ABSTRACT

Merosin deficient congenital muscular dystrophy type 1A (MDC1A) is caused by the loss of laminin-211 and laminin-221 heterotrimers which are most abundant in skeletal and cardiac muscle basal lamina; mutations in the LAMA2 gene cause the loss of these laminin isoforms. This absence of laminin-211/221 in MDC1A reduces the capacity for myofiber adhesion, loss of sarcolemmal integrity and subsequently the ability of the skeletal muscle syncytium to generate force in a coordinated and efficient manner. Patients experience progressive muscle wasting which confines them to a wheelchair at an early age and respiratory failure that leads to their untimely death. Currently, there is no effective treatment or cure for this devastating disease.

Previous studies have shown that laminin-111, an embryonic form of laminin, delivered before disease onset can reduce muscle pathology and improve viability in the $dy^W/-$ mouse model of MDC1A. These studies suggested that laminin-111 may act to strengthen and reinforce the sarcolemma and provide a protective niche for muscle repair. Since most patients are diagnosed with MDC1A after disease onset, we determined if laminin-111 could be beneficial after disease onset. Our studies suggest $dy^W/-$ mice treated with laminin-111 after disease onset show improvement in muscle function and histology. Results from this study along with an understanding of laminin-111 pharmacokinetics will help pave the way in developing this protein as an exciting potential therapeutic for MDC1A patients.

Duchenne Muscular Dystrophy (DMD) is the most common X-linked disease affecting 1 in 3,300 live male births. Patients with DMD suffer from severe, progressive muscle wasting and weakness with clinical symptoms first detected between 2 to 5 years of age; as the disease progresses patients are confined to a wheelchair in their teens and die in their early 20s mainly due to cardiopulmonary complications. DMD is caused by the loss of the sarcolemmal protein dystrophin (427kDa) due to mutations in the dystrophin gene. When present, dystrophin acts as a scaffold linking the cell cytoskeleton to the extracellular matrix. This loss of dystrophin in DMD results in patients experiencing greater susceptibility to muscle damage via reduced structural and functional integrity of their muscle.

One potential therapeutic avenue that needs to be explored involves increasing the levels of the $\alpha7\beta1$ integrin in order to compensate for the loss of dystrophin. To test this hypothesis, a muscle cell-based assay was developed in order to report $\alpha7$ integrin promoter activity with the intent of identifying molecules that promote $\alpha7$ integrin expression. Laminin-111 was identified as an enhancer of $\alpha7$ integrin expression. Theoretically, the identification of $\alpha7$ integrin enhancing compounds that help boost $\alpha7\beta1$ integrin expression as part of drug-based therapies may lead to a novel therapeutic approach for the treatment of this disease.

Systemic laminin-111 treatment significantly reduces myofiber degeneration in both forms of MDC1A and DMD muscular dystrophy. This dissertation reinforces the potential of laminin-111 as a systemic protein therapy,

capable of restoring sarcolemmal integrity thus reducing muscle disease progression. The importance of $\alpha 7$ integrin in skeletal and cardiac muscle was highlighted here through the generation of the $\alpha 7^{-/-}::$ laminin- $\alpha 2^{-/-}$ double knockout mouse model. This mouse has never been studied before and could prove to be another important mouse model needed to explore therapeutic avenues for muscular dystrophy.

DEDICATION

To my Mum, Dad, Dearest Family and Friends

I will be forever grateful for your continuous love and support.

Thank you with all my heart. I hope that I have made you proud.

Non Providentia Sed Victoria.

ACKNOWLEDGEMENTS

A special thanks to Dr. Dean Burkin for giving me this wonderful opportunity. Notwithstanding, my sponsor Tracy McCausland, founder of Struggle Against Muscular dystrophy (SAM) charity in Northern Ireland for providing me with a fellowship to carry out the research for my dissertation. Tracy's determination to save her son, Sam who currently suffers from MDC1A inspired me to take the challenges regards finding a cure. Throughout the course of my dissertation, I would like to express sincere gratitude to CureCMD and all scientists worldwide for all their commitment and hard work trying to find cures for diseases. My undergraduate students Vivian Cruz, Annemarie Vogedes, and Chelsea Lamb. I would also like to thank Dr Jachinta Rooney whom I had the opportunity to work under for a year when I was an undergraduate and also Dr. Jinger Doe for her unstinting support with my work.

I want to thank my dissertation committee Dr. Sean Ward, Dr. Normand Leblanc, Dr. Subhash Verma and Dr. Josh Baker. I would like to thank Dr. Ward especially for helping me towards the later stages of my PhD. Without you, I would not have been able to have a place to finish my lab work. I will always be grateful to you for giving me the opportunity to arrive at UNR all those years ago for the International Undergraduate research Program (IURP). It was the most exciting time of my life and I am truly indebted to you for helping me in my hour of need in recent times.

Dr. Sang Don Koh offered me very helpful advice a few months ago, science involves passion, pain and perseverance. There are many people I wish to thank and I will try to include everyone in this next paragraph. Please accept my apologies if I have left anyone out as I really do appreciate those who have helped me. Dr. Leonie Corrigan, a big thank you to you for guiding me through CMPP. Yulia Bayguinov and Dr. Sung Jin Hwang for their continuous help within the lab this past year. Also special thanks to Sima, Breeana & Mark, Jolie, Lara & Peter, Caroline, Robert, Jon, Monica, Robyn, Prabath, and Rahul and to everyone who helped provide me with transport in order to go purchase groceries from time to time; I really appreciated it! Queen's University Belfast, Dr. Tom Gardiner whose unstinting encouragement and support inspired me and also Dr. Mihaela Ghita, Dr Guiseppe Schettino and Dr. Kevin Prise, Pro-Vice Chancellor Dr. Patrick Johnston, and Dr. Stephen McCullough. Lab animal medicine especially Dr. Walt Mandeville and his team for their expertise and care of the mice I worked with. Dr. Kent Sanders and Dr Iain Buxton for their constructive and helpful advice. All the physiology and pharmacology administrative staff, Dr. Paul Brewer, and Dr. Andrea Agarwal for echocardiography data analysis. Dr. David Zeh for his time and helpful advice. I would like to thank Dr. Joseph Fass and Dr. Ryan Kim for generating and processing the RNA-Seq data at the UC Davis Genome center. UNR Campus escort service, IT staff, Janitors in the medical school for always being so friendly and providing a clean environment to work in.

Thank you to Kevin Van Ry and Thomas Knapp for their much needed muscle power when I had to move apartments. Office of International Students and Scholars (OISS), my Japanese friends at Intensive English Language center (IELC). My hairdresser Antonio for always being a friendly person. Canteen staff for providing delicious snacks. I would also like to give shout out to the UNR bus drivers especially to Tina and KJ who supported me throughout and became two of my best friends, for always getting me safely to my destination on campus and always with a smile ☺. My medical team for their much needed support through this past year. You are all so wonderful!

Thank you to my Mum, Donna, my Dad, James and my younger sister, Natalie for listening to me and providing support for me on the phone 24/7 no matter what happened throughout the entire course of my PhD. To my extended family, Bernadette, Nicola, Carmela, Jim, Maureen, Stefin, Mary in Co. Donegal Ireland. My American family, Eamonn, Lisa, Liam and Zara for their continued support in San Francisco (and for letting me stay each time I was there!)..... I have some really great memories there with you all and will never forget them.

It only feels like yesterday that I was graduating from Queen's University Belfast. There is one very poignant message that I will never forget from the graduation speech delivered to all the graduants that day. The life message was "Sail away from the great harbor, catch the trade winds in your sails. Dream, Explore and Discover" ~Mark Twain. I aim to follow this approach throughout my life and I hope never to forget that.

UNR has been an amazing journey and I am so glad that I embarked on this adventure. I got to meet some truly inspirational people from all corners of the globe and embrace their cultures whilst I was living, studying and working independently in Reno. As a young girl growing up in Northern Ireland, I honestly never thought that I would be able to visit USA let alone be making a life for myself here 5,000 miles away from my home. It's been an emotional rollercoaster driving me through some very happy and indeed some incredibly dark times. But despite this I am grateful for this life journey that I have experienced. I hope to be able to have many more adventures in the future. Not only did the PhD help me to develop as an academic but also into an independent young woman who is constantly learning. All my friends and family here in USA, United Kingdom and scattered across the world; thanks for keeping in contact with me.

Thank you to my parents for teaching me to always stand up for what is true no matter what the consequence; one essential part of life. I would like to thank everyone who helped me at every stage throughout my PhD journey. Your help was much appreciated. I thank the people of Reno for making me feel so welcome. I will miss you lots but I'll be back to visit one day. Thank you to everyone who believed in me. I am truly grateful.

Sláinte!

Chapter I
Introduction

Muscular Dystrophy

There are many different types of muscular dystrophy which are all caused by genetic defects within the contractile machinery or cell-matrix adhesion components in skeletal muscle¹⁻²³. Despite extensive research over the years, only palliative care is available which proves to be expensive as there is still no cure for these neuromuscular diseases²⁴⁻²⁶.

Myogenesis and Muscle development

Myogenesis happens when the myotome is formed from a portion of somites²⁷⁻³⁰. Muscle development regulates $\alpha 7$ integrin and $\alpha 7\beta 1$ integrin has been shown to participate in the formation of skeletal muscle during development with detection of $\alpha 7\beta 1A$ integrin occurring when myocytes migrate to the peripheral targets from the myotome^{30,31}. Several rounds of proliferation are carried out by muscle precursor cells prior to myoblast fusion to form myofibers^{27,32}. Formation of myofibers happens in two processes, primary and secondary myogenesis. There is alignment of primary myoblasts into rows and their subsequent fusion to form multinucleated cells which are then ensheathed by a basal lamina enriched by laminin^{33,34}. Secondary myoblasts fuse forming binucleate cells and then there is insertion of additional myoblasts along the entire length of the myofiber in order to help elongate the developing muscle cell³⁵. It is thought that the $\alpha 7\beta 1$ integrin helps to home primary myoblasts to regions of myofiber formation and to laminin during development^{27,29,36-38}.

Differentiation happens whenever the muscle cells become quiescent³⁵. Once this occurs, there is an increase in the accumulation of muscle-specific genes and myofiber proteins of the contractile apparatus³⁹. Motor units therefore start to form via differentiation of the dynamic developing cells^{39,40}.

Skeletal muscle

Skeletal muscle is responsible for almost all movements made under voluntary control⁴¹. It is made up of bundles of muscle fibers which are formed when myoblasts fuse into long cylindrical multi-nucleated cells which are held together by connective tissue. Satellite cells are ever present in the periphery of the muscle in order to help regenerate the muscle after damage⁴². The satellite cell supply becomes exhausted whenever there is too much repetitive damage occurring to the muscle and therefore there is a much more exaggerated clinical phenotype in dystrophic patients⁴³⁻⁴⁷.

Sarcolemma

The sarcolemma consists of at least three systems that are able to protect the muscle during the sheer forces of muscle contraction⁴⁸⁻⁵¹. The three systems couple the contractile apparatus to the muscle membrane and surrounding extracellular matrix^{48-52,53}. These complexes form molecular associations with laminin in the basal lamina that surrounds each myofiber to cytoskeletal F-actin within myofibers⁵⁸⁻⁵⁶. The sarcolemmal complexes are known as the dystrophin glycoprotein (DGC) complex, utrophin protein complex and the $\alpha 7\beta 1$ integrin

complex⁴⁸⁻⁵¹ (Figure 1). The $\alpha7\beta1D$ integrin is found to be enriched around costameres where they are thought to be able to facilitate transmission of lateral contractile force⁶²⁻⁶⁸.

$\alpha7\beta1$ integrin

The $\alpha7\beta1$ integrin is a heterodimeric cell surface receptor member of the large family of integrins⁶⁰ (Figure 1). The α chain and β chain are noncovalently linked and integrins in general are evolutionarily conserved^{55,61}. Integrins act as receptors for a variety of cellular components to include, leukocytes, RGD, collagen and laminin⁵⁵. The $\alpha7\beta1$ integrin is prevalent within skeletal, cardiac and vascular smooth muscle. There are many splice variants of $\alpha7\beta1$ integrin that exist. There are 3 intracellular ($\alpha7A$, $\alpha7B$ and $\alpha7C$) and 2 extracellular (X1 and X2) splice variants^{28,62,63,64}. The $\beta1$ integrin possesses variants $\beta1A$ and $\beta1D$, with $\beta1D$ being the major isoform in mature skeletal muscle⁵¹. The $\alpha7\beta1$ integrin complex is elevated in order to compensate for the instability of the dystrophin glycoprotein (DGC) laminin binding complex due to loss of dystrophin in Duchenne Muscular dystrophy (DMD)⁵⁰. $\alpha7$ integrin overexpression is able to rescue the severe dystrophic phenotype of *mdx/utr*^{-/-} mice and improve the viability of these mice⁵¹. MDC1A patients have decreased $\alpha7\beta1$ integrin expression⁶⁵. This integrin is found localized at costameres, myotendinous junctions and neuromuscular junctions^{59,60}.

Dystrophin glycoprotein laminin binding complex

The dystrophin glycoprotein (DGC) complex is found in skeletal, cardiac and vascular smooth muscle (Figure 1). It plays a very important function in providing structural integrity and signaling roles to all of these muscle types, especially skeletal muscle⁶⁶. Laminin in the extracellular matrix binds to this DGC complex⁴⁹. Dystrophin (427 kDa) protein is a major component to this complex and links laminin in the extracellular matrix to cytoskeletal F-actin⁵⁶. The N-terminus binds to actin and the C-terminus of dystrophin associates with β -dystroglycan which is a transmembrane protein and it interacts with α -dystroglycan, the sarcoglycans and sarcospan⁶⁷. α -dystroglycan can bind extracellular matrix components such as laminin, perlecan and agrin⁶⁷. The C-terminus of α -dystroglycan interacts with cytoplasmic proteins to include dystrobrevins and syntrophins¹¹.

Dystrophin plays a structural role within muscle by providing a link between myofibers and the ECM. This structural scaffold helps aid muscle contraction and strength to withstand the sheer mechanical stress associated with normal contraction. Dystrophin is more prevalent around costameres of the sarcolemma, myotendinous junctions and neuromuscular junctions^{68,69}. Signaling pathways become mis-regulated whenever dystrophin is missing which causes weakness within the structure of muscle⁶⁷. Muscular dystrophy arises when there is any loss of DGC protein causing weakness in this link between cytoskeletal F-actin and the extracellular matrix. The DGC proteins are not able to compensate

for the loss of dystrophin which is the main gatekeeper for the entire structure and function of the DGC complex needed for integrity of muscle.

Laminin- α 2

Laminin- α 2 is also produced by Schwann cells in the Peripheral Nervous System (PNS). In MDC1A, the laminin- α 2 deficiency means that the Schwann cells are unable to myelinate the nodes of Ranvier on the nerves. As a consequence, peripheral neuropathy and impaired conduction velocity ensue⁷⁰. Laminin- α 2 is the major laminin chain in the basement membrane of adult skeletal muscle⁷¹. MDC1A is caused by mutations in the laminin- α 2 gene. This laminin- α 2 deficiency has been modeled in mice to include the *dy^W -/-* mouse model which is described and studied in this dissertation. This mouse model is able to emulate the symptoms experienced by MDC1A patients which include muscle weakness, hypotonia from birth and joint contractures at an early age. With these symptoms in mind, this mouse model offers a good baseline to study MDC1A due to its overt phenotype. Two protein complexes rely on this association of laminin- α 2 binding to myofibers^{72,73}. These complexes are known as the dystroglycan and α 7 β 1 integrin. Laminin- α 2 is the major ligand for the α 7 β 1 integrin although it can interact with alternative isoforms of laminin to include laminins α 1, α 4 and α 5 as well as galectin-1 and fibronectin³².

Cardiac muscle

Cardiac muscle is very similar to skeletal muscle as it contains sarcomeres due to precise alignment of actin and myosin filaments, although

cardiac organization is not as regular and only offers involuntary contractions vital to its function. Cardiac muscle is the most extensively used muscle within the body having to contract more than 3×10^9 throughout the life of an average human. Cardiomyocytes express specific isoforms of myosin and actin. Serious heart disease can occur even with very subtle changes in these contractile apparatus proteins. Because of the frequency of repetition in the cardiac muscle, such tiny abnormalities in the contractile apparatus can gradually degrade the heart over time causing serious health defects such as familial hypertrophic cardiomyopathy as a result of 1 of 40 subtle point mutations in genes encoding cardiac β myosin heavy chain or contractile proteins causing cardiac arrhythmias⁷⁴. Dilated cardiomyopathy can also result in heart failure due to minor missense mutations in the cardiac actin gene. These are only a few examples to emphasize how subtle changes can cause detrimental effects^{41,52,75}.

Adherens junctions anchor the actin bundles of the contractile apparatus and act in parallel to desmosome junctions to link the contractile cells end-end. Stained light-microscope sections show these cell-cell adhesions very clearly as they are visible as intercalated discs which are a unique characteristic of cardiac muscle⁷⁶⁻⁷⁸. Action potentials fired along cardiac muscle typically last > 200 msec⁵³ allowing the cardiac muscle to relax during a refractory period before blood filling again whereas many skeletal muscle action potentials are fired typically lasting 1-5 msec.

Laminins

Laminins comprise a large family of heterotrimeric glycoproteins comprised of an α chain, β chain and γ chain. They are highly conserved extracellular matrix proteins throughout evolution⁷⁹. To date, 16 different laminin heterotrimers have been identified with which there are different combinations of 5 α , 2 β and 3 γ chains^{80,51}. The isoforms of laminin have different preferences for their tissue distribution^{80,81}. The α chain is the most variable and dictates binding specificity of the laminin heterotrimer⁸⁰. $\alpha 1$ and $\alpha 5$ chains are important for embryonic development and organogenesis while $\alpha 2$, $\alpha 3$ and $\alpha 4$ are critical for postnatal developmental processes⁸². The basal lamina underlying epithelia, nerve and muscle, is essentially composed of laminins, collagen IV, nidogens, perlecan and agrin⁷¹. Laminins have special functions in creating structural integrity through cell-extracellular matrix adhesions and cell signaling such as tissue proliferation, survival, migration and differentiation⁷¹.

Two major receptors for laminins- 111, 211 and 221 are α -dystroglycan (a member of the dystrophin glycoprotein (DGC) laminin binding complex) and the $\alpha 7 \beta 1$ integrin. α -dystroglycan interacts with laminin- $\alpha 2$ via the G-domain (COOH-terminus)^{71,72}. The polymerization of individual laminin proteins occurs at the N-terminus of laminin. Laminin is a distinct membrane protein which can be separated from collagens and fibronectin in their description⁷².

Muscle contraction and Force transduction

Normal muscle function requires very precise organization of all the contractile machinery within the muscle ultrastructure. The muscle syncytium needs to be able to contract in unison for efficient movement. Skeletal muscle is controlled by the central nervous system (CNS). Each myofiber is innervated by an α motor neuron. The neuromuscular junction forms at a specialized cholinergic synapse at an α neuron called an end-plate. An action potential is produced in a myofiber after neuromuscular transmission^{74,75}. A motor unit comprises of the motor nerve and all the muscle fibers innervated by the nerve. It is described as the functional contractile unit because all the myofibers within a motor unit contract synchronously when the motor unit fires an action potential. Activation of varying numbers of motor units within a muscle is one way in which muscle tension can be controlled^{74,75}.

Acetylcholine released from the motor neuron initiates an action potential < 5 msec in the myofiber that rapidly spreads along the length of the myofiber⁷⁴. The short duration of the skeletal muscle action potential allows very rapid contractions of the myofiber and provides a mechanism by which the force of contraction can be increased. This increasing muscle tension by repetitive stimulation of the muscle is called tetanus⁷⁴. The method by which skeletal muscle contracts is known as excitation-contraction coupling. It is when an action potential is transmitted along the sarcolemma and then into T-tubules, Ca^{2+} is then released from the terminal cisternae sarcoplasmic reticulum (SR) into the myoplasm and binds to Troponin C. This release of Ca^{2+} from the SR raises

intracellular Ca^{2+} which in turn promotes actin-myosin interaction and contraction called a twitch. Relaxation of skeletal muscle occurs as intracellular Ca^{2+} is resequenced by the SR⁷⁴.

The process of skeletal muscle contraction is not only regulated by intracellular calcium but also by the thin filament actin. Once Ca^{2+} released from the SR binds to troponin C there is a movement of tropomyosin initiated towards the cleft of the actin myofilament⁷⁴. This movement exposes the myosin binding site on the actin filament and allows a cross-bridge to generate tension. Troponin C has 4 Ca^{2+} binding sites in total and two of these sites have a high affinity for Ca^{2+} switch their preference to Mg^{2+} at rest. These sites control interactions with troponin I and troponin T. The other two binding sites have a lower affinity for Ca^{2+} but bind Ca^{2+} when it is released from the SR. Tropomyosin gets further shifted due to myosin heads binding to actin filaments. It is thought that one myosin head binding to actin filaments can cause a shift in tropomyosin perhaps exposing myosin binding sites for up to 14 actin molecules⁷⁴.

Actin filaments get moved towards the center of the sarcomere due to ATP-dependent conformational changes of myosin molecule after myosin and actin have bound to each other. Such movement of actin results in sarcomere shortening and therefore contraction of the myofiber. These repetitive movements are known as cross-bridge cycling-sarcomere shortening⁷⁴. The collective term for the entire process is the sliding filament theory because the myosin cross-bridge is pulling the actin thin filament toward the center of the

sarcomere thereby sliding the thin filament past the myosin thick filament⁷⁴. The skeletal muscle syncytium means that each one of these muscle twitches described get amplified into a huge force generation within the muscle which is needed for movement.

Merosin Deficient Congenital Muscular Dystrophy

Merosin deficient congenital muscular dystrophy (MDC1A) is caused by the loss of Laminin-211 and Laminin-221 heterotrimers which are most abundant in skeletal and cardiac muscle basal lamina; mutations in the *LAMA2* gene cause the loss of these Laminin isoforms. This reduction of laminin reduces the capacity for myofiber adhesion, loss of sarcolemmal integrity and subsequently affects the ability of the skeletal muscle syncytium to generate force in a coordinated and efficient manner^{3,5,73,91-87}. Patients, from birth, experience progressive muscle wasting which confines them to a wheelchair at an early age and respiratory failure that leads to their untimely death. Currently, there is still no effective treatment or cure for this devastating disease.

Merosin deficient congenital muscular dystrophy (MDC1A) affects approximately 0.89/100,000 individuals worldwide (1:100,000 - 1:500,000) and is thought to be the most common form of congenital muscular dystrophy affecting 30-40% of all diagnosed CMD cases⁸⁸. Loss of merosin (Laminin- α 2 protein) is caused by mutations occurring in the *LAMA2* gene which is located on chromosome 6q22-23 spanning ~260 kb with 64 exons^{73,89-100}. This loss of Laminin- α 2 protein in MDC1A results in the absence of Laminin-211 and

Laminin-221 heterotrimers which are abundant in skeletal and cardiac muscle basal lamina. Patients, also experience demyelinating neuropathy, muscle atrophy, limited eye movement and also respiratory failure that leads to their untimely death which can be as early as the first decade of life^{88,92-94}. There is an increased likelihood of seizures occurring after six months of age due to changes in white matter of the brain^{97,101-102}. Symptoms depend on where the mutation occurs and a mutation which results in no laminin- α 2 protein being produced will result in a more severe clinical phenotype compared to a mutation which produces a truncated form of laminin- α 2. Currently, there is still no effective treatment or cure for this cruel disease^{24,88}.

Duchenne Muscular Dystrophy

Duchenne Muscular Dystrophy is a genetic disorder that affects the skeletal and cardiac muscle. Duchenne Muscular Dystrophy (DMD) is the most common type of muscular dystrophy in boys⁹⁵. It is an X-linked disorder that affects 1 in every 3,300 live male births. This disorder results from a mutation in the DMD gene which produces three isomers of the protein Dystrophin. Dystrophin is a protein that connects muscle fiber cytoskeleton to surrounding laminin in the extracellular matrix. This connection provides structural integrity during muscle contractions. The failure to produce dystrophin results in the inability for the formation of the dystrophin-laminin binding complex which results in severe muscle weakness⁹⁶. Children with DMD are not able to walk and are wheelchair-bound by their teenage years⁹⁵. The progressive nature of DMD leads

to feeding tube placement, cardiomyopathy, ventilator assistance and results in the untimely death of DMD patients⁹⁷⁻⁹⁸. Although the dystrophin gene has been known for well over 20 years there is still no effective treatment or cure for this disease.

