group (62.1% vs 52.6%; $p=0.029$). Pain severity was higher in patients with PD, but this difference was not significant (6.4 ± 2.6 vs 5.9 ± 2.4 ; $p=0.069$). Long-lasting pain was more frequently located in left lower abdomen in patients with PD (53.6% vs 23.7%; $p<0.01$), whereas more frequently was diffuse in SUDD patients (17.3% vs 7.1%; $p<0.001$). Moreover, in patients with PD, pain lasting >24h was more often associated to fever (28.6% vs 6.4%; $p<0.001$), confinement to bed (35.7% vs 18.6%; $p=0.002$), medical consultation (38.6% vs 23.7%; $p=0.013$), need for therapy (42.9% vs 19.2%; $p<0.001$), and hospitalization (28.6% vs 8.3%; $p<0.001$).

Conclusion: SUDD and PD patients show some peculiar clinical features of abdominal pain. SUDD patients frequently complained abdominal diffuse and short lasting pain. In contrast patients with PD frequently complained pain located in the left lower abdomen lasting for more than 24h. Our results suggest that these features are useful indicators to distinguish patients with SUDD and PD and should be carefully assessed in clinical work-up of diverticular disease.

Introduction: Colonic diverticulosis, as well as diverticular disease, is a multifactorial disorder characterized by neuro-muscular alterations consisting in impaired contraction, inflammation and fibrosis. Mesenchymal smooth muscle cells (SMC) are able to switch from a contractile phenotype to a less mature synthetic phenotype, characterized by a loss of differentiation with decreased expression of contractile markers as well as synthesis and release of several pro-inflammatory cytokines. Different organ specific pathways have been demonstrated to induce this mesenchymal transition. Renal fibrosis is driven by transforming growth factor- β (TGF- β) through inverse regulation of Smad2/3 while vascular fibrosis by PDGF- β , ending in downregulation of marker gene Trb3 expression.

Aims & Methods: Aim of this study was to determine, both in human uninvolved and involved tracts of asymptomatic diverticulosis (AD⁻, AD⁺) and in stenotic segments of complicated diverticular disease (CDD), the alterations intrinsic to smooth muscle. Circular and longitudinal smooth muscle strips and cells (SMC) were isolated separately from surgical colon specimen of 18 patients (58 < age < 80years) affected either by sigmoid AD (6) or CDD (6) and patients (61 < age < 80years) submitted to surgery for cancer (6) (CTR). Contraction was tested in response to carbachol and relaxation in response to VIP. qPCR analysis, expressed as Relative Quantification, was performed for transcription of mRNA encoding for TNF- α , inflammasome components (NLRP3, ASC, CASP1, IL-1 β) and for SMC phenotypic switch molecules (Collagen I, α -SMA, TGF- β , PDGF- β , Trb3, Smad2/3). Data were normalized to β -actin mRNA and expressed as mean \pm SE. In addition, the activation of inflammasome complex was indirectly tested through quantification of IL-1 β secretion by commercial ELISA kit.

Results: In both muscle layers, AD⁻ and AD⁺ SMC, compared to CTR, showed an overall increase in inflammatory gene expression, with a trend of decrease from AD⁻ to AD⁺, the lowest expression been observed in CCD. This inflammatory state was associated with an increase in IL-1 β secretion in SMC culture medium compared to CTR and a progressive inhibition of contraction to carbachol, already in AD⁻ in circular strips and SMC. In contrast relaxation in response to VIP resulted significantly decreased only in AD⁺ both on strips and SMC with no alteration in AD⁻ and CDD. Peculiarity of circular SMC was a progressive increase in Col1 expression from AD to CDD compared to CTR (3 hundred fold increase) paralleled to about 50% decrease in the contractile protein α -SMA. Differently, longitudinal SMC, both in AD and CDD, presented a homogenous increased Col1 expression, decrease in α -SMA and reduction of contraction. VIP-induced relaxation was significantly decreased in CCD. Phenotypic switch was only observed in CDD, driven in circular layer, by a TGF- β -dependent pathway (increased expression for TGF- β : 2.88 ± 0.6 and Smad3: 1.67 ± 0.12 and reduced Smad2: 0.39 ± 0.11) while in longitudinal driven by PDGF- β -dependent pathway (increase of PDGF- β : 2.27 ± 0.44 and parallel decrease of Trb3: 0.58 ± 0.13).

Conclusion: Intrinsic myogenic alterations are present in colonic asymptomatic diverticulosis and complicated diverticular disease, both in the circular and

longitudinal layers characterized by a myogenic pro-inflammatory state and an impaired contractile activity that, in complicated diverticular disease, ended in a muscular synthetic pro-fibrotic switch.

Introduction: Aberrant Notch activation has been implicated in multiple malignancies, including gastric cancer (GC). However, the clinical significance of Notch receptors and their functional role in gastric carcinogenesis remain unclear.

Aims & Methods: We aim to delineate the dysregulated Notch signaling in GC and comprehensively reveal its activation by silenced microRNAs (miRNAs) in gastric carcinogenesis. The expression clinical relevance of NOTCH1-4 in GC were achieved from online available dataset. The mRNA and protein expression of NOTCH3 were examined by qRT-PCR and Western blot. The biological function of NOTCH3 in GC was demonstrated by MTT proliferation, mono-layer colony formation, cell invasion and migration assays through siRNA-mediated knockdown. The prediction of miRNAs which potentially target NOTCH3 was performed by www.microRNA.org and TargetScan. The regulation of NOTCH3 by putative miRNAs was confirmed by qRT-PCR, Western blot and dual luciferase activity assays through ectopic overexpression of miR-491-5p and miR-875-5p. The functional downstream targets of NOTCH3 were identified by gene expression microarray.

Results: NOTCH3, but not NOTCH1, 2, 4, is uniformly up-regulated and significantly correlated with poor survival in multiple GC datasets. Knockdown of NOTCH3 in AGS and MKN28 cells exhibited significant anti-oncogenic effect *in vitro*. NOTCH3 downregulation suppressed cell proliferation, reduced mono-layer colony formation, and inhibited cell invasion ability. Moreover, NOTCH3 knockdown significantly promoted cleaved caspase-3 and cleaved-PARP expression to induce apoptosis, which was further revealed by the gene set enrichment analysis (NCBI/GEO/GSE57303 and NCBI/GEO/GSE57303 database). NOTCH3 was further confirmed to be a direct target of tumor-suppressive miRNAs, miR-491-5p and miR-875-5p. Enforced overexpression of miR-491-5p and miR-875-5p in GC cells also exerted tumor-suppressive function by inhibiting cell proliferation and inducing apoptosis. More importantly, the expression of miR-491-5p showed negative correlation with NOTCH3 mRNA expression in primary GC samples and re-overexpression of NOTCH3 rescued the inhibitory effect of miR-491-5p and miR-875-5p. Pleckstrin Homology Like Domain Family B Member 2 (PHLDB2) is identified as the functional downstream of NOTCH3 in GC. Concordantly, PHLDB2 knockdown significantly inhibited cell proliferation and promoted apoptosis, which phenocopied NOTCH3 knockdown or miR-491-5p/miR-875-5p overexpression. In primary GC samples, the expression of PHLDB2 and NOTCH3 showed positive correlation in The Cancer Genome Atlas (TCGA) cohort. Thus, the miR-491-5p/miR-875-5p-NOTCH3-PHLDB2 oncogenic cascade was constructed.

Conclusion: NOTCH3 is over-expressed and plays an oncogenic role in gastric carcinogenesis through its direct downstream PHLDB2. The activation of NOTCH3 in GC is partly due to the silence of tumor-suppressive miRNAs, miR-491-5p and miR-875-5p. These findings comprehensively revealed the activation of Notch signaling pathway and provided clinical translational potential for GC.

Introduction: We found that tumor suppressor gene FOXF2 was silenced in gastric cancer (GC) through promoter hypermethylation. Restoration of FOXF2 suppressed GC tumorigenicity through inhibition of canonical Wnt

signaling pathway. However, the molecular mechanism of FOXF2 in GC is still unknown.

Aims & Methods: We hypothesize that FOXF2 transcriptional upregulates a novel E3 ligase that targets β -catenin for degradation. We aim to investigate the molecular mechanism of FOXF2 in GC and identify such E3 ligase by PCR array, Chromatin Immunoprecipitation (ChIP) assay and luciferase assay.

Results: FOXF2 significantly decreased both nuclear and cytosolic levels of β -catenin in a GSK-3 β independent manner and promoted β -catenin degradation via ubiquitin-proteasome pathway in gastric cells. Using Human Ubiquitin Ligases RT² Profiler PCR Array and western blot, we identified that IRF2BPL was upregulated upon FOXF2 overexpression and was a promising E3 ligase for β -catenin. Overexpression of IRF2BPL suppressed the TOP-flash luciferase reporter and reduced Wnt target gene c-myc expression in GC cells. Overexpression of IRF2BPL significantly increased β -catenin ubiquitination and reduced β -catenin protein without alteration of its mRNA level. Conversely, knockdown of IRF2BPL significantly decreased endogenous β -catenin ubiquitination. Immunoprecipitation assay suggested that IRF2BPL interacted with β -catenin. These results reveal that IRF2BPL is a potential E3 ligase that targets β -catenin for degradation. To investigate whether FOXF2 directly regulates IRF2BPL transcription, we performed ChIP assay and found that FOXF2 bound on to the IRF2BPL promoter region. We cloned the IRF2BPL promoter region (-2700 bp to TSS) into pGL3-basic plasmid and performed a luciferase activity assay. Wild-type FOXF2 but not the mutant Δ FOXF2 significantly activated the luciferase reporter in AGS and 293 ft cells, suggesting that FOXF2 directly activated IRF2BPL transcription. Moreover, FOXF2 significantly increased the level of H3K27Ac (a marker to distinguish active from inactive enhancer element) on the 5'-flanking region of IRF2BPL gene, suggesting that FOXF2 positively regulated IRF2BPL gene transcription. In addition, IRF2BPL was significantly downregulated in human GC tissues compared to the adjacent normal tissues (N = 30, $P < 0.01$) by real-time PCR analysis. IRF2BPL mRNA showed a positive correlation with FOXF2 in gastric cancer in a Chinese cohort (N = 30, Spearman's $\rho = 0.42$, $P < 0.05$) and in the TCGA cohort (N = 421, Spearman's $\rho = 0.38$, $P < 0.001$).

Conclusion: We reported a novel FOXF2-IRF2BPL- β -catenin signaling axis in gastric cells. FOXF2 is a critical tumor suppressor in gastric carcinogenesis through promoting β -catenin degradation by transcriptionally upregulating E3 ligase IRF2BPL.

Introduction: Gastric adenocarcinoma with enteroblastic differentiation (GAED) is a rare variant of gastric carcinoma. It is well known that GAED is associated with poor prognosis [1, 2]. However, the clinicopathological and molecular biological features have not been elucidated enough. We performed comprehensive analysis by next generation sequencing (NGS) to clarify the clinicopathological features of GAED and to find new therapeutic targets.

Aims & Methods: Among 1003 patients with primary gastric cancer who underwent surgery or endoscopic resection in our hospital between April 2008 and February 2017, we enrolled 52 cases (early:17, advanced:35) of GAED defined as having tubular to papillary or solid structure with clear cytoplasm and immunohistochemical positivity for at least one of the following antibodies; AFP, Glypican-3 and SALL4. NGS was performed for 24 cases of formalin-fixed paraffin-embedded samples (early: 2, advanced: 22) using Ion PGM™ system with cancer hotspot panel v2 targeting 50 genes (Thermo Fisher Scientific). Immunohistochemical staining (IHC) was carried out to validate genetic alterations. We also analyzed the association among these genetic alterations, clinicopathological factors and prognosis.

Results: As a previous study has shown, lymphatic and venous invasion, lymph nodes metastasis and liver metastasis were frequently observed in this tumor (67.3, 67.3%, 69.2% and 32.7%, respectively). Immunohistochemically, even though AFP positive rate was low (32.7%), most cases were diagnosed by positivity of either of other two markers; glypican-3 (80.8%), SALL4 (80.8%). There were significant association between lymphatic invasion, liver metastasis and prognosis. NGS revealed that most cases harbored TP53 mutation (19/24, 79.2%), and other mutations such as CTNNB1 (2/24, 8.3%), APC (1/24, 4.2%), ATM (1/24, 4.2%), FBXW7 (1/24, 4.2%) were also detected. Compared with the public data of conventional gastric carcinoma (CGA) [3], TP53 mutation rate was significantly higher in GAED (79.2% vs. 47.8%, $p < 0.01$). However, there was no association between TP53 mutation and clinicopathological factors including patients' prognosis. With regard to the correlation between TP53 mutation and p53-IHC, all cases with TP53 missense mutation (n = 12) showed p53 overexpression. We found p53 overexpression by IHC in 29 out of 52 GAED cases (55.8%), however, this did not affect patients' prognosis. We also detected ERBB2 amplification in 9 out of 24 cases (37.5%) by analyzing copy number variation, and this rate was significantly higher than that reported in CGA (13.0%) ($p < 0.01$) [3]. Most of GAED with ERBB2 amplification showed HER2 overexpression by IHC.

Conclusion: GAED shows generally aggressive behavior characterized by frequent lymphatic invasion and liver metastasis. TP53 mutation rate and ERBB2 amplification rate in GAED is significantly higher than those of CGA. HER2 overexpression associated with ERBB2 amplification could be a new therapeutic target in GAED.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Ten percent of all gastric cancers show familial aggregation and may account for at least three syndromes^{1, 2}: hereditary diffuse gastric cancer (HDGC), gastric adenocarcinoma and proximal polyposis of the stomach (GAPPS)³, and familial intestinal gastric cancer (FIGC)⁴. Whilst germline defects at the *CDH1*⁵, *APC*⁷ genes have been found for HDGC and GAPPS families, respectively, FIGC remains genetically unexplained.

Aims & Methods: We hypothesised that the rare FIGC syndrome is caused by germline co-occurrence of moderate-risk alleles and represents a polygenic, rather than a classical monogenic disease. Therefore, this study aimed at dissecting the germline and somatic landscapes of the largest FIGC cohort ever studied. Constitutional and tumour DNA from probands of 53 families, fulfilling clinical criteria of FIGC, were screened for 55 candidate gastrointestinal cancer-associated genes with Illumina's MiSeq-platform, and classified according to the American College of Medical Genetics and Genomics (ACMG) guidelines. Somatic second hits, such as second mutation, loss of heterozygosity and promoter methylation, were searched for in FIGC tumours at potentially causative genes by PCR-Sequencing.

Results: Twenty-five out of 53 (47%) FIGC families harboured germline variants, and co-occurrence of germline moderate-risk alleles was found in ten families. From these ten families, seven harboured one pathogenic or likely pathogenic variant combined with one or more unclassified novel variants. The remaining three families carried solely clusters of novel unclassified variants. Moderate-risk alleles of BRCA2, MAP3K6, MSH6, MSRI, SDHB and SDHD were the most frequently found in this cohort. In addition, tumours arising in these 10 families were enriched in somatic variants within DNA repair genes and often display microsatellite instability phenotype.

Conclusion: The clinical homogeneity and relatively high number of FIGC families herein studied allowed supporting the hypothesis that FIGC may be a polygenic syndrome caused by moderate-risk alleles in gastrointestinal cancer-associated genes.

Introduction: Endoscopic submucosal dissection (ESD) is widely accepted to treat large superficial esophageal neoplasms. However, esophageal stenosis after ESD has become a key complication. To prevent such stenosis, we developed new regenerative therapies that suppresses contracture and stenosis. About two weeks prior to the esophageal ESD, autologous oral mucosal epithelial cell sheets were fabricated from the patient's own oral mucosal tissue. The cell sheets were then endoscopically transplanted onto the ulcer surface immediately after ESD. To date, this cell sheet treatment, which resembles cultured epidermal cell sheet transplantation in severe burn cases, has been clinically applied, and successful outcomes have been obtained at several institutions in Japan and Sweden. In addition to preventing stenosis by the simple dressing of the ulcer's surface area, anti-inflammatory and wound-heal promoting functions of the cell sheets were expected.

Aims & Methods: For understanding the therapeutic effects of the cell sheet transplantation, we investigated the morphological and histological features of the human oral mucosal epithelial cell sheets, in addition to the cellular gene and protein expressions. From a small biopsy of human volunteer donors' oral mucosal tissue, we isolated and cultured epithelial cells, which were then fabricated into transplantable cell sheets using a previously described procedure. The cell sheets were examined by immunohistochemistry (IHC) and electron microscopy as well as the gene and protein expression analysis by RT-PCR, with a DNA array. Furthermore, the culture supernatant obtained immediately before the transplantation, were analyzed with a cytokine array.