Mouse models

Mdx

The *mdx* mouse model has a point mutation in the dystrophin gene that produces a nonsense codon, resulting in a premature termination of translation and a lack of dystrophin protein^{99,100}. *Mdx* mice have a very different phenotype to DMD patients. The *mdx* mice exhibit a near normal lifespan and the dystrophy phenotype they exhibit is relatively mild compared to that of DMD patients. The *mdx* mouse goes through rounds of muscle degeneration followed by complete regeneration between 3 and 10 weeks of age. After this time-point, muscle degeneration ceases in limb muscles and lack of evidence of scar tissue formation¹¹⁰⁻¹¹¹. Diaphragm muscle harvested from *mdx* mice does however retain muscle pathology throughout its lifetime¹¹²⁻¹¹³. The GRMD dog model recapitulates the disease in DMD patients and is considered the gold standard to mouse muscle pathology and therapeutics¹⁰⁵.

dy^W -/-

The *dy^W -/-* mouse is a knockout mouse model for which there are other models offered. Three other mouse models offer spontaneous mutations to study¹⁰⁶⁻¹¹¹. *dy^W -/-* mice have decreased transcript and protein levels of the $\alpha 7$

integrin chain and the $\beta 1D$ integrin isoform is thought to be responsible for a more differentiated state in $dy^W/-$ mice. Protein levels of $\alpha 7$ integrin are also decreased in laminin- $\alpha 2$ deficient patients. Utrophin, dystrophin and associated proteins remain unchanged in laminin- $\alpha 2$ deficient $dy^W/-$ mice and MDC1A patients^{73,112}. There is significant strain variation noticed across published studies for $dy^W/-$, dy/dy , dy^{2J}/dy^{2J} and $dy3k/-$.

$\alpha 7dy$

The $\alpha 7dy$ double knockout mouse model of both laminin- $\alpha 2$ and $\alpha 7$ integrin talked about in this dissertation is the first known study of its kind for this particular $dy^W/-$ mouse model.

Laminin-111

Isolation and identification of laminin-111 from Engelbreth-Holm Swarm (EHS) mouse sarcoma was the first time that the laminin family was described¹¹³. Laminin-111 ($\alpha 1$, $\beta 1$ and $\gamma 1$) is the predominant laminin isoform during embryonic development and is replaced by laminins 211 and 221 in mature differentiated skeletal muscle^{71,114–116} (Figure 2). This genetic switch from laminin-111 to laminin- $\alpha 2$ occurs at embryonic day 11 in mice and within humans it is at 7 weeks gestation with maximal expression at 21 weeks gestation^{117–119}. The role of embryonic laminin-111 and laminin- $\alpha 2$ is to anchor the myofibers to the basement membrane. Laminin- $\alpha 2$ is highly glycosylated due to post-translational modifications before being secreted by myofibers⁷¹. In MDC1A patients, laminins $\alpha 4$ and $\alpha 5$ are upregulated^{71,120}.

In MDC1A, apoptosis is a common characteristic due to the laminin- α 2 deficient myotubes being unable to anchor myofibers to the extracellular matrix therefore causing instability within the muscle¹³⁰⁻¹²³. *In vitro* studies support this claim due to laminin- α 2 deficient C2C12 myoblasts being unable to form stable myotubes and whenever laminin- α 2 expression is reinstated then myotube stability is returned¹²¹. Laminin- α 2 deficient myotubes are also responsible for decreased regenerative capacity after injury¹²⁴.

Summary

The main hypothesis of this dissertation is that laminin-111 will act as an effective replacement protein therapy for the loss of laminin- α 2 in the *dy*^W*-/-* model of MDC1A and dystrophin in *mdx* model of DMD. Similar to how experimental animals were designed as double knockouts to lack both dystrophin and α 7 integrin (*mdx*/ α 7^{-/-}) and resulted in a more severe phenotype than single knockout animals, a double knockout of both laminin- α 2 and α 7 integrin was created in order to study the full extent to which α 7 integrin plays in laminin- α 2 deficient muscle.

Chapter 2 discusses laminin protein therapy after disease onset. Laminin-111 treatment was effective in reducing percentage (%) muscle fatigue in 8 week old *dy*^W*-/-* mice. Treatment with laminin also helped to improve the overall integrity of the muscle whilst helping to reduce scar tissue formation. This in turn helped to improve activity of these animals post-treatment after disease onset.

Chapter 3 looks at transcriptional changes within diaphragm muscle in a *dy^W*^{-/-} mouse model treated before disease onset. RNA-Seq experiments helped to identify osteoactivin (GPNMB) as a novel biomarker of MDC1A disease progression. Our results also reemphasized the role of Galectin-3 as a biomarker in this disease. Laminin-111 treatment also helped to restore many sarcolemmal proteins and improved muscle function by reducing muscle fibrosis. This study will help pave the way in teasing out the molecular pathways associated with MDC1A disease progression and treatment.

Chapter 4 looks at long term laminin treatment of *mdx* mice. This study basically showed that extensive treatment with laminin-111 had no added benefit compared to short-term treatments in younger mice. The lack of significance in the results for laminin treated animals could reflect the fact that the *mdx* mice have no overt dystrophic phenotype after 10 weeks of age. Repetitive treatment over a period of 1 year was expected to have a positive effect but the data was disappointing and may be explained by receptor desensitization. However, there was elevated EBD uptake and increased kyphosis within PBS treated animals. Laminin treatment helped to reduce muscle hypertrophy at 10 weeks old. Treatment also reduced muscle fatigue experienced and there was an increase in the sarcolemmal protein, β -DG.

Chapter 5 studies the new mouse model α 7 integrin ^{-/-}: laminin- α 2 ^{-/-} double knockout for muscular dystrophy. This study analyzes the effects on skeletal and cardiac muscle with severe kyphosis and atrial flutter/fibrillation

occurring within this new double knockout mouse model¹²⁵⁻¹³⁰. There was also elevated scar tissue deposition within cardiac muscle and embryonic lethality experienced. Laminin- α 2 presence proved to be most critical for prevention of MDC1A disease severity.

Chapter 6 offers conclusions and future directions associated with this work. In summary, this dissertation provides evidence that laminin-111 is beneficial with treatment before disease onset by reducing muscle pathology and increasing functional activity within mice. It is also the first time that the α 7 integrin $-/-$: laminin- α 2 $-/-$ double knockout mouse model has been studied and described for this particular dy^W $-/-$ mouse model.

Figure 1. Main sarcolemmal proteins associated with both the extracellular matrix and intracellular cytoplasm present in each individual myofiber

Diagrammatic representation of skeletal muscle which is magnified in order to show how the skeletal muscle is attached to the bone via tendons. Bundles of myofibers (fascicles) are surrounded by connective tissue called the perimysium, which is in turn enveloped by the epimysium. Individual myofibers are surrounded by connective tissue known as endomysium. At the top of the diagram, there is a schematic diagram highlighting the main sarcolemmal proteins present in each healthy individual myofiber.

Figure 2. Schematic structure of laminin-111 protein

Laminin-111 protein consists of three chains (α 1, β 1, γ 1) that each have their own globular domains. The overall laminin-111 protein shape and coiled-coil domain, contributes to its very distinctive cruciform structure. The base of laminin-111 cruciform provides binding sites for cell surface receptors such as α 7 β 1 integrin and sarcolemmal proteins such as α -dystroglycan.

Chapter II

Laminin-111 protein therapy after disease onset in the *dy^w* mouse model for MDC1A

ABSTRACT

Merosin deficient congenital muscular dystrophy type 1A (MDC1A) is caused by the loss of laminin-211 and laminin-221 heterotrimers which are most abundant in skeletal and cardiac muscle basal lamina; mutations in the LAMA2 gene cause the loss of these laminin isoforms. This absence of laminin-211/221 in MDC1A reduces the capacity for myofiber adhesion, loss of sarcolemmal integrity and subsequently the ability of the skeletal muscle syncytium to generate force in a coordinated and efficient manner. Patients experience progressive muscle wasting which confines them to a wheelchair at an early age and respiratory failure that leads to their untimely death. Currently, there is no effective treatment or cure for this devastating disease.

Previous studies have shown that laminin-111, an embryonic form of laminin, delivered before disease onset can reduce muscle pathology and improve viability in the $dy^{W/-}$ mouse model of MDC1A. These studies suggested that laminin-111 may act to strengthen and reinforce the sarcolemma and provide a protective niche for muscle repair. Since most patients are diagnosed with MDC1A after disease onset, we determined if laminin-111 could be beneficial after disease onset. Our studies suggest $dy^{W/-}$ mice treated with laminin-111 after disease onset show improvement in muscle function and histology. Results from this study along with an understanding of laminin-111 pharmacokinetics will help pave the way in developing this protein as an exciting potential therapeutic for MDC1A patients.

INTRODUCTION

Patients with MDC1A are usually diagnosed after disease onset whenever little children are not able to walk properly and fall over easily. Previous studies have shown that laminin-111, an embryonic form of laminin, delivered before disease onset can reduce muscle pathology and improve viability in the dy^W $-/-$ mouse model of MDC1A¹³¹. These studies suggested that laminin-111 may act to strengthen and reinforce the sarcolemma and provide a protective niche for muscle repair. Because systemic laminin-111 treatment was able to have many beneficial effects before disease onset (previously published)^{131,132}, we therefore carried out this study to investigate whether laminin-111 protein would be able to have the same beneficial effects when treatment was started after disease onset in dy^W $-/-$ mice. This study would be a step towards trying to link what happens at the patient bedside to one of the current accepted mouse models used to study this disease^{124,133}.

MATERIALS AND METHODS

Generation of laminin- α 2 $-/-$ mice

All experiments involving mice were performed under an approved protocol from the University of Nevada, Reno Institutional Animal Care and Use Committee. The dy^W $+/-$ mice were a gift from Eva Engvall via Paul Martin (The Ohio State University, Columbus, OH, USA). Male and female heterozygous mice were bred. In order to genotype mice, genomic DNA was isolated from tail snips

or ear notches using a Wizard SV DNA purification system (Promega, Madison, WI) following manufacturers instructions. To detect the mutation in the laminin- $\alpha 2$ gene, the following primers were used: DYWF (5'-ACTGCCCTTTCTCACCCACCCTT-3'), LAMA2exonR1 (5'-GTTGATGCGCTTGGGAC-3') and Lac/ZR2 (5'-GTCGACGACGACAGTATCGGCCTCAG-3'). PCR conditions were as follows: 95°C for 5 minutes then 33 cycles of 94°C for 20 seconds, 62°C for 30 seconds and 72°C for 45 seconds. After these cycles, then 72°C for 10 minutes. A wild-type band was 250 bp whereas the laminin- $\alpha 2$ targeted allele produced a 480 bp band.

Experimental procedures were performed once mice were 4 weeks of age with weekly weighing until the end of study which was at 8 weeks of age where all mice were subject to *in vivo* experiments. To reduce experimental bias, investigators assessing and quantifying experimental outcomes were blinded to the treatment and control groups.

Animal husbandry

dy^W $-/-$ mice were housed with their wild-type littermates alongside the provision of mashed kibble and access to water. Husbandry and protocols were carried out via IACUC approval. Knockout mice that lost $\geq 20\%$ body weight (g) were euthanized. Pups were genotyped at 10 days old and at the end of each study, the female WT and dy^W $-/-$ mice were euthanized by CO₂ inhalation in accordance with a protocol approved by the University of Nevada, Reno Animal

Care and Use Committee. The diaphragm muscles from these mice were dissected, flash-frozen in liquid nitrogen and stored at -80°C as previously reported by ¹³⁴.

Laminin-111 protein treatments

dy^W $-/-$ mice were intraperitoneally injected with 0.01 mg/g/week of laminin-111 protein (Invitrogen). Laminin-111 was stored at -80°C and thawed slowly at 4°C overnight before use. dy^W $-/-$ mice were intraperitoneally injected (weekly) from 4 weeks old until 8 weeks old.

Experimental Design

4 week old female Wild-type (n=22) and dy^W $-/-$ (n=10) mice systemically treated with (0.01 mg/g/week) EHS mouse laminin-111 until 8 weeks old. Alongside this treatment group dy^W $-/-$ control mice (n=14) were systemically injected with a volume of sterile Phosphate buffered saline (PBS) that equated to such in the laminin-111 treatment group. At 8 weeks of age, PBS and laminin-111 treated dy^W $-/-$ mice were sacrificed following a protocol approved by the Animal Care and Use Committee at the University of Nevada, Reno. Analysis of WT, PBS and laminin-111 treatment groups at 8 weeks of age was planned with the hope of identifying what changes occur within the functional activity and muscle pathology of these animals.

Weights

Weights for all mice of each genotype were recorded on a weekly basis. Softened kibble was provided fresh daily in a petri dish on the bottom of the cage in order to ensure there was no significant weight loss within the mice.

Muscle Strength

Muscle strength assessed at 10 weeks of age using the Chatillon DFE Digital Force Gauge (San Diego Instruments Inc., San Diego, CA). A total of six measurements per mouse were recorded and all results averaged for each group. The mice were analyzed by grasping a horizontal platform with their forelimbs and pulled backwards. The peak tension (grams of force) was recorded on a digital force gauge as mice released their grip.

Functional and activity

Opto-Varimex 4 Activity Meter (Columbus Instruments) offered unbiased data due to the machine possessing lasers that monitor and auto-track the activity of each mouse for a period of 30 minutes.

Plethysmography

Animals were subjected to plethysmography at 8 weeks of age. Animals for each genotype were used. Animals were placed in the plethysmography chamber (unrestrained) and then subjected to increasing doses of aerosolized Acetyl-methacholine (6.25, 12.5, 25, 50 and 100 mg/mL), after an initial time

period to acclimatize in the chamber^{135,136,137}. First mice were exposed to aerosolized PBS to gather baseline data. Experimental values were automatically generated by the pneumograph in the wall of the chamber. FinePointe software (Buxco©) was used to collect all data.

Hematoxylin and Eosin staining

Tibialis Anterior muscle was cryosectioned and 10 µm sections were placed on surgipath microscope slides. Tissue sections were fixed with ice-cold 95 % ethanol for 2 minutes followed by 70 % ethanol for 2 minutes and then re-hydrated in running water for 5 minutes. Gill's hematoxylin (Fisher Scientific, Fair Lawn, NJ) was then used to stain the sections and rinsed in water for 5 minutes. Scott's solution (0.024 M NaHCO₃, 0.17 M MgSO₄) was then applied for 3 minutes and rinsed in water for 5 minutes. Tissue cryosections were then immersed in eosin solution (Sigma-Aldrich, St. Louis, MO) for 2 minutes. Sections were then dehydrated in ice cold 70 % and 95 % ethanol for 30 seconds each, followed by 100 % ethanol for 2 minutes. Xylene was then used to clear the sections for 5 minutes prior to mounting with DepeX mounting medium (Electron Microscopy Services, Washington, PA). Centrally located Nuclei were counted from images composing representative montages for each mouse. Images were assessed at 100 X magnification by bright field microscopy. The number of centrally located nuclei per muscle fiber was determined by counting each image which contributed to myofibers being counted per treatment group. At least 4 animals from each treatment group were analyzed.

Isolation of skeletal muscle

8 week old female wild-type and *dy^W* *-/-* mice were euthanized by CO₂ inhalation in accordance with a protocol approved by the University of Nevada, Reno Animal Care and Use Committee. Muscles from these mice were dissected, flash-frozen in liquid nitrogen and stored at -80°C.

Sirius Red Staining

TA muscle sections were stained with Sirius Red to measure fibrosis in the skeletal muscle tissue. 10 µm cryosections on slides were fixed in 100% ethanol and then hydrated through an alcohol series (95 and 80% ethanol) and rinsed in tap water. The sections were stained with Sirius Red (0.1% in saturated aqueous picric acid solution, Rowley Biochemical Institute, Danvers, MA, USA) for 30 min followed by two washes in acidified water. The sections were dehydrated through an alcohol series, rinsed in xylene and mounted with DEPEX Mounting media (Electron Microscopy Science, Hatfield, PA, USA). Representative montages were captured and analyzed using Axiovision 4.8 software. Montages were assembled using Photoshop and Microsoft Powerpoint. Images were captured at 100 X magnification. Areas of red in the TA were considered fibrotic. Circled fibrotic areas were added together, and any non-fibrotic fibers within the fibrotic area were subtracted from the calculated area. The percentage of muscle fibrosis was quantified in treated and control muscles as a percentage of total TA muscle area. Sirius red slides were also used to measure minimal feret's diameter for mice of all 4 genotypic groups. All muscle

fibers within an entire TA montage were used to determine the minimal feret's diameter.

Statistical Analysis

All averaged data are reported as the mean \pm s.d or as denoted on specific figures as mean \pm SEM. *P*-values of < 0.05 were considered to be statistically significant. One-way or Two-Way ANOVA statistical testing alongside a student *t*-test was used.

RESULTS

Treatment regime and analysis of muscle strength in 8 week old WT, dy^W $^{-/-}$ + PBS and dy^W $^{-/-}$ + mLAM-111 mice

Female dy^W $^{-/-}$ mice were treated from 4 weeks of age with weekly systemic injection of laminin-111 (0.01 mg/g) in Figure 4 A. Littermate control dy^W $^{-/-}$ mice were also injected with the same volume of sterile Phosphate buffered saline (PBS). There was not much difference between PBS or laminin treatment groups with regards forelimb grip strength (Figure 4 B) and stand-up activity (Figure 4 C). There was however a trend towards WT with Percentage (%) forelimb muscle fatigue (Figure 4 D) but overall laminin-111 treatment did not improve muscle performance relative to WT muscle.

Histological Analysis Quantifying Centrally Located Nuclei in 8 week old WT, dy^W $^{-/-}$ + PBS and dy^W $^{-/-}$ + mLAM-111 mice

Representative montages for Tibialis anterior (TA) muscle stained with H & E (Figure 5 A) for each treatment group revealed that laminin-111 treatment did help to halt any further muscle degeneration (Figure 5 A). There was a steep elevation in the Percentage (%) of centrally located nuclei (CLN) (Figure 5 B), this could be a possible halt in degradation or indeed *de novo* muscle formation and these centrally located nuclei represent this muscle fusion of new myotubes. Due to the heterogeneity of the myofiber sizes and the fact that mature skeletal muscle is formed by the fusion of myoblasts into myotubes. Mature skeletal muscle possesses many nuclei along the periphery of each myofiber. Only when there is degeneration or regeneration will nuclei move into the center of each myofiber and in the case of mice, the nuclei will stay there permanently once they have moved into the center.

Fibrotic tissue reduced in 8 week old Tibialis Anterior muscle by laminin-111

Even after disease onset, treatment with laminin-111 helped to halt any further degradative environment of fibrotic scar tissue deposition within $dy^{W/-}$ mice (Figure 6 A). This finding was proven to be statistically significant (Figure 6 B), the PBS treated animals had 12.91 % fibrotic tissue \pm 1.481 % whilst mLAM-111 treated animals had 9.363 % fibrotic tissue \pm 0.9431 %. This was alongside an elevation in the size of myofibers by minimal feret's diameter measurements (Figure 6 C). Minimal feret's diameter is a method for measuring the size of the

myofibers. When comparing PBS and mLAM-111 treated animals their myofiber sizes were $25.67 \mu\text{m} \pm 0.2741 \mu\text{m}$ and $26.92 \mu\text{m} \pm 0.2397 \mu\text{m}$ respectively.

Activity and Function of 8 week old WT, $dy^W/-$ + PBS and $dy^W/-$ + mLAM-111 mice

There was a slight increase with the distance (cm) and speed (cm/sec) with which moved for $dy^W/-$ mice treated with laminin-111 compared to PBS treated $dy^W/-$ mice (Figure 7). WT moved $9937 \text{ cm} \pm 2844.267 \text{ cm}$, PBS treated animals moved $3693.55 \text{ cm} \pm 1877.44 \text{ cm}$ and mLAM-111 treated animals moved $4477 \text{ cm} \pm 234.98 \text{ cm}$. Laminin treatment created a 21.21 % improvement in distance moved compared to PBS treated animals. Laminin treatment also caused a 7 % increase in the speed with which moved by the mice compared to PBS controls.

Respiratory function of 8 week old WT, $dy^W/-$ + PBS and $dy^W/-$ + mLAM-111 mice

Plethysmography analysis of important respiratory parameters in Figure 8 proved to be significant for all three parameters, frequency of breathing, PenH, and TVb when compared to wild-type. However, there was no significant difference between laminin treated and PBS treated $dy^W/-$ mice. Treatment after disease onset was not effective in targeting and importantly relieving a main marker in disease progression.

DISCUSSION

As mentioned at the start, patients with MDC1A are usually diagnosed after disease onset. Because systemic laminin-111 treatment was able to have many beneficial effects before disease onset (previously published)^{131,132}, we carried out this study to investigate whether laminin-111 protein would have the same beneficial effects when treatment was started after disease onset in the *dy^W* *-/-* mice.

This study would be a step towards trying to link what happens at the patient bedside to one of the current mouse models used to study this disease. As with all scientific studies it is important that they correlate to what is currently experienced in the medical field. Our studies suggest *dy^W* *-/-* mice treated with laminin-111 protein after disease onset show improvement in muscle function by reducing the percentage of forelimb muscle fatigue (Figure 4 D) and reduced fibrosis as shown in the histology data presented in Figure 6 A.

Overall laminin-111 protein delivered after disease onset is not as effective as treatment before disease onset. As with any disease there needs to be early detection and treatment before disease progression in order to see a significant beneficial effect. Galectin-1 protein, a modifier in apoptosis and inflammation, has been recently been shown to be beneficial in the treatment of *mdx* mice¹³⁸. Perhaps this galectin-1 protein in combination with laminin-111 protein delivered as a cocktail therapy may prove to be a beneficial avenue of investigation for the treatment of MDC1A. Omgapill has been shown to block

apoptosis which is a primary cell process involved in MDC1A disease progression^{139,140}. An enzyme called GAPDH is heavily involved with apoptosis and omigapill was found to bind directly to GAPDH and blocking its actions therefore preventing the cell death pathway¹⁴¹. Additionally, apoptosis inhibitors and mini-agrin have been proven to be effective in the treatment of congenital muscular dystrophy¹.

Results from this study along with an understanding of laminin-111 pharmacokinetics will help pave the way in developing this protein as an exciting potential therapeutic for MDC1A patients.

ACKNOWLEDGEMENTS

I would like to thank Vivian Cruz and Chelsea Lamb for their technical assistance with histological staining and analysis. Rebecca Evans for genotyping and providing the mice for this study. Dr Cherie Singer for kindly allowing access to the Buxco whole body plethysmography (WBP) system.

Figure 3. Dy^W $-/-$ mice display greatly reduced body size and mass

The dy^W $-/-$ mutant mouse, shown here on the left lacks laminin- $\alpha 2$. Notice the fragility of the mutant mouse (left) compared to the WT mouse (right). Both mice are 8 weeks old.

Figure 4. Treatment regime and analysis of muscle strength in 8 week old WT, $dy^{W-/-}$ + PBS and $dy^{W-/-}$ + mLAM-111 mice

A) Laminin-111 protein was detected in Tibialis Anterior cryosections of 8 week old $dy^{W-/-}$ mice after intraperitoneal treatment. The treatment regime was started

after disease onset with intraperitoneal injection of 0.01 mg/g/week EHS mLAM-111 from 4 weeks old to 8 weeks old. Upon completion of the study, mice were subjected to functional studies and then were sacrificed for immunohistochemical and Western analysis. B) Functional activity was recorded at 8 weeks old to include grip strength. There was no difference in grip strength between mLAM-111 treated and untreated dy^W -/- mice. Significance in grip strength for dy^W -/- mice compared to WT mice was indicated with a p -value <0.001 after Two-way ANOVA was performed.