Results: Histological and morphological analyses revealed that tissue-engineered stratified epithelial cell sheets have an apical-basal polarity, and that the junctions between the basal cells of the sheets were significantly loose, due to dissociating desmosomes, which were also fewer in numbers. IHC showed that the expression levels of E-cadherin and desmosomal cadherins were downregulated in the basal cells of the epithelial cell sheets, but mesenchymal markers (N-cadherin, vimentin, and fibronectin) were upregulated. Taken together, these findings implied that epithelial mesenchymal transition (EMT) was induced in the basal cells. The results of the cytokine array showed that the cell sheets secreted EMT-related proteins, growth factors (progranulin and epiregulin), and antimicrobial proteins (b-defensin).

Conclusion: The EMT of the basal cell layer of epithelial cell sheets may contribute to the improved engraftment after cell sheet transplantation. The secretion of antibacterial peptides and various growth factors from the cell sheets would exhibit anti-inflammatory effects, and promote wound-healing compared to reinforcement of esophagus with absorbable synthetic materials such as polymer membrane of polyglycolic acid and polylactic acid.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Obestatin, a 23-amino acid peptide derived from the ghrelin peptide precursor, was originally isolated from stomach and characterized to bind selectively to the G protein-coupled receptor GPR39 (1). We have recently described the expression of obestatin/GPR39 system in healthy human stomach as well as in human gastric adenocarcinoma. In healthy human stomachs, obestatin expression was observed in the neuroendocrine cells and GPR39 expression was localized mainly in the chief cells of the oxyntic glands. In human gastric adenocarcinomas, the reported data strongly suggest the involvement of the obestatin/GPR39 system in the pathogenesis and/or clinical outcome, and highlight the potential usefulness of GPR39 as a prognostic marker in gastric cancer (2). However, the physiological role of the obestatin/GPR39 system in healthy stomach remains unknown.

Aims & Methods: To investigate the implication of the obestatin/GPR39 system in the regulation of pepsinogen secretion. GPR39, obestatin and pepsinogen I (PGI) expression was determined in the AGS cell line by immunocytochemistry; and in endoscopic biopsies of human healthy stomachs by immunohistochemistry and immunofluorescence. PGI secretion was measured after exogenous administration of obestatin (hemoglobin method, immunoblot) in AGS cells and in an in vitro explant culture of human stomach tissues obtained from

surgical specimens after bariatric surgery. The influence of the acute GPR39 deficiency on PGI secretion was determined using siRNA GPR39.

Results: AGS cells expressed obestatin, GPR39 and PGI. In these cells, exogenous administration of obestatin (200 nM, 40 min) stimulated PGI secretion (60% over control). This effect was exerted via the GPR39 receptor. In the human healthy stomach, GPR39 expression was detected mainly in the chief cells of the oxyntic glands but also in a few cells of the neck section (pre-chief cells). This expression co-localized with PGI expression in both cell types. The mucous neck cells were positive for PGI and negative for GPR39. Obestatin also exerted a dose-dependent stimulatory effect on PGI secretion in the in vitro explant culture of human stomach, being significant for 100 and 200 nM compared to the control sample at 20 min (39% and 66% over control, respectively), for 200 nM at 40 min (51% over control) and 100 nM at 60 min (64% over control).

Conclusion: The obestatin/GPR39 system is physiologically involved in the stimulation of pepsinogen secretion in the healthy human stomach.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0503 SERUM EXOSOMAL MIRNAS EXPRESSION AS NOVEL BIOMARKERS FOR DETECTION OF ESOPHAGEAL ADENOCARCINOMA

H. Chen

Jiangsu Province Hospital, Nanjing/China

Contact E-mail Address: chenhan068@hotmail.com

Introduction: Novel biomarkers for the diagnosis of esophageal adenocarcinoma (EAC) are urgently required. Currently, there is increasing evidence suggesting that serum exosomal miRNAs may be potential noninvasive biomarkers for certain diseases. The objective of the present study was to find and investigate whether exosomal miRNAs could be effective biomarkers for EAC.

Aims & Methods: In the present study, exosomes were isolated from the serum of both EAC patients and normal controls. Total RNA was extracted from exosomes and miRNA levels were compared between EAC and control patients in serum exosomes. We also sought to investigate the relevance of exosomal miRNA expression to clinicopathological factors in EAC.

Results: We measured levels of several exosomal miRNAs, including miR-21, miR-16, miR-25, miR-155, miR-192, miR-92a, in 9 EAC patients and 9 controls. These miRNAs were chosen because they have been shown to function as onco-miRs in previous studies. Levels of miR-21, miR-16, miR-25 and miR-155 were significantly higher in EAC patients than in controls (fold-change 35.36, 30.87, 9.24 and 2.26, respectively). The level of miR-192 was significantly lower in EAC patients than in controls (Fold-change: 0.35). We did not observe a significant fold-change in miR-92a expression levels between EAC and controls. P-values did not achieve statistical significance, possible due to large standard deviations and relatively small sample sizes. We also visualized exosomes isolated from both cell culture medium and sera of EAC patients and control subjects, with diameter ranging from 30 to 100 nm using transmission electron microscopy.

Conclusion: Serum exosomal miRNAs can be isolated, measured, and may serve as potential biomarkers in EAC patients. miRNA microarray or next-gen sequencing analyses and larger sample sizes are needed to validate these early results.

Introduction: Endoscopic variceal band ligation (EVL) is an effective procedure to control and prevent variceal bleeding in patients with liver cirrhosis. Although EVL has some complications, yet these complications are related to post-EVL ulcers. Few data exist regarding therapy of post-ligation ulcer and treatment been mostly empirical with drugs used for peptic ulcer diseases.

Aims & Methods: We aimed to compare between the efficacy of rebamipide, sucralfate and pantoprazole in treatment of post banding variceal ulcers. Seventy-five patients with esophageal varices eligible for elective band ligation represented the population of the study. The patients were allocated into three groups; rebamipide group, they received rebamipide 100mg 3 times daily; pantoprazole group, they received pantoprazole 40 mg/day orally at morning; sucralfate group, they received sucralfate 1gm every 6 hours, for 14 days beginning at the next day of band ligation. Subjects underwent EGD 14 days after banding.

Primary outcomes included the size and number of ulcers and the subjects' reports of bleeding, dysphagia, chest pain and vomiting.

Results: At follow-up endoscopy, the number of patients with post-band ulcers and size of ulcers were similar in the three groups. However, the number of ulcers for each patient is statistically significant less in rebamipide group when compared to pantoprazole and sucralfate ($P < .001$). Chest pain, dysphagia and vomiting scores were not significantly different. Dysphagia was by far the most common symptom with no case of bleeding was reported in all patients of the studied groups.

Conclusion: Rebamipide is effective in decreasing the post banding complication and reducing size of ulcer as well as the number of ulcers with no significant effect on post banding ulcer formation. Rebamipide can be used routinely in settings of post-EVL as a good alternative to pantoprazole and sucralfate.

³Department Of Gastroenterology, Vivantes Klinikum in Friedrichshain, Berlin/Germany

Contact E-mail Address: edris1@web.de

Introduction: The over-the-scope-clip (OTSC) overcomes limitations of standard clips and achieves a more efficient and reliable haemostasis in non-variceal upper gastrointestinal bleeding (NVUGIB). The study aims to evaluate mortality, rebleeding and mortality after rebleeding of patients in whom the OTSC was used as first-line endoscopic treatment (FLET) of NVUGIB. Data on OTSC use for NVUGIB in high-risk patients is currently limited.

Aims & Methods: In total, 118 patients (FLET cohort) with a median age of 73.5 years (range 29–93 years; mean (\pm SD) 71.39 ± 12.39 years) were included. The distribution of patients with respect to risk category revealed a median Rockall score (RS) of 7 (range 3–10; mean (\pm SD) 7.25 ± 1.51). For hypothesis testing, the FLET cohort was categorized into 3 risk groups taking into account the Rockall score: low risk (Rockall risk category (RRC) ≤ 3), moderate risk (RRC 4–7), and high-risk (RRC ≥ 8). Event rates (mortality, re-bleeding and mortality after rebleeding) observed per risk group were compared to predicted event rates (Rockall cohort) using Fisher's Exact Test.

Results: Primary successful haemostasis (PSH) was achieved in 92.4% either by FLET alone or in combination with an additional haemostasis technique in 1.7% (SCS = secondary clinical success). In 7.5 % of the FLET cohort PSH couldn't be achieved. Mortality in the FLET cohort was in the high-risk group (RRC ≥ 8) lower compared to RRC prediction, but no significant difference. However mortality after re-bleeding was significantly reduced from 27.9 % to 10.9 % in the high-risk group (RRC ≥ 8) treated with FLET ($p < 0.011$). Furthermore, occurrence of re-bleeding or continued bleeding was significantly lower in the moderate risk group (RRC 4–7) with 4.9 % as well as in the high-risk group (RRC ≥ 8) with 21.4 % compared to RRC 24.0 % and 53.2 %, respectively, as predicted by the Rockall scoring system ($p < 0.001$).

Conclusion: Our study shows that OTSC is superior to standard clipping techniques and FLET of OTSC reduces significantly re-bleeding and re-bleeding associated mortality in NVUGIB and it is for this reason we recommend FLET for NVUGIB in high-risk patients.

P0506 A NEW PREDICTION RULE FOR UPPER GASTROINTESTINAL BLEEDING USING THE GLASGOW BLATCHFORD SCORE AND CT NUMBER

M. Tsudome, K. Fujita, A. Sugahara

Department Of Gastroenterology, Yodogawa Christian Hospital, Osaka/Japan

Contact E-mail Address: marie_t@zpost.plala.or.jp

Introduction: Upper gastrointestinal bleeding can have various severities, with some cases needing for intensive care while, others allow for patient to go home. Thus, it is important to detect the patients who need endoscopic treatment. The Glasgow Blatchford score (GBS) is currently regarded as the best score for predicting endoscopic treatment (area under the receiver operating characteristic curve (AUROC) 0.75)[1]. Contrast-enhanced CT is also useful for patients with gastrointestinal bleeding [2]. However, it is a complicated procedure and it cannot be used for patients with renal failure.

Aims & Methods: The aim is to analyze the accuracy of the GBS and non-enhanced CT in predicting the necessity of endoscopic treatment for patients with upper gastrointestinal bleeding. This study was designed as a hospital-based observation study. Patients who were hospitalized for upper gastrointestinal bleeding and had an endoscopy performed within 24 hours from April 2013 to March 2014 at Yodogawa Christian Hospital were studied. The clinical utility of the GBS and CT were assessed separately and in combination

Results: A total of 113 patients were included in the study. The median GBS was 10 (interquartile range (IQR) 7–12). The score did not discriminate well with AUROC of 0.63. The median CT number was 48HU (IQR 26.7–60.7). The CT number also did not discriminate well with AUROC of 0.65. We set the cut off for GBS at 4, and a CT number at 50HU. The endoscopic treatment percentage of the group of $GBS \geq 4$ and CT number $\geq 50HU$ was 63.5%, $GBS \geq 4$ and CT number $< 50HU$ was 30.6%, $GBS < 4$ and CT number $\geq 50HU$ was 33.3%, $GBS < 4$ and CT number $< 50HU$ was 11.1%. We counted that $GBS \geq 4$ was 1 point, CT number $\geq 50HU$ was 1 point. The points were added up to a total score that predicts the necessity for endoscopic treatment. Those scoring 2 points was about 60 percentage for the necessity for endoscopic treatment, 1 points was about 30 percentage, 0 point was about 10 percentage. AUROC of this model was 0.69.

Conclusion: Using both the GBS and CT in combination performed better for predicting the necessity of endoscopic treatment for patients presenting with upper gastrointestinal bleeding.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0507 FIBRIN GLUE CAN PREVENT BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION

L. Yu, Y. Wang

Jiangsu Province Hospital, Nanjing/China

Contact E-mail Address: ylianzen@126.com

Introduction: Fibrin glue can prevent bleeding after endoscopic submucosal dissection.

Aims & Methods: We aimed to explore the utility of fibrin glue in prevention of bleeding after endoscopic submucosal dissection and to investigate the risk factors for bleeding after endoscopic submucosal dissection. 330 patients who underwent ESD between July 2015 and June 2016 in Jiangsu Province Hospital were enrolled in this study, the patients were randomly divided into two groups, fibrin glue was sprayed during the operation in 161 patients of Group A, while 169 patients in group B were treated with routine hemostasis method. postoperative bleeding was defined as hematemesis or melena or Hb $> 2g/dL$ decrease after the end of ESD within 30 days. Delayed postoperative bleeding was defined as bleeding 7 to 30 days after operation. Then bleeding rate after ESD, average length of stay and average hospitalization expenses were compared between the two groups to explore the clinical effect of fibrin glue. 37 patients experienced bleeding after ESD were grouped into bleeding group, the remaining 293 patients were divided into non-bleeding group, several factors were compared between the two groups to analyse the risk factors of bleeding after ESD.

Results: There are no differences in age, gender, lesion location, underlying disease, taking anticoagulant drugs or not, invasive depth, pathological type and procedure time between Group A and Group B. Bleeding rate after ESD was lower in group A. ($P < 0.05$). And Intraoperative hemostasis rate was higher in group A. ($P < 0.05$). 2 patients in group B experienced delayed postoperative bleeding, while none in group A experienced delayed postoperative bleeding. Patients in group B spent more time staying in hospital than group A, while the average hospitalization expense was higher in Group B. 37 patients experienced bleeding after ESD, among whom 22 occurred within 24 hours after ESD, 13 within 1 week and 2 after 1 week. Univariate analysis revealed that resection size and procedure time over 120 minutes are risk factors for bleeding after ESD. The use of fibrin glue can reduce the bleeding rate after ESD. Multivariate analysis revealed that resection size greater than or equal to 3cm and the absence of fibrin glue are independent risk factor for bleeding after ESD.

Conclusion: The use of fibrin glue is safe, effective and economical in the procedure of ESD. Resection size and procedure time over 120 minutes are risk factors for bleeding after ESD. The use of fibrin glue can reduce the bleeding rate after ESD. Resection size greater than or equal to 3cm and the absence of fibrin glue are independent risk factor for bleeding after ESD. So adequate preparation and close monitoring are needed during the procedure of ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

³Dept. Of Gastroenterology, Osaka City General Hospital, Osaka/Japan

Contact E-mail Address: saka_t.med@icloud.com

Introduction: Proton pump inhibitors (PPIs) have been widely used for the treatment of endoscopic submucosal dissection-induced gastric ulcers. However, post-operative bleeding is still one of the most important adverse side effects.^{1, 2} Vonoprazan (VPZ), a potassium-competitive acid blocker, is a new class of acid-suppressing agents, and it is expected to reduce bleeding after gastric endoscopic submucosal dissection (ESD) by strongly inhibiting gastric acid secretion compared with PPIs.³

Aims & Methods: We compared the incidence of bleeding after gastric ESD between subjects treated with VPZ and those treated with esomeprazole (EPZ). Data for 101 patients who underwent gastric ESD from December 1, 2014 to December 31, 2016 in Osaka City General Hospital and started to take VPZ (n = 22) or EPZ (n = 79) by the day before ESD was reviewed. Twelve of them (3 in the VPZ group, 9 in the EPZ group) were excluded for simultaneous resection of two or more sites. A case in which active bleeding or exposed vessels were observed on the bottom of ulcers with hematemesis, melena or a drop of not less than 2 g/dl of Hemoglobin within 4 weeks after ESD was defined as “post-ESD bleeding”. In addition, we perform second-look endoscopy on the day after ESD. A case in which hemostasis was needed with hemorrhage of Forrest IIa or more when we underwent second-look endoscopy was defined as “next-day hemostasis case”. We investigated retrospectively post-ESD bleeding rate and next-day hemostasis rate in the VPZ group and the EPZ group.

Results: Gender, age, resected specimen diameter, oral antithrombotic drug administration, and dialysis were not significantly different in both groups. Two of the 19 patients in the VPZ group (10.5%) and 6 of the 70 patients in the EPZ group (8.6%) had Post-ESD bleeding (Table). In addition, 6 patients in the VPZ group (31.6%) and 37 patients in the EPZ group (52.9%) had next-day hemostasis. There was no significant difference in both groups regarding post-ESD bleeding (p=0.678) and next-day hemostasis (p=0.197). However, next-day hemostasis rate was somewhat higher in the EPZ group than that in the VPZ group. That is possibly because EPZ or VPZ was first administered mostly from the day before ESD in both groups in our hospital, moreover, VPZ rapidly inhibited gastric acid secretion after administration compared with PPIs.³

Table: Incidence of post-ESD bleeding and next-day hemostasis

	Vonoprazan group, n (%)	Esomeprazole group, n (%)	P-Value
Total	19	70	
Post-ESD bleeding	2 (10.5)	6 (8.6)	0.678
Next-day hemostasis	6 (31.6)	37 (52.9)	0.197

Conclusion: VPZ didn't significantly reduce post-endoscopic submucosal dissection bleeding compared with EPZ.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute gastrointestinal bleeding (AGIB) can carry poor outcomes unless prompt endoscopic haemostasis is achieved. Hemospray is a novel proprietary mineral blend that forms a mechanical barrier over the bleeding site when applied endoscopically.