Figure 4. Treatment regime and analysis of muscle strength

C) Stand-up activity was recorded for a period of 5 minutes. The number of stand-ups accomplished by each 8 week old mouse was noted. There was no statistical significance found between the treatment groups (P -value= 0.8824).

Mean \pm SEM for each treatment group were as follows: PBS (49.63 stand-ups \pm 7.442), mLAM-111 (48.29 stand-ups \pm 4.150). D) Percentage (%) forelimb muscle fatigue was calculated based on the previous grip strength data in Figure 4 B, gathered at 8 weeks of age.

Figure 5. Histological Analysis Quantifying Centrally Located Nuclei

A) Hematoxylin and Eosin staining on 10 μ m 8 week old TA cryosections. Magnification: 100 X, scale bar = 200 μ m. B) Percentage (%) myofibers with centrally located nuclei (CLN) were quantified as CLN are used as a marker of degeneration and regeneration. A *t*-test was performed to compare PBS (42.9 % CLN \pm 2.296 %) treated and mLAM-111 treated animals (49.96 % CLN \pm 2.852

%) and there was no statistical significance with the generated P -value of 0.0749. There was however statistical significance upon One-way *ANOVA* analysis of the 3 treatment groups generating a P -value = 0.0003.

Figure 6. Fibrotic tissue reduced in 8 week old Tibialis Anterior muscle by laminin-111

A) Sirius red staining on 10 μ m TA cryosections was used to calculate percentage (%) of fibrosis. Magnification 100 X, scale bar 200 μ m. B) The PBS

treated animals had 12.91 % fibrotic tissue \pm 1.481 % whilst mLAM-111 treated animals had 9.363 % fibrotic tissue \pm 0.9431 %. The *P*-value generated was 0.0462 using a *t*-test to compare PBS and mLAM-111 treatment groups.

Figure 6. Fibrotic tissue reduced in 8 week old Tibialis Anterior muscle by laminin-111 C) Sirius red stained 10 μm TA cryosections were used to measure minimal feret's diameter (μm). Minimal feret's diameter is a method for measuring the size of the myofibers. When comparing PBS and mLAM-111 treated animals their myofiber sizes were 25.67 μm ± 0.2741 and 26.92 μm ± 0.2397 respectively. The *P*-value was 0.0006 using a *t*-test. Using One-way ANOVA statistical testing for all 3 groups the *P*-value generated was <0.0001.

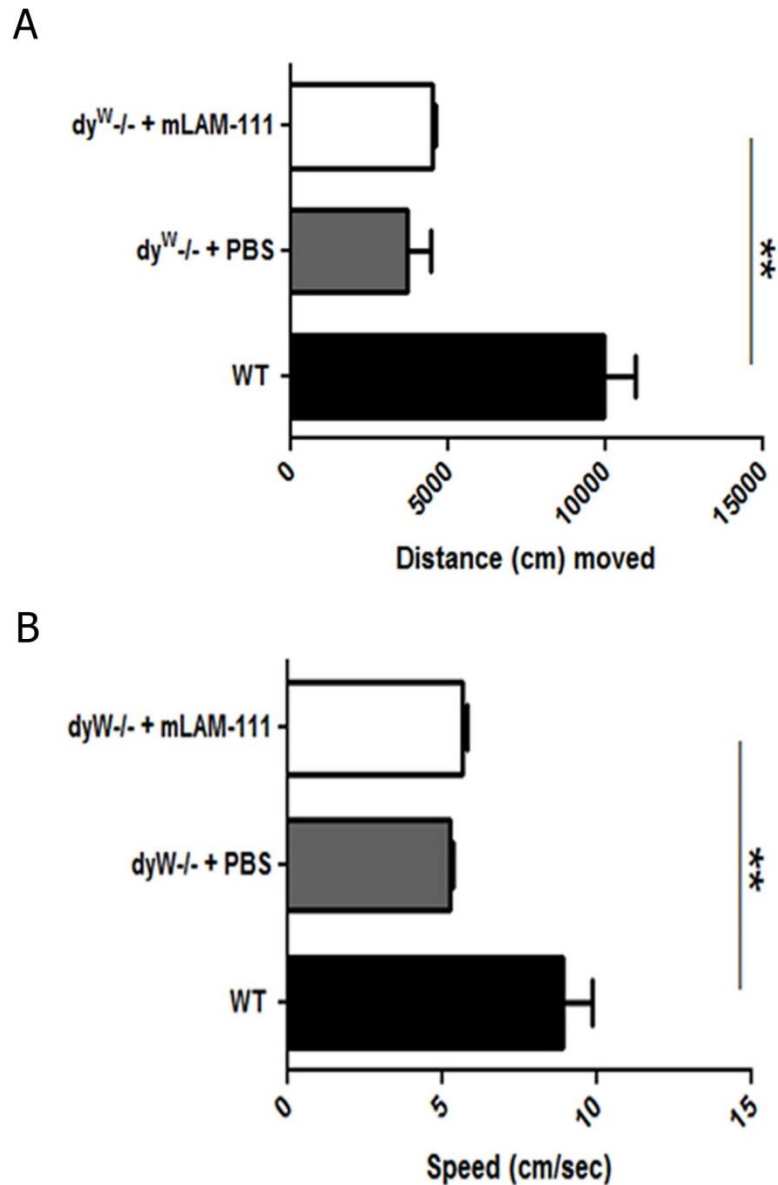

Figure 7. Activity and Function of 8 week old WT, $dy^{W-/-}$ + PBS and $dy^{W-/-}$ + mLAM-111 mice

Activity box data showing distance (cm) (Figure 7 A) and speed (cm/sec) (Figure 7 B) with which the 8 week old mice moved for each treatment group. WT moved 9937 cm \pm 2844.267 cm, PBS treated animals moved 3693.55 cm \pm 1877.44 cm and mLAM-111 treated animals moved 4477 cm \pm 234.98 cm. Laminin treatment

created a 21.21 % improvement in distance moved compared to PBS treated animals. Laminin treatment also caused a 7 % increase in the speed with which moved by the mice compared to PBS controls. *P*-values for both distance (cm) and speed (cm/sec) with which moved comprised of comparing all 3 treatment groups were <0.05 with One-way *ANOVA* and a Bonferroni's Multiple comparison test.

Figure 8. Respiratory function of 8 week old WT, $dy^{W-/-}$ + PBS and $dy^{W-/-}$ + mLAM-111 mice

Plethysmography data are presented here showing important respiratory parameters for 8 week old mice. Frequency of breathing (Figure 8 A), PenH

(Figure 8 B) and Tidal volume (TVb) (Figure 8 C) were recorded and normalized to body weight (g). PenH (enhanced pause) is correlated to but not a direct measurement of airway resistance. There was a 5.1 % decrease in Frequency of breathing, a 2.3 % increase in PenH and a 16.4 % decrease in Tidal volume when treated with laminin-111 compared to PBS treatment. There was no statistical significance between PBS and laminin-111 treated animals but *P*-values were <0.05 with One-way *ANOVA* and a Bonferroni's Multiple comparison test of the 3 treatment groups.

Chapter III

Laminin-111 Treatment Modifies Transcriptional Changes in the Diaphragm

Muscle of a Mouse Model of MDC1A

ABSTRACT

Merosin deficient congenital muscular dystrophy type 1A (MDC1A) is caused by loss of laminin-211 and laminin-221 within the basal lamina of skeletal and cardiac muscle. This absence of laminin-211/221 reduces the capacity for myofiber adhesion resulting in loss of sarcolemmal integrity and subsequently the ability of the skeletal muscle to generate force in a coordinated and efficient manner. Patients experience progressive muscle wasting resulting in loss of ambulation and death from respiratory failure. Currently, there is no effective treatment or cure for this devastating disease. Recently we have shown that laminin-111, an embryonic form of laminin, can act as a protein replacement therapy in the *dy^W* mouse model of MDC1A. This study set out to determine the transcriptional changes that occur within the diaphragm muscle during MDC1A disease progression and after laminin-111 treatment using RNA-Seq technology. Our results show major transcriptional changes with age in pathways associated with immune response, cell growth and survival and muscle repair. Galectin-3 is known to help stabilize myofibers and these transcripts were found to be upregulated (six-fold) in diseased muscle compared to wild-type muscle. Together, this study will help to identify novel therapeutic targets that may be useful in the treatment of MDC1A.

INTRODUCTION

Merosin deficient congenital muscular dystrophy (MDC1A) is caused by the loss of Laminin-211 and Laminin-221 heterotrimers which are most abundant

in skeletal and cardiac muscle basal lamina; mutations in the *LAMA2* gene cause the loss of these laminin isoforms. Laminin-211/221 are critical to muscle integrity and loss of these heterotrimers causes reduced muscle function, ability to repair and myofiber loss. Patients experience progressive muscle wasting from birth which confines them to a wheelchair at an early age and leads to respiratory failure. Currently, there is no effective treatment or cure for this devastating disease.

Merosin deficient congenital muscular dystrophy (MDC1A) affects approximately 0.89/100,000 individuals worldwide (1:100,000 - 1:500,000) and is considered to be one of the most common forms of congenital muscular dystrophy. Loss of merosin (Laminin- α 2 protein) is caused by mutations occurring in the *LAMA2* gene which is located on chromosome 6q22-23^{73,89}. This results in the absence of Laminin-211 and Laminin-221 heterotrimers which are abundant in skeletal and cardiac muscle basal lamina. Patients also experience demyelinating neuropathy, muscle atrophy, limited eye movement and also respiratory failure that leads to their untimely death which can be as early as the first decade of life^{88,92,94}. There is an increased likelihood of seizures occurring after six months of age due to changes in white matter of the brain^{88,92,93}. Recently we have shown that laminin111, an embryonic form of laminin, can act as a protein replacement therapy in a mouse model of MDC1A¹⁴². The presence of laminin-111 prevented muscle disease progression and improves muscle repair^{132,142}. To explore the on-target and off-target activity of laminin-111, we conducted RNA-seq analysis to identify transcript changes in the

diaphragm muscle of dy^W mice. Our results showed 828 transcripts changed significantly in the diaphragm muscle of untreated dy^W animals compared to wild-type mice with 81 transcripts changes that were specific only to laminin-111 treatment. This study identifies transcript changes caused by disease progression in the diaphragm muscle and on- and off-target activity of laminin-111 protein therapy.

MATERIALS AND METHODS

Animal Care and Laminin-111 Treatment Schedule

The $dy^W/-$ mice used in the study were generated by crossing $dy^W+/-$ x $dy^W+/-$ animals. The $dy^W/-$ mice were housed with wild-type littermates under a protocol approved by the Animal Care and Use Committee at the University of Nevada, Reno. Pups were genotyped at 10 days old and genotypes confirmed at the end of the study. In order to genotype mice, genomic DNA was isolated from tail snips or ear notches using a Wizard SV DNA purification system (Promega, Madison, WI) following manufacturers instructions.

To detect the mutation in the laminin- $\alpha 2$ gene, the following primers were used: DYWF (5'-ACTGCCCTTTCTCACCCACCCTT-3'), LAMA2exonR1 (5'-GTTGATGCGCTTGGGAC-3') and Lac/ZR2 (5'-GTCGACGACGACAGTATCGGCCTCAG-3'). PCR conditions were as follows: 95°C for 5 minutes then 33 cycles of 94°C for 20 seconds, 62°C for 30 seconds and 72°C for 45 seconds. After these cycles, then 72°C for 10 minutes. A wild-

type band was 250 bp whereas the laminin- α 2 targeted allele produced a 480 bp band.

Experimental procedures were performed once mice were 10 days and 2 weeks of age with weekly weighing until the end of study which was at 2 weeks and 5 weeks of age where all mice were subject to *in vivo* experiments. To reduce experimental bias, investigators assessing and quantifying experimental outcomes were blinded to the treatment and control groups.

Mice were euthanized by CO₂ inhalation in accordance with a protocol approved by the University of Nevada, Reno Animal Care and Use Committee. Tissues from these mice were dissected, flash-frozen in liquid nitrogen and stored at -80°C as previously reported by ¹³⁴. All mice used in these studies were female.

Two separate experimental mouse groups were included in this study. One experimental data group included wild-type (WT; n=5) and dy^W $-/-$ (n=5) mice which were untreated and sacrificed at 14 days of age. A second experimental data group consisted of mice treated weekly with either Laminin-111 (dy^W $-/-$) or Phosphate buffered Saline (PBS; WT and dy^W $-/-$) from 10 days old until 5 weeks old, at which time mice were sacrificed. Laminin-111 was stored at -80°C and thawed slowly at 4°C overnight before use. Mice were injected intraperitoneally (i.p.) with 0.01 mg/g/week of laminin-111 protein (Invitrogen) or an equal volume of PBS. This experimental group consisted of Laminin-111 treated dy^W $-/-$ (n=5) or PBS-treated WT (n=4) and dy^W $-/-$ (n=4).

Immunofluorescence

TA and gastrocnemius muscles were embedded in Tissue-Tek OCT and 10 µm cryosections were cut using a Leica CM 1850 cryostat (Leica, Wetzlar, Germany). Sections were placed on pre-cleaned Surgipath slides (Surgipath Medical Industries, Richmond, IL) and fixed using 4% paraformaldehyde (PFA). ERK1/2 was detected using a rabbit anti-mouse ERK polyclonal antibody (Cell Signaling, 1:100) followed by a FITC-conjugated goat anti-rat-IgG secondary antibody (1:5000; Li-Cor Biosciences).

Osteoactivin was detected using rabbit anti-osteactivin antibody (AbCAM; 1:100) overnight followed by fluorescein isothiocyanate (FITC)-conjugated anti-rabbit IgG secondary antibody. These slides were also treated with Texas Red labeled wheat germ agglutinin (WGA, 1:250, Molecular Probes, Invitrogen detection technologies, Eugene, OR). Slides were mounted using Vectashield Hard Set with DAPI (Vector Laboratories Inc., Burlingame, CA).

Images were captured using an Olympus FluoviewFV1000 Laser scanning biological confocal microscope using the Olympus micro FV10-ASW 3.1 software. Representative images for publication were taken at 400 X using the Olympus FluoviewFV1000 Laser scanning biological confocal microscope.

Immunoblotting

The TA muscles were carefully dissected and protein extracted using RIPA buffer supplemented with protease inhibitors. Proteins were separated using an 8% SDS-PAGE gel electrophoresis, transferred to nitrocellulose

membrane and blocked using 2.5% Coronation dry milk in TBST for 1 hour. Blots were incubated with primary antibody overnight before being incubated with secondary antibody for 1 hour and then washed with 1X TBST buffer. Proteins were imaged using the LiCor Odyssey system.

RNA-Seq

Diaphragm tissue was homogenized and suspended in TRIzol reagent (GibcoBRL, Life Technologies). Total RNA was isolated following the manufacturer's instructions (Gibco BRL, Life Technologies). The RNA samples were treated with 5 units of DNase I and purified using RNeasy Mini Spin Columns (Qiagen) according to the manufacturer's instructions. Total RNA concentration and purity was assessed by measuring A260/280. RNA was pooled equally for each experimental group (2-week untreated WT, 2-week untreated $dy^{W/-}$, 5-week PBS WT, 5-week PBS $dy^{W/-}$, and 5-week Laminin-111 $dy^{W/-}$) and sent to UC Davis Genome Center (UC Davis Genome Center, 451 Health Sciences Drive, Davis, CA 95616). UC Davis made libraries from the pooled RNA with indexes following Illumina's TruSeq library prep kit and libraries were sequenced for single end 50 bases using Illumina HiSeq2000 following manufacturer's standard procedures. Illumina reads were aligned to the reference using Bowtie 2 with end-trimming enabled and indels penalized with a score equivalent to 3 mismatches. The best alignments were retained for downstream analysis for read counts and variant calls using filtering criteria for polymorphisms that required at least 8 uniquely aligned reads to call the variant

within a given sample, with an average quality of ≥ 20 for bases calling the variant, and having a variant frequency of $\geq 20\%$ within all reads covering that position in that sample. Changes in the transcriptome were compared between disease and control data sets. Excess Total RNA was stored separately at -80°C for later individual qRT-PCR assessment of highly affected transcripts.

Statistical Analysis of RNA-Seq data

Each sample was subjected to alignment and counting of mapped reads. For this, TopHat was used for alignment to the genome, then reads were counted per locus (all isoforms counted together for one gene) using htseq-counts. In order to adjust for large differences in the number of mapped reads in each sample (with the sample with the most reads having more than 6 times as many reads as the sample with the fewest reads), prior to analysis, counts were down-sampled using binomial sampling as described by¹⁴³. Genes with less than 1 count per million reads in all 8 samples were filtered from the counts table, leaving 15,026 genes in the analysis. Differential expression analysis was conducted using the Bioconductor package edgeR, version 3.4.2¹⁴⁴⁻¹⁴⁷. Analysis was conducted using a multifactorial GLM with factors for time, group (WT, PBS treated $dy^{W/-}$ and LAM-111 treated $dy^{W/-}$), and their interaction. This multifactorial method was chosen during analysis as it is considered to be more powerful than running each discrete comparison. Due to the lack of replication, tagwise dispersion parameters were estimated from a multifactorial GLM with factors for time and group but no interaction effect. *P*-values were adjusted for

multiple testing using the false-discovery rate (FDR) method of Benjamini and Hochberg (1995)¹⁴⁸. Log₂-fold changes and FDR-adjusted p-values less than 0.1 for all 15,026 genes included in the analysis.

qRT-PCR

Quantitative Real Time PCR (qRT-PCR) was used to confirm individual mouse changes from cherry picked transcripts identified as altered in the RNA-seq study. Individual mouse diaphragm cDNA was made from previously isolated Total RNA using Superscript III (Invitrogen) following standard procedures. qRT-PCR using SYBR-green PCR mix (VWR) and primers (IDT DNA) against Aggrecan, GPNMB (Osteoactivin), Elane, MMP8, MMP9, BGLAP1, BGLAP2, PRTN3, DMP1, CALCA1, SERCA1, SERCA2, IBSP, LAMA2, Tenascin C, LGALS3, WISP1, and ADAM8 transcript Ct values were normalized to GAPDH (Doe et al.) Ct values in order to establish a fold-difference between treatment groups.

Muscle transcripts

The muscle transcript ontology groups of interest included: Integrin signaling, Inflammation, Fibrosis, Apoptosis (ILK, AKT), Extracellular Matrix signaling, Cell surface receptors and signaling (integrins and dystrophin and utrophin glycoproteins) and Cell Survival pathways (AKT).

Data Analysis

Microsoft Excel and Ingenuity Pathway Analysis (IPA) software were employed in order to visualize the signaling pathways affected within the treatment groups. Protein expression levels were analyzed and processed using GraphPad Prism software. Fold-changes in protein were calculated using changes in intensity within ImageJ software.

RESULTS

Transcriptional changes in the diaphragm muscle of laminin- α 2 deficient Mice

Previous studies have shown laminin-111 can act as a protein replacement therapy for the loss of laminin-211/221. In this study we sort to identify transcriptional changes during disease pathogenesis in the diaphragm muscle of dy^W mice at 2 and 5-weeks of age. Compared to wild-type animals, 2 week old dy^W mice show 138 transcript changes in the diaphragm muscle (Table 5). 27 transcripts were reduced more than 4-fold and 111 transcripts were increased more than 4-fold. These changes include increased transcripts associated with immune response, muscle apoptosis in 2 week old animals and muscle necrosis in 5 week old animals. Of special interest were genes associated with muscle necrosis at 5 weeks old which are involved in creating and recruiting signaling players for a cyclical degradative environment which ultimately destroys muscle.

Laminin-111 alters the transcript profile in dy^W diaphragm muscle

We next compared transcriptome changes caused by normal disease progression with the impact laminin-111 protein therapy has on transcript levels. RNAseq studies revealed 468-specific transcripts in total were altered by laminin-111 treatment (Table 6). 356 transcripts were increased more than 4-fold and 112 transcripts were reduced more than 4-fold. Transcripts associated with bone growth and maintenance, muscle and ECM associated genes. These include tenascin N, elastase, aggrecan, MMP8, MMP9, MMP13, proteinase-3 were significantly altered.

Osteoactivin is increased in laminin- α 2 deficient muscle

Our RNAseq study identified that osteoactivin transcript (GPNMB) is significantly upregulated in the dy^W $-/-$ diaphragm. Osteoactivin is a transmembrane protein that promotes bone formation by increasing the activity of osteoblasts^{149,150}. Osteoactivin can induce transdifferentiation of myoblasts into osteoblasts and has recently been shown to protect muscle from degeneration. That has been reported to be associated with integrins.

Transcriptome data analysis encompassed changes in 5 week old diaphragm tissue harvested from PBS treated dy^W $-/-$ mice versus LAM-111 treated dy^W $-/-$ mice. There were relatively few significant changes (~275 total genes), most genes had little to do with muscle or the extracellular matrix (ECM). However there were many genes found misregulated that were associated with

bone growth and maintenance. Of the few muscle and ECM associated genes found to be significantly altered, were tenascin N, elane (elastase), aggrecan, MMP8, MMP9, MMP13, proteinase-3. There were several genes associated with neuronal signaling that were found to be altered in the disease state. Our results at this age may represent individual disease state changes and not changes specifically associated with Laminin-111 treatment. 5 week old diaphragm from Wild-type versus Untreated $dy^{W/-}$ changes: Over 15,000 genes were significantly altered, current analysis is continuing on the known functions for all genes on the list but one of the most interesting genes that were upregulated in the $dy^{W/-}$ diaphragm is osteoactivin (*GPNMB*).

RNA-Seq summary (WT vs $dy^{W/-}$, 2 week, 5 week and 8 week): sets baseline transcripts

2 week $dy^{W/-}$ transcripts that are upregulated include Ankyrin (*Ankrd1*), Myosin Heavy chain 3 (*Myh3*), Interleukin-8 (*IL-8*), Dyenin (*Dnahc1*), Troponin T type 2 (*Tnnt2*) (Supplemental Table 1). Interleukin 8 and laminin- α 2 transcripts are downregulated. These results are good in offering a baseline view of what happens in $dy^{W/-}$ before disease onset.

2 week \geq 4-fold changes summary

A summary of 138 transcripts misregulated \geq 4-fold between WT and $dy^{W/-}$ at 2 weeks old were narrowed down to 14 transcripts shown in Supplemental Table 2.

5 week \geq 4-fold changes summary

A summary of 169 transcripts misregulated ≥ 4 -fold between dy^W $-/-$ PBS treated and dy^W $-/-$ laminin treated mice at 5 weeks old were narrowed down to 34 transcripts shown in Supplemental Table 3.

RT-PCR results confirming important transcriptional changes in genes associated with the extracellular matrix in 2 week old and 5 week old WT and dy^W $-/-$ + PBS mice

In Figure 9, *LAMA2* transcript was confirmed to be decreased in dy^W $-/-$ mice which is as expected due to the deficiency of laminin- $\alpha 2$. Tenascin C and LGAL3 transcripts were highly elevated in dy^W $-/-$ mice. GPNMB (Osteoactivin) was upregulated consistently within 2 week old dy^W $-/-$ TA and 5 week old TA and Gastroc muscles which supports data provided in Figures 9 - 14.

Immunofluorescence on critical protein changes identified from gene transcripts in TA muscle from 5 week old WT, dy^W $-/-$ + PBS and dy^W $-/-$ + mLAM-111 treated mice

Osteoactivin (GPNMB) protein is also elevated amongst PBS treated dy^W $-/-$ TA muscle and also MDC1A diseased patient tissue. As the disease progresses we have shown the stage where Osteoactivin (OA) becomes misregulated. In normal wild-type muscle, osteoactivin is a type I transmembrane protein which can interact with integrins and other receptors^{149,151}. It is maintained as an intact protein. Loss of laminin-211 causes a transcript increase

osteoactivin transcription, but the protein is cleaved by ADAM12¹⁵²⁻¹⁵⁵ giving rise to two fragments which is previously known. The internal fragments we see in patient muscle are completely osteoactivin positive and often surrounded by fibrotic tissue. The external peptide fragment activates myofibroblasts to secrete MMPs, especially MMP3 (this is known) and pathways (TGF β) that promote fibrosis. When mice are treated with laminin-111, although we do not see a reduced osteoactivin transcript in Figure 10 A, there is a change in protein localization. All the osteoactivin is now back at the membrane (as in wild-type muscle) suggesting it is no longer cleaved. So laminin-111 treatment possibly prevents ADAM12 activity^{152,153} and preserves the intact osteoactivin protein.