Aims & Methods: The primary aim of this international multicentre registry is to collect data on the successful cessation of GI bleeding following application with Hemospray. Secondary outcomes of recurrent bleeding (within 72 hours), 30 day mortality, disease and procedure specific outcomes were also collected.

Method: Data was collected prospectively (January 2016 – April 2017) on the use of Hemospray in acute upper and lower GI bleeding, from 3 initial centres in the international registry. The use of Hemospray in GI bleeding was at the endoscopist's discretion at the time of endoscopy. Hemospray use was either as monotherapy, as dual-therapy with standard endoscopic techniques or as rescue therapy once standard methods had failed.

Results: To date 56 cases have been recruited (39 male and 17 female). The Forrest Classification of the bleeding lesions were in 5 (9%) cases Forrest Ia bleed, 41 (73%) Ib, 3 (5%) IIa, 4 (7%) IIb and 3 (5%) Forrest III bleed. Sources of GI bleed included Peptic ulcer disease 24 (43%), post endoscopic therapy 9 (16%), malignancy 11 (20%), inflammation 3 (5%), Mallory Weiss tear 2 (4%), angiodysplasia 1 (2%), bleeding polyp 2 (4%), duodenal diverticular bleed 1 (2%), oesophageal variceal bleed 1 (2%), post radiation 1 (2%), and bleed post NGT insertion 1 (2%). A total of 48 patients (86%) achieved immediate haemostasis after Hemospray endoscopic therapy. 8 patients did not achieve haemostasis. 2 managed conservatively, 1 treated by radiological intervention and 5 died. Hemospray was used in 25 patients (45%) as monotherapy [haemostasis achieved in 22/25 (88%)], in 22 patients (39%) in combination with other modalities [haemostasis achieved in 17/22 (77%)] and in 9 patients (16%) used as rescue therapy where other modalities failed [haemostasis achieved in 9/9 (100%)]. 9 patients (16%) were anticoagulated at the time of emergency endoscopy. Haemostasis was achieved in all anticoagulated patients. There were 6 cases of delayed re-bleeding of which 1 occurred in less than 24 hours post initial endoscopy, 2 at 24–72 hours, 1 at 4–7 days, 1 at 7–14 days and 1 more than 14 days after the initial endoscopy. There was no prior use of anticoagulation in any of these patients. There were no reported immediate or delayed complications from the treatment.

Conclusion: Early data from our registry show a high rate of immediate haemostasis (86%) with Hemospray and an excellent safety profile. The imminent expansion of this registry to other centres in Europe will provide invaluable data on the efficacy of Hemospray in various disease and patient types over the coming years.

P0511 RISK FACTORS OF GASTROINTESTINAL BLEEDING IN PATIENTS RECEIVED DUAL ANTIPLATELET THERAPY

W. Yingyongthawat¹, A. Pulsombat²

¹Department Of Medicine, Faculty of Medicine Ramathibodi Hospital, Bangkok/Thailand

²Department Of Medicine, Faculty of Medicine Ramathibodi Hospital, Bangkok/Thailand

Contact E-mail Address: Dr.worapoth@gmail.com

Introduction: Current guidelines suggest dual antiplatelet therapy (DAPT), clopidogrel or ticagrelor with aspirin, for patients with acute coronary syndrome. Other indications of DAPT include recurrent ischemic stroke and peripheral vascular disease. Gastrointestinal bleeding (GIB) is one of the most common adverse effects of DAPT, potentially causing hospital admission and death. Scanty information regarding safety of DAPT in Thailand is available.

Aims & Methods: The objectives were to determine cumulative incidence and risk factors of GIB in patients received DAPT, clopidogrel with aspirin and ticagrelor with aspirin among Thai patients.

A retrospective cohort study was conducted. We reviewed the medical records of patients received clopidogrel with aspirin or ticagrelor with aspirin between January 2013 and June 2015 at Ramathibodi hospital. In patients with GIB, the endoscopic finding with stigmata of recent hemorrhage was also recorded.

Results: A total of 201 patients received clopidogrel with aspirin and 199 patients received ticagrelor with aspirin were recruited. Mean \pm standard deviation age was 66.2 ± 11.3 years and 63.3% of patients were male. The most common indication of DAPT was acute coronary syndrome (85.4% in clopidogrel group vs. 100% in ticagrelor group). Duration of treatment with clopidogrel and ticagrelor were 121.5 days vs. 231 days, respectively ($p=0.216$). There were 20 (10.1%) GIB events in clopidogrel group and 11 (5.5%) in ticagrelor group. The most endoscopic findings of GIB was gastric erosion (44 % in clopidogrel group vs. 66.7 % in ticagrelor group). Risk ratio (RR) of GIB event of clopidogrel compared to ticagrelor was 1.84 [95% confidence interval (CI) 0.9–3.7, $p=0.093$]. By multivariate logistic regression analysis, duration of DAPT <180 days (RR 3.28; 95% CI 1.89–5.69, $p < 0.001$) and history of previous GIB were associated with GIB events (RR 10.35; 95% CI 6.04–17.71, $p < 0.001$).

Conclusion: Risk of GIB is almost two times higher among patients received clopidogrel with aspirin compared to those received ticagrelor with aspirin. Closed monitoring patients who had duration of DAPT <180 days and previous GIB might be minimized the risk of GIB event after receiving DAPT.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0512 REAL-LIFE ANALYSIS OF FREQUENCY, LOCATIONS AND BLEEDING SOURCES IN UNSELECTED EMERGENCY PATIENTS DURING NON-VITAMIN K ANTICOAGULANT (NOAC) THERAPY AND COMPARISON TO CONTROLLED APPROVAL STUDIES

M. Raithel¹, H. Albrecht², L. S. Maass², S. Peter¹, A.K. Kluger¹, M.F. Neurath³, A. F. Hagel²

Introduction: Non-vitamin K direct oral anticoagulants (NOAC) are increasingly used in thromboembolic disorders due to an efficacy at least equally as vitamin K antagonists (VKA) and/or significantly higher safety for intracerebral bleeding or major bleedings of any source. In the approval studies, there was no generally increased bleeding rate for all types of bleeding, but different gastrointestinal bleeding (GIB) rates for apixaban, dabigatran, edoxaban and rivaroxaban.

Aims & Methods: The patient cohort included consecutive unselected patients manifesting with a GI bleeding under anticoagulation in 2014. All patients who were diagnosed with a GI bleeding under NOAC or VKA therapy in the emergency department of the University Hospital Erlangen were analyzed. Their data were entered in a registry and evaluated in terms of bleeding type, localization, use of proton pump inhibitor and frequencies. These real-life results were then compared with the published data from important approval studies, reporting each on the above mentioned NOACs.

Results: In 213 patients with GI bleeding, 31 patients received VKA (14.5%) and 23 patients (10.8%, n.s.) had NOAC with major bleeding rates of 68% and 61%, resp.. In patients with VKA 87% had an upper GIB, 12% a lower GIB, and none had a rectal bleeding (0%). During NOAC therapy, a similar distribution was found with 71% and 17%, but the proportion of rectal bleeding was higher with 10%.

This frequency of GIB rates in unselected emergency patients is significantly higher than reported in the controlled NOAC approval studies that included selected patients (1.8–3.6% GIB!). In these NOAC studies a lower rate of upper GIB (55%, 0–71%), a higher rate for lower GIB (32%, 17–84%) and rectal bleeding (15%, 10–47%) was found. Although NOACs are associated with a lower rate for GIB than VKA in the setting of emergency patients, NOACs show a shift of the type of bleeding to lower GIB or rectal bleeding sources in our analysis from emergency patients and in the NOAC approval

studies. Only 50% of patients with NOAC were on proton pump inhibitor therapy.

Conclusion: The frequency of GIB in everyday life is approximately 10% higher than reported from the controlled NOAC studies, irrespective of the type of anticoagulation used. NOACs were associated with a non-significantly lower bleeding rate compared with VKA, but major GIB rates were similar. VKA with a bioavailability of 100% after oral ingestion showed a tendency of higher rates of upper GIB, while NOACs with a reduced GI absorption rate of 7–68% were found to occur more frequently at lower GIB sites. Thus, prior to any anticoagulation, a pre-therapeutic risk analysis for the occurrence of GIB is still required. Certain patient groups (anemia, aortic valve stenosis, renal insufficiency, NSAIDs, etc.) can benefit from proton pump inhibitor therapy, early endoscopy with intervention, or NOAC differential therapy.

P0513 REDUCED INTERSTITIAL CELLS OF CAJAL DENSITY AND INCREASED INTRAEPITHELIAL LYMPHOCYTES ARE ASSOCIATED WITH DEVELOPMENT OF SMALL INTESTINAL BACTERIAL OVERGROWTH IN POST-INFECTIOUS IBS MOUSE MODEL

Introduction: Small intestinal bacteria overgrowth (SIBO) is common in patients with irritable bowel syndrome (IBS), and symptoms of IBS improve after treatment of SIBO with antibiotics. Although the pathogenesis of SIBO specifically in IBS patients is not well defined, intestinal dysmotility and immune activation are likely involved.

Aims & Methods: We aimed to investigate the role of interstitial cells of Cajal (ICC) and intestinal inflammation in the development of SIBO using a post-infectious IBS (PI-IBS) mouse model. Sixty NIH mice were randomly assigned in a 2:1 fashion into T.spiralis infected PI-IBS vs. healthy control group. Visceral sensitivity was evaluated by measuring abdominal withdrawal reflex (AWR) in response to colorectal distension (CRD) before infection and at 8-weeks post-infectious (PI). Fecal consistency and the number of stool pellets were evaluated by visual inspection. Intestinal bacteria counts from jejunum and ileum were measured by quantitative real-time PCR to evaluate the presence of SIBO. ICC density in ileum was evaluated by immunohistochemistry and expressed as number of DMP-ICC per villus. Intraepithelial lymphocytes (IELs) in sections of bowel was counted in hematoxylin and eosin (H&E) staining slice and expressed as number of lymphocytes per 100 epithelial cells. Intestinal cytokine levels (IL-1 β , IL-6, Toll-like receptor-4 (TLR-4), IL-10) in the ileum were also examined.

Results: PI-IBS mice demonstrated increased mean AWR scores, decreased pain and volume thresholds compared with the control group suggested that infected group as a good model of PI-IBS with visceral hyperalgesia. One-third of the PI-IBS mice developed SIBO (SIBO+/PI-IBS) and was more likely to have altered stool form compared with SIBO negative PI-IBS (SIBO-/PI-IBS) mice but without difference in mean number of fecal pellets and visceral sensitivity. There was reduced number of ICC in SIBO+/PI-IBS compared with SIBO-/PI-IBS mice (0.47 ± 0.35 vs. 1.58 ± 0.89 , $P=0.01$) and control mice (1.44 ± 0.77 , $P=0.02$). IELs counts were higher in SIBO+/PI-IBS mice compared with SIBO-/PI-IBS mice in ileum (24.2 ± 6.5 vs. 15.0 ± 4.4 , $P=0.01$) and rectum (12.7 ± 3.2 vs. 8.2 ± 1.8 , $P=0.01$). In duodenum, jejunum, ileum, left colon and rectum, IELs counts were significantly increased in PI-IBS group compared with control group. No difference in inflammatory cytokine expression levels were detected between the groups except for increased TLR-4 among PI-IBS mice compared with the control group.

Conclusion: The development of SIBO in PI-IBS mice was associated with reduced ICC density and increased IELs counts in the ileum. Our findings support the role of intestinal dysmotility and inflammation in the pathogenesis of SIBO in IBS and may provide potential therapeutic targets.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0514 CLINICAL CHARACTERISTICS OF FUNCTIONAL DYSPESIA PATIENTS DEPENDING ON WHETHER THEY ARE CHEMOSENSITIVE OR NOT

V. Hammer, K. Hammer, M. Führer, J. Hammer

Department Of Gastroenterology And Hepatology, Medical University of Vienna, Wien/Austria

Contact E-mail Address: jcapsaicin@yahoo.com.au

Introduction: Augmented chemosensitivity to capsaicin has been demonstrated in approximately half of functional dyspepsia patients, as can be determined by the oral capsaicin capsule test (Hammer et al. *NGM* 2008). Sensations induced by gastric capsaicin are distinct from sensations induced by stimulation of mechanoreceptors (Hammer & Vogelsang, *NGM* 2007).

Aims & Methods: The aim of the study was to determine clinical characteristics of FD patients with and without chemical hypersensitivity at baseline and after capsaicin ingestion for 4 weeks. N=49 outpatients with confirmed FD received an oral sensitivity test with 0.75 mg capsaicin at two occasions, before and after ingesting 0.25 mg capsaicin tid for four weeks. Symptomatic response to capsaicin at the initial test allowed stratification to a capsaicin positive (chemosensitive) and a capsaicin negative (not chemosensitive) patient group. Symptom diaries for upper and lower gastrointestinal symptoms (visual analogue scales) were completed in the week before and during capsaicin ingestion and weekly aggregate symptom scores were calculated. Results are given as median; 25%/75%, $p < 0.05$ was considered significant.

Results: 53% FD had a positive capsaicin test. Basic clinical characteristics (age, gender, FD subtype, medication, psychological profile) were comparable in capsaicin positive and negative FD, but median daily aggregate upper gastrointestinal symptoms scores were significantly higher in capsaicin positive (median: 9.4; 5.4/11.7) than in capsaicin negative patients (6.6; 4.1/8.1) ($p < 0.05$). Median scores for epigastric pain, nausea and epigastric distension were similar in capsaicin positive and negative patients ($p > 0.05$). On the contrary, capsaicin negative patients had significantly lower scores for satiety ($p < 0.001$) and epigastric bloating ($p < 0.01$) than capsaicin positive patients. Lower abdominal symptoms were comparable in capsaicin positive and negative patients at baseline (NS). After capsaicin ingestion, aggregate upper gastrointestinal symptoms scores were reduced by -3.3 ($-4.9/-1.9$; $p < 0.001$) in capsaicin positive and -2.6 ($-3.8/-0.3$; $p < 0.05$) in capsaicin negative patients. Lower abdominal symptoms scores after capsaicin ingestion were reduced by -1.0 ($-1.8/-0.1$; $p < 0.05$) in capsaicin positive but not significantly altered (-0.6 ; $-1.7/+0.9$; NS) in capsaicin negative patients. After long-term capsaicin ingestion, the capsaicin test turned negative in 53% of chemosensitive patients ($p < 0.01$).

Conclusion: Differences in upper GI symptoms distinguished capsaicin positive and negative patients at baseline. Symptom improvement after long-term capsaicin ingestion was indirect proportional to the result during the initial capsaicin test. Sensitivity to orally ingested capsaicin decreases after long-term capsaicin ingestion.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0515 NUCLEAR LORICRIN AND A DYSREGULATION OF BARRIER PROTEINS OBSERVED IN GASTRO-OESOPHAGEAL REFLUX DISEASE AFFECTED OESOPHAGEAL EPITHELIUM

L. A. McGinty, J. Ooi, P. Woodland, D. Kellsell, D. Blyden
Blizard Institute, London/United Kingdom

Contact E-mail Address: l.a.mcgintry@qmul.ac.uk

Introduction: Gastro-oesophageal reflux disease (GORD) is one of the most common disorders encountered in clinical gastroenterology. GORD patients can be categorised as having erosive oesophagitis or non-erosive reflux disease (NERD), with the latter being more frequently encountered in clinical practice. In NERD, even though the endoscopic presentation of the oesophageal mucosa appears visibly normal, histological changes within the oesophageal epithelium such as dilated intercellular spaces and basal cell hyperplasia are present, which are indicative of an altered epithelial barrier (Tobey et al 1996).

Aims & Methods: Here, via immunohistochemical staining and subsequent immunofluorescent (IF) microscopic analysis, we investigate differences in the expression intensity, localisation and activity of key barrier function proteins present within the stratified squamous epithelium of proximal and distal biopsies derived from 13 patients with typical GORD symptoms. We compared this to biopsies taken from 5 healthy controls. Endoscopic oesophageal mucosal biopsies were taken from 5 cm above the LOS (distal) and at 20 cm from the incisors (proximal). Where no erosions were seen, NERD was confirmed by wireless pH capsule.