Immunoblotting for ERK and phospho-ERK protein

Protein levels of total ERK were decreased for Laminin treated animals, and in addition the levels of phospho-ERK protein steeply increased upon laminin-111 treatment (Figure 11). This data suggests that increased phospho-ERK will restore MAPK signaling and increase survival by laminin-111 treatment.

Immunoblots on critical protein changes identified from transcripts for 5 week old *dy^W*^{-/-} mice

Quantification of changes in protein expression as a direct result of laminin-111 treatment of *dy^W*^{-/-} mice is shown in Figure 12. Statistical analysis via One-way ANOVA showed significance in LAM-111 treated animals relative to

PBS treated animals in α 7A, α 7B and α DG expression with p -values (0.0032, 0.0165, 0.0016) respectively.

RNA-Seq data for $dy^{W/-}$ +PBS vs $dy^{W/-}$ +LAM-111

This data in Supplemental Table 4 presents an overview of gene expression changes discovered for 2 week old $dy^{W/-}$ mice between WT and laminin- α 2 deficient mice. Gene expression changes were tabulated for 5 week old $dy^{W/-}$ mice between PBS treated and mLAM-111 treated groups. 5 week old $dy^{W/-}$ transcripts of interest include: Integrin binding Sialoprotein (Ibsp), Osteocalcin (Bglap), MMP-13 (MMP13), Cartilage Oligomeric Matrix Protein (Fam150b), WNT Inhibitory Factor 1 (Adra1b), Calcitonin (BC089597), Integrin B (Bhmt2), Ficolin (Akr1b7), Interleukin-8 (IL-8) and Vitamin D (Ugt1a5).

RT-PCR results confirming important transcript changes in 5 week old LAM-111 treated $dy^{W/-}$ mice

Presented in Supplemental Table 5, is a comparison of expression changes (MMP8, MMP9, Aggrecan, IBSP and BGLAP2) as disease progresses in treated versus untreated $dy^{W/-}$ genes. This data is good at showing whether the gene expressions changes we observe are global or are they indeed due to one mouse skewing the data.

Histology and functional data obtained from 5 week old dy^{W} mice

Activity box data distance (cm) and speed (cm/sec) with which moved showed that there was more than a trend towards wild-type activity upon laminin-

111 treatment of $dy^{W/-}$ mice (Figure 13). P -values were (0.0221 and 0.0190) respectively with One-way ANOVA. Grip strength displayed as grams of force (g) normalized to body weight (g) was quantified for each treatment group. The results proved to be statistically significant for the comparison of $dy^{W/-}$ mice treated with either PBS or laminin-111. This data showed that laminin treatment improved forelimb muscle strength in $dy^{W/-}$ mice. P -values were (< 0.0001 and 0.05) respectively with Two-way ANOVA. Percentage (%) fatigue was quantified based on grip strength recorded but there was no statistical significance observed with this specific result.

Histology and respiratory function in 5 week old WT, $dy^{W/-}$ + PBS and $dy^{W/-}$ + mLAM-111 treated mice

Sirius red staining of TA cryosections showed visually that there was a reduction in fibrotic area for laminin-111 treated mice compared to PBS treated $dy^{W/-}$ mice (Figure 14 A). Despite this, there was no significance in regards myofiber sizes regardless of the treatment group in question (Figure 14 B). Percentage (%) fibrosis showed a trend towards WT upon laminin-111 treatment. This was statistically significant with One-way ANOVA and p -value of 0.002. Plethysmography data was obtained using the Buxco system (Figure 14 C). Parameters of interest included: Frequency of breathing, Tidal Volume (TVb) and PenH. Each parameter was normalized to body weight (g). There was a significant peak in breath frequency in laminin treated $dy^{W/-}$ mice. P -value was 0.0126 with One-way ANOVA.

Model of Laminin-111 action on Osteoactivin (OA) restoration

A model of Laminin-111 protein action on Osteoactivin restoration is presented in Figure 15. WT muscle possesses intact Osteoactivin (OA) protein. Loss of laminin- α 2 in *dy^W/-* muscle causes increased Osteoactivin transcription but the protein is cleaved into two fragments by ADAM12. The internal fragment is visible in fibrotic patient tissue. The external fragment is free to activate myofibroblasts that secrete matrix metalloproteinases and trigger fibrotic pathways. Treatment with laminin-111 does not affect Osteoactivin transcription but does however change Osteoactivin protein localization. With LAM-111 treatment, Osteoactivin moves back to the sarcolemma like WT therefore suggesting that ADAM12 cleavage is prohibited and there is intact Osteoactivin protein.

DISCUSSION

Merosin deficient congenital muscular dystrophy (MDC1A) is a common congenital muscular dystrophy with an incidence estimated at 0.89/100,000. MDC1A is caused by mutations in the *LAMA2* gene which encodes laminin- α 2 protein. The *LAMA2* gene is located on human chromosome 6q22-23, spans approximately 260kb and is encoded by 64 exons (Helbling-Leclerc et al., 1995; Naom et al., 1997). Loss of laminin- α 2 protein in MDC1A results in the absence of laminin-211/221 (merosin), a major component of the basal lamina, that surrounds skeletal and cardiac muscle. MDC1A patients exhibit severe muscle weakness from birth, demyelinating neuropathy, muscle atrophy and limited eye

movement^{88,92-94,117}. Patients exhibit feeding problems and/or respiratory difficulties and often require the placement of a feeding tube and/or ventilator assistance⁹³. Most MDC1A patients are unable to walk without assistance and are confined to a wheelchair⁸⁸. There is currently no cure or treatment for this devastating muscle wasting disease.

Recently we have shown that EHS derived mouse laminin-111 protein can act as a substitution therapy in laminin- α 2 deficient mice¹⁴². Our studies showed that $dy^W/-$ mice treated with laminin-111 showed reduced muscle pathology, maintained muscle strength and dramatically increased longevity¹⁴². In this study we investigated the transcriptional changes that occur during disease progression within diaphragm muscle of the $dy^W/-$ mouse model of MDC1A. We also examined how treatment with laminin-111 protein altered transcriptional changes in the diaphragm muscle to identify on-target and off-target drug action.

Using RNAseq technology we were able to show that more than 800 transcripts were altered as a result of disease progression in the diaphragm muscle of 2 week old $dy^W/-$ mice. Our studies showed that at 2 weeks of age transcript variability in the diaphragm muscle between animals is low. At 5 weeks of age there is significant variability in transcript abundance in the diaphragm muscle between animals. QRT-PCR data analysis on individual animals revealed the variability observed at 5 weeks of age occurred due to one animal. Laminin-111 treatment reduced the number of transcripts that changed and we identified several specific transcripts that changed as a result of laminin-111 treatment.

An interesting transcript that changed as a result of disease progression was osteoactivin. Osteoactivin is a (*Dchil*) dendritic-cell associated heparin sulphate proteoglycan- dependent integrin ligand^{155,156}. In humans, Osteoactivin is known as the *GPNMB* gene. The osteoactivin gene encodes a protein of 572 amino acids and is localized to the membrane as a Type-1 transmembrane glycoprotein^{151,156}. Osteoactivin is expressed in osteoblasts actively involved in bone matrix production and mineralization. Osteoactivin is also necessary for osteoblast differentiation *in vitro*¹⁵⁰. Syndecan-4 is a receptor on T-cells for Osteoactivin which therefore initiates an inhibitory function on T cell activation¹⁵⁷. Osteoactivin is upregulated in muscle denervation and unloading stress. The regulatory mechanisms of Osteoactivin in muscle and bone have not yet been determined, however the role of Osteoactivin in transdifferentiation of myoblasts into osteoblasts has been alluded to in a published study¹⁴⁹. Interestingly, osteoblast differentiation is characteristically identified by expression of markers which include Osteoactivin (*Gpnmb*) and Osteocalcin (*Bglap*)¹⁵⁸. Transdifferentiation is the manner in which a somatic cell retains plasticity and can be transformed into another somatic cell. This process can also be described as lineage reprogramming. It was first demonstrated whenever mouse embryonic fibroblasts became myoblasts by forced expression of MyoD¹⁵⁹.

Given the transcript and protein level changes in Osteoactivin observed during disease progression in the *dy^W -/-* mouse model, we next wanted to confirm that this occurred on patient muscle. Immunofluorescence for Osteoactivin using muscle from an MDC1A patient and unaffected control

showed that Osteoactivin is normally located in the extracellular matrix in unaffected muscle, but in the MDC1A muscle it is localized within the muscle cells. This may cause misregulation of MAPK signaling (and potentially activation of TGF-beta and fibrotic pathways) in muscle cells. Although laminin-111 treatment did not change transcript levels, treatment in mice appears to restore normal localization of Osteoactivin in skeletal muscle and therefore would potentially restore MAPK signaling in muscle and prevent further fibrosis.

In this study we show that loss of laminin-211/221 in the diaphragm muscle of mice results in a large number of transcript changes that may serve as markers for disease progression and to report the efficacy of potential therapies. At early stages of muscle disease, the transcriptome changes are relatively uniform, however as disease progresses there is increasing variation in transcript abundance between individuals. Laminin-111 treatment results in changes in transcripts that are mis-regulated in dystrophic muscle and in addition restores that localization of proteins in which may negatively impact muscle integrity and survival. These studies identify potential new markers to track disease progression in MDC1A. In addition we identify on- and off-target activity for laminin-111 protein therapy and potential new therapeutic targets that may be useful in the treatment of MDC1A.

The aim of this study was to identify transcriptional changes within diaphragm muscle for the MDC1A mouse model compared to wild type controls. Muscle contraction causes acute damage to the integrity of the sarcolemma within healthy skeletal muscle resulting in myofiber rupture that releases many

susceptible candidates for immune targeting. This process may be aberrantly activated in the progressive disease state of Laminin- α 2 deficient skeletal muscle resulting in chronic injury with the prolonged release of many intracellular molecules including proinflammatory cytokines, growth factors and cytosolic calcium which is directly involved in the activation and recruitment of T-lymphocytes facilitating a positive feedback mechanism for further myofiber contraction, rupture, apoptosis and fibrotic scar tissue formation. It is unclear from past and current studies what exact role or what key immune players have in the pathophysiology of MDC1A. Treatment with Laminin-111 (found embryonically) reduces muscle pathology and improves viability in the $dy^{W/-}$ -MDC1A mouse model. Laminin-111 helps to strengthen and reinforce the sarcolemma in the $dy^{W/-}$ mouse during prolonged progressive muscle injury induced by contraction offering a protective niche against the occurrence of this degenerative scenario by reducing inflammation, fibrosis and apoptosis via improved matrix-mechanotransduction.

At 2 weeks of age the variability between animals is low and the RNA-Seq data appears uniform. At 5 weeks of age there is significant variability between mice and the RNA-Seq data requires more interpretation. The changes observed in some of the transcripts were the result of only one mouse in the 5 week study. RT-PCR data analysis confirms this result. Osteoactivin is involved in differentiation of skeletal and muscle tissue and may serve as a novel biomarker for disease progression. RT-PCR confirmed that it is increased in mice and also now in an MDC1A patient muscle that we have in our tissue archive.

Laminin-111 is the predominant Laminin isoform found in the basal lamina of developing embryonic skeletal muscle ¹¹⁵. However in adult skeletal and cardiac muscle Laminin-111 is replaced by Laminin-211 and Laminin-221 isoforms which help to anchor myofibers to the basement membrane and form neuromuscular junctions ^{116,160}. Laminin- α 2 protein is an essential component of the basal lamina that surrounds muscle fibers and is composed of α , β , and γ heterotrimers ¹⁶¹. MDC1A is caused by the loss of Laminin- α 2 protein. Regeneration of Laminin- α 2 deficient muscle is also dependent on the presence of Laminin ^{124,162}. Molecules that reinforce muscle-basal lamina interactions and restore normal survival signaling pathways are likely candidates for drug-based therapeutics for MDC1A.

Laminin-111 can be systemically delivered to all major muscles affected in MDC1A patients helping to enhance muscle integrity and addresses the primary defect of cellular adhesion in MDC1A. Laminin-111 is unlikely to elicit an immune response since it is naturally expressed during embryonic development and in the adult kidney basement membrane ¹⁴². Treatment with Laminin-111 has been shown recently to reduce muscle pathology and improve viability in the ($dy^{W/-}$) MDC1A mouse model ¹³¹. In one such study, Evan's Blue Dye uptake was used to examine the integrity of the sarcolemma and Laminin-111 treatment had beneficial effects in Laminin- α 2 deficient muscle by causing a 7.3-fold reduction in sarcolemmal rupture. The α 7 β 1 integrin is the major Laminin-binding integrin in cardiac and skeletal muscle ¹⁶³. MDC1A patients and $dy^{W/-}$ mice have reduced levels of α 7 integrin contributing to severe muscle pathology ¹⁶⁰ Laminin-111 has

been shown to increase $\alpha 7$ integrin expression in mouse and human muscle cells

164

Immunofluorescence for Osteoactivin using muscle from an MDC1A patient and unaffected control showed that Osteoactivin is normally located in the ECM in unaffected muscle, but in the MDC1A muscle it is localized within the muscle cells. This may cause misregulation of MAPK signaling (and potentially activation of TGF-beta and fibrotic pathways) in muscle cells. Laminin-111 treatment in mice appears to block Osteoactivin expression and therefore would potentially restore MAPK signaling in muscle and prevent further fibrosis. The immunofluorescence data confirms in patients the mouse RNA-Seq data and RT-PCR studies.

ACKNOWLEDGEMENTS

Dr. Ryan Wuebbles for assistance with RNA-Seq and qRT-PCR studies. I would like to thank Dr. Joseph Fass and Dr. Ryan Kim for generating and processing the RNA-Seq data at the UC Davis Genome center. I would also like to thank Dr. Paul Brewer for kindly performing the ERK immunoblots and Rebecca Evans for genotyping the $dy^W/-$ mice.

TA

Fig 10. Immunofluorescence on critical protein changes identified from gene transcripts in TA muscle from 5 week old WT, $dy^{W/-}$ + PBS and $dy^{W/-}$ + mLAM-111 treated mice

A) Osteoactivin protein detection in 10 μ m TA cryosections shown in red. Wheat-germ Agglutinin (WGA) shown in green was used to outline the myofibers. Scale bar =100 μ m Magnification = 400 X. PBS treated $dy^{W/-}$ muscle showed elevated Osteoactivin and an increase in the localization of Osteoactivin protein within the myofibers suggesting that the Osteoactivin protein is cleaved and able to enter the ruptured myofibers. Laminin-111 treated muscle showed that the sarcolemma

is stabilized and therefore osteoactivin is unable to enter the myofibers and is located around the periphery of the myofibers.

Fig 10. Immunofluorescence on critical protein changes identified from gene transcripts in TA muscle from 5 week old WT, $dy^{W/-}$ + PBS and $dy^{W/-}$ + mLAM-111 treated mice

B) Osteoactivin protein detection in 10 μ m TA cryosections shown in red. Wheat-germ Agglutinin (WGA) shown in green was used to outline the myofibers. Scale bar = 200 μ m and Magnification = 100 X. PBS treated $dy^{W/-}$ muscle showed elevated Osteoactivin and an increase in the localization of Osteoactivin protein within the myofibers suggesting that the Osteoactivin protein is cleaved and able to enter the ruptured myofibers. These micrographs are at a smaller

magnification of the same tissue shown at a higher magnification in Figure 10 A

i).

Model for the action of osteoactivin in dystrophic muscle

Fig 10. Immunofluorescence on critical protein changes identified from gene transcripts in TA muscle from 5 week old WT, $dy^{W-/-}$ + PBS and $dy^{W-/-}$ + mLAM-111 treated mice

D) Levels of Osteoactivin protein in human skeletal muscle tissue are similar to the levels of osteoactivin in $dy^{W/-}$ mouse tissue in Figure 10 A. Elevation of intracellular osteoactivin in diseased muscle compared to WT muscle. E) Schematic model of MDC1A disease progression showing the stage where Osteoactivin (OA) protein becomes misregulated. In WT muscle osteoactivin protein is intact and located as a transmembrane protein. However, in dystrophic muscle osteoactivin is subject to cleavage by ADAM12 and is split into two pieces. The intracellular osteoactivin component is detected by immunofluorescence in dystrophic muscle (Figure 10 A) and the extracellular component is able to participate in cell signaling and recruit fibroblasts via the ERK1/2 pathway and recruitment of matrix metalloproteinases. Figures 10 D & E were kindly provided by Dr. Dean Burkin and Dr. Ryan Wuebbles.

Figure 11. Immunoblotting for ERK and phospho-ERK protein

A) Immunoblots showing that laminin-111 treatment causes a decrease in total ERK protein and a corresponding elevation in phosphorylated-ERK protein when compared to PBS treated animals. B) Quantification of the immunoblots shown in Figure 11 A. The data and figure were kindly provided by Dr. Paul Brewer.

Figure 12. Immunoblots on critical protein changes identified from transcripts for 5 week old $dy^{W/-}$ mice

A) Representative immunoblots for 5 week old $dy^{W/-}$ TA muscle. B) Quantification of changes in protein expression. Statistical analysis via One-way

ANOVA showed significance in $\alpha 7A$, $\alpha 7B$ and αDG expression with p -values (0.0032, 0.0165, 0.0016) respectively.

A

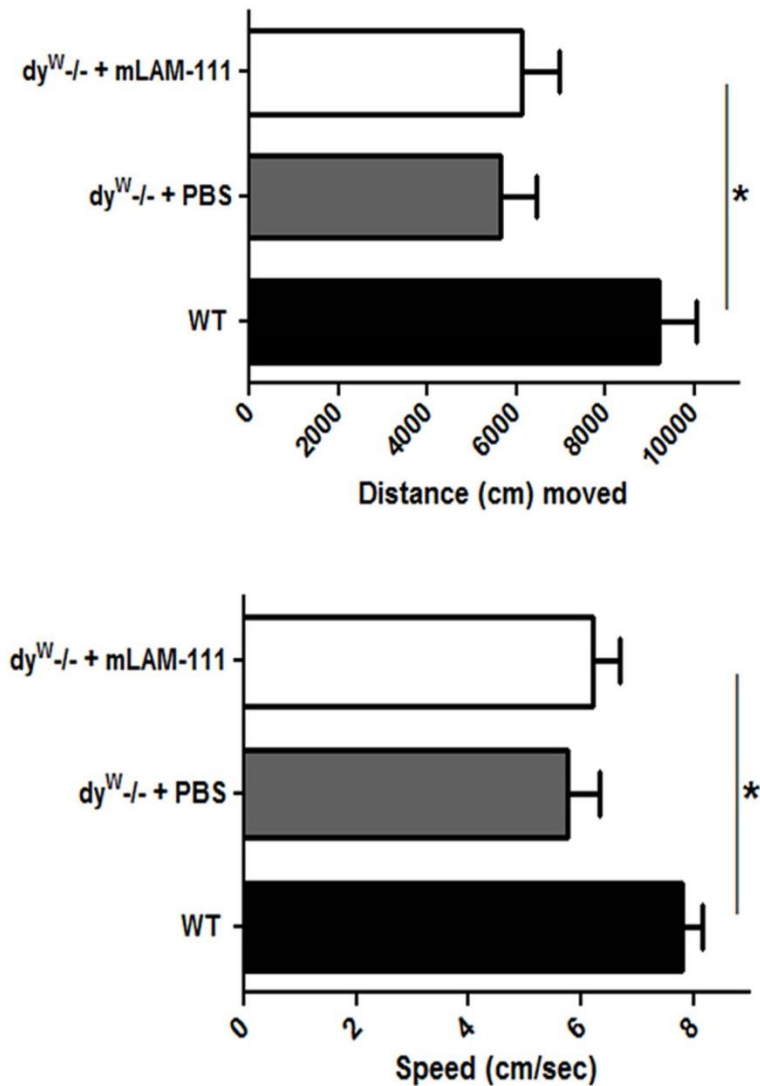

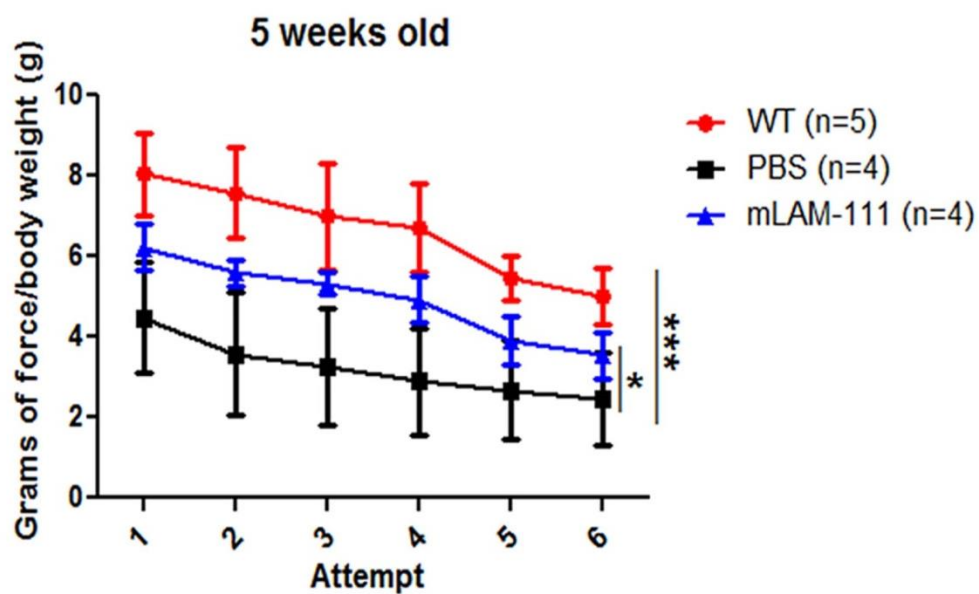

Figure 13. Histology and functional data obtained from 5 week old $dy^{W/-}$ mice

A) Activity box data was recorded for distance (cm) and speed (cm/sec) with which moved. WT animals moved an average of 9217.2 cm \pm 1866.79 cm, PBS treated animals moved an average of 5631.25 cm \pm 1646.27 cm and mLAM-111 treated animals moved an average of 6128.75 cm \pm 1664.51 cm. Laminin-111 treatment was able to improve the speed with which moved when compared to

PBS treated animals by 7.7 %. *P*-values were (0.0221 and 0.0190) respectively with One-way ANOVA.

B

C

Figure 13. Histology and functional data obtained from 5 week old dy^W mice

B) Grip strength displayed as grams of force (g) normalized to body weight (g) was quantified for each treatment group. P -values were (< 0.0001 and 0.05)

respectively with Two-way *ANOVA*. C) Percentage (%) fatigue was quantified based on grip strength recorded in Figure 13 B and there was no statistical significance found meaning that there was no difference in how fast forelimb muscle fatigued in either PBS or laminin-111 treated animals.

A i.

A ii.

Figure 14. Histology and respiratory function in 5 week old WT, $dy^{W/-}$ + PBS and $dy^{W/-}$ + mLAM-111 treated mice

A) i) Representative montages of 10 μ m TA cryosections stained with Sirius Red. Sirius red staining is used as a measure of fibrosis and is indicated with increased red color. Magnification = 100 X and scale bar = 200 μ m. There is increased fibrotic tissue present within the PBS treatment group. Laminin-111 treatment helps to prevent this fibrotic environment. ii) Percentage (%) fibrosis for the Sirius red montages in Figure 14 A i were calculated. One-Way ANOVA showed statistical significance.