Results: IF analysis of loricrin (LOR), exhibits upregulated expression levels in 11 out of 13 GORD biopsies when compared to controls. This is also accompanied by an increased level of specific nuclear localisation, away from its more frequently observed membranous or cytoplasmic site. In addition, IF analysis of involucrin (INV), revealed sporadic regions of cytoplasmic localisation in multiple GORD biopsies, different from the specific membranous localisation observed in all control samples analysed. The transglutaminase-1 (TGM-1) enzyme functions to reinforce barrier function through its ability to crosslink LOR and INV during terminal differentiation in epithelial tissues at the cellular membrane. Analysis of TGM-1 enzymatic activity was performed in all GORD

and control biopsies using a targeted assay combined with subsequent IF analysis. When compared to controls, we observed a dysregulation in TGM-1 activity levels throughout our GORD biopsies. This result also correlates with an observed reduction in the expression of ADAM17, a regulator of TGM-1 activity.

Conclusion: The observed increase in nuclear LOR combined with the sporadic cytoplasmic INV localisation, dysregulation of TGM-1 activity and reduced A17 expression levels in our GORD epithelial samples are all indicative of an altered epithelial barrier present within these individuals. For the first time, we highlight the importance of these barrier proteins in GORD pathogenesis. Further investigation into these barrier proteins and their associated signalling pathways could provide possibilities for the development of novel therapies designed to specifically target patients suffering from GORD.

P0516 INFLUENCE OF PRUCALOPRIDE ON SECONDARY PERISTALSIS IN REFLUX PATIENTS WITH INEFFECTIVE ESOPHAGEAL MOTILITY

C. Chen, W. Lei, C. Yi, T. Liu, J. Hung

Department Of Medicine, Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation and Tzu Chi University, Hualien/Taiwan

Contact E-mail Address: harry.clchen@msa.hinet.net

Introduction: Ineffective esophageal motility (IEM) is frequently found in patients with gastroesophageal reflux disease (GERD). Secondary peristalsis functions to maintain an empty esophagus by clearing refluxed gastric contents. Prucalopride, a high-affinity 5-hydroxytryptamine 4receptors agonist, is useful in the treatment of chronic constipation by improving colon motility. Prucalopride also promotes secondary peristalsis in healthy adults (*Clin Transl Gastroenterol*. 2016).

Aims & Methods: We aimed to determine whether prucalopride would augment secondary peristalsis in reflux patients with IEM. After a baseline recording of primary peristalsis, secondary peristalsis was stimulated by slow and rapid mid-esophageal injections of air in 15 patients. Two separate sessions with 4 mg oral prucalopride or placebo were randomly performed.

Results: Prucalopride significantly increased primary peristaltic wave amplitude (68.1 ± 10.0 vs. 55.5 ± 8.8 mmHg, $p = 0.02$). The threshold volume for triggering secondary peristalsis was significantly decreased by prucalopride during slow (9.3 ± 0.8 vs. 12.0 ± 0.8 mL; $p = 0.04$) and rapid air injection (4.9 ± 0.3 vs. 7.1 ± 0.1 mL; $p = 0.01$). Secondary peristalsis was triggered more frequently after application of prucalopride (55% [43-70%]) than placebo (45% [33-50%]) ($p = 0.008$). Prucalopride didn't change pressure wave amplitudes during slow air injection (84.6 ± 8.1 vs. 57.4 ± 13.8 mmHg; $p = 0.19$) or pressure wave amplitudes during rapid air injection (84.2 ± 8.6 vs. 69.5 ± 12.9 mmHg; $p = 0.09$).

Conclusion: Prucalopride enhances mechanosensitivity of secondary peristalsis and promotes motor properties of primary peristalsis in IEM patients. Our study suggests that prucalopride could be a therapeutic option in the management of GERD patients with significant esophageal hypomotility.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Symptoms compatible with diabetic gastroparesis (DG) affect up to 1 in 5 patients with type I diabetes mellitus. Those affected suffer postprandial

nausea, vomiting, abdominal pain and impaired glycaemic control. Repeated hospital admissions are common. Endoscopy is normal in most patients. Impaired gastric function is thought to cause the condition. DG does not respond reliably to intensive insulin regimes or prokinetic medications. Jejunal nutrition (JN) is an option in patients that cannot maintain their weight. The benefits are thought to follow improved nutrition and glycaemia; however, we have observed that some DG patients eat normally during and after JN (i.e. a quasi-pharmacological effect). One explanation could be that DG represents a failure of oral nutrition to "switch" the stomach from the fasted to the fed state. According to this hypothesis, nutrition delivered direct to the small bowel triggers the release of peptide hormones that induce normal gastric function.

Aims & Methods: The study tests the hypothesis that JN prior to a test meal improves postprandial symptoms (primary outcome) and gastric function. Diabetic patients with severe symptoms (gastroparesis cardinal symptom index (GCSI) >27), diabetic controls (GCSI <14) and healthy controls entered a randomized, double blind, controlled trial. An insulin/glucose infusion controlled glycaemia. A JN feeding tube was placed at endoscopy with biopsies taken from the stomach and duodenum. Either liquid nutrient (2 kcal/min) or water was infused for 60 min. Afterwards the Nottingham Test Meal was ingested (NTM liquid: 400 mL, 300 kcal; solid: 12 non-nutrient agar beads)¹. Symptoms were documented by VAS, gastric function by MRI and the GI-peptide response was monitored over 120 min using published methodology. Bayesian methods provided 95% posterior ("credible") intervals and mixed model analysis compared response to intervention and between groups.

Results: 9 DG patients, 9 diabetic and 12 healthy controls were recruited. There was no difference in sex distribution, age, weight, medical history (e.g. duration of disease) or endoscopic findings (including histology) between groups. DG patients had more psychiatric co-morbidity and reported higher satiety, bloating and pain after ingestion of the NTM than diabetic and healthy controls ($p < 0.05$). Sensations were not affected by JN in the controls; however, fullness, bloating and pain were reduced by JN in DG patients ($p < 0.05$). Compared to water, JN induced a greater GI-peptide response (e.g. PP, GLP-1) and initial liquid GE was slower (gastric content volume after meal: GCV₀ 31 ± 13 mL higher, $p = 0.019$). Subsequent liquid GE was similar in both study conditions ($T_{50} \pm 3 \pm 8$ min, $p = 0.727$). Antral contraction wave (ACW) frequency was 2.7 (2.6–2.9)/min in health and was highest in diabetic controls (3.1 (2.7 to 3.3)/min). Solid GE was more rapid after JN than water (2 (1 to 3) beads emptied @60 min) and, again, was highest in diabetic controls (3 (1 to 7) beads emptied @60 min). Numerically the GI-peptide response was less pronounced in both diabetic groups than healthy controls; however, the difference was not significant and a correlation with postprandial symptoms or gastric function was not identified.

J4G study results from mixed model analysis

Measurement	DG Patient JN	DG Patient Water	DM control JN	DM control Water	HV control JN	HV control Water
median GCSI (range)	30 (27–39)		4 (1–12)		7 (1–9)	
Liquid GE (T_{50}) ± SE	68 ± 7	72 ± 11	55 ± 7*	59 ± 11*	75 ± 7	79 ± 11
Solid GE (beads/hr) ± CI	3 (1–6)	2 (1–3)	3 (1–5)*	4 (2–8)*	3 (1–5)	2 (1–3)
ACW frequency ± CI	2.9 (2.7–3.1)	2.9 (2.7–3.1)	3.1 (2.8–3.3)*	3.1 (2.8–3.3)*	2.7 (2.6–2.9)	2.7 (2.6–2.9)
Fullness (VAS) ± SE	16 ± 7 [§]	27 ± 11*	15 ± 11	23 ± 11	20 ± 11	20 ± 7
Nausea (VAS) ± SE	4 ± 9 ^{§§}	8 ± 9*	2 ± 9	4 ± 9	2 ± 6	2 ± 6
Bloating (VAS) ± SE	16 ± 12 [§]	27 ± 11*	4 ± 6	5 ± 7	5 ± 7	5 ± 7
Pain (VAS) ± SE	2 ± 6 ^{§§}	12 ± 6*	0 ± 6	0 ± 6	0 ± 6	0 ± 6

VAS - visual analogue score over course of study * $p < 0.05$ ** $p < 0.01$ vs. HV; [§] $p < 0.05$ ^{§§} $p < 0.01$ JN vs. water infusion

Conclusion: This clinical study demonstrates beneficial effects of prior JN on fullness, bloating and pain after a 400 mL test meal in diabetic patients with moderate-severe symptoms compatible with gastroparesis (GCSI > 27). Additionally, solid GE was accelerated after JN; however, this effect was not limited to DG patients and, thus, the treatment effect that improved symptoms could not be identified. Few patients in the DG group had objective evidence of abnormal gastric motor function and the benefit of "prior JN" on symptoms was not limited to patients with slow GE. However, it was observed that diabetic controls had relatively rapid ACW and solid GE. Future studies will identify patients likely to benefit from this novel approach to treatment. (ClinicalTrials.gov Identifier: NCT01919021, NCT00944593)

Disclosure of Interest: All authors have declared no conflicts of interest.

P0518 PER-ORAL ENDOSCOPIC MYOTOMY IN TREATMENT NAÏVE VERSUS PRIOR TREATMENT FAILURE CASES –OUTCOME IN OVER 500 PATIENTS

Z. Nabi, M. Ramchandani, R. Chavan, S. Darisetty, R. Kalapala, D.N. Reddy *Gastroenterology, Asian Institute of Gastroenterology, Hyderabad/India*

Contact E-mail Address: zaheernabi1978@gmail.com

Introduction: Per-oral endoscopic myotomy (POEM) has emerged as an efficacious treatment modality for achalasia cardia (AC). Prior treatment (PT) may affect the outcomes of subsequent. The impact of prior treatment on technical and clinical success of POEM is not well known. Small studies with short follow-up indicate that POEM is safe and feasible in PT failure cases. However, there is paucity of large studies with long-term follow-up.

Aims & Methods: In this study we aim to compare the safety and efficacy of POEM in treatment naïve (TN) cases versus prior treatment (PT) failure cases. The data of consecutive patients with AC who underwent POEM at a single tertiary care center from (January 2013 to November 2016) was analysed retrospectively. A comparative analysis was performed between TN and PT failure cases. Technical and clinical success, adverse events (AE), operative time (OT) for POEM were compared between TN versus PT failure cases.

Results: Overall, 502 patients with AC underwent POEM during the study period. 260 patients (51.8%) were TN and 242 (48.2%) patients had PT. Type II AC was the most common subtype in both the groups (TN -63.5% vs PT -57.8%) followed by type I and type III. There was no significant difference with regards to AC subtypes between the two groups. The distribution of patients according to prior treatment history is as follows – PBD (205), LHM (23), LHM and PBD both (7), botulinum toxin injection (4) and POEM (3). Significantly more patients in the PT group had sigmoid oesophagus (47 vs 18). Mean OT was significantly more in the PT group when compared to the TN group (PT vs TN -74.9 ± 30.6 vs 67.0 ± 27.1 min; $P = 0.002$). On multivariate analysis- type of AC, dilated esophagus (> 6 cm) and type of knife used were significant predictors of OT. Technical (98.1% vs 97.1%, $P > 0.05$) and clinical success (94.9% vs 91.9%) of POEM procedure was similar in TN and PT cases. Gas related events and mucosotomies were equal in both groups (TN-35.7% vs PT-33.1%; $p=0.57$). Objective evidence of gastroesophageal reflux was found in 17/53 patients (32.1%) in PT group as compared to 11/44 (25%) in TN group ($p=0.50$).

Predictors of operative time on multivariate analysis

Factor	OR	p value	95% CI
1. Type of AC (III/I-II)	16.24	0.002	2.66 99.1
2. Esophageal diameter (>6/ <6 cm)	2.76	0.012	1.24 6.13
3. Knife(TT/TTJ)	14.41	0.001	5.68 36.5
4. Adverse events	0.98	0.941	0.59 1.62
5. Prior treatment	1.16	0.480	0.75 1.81
6. Pediatric Achalasia	0.71	0.544	0.23 2.13

Conclusion: POEM is equally efficacious and safe in treatment naïve and prior treated cases. POEM should be considered in treatment failure cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0519 ESOPHAGEAL REFLUX BURDEN IN RELATIONSHIP TO ESOPHAGOGASTRIC JUNCTION (EGJ) AND ESOPHAGEAL BODY FUNCTION ON HIGH RESOLUTION MANOMETRY (HRM)

Introduction: Both EGJ and esophageal body motor abnormalities are found on esophageal HRM in reflux disease, and contribute to reflux burden assessed using acid exposure time (AET) on ambulatory reflux monitoring. Mean nocturnal baseline impedance (MNBI) represents a new paradigm that may assess longitudinal esophageal reflux burden, but its precise role in clinical esophagology, particularly in relationship to AET, remains unclear.

Aims & Methods: Our aim was to evaluate the complex interrelationships between EGJ and esophageal motor abnormalities, and esophageal reflux burden in this ongoing multicenter collaboration. Esophageal function studies from patients with persisting reflux symptoms were reviewed from four centers (2 each in Europe and US) for this preliminary report. EGJ morphology was categorized using HRM into hypotensive (EGJ-CI < 46 mmHg.cm), hiatus hernia (HH, manometric separation between lower esophageal sphincter and crural diaphragm) and intact EGJ (normotensive EGJ-CI, no HH). Esophageal body metrics were characterized using Chicago Classification v 3.0 into intact, ineffective esophageal motility (IEM) and absent contractility. Total and supine AET were extracted from ambulatory pH-impedance studies. Baseline impedance was calculated at the 5 cm impedance channel (to correspond to AET) at three stable 10-min time periods (1, 2, and 3 AM) during the ambulatory pH-impedance study, and averaged to yield MNBI (normal > 2292 ohms). Univariate and multivariate analyses were performed to assess EGJ and esophageal body predictors of esophageal reflux burden, and to discern the value of MNBI in comparison to AET.

Results: 1244 patients (53.4 ± 0.4 yr, 59.6%F) undergoing esophageal motor testing using HRM (Medtronic, Duluth, GA) and ambulatory pH or pH-impedance monitoring studies performed off antisecretory therapy were included. A hypotensive EGJ was noted in 70.9%, HH in 34.0%, IEM in 26.3% and absent contractility in 3.5%. A disrupted EGJ and absent contractility had the highest proportions with AET > 6%; combinations thereof raised the proportions even higher (Table, $p < 0.001$ for each comparison to intact EGJ and/or esophageal body). Compared to an intact EGJ, the odds ratio (OR) of total AET > 6% with HH was 2.0 (95% CI 1.1–3.9, $p = 0.04$). Supine AET > 2% was even more impacted (HH: OR 2.4, 95% CI 1.3–4.5, $p = 0.007$; HH + hypotensive EGJ: OR 3.3, 95% CI 2.1–5.2, $p < 0.001$). A hypotensive EGJ was not discriminative of AET or MNBI values. Concordance between AET and MNBI thresholds was noted in 401 of 596 studies (67.2%; both abnormal in 24.8%, both normal in 42.4%). When concordant and abnormal, proportions with EGJ and esophageal body abnormalities were highest ($p \leq 0.005$) compared to concordant and normal AET/MNBI, and discordant studies. On multivariate regression with categorical and linear EGJ and esophageal body motor findings as dependent variables, presence of HH ($p < 0.0001$), IEM ($p = 0.032$), and absent contractility ($p = 0.0012$) were independent categorical predictors of AET > 6%; HH size ($p < 0.0001$), lower EGJ-CI ($p = 0.002$), and increasing numbers of ineffective swallows ($p = 0.043$) were independent linear predictors. Only the presence of HH was an independent categorical predictor of abnormal MNBI ($p < 0.0001$), increasing HH size ($p < 0.0001$) and proportions of ineffective swallows ($p < 0.0001$) were independent linear predictors.

Proportions with abnormal reflux burden in relationship to EGJ and esophageal body motor findings on high resolution manometry

	AET > 6% <i>n</i> = 431	AET < 4% <i>n</i> = 642	MNBI < 2292 ohms <i>n</i> = 596
EGJ findings			
Intact EGJ (<i>n</i> = 280)	25.7%	60.7%**	58.3% (63/108)
Hypotensive EGJ (<i>n</i> = 862)	36.5%*	49.2%**	56.3% (259/460)
Hiatus hernia (<i>n</i> = 422)	49.0%*	36.5%**	69.8%* (138/199)
Both (<i>n</i> = 342)	49.4%*	34.8%**	70.9%* (124/175)
Esophageal body motor findings			
Intact esophageal body (<i>n</i> = 686)	31.0%	56.9%**	46.5% (158/340)
IEM (<i>n</i> = 326)	41.4%*	44.8%	69.6%* (94/135)
Absent contractility (<i>n</i> = 43)	53.5%*	39.5%	88.2%* (15/17)
Combined EGJ & esophageal body motor findings			
Intact EGJ and body (<i>n</i> = 170)	25.3%	61.2%**	49.3% (36/73)
Hypotensive EGJ, HH, IEM (<i>n</i> = 105)	56.2%*	24.8%**	83.0%* (44/53)
Hypotensive EGJ, HH, absent contractility (<i>n</i> = 7)	71.4%*	14.3%	100%* (5/5)

* $p < 0.05$ compared to intact EGJ and/or esophageal body function ** $p < 0.05$ compared to AET > 6% EGJ: esophagogastric junction; AET: acid exposure time; MNBI: mean nocturnal baseline impedance; IEM: ineffective esophageal motility, HH: hiatus hernia

Conclusion: A disrupted EGJ and IEM on esophageal HRM are independent predictors of elevated esophageal reflux burden. Hierarchical HRM evaluation of EGJ and esophageal body metrics adds confidence to categorization of esophageal reflux burden.

Introduction: Electrical stimulation therapy is a new way to treat digestive disorders such as constipation, colonic inertia. It is necessary to understand the physiology of smooth muscle contraction in developing novel medical devices related with electrical stimulation therapy. The aims of this study were to measure the active characteristics of smooth muscle with acetylcholine in porcine intestine segment.

Aims & Methods: We used five female pigs and obtained ten centimeters of each porcine small intestine. To measure passive characteristics of small intestine, a universal testing machine with a tensile rate of 30 mm/min. To estimate the active characteristic parameters of smooth muscle and isometric and isotonic intestinal motility of smooth muscle, muscle contraction was induced by applying the stimulation solution (HTK solution containing 1 mM of acetylcholine chloride). Then, we obtained the maximum muscle contractile force of the specimens to measure the isometric and isotonic intestinal motility.

Results: In tensile test, the maximum repulsive force, that indicate passive muscle force of smooth muscle 0.702 N, was measured. In the isometric and isotonic contractions in the porcine small intestine, the maximum myotility, 12.35 mN, was obtained in isometric experiments, and the maximum velocity of muscular contraction, 0.4476 mm/min, was obtained in isotonic experiments. We demonstrated that in equal lengths, the muscle contraction velocity of the smooth muscle is 10–100 times slower than that of the skeletal muscle indicating force-velocity relationship of smooth muscle. And we obtained that the maximum contraction force from each individual percentage of active force (25%, 50%, and 100%) was achieved at $L/L_{opt} = 1$.

Conclusion: We straighten out the active and passive property of porcine intestinal smooth muscle. Our study may be helpful for developing novel medical devices and understanding the physiology of smooth muscle in the porcine small intestine.

Introduction: Partial recovery of esophageal peristalsis has been reported in up to 47% of achalasia patients treated by myotomy (either per-oral endoscopic myotomy (POEM) or laparoscopic Heller's myotomy) in several rather small studies. The aim of our study was to assess motility patterns focusing on possible "recovery" of esophageal peristalsis in a large cohort of patients after POEM.

Aims & Methods: We performed a retrospective analysis of prospectively collected data of patients undergoing POEM at our tertiary referral center. All patients in whom high-resolution manometry (HRM) studies were performed prior to and 3 months after POEM and who completed at least 6-month follow-up were included. All HRM studies were reviewed and the Chicago Classification (CC) v3.0 of motility disorders was applied to characterize both pre- and post-POEM motility patterns.

Results: From 192 patients who underwent POEM since 2012, 127 patients met the inclusion criteria. The initial CC diagnoses before POEM were as follows: type I achalasia – 20 pts (16%), type II achalasia – 100 pts (79%), type III achalasia – 5 pts (4%), other (esophago-gastric junction outflow obstruction (EGJO) and Jackhammer) – 2 pts (1%). Only 6 patients (5%; type III achalasia, Jackhammer, EGJO) had had some signs of esophageal contractility before POEM. After POEM, peristaltic fragments were present in 28/127 patients (22%) – 9x ineffective esophageal motility, 5x fragmented peristalsis, 2x distal esophageal spasm, 5x EGJO, 7x type III achalasia. Thus, the partial "recovery" of esophageal peristalsis was observed in 22/121 patients (18%) and it only occurred in patients with type II achalasia; contractile activity was not detected in any patient with type I achalasia after POEM (22/100 vs. 0/20, $p = 0.023$). Panesophageal pressurization completely resolved in 88 patients (88%) with

achalasia type II. The mean integrated-relaxation pressure (IRP) decreased from 27 (± 13) mmHg to 13 (± 5) mmHg ($p < 0.0001$). The presence of partial peristaltic recovery was neither associated with normalization of IRP (IRP normalized in 17/28 (61%) patients with peristaltic recovery and in 72/99 (73%) patients without, $p = 0.25$), nor with overall treatment success of POEM (Eckardt score < 3).

Conclusion: In this so far largest case-series investigating the rate of peristaltic recovery after POEM this was present in 18% of patients, therefore, the rate may be lower than previously reported. Peristaltic recovery seems to have no clinical impact on post-POEM symptomatology. Esophageal contractility after POEM was not observed in any patient with achalasia type I.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Medical treatments, endoscopic balloon dilatation, Botox and Heller myotomy are treatment modalities for managing achalasia. Recently per-oral endoscopic myotomy (POEM) has become a new option for achalasia patients and since 2010 it has become widespread. Earlier, anterior myotomy was used in this technique but in the last few years there are studies reporting that posterior myotomy is more effective. However, there are limited numbers of publications comparing anterior and posterior myotomy. This study aimed to investigate the effect of myotomy site on POEM, to our knowledge it is the first time in Europe and our country.

Aims & Methods: Between May 2014 and January 2017, POEM was performed to 225 achalasia patients at the gastroenterology clinics under general anesthesia by an endoscopist experienced at endoscopic submucosal dissection and trained for POEM. Demographic data, previous history for balloon dilatation and results of the procedure were recorded prospectively. Patients with anterior myotomy were grouped as "group A" and those with posterior myotomy as "group P", and the results were compared.

Demographic features and results of POEM procedures

	Group Anterior N = 114	Group Posterior N = 111	p
Sex (Male/Female), n	56/58	58/53	0.639
Age mean (SD) (median; range) year	41.05 \pm 14.89 (41.5; 12–73)	42.24 \pm 13.52 (41; 18–75)	0.905
Prior achalasia treatment, n (yes or No)	48/66	36/75	0.087
Achalasia sub-type: Unknown I/II/III, n	3/6/94/11	0/17/86/8	0.029
Tunnel length, mean (SD) (median; range) cm	17.07 \pm 2.63 (17; 12–27)	17.32 \pm 2.49 (17; 12–25)	0.278
Myotomy length, mean (SD) (median; range) cm	13.79 \pm 2.46 (14; 10–25)	14.04 \pm 2.44 (14; 8–21)	0.235
Procedure Time, mean (SD) (median; range) min	58.63 \pm 21.47 (53; 27–153)	46.58 \pm 13.49 (44; 26–107)	< 0.001
Tunnel time, mean (SD) (median; range) min	34.60 \pm 14.67 (30; 12–82)	27.02 \pm 9.74 (25; 10–68)	< 0.001
Myotomy time, mean (SD) (median; range) min	12.11 \pm 6.67 (10; 4–40)	10.08 \pm 4.89 (9; 3–30)	0.012
Dysphagia Score pre-operative/postoperative (median; range)	(3; 3–4)/(0; 0–2)	(3; 3–4)/(0; 0–1)	
Eckardt Score, pre-operative/postoperative (median; range)	(8; 6–12)/(0; 0–2)	(8; 5–12)/(0; 0–2)	
	38 3	33 0	0.176

(continued)

Continued

Demographic features and results of POEM procedures

	Group Anterior N = 114	Group Posterior N = 111	p
Adverse events, n -			
Capnoperitoneum -			
Mucosal injury			

Results: There were 114 patients in group A, 111 patients in group P. There was no statistical difference between the groups in regards of tunnel length, myotomy length, tunnel entrance time and frequency of homeostatic forceps use ($p > 0.05$). However duration of opening the tunnel, myotomy, closure of the tunnel and total procedure time were significantly shorter in group P ($p < 0.05$). Eckardt and dysphagia scores before the procedure were similar in both groups. After the procedure Eckardt scores were significantly low in all patients ($p < 0.005$). Demographic features and data of the procedures are shown in the table below. Mucosal damage during the procedure occurred in 3 patients and capnoperitoneum developed in 71 patients. All complications were treated endoscopically. Control endoscopy was performed to 151 patients at 3rd month; that revealed esophagitis grade A in 24, grade B in 6 and grade C in 3 patients.

Conclusion: According to our results posterior approach can shorten the procedure time in POEM compared to anterior myotomy. This may be due to a better angle of approach with endoscopic equipments for posterior myotomy. We believe that long-term results will also show the effects of myotomy site on clinical outcome of patients.

Introduction: Peroral endoscopic myotomy (POEM) has gained trust by proven safety and short-term efficacy and at present, it is considered to be a standard method for treatment of esophageal achalasia. However, long-term data concerning the efficacy and safety especially with regard to post-POEM reflux are still awaited.

Aims & Methods: The aim of this prospective single-center case series was to assess the long-term clinical outcome of POEM with emphasis on post-POEM reflux evaluated by pH monitoring, endoscopy findings, reflux symptoms and use of proton pump inhibitors (PPIs). Since 2012, a total of 192 patients with achalasia underwent 202 POEM procedures. Follow-up visits at 3, 12, 24 and 36 months were completed in 160, 116, 70 and 27 patients. Upper GI endoscopy, high-resolution manometry (HRM) and 24-hour pH monitoring were performed 3 months after POEM; endoscopy was then repeated between 24–36 months. Main outcomes were treatment success defined as Eckardt score < 3 , recurrence rate and post-POEM reflux.

Results: At 3, 12, 24 and 36 months, treatment success was achieved in 97% (95% CI: 94–100), 95% (CI 91–99), 88% (CI 82–95) and 81% (CI 69–93) of patients. A total of 14 patients experienced treatment failure ($n = 5$) or recurrence ($n = 9$). The recurrences occurred most often in patients with HRM type I achalasia (4 out of 26, 15.4%) followed by type II (3 out of 113, 2.6%) vs. none in type III achalasia (0 out of 10, 0%); $p = 0.022$. At 3 months, reflux esophagitis was diagnosed in 63/160 patients (39.4%); severe esophagitis LA C or D in 8 patients). Abnormal acid exposure on pH-metry studies was detected in 58/146 (39.7%). At 24–36 months, endoscopy was performed in 41 patients and reflux esophagitis was present in 9 patients (21.9%); none of the patients has been treated with PPIs. At 3 and 24M, a proton pump inhibitor was administered to 33.5% and 31.4% of patients.

Conclusion: POEM is effective treatment modality for achalasia with treatment success around 90% at 2 years, slightly dropping down to 81% at 3 years. Generally mild reflux esophagitis and abnormal esophageal acid exposure are diagnosed in about 40% of patients 3 months after POEM but are successfully manageable with proton pump inhibitors. Occurrence of reflux esophagitis tends to decrease with time.

dyspeptic symptoms after a controlled meal. Secondary objectives were to evaluate its relation with postprandial GER and gastric accommodation and to evaluate its relation with daily digestive symptoms under real conditions.

Aims & Methods: Healthy people over 18 years old, free of frequent digestive symptoms (<once a week) and GER disease (GERD), were included. Basal symptoms were assessed through PAGI-SYM(3) and QOLRAD (4) questionnaires, both validated to Spanish. Study was divided in two substudies based on the study intervention: 33 cl of regular beer (substudy 1) and the same amount of non-alcohol beer (substudy 2). Mineral water (33 cl) was the control intervention in both substudies. Each participant was its own control. The study lasted two weeks (control study week and intervention study week). Each week started with a visit to the laboratory at 7:30 h am, when a pHimpedance catheter was placed and taken off 24 hours later. Gastric accommodation was assessed through the maximum tolerated volume during a nutrient drink test (ENSURE® HN, 500 ml) in a rhythm of 15 ml/minutes, after the ingestion of beer (intervention) or water (control). It was defined as the volume after which the test finished or the participant reported the maximum punctuation for any dyspeptic symptoms (early satiety, bloating, epigastric pain and nausea), which were asked every 5 minutes (1 meant no symptom and 5 meant the highest perception). GER was evaluated in the postprandial period and during 24 hours through pHimpedance register. Weekly symptoms evaluation was made through a diary adapted from PAGYSYM questionnaire and sum of symptoms was used for analysis. Data were collected daily through email. Variables were compared between both visits and weeks in both substudies using a non parametric test for matching data. Participants should drink 33 cl of beer before lunch and dinner during the intervention week. Other alcohol drinks were prohibited during the study.

Results: Ten participants were enrolled in substudy 1, mean aged 24 years old (SD 4, 1 (18-32)); 80% were men. Twenty participants were enrolled in substudy 2, mean aged 23.4 years (SD 5.5 (20-38)); 65% were men. No significant differences were detected in the increase of symptoms during the nutrient drink test between control and intervention visits in both substudies (table 1). Maximum tolerated volume did not show any difference between visits in both substudies. Reflux episodes after nutrient drink test and reflux episodes registered in 24 hours did not show significant differences between control and study visits. The sum of weekly symptoms did not show any difference between control and intervention weeks in both substudies.

Conclusion: Moderate beer consumption (regular and non-alcohol beer) does not cause an increase of dyspeptic symptoms and reflux in healthy people. It has been shown in a controlled situation (nutrient drink test and pH impedance register) as well as real life (diary weekly symptoms). Gastric accommodation and reflux episodes have either shown to be affected by moderate beer consumption.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Rumination syndrome is a functional gastrointestinal disorder characterized by effortless, post-prandial regurgitation of food. In addition to regurgitation, a large proportion of patients report functional dyspepsia (FD) symptoms including post-prandial discomfort, early satiety and nausea^{1, 2}. Recently, duodenal eosinophilia has been described both in adult and pediatric patients with FD³⁻⁵. Because of the significant symptomatic overlap between FD and rumination syndrome we hypothesized that histological changes similar to those described in FD might exist among patients with rumination syndrome.

Aims & Methods: We therefore aimed to assess histology of duodenal biopsies from patients with rumination syndrome and compared these to healthy controls. Rumination syndrome was diagnosed with post-prandial esophageal high resolution impedance manometry (HRIM) and/or fulfilled ROME II/III criteria. This study was approved by the Institutional Review Board. We included persons aged 18 and above with a diagnosis of rumination syndrome in whom we had also obtained 4-6 duodenal biopsies from diagnostic upper endoscopy. Normal controls were aged 18 and above without any gastrointestinal symptoms in whom 4-6 duodenal biopsies were obtained for research purposes. Cases and controls with a personal history of an eosinophilic disorder, gastric or esophageal surgery, recent (within 30 days) intake of NSAIDs and pregnant and/or lactating females were excluded. Duodenal biopsies obtained were routinely processed to formalin-fixed paraffin-embedded tissue blocks which were cut at 3 µm, stained with H&E and scanned to digital images (Aperio). The pathologist, blinded to the case-control status, analyzed de-identified digital images of the biopsy specimens and assessed for eosinophil counts/mm² in sections. Individual sections were also assessed for the presence of Brunner's glands (BG) and intraepithelial lymphocyte counts (IEL)/100 enterocytes. This was done in order to distinguish the first part of the duodenum with BG, D1 and the second part, generally without BG, (D2) and intraepithelial lymphocyte counts (IEL)/100 enterocytes.

Results: Patients with rumination syndrome (22) had a mean age of 39.2 years (range 19-71) and 77% were female. Controls (11) had a mean age of 34.3 (range 19-69) and 80% were female. The mean eosinophil counts/biopsy fragment +/- Brunner's glands (BG), showed no difference in counts in the sections +/- BG (D1 vs D2), p=0.8. No overt pathology was noted, but IEL counts were significantly higher in rumination patients (mean 15, range 8-29, and 2 cases had lymphocytic duodenitis) vs controls (mean 11, range 11-18), p=0.02. Compared to controls, there was a significant increase in the mean eosinophil count among the patients with rumination syndrome rumination, 26 per mm² (range 16-42), vs 18 mm² (range 10-28), p=0.006.