B

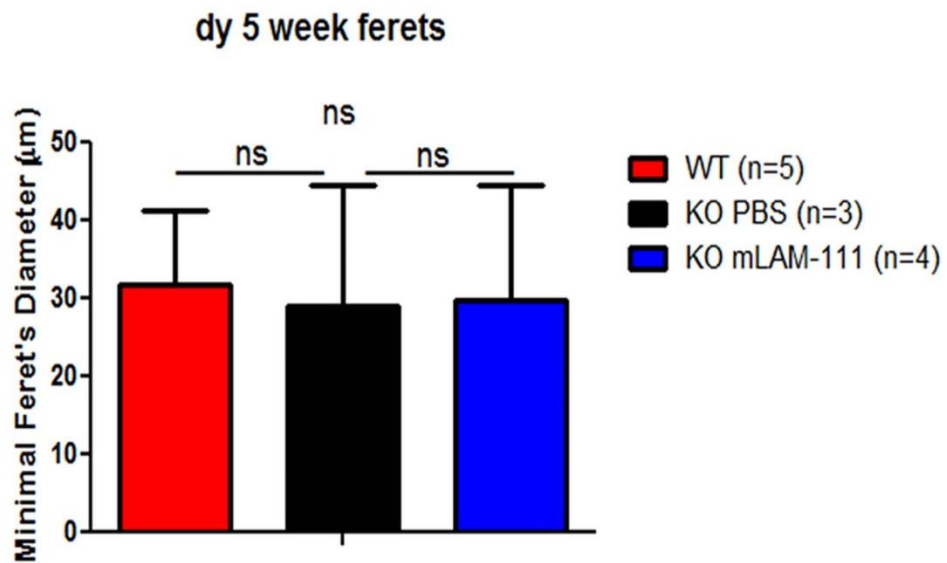

Figure 14. Histology and respiratory function in 5 week old WT, $dy^{W/-}$ + PBS and $dy^{W/-}$ + mLAM-111 treated mice

B) Minimal feret's diameter (μm) is a measure of myofiber size and was calculated for TA cryosections for each treatment group. No statistical significance was found.

Figure 14. Histology and respiratory function in 5 week old WT, $dy^{W/-}$ + PBS and $dy^{W/-}$ + mLAM-111 treated mice

C) Plethysmography data obtained using the Buxco Whole Body Plethysmography (WBP) system. Parameters of interest included: Frequency of breathing, Tidal Volume (TVb) and PenH. PenH (enhanced pause) is correlated to but not a direct measurement of airway resistance. Each parameter was normalized to body weight (g). *P*-value was 0.0126 with One-way ANOVA.

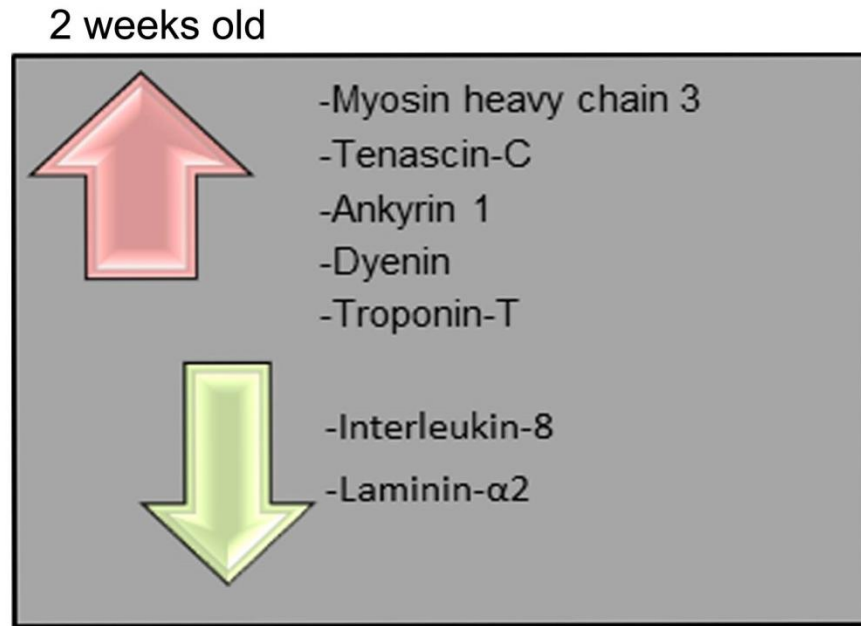

Figure 15. Model of Laminin-111 action on Osteoactivin (OA) restoration

WT muscle possesses intact osteoactivin (OA) protein. Loss of laminin- $\alpha 2$ in $dy^{W-/-}$ muscle causes increased OA transcription but the protein is cleaved into two fragments by ADAM12. The internal fragment is visible in fibrotic patient tissue. The external fragment is free to activate myofibroblasts that secrete matrix metalloproteinases and trigger fibrotic pathways. Treatment with laminin-111 does not affect OA transcription but does however change OA protein localization. With LAM-111 treatment, OA moves back to the sarcolemma like

WT therefore suggesting that ADAM12 cleavage is prohibited and there is intact OA protein. The data and figure were kindly provided by Dr. Ryan Wuebbles.

Supplemental Table 1: RNA-Seq baseline transcript summary for WT vs $dy^{W/-}$ 2 week old animals

Transcripts found to be upregulated in 2 week old $dy^{W/-}$ mice include: Ankyrin (Ankrd1), Myosin Heavy chain 3 (Myh3), Dyenin (Dnahc1), Troponin T type 2 (Tnnt2). Interleukin-8 (IL-8) was found to be down-regulated as was laminin- α 2.

	2 week Down-regulated 4-fold
Il8	Interleukin-8 important mediator of the innate immune response
Lama2	Laminin- α 2
	2 week up-regulated 4-fold
Stx11	Syntaxin 11 SNARE that acts to regulate protein transport between late endosomes and the trans-Golgi network
Card14	Caspase Recruitment Domain Family, Member 14 Plays a role in signaling mediated by TRAF2, TRAF3 and TRAF6 and protects cells against apoptosis. Activates NF-kappa-B via BCL10 and IKK. Stimulates the phosphorylation of BCL10
Ankrd1	Ankyrin Repeat Domain 1 (Cardiac Muscle) May play an important role in endothelial cell activation. May act as a nuclear transcription factor that negatively regulates the expression of cardiac genes. Induction seems to be correlated with apoptotic cell death in hepatoma cells
Lgals3	Lectin, Galactoside-Binding, Soluble, 3 Involved in acute inflammatory responses including neutrophil activation and adhesion, chemoattraction of monocytes macrophages, opsonization of apoptotic neutrophils, and activation of mast cells
Tnc	Tenascin C Extracellular matrix protein implicated in guidance of migrating neurons as well as axons during development, synaptic plasticity as well as neuronal regeneration. Promotes neurite outgrowth from cortical neurons grown on a monolayer of astrocytes. Ligand for integrins alpha-8/beta-1, alpha-9/beta-1, alpha-V/beta-3 and alpha-V/beta-6
Myh3	Myosin, Heavy Chain 6, Cardiac Muscle, Alpha Muscle contraction
Tlr13	Toll-Like Receptor 3 Toll-like receptors (TLRs) are single transmembrane cell-surface receptors, which have a key role in the innate immune system.
Myl7	Myosin, Light Chain 7, Regulatory mediates plus-ended movement along microfilaments. It is involved in muscle contraction through cyclic interactions with actin-rich thin filaments, creating a contractile force. It is regulated by phosphorylation via myosin light chain kinase (MLCK) and by intracellular Ca ²⁺ concentrations.
Tnnt2	Troponin T Type 2 (Cardiac) Troponin T is the tropomyosin-binding subunit of troponin, the thin filament regulatory complex which confers calcium-sensitivity to striated muscle actomyosin ATPase activity
Timp1	Tissue inhibitor metalloproteinases
Myl4	Myosin, Light Chain 4, Alkali; Atrial, Embryonic Regulatory light chain of myosin. Does not bind calcium
Dnahc1	Dynein, Axonemal, Heavy Chain 1 Force generating protein of respiratory cilia. Produces force towards the minus ends of

	microtubules. Dynein has ATPase activity; the force-producing power stroke is thought to occur on release of ADP. Involved in sperm motility; implicated in sperm flagellar assembly (By similarity)
--	--

Supplemental Table 2: Summary of 2 week old ≥ 4 -fold transcriptional changes in WT and untreated $dy^{W/-}$ mice

A total of 138 transcripts found to be up- or down- regulated ≥ 4 -fold in 2 week old $dy^{W/-}$ mice were narrowed down to 14 transcripts of interest in this table.

	5 week Down-regulated 4-fold
Ibsp	integrin binding sialoprotein cell to matrix interaction espcecially bone
Bglap	Osteocalcin Bone Gamma-Carboxyglutamate (Gla) Protein bone building
Dmp1	Dentin Matrix Acidic Phosphoprotein 1
Tnn	Tenascin N neuron outgrowth and cell migration
Mmp13	Matrix metalloproteinase 8 are zinc-dependent endopeptidases that are the major proteases involved in ECM degradation.
Fam150b	cartilage oligomeric matrix protein play a role in structural integrity of cartilage via its interaction with othere extracellular matrix proteins such as collagens and fibronectin.
Galnt3	Baculoviral IAP Repeat Containing 5 dual roles in promoting cell proliferation and preventing apoptosis.
Mmp8	Matrix Metallopeptidase 3 (Stromelysin 1, Progelatinase) Can degrade fibronectin, laminin, gelatins of type I, II, IV, and V; collagens III, IV, X, and IX, and cartilage proteoglycans. Activates procollagenase
Irf4	Myosin, Heavy Chain 6, Cardiac Muscle, Alpha Muscle contraction
Pax5	Alanine--Glyoxylate Aminotransferase 2 ADMA is a potent inhibitor of nitric-oxide (NO) synthase, and this activity provides mechanism through which the kidney regulates blood pressure
	5 week up-regulated 4-fold
Adra1b	WNT Inhibitory Factor 1 Binds to WNT proteins and inhibits their activities
Mettl7b	Spectrin, Alpha, Erythrocytic 1 (Elliptocytosis 2) Spectrin is the major constituent of the cytoskeletal network underlying the erythrocyte plasma membrane. It associates with band 4.1 and actin to form the cytoskeletal superstructure of the erythrocyte plasma membrane
1810053B23Rik	Tenascin N neuron outgrowth and cell migration
Cyp4f15	Desmoglein 11 Component of intercellular desmosome junctions. Involved in the interaction of plaque proteins and intermediate filaments mediating cell-cell adhesion
Tm6sf2	carbonic anhydrase 3 slow twitch skeletal muscle and myogenesis
Aspg	WNT outside to inside cell signaling

Pax7	PAx7 Secreted Phosphoprotein 2, 24kDa Could coordinate an aspect of bone turnover (By similarity)
Itih1	Myosin, Light Chain 7, Regulatory mediates plus-ended movement along microfilaments. It is involved in muscle contraction through cyclic interactions with actin-rich thin filaments, creating a contractile force. It is regulated by phosphorylation via myosin light chain kinase (MLCK) and by intracellular Ca ²⁺ concentrations.
Ugt2a3	Paired Box 7 Transcription factor playing a role in myogenesis through regulation of muscle precursor cells proliferation (By similarity)
Lect2	EGF-Like Repeats And Discoidin I-Like Domains 3 Promotes adhesion of endothelial cells through interaction with the alpha-v/beta-3 integrin receptor. Inhibits formation of vascular-like structures. May be involved in regulation of vascular morphogenesis of remodeling in embryonic development
BC089597	Calcitonin acts to reduce blood calcium
Nr1i2	vitronectin Vitronectin is a cell adhesion and spreading factor found in serum and tissues. Vitronectin interact with glycosaminoglycans and proteoglycans. Is recognized by certain members of the integrin family and serves as a cell-to-substrate adhesion molecule. Inhibitor of the membrane-damaging effect of the terminal cytolytic complement pathway
Cyp3a13	claudins are found at tight junctions as a physical barrier and known for maintaining cell polarity and signal transductions
Abcg8	Osteocalcin Bone Gamma-Carboxyglutamate (Gla) Protein bone building
Fbp1	desmoglein 2 Component of intercellular desmosome junctions. Involved in the interaction of plaque proteins and intermediate filaments mediating cell-cell adhesion
Bhmt2	integrin b cell adhesion cell to matrix adhesion
0610005C13Rik	integrin binding sialoprotein cell to matrix interaction especially bone
Akr1b7	ficolin B marks apoptotic and necrotic cells
Etnk2	Monocyte to macrophage differentiation associated 2 key player in muscular dystrophy
Agxt	Synaptotagmin I regulatory role in the membrane interactions during trafficking of synaptic vesicles at the active zone of the synapse.
0610031O16Rik	Osteocalcin Bone Gamma-Carboxyglutamate (Gla) Protein bone building
2810459M11Rik	aggrecan proteoglycan in ECM aims to resist compression in cartilage
Ugt1a5	Vitamin D (1,25- Dihydroxyvitamin D3) Receptor Plays a

	central role in calcium homeostasis
Il8	Interleukin-8 important mediator of the innate immune response

Supplemental Table 3: Summary of 5 week old ≥ 4 -fold transcriptional changes in PBS treated versus LAM-111 treated $dy^{W/-}$ mice

A total of 468 transcripts found to be up- or down- regulated ≥ 4 -fold in 5 week old laminin-111 treated $dy^{W/-}$ mice were narrowed down to 34 transcripts of interest in this table.

Chapter IV

Long term Laminin-111 protein therapy within the *mdx* mouse model for Duchenne muscular dystrophy

ABSTRACT

Duchenne Muscular Dystrophy (DMD) is the most common X-linked disease affecting 1 in 3,500 live male births. Patients with DMD suffer from severe, progressive muscle wasting and weakness with clinical symptoms first detected between 2 to 5 years of age; as the disease progresses patients are confined to a wheelchair in their teens and die in their early 20s mainly due to cardiopulmonary complications. DMD is caused by the loss of the sarcolemmal protein dystrophin (427kDa) due to mutations in the dystrophin gene. When present, dystrophin acts as a scaffold linking the cell cytoskeleton to the extracellular matrix. This loss of dystrophin in DMD results in patients experiencing greater susceptibility to muscle damage via reduced structural and functional integrity of their muscle. One potential therapeutic avenue that needs to be explored involves increasing the levels of the $\alpha7\beta1$ integrin in order to compensate for the loss of dystrophin. To test this hypothesis, a muscle cell-based assay was developed in order to report $\alpha7$ integrin promoter activity with the intent of identifying molecules that promote $\alpha7$ integrin expression. Theoretically, the identification of $\alpha7$ integrin enhancing compounds that help boost $\alpha7\beta1$ integrin expression as part of drug-based therapies may lead to a novel therapeutic approach for the treatment of this disease.

INTRODUCTION

Duchenne Muscular Dystrophy is a genetic disorder that affects the skeletal and cardiac muscle. Duchenne Muscular Dystrophy (DMD) is the most common type of muscular dystrophy in boys⁹⁵. It is an X-linked disorder that affects 1 in every 3,300 live male births¹⁶⁵. This disorder results from a mutation in the DMD gene which produces three isomers of the protein Dystrophin¹⁶⁶. Dystrophin is a protein that connects muscle fiber cytoskeleton to surrounding laminin in the extracellular matrix¹⁶¹. This connection provides structural integrity during muscle contractions. The failure to produce dystrophin results in the inability for the formation of the dystrophin-laminin binding complex which results in severe muscle weakness¹⁶⁷. Children with DMD are not able to walk and are wheelchair-bound by their teenage years⁹⁵. The progressive nature of DMD leads to feeding tube placement, ventilator assistance and results in the untimely death of DMD patients. Although the dystrophin gene has been known for well over 20 years there is still no effective treatment or cure for this disease¹⁶⁵.

Treatment with Engelbreth-Holm Swarm (EHS) laminin (found embryonically has been shown recently in the Burkin lab to reduce muscle pathology and improve viability before disease onset in the *mdx* mouse model¹⁶². The *mdx* mouse model has a mutation in the dystrophin gene. It is the ideal mouse model for DMD due to the absence of dystrophin in skeletal muscle and undergoes rounds of muscle degeneration and regeneration similar to that experienced by patients. Pharmacokinetic and histopathological analysis of

treated mdx tissue in these proposed experiments will help to determine whether lamininin-111 will be an effective therapy after disease onset in *mdx* mice.

The research objective for this study is to evaluate whether laminin-111 can prevent muscular dystrophy after disease onset in the *mdx* mouse model of DMD by showing that treatment reduces muscle pathology while increasing muscle strength. In addition a more complete insight into the action of laminin-111 will be achieved by investigating the pharmacokinetics and pharmacodynamics of laminin-111 administered to *mdx* mice and this data is presented in Appendix A.

MATERIALS AND METHODS

Generation of *mdx* mice

All experiments involving mice were performed under an approved protocol from the University of Nevada, Reno Institutional Animal Care and Use Committee. *Mdx* (C57BL10ScSn-Dmd strain) and wild-type (C57BL10ScSn strain) were bred separately. The wild-type control strain used in this study was C57BL10ScSn. Age-matched littermate controls were used for analysis. In order to genotype mice, genomic DNA was isolated from tail snips or ear notches using a Wizard SV DNA purification system (Promega, Madison, WI) following manufacturers instructions.

The mutation in the dystrophin gene was detected using a modified ARMS assay. The following primers were used: p259E (5'GTCACCTCAGATAGTTGA

AGCCATTTAA-3'), p260E (5'-GTCACTCAGATAGTTGAAGCCATTTAG-3') and p306F (5'-CATAGTTATTAATGCATAGATATTCAG-3'). PCR conditions were as follows: 95°C for 4 minutes then 34 cycles of 95°C for 1 minute, 55°C for 1 minute and 72°C for 1 minute. Primer set p259 and p306 produced a 275bp wild-type dystrophin allele. Primer set p260 and p306 detects the *mdx* point mutation which produced a 275bp product. To genotype the dystrophin gene, separate PCR reactions were performed since the product sizes are identical in wild-type and *mdx* mice.

Experimental procedures were performed once mice were 14 days of age with fortnightly weighing until the end of study which was at 1 year of age where all mice were subject to *in vivo* experiments. To reduce experimental bias, investigators assessing and quantifying experimental outcomes were blinded to the treatment and control groups.

Laminin-111 Treatment Regime

7 week

Five 5 week old WT mice were treated with phosphate buffered saline (PBS) alongside five 5 week old *mdx* mice in each treatment group receiving either PBS or EHS mLAM-111 treatment (0.01 mg/g/week). The study ended at 7 weeks old.

10 week

In order to test the hypothesis that laminin-111 can serve as an effective treatment for DMD after disease onset, five 8 week old WT mice were treated with phosphate buffered saline (PBS) alongside five 8 week old mdx mice receiving either PBS or EHS mLAM-111 treatment (0.01 mg/g//week). The study ended at 10 weeks old.

1 year

Male *mdx* mice were treated systemically (0.01 mg/g/fortnight) from 2 weeks of age until they were 1 year old with either sterile PBS or EHS mLAM-111. Original number of mice to be treated: WT (n=5) (1 died at 10 months), PBS (n=7) (2 died between 10 and 12 months), mLAM-111 (n=5) (all survived).

Evan's Blue Dye

Mice were intraperitoneally injected with 50 μ L per 10 g of body weight sterile Evan's blue dye solution (10 mg/mL). Mice were sacrificed 8 hours post-injection. Muscles were harvested and flash frozen in liquid nitrogen. 10 μ m cryosections were fixed with 4% paraformaldehyde and myofibers were outlined with Oregon Green 488 nm-conjugated Wheat Germ Agglutinin (Molecular Probes, Eugene, OR). Evans blue dye positive myofibers were counted per animal. Images were captured at 200 X magnification and processed using Photoshop to create the representative montages.

Survival and weights

Weights for all mice of each genotype were recorded on a fortnightly basis. Softened kibble was provided fresh daily in a petri dish on the bottom of the cage in order to ensure there was no significant weight loss within the mice.

Muscle strength

Force Gauge (San Diego Instruments Inc., San Diego, CA). A total of six measurements per mouse were recorded and all results averaged for each group. The mice were analyzed by grasping a horizontal platform with their forelimbs and pulled backwards. The peak tension (grams of force) was recorded on a digital force gauge as mice released their grip.

X-ray digital imaging

Radiographs were obtained for each mouse at the end of the 10 week study through the use of a Summit digital x-ray unit model 50-520, allowing radiographic measurement of kyphotic index. Calculations for Kyphotic Index were carried out as previously described by Hoey et al. 1985.

Activity

Opto-Varimex 4 Activity Meter (Columbus Instruments) offered unbiased data due to the machine possessing lasers that monitor and auto-track the activity of each mouse for a period of 120 minutes.

Plethysmography

Animals were subjected to plethysmography at 10 weeks of age. Animals for each genotype were used. Animals were placed in the plethysmography chamber (unrestrained) and then subjected to increasing doses of aerosolized Acetyl-methacholine (6.25, 12.5, 25, 50 and 100 mg/mL), after an initial time period to acclimatize in the chamber. First mice were exposed to aerosolized PBS to gather baseline data. Experimental values were automatically generated by the pneumograph in the wall of the chamber. FinePointe software (Buxco©) was used to collect all data.

Echocardiography

In vivo echocardiography was performed on mice using a VisualSonics Vevo 2100 system with a MS 550D transducer. This allowed ultrasound imaging of the heart to take place. Mice were anesthetized with 1.5-2.0% isoflurane and placed in a supine position on a heated stage. 2-D short-axis recordings of the left ventricle at the level of the papillary muscle were obtained in M-mode. Measurements were taken to help compare the efficiency of the left ventricle during diastole and systole. Heart rate and body temperature were monitored during imaging. Left ventricle wall thickness and cavity dimensions were measured at systole and diastole for three cycles, averaged, and used with Vevo 2100 software to calculate values for fractional shortening, ejection fraction, and LV mass. Comparisons between groups of mice were made using single-factor

ANOVA in Microsoft Excel; P values < 0.05 were considered statistically significant.

Isolation of skeletal muscle

1 year old male wild-type and *mdx* mice were euthanized by CO₂ inhalation in accordance with a protocol approved by the University of Nevada, Reno Animal Care and Use Committee. Muscles from these mice were dissected, flash-frozen in liquid nitrogen and stored at -80C.

Immunoblotting

The TA muscle from 10 week old male mice was ground in liquid nitrogen. Protein was extracted in RIPA buffer and 1:200 dilution of Protease inhibitor Cocktail Set III (Calbiochem, EMD Biosciences, San Diego, CA) for the detection of α 7A and α 7B integrin. Protein was quantified by BSA assay and protein was separated on 12% SDS –page gels under reduced conditions and transferred to nitrocellulose membranes. Membranes were blocked with a dilution of carnation milk buffer. The α 7A integrin was detected with a 1:1000 dilution of anti- α 7A (A2 345) and α 7B integrin was detected by anti- α 7B (B2 347) rabbit polyclonal antibodies.

Immunofluorescence

Tibialis Anterior (TA) muscles were embedded in Tissue-TEK Optimal Cutting Temperature compound (Sakura Finetek USA Inc, Torrance, CA). 10 μ m sections were cut using leica CM1850 cryostat and placed onto Surgipath

microscope slides (surgipath Medical Industries, Richmond, IL). Laminin-111 was probed for by an antibody dilution of 1:50 against laminin- α 1. β -dystroglycan was assessed with incubation of 1:25 dilution of β -dystroglycan antibody. It was then detected with a 1:1000 dilution of FITC anti-rabbit antibody.

Hematoxylin & Eosin staining

Tibialis Anterior muscle was cryosectioned and 10 μ m sections were placed on surgipath microscope slides. Tissue sections were fixed with ice-cold 95% ethanol for 2 minutes followed by 70% ethanol for 2 minutes and then re-hydrated in running water for 5 minutes. Gill's hematoxylin (Fisher Scientific, Fair Lawn, NJ) was then used to stain the sections and rinsed in water for 5 minutes. Scott's solution (0.024 M NaHCO₃, 0.17 M MgSO₄) was then applied for 3 minutes and rinsed in water for 5 minutes. Tissue cryosections were then immersed in eosin solution (Sigma-Aldrich, St. Louis, MO) for 2 minutes. Sections were then dehydrated in ice cold 70% and 95% ethanol for 30 seconds each, followed by 100% ethanol for 2 minutes. Xylene was then used to clear the sections for 5 minutes prior to mounting with DepeX mounting medium (Electron Microscopy Services, Washington, PA). Centrally located Nuclei were counted from images composing representative montages for each mouse. Images were assessed at 200 X magnification by bright field microscopy. The number of centrally located nuclei per muscle fiber was determined by counting each image which contributed to myofibers being counted per treatment group. At least 4 animals from each treatment group were analyzed.