Conclusion: These findings demonstrate that patients with rumination syndrome have duodenal eosinophilia and increased IEL counts compared to healthy controls. To our knowledge, histopathological changes among patients with rumination syndrome compared to controls have not previously been described. Therefore, a potential role of duodenal immune mechanisms in the pathophysiology of rumination syndrome warrants further enquiry.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0527 CHRONIC POSTSTROKE OROPHARYNGEAL DYSPHAGIA IS ASSOCIATED WITH IMPAIRED CORTICAL ACTIVATION TO PHARYNGEAL SENSORY INPUTS

Introduction: The role of afferent sensory pathways in the pathophysiology of post-stroke oropharyngeal dysphagia (OD) is not known [1]. We hypothesized that chronic post-stroke patients with OD (PSD) would show impaired sensory cortical activation in the affected hemisphere.

Aims & Methods: We studied 28 chronic unilateral post-stroke patients (17 PSD and 11 nondysphagic [PSnD]) and 11 age-matched healthy volunteers (HV). Electroencephalography was used to assess event-related sensory evoked potentials to pharyngeal stimulation (pSEP) and sensory thresholds with a naso-pharyngeal catheter with two electrodes passed through the nostrils 14–15 cm until the pharynx (Gaeltec Ltd, Dunvegan, Scotland) [2]. We analyzed pSEP peak-latency and amplitude (N1, P1, N2, P2) and neurotopographic stroke characteristics from brain MRI.

Results: HV presented a highly symmetric bi-hemispheric cortical pattern of brain activation at centro-parietal areas (N1-P1, N2-P2) to pharyngeal stimuli. In contrast, an asymmetric pattern of reduced ipsilesional activation was found in PSD (N2-P2; $p=0.026$) but not in PSnD. PSD presented impaired safety of swallow (Penetration-Aspiration score: 4.3 ± 1.6) and delayed laryngeal vestibule closure (360.0 ± 70.0 ms), and higher NIHSS (7.0 ± 6.2 vs. 1.9 ± 1.4 , $p=0.001$) and Fazekas scores (3.0 ± 1.4 vs. 2.0 ± 1.1 ; $p < 0.05$) than PSnD. pSEP showed a unilateral delay at stroke site exclusively for PSD (peak-latency inter-hemispheric difference vs. PSnD: N1, 6.5 ± 6.7 vs. 1.1 ± 1.0 ms; N2, 32.0 ± 15.8 vs. 4.5 ± 4.9 ms; $p < 0.05$).

Conclusion: Chronic post-stroke OD is associated with stroke severity and degree of leukoaraosis. Impaired conduction and cortical integration of pharyngeal sensory inputs at stroke site is a key feature of chronic PSD. These findings highlight the role of sensory pathways in the pathophysiology of post-stroke OD and offer a potential target for future treatments.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastroparesis is characterized by abnormal gastric motor function with delayed gastric emptying in the absence of mechanical obstruction. In our tertiary referral centre, patients are treated with a stepwise approach, starting with dietary and lifestyle advice and prokinetics followed by pyloric botulinum toxin. When these initial measures fail, in the presence of malnutrition, one of the following interventions are considered: three months nasoduodenal tube feeding with 'gastric rest' and placement of a percutaneous endoscopic gastrostomy with jejunal extension (PEG-J). Our primary aim was to evaluate the effect of nutritional treatment entities in patients with gastroparesis who fail previous treatments, on weight and symptoms.

Aims & Methods: Prospectively collected data of all referred gastroparesis patients between 2008 and 2016 were reviewed.

Results: A total of 101 gastroparesis patients (71% female, 20–86yrs, mean 55yrs) were analyzed. Etiologies were idiopathic (37%), diabetes mellitus (30%), post-surgical (27%) and other (7%). Of the 101 patients, 51 patients had adequate responses to dietary advice and prokinetics, not requiring further therapeutic interventions. For the remaining 60 patients, various treatments were used. With respect to nutritional interventions, 36 patients were treated with three months of gastric rest via complete nasoduodenal tube feeding. Enteral tube feeding was well accepted, occlusion occurred in 8% of patients. Mean weight gain in symptom responders was 3.5% (2.4 kg, $p=0.02$), in non-responders 3.7% (2.4 kg, $p=0.01$). These 19 patients with insufficient symptomatic response after 3 months gastric rest continued treatment with enteral feeding through PEG-J. A significant weight gain of 8.2% was seen (mean 5.0 kg, range –6% to +29%), $p=0.003$ within 3–6 months after PEG-J placement. Thereafter only 3 patients (16%) have been able to resume complete oral intake, the PEG-J was removed after a mean treatment time of 11 months. In 84% of patients the PEG-J is still in use, with a mean treatment time of 894 days. Over 75% of patients report adequate effect on symptoms. Most frequent complication was luxation of the jejunal extension to the stomach (32% of patients). Other complications were peristomal infection (11% within 30 days, 16% after 30 days) and buried bumper (16%).

Conclusion: This study describes the sequelae of a large group of tertiary referral gastroparesis patients treated with PEG-J treatment. In gastroparesis patients who failed all previous treatment, PEG-J is an excellent option to regain and maintain adequate nutritional status with marked symptom control.

Introduction: Reduced sleep quality has been linked to gastroesophageal reflux disease (GERD) and functional gastrointestinal disorders. It is unknown whether GERD, functional dyspepsia (FD) and irritable bowel syndrome (IBS) are more prevalent in subjects with significant sleep disturbance (SD) than those without SD.

Aims & Methods: The aim of the study was to investigate gastrointestinal symptoms, clinical characteristics, and psychological factors in subjects with and without SD in a general population undergoing health checkups. We enrolled 2752 consecutive subjects who received upper gastrointestinal endoscopy and colonoscopy during their health checkups. All participants underwent an evaluation with questionnaires including Reflux Disease Questionnaire score, Pittsburgh Sleep Quality Index (PSQI), Taiwanese Depression Questionnaire, and State-Trait Anxiety Inventory before receiving endoscopic exam. Demographic characteristics and biochemical data were also recorded. FD and IBS were based on Rome III diagnostic criteria, and metabolic syndrome was defined by the National Cholesterol Education Program Adult Treatment Panel III definition. Sleep disturbance was confirmed when PSQI score was greater than 5. We compared the clinical and psychological factors between subjects with and without sleep disturbance.

Results: Among the study population ($n=2674$), 956 (36%) individuals had SD. SD subjects had more female gender, older age, lower level of education, higher systolic blood pressure, higher serum high-density lipoprotein levels, and higher prevalence of FD and IBS than those without SD. In addition, SD patients also had more depression, more anxiety, more severe GERD symptoms, and higher prevalence of non-erosive reflux disease (NERD) ($p < 0.001$). Multivariate analysis revealed that female sex (OR=1.75, $p < 0.001$), older age (OR=1.03, $p < 0.001$), more severe GERD symptoms (OR=1.03, $p < 0.033$), NERD (OR=1.63, $p=0.023$), IBS (OR=1.48, $p=0.05$), and depression (OR=1.16, $p < 0.001$) were positive predictive factors for SD, whereas higher level of education (OR=0.57, $p < 0.001$) was negative predictive factor for SD.

Conclusion: Our study demonstrates that SD is associated with female sex, older age, lower education level, greater GERD symptom burden, greater depression, and higher prevalence of NERD and IBS. Future studies will be needed to clarify the relationship between functional gastrointestinal diseases and sleep disorders.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The prevalence and frequency of esophageal symptoms suggestive of a functional esophageal disorder according to the Rome IV criteria are unknown. This study aimed to describe the general population prevalence and risk factors for esophageal symptoms compatible with functional esophageal disorders.

Aims & Methods: Data from an online survey of 6300 individuals age ≥ 18 years in the United States, United Kingdom and Canada (2100 in each country) including the Rome IV diagnostic questionnaire for adults and demographic questions was used. Quota-based sampling ensured equal proportions of sex, age groups, and education distributions across countries. Prevalence and frequency of esophageal symptoms in the past 3 months and putative functional esophageal disorders were retrieved from the Rome IV questionnaire. Symptoms were considered present if they occurred at least weekly for dysphagia, chest pain, and globus, and at least twice weekly for heart burn. Variables with a $p \leq 0.1$ in univariate analyses were entered into a multivariate analysis (logistic regression) to identify factors independently related to esophageal symptoms. As endoscopy and pH measurement are parts of the clinical diagnosis of esophageal disorders in the Rome IV criteria, we only describe esophageal symptoms compatible with functional esophageal disorders. Somatization was assessed with the Patient Health Questionnaire (PHQ)-12.

Results: Data from 5177 participants (47.8% female; mean age 46.7 (range 18–92) years; 1645 US, 1734 UK, 1798 Canada) were retained for analysis after 369 inconsistent responders and 754 previously diagnosed with gastroesophageal reflux disease (GERD) were excluded. Esophageal symptom prevalence was: feeling of a lump or something stuck in the throat (globus) 8.1% (n=420), heartburn 6.5% (n=334), dysphagia 4.5% (n=233) and chest pain 5.2% (n=269). Independent predictors for increased risk of esophageal symptoms included younger age, symptoms consistent with other FGIDs, using medications for gastrointestinal symptoms, somatization, cannabis use, and certain foods (see table 1). When individuals with GERD were included in re-analyses, GERD was a significant predictor for chest pain and heartburn (OR 1.939 and 1.525), but not globus and dysphagia. The prevalence of symptom constellations consistent with Rome IV esophageal diagnoses was 1% for globus, 3.2% for functional dysphagia, 0.7% for reflux hypersensitivity, 0.8% for functional chest pain, and 1.1% for functional heartburn. There was a significant difference in symptoms consistent with any functional esophageal disorder between USA 7.0%, UK 4.3% and Canada 5.9% ($p=0.003$).

Table 1: Factors independently associated with presence of esophageal symptoms compatible with a functional esophageal disorder

Symptom	Factor	Odds ratio	95 % Confidence interval	R ² value
Globus	PHQ12	1.138	1.105–1.172	0.189
	Medication for constipation	1.718	1.146–2.577	
	Diet rich in pasta	1.068	1.000–1.139	
	Gastroduodenal disorder	2.616	2.006–3.412	
	Bowel disorder	1.318	1.032–1.684	
	Anorectal disorder	1.699	1.243–2.321	
Chest pain	Cannabis consumption	1.949	1.215–3.128	0.301
	Previously diagnosed with functional dyspepsia	6.492	1.342–31.417	
	Medication for acid/heartburn	1.488	1.039–2.130	
	PHQ12	1.214	1.171–1.259	
	Gastroduodenal disorder	2.820	2.051–3.877	
	Bowel disorder	1.791	1.311–2.446	
Heartburn	Anorectal disorder	1.536	1.058–2.230	0.315
	Diet rich in tofu	1.192	1.058–1.343	
	Home with electricity as a child	2.509	1.256–5.011	
	PHQ12	1.074	1.035–1.114	

(continued)

Table 1 Continued

Symptom	Factor	Odds ratio	95 % Confidence interval	R ² value
Dysphagia	Medication for acid/heartburn	11.427	8.602–15.179	0.242
	Gastroduodenal disorder	2.789	2.049–3.798	
	Bowel disorder	2.165	1.632–2.872	
	Diet rich in pasta	1.113	1.026–1.206	
	Age	0.990	0.980–1.000	
	Medication for diarrhea	1.882	1.100–3.221	
	Medication for acid/heartburn	1.456	1.007–2.106	
	Medication for gas/bloating	1.913	1.178–3.106	
	Gastroduodenal disorder	4.368	3.146–6.065	
	Anorectal disorder	1.585	1.072–2.343	
	Diet rich in rice	1.097	1.006–1.196	
	PHQ12	1.110	1.069–1.154	

Variables with a p-value of 0.1 or less in univariate analysis were entered into a multivariate analysis (logistic regression) in order to identify factors independently associated with esophageal symptoms (up to 33 variables).

Conclusion: Esophageal symptoms compatible with a functional esophageal disorder are common in the Western population. Age and presence of other GI and non-GI symptoms are associated with reporting esophageal symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0531 DETERMINANT FACTORS OF QUALITY OF LIFE IN ADULT PATIENTS WITH EOSINOPHILIC ESOPHAGITIS

A. J. Lucendo Villarin¹, L. Arias-González¹, J. Molina-Infante², Á. Arias¹

¹Dept. Of Gastroenterology, Hospital General de Tomelloso, Tomelloso/Spain

Contact E-mail Address: ajlucendo@hotmail.com

Introduction: Eosinophilic esophagitis (EoE) affects children and young adults and has rapidly grown over the past decade, especially in developed countries. Presently, it represents the second leading cause of chronic esophagitis after gastroesophageal reflux disease (GERD) and the main cause of dysphagia in children and young adults. EoE affects health-related quality of life (HRQoL). Data on determinant factors and the influence of dietary interventions are scarce.

Aims & Methods: In this study we aimed (1) to determine for the first time the health-related QoL in a representative sample of Spanish adults with EoE, and (2) to identify determinants of impaired HRQoL, including the effect of dietary restrictions. Multicentre observational, cross-sectional study in eight Spanish centers attending adult EoE patients throughout several Spanish Regions. A validated Spanish version of the self-administered Adult Eosinophilic Esophagitis Quality of Life (EoE-QoL-A) questionnaire was used, as well as a survey of demographic and clinical data. Multiple linear regression was used to identify and quantify determinant factors of HRQoL.

Results: Responses provided by 170 patients were assessed (73.5% male; mean age 33.5 ± 11.4 y). Overall mean score for the EoE-QoL-A index was 1.4 ± 0.8 , with no differences between patients on dietary or pharmacological therapy (1.82 ± 0.8 vs. 1.62 ± 0.8 ; $p=0.132$). Disease anxiety showed the highest. The mean score (2.13 ± 0.9 points), followed by choking anxiety 1.97 ± 1.1 ; social impact, 1.77 ± 1.1 , and diet/eating impact 1.68 ± 0.9 points. Emotional impact had the lowest rating (1.15 ± 0.9), and the only with a significantly worse score in patients under dietary restrictions. Recurrent food impaction, a higher educational level, dietary interventions and symptom duration were all independent determinant factors significantly impairing HRQoL. Female gender and empiric elimination diets negatively influenced on diet/eating impact.

Conclusion: HRQoL is impaired in adult EoE patients, especially disease and choking anxiety. Recurrent food impaction, dietary interventions and symptom duration are the most important factors influencing the perception of HRQoL in EoE.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0532 THE ASSOCIATION BETWEEN ATOPIC MANIFESTATIONS AND EOSINOPHILIC ESOPHAGITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Introduction: Eosinophilic oesophagitis (EoE) is a chronic, immune-mediated, inflammatory disorder, defined symptomatically by esophageal dysfunction and histologically by eosinophil-predominant inflammation of the esophagus.

Several studies have provided information on the prevalence of different atopic conditions in paediatric and adult EoE patients and compared them with several groups of control subjects. The findings indicate that, overall, EoE patients show a higher frequency of asthma, rhinoconjunctivitis, eczema, and food allergies than control groups; however, definitions for the associated atopic conditions have not always been provided and the selection process for the controls has not been such that they can be considered universally representative of the general population without EoE. These two limitations have hampered researchers in their efforts to clearly assess the magnitude of the association between atopy and EoE. We aim to conduct a systematic review of the literature and to perform a meta-analysis in order to evaluate the presence of atopic diatheses in patients with EoE as well as to summarize the prevalence of atopic conditions in both paediatric and adult EoE patients in comparison with the non-EoE control population.

Aims & Methods: A highly sensitive search strategy was designed to identify and retrieve all documents dealing with the relationship between atopy and EoE in children and adults. This systematic literature search was performed independently by two researchers (AA and AJL) on April 6th, 2016 in three major bibliographic databases (PubMed, EMBASE, and Scopus) for the period up to March 2016. The search was not restricted with regard to the language of publication. A predetermined protocol was used in accordance with the quality standards for reporting meta-analyses of observational studies in epidemiology. Four reviewers (JG-C, AA, MM-CM, and AJL) independently extracted relevant information from each eligible study using a standardized data extraction sheet and then proceeded to cross-check the results. Estimates for the prevalence of each atopic manifestation in EoE patients and controls were summarized with the aid of a fixed- or random-effects meta-analysis, depending on intra-study heterogeneity, weighted for inverse variance following the method elaborated by DerSimonian and Laird. Summary estimates, including 95% confidence intervals (CI), were calculated for each season and month, whenever possible.

Results: Of the 2954 references identified, data was collected from 21 studies including a total of 53,542 EoE patients and 54,759 controls. The criteria for defining a diagnosis of atopy in either EoE patients or controls was not structurally considered in most of the studies. The frequency or prevalence of the different atopic manifestations among EoE patients was compared with that observed in several types of control populations, including series of patients with gastroesophageal reflux disease (GORD), other patients, and healthy volunteers, all of whom were endoscopically assessed with a diagnosis of EoE specifically ruled out. In all cases, EoE was considered as independent from GORD and other upper GI tract diseases. Some studies included database-registered subjects as control groups. The criteria for defining a diagnosis of atopy among EoE patients and control subjects varied widely across the different studies, from self-reported/parent-reported atopic background to strict allergist/immunologist-provided diagnoses. Overall, allergic rhinitis was significantly more common among EoE patients compared to control subjects (OR 5.58; 95% CI, 3.27, 9.53; $I^2 = 86\%$) as were bronchial asthma (OR 3.06 (95% CI, 2.01, 4.66; $I^2 = 83.4\%$) and eczema (OR 2.86; 95% CI, 1.88, 4.36; $I^2 = 57.2\%$). Food allergies and other atopic conditions were also assessed. No significant publication bias was found for studies dealing with allergic rhinitis and eczema in EoE. Finally, our search uncovered two papers that reported on the frequency of drug allergy in EoE patients compared to controls, showing no significant differences between these two populations (OR = 0.981; 95% CI, 0.07, 14.72).

Conclusion: The present study shows that an accurate diagnosis of atopy is lacking in most of the research evaluating the prevalence of asthma, rhinitis, and eczema among EoE patients. Still, the prevalence of these three conditions seems to be significantly higher in children and adults with EoE as compared to control subjects representative of the general population. Further research should clearly document and use standard definitions of allergic rhinitis, asthma (including its severity and level of control), skin allergy, and food allergy (rather than mere sensitization) when assessing and documenting concurrent allergic diseases in patients with EoE.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0534 A PHASE 1 STUDY TO ASSESS THE PHARMACOKINETICS, SAFETY, AND TOLERABILITY OF SINGLE DOSE APT-1011 ADMINISTERED UNDER FED OR FASTED CONDITIONS OR AT BEDTIME IN A RANDOMISED THREE-WAY, CROSSOVER DESIGN

G. M. Comer, B. A. Meltzer

Adare Pharmaceuticals, Inc., Lawrenceville/United States of America/NJ

Contact E-mail Address: brian.meltzer@adarepharma.com

Introduction: APT-1011 is an orally disintegrating tablet (ODT) formulation of fluticasone propionate (FP) that provides a novel approach for the treatment of eosinophilic esophagitis (EoE).

Aims & Methods: A randomised, single-dose, three-way, crossover study was conducted in healthy volunteers to compare the pharmacokinetics (PK), safety, and tolerability of APT-1011 when administered under morning (AM) fed or fasted conditions or before bedtime (HS). Participants were administered 6 mg APT-1011 following these three different administration schedules, with a 7-day washout separating the three periods. Serial plasma samples for FP PK were collected predose and up to 72 hours following each dose. Noncompartmental and statistical analyses were performed for PK parameters.

Results: A total of 24 participants enrolled and 22 (92%) completed the study. A summary of the PK parameters by test group is presented in Table 1. AM dosing was associated with a higher rate of absorption under fed compared to fasted conditions. Following a high fat meal, there was a higher peak concentration (C_{max} : ratio [90% CI (confidence interval)] = 120.65% [99.84%–145.79%]) and a faster time to peak concentration compared to the fasted state (T_{max} :

fed = 5.00 h, fast = 10.00 h). However, lower total exposure in the fed compared to the fasted state {AUC [area under the curve]_{last}: ratio (90% CI) = 76.97% [67.64%–87.59%]} was observed. HS dosing was found to slow the rate of absorption compared to AM dosing conditions. Specifically, the time to peak concentration with HS dosing (T_{max} = 14 h) was longer than with AM dosing (T_{max} : fast = 10 h, fed = 5 h). HS dosing was associated with higher overall exposure (AUC_{inf}: ratio [90% CI] = 122.36% [107.02%–139.88%]) and lower C_{max} (C_{max} : ratio [90% CI] = 67.79% [56.29%–81.64%]) versus the fed dosing regimen. Compared to the fasted regimen, HS dosing yielded lower overall exposure (AUC_{inf}: ratio [90% CI] = 87.00% [75.24%–100.59%]) and lower C_{max} (C_{max} : ratio [90% CI] = 81.78% [67.93%–98.47%]). Across all dosing regimens, the C_{max} of FP with APT-1011 ranged from 5.97–200 pg/mL. Seven subjects (29%) reported 12 treatment-emergent adverse events over the course of the study; all were mild in severity. No serious adverse events or deaths were reported.

Conclusion: Oral APT-1011 was safe and well-tolerated when administered under AM fasted, AM fed, or HS conditions to healthy subjects. While there was faster absorption of APT-1011 under fed conditions and slower absorption at bedtime, overall absorption of FP with this ODT formulation is low (<200 pg/mL). Slower absorption with HS dosing suggests a potential for longer dwell times in the esophagus; the relationship of HS dosing with histological efficacy in both the proximal and distal portions of the esophagus will be explored in future studies of APT-1011 in EoE.

Table 1: Plasma FP PK Parameters

Parameter	AM Fast Geometric Mean (CV%)	AM Fed Geometric Mean (CV%)	HS Geometric Mean (CV%)
C_{max} (pg/mL)	31.1 (103.6)	34.2 (102.3)	23.8 (111.9)
T_{max} (h)*	10.00 (2.00–30.00)	5.00 (1.00–10.00)	14.00 (2.00–20.00)
AUC ₀₋₂₄ (pg/h/mL)	366.607 (115.8)	361.277 (105.5)	359.541 (100.5)
AUC _{inf} (pg/h/mL)	1044.308 (90.1)	587.890 (107.2)	726.451 (100.2)

CV% = percentage coefficient of variation. *Median and range are presented.

Introduction: Eosinophilic esophagitis (EE) is a chronic condition of the esophagus with pathognomonic clinical, endoscopic and histologic features. We aimed to prognosticate which cohort of patients respond best to proton pump inhibitor monotherapy or topical steroids based on index endoscopy and histology in conjunction with symptoms at presentation and on follow-up.

Aims & Methods: All patients referred with dysphagia or with an incidental histology finding of >15 eosinophils/high power field (eos/hpf) between Feb 2013 and Dec 2015 were analyzed by retrospective case note review and patient communication. Univariate analysis and binary logistic regression was used to identify associations between patient characteristics, presentation, endoscopic findings, degree of eosinophilia and subsequent response to treatment. Associations were assessed by Fishers exact test, t-test and Mann-Whitney for nominal, continuous parametric and non-parametric variables respectively.

Results: 1653 patients fulfilled the entry criteria. 544 with previous cancer, achalasia, post-operative strictures or Barrett's endotherapy were excluded. 95 patients had histological eosinophilia in keeping with EE; 85 with dysphagia and 10 with reflux as their presenting complaint (67 male, mean age 42 ± 17 years). 31(32%) of these had at least one presentation with food bolus obstruction (FBO). There was a trend towards a higher eos/hpf in patients who presented with FBO (47 ± 21) compared to dysphagia (38 ± 17) and reflux (38 ± 17) (p = 0.073). Endoscopic evidence of chronic stricture disease was associated with a higher eos/hpf than those with no strictures (mean 50.3 vs 38.6; p = 0.04). 31 patients had endoscopic biopsies taken at least 3 months post therapy. Those with index features of chronic disease were more likely to be associated with failure of the eosinophilia to normalize regardless of medical treatment compared to those with acute changes (furrows, exudates) (33% vs. 75%; p = 0.02). Furthermore, patients with dysphagia or FBO demonstrated a reduced normalisation of eos/hpf following either steroid or PPI therapy compared to those not presenting with these symptoms at a minimum of 3 months (46% vs. 100%; p = 0.03). Overall, there were no significant associations between concentration of eos/hpf and response to steroids or PPI. On the other hand, regardless of endoscopic findings, patients presenting with dysphagia and/or FBO demonstrated a higher response to steroids than those with reflux symptoms (50% vs 9% p = 0.018) who responded best to PPI (91%). 78 patients were contactable a minimum of 3 months following initiation of treatment. Patients with chronic EE findings at initial endoscopy were less likely to respond symptomatically to PPI monotherapy compared to those with normal or acute endoscopic findings (32% vs. 68%; p = 0.003) while they were more likely to respond

to steroids (64% vs 36%; $p=0.002$. Specifically, the presence of strictures indicated a more likely clinical response to steroids compared to PPI alone. ($p=0.007$).

Conclusion: A higher eos/hpf was found in patients with chronic EE features at index endoscopy than those with normal or acute endoscopic signs. In those with normal or acute EE changes and without dysphagia as a presenting complaint, a clinical response was noted with PPI therapy alone. In those with chronic EE changes or with dysphagia/FBO, steroids appear to be the preferred therapeutic option, although at 3 months follow up a clinical response might precede a histological one.

Introduction: Proton Pump Inhibitor-response esophageal eosinophilia (PPI-REE) is an emerging condition characterized by a constellation of clinical, endoscopic, and histopathologic features in the setting of eosinophilic inflammation on esophageal biopsies responding to a course of proton pump inhibitor (PPI) therapy. A recent meta-analysis explored the role of different PPIs in inducing clinical and histologic remission in patients with esophageal eosinophilia without observing significant differences among them due to several limitations (i.e. limited number of studies using each PPI drug, small sample size, and heterogeneity among the various studies).

Aims & Methods: We aimed to prospectively compare the effect of different PPIs in inducing endoscopic and histologic remission in patients with PPI-REE. Consecutive patients with symptoms suggestive of EoE underwent upper endoscopy to assess the presence of at least 15 eos/hpf on oesophageal biopsies at mid/proximal esophagus and, then, were treated with twice-daily PPI for at least 8 weeks. Patients were assigned to receive esomeprazole 20mg bid, rabeprazole 20mg bid or pantoprazole 40mg bid in a 1:1:1 ratio. Thereafter, patients repeated upper endoscopy and PPI-REE was identified in case of less than 15 eos/hpf and a 50% decrease from baseline. Endoscopic, according to Endoscopic Reference Score (EREFs), and histologic features were blindly reviewed for each patient and treatment

Results: Twenty-eight patients [23M/5F; mean age 35] reporting dysphagia (93%), bolus impaction (68%) and chestpain (25%) were diagnosed with PPI-REE. According to treatment allocation, 8 (29%) patients received esomeprazole, 9 (32%) rabeprazole and 11 (39%) pantoprazole. At baseline, demographic and clinical data, including age, sex, BMI, *H. pylori* infection, concomitant allergy conditions and latency from diagnosis were similar ($p=ns$). Moreover, no differences were found in terms of frequency of symptoms reported ($p=ns$). Endoscopic and histologic features at baseline and after PPI therapy are shown in the Table. Esomeprazole, rabeprazole and pantoprazole reached the same degree of efficacy in inducing endoscopic and histologic changes in PPI-REE patients ($p=ns$).

Table: Endoscopic and histologic features at baseline and after PPI therapy in PPI-REE

	Esomeprazole Group (n = 8)		Rabeprazole Group (n = 9)		Pantoprazole Group (n = 11)	
	After-Baseline	After-Therapy	After-Baseline	After-Therapy	After-Baseline	After-Therapy
<i>Endoscopic Features, %</i>						
Rings	75%	26%	67%	22%	63%	18%
Linear furrows	62%	13%	55%	11%	54%	9%
Whitish exudates	50%	13%	44%	11%	54%	18%
Edema	26%	13%	33%	11%	27%	9%
Crepe paper	13%	0%	0%	0%	9%	0%
Strictures	13%	13%	22%	11%	18%	9%
Mean EREFS Score	7.3	1.2	8.1	1.6	8.4	1.7

(continued)

Table Continued

	Esomeprazole Group (n = 8)		Rabeprazole Group (n = 9)		Pantoprazole Group (n = 11)	
	After-Baseline	After-Therapy	After-Baseline	After-Therapy	After-Baseline	After-Therapy
<i>Histologic Features, n or %</i>						
Median maximum eos count*	75	6	87	5	95	6
Median eos count (of 5 HPFs)*	55	4	68	3	62	5
Degranulation present	88%	13%	100%	11%	90%	18%
Microabscess present	63%	13%	55%	11%	48%	9%
Basal layer present	100%	26%	100%	22%	100%	18%
Spongiosis present	88%	26%	88%	11%	90%	18%
Subepithelial tissue present	75%	13%	55%	11%	81%	9%
Lamina propria fibrosis present	0%	0%	0%	0%	9%	0%

Eos = eosinophils *Calculated for an HPF area = 0.24 mm²

Conclusion: Esomeprazole, rabeprazole and pantoprazole administered at double daily dose were equally effective in determining endoscopic and histologic remission in patients with PPI-REE. These data, although obtained in a small sample of patients, suggest that the pharmacokinetic and pharmacodynamic differences among these drugs do not affect their effect on PPI-REE patients.

P0537 THE « GARD (GASTRO-ESOPHAGEAL ANTI-REFLUX DEVICE): A NEW ENDOSCOPIC MEDICAL DEVICE TO DIAGNOSE, MANAGE AND TREAT GERD

N. Godin

Private Practice, Geneva/Switzerland

Contact E-mail Address: dr.godin68@gmail.com

Introduction: The « GARD» (Gastroesophageal Anti-Reflux Device) is an anti-reflux tubular valve placed in the lower esophagus under endoscopic control allowing normal ingestion of food and beverages but blocking all gastro-esophageal refluxate mechanically (fluid, solids and gas)

Aims & Methods: The « GARD» has an upper ring sized to the diameter of the patient's esophagus with an accessory called the « calibration device » placed through the 2.8mm working channel of a standard gastroscope. The GARD is held in place by pressure. The upper ring holds an anti-reflux thin-walled tubular valve moulded in one piece under the ring. After placement of a standard guide-wire, the « GARD» is placed through the patient's mouth and is released in the lower esophagus. The procedure is performed under sedation on an ambulatory basis in about 15 minutes when experienced. The « GARD» was placed in the esophagus of 8 pigs during 7 days to evaluate placement, feeding, weight gain, absence of migration as well as removal. Deployment of the « GARD » was easy, there was no migration in the stomach and removal of the GARD with the developed accessories was easily achieved. However, pigs have a strong lower esophageal sphincter and have no reflux so gastro-esophageal reflux could not be evaluated. In a human volunteer with very severe gastro-esophageal reflux who had previously failed anti-reflux surgery and had an unsatisfactory response to clinical and pH metric measurement under 80 mg of esomeprazole, the « GARD» was placed preoperatively. Hereafter are this patient's pH metric results without PPIs (table 1); with the patient taking 80 mg/day PPIs (table 2) and after GARD placement and PPIs stopped for 10 days, table 3.

Results: Fig 1. First pH metric study (no PPIs for 10 days): The patient has very severe reflux with 63% of the time with a pH under 4 (normal less than 4% of the time at a pH under 4) after PPIs were stopped for 10 days. Fig 2. Patient is taking 80 mg of esomeprazole a day. pH metric measurement remains highly pathological at 23% of the time under pH 4 once PPIs have been resumed at 80 mg of PPIs daily. Fig 3. After placement of the GARD and PPIs have been stopped for 10 days, there is no longer any reflux measured. The pH tracing does not drop under the red line at pH 4.

Conclusion: a new medical device blocking GERD is presented. A first clinical trial is scheduled to start in 2018 to help diagnose and manage Refractory GERD. Further clinical indications are at the planning stage including treatment of Refractory GERD and LPR.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0538 SYMPTOM PATTERNS AND TYPES OF GASTROESOPHAGEAL REFLUXES SIGNIFICANTLY DIFFER IN GROUPS OF EROSIVE ESOPHAGITIS AND NON-EROSIVE FORM OF GASTROESOPHAGEAL REFLUX DISEASE (GERD) PATIENTS

Introduction: Patients with gastroesophageal reflux disease (GERD) demonstrate a range of different symptoms (esophageal and extraesophageal) however the relationship between symptoms and types of reflux was not evaluated.

Aims & Methods: The aim of the study was to assess the relationship between GERD patients' symptoms with characteristics of refluxes obtained by 24-h esophageal pH-impedance. One hundred fifty eight GERD patients (68 men, 89 women, age (M ± m) 42 ± 4.8 yrs) and 49 controls (22 men, 27 women, age (M ± m) 46 ± 6.7 yrs) were examined using 24-hours esophageal pH-impedance recordings (Omega, MMS, the Netherlands; 2pH-6 impedance channels catheters, UnisensorAG, USA) and validated GERD-Q questionnaire. According to baseline endoscopy 91 patients were classified as non-erosive reflux disease (NERD) and 67 as erosive reflux disease (ERD) patients. Patients' symptoms were classified according to Montreal classification.

Results: Extraesophageal symptoms as well as weak acid gastroesophageal refluxes were found significantly more often in patients with NERD compared to ERD group (table 1). However higher number of acid refluxes, higher GERD-Q score and DeMeester score were present in ERD. The total number of gastroesophageal refluxes didn't differ between ERD and NERD groups of patients.