Sirius Red Staining

TA muscle sections were stained with Sirius Red to measure fibrosis in the skeletal muscle tissue. 10 μm cryosections on slides were fixed in 100% ethanol and then hydrated through an alcohol series (95 and 80% ethanol) and rinsed in tap water. The sections were stained with Sirius Red (0.1% in saturated aqueous picric acid solution, Rowley Biochemical Institute, Danvers, MA, USA) for 30 min followed by two washes in acidified water. The sections were dehydrated through an alcohol series, rinsed in xylene and mounted with DEPEX Mounting media (Electron Microscopy Science, Hatfield, PA, USA). Representative montages were captured and analyzed using Axiovision 4.8 software. Montages were assembled using Photoshop and Microsoft Powerpoint. Images were captured at 200 X magnification. Areas of red in the TA were considered fibrotic. Circled fibrotic areas were added together, and any non-fibrotic fibers within the fibrotic area were subtracted from the calculated area. The percentage of muscle fibrosis was quantified in treated and control muscles as a percentage of total TA muscle area. Sirius red slides were also used to measure minimal feret's diameter for mice of all 4 genotypic groups. All muscle fibers within an entire TA montage were used to determine the minimal feret's diameter.

Statistical Analysis

All averaged data are reported as the mean \pm s.d. *P*-values of < 0.05 were considered to be statistically significant. GraphPad Prism Software was used to analyze and test the data.

RESULTS

Evan's Blue dye uptake within 1 year old *mdx* mice

Visibly, it is quite clear that PBS treated *mdx* mice had a higher retention of Evans blue dye within the body in Figure 16. Also, it is evident that there is Evan's blue uptake in the TA muscle in PBS treated *mdx* mice (indicated with the blue arrow in Figure 16). These results triggered the histological analysis of the TA muscle for Evan's Blue dye uptake in Figure 17.

Evan's Blue Dye Montages for 1 year old *mdx* mice

As predicted, Tibialis Anterior muscle from PBS treated *mdx* mice had a higher retention of Evan's blue dye within the muscle (Figure 17). The representative montages indicated that there was much clustering of Evan's blue dye positive myofibers to two areas of the PBS treated TA muscle. This was a drastic comparison to the more stochastic and punctate presence of Evan's blue dye positive myofibers in the TA of Laminin-111 treated *mdx* mice. This result was then verified via statistical analysis which categorically showed that this result was statistically significant. This indicated with enhanced EBD uptake that

there was indeed more damage occurring within the muscle of PBS treated animals over the course of the 1 year time frame.

Kyphosis Analysis of 1 year old *mdx* mice

The Kyphotic index calculations were carried out following a technique previously described by Hoey *et al.* 1985. Radiographs were assessed (Figure 18) in a blinded manner and visibly there is no evidence of an increase in severity of kyphosis occurring in PBS treated *mdx* mice compared to mLAM-111 treated animals. This was later quantified and indeed there was no statistical significance between wild-type, PBS treated and the laminin-111 treated mice.

Echocardiography of 1 year old *mdx* mice

Using the Vevo2100 system and Vevo 2100 software 1.4.0 we analyzed the cardiac muscle of all three treatment groups (Figure 19). Between all the 1 year old mice, there were no enhanced cardiac problems with or without treatment with laminin-111. All representative M-mode screenshots presented here, help to convey this result. There was no statistical significance with data analysis for these echocardiography results (shown in Table 2).

Respiratory function within 1 year old *mdx* mice

Plethysmography data indicates also within the 1 year old mice that there was no statistically significant difference between the three treatment groups either for Frequency of breathing, PenH or TVb which are the three main parameters to scrutinize in plethysmography data (Figure 20).

Histology of 1 year old *mdx* Tibialis Anterior muscle

TA muscle was embedded in OCT and cryosectioned for pathological assessment via Hematoxylin and Eosin (H&E) staining (Figure 21). This stain was used to quantify the number of centrally located nuclei (CLN) which is a marker for degeneration and regeneration. As expected WT data possessed very low numbers of CLN in comparison to *mdx* mice. Despite laminin-111 treatment for 1 year there was no difference between the number of CLN detected and the number of CLN detected in the PBS treated *mdx* muscle.

Fibrotic tissue in Tibialis Anterior muscle of 1 year old *mdx* mice

The picrosirius red slides were used to quantify myofiber size and general pathology of LAM-111 treated versus PBS treated control tissue (Figure 22). There was no statistical significance in the quantification of minimal feret's diameter or indeed percentage fibrosis after 1 year treatment.

Activity and Function in 1 year old *mdx* mice

As above, activity box data reflected the results that indicated there was no statistically significant difference in functional activity of PBS or laminin-111 treated *mdx* mice over a 120 minute time period (Figure 23).

Myofiber sizes of Tibialis Anterior muscle in 7 weeks old and 10 weeks old *mdx* mice

Within 7 week old *mdx* TA treated with laminin-111 there was a visible increase in myofiber size whenever Minimal Feret's diameter was measured compared to WT and PBS treated animals (Figure 24). There was statistical significance within 10 week old TA muscle assessed for Minimal feret's diameter. The results indicated that laminin-111 treatment was successful in reducing the size of the myofibers. This result is promising as myofiber hypertrophy is indicative of DMD disease pathology.

Laminin-111 detection in *mdx* TA muscle after intraperitoneal treatment

Upon systemic laminin-111 treatment, laminin-111 was clearly able to travel to the target muscles as laminin- α 1 was detected via immunofluorescence in Tibialis Anterior muscle (Figure 25).

Muscle strength was assessed for 10 week old *mdx* mice

In Figure 26, 10 week old grip strength assessment (Figure 26 A) indicated that there was no difference in forelimb muscle strength between PBS and laminin-111 treated *mdx* mice. Despite this result in 10 week old mice, there was reduced percentage forelimb muscle fatigue evident in laminin-111 treated mice (Figure 26 B). The percentage of Centrally located nuclei showed a statistically significant elevation in CLN within PBS treated animals. This elevation in CLN is, as mentioned previously mentioned, indicative of degeneration.

Sarcolemmal proteins after laminin treatment in 10 week old *mdx* mice

Likewise for 10 week old *mdx*, there was no difference in α 7A or α 7B integrin protein levels after immunoblotting upon laminin-111 treatment (Figure 27). However, there is a trend towards WT within immunofluorescent assessment of β -dystroglycan protein levels in 10 week old animals treated with laminin-111.

DISCUSSION

This study was performed in order to test how effective laminin-111 protein therapy would be as a long-term therapeutic after observing how effective this treatment had been within younger *mdx* mice¹⁶². There was no improvement in functional activity (Figure 23) of 1 year old treated *mdx* mice and there was absolutely no improvement in the muscle histology (Figure 21 and Figure 22). There was however reduced muscle damage indicated by a lower amount of Evan's Blue Dye uptake (Figure 17). It is important to keep in mind that these older *mdx* mice may have been very inert because of their age and size¹⁶⁸ (> 30 g).

It is important to keep in mind that the long-term treatment regime consisted of only one injection per fortnight so therefore laminin-111 protein could have been degraded within a short amount of time post-injection and therefore the mouse is still subject to muscle damage before the next injection is due. Repetitive treatment over a period of 1 year was expected to have a positive effect but the data was disappointing and may be explained by receptor desensitization¹⁶⁹⁻¹⁷¹ and tolerance¹⁷¹ to the protein. Despite the presence of laminin-111 in the kidney, an immune response¹⁷² may have been mounted to

this protein being injected repeatedly over a long time period (1 year) and therefore made the beneficial effects caused by laminin-111 in younger *mdx* mice redundant in these older *mdx* mice.

Future directions will include assessing TA muscle via immunoblotting for any change in the abundance of sarcolemmal proteins that are related to the dystrophin-glycoprotein laminin-binding complex after treatment compared to PBS controls. These proteins will include the dystroglycans, sarcoglycans and sarcospan. Immunofluorescence will also be used on the same TA muscle in order to confirm the immunoblot results. There may be a better result in delivering laminin-111 in a cocktail recipe of additional therapeutic drugs in order to have a more improved effect as delivering laminin-111 protein as part of a long-term therapy was not effective.

ACKNOWLEDGEMENTS

I would like to thank Vivian Cruz, Annmarie Vogedes and Connie Spelius for their technical assistance regards tissue collection and histological analysis. A special thanks for the immunoblotting results provided by Apurva Sarathy. I would also like to thank Rebecca Evans for animal breeding and Lab Animal Medicine for their continued monitoring of the mice especially for this 1 year study. Special thanks go to both Walt Mandeville and Rebecca Evans for collecting the radiography data.

Figure 16. Evan's Blue dye uptake within 1 year old *mdx* mice

Evan's blue dye (EBD) is used as a marker for muscle damage. This blue dye is able to enter the ruptured myofiber and bind to albumin therefore resulting in red fluorescence which is then used as a marker for muscle damage. TA and diaphragm tissue uptake are also presented. PBS treated animals had distinctly increased EBD uptake within TA muscle (arrow) and less uptake within diaphragm muscle suggesting that there was more damage occurring in TA muscle. It is not clear why laminin-111 treatment caused more EBD uptake within diaphragm muscle.

Figure 17. Evan's Blue Dye Montages for 1 year old *mdx* mice

A) and B) Representative montages for Evan's Blue Dye (EBD) uptake. PBS (n= 2) and mLAM-111 (n= 2). Images were captured at 200 X magnification. Scale

bar = 200 μm . There is increased EBD uptake in PBS treated muscle due to elevated red fluorescence indicating more muscle damage. Notice how most of the damage is occurring in one area of the muscle. However with laminin-111 treatment there was reduced EBD uptake indicated by reduced red fluorescence therefore showing that the sarcolemma was restored, preventing rupture and muscle damage after laminin-111 treatment.

C

Figure 17. Evan's Blue Dye Montages for 1 year old *mdx* mice

C) Quantification of EBD positive myofibers for TA montages shown in Figure 17 A and B. PBS (n= 2) and mLAM-111 (n= 2). Captured at 200 X magnification. Scale Bar = 200 μ m. The PBS treatment group had 8.4 % EBD positive myofibers \pm 0.05 % while the laminin-111 treated group had 2.08 % EBD positive myofibers \pm 0.02 %. A student's *t*-test revealed the *P*-value < 0.0001.

A

Figure 18. Kyphosis Analysis of 1 year old *mdx* mice

A) Representative radiographs for 1 year old *mdx* mice are depicted here. Kyphosis is used to describe the curvature of the spine. In muscular dystrophy there is degradation of muscles associated with the spine and therefore more

spinal curvature (kyphosis) occurs as the disease progresses. Visibly there is no difference in the degree of kyphosis regardless of treatment group.

B

Figure 18. Kyphosis Analysis of 1 year old *mdx* mice

B) Quantification of radiographs shown in Figure 18 A, for 1 year old *mdx* mice. A lower kyphotic index indicates a higher degree of kyphosis present. In this way, WT animals had a higher kyphotic index therefore indicating less kyphosis occurring. A trend towards WT kyphotic index was evident within the EHS mLAM-111 treatment group. There was no statistical significance found when using One-Way ANOVA.

Figure 19. Echocardiography of 1 year old *mdx* mice.

A), B) & C) Representative B-mode screenshots are presented here providing a view into cardiac muscle as short-axis echoes. Papillary muscles were used as landmarks for consistency in data collection. Visibly there was no distinct

difference between the treatment groups suggesting that long-term laminin-111 treatment had no effect possibly due to receptor desensitization.

Figure 19. Echocardiography of 1 year old *mdx* mice.

D) There was no distinct difference in heart weights normalized to body weight between the treatment groups only that there was hypertrophy within cardiac muscle for *mdx* mice (PBS and mLAM-111 treatment groups).

Table 2. M-mode measurements of 1 year *mdx* echocardiography

Calculations are presented here in a tabular format for echocardiography M-mode measurements for 1 year old *mdx* mice. Most notably there was a 19.7 % increase in ventricular volume during diastole and a 16.2 % increase in ventricular volume during systole after laminin-111 treatment. Despite this there was not a change in Ejection Fraction or Fractional shortening showing that the effective pumping of the heart was not improved with laminin-111 treatment.

Figure 20. Respiratory function within 1 year old *mdx* mice

Plethysmography data was collected and analyzed. There was no difference between any of the treatment groups for respiratory function parameters which

included Frequency of breathing (Figure 20 A), PenH (Figure 20 B) and tidal volume (TVb) (Figure 20 C). PenH (enhanced pause) is correlated to but not a direct measurement of airway resistance. This suggests that whole body plethysmography analysis of 1 year old mice may not have been the best way to analyze the respiratory function of these larger animals.

Figure 21. Histology of 1 year old *mdx* Tibialis Anterior muscle

A) Hematoxylin and Eosin staining was carried out on 10 μ m TA cryosections and images were captured at a magnification of 200 X. Scale bar = 200 μ m. B)

Centrally located nuclei are used as a marker of degeneration and regeneration in muscle. Percentage (%) of Centrally Located nuclei (CLN) were calculated for each treatment group. WT had 4.3 % CLN \pm 1.7 %, PBS had 4.4 % CLN \pm 1.4 % and mLAM-111 treated animals had 4.49 % CLN \pm 2.96 %. One-Way ANOVA demonstrated that there was no statistical difference amongst the treatment groups with P -value = 0.9915. It is important to remember that within mouse muscle once damage occurs, nuclei will become centrally located and will remain their throughout the lifetime of the animal. Therefore this may help to answer why there was no difference in the percentage of CLN for the treatment groups due to the 1 year old mice enduring more damage throughout their lifetime as they are older mice. Also the treatment regime was only one injection per fortnight so therefore laminin-111 protein could have been degraded within a short amount of time post-injection and therefore the mouse is still subject to muscle damage before the next injection is due.

Figure 22. Fibrotic tissue in Tibialis Anterior muscle of 1 year old *mdx* mice

A) Representative TA montages stained with Sirius red presented for 1 year old *mdx* mice. Magnification = 100 X. Scale bar = 200 μ m. Increased red color indicates that there is more fibrotic tissue present. B) Sirius red staining was

carried out in order to calculate the percentage (%) of fibrotic tissue within TA cryosections shown in Figure 22 A. One-Way ANOVA revealed no statistical significance with P -value = 0.4979.

Figure 22. Fibrotic tissue in Tibialis Anterior muscle of 1 year old *mdx* mice

C) Minimal Feret's diameter was also calculated for the same 1 year old muscle groups shown in Figure 22 A. Minimal ferret's diameter is used to measure the size of myofibers. Statistical significance was recorded when P -values were < 0.05 . One-Way ANOVA revealed statistical significance for comparison of the 3 treatment groups but there was no statistical significance found between PBS and laminin-111 treatment. This lack of significance shows that laminin-111 treatment had no effect on myofiber size.

A

Figure 23. Activity and Function in 1 year old *mdx* mice

A) 1 year old mice were placed individually into the activity box and assessed for movability during a period of 120 minutes. Distance (m) and Velocity (m/sec) parameters were recorded. WT moved 317.6 m ± 99.9 m, PBS moved 180.7 m ± 64.6 m, mLAM-111 moved 163.7 m ± 62.8 m. Speed with which the mice moved

were for WT $9.23 \text{ m/sec} \pm 2.3 \text{ m/sec}$, PBS $6.2 \text{ m/sec} \pm 0.8 \text{ m/sec}$ and mLAM-111 $6.3 \text{ m/sec} \pm 0.3 \text{ m/sec}$. One-Way ANOVA showed statistical significance when comparing all 3 treatment groups. Statistical significance was evident when *P*-values were < 0.05 . However there was no difference between PBS and laminin-111 treated animals for either distance moved or velocity.

Figure 23. Activity and Function in 1 year old *mdx* mice

B) Mice were placed individually into the activity box and assessed for a period of 120 minutes. Resting time (sec) and vertical counts were recorded. One-Way

ANOVA showed no statistical significance when comparing all 3 treatment groups. Statistical significance was evident when *P* values were < 0.05 .

Figure 24. Myofiber sizes of Tibialis Anterior muscle in 7 weeks old and 10 weeks old *mdx* mice

Measurements for Minimal Feret's diameter were carried out on younger mice that were 7 weeks old and 10 weeks old. 7 weeks old PBS treated animals had an average myofiber diameter of $35.72 \mu\text{m} \pm 0.1783 \mu\text{m}$, and mLAM-111 treated animals had an average myofiber diameter of $41.88 \mu\text{m} \pm 0.23 \mu\text{m}$. A student's *t*-test revealed *P*-value < 0.0001. 10 week old PBS treated animals had an average myofiber diameter of $43.65 \mu\text{m} \pm 0.2 \mu\text{m}$ and mLAM-111 treated

animals had an average myofiber diameter of $41.88 \mu\text{m} \pm 0.20 \mu\text{m}$. Statistical significance was when P values were < 0.05 . One-Way ANOVA showed statistical analysis with P -value < 0.0001 . There was an increase in myofiber size for 7 week old laminin-111 treated animals and a decrease in myofiber size for 10 week old laminin-111 treated animals.

Figure 25. Laminin-111 detection in *mdx* TA muscle after intraperitoneal treatment

Immunofluorescence revealed that laminin-111 protein was able to be detected in *mdx* TA muscle after intraperitoneal injection. Scale bar = 20 μ m. Magnification = 630 X. Laminin-111 is represented by green and nuclear label (DAPI) is represented by blue. WT and mutant muscle do not possess laminin-111, it is only detected after treatment.

Figure 26. Muscle strength and histology was assessed for 10 week old *mdx* mice

A) Grip strength measurements for forelimb muscle strength were calculated and normalized to body weight. There was no statistical significance between the treatment groups after a *t*-test was performed the *P*-value = 0.7912. B) Percentage (%) fatigue was calculated based on grip strength shown in Figure 26 A. There was no statistical difference in forelimb muscle fatigue. Therefore laminin-111 treatment was not effective in increasing muscle strength.

Figure 26. Muscle strength and histology was assessed for 10 week old *mdx* mice

C) Centrally located nuclei quantification is used as a marker for degeneration and regeneration. One-Way ANOVA statistical analysis of the 3 treatment groups showed P -value < 0.0001 . Laminin-111 helped to prevent muscle damage as there was reduced percentage CLN when compared to PBS treated animals.

Figure 27. Sarcolemmal proteins after laminin treatment in 10 week old *mdx* mice

A) Immunoblotting shows that there is no effect on levels of $\alpha 7$ integrin protein after laminin-111 treatment for a two week treatment regime. B) However there is a distinct increase in β -Dystroglycan protein upon laminin treatment compared to PBS treatment visualized via confocal microscopy and this is quantified in Figure 27 B. Magnification = 400 X. Scale bar = 40 μ m. Figure 27A was kindly provided by Apurva Sarathy.

Figure 27. Sarcolemmal proteins after laminin treatment in 10 week old *mdx* mice

C) Quantification of β -DG protein levels measured from confocal images shown in Figure 27 B. Intensity was normalized by High Intensity/ Low intensity for individual images and averaged for each treatment group. PBS treatment had a normalized intensity of 274.5 ± 204.2 and laminin-111 treatment had a normalized intensity of 3128 ± 2121 . Statistical *t*-testing revealed the *P*-value = 0.2561.

Chapter V

Loss of alpha7 integrin exacerbates skeletal and cardiac dysfunction in the dy^W mouse model of MDC1A

ABSTRACT

Merosin-deficient congenital muscular dystrophy type 1A (MDC1A) is caused by the loss of Laminin-211 and Laminin-221 heterotrimers which are most abundant in skeletal and cardiac muscle basal lamina; mutations in the LAMA2 gene cause the loss of these Laminin isoforms. This reduction of Laminin reduces the capacity for myofiber adhesion, loss of sarcolemmal integrity and subsequently affects the ability of the skeletal muscle syncytium to generate force in a coordinated and efficient manner. Patients experience progressive muscle wasting which confines them to a wheelchair at an early age and respiratory failure that leads to their untimely death. Currently, there is still no effective treatment or cure for this devastating disease. Recently, our lab has shown that transgenic overexpression of the $\alpha7$ integrin reduces muscle pathology and improves viability in the laminin- $\alpha2$ deficient mouse model of (MDC1A)⁶⁵. However, what remains unclear is what role other significant sarcolemma related proteins play towards this rescue in MDC1A disease progression; complete ablation of both $\alpha7$ integrin and laminin- $\alpha2$ has never been characterized in the dy^W mouse model¹⁷³. Thus, the overall hypothesis to be tested is that a loss of both $\alpha7$ integrin and laminin- $\alpha2$ will increase the overall degeneration of skeletal and cardiac muscle in this $\alpha7$ integrin/ laminin- $\alpha2$ double knockout (dko) mouse model¹⁷³.

INTRODUCTION

Merosin deficient congenital muscular dystrophy (MDC1A) affects approximately 0.89/100,000 individuals worldwide (1:100,000 - 1:500,000) and is thought to be the most common form of congenital muscular dystrophy affecting 30-40% of all diagnosed CMD cases⁸⁸. Loss of merosin (Laminin- α 2 protein) is caused by mutations occurring in the *LAMA2* gene which is located on chromosome 6q22-23 spanning ~260 kb with 64 exons^{73,89-100}. This loss of Laminin- α 2 protein in MDC1A results in the absence of Laminin-211 and Laminin-221 heterotrimers which are abundant in skeletal and cardiac muscle basal lamina. Patients, also experience demyelinating neuropathy, muscle atrophy, limited eye movement and also respiratory failure that leads to their untimely death which can be as early as the first decade of life^{88,92-94}. There is an increased likelihood of seizures occurring after six months of age due to changes in white matter of the brain^{97,101-102}. Symptoms depend on where the mutation occurs and a mutation which results in no laminin- α 2 protein being produced will result in a more severe clinical phenotype compared to a mutation which produces a truncated form of laminin- α 2. Currently, there is still no effective treatment or cure for this cruel disease^{24,88}.

The α 7 β 1 integrin is a heterodimeric cell surface receptor member of the large family of integrins⁶⁰ (Figure 1). The α chain and β chain are noncovalently linked and integrins in general are evolutionarily conserved^{55,61}. Integrins act as receptors for a variety of cellular components to include, leukocytes, RGD,

collagen and laminin⁵⁵. The $\alpha7\beta1$ integrin is prevalent within skeletal, cardiac and vascular smooth muscle. There are many splice variants of $\alpha7\beta1$ integrin that exist. There are 3 intracellular ($\alpha7A$, $\alpha7B$ and $\alpha7C$) and 2 extracellular (X1 and X2) splice variants^{28,62,63,64}. The $\beta1$ integrin possesses variants $\beta1A$ and $\beta1D$, with $\beta1D$ being the major isoform in mature skeletal muscle⁵¹. The $\alpha7\beta1$ integrin complex is elevated in order to compensate for the instability of the dystrophin glycoprotein (DGC) laminin binding complex due to loss of dystrophin in Duchenne Muscular dystrophy (DMD)⁵⁰. $\alpha7$ integrin overexpression is able to rescue the severe dystrophic phenotype of *mdx/utr*^{-/-} mice and improve the viability of these mice⁵¹. MDC1A patients have decreased $\alpha7\beta1$ integrin expression⁶⁵. This integrin is found localized at costameres, myotendinous junctions and neuromuscular junctions^{59,60}.

The absence of laminin- $\alpha2$ in Merosin Deficient Congenital muscular dystrophy (MDC1A) has been well documented in the *dy*^W mouse model^{124,133}. What remains unclear is the exact role of $\alpha7$ integrin (laminin- $\alpha2$ binding partner) and the biological effects caused by the absence of $\alpha7$ integrin. Hence, we generated double knockout (dco) $\alpha7$ *-/-*:: Laminin- $\alpha2$ *-/-* mice and studied them alongside their littermate controls. Results from this study correlate with findings from a recent publication that suggests deletion of alpha7 integrin in laminin- $\alpha2$ deficient *dy3k**-/-* mice does not increase severity of the phenotype.

MATERIALS AND METHODS

Generation of $\alpha7$ *-/-*:: Laminin- $\alpha2$ *-/-* mice

All experiments involving mice were performed under an approved protocol from the University of Nevada, Reno Institutional Animal Care and Use Committee. $\alpha 7$ +/- mice (C57BL6- $\alpha 7\beta gal$ strain) produced in the Nevada Transgenic Center were bred with Dy^{W} +/- (C57BL6 strain) mice. The dy^{W} +/- mice were a gift from Eva Engvall via Paul Martin (The Ohio State University, Columbus, OH, USA). The resulting F1 progeny generated from mating mice that were heterozygous at both the $\alpha 7$ locus and laminin- $\alpha 2$ locus were genotyped in order to detect $\alpha 7$ -/-:: Laminin- $\alpha 2$ -/- double knockouts. The wild-type control strain used in this study was C57BL6. Age-matched littermate controls were used for analysis.

In order to genotype mice, genomic DNA was isolated from tail snips or ear notches using a Wizard SV DNA purification system (Promega, Madison, WI) following manufacturers instructions. Mice were genotyped using multiplex PCR to detect the wild-type and targeted $\alpha 7$ integrin allele using the following primers: $\alpha 7F10$ (5'-TGAAGGAATGAGTGCACAGTGC-3'), $\alpha 7$ exonR1 (5'-AGATGCCTGTGGGCAGAGTAC-3') and $\beta galR2$ (5'-GACCTGCAGGCATGCAAG-3'). PCR conditions for $\alpha 7$ integrin were as follows: 94°C for 3 minutes, then 35 cycles of 94°C for 20 seconds, 62°C for 30 seconds, 72°C for 1 minute. After these cycles, then 72°C for 10 minutes. A wild-type band was 727 bp, whereas the $\alpha 7$ integrin targeted allele produced a 482 bp band. To genotype the $\alpha 7$ integrin gene, separate PCR reactions were performed since

there were two different reverse primers needed in wild-type and $\alpha 7$ integrin null mice.

To detect the mutation in the laminin- $\alpha 2$ gene, the following primers were used: DYWF (5'-ACTGCCCTTTCTCACCCACCCTT-3'), LAMA2exonR1 (5'-GTTGATGCGCTTGGGAC-3') and Lac/ZR2 (5'-GTCGACGACGACAGTATCGGCCTCAG-3'). PCR conditions were as follows: 95°C for 5 minutes then 33 cycles of 94°C for 20 seconds, 62°C for 30 seconds and 72°C for 45 seconds. After these cycles, then 72°C for 10 minutes. A wild-type band was 250 bp whereas the laminin- $\alpha 2$ targeted allele produced a 480 bp band.

Experimental procedures were performed once mice were 14 days of age with weekly weighing until the end of study which was at 10 weeks of age where all mice were subject to *in vivo* experiments. To reduce experimental bias, investigators assessing and quantifying experimental outcomes were blinded to the treatment and control groups.

Survival and weights

Weights for all mice of each genotype were recorded on a weekly basis. Softened kibble was provided fresh daily in a petri dish on the bottom of the cage in order to ensure there was no significant weight loss within the mice.

Muscle strength

Muscle strength assessed at 10 weeks of age using the Chatillon DFE Digital Force Gauge (San Diego Instruments Inc., San Diego, CA). A total of six measurements per mouse were recorded and all results averaged for each group. The mice were analyzed by grasping a horizontal platform with their forelimbs and pulled backwards. The peak tension (grams of force) was recorded on a digital force gauge as mice released their grip.

X-ray digital imaging

Radiographs were obtained for each mouse at the end of the 10 week study through the use of a Summit digital X-ray unit model 50-520, allowing radiographic measurement of kyphotic index. Calculations for Kyphotic Index were carried out as previously described by Hoey *et al.* 1985.

Activity

Opto-Varimex 4 Activity Meter (Columbus Instruments) offered unbiased data due to the machine possessing lasers that monitor and auto-track the activity of each mouse for a period of 30 minutes.

Plethysmography

Animals were subjected to plethysmography at 10 weeks of age. Animals for each genotype were used. Animals were placed in the plethysmography chamber (unrestrained) and then subjected to increasing doses of aerosolized

Acetyl-methacholine (6.25, 12.5, 25, 50 and 100 mg/mL), after an initial time period to acclimatize in the chamber. First mice were exposed to aerosolized PBS to gather baseline data. Experimental values were automatically generated by the pneumograph in the wall of the chamber. FinePointe software (Buxco©) was used to collect all data.

Echocardiography

In vivo echocardiography was performed on mice using a VisualSonics Vevo 2100 system with a MS 550D transducer¹⁷⁴. This allowed ultrasound imaging of the heart to take place. Mice were anesthetized with 1.5-2.0% isoflurane and placed in a supine position on a heated stage. 2-D short-axis recordings of the left ventricle at the level of the papillary muscle were obtained in M-mode. Measurements were taken to help compare the efficiency of the left ventricle during diastole and systole. Heart rate and body temperature were monitored during imaging. Left ventricle wall thickness and cavity dimensions were measured at systole and diastole for three cycles, averaged, and used with Vevo 2100 software to calculate values for fractional shortening, ejection fraction, and LV mass^{175,176,177}. Comparisons between groups of mice were made using single-factor ANOVA in Microsoft Excel; *P* values < 0.05 were considered statistically significant.

Isolation of skeletal muscle

10 week old wild-type, $\alpha 7^{WT}::$ laminin- $\alpha 2^{-/-}$, $\alpha 7^{-/-}::$ laminin- $\alpha 2^{WT}$, and $\alpha 7^{-/-}::$ laminin- $\alpha 2^{-/-}$ mice were euthanized by CO₂ inhalation in accordance with a protocol approved by the University of Nevada, Reno Animal Care and Use Committee. The Tibialis Anterior and cardiac muscles from these mice were dissected, flash-frozen in liquid nitrogen and stored at -80°C.

Immunofluorescence

Tibialis Anterior (TA) muscle were embedded in Tissue-TEK Optimal Cutting Temperature compound (Sakura Finetek USA Inc, Torrance, CA). 10 μ m sections were cut using leica CM1850 cryostat and placed onto Surgipath microscope slides (surgipath Medical Industries, Richmond, IL). The $\alpha 7$ integrin was detected with a 1:500 dilution of CA5.5 mouse monoclonal antibody (Sierra Biosource, Morgan Hill, CA) followed by a 1:100 dilution of FITC-conjugated anti-mouse IgG. Myofibers were outlined with a 1:1000 dilution of FITC-conjugated Wheat Germ Agglutinin. Laminin- $\alpha 2$ was detected with a 1: 500 dilution of *LAMA2* mouse monoclonal followed by a 1: 200 dilution of Alexa Fluo 594 nm anti-mouse IgG. Myofibers were outlined with a 1:1000 dilution of TexasRed-conjugated Wheat Germ Agglutinin.

Sirius Red Staining

TA muscle sections were stained with Sirius Red to measure fibrosis in the skeletal muscle tissue. 10 μ m cryosections on slides were fixed in 100%

ethanol and then hydrated through an alcohol series (95 and 80% ethanol) and rinsed in tap water. The sections were stained with Sirius Red (0.1% in saturated aqueous picric acid solution, Rowley Biochemical Institute, Danvers, MA, USA) for 30 min followed by two washes in acidified water. The sections were dehydrated through an alcohol series, rinsed in xylene and mounted with DEPEX Mounting media (Electron Microscopy Science, Hatfield, PA, USA). Representative montages were captured and analyzed using Axiovision 4.8 software. Montages were assembled using Photoshop and Microsoft Powerpoint. Images were captured at 200 X magnification. Areas of red in the TA were considered fibrotic. Circled fibrotic areas were added together, and any non-fibrotic fibers within the fibrotic area were subtracted from the calculated area. The percentage of muscle fibrosis was quantified in treated and control muscles as a percentage of total TA muscle area. Sirius red slides were also used to measure minimal feret's diameter for mice of all 4 genotypic groups. All muscle fibers within an entire TA montage were used to determine the minimal feret's diameter.

Masson's Trichrome Staining

TissueTek OCT-embedded TA muscles were cryosectioned and stained using a Masson's Trichrome Staining Kit (American Master Tech Scientific, Lodi, CA). Images were captured at 100 X magnification under bright field using a Zeiss Axioskop 2 Plus fluorescent microscope, and images were captured with Hamamatsu Color Chilled 3CCD digital camera with HPS-SCSI (C5810)

software. Images were processed and measured with the use of Axiovision 4.8 software. All muscle fibers within an entire montage were used to determine the percentage (%) of blue collagen deposition. Therefore helping to determine the extent to which fibrosis is occurring within cardiac muscle.

Statistical Analysis

All averaged data are reported as the mean \pm s.d. *P*-values of < 0.05 were considered to be statistically significant.

RESULTS

Mendelian Inheritance for F1 progeny (n =341) produced from breeding parent mice that are both heterozygous for $\alpha 7$ integrin and laminin- $\alpha 2$

Categories for progeny genotypes are as described in tables 3 & 4. Chi-squared analysis was used as a statistical test for these results for Mendelian Inheritance. $X^2 = 35.3546$ with 3 degrees of freedom. Embryonic lethality is observed for $\alpha 7^{-/-}:: dy^{-/-}$ with an approximate 66% deviation from the higher expected number of double knockout mice.

Immunofluorescence to show laminin-alpha2 reduction in the $\alpha 7^{-/-}:: dy^{-/-}$ mouse model

Laminin- $\alpha 2$ protein is minimally present within the laminin- $\alpha 2$ knockout mouse genotype as it is only a partial knockout within the Dy^{W} laminin- $\alpha 2$

deficient strain of mice (Figure 30). $\alpha 7$ WT :: dy WT ($n= 12$), $\alpha 7$ WT :: dy -/- ($n= 11$), $\alpha 7$ -/- :: dy WT ($n= 5$), $\alpha 7$ -/- :: dy -/- ($n= 5$).

Immunofluorescence to show both alpha7 reduction in the $\alpha 7$ -/- :: dy -/- mouse model

$\alpha 7$ integrin protein is reduced within $\alpha 7$ -/- ($\alpha 7$ -/-:: dyWT and $\alpha 7$ -/-:: dy -/-) tissues (Figure 31). $\alpha 7$ WT :: dy WT ($n= 12$), $\alpha 7$ WT :: dy -/- ($n= 11$), $\alpha 7$ -/- :: dy WT ($n= 5$), $\alpha 7$ -/- :: dy -/- ($n= 5$).

Kyphosis analysis via digital X-rays comparing $\alpha 7$ WT :: dy WT, $\alpha 7$ WT :: dy -/-, $\alpha 7$ -/- :: dy WT, and $\alpha 7$ -/- :: dy -/- 10 week old mice

The kyphotic index calculations were carried out following a technique previously described¹⁷⁸. Radiographs were assessed in a blinded manner and visibly there is a similar increase in the severity of kyphosis occurring in $\alpha 7$ -/-:: dy -/- animals compared with $\alpha 7$ WT::dy -/- animals (Figure 32). This result is visible in the representative radiographs presented. Statistically this result was significant.

Weights and muscle function assessment comparing $\alpha 7$ WT :: dy WT, $\alpha 7$ WT :: dy -/-, $\alpha 7$ -/- :: dy WT, and $\alpha 7$ -/- :: dy -/- mice

No statistical significance was observed for $\alpha 7$ -/-:: dy -/- grip strength assessing forelimb muscle strength compared to the other 3 genotypes (Figure 33). Percentage of forelimb muscle fatigue was also elevated within $\alpha 7$ -/-:: dy -/- compared to the other genotypes. Activity box data showed consistent statistical

significance with regards to distance moved and ambulatory time which was severely reduced in $\alpha 7^{-/-}:: dy^{-/-}$ mice. The number of vertical stand-ups were also reduced for $\alpha 7^{-/-}:: dy^{-/-}$ animals and this was coupled with an extension in resting time for these animals.

Heart analysis comparing $\alpha 7$ WT :: dy WT, $\alpha 7$ WT :: dy $-/-$, $\alpha 7$ $-/-$:: dy WT, and $\alpha 7$ $-/-$:: dy $-/-$ 10 week old mice

Whenever heart weight was normalized to body weight there was an increase in mass evident for $\alpha 7^{-/-}:: dy^{-/-}$ mice which was similar to $\alpha 7$ WT:: dy $-/-$. Within *in vivo* echocardiography, the representative B-mode screenshots reflect the vast range of cardiac functions within all genotypes of this study (Figure 34). The worst phenotype was observed in $\alpha 7^{-/-}:: dy^{-/-}$ mice with atrial flutter/fibrillation evident and increased Left Ventricular wall thickness. These $\alpha 7^{-/-}:: dy^{-/-}$ mice had very much reduced left ventricular volume during systole.

Echocardiography data comparing $\alpha 7$ WT :: dy WT, $\alpha 7$ WT :: dy $-/-$, $\alpha 7$ $-/-$:: dy WT, and $\alpha 7$ $-/-$:: dy $-/-$ 10 week old mice

For $\alpha 7$ WT:: dyWT versus $\alpha 7$ WT:: dy $-/-$ the most significant differences are with Left ventricular Internal diameter (LVID) in both diastole and systole (Figure 35 A). There was also a huge reduction in the ability of the left ventricle to pump blood and this is indicated by the significant reduction in Left ventricular volume for both diastole and systole.

For $\alpha 7$ WT:: dyWT versus $\alpha 7$ -/-:: dy-/- it is a very similar situation to the one previously described, small internal diameter and therefore less efficient blood pumping due to the decreased size of the ventricle and reduced volume in both diastole and systole (Figure 35 B).

For $\alpha 7$ -/-:: dyWT versus $\alpha 7$ WT:: dy-/-, it is the same situation. These results indicate that $\alpha 7$ integrin plays a critical role in rescuing cardiac muscle whenever laminin- $\alpha 2$ is absent (Figure 35 C). In the absence of both $\alpha 7$ integrin and laminin- $\alpha 2$ there are detrimental consequences with regards heart function due to reduced blood filling capacity with reduced ventricular volume during systole and the occurrence of atrial flutter.

Increased collagen visible within $\alpha 7$ -/- :: dy -/- cardiac muscle

Heart tissue cryosections show elevated blue fibrotic tissue deposition within the cardiac montages for $\alpha 7$ -/-::dy-/- (Figure 36). Quantification of this shows that laminin- $\alpha 2$ deficiency has similar effects for both $\alpha 7$ WT:: dy-/- and $\alpha 7$ -/-:: dy-/. This result therefore indicates that laminin- $\alpha 2$ is important for protection against collagen deposition however this result was not statistically significant and would warrant the need for more *n* numbers.

Fibrotic tissue analysis within Tibialis Anterior muscle of $\alpha 7$ WT :: dy WT, $\alpha 7$ WT :: dy -/-, $\alpha 7$ -/- :: dy WT, and $\alpha 7$ -/- :: dy -/- 10 week old mice

Again, as above, montages were assembled this time for TA muscle (Figure 37). Visibly laminin- $\alpha 2$ deficiency for both $\alpha 7$ WT:: dy-/- and $\alpha 7$ -/-:: dy-/-

mice results in a more degradative muscle pathology due to excessive scar tissue formation indicated here by red color which is labeled fibrotic tissue. There was no statistical significance but single loss of laminin- α 2 seemed to have a more severe effect but very similar to double knockout of both α 7 integrin and laminin- α 2. Single loss of only α 7 integrin resulted in the most muscle hypertrophy when assessing myofiber minimal ferret's diameter.

DISCUSSION

The α 7 integrin is an important transmembrane cell surface receptor in skeletal, cardiac and vascular smooth muscle. Laminin- α 2 is an important binding partner for α 7 integrin^{92,108,117}. It connects the extracellular matrix to the integrin on the sarcolemma. α 7 integrin plays an important role in cell signaling as it binds to talin and cytoskeletal F-actin. Laminin-integrin binding complex helps to transduce external mechanical stresses involved with muscle contraction and connect them with a cellular response via signaling. It is important to remember that this laminin-integrin interaction is very much a two-way system i.e. there can be inside- outside signaling and also outside-inside signaling. The relationship between them is very much a bi-directional one. Disruption of these components causes neuromuscular disease in both humans and mice. This emphasizes the importance of this binding complex in maintaining the integrity of the sarcolemmal to withstand the mechanical forces associated with muscle contraction.

Together these results suggest that laminin- $\alpha 2$ plays a critical role in maintaining proper function of skeletal and cardiac muscle. Transgenic overexpression of $\alpha 7$ integrin in skeletal muscle in previous studies demonstrated that overexpression can help partially rescue the disease phenotype and extend the lifespan of the mice. This study helps to reiterate previous literature¹⁷³. The severe embryonic lethality of double knockout $\alpha 7^{-/-}:: dy^{-/}$ mice furthers this previous knowledge and emphasizes the importance of $\alpha 7$ integrin in rescuing the loss of laminin- $\alpha 2$ ⁶⁵. The duplicity of their bi-directional relationship of protecting the structural and functional integrity of muscle is very much highlighted in the generation of this double knockout mouse model.

We observed severe muscle pathology in 10 week old $\alpha 7^{-/-}:: dy^{-/}$ mice which is a new result for this field of study as no one has ever created this particular double knockout mouse model in the $dy^{W-/-}$ ¹⁷³. Partial knockdown of both proteins in $\alpha 7^{-/-}:: dy^{-/}$ mice results in severe skeletal and cardiac muscle degeneration, reduced functional activity and fibrotic scar tissue deposition. Here, compensation by $\alpha 7$ integrin helps these mice to maintain functional integrity. The $\alpha 7^{-/-}:: dy^{-/}$ mice analyzed in this study exhibited a phenotype similar to that of single knockout of laminin- $\alpha 2$ in $dy^{W-/-}$ mice. This phenotypic similarity between these two genotypes suggests that there is functional overlap in the role of $\alpha 7$ integrin in maintaining muscle structure and function. The $\alpha 7$ integrin has a redundant role as loss of laminin- $\alpha 2$ is detrimental to muscle pathology. Double knockout $\alpha 7^{-/-}:: dy^{-/}$ mice exhibit a severe cardiac phenotype similar to

that of the *dy*^{-/-} mice suggesting that laminin- α 2 is very critical to cardiac muscle function by its presence¹⁷⁹⁻¹⁸⁵. It also suggests there is no active sarcolemmal complex able to cope and compensate for the loss of both of them. Therefore, the heart is not able to pump efficiently in a coordinated manner and we see the atrial fibrillation occurring^{175-177,186}.

The α 7^{-/-}:*dy*^{-/-} mouse is a new mouse model for muscular dystrophy that has been identified which lacks both α 7 integrin and laminin- α 2. This has never been studied before in this particular *dy*^W ^{-/-} mouse model¹⁷³. Further investigation will reveal the effects on pathophysiology and expression of sarcolemmal proteins. Results from characterization of this new α 7 integrin / laminin- α 2 double knockout mouse model will aid in understanding the exact role that α 7 integrin and laminin- α 2 play in MDC1A. It will also potentially help with the identification of novel therapeutic targets for this devastating neuromuscular disease.

ACKNOWLEDGEMENTS

The project described was supported by grants from the National Center for Research Resources (SP20RR016464-11), Institute of General Medical Sciences (8 P20 GM103440-11) from the National Institutes of Health, CureCMD and Struggle Against Muscular Dystrophy. I would especially like to thank Dr. Andrea Agarwal for Echocardiography training and blinded analysis.

Figure 28. Schematic representation of the α 7 integrin- laminin- α 2 binding complex

α 7 integrin binding to laminin- α 2 acts as a strengthening molecular glue in the WT sarcolemma. However, this strength is lost upon the absence of laminin- α 2 in muscle. We wish to investigate ablation of the α 7 integrin- laminin- α 2 binding complex in this α 7/laminin- α 2 double knockout (DKO mouse model).

Figure 29. Photographs of 10 week old $dy^{w/-}$ and $\alpha7^{-/-} :: dy^{-/-}$ mice

$\alpha7$ integrin-laminin- $\alpha2$ double knockout (DKO) mouse alongside its littermate control laminin- $\alpha2$ knockout ($Dy^{w/-}$) mouse at 10 weeks of age. More advanced kyphosis is evident within the DKO mouse.

Category	Observed	Expected	Actual %	Expected %

Table 3 & Table 4: Mendelian Inheritance for F1 progeny (n =341) produced from breeding parent mice that are both heterozygous for α 7 integrin and laminin- α 2

Categories for each genotype are labeled here in order to define how Mendelian inheritance was calculated. Chi-squared value was 35 with 3 degrees of freedom. Embryonic lethality is evident within the DKO mouse.

Figure 30. Immunofluorescence to show laminin-alpha2 reduction in the $\alpha 7$ -/- :: dy -/- mouse model

Confocal microscopy was employed to show presence or reduction of laminin- $\alpha 2$ protein in TA muscle cryosections. Wheat germ agglutinin (WGA) was used to outline the myofibers. Magnification = 400 X. Scale bar = 100 μ m. Green

represents WGA and red represents laminin- α 2. α 7^{-/-} :: *dy*^{-/-} protein localization in muscle is more disorganized compared to the other 3 genotypes.

Figure 31. Immunofluorescence to show alpha7 reduction in the $\alpha 7$ -/- :: dy -/- mouse model

Confocal images were collected and analyzed for the presence of alpha7 integrin protein. Wheat germ Agglutinin (WGA) was used to outline the myofibers. Magnification = 400 X. Scale bar = 100 μ m. Red represents WGA and green

represents $\alpha 7$ integrin presence. alpha7 integrin protein was greatly reduced in *dy*^{-/-} animals.

 $\alpha 7$ WT:: dy WT $\alpha 7$ WT:: dy -/- $\alpha 7$ -/-:: dy WT $\alpha 7$ -/-:: dy -/-

Figure 32. Kyphosis analysis via digital X-rays comparing $\alpha 7$ WT :: dy WT, $\alpha 7$ WT :: dy -/-, $\alpha 7$ -/- :: dy WT, and $\alpha 7$ -/- :: dy -/- 10 week old mice

(B) Kyphosis is used to describe the curvature of the spine. In muscular dystrophy there is degradation of muscles associated with the spine and

therefore more spinal curvature (kyphosis) occurs as the disease progresses. Kyphotic Index calculations for each of the genotypes: $\alpha 7$ WT :: dy WT ($n= 12$), $\alpha 7$ WT :: dy -/- ($n= 11$), $\alpha 7$ -/- :: dy WT ($n= 5$), $\alpha 7$ -/- :: dy -/- ($n= 5$). A lower kyphotic index indicates a higher degree of kyphosis present. In this way, WT animals had a higher kyphotic index therefore indicating less kyphosis occurring. The calculations were based on radiographs as shown in Figure 32 B. Loss of laminin- $\alpha 2$ protein causes severe kyphosis and whenever alpha7 integrin protein is reduced in addition, it causes slightly more kyphosis. One-Way ANOVA analysis produced a P -value = 0.0026.

B

Figure 32. Kyphosis analysis via digital X-rays comparing $\alpha 7$ WT :: dy WT, $\alpha 7$ WT :: dy -/-, $\alpha 7$ -/- :: dy WT, and $\alpha 7$ -/- :: dy -/- 10 week old mice

(A) Representative X-ray radiographs for each of the genotypes: $\alpha 7$ WT :: dy WT (n= 12), $\alpha 7$ WT :: dy -/- (n= 11), $\alpha 7$ -/- :: dy WT (n= 5), $\alpha 7$ -/- :: dy -/- (n= 5). Visibly, the severity of kyphosis looks similar for both $\alpha 7$ WT :: dy -/- mice and $\alpha 7$ -/- :: dy -/- mice. Kyphotic index calculations are presented in Figure 32 A.