Table 1: Results of the study

	Controls (n=49)	NERD (n=91)	ERD (n=67)	p
Number of refluxes/day, n	17 ± 1.3	55 ± 3.07*	55 ± 4.7*	*p = 0.729
Number of acid refluxes/day, n	6 ± 1.0	27 ± 2.2*	33 ± 3.7*	*p = 0.040
Number of weak acid refluxes/day, n	7 ± 0.93	22 ± 2.1*	15 ± 2.3*	*p = 0.038
Number of high gastroesophageal refluxes/day, n	2 ± 0.47	15 ± 1.4*	12 ± 2.2*	*p = 0.347
DeMeester score	3.16 ± 1.75	13.3 ± 2.0*	26.92 ± 6.2*	*p = 0.0001
GERD-Q score	5 ± 0.31 × †	10 ± 0.24 ×	13.1 ± 0.22*†	* × † p = 0.0001
Extraesophageal symptoms (cough, laryngitis, etc.) (presence, % in group)	0	61.5*	31.3*	*p = 0.0001

Conclusion: ERD and NERD groups of patients are characterized by different symptom patterns and types of gastroesophageal refluxes registered with 24-hours esophageal pH-impedance monitoring. These findings could reflect differences in pathogenesis and clinical manifestations of mentioned forms of GERD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0539 LARYNGEAL DISORDERS AND CHRONIC COUGH IN ADULTS WITH AND WITHOUT EROSIVE ESOPHAGITIS: A CASE-CONTROL STUDY IN ALBANIA

Introduction: Several clinical-based studies from Western countries have investigated the prevalence of extra-esophageal symptoms in various degrees of reflux erosive esophagitis. However, the independent factors related to the development extra-esophageal manifestations remain unclear.

Aims & Methods: Our aim was to assess the prevalence of extra-esophageal symptoms (laryngeal disorders and chronic cough) in adults with (cases) and those without (controls) erosive esophagitis in Albania, a developing Southeast European country. A case-control study was conducted at the Regional Hospital

of Durres, the second main district in Albania, a transitional country in South Eastern Europe, including 248 patients with erosive esophagitis (aged 46.5 ± 16.3 years) and 273 controls (aged 46.4 ± 16.0 years; response rate: 70%) enrolled during the period January 2013 – June 2014. Both cases and controls underwent upper endoscopy. Information on socio-demographic characteristics and lifestyle factors was also collected. Binary logistic regression was used to assess the association of erosive esophagitis and extra-esophageal symptoms.

Results: Patients with erosive esophagitis had a higher prevalence of excessive alcohol consumption, smoking, sedentarity and obesity compared to their control counterparts (9% vs. 5%, 70% vs. 49%, 31% vs. 17% and 22% vs. 9%, respectively). The prevalence of hiatal hernia was higher in cases than in controls (21% vs. 8%, respectively), whereas the prevalence of gastric-duodenal ulcer was similar in both groups (13% vs. 14%, respectively). Upon adjustment for all socio-demographic characteristics and lifestyle/behavioral factors, there was evidence of a strong association of erosive esophagitis with chronic cough (OR = 3.1, 95%CI = 1.7–5.7), and even more so with laryngeal disorders (OR = 4.4, 95%CI = 2.6–7.4). In all models, the association of erosive esophagitis with any extra-esophageal symptoms was strong and mainly consistent with each of the symptoms separately (fully-adjusted model: OR = 4.6, 95%CI = 2.9–7.3).

Conclusion: Our findings indicate that the prevalence of extra-esophageal symptoms is higher among patients with erosive esophagitis in a transitional country characterized conventionally by the employment of a Mediterranean diet. Therefore, the upper endoscopy should be part of the evaluation in patients with suspected reflux-related chronic cough and laryngeal disorders.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0540 ASSESSMENT OF EXHALED BREATH CONDENSATE FOR NON-INVASIVE DIAGNOSIS OF GASTROESOPHAGEAL REFLUX DISEASE IN CORRELATION WITH MII-PH AND PEPTEST

Introduction: Gastroesophageal reflux disease (GERD) is a disease caused by backflow of gastric contents into the esophagus due to the failure of physiological antireflux mechanisms and can lead to esophageal and extraesophageal symptomatology. Extraesophageal reflux (EER) is a condition where refluxate penetrate above the upper esophageal sphincter (UES) in to the oral cavity, pharynx, upper and lower respiratory tract and leads to pathological changes like e.g. chronic cough, globus pharyngis, laryngitis, pharyngitis, rhinosinusitis, otitis media, bronchial asthma, COPD, sleep apnea and noncardiac chest pain. Currently there is no suitable, non-invasive diagnostic method applicable for GERD in clinical practice. Exhaled breath condensate (EBC) and saliva are two easily obtained samples that could be used in monitoring of patients suffering from extraesophageal symptoms of GERD. The aim of this study was to compare the pH and total ionic profile of EBC with 24-hour multichannel intraluminal impedance and pH monitoring (MII-pH) and salivary Peptest in a group of patients with acid reflux (pH < 4), weakly acid reflux (pH 4–7) and healthy controls.

Aims & Methods: A portable EBC sampler was used for collection of EBC. 10 µL sample aliquots of EBC were analyzed. For pH measurement, the CO₂ from EBC was removed with N₂ gas for 5 min. The pH of EBC was measured with a pH-microelectrode and total ionic profile (anions, cations, organic acids - NH₄⁺, K⁺, Ca²⁺, Na⁺, Mg²⁺, Cl⁻, NO₂⁻, NO₃⁻, SO₄²⁻, acetate, lactate, propionate, butyrate) was analyzed by capillary electrophoresis in each sample. Saliva was collected using the commercial Peptest sampling containers, applied to the Peptest lateral flow devices and analyzed using the device reader. The data from EBC were compared with MII-pH and Peptest. In total the study comprised of 39 participants. The patients were divided by dominant findings from MII-pH in to groups with acid reflux (n = 17), weakly acid reflux (n = 8) and without reflux (n = 14).

Results: The values of pH (after CO₂ removal with N₂) were significantly higher in the group with acid reflux (p < 0.01), (mean pH 7.13, interquartile ranges 6.83–7.47) and in the group with weakly acid reflux (p < 0.01) (7.37, (7.18–7.57)) vs. healthy controls (6.8, (6.65–6.99)). Butyric acid (BA) was the second most significant parameter that was significantly elevated (p < 0.01) in both patient groups (acid reflux- mean BA 2.29 µM, weakly acid reflux- mean BA 3.33 µM) compared to healthy subjects (mean BA 0.69 µM).

Further statistically significant differences were found in chloride (Cl⁻), nitrate (NO₃⁻) and sodium (Na⁺) ions concentration. Cl⁻ was elevated (p < 0.01) in group with acidic reflux vs. healthy controls and NO₃⁻ and Na⁺ were elevated (p < 0.01) in group with weakly acidic reflux vs. healthy controls. Peptest for saliva sampling and pepsin analysis showed no statistically significant differences within the groups. In the groups of patients with acid reflux, the incidence of high pepsin concentration (above 75 ng/ml) was found only in 50% of the patients.

Conclusion: We found statistically significant difference in pH and selected ions from EBC between different groups of patients and healthy controls. The analysis of selected parameters in EBC could provide a fast and non-invasive diagnostic method for GERD patients with EER symptoms in the future. This can

potentially reduce the diagnostic cost and avoid unnecessary invasive MII-pH testing in future. Unlike the EBC, pepsin analysis using Peptest did not provide any diagnostic value.

Introduction: Impedance-pH testing is actually considered the gold standard diagnostic tool for reflux assessment. In fact, it allows to characterize any type of gastro-esophageal reflux (GER), namely acid and non-acid, and therefore permits – in presence of typical reflux symptoms – to diagnose functional heartburn (FH) based on the lack of abnormal acidic or non-acidic refluxate (i.e. normal number of reflux episodes and negative reflux-symptom association). Gastrin-17 (G17) has been proposed as a non-invasive marker of GERD, due to the negative feedback between acidic output and this hormone. Indeed, preliminary data showed that intermediate values of G17, between very low to normal levels, may identify GERD subjects with abnormal non-acid reflux.

Aims & Methods: We aimed to correlate various patterns of refluxate (i.e. predominant acidic refluxate, predominant non-acidic refluxate and no reflux at all), as assessed by impedance-pH, with different levels of G17 in endoscopy-negative subjects with heartburn. Thirty-five consecutive patients (19F/16M, mean age 47 years, range 31–56 years), all reporting heartburn since 6 months with at least 3 episodes/week, entered the study. All patients underwent upper endoscopy off-medication and in case of no lesions were classified as endoscopy-negative. In all subjects, impedance-pH was performed off-therapy and blood determination of G17® (Biohit Oji, Finland; normal values: 1–9 pmol/l) was evaluated on the same day of reflux monitoring. Impedance-pH tracings were blindly and manually analyzed to detect the distal acid exposure time (AET abnormal if $\geq 3.2\%$ over 24 hours) and the number as well as the characteristics of reflux episodes (acidic/weakly acidic refluxate). Patients were then divided in three groups according to the results of impedance-pH: a) Group A: subjects with increased number of acid refluxes or abnormal AET; b) Group B: subjects with increased episodes of non-acid reflux and normal AET; c) Group C: subjects without increased of any kind of reflux and normal AET.

Results: According to impedance-pH results, 14 out of 35 patients had increased acid reflux episodes or abnormal AET (Group A), 14 patients showed increased non-acid reflux episodes (Group B) and 7 patients had no increased number of any kind of GER (Group C). In the Group A, the mean value of G17 was 0.9 pmol/l, in the Group B was 2.6 pmol/l, and, in the Group C was 5.1 pmol/l ($p < 0.01$). Very low G17 levels were significantly associated with increased acid reflux episodes or abnormal AET, confirming the background of the negative

feedback between acidic output and G17 levels. Interestingly, when impedance-pH showed a feature of non-acid reflux pattern (Group B), levels of G17 were always low, but higher than in case of acid reflux pattern (Group A) ($p < 0.05$). Finally, when impedance-pH did not show any kind of abnormal reflux, suggesting a diagnosis of FH, G17 levels were always normal.

Conclusion: In this preliminary study, G17 levels well correlated with the three different categories of patients suffering of heartburn and included in the NERD umbrella (i.e. NERD patients with increased acid reflux episodes or abnormal AET, endoscopy-negative patients with increased non-acidic reflux and subjects with FH), suggesting its use as surrogate marker of NERD or non-acid reflux disease, without the need of performing invasive tests.

P0542 ANTI REFLUX MUCOSECTOMY (ARMS) FOR REFRACTORY GASTRO ESOPHAGEAL REFLUX DISEASE (GERD) - ARE WE THERE YET?

R. Shah, A. P. Maydeo, V. Dhir

Gastroenterology, Baldota Institute of Digestive Sciences, Global Hospital, Mumbai/India

Contact E-mail Address: rahulshah@hotmail.com

Introduction: As a treatment for gastro esophageal reflux disease (GERD), proton pump inhibitors (PPIs) are the mainstay of medical therapy. Laparoscopic fundoplication is generally advised when symptoms are poorly controlled with PPIs and is regarded as a gold standard of treatment, with excellent control in the short- and midterm. Long-term results, however, remain equivocal. Following on from the principles of surgical fundoplication, a variety of endoscopic procedures for GERD have been proposed to achieve non-surgical control. Linx procedure, Stretta have been proposed as less invasive options.

Aims & Methods: We recruited all patients who had GERD refractory to standard medical therapy to see whether anti reflux mucosectomy prevents acid reflux into the esophagus. We screened all GERD patients who were refractory to proton pump inhibitors, hydrogen 2 receptor blockers and alginates and had an endoscopy suggestive of a lax cardia with mucosal flap valve grading of 1 to 3. We performed a baseline screening endoscopy to rule out a hiatus hernia and to exclude helicobacter infection. A GERDQ questionnaire was filled by all the patients indicative of severity of reflux. All patients had a high resolution manometry (Sandhill scientific) to exclude significant dysmotility and 24 hour pH measurements using Zephyr pH probe (Sandhill scientific) on therapy to demonstrate significant acid reflux. Only patients with mucosal flap valve grading 1, 2 or 3 were selected for anti reflux mucosectomy.

Results: Technique: Crescentic ARMS of the esophagogastric junctional (EGJ) mucosa was conducted with the standardized technique of endoscopic mucosal resection (EMR) of at least 3 cm length in the stomach, with the length of mucosal resection at the cardia measured in retroflexion from the gastric side. ARMS was conducted along the lesser curve of the stomach, thus preserving a sharp mucosal valve at gastric cardia. All the patients who underwent ARMS had a significant reduction in the DeMeester score, with predominant decrease in the recumbent acid exposure. 7/12 patients were able to discontinue all the medical therapy. PPI dose reduction was possible in the other patients with a mean reduction of 50%, alginates were stopped in all patients and H2RA were also discontinued.

Conclusion: Results suggest a potential anti-reflux effect of ARMS. The mechanism is presumed to be due to scar formation after healing of the mucosal defect. On the gastric side, this induces narrowing of the gastric cardia opening, while preserving and/or re-creating a robust his angle. After ARMS, the lesser curve of the gastric cardia takes on an almost “mechanically-stitched” appearance. The mucosal flap is rebuilt and looks well-defined. Furthermore, the lesser curve side

of the EGJ is shortened with scar formation, and greater curve of EGJ (his angle side) is kept non-scarred and therefore retains its flexibility as a mucosal flap valve. The quantity of mucosa to be resected to induce appropriate ("not too tight and not too loose") scar formation is a key issue in this procedure. Total circumferential resection causes stricturing as demonstrated in previous studies, while subtotal dissection, which we have termed crescentic, produces better results in this regard, while still resulting in symptom control. Mucosal flap valve grading is not only a good predictor of reflux in these patients but also is a prognostic marker of effectiveness of ARMS, i.e. higher the grade worse the outcome. Perhaps tailoring the extent and type of mucosal resection (EMR vs. ESD) according to the mucosal flap valve grading may be a better predictor of outcome than a box standard procedure. This technique has a potential role in people with oesophageal dysmotility wherein Nissen's fundoplication is relatively contraindicated.

Introduction: Observational and epidemiologic data have suggested an association between proton pump inhibitor (PPI) use and osteoporotic fractures. To evaluate potential mechanisms for this association, we measured bone turnover, bone mineral density (BMD), true fractional calcium absorption (TFCA), and serum and urine mineral levels in healthy postmenopausal women taking PPIs or placebo for 26 weeks.

Aims & Methods: Postmenopausal women aged 45–75 were randomised to daily oral 60-mg dexlansoprazole (DEX), 40-mg esomeprazole (ESO), or PBO for 26 wks with follow-up at wk 52. Primary endpoints were 26-wk % change vs placebo in procollagen type 1 N-terminal propeptide (P1NP) and C-terminal telopeptide of type 1 collagen (CTX). Additional endpoints included changes in BMD (26 and 52 wks) and serum and urine mineral levels (26 wks). Fractures between baseline and wk 26 were recorded as adverse events. TFCA (0 and 26 wks) was measured in a subset (n = 34) of patients.

Results: Excluding 1 disqualified site, 115 women were randomised and 93 completed the study. There were no substantial differences in age, BMI, baseline serum calcium, or vitamin D levels between groups. The bone turnover markers P1NP and CTX remained within normal range during 26 wks of PPI therapy. Within each group, there was no statistically significant 26-wk change in bone turnover, except a small increase in CTX levels with DEX (0.12 ng/mL, 95% CI 0.03–0.23). The 26-wk median % increases in P1NP from baseline vs PBO (difference in median % change [95% CI] were 19% (7%–30%) for DEX and 18% (7%–30%) for ESO. CTX levels increased vs PBO by 27% (13%–43%) for DEX and 22% (8%–36%) for ESO. PPI effects on BMD, serum and urine mineral levels, and parathyroid hormone were not statistically different vs PBO. Median % change from baseline in TFCA vs PBO was not statistically significant for DEX, but was significant for ESO (6%, 95% CI 2%–11%). No spontaneous fractures occurred during treatment; 1 traumatic foot fracture (DEX) and 1 humerus fracture (circumstance unknown; ESO) occurred during follow-up.

Conclusion: 26 wks of DEX or ESO therapy increased bone turnover markers, but did not reduce BMD, TFCA, or serum or urine mineral levels. ESO increased TFCA by <1%. Although bone turnover markers increased with PPI therapy, levels remained within the normal ranges. No clear explanation for an association between PPI therapy and fracture risk was found in this study.

Disclosure of Interest: K.E. Hansen: Takeda paid me for my work as a consultant in the design of the study, and for my work in conducting the study at my medical center.