A

Figure 33. Weights and muscle function assessment comparing $\alpha 7$ WT :: dy WT, $\alpha 7$ WT :: dy -/-, $\alpha 7$ -/- :: dy WT, and $\alpha 7$ -/- :: dy -/- mice

(A) Weights (g) were recorded in a weekly manner for all mice until 10 weeks old. Each genotype weighed on average at 10 weeks old : $\alpha 7$ WT :: dy WT mice weighed $19.07 \text{ g} \pm 1.723 \text{ g}$, $\alpha 7$ WT :: dy -/- mice weighed $12.44 \text{ g} \pm 1.025 \text{ g}$, $\alpha 7$ -/- :: dy WT mice weighed $16.43 \text{ g} \pm 1.306 \text{ g}$, and $\alpha 7$ -/- :: dy -/- mice weighed $12.32 \text{ g} \pm 0.8777 \text{ g}$ at 10 weeks old. One-Way ANOVA statistical analysis revealed the P -value = 0.0013. $\alpha 7$ WT :: dy -/- mice and $\alpha 7$ -/- :: dy -/- mice had very similar weight gain over the entire period of the study therefore suggesting that there was no detrimental effect by additionally reducing alpha7 integrin alongside laminin- $\alpha 2$.

Figure 33. Weights and muscle function assessment comparing $\alpha 7$ WT :: dy WT, $\alpha 7$ WT :: dy -/-, $\alpha 7$ -/- :: dy WT, and $\alpha 7$ -/- :: dy -/- 10 week old mice

(B) Forelimb muscle grip strength measurements (six in total) were recorded (grams of force) and normalized to body weight. The percentage (%) fatigue for forelimb muscles was calculated. No statistical significance was found between the 4 different genotypes.

C

Figure 33. Weights and muscle function assessment comparing $\alpha 7$ WT :: dy WT, $\alpha 7$ WT :: dy -/-, $\alpha 7$ -/- :: dy WT, and $\alpha 7$ -/- :: dy -/- 10 week old mice

(C) Activity box data was collected for mice in a non-biased way for 30 minutes. The results for resting time (sec) and ambulatory time (sec) are presented. $\alpha 7$ WT :: dy WT mice had a resting time of 318.8 sec \pm 34.03 sec and ambulatory

time of 1052 sec \pm 48.24 sec, $\alpha 7$ WT :: *dy* $-/-$ mice had a resting time of 542.7 sec \pm 47.88 sec and ambulatory time of 768.0 sec \pm 39.67 sec, $\alpha 7$ $-/-$:: *dy* WT mice had a resting time of 308.0 sec \pm 34.37 sec and ambulatory time of 1074 sec \pm 48.75 sec, $\alpha 7$ $-/-$:: *dy* $-/-$ mice had a resting time of 860.3 sec \pm 277.9 sec and ambulatory time of 589.0 sec \pm 194.5 sec. Student *t*-test's revealed a ** *P*-value = 0.0063 for resting time (sec) and ** *P*-value = 0.0048 for ambulatory time (sec).

D

Figure 33. Weights and muscle function assessment comparing $\alpha 7$ WT :: dy WT, $\alpha 7$ WT :: dy -/-, $\alpha 7$ -/- :: dy WT, and $\alpha 7$ -/- :: dy -/- 10 week old mice

(D) Activity box data was collected for mice in a non-biased way for 30 minutes. The results for distance moved (cm) and vertical counts are presented. Vertical counts act as a way of measuring how many stand-ups each mouse can accomplish. $\alpha 7$ WT :: dy WT moved 7296 cm \pm 756.4 cm and stood 374.0 times \pm 59.40, $\alpha 7$ WT :: dy -/- moved 4319 cm \pm 360.1 cm and stood 136.0 times \pm 38.33, $\alpha 7$ -/- :: dy WT moved 7883 cm \pm 939.2 cm and stood 315.0 times \pm

60.37, $\alpha 7$ -/- :: dy -/- moved $3385 \text{ cm} \pm 1146 \text{ cm}$ and stood $62.00 \text{ times} \pm 27.00$. Student t -tests revealed for distance moved ** P -values = 0.0039 and * = 0.0174, for vertical counts P -values were 0.0050 and 0.0092 respectively. Therefore based on these results it looks as though $\alpha 7$ -/- :: dy -/- knockdown produces no additive effects.

B

Figure 36. Increased collagen visible within $\alpha 7^{-/-} :: dy^{-/-}$ cardiac muscle

A) Masson's trichrome staining was carried out on heart cryosections to analyze the presence of collagen within cardiac muscle. Collagen is represented by blue color. Magnification = 100 X. Scale bar = 200 μm . B) The percentage of collagen present in cardiac muscle shown in Figure 36 A was quantified. No statistical significance was found and One-Way ANOVA analysis was performed with P -value = 0.3032. Surprisingly, there is a lot of fibrosis evident in WT cardiac muscle and this was consistently found. Again, $\alpha 7^{\text{WT}} :: dy^{-/-}$ and $\alpha 7^{-/-} :: dy^{-/-}$ have similar phenotypes further suggesting that the double knockout has no additive effects.

Figure 37. Fibrotic tissue analysis within Tibialis Anterior muscle of $\alpha 7^{WT} :: dy^{WT}$, $\alpha 7^{WT} :: dy^{-/-}$, $\alpha 7^{-/-} :: dy^{WT}$, and $\alpha 7^{-/-} :: dy^{-/-}$ 10 week old mice

A) Representative TA cryosections stained with Sirius red. Increased red color indicates that there is more fibrotic tissue present. Magnification = 200 X. Scale bar = 200 μ m. B) Sirius red staining was carried out in order to calculate the percentage (%) of fibrotic tissue within TA cryosections shown in Figure 37 A. One-Way ANOVA showed statistical significance with *P*-value = 0.0039. Elevated fibrosis is evident for both $\alpha 7^{WT}:: dy^{-/-}$ and $\alpha 7^{-/-}:: dy^{-/-}$ muscle showing that loss of laminin- $\alpha 2$ alone is sufficient enough to cause a fibrotic environment.

C

Figure 37. Fibrotic tissue analysis within Tibialis Anterior muscle of $\alpha 7$ WT :: dy WT, $\alpha 7$ WT :: dy $-/-$, $\alpha 7$ $-/-$:: dy WT, and $\alpha 7$ $-/-$:: dy $-/-$ 10 week old mice

C) Minimal Feret's diameter was also calculated for muscle groups shown in Figure 37 A. Minimal ferret's diameter is used to measure the size of myofibers. One-way ANOVA resulted in P -value = 0.1454 and therefore no statistical significance was found. Interestingly, $\alpha 7^{WT}::dy^{-/-}$ and $\alpha 7^{-/-}::dy^{-/-}$ muscle showed similar myofiber sizes.

Chapter VI

Conclusions and Future Directions

The main hypothesis of this dissertation is that laminin-111 can act as an effective replacement protein therapy for the loss of laminin- α 2 in $dy^{W/-}$ (MDC1A) and indeed dystrophin in mdx (DMD).

Patients with MDC1A are usually diagnosed after disease onset. Because systemic laminin-111 treatment was able to have many beneficial effects before disease onset (previously published), we therefore carried out this study to investigate whether laminin-111 protein would be able to have the same beneficial effects when treatment was started after disease onset in the $dy^{W/-}$ mice. Chapter 2 discusses laminin protein therapy after disease onset.

Laminin-111 treatment was effective in reducing percentage (%) muscle fatigue in 8 week old $dy^{W/-}$ mice. Our studies suggest that treatment with laminin-111 after disease onset had a minimal effect to improve the overall integrity of the muscle whilst helping to reduce scar tissue formation. This in turn helped to minimally improve activity of these animals post-treatment after disease onset. This study would be a step towards trying to link what happens at the patient bedside to one of the current mouse models used to study this disease. As with all scientific studies it is important that they correlate to what is currently experienced in the medical field. Results from this study along with an understanding of laminin-111 pharmacokinetics will help pave the way in developing this protein as an exciting potential therapeutic for MDC1A patients.

Recently we have shown that EHS derived mouse laminin-111 protein can act as a substitution therapy in laminin- α 2 deficient mice ¹⁴². Our studies showed

that $dy^{W/-}$ mice treated with laminin-111 showed reduced muscle pathology, maintained muscle strength and dramatically increased longevity (Rooney et al., 2012). In this study presented in Chapter 3, we investigated the transcriptional changes that occur during disease progression within diaphragm muscle of the $dy^{W/-}$ mouse model of MDC1A. We also examined how treatment with laminin-111 protein before disease onset altered transcriptional changes in the diaphragm muscle to identify on-target and off-target drug action.

Using RNAseq technology we were able to show that more than 800 transcripts were altered as a result of disease progression in the diaphragm muscle of 2 week old $dy^{W/-}$ mice. Our studies showed that at 2 weeks of age transcript variability in the diaphragm muscle between animals is low. At 5 weeks of age there is significant variability in transcript abundance in the diaphragm muscle between animals. Laminin-111 treatment reduced the number of transcripts that changed and we identified several specific transcripts that changed as a result of laminin-111 treatment.

These RNA-Seq experiments helped us to identify osteoactivin (GPNMB) as a novel biomarker of MDC1A disease progression. Given the transcript and protein level changes in Osteoactivin observed during disease progression in the $dy^{W/-}$ mouse model, we next wanted to confirm that this occurred on patient muscle. Immunofluorescence for Osteoactivin using muscle from an MDC1A patient and unaffected control showed that Osteoactivin is normally located in the extracellular matrix in unaffected muscle, but in the MDC1A muscle it is localized within the muscle cells. This may cause misregulation of MAPK signaling (and

potentially activation of TGF-beta and fibrotic pathways) in muscle cells. Although laminin-111 treatment did not change transcript levels, treatment in mice appears to restore normal localization of Osteoactivin in skeletal muscle and therefore would potentially restore MAPK signaling in muscle and prevent further fibrosis.

Our results also reemphasized the role of Galectin-3 as a biomarker in this disease. Laminin-111 treatment also helped to restore many sarcolemmal proteins and improved muscle function by reducing muscle fibrosis. Laminin-111 treatment is likely acting to stabilize proteins and is not altering signaling pathways in skeletal muscle to a great extent. Laminin-111 helps to strengthen and reinforce the sarcolemma in the $dy^{W/-}$ mouse during prolonged progressive muscle injury induced by contraction offering a protective niche against the occurrence of this degenerative scenario by reducing inflammation, fibrosis and apoptosis via improved matrix-mechanotransduction. Significant changes may be being masked by huge misregulation in individuals. This study may help to pave the way in teasing out the molecular pathways associated with MDC1A disease progression and treatment. In this study we show that loss of laminin-211/221 in the diaphragm muscle of mice results in a large number of transcript changes that may serve as markers for disease progression and to report the efficacy of potential therapies.

Future avenues of research experiments will include continued evaluation and individual mouse transcriptome confirmation of the RNA-seq data to identify a set of genes misregulated in all animals. For this analysis we will focus on the 2-week and 5-week Wild-type versus untreated $dy^{W/-}$ data. Genes which are

altered early in the process will be evaluated during embryogenesis (for example Osteoactivin). Immunofluorescence will be used to confirm altered protein levels in skeletal muscle of

Chapter 4 looks at long term laminin treatment of *mdx* mice. The lack of significance in the results for laminin treated animals could reflect the fact that the *mdx* mice have no overt dystrophic phenotype after 10 weeks of age. However, there was elevated EBD uptake and increased kyphosis within PBS treated animals. Laminin treatment helped to reduce muscle hypertrophy at 10 weeks old. Treatment also reduced muscle fatigue experienced and there was an increase in the sarcolemmal protein, β -DG. There may be a better result in delivering laminin-111 in a cocktail recipe of additional therapeutic drugs in order to have a more improved effect. Future directions will include assessing TA muscle via immunoblotting for any change in the abundance of sarcolemmal proteins that are related to the dystrophin-glycoprotein laminin-binding complex after treatment compared to PBS controls. These proteins will include the dystroglycans, sarcoglycans and sarcospan. Immunofluorescence will also be used on the same TA muscle in order to confirm the immunoblot results.

The rhLam-111 recombinant protein is still in the early stages of trial production and it is difficult to produce due to its large size (~900 kDa). Various avenues of human laminin-111 production were explored to date. The main method of production of human recombinant laminin (rhLAM-111) involved transient transfection with laminin- α 1 into a stable CHO_S cell line that produced

the $-\beta$ and $-\gamma$ chains of laminin. Talon technology could be used in order to knockout hamster α -4 and α -5 produced by the CHO_S cells. However, the purification protocol may have precipitated out most of the laminin-111 with which we are interested. The exact concentration of hrLAM-111 will need to be determined. A new strategy has been devised in order to generate a huge batch of hrLAM-111 with the CHO_S system and the resulting media will be harvested and sent for FPLC purification.

The α 7 β 1 integrin is an important transmembrane cell surface receptor in skeletal, cardiac and vascular smooth muscle. Laminin- α 2 is an important binding partner for α 7 integrin. It connects the extracellular matrix to the integrin on the sarcolemma. α 7 integrin plays an important role in cell signaling as it binds to talin and cytoskeletal F-actin. Laminin-integrin binding complex helps to transduce external mechanical stresses involved with muscle contraction and connect them with a cellular response via signaling. Disruption of these components causes neuromuscular disease in both humans and mice. This emphasizes the importance of this binding complex in maintaining the integrity of the sarcolemmal to withstand the mechanical forces associated with muscle contraction. Transgenic overexpression of α 7 integrin in skeletal muscle in previous studies demonstrated that overexpression can help partially rescue the disease phenotype and extend the lifespan of the mice.

Similar to how experimental animals were designed as double knockouts to lack both dystrophin and α 7 integrin (*mdx/ α 7^{-/-}*) and resulted in a more severe

phenotype than single knockout animals, a double knockout of both laminin- α 2 and α 7 integrin was created in order to study the full extent to which α 7 integrin plays in laminin- α 2 deficient muscle. Chapter 5 studies the new mouse model α 7 integrin $-/-$: laminin- α 2 $-/-$ double knockout for muscular dystrophy. Together these results suggest that both α 7 integrin and laminin- α 2 play critical roles in maintaining proper function of skeletal and cardiac muscle. This study analyzes the effects on skeletal and cardiac muscle with severe kyphosis and atrial fibrillation occurring within this new double knockout mouse model. There was also elevated scar tissue deposition within cardiac muscle and embryonic lethality experienced.

The severe embryonic lethality of double knockout α 7 $-/-$: dy $-/-$ mice furthers previous knowledge and emphasizes the importance of α 7 integrin in rescuing the loss of laminin- α 2. The duplicity of their bi-directional relationship of protecting the structural and functional integrity of muscle is very much highlighted in the generation of this double knockout double knockout mouse model. We observed severe muscle pathology in 10 week old α 7 $-/-$: dy $-/-$ mice which is a new result for this field of study as no one has ever created this double knockout mouse model. Absence of both proteins in α 7 $-/-$: dy $-/-$ mice results in severe skeletal and cardiac muscle degeneration, reduced functional activity and fibrotic scar tissue deposition. Here, compensation by α 7 integrin helps these mice to maintain functional integrity.

The $\alpha 7^{-/-}:: dy^{-/-}$ mice analyzed in this study exhibit a phenotype similar to that of single knockout of $\alpha 7$ integrin. This phenotypic similarity between these two genotypes suggests that there is functional overlap in the role of $\alpha 7$ integrin in maintaining muscle structure and function. Double knockout $\alpha 7^{-/-}:: dy^{-/-}$ mice exhibit a hugely severe cardiac phenotype suggesting that both $\alpha 7$ integrin and laminin- $\alpha 2$ are very critical to cardiac muscle function by their presence. It also suggests there is no active sarcolemmal complex able to cope and compensate for the loss of both of them. Therefore, the heart is not able to pump efficiently in a coordinated manner and we see the atrial fibrillation occurring.

The $\alpha 7^{-/-}:: dy^{-/-}$ mouse is a new mouse model for muscular dystrophy that has been identified which lacks both $\alpha 7$ integrin and laminin- $\alpha 2$. This has never been studied before in the dy^W mouse model¹⁷³. Further investigation will reveal the effects on pathophysiology and expression of sarcolemmal proteins. Future directions will include TA, heart and diaphragm tissue being assessed via immunoblotting for any changes in the abundance of proteins that are related to the dystrophin-glycoprotein laminin binding complex. These proteins will include dystroglycans, sarcoglycans, sarcospan, integrin-linked kinase and AKT. Immunofluorescence will be used on the same TA, heart and diaphragm muscle in order to confirm the immunoblot results.

Results from characterization of this new $\alpha 7$ integrin / laminin- $\alpha 2$ dko mouse model will aid in understanding the exact role that $\alpha 7$ integrin and laminin-

$\alpha 2$ play in MDC1A. It will also potentially help with the identification of novel therapeutic targets for this devastating neuromuscular disease.

This dissertation provides evidence that laminin-111 is beneficial with treatment before disease onset by reducing muscle pathology and increasing functional activity within mice. It is also the first time that the $\alpha 7$ integrin $-/-$: laminin- $\alpha 2$ $-/-$ double knockout mouse model has been studied and described for this particular $\alpha 7$ $-/-$ mouse model.

Appendix A

Laminin-111 pharmacokinetics/ pharmacodynamics and rhLam-111 production

MATERIAL AND METHODS

EHS mLAM-111

Engelbreth-Holm Swarm mouse laminin-111 supplied at 1 mg in 50 mM Tris-HCL (pH 7.4), 0.15 M NaCl was used to treat mice. The laminin was thawed slowly overnight at 4°C.

Generation of laminin-111 DNA

DNA for rhLAM-111 transfection into the CHO_S system was prepared and cleaned via illustra plasmidPrep Midi Flow kit (GE Healthcare). It had to be RNased via the RNAeasy kit following manufacturers guidelines. The α chain was on one plasmid and β & γ chains on the second plasmid. The plasmids had to be linearized before transfection into the CHO_S cells. Lipofectamine transfection reagent was needed and DNA had to be purified in order to perform the transient transfections into the naïve CHO_S cell system in order to harvest a huge batch of rhLam-111 media to be sent for FPLC purification. A key note with regards to the previous attempt is that any rhLAM-111 protein that had been produced may have degraded before harvest during the seven day experiment which was at 37 °C. So far I have performed MIDI preps, extracted and purified both α and β & γ DNA in preparation for transfection. However, the DNA yield has been low due to their large size. Therefore, more reagents will be needed in order to grow and purify more DNA that is necessary for large scale rhLAM-111 production.

Purification of recombinant human laminin-111 protein

rhLam-111 protein was concentrated and then was dialyzed in Tris buffered Saline (TBS).

Silver staining

ProteoSilver Stain kit (Sigma) was used to stain after SDS-PAGE gel electrophoresis. Gels were fixed for 20 minutes then subject to a 10 minute 30% ethanol wash, 10 minute water wash. After this step, the gels were immersed in sensitizer solution for 10 minutes, the gels were then washed for 10 minutes and put into silver solution for 10 minutes. There was then a water wash and gel development before stop solution was finally added.

Coomassie Staining

Coomassie staining was performed using a Fairbanks Quick coomassie staining protocol.

Immunoblotting

Protein was harvested from CHO's cell media. Proteins were separated via 4% SDS-PAGE gel electrophoresis with no stacking gel. They were then transferred to nitrocellulose membrane and blocked with (carnation milk) for 1 hour. Proteins were incubated with primary antibody overnight before being incubated with secondary antibody (1 hour) and washed with 1X TBST buffer. Protein sizes were: α 400 kDa, β 200 kDa & γ 180 kDa. Proteins were imaged using the Licor Odyssey system after detection with Laminin α -1 (H-300): sc

5582, Laminin β -1 (H-300): sc 5583, and Laminin γ -1 (H-190): sc-5584 (Santa Cruz) antibodies.

Generation of mice

Laminin- α 2 $-/-$ mice

All experiments involving mice were performed under an approved protocol from the University of Nevada, Reno Institutional Animal Care and Use Committee. The $dy^{W/+}$ mice were a gift from Eva Engvall via Paul Martin (The Ohio State University, Columbus, OH, USA). Male and female heterozygous mice were bred. In order to genotype mice, genomic DNA was isolated from tail snips or ear notches using a Wizard SV DNA purification system (Promega, Madison, WI) following manufacturers instructions. To detect the mutation in the laminin- α 2 gene, the following primers were used: DYWF (5'-ACTGCCCTTTCTCACCCACCCTT-3'), LAMA2exonR1 (5'-GTTGATGCGCTTGGGAC-3') and Lac/ZR2 (5'-GTCGACGACGACAGTATCGGCCTCAG-3'). PCR conditions were as follows: 95°C for 5 minutes then 33 cycles of 94°C for 20 seconds, 62°C for 30 seconds and 72°C for 45 seconds. After these cycles, then 72°C for 10 minutes. A wild-type band was 250 bp whereas the laminin- α 2 targeted allele produced a 480 bp band.

Experimental procedures were performed once mice were 10 days and 2 weeks of age with weekly weighing until the end of study which was at 2 weeks and 5 weeks of age where all mice were subject to *in vivo* experiments. To

reduce experimental bias, investigators assessing and quantifying experimental outcomes were blinded to the treatment and control groups.

Mdx mice

The mutation in the dystrophin gene was detected using a modified ARMS assay. The following primers were used: p259E (5'GTCACTCAGATAGTTGAAGCCATTTAA-3'), p260E (5'-GTCACTCAGATAGTTGAAGCCATTTAG-3') and p306F (5'-CATAGTTATTAATGCATAGATATTCAG-3'). PCR conditions were as follows: 95°C for 4 minutes then 34 cycles of 95°C for 1 minute, 55°C for 1 minute and 72°C for 1 minute. Primer set p259 and p306 produced a 275 bp wild-type dystrophin allele. Primer set p260 and p306 detects the *mdx* point mutation which produced a 275 bp product. To genotype the dystrophin gene, separate PCR reactions were performed since the product sizes are identical in wild-type and *mdx* mice.

Husbandry

dy^W-/- mice and *mdx* were housed with their wild-type littermates alongside the provision of mashed kibble and access to water. Husbandry and protocols were carried out via IACUC approval. Knockout mice that lost $\geq 20\%$ body weight (g) were euthanized. Pups were genotyped at 10 days old and at the end of each study, the female WT and *dy^W-/-* mice were euthanized by CO₂ inhalation in accordance with a protocol approved by the University of Nevada, Reno Animal Care and Use Committee. The diaphragm muscles from these mice

were dissected, flash-frozen in liquid nitrogen and stored at -80°C as previously reported by ¹³⁴.

Treatment with rhLam-111 and EHS mLam-111 in $dy^{W/-}$

Female $dy^{W/-}$ mice were systemically injected at 11 days old weekly with 0.01mg/g of rhLam-111 or EHS mLam-111 until they were 5 weeks old. Control littermate $dy^{W/-}$ mice were injected with the equivalent volume of sterile Tris buffered saline (TBS). Male $dy^{W/-}$ mice were systemically injected at 2 weeks old weekly with 0.01 mg/g of rhLam-111 or EHS mLam-111 until they were 10 weeks old. Control littermate $dy^{W/-}$ mice were injected with the equivalent volume of sterile Phosphate buffered Saline (PBS).

Pharmacokinetic Intramuscular *in vivo* Imaging

Intramuscular Injection with DyLight-488nm labelled laminin-111 was at the same volume that would be administered as if giving a 0.01 mg/g systemic injection. The IVIS system (XENOGEN, VivoVision systems, CA) was employed to image the mouse post-intramuscular injection.

Muscle Strength

Muscle strength assessed at 5 weeks & 10 weeks of age for male mice using the Chatillon DFE Digital Force Gauge (San Diego Instruments Inc., San Diego, CA). A total of six measurements per mouse were recorded and all results averaged for each group. The mice were analyzed by grasping a horizontal

platform with their forelimbs and pulled backwards. The peak tension (grams of force) was recorded on a digital force gauge as mice released their grip.

ELISA

For Pharmacokinetic analysis of laminin-111, systemic injection of EHS mLAM-111 in *dy^W -/-* and *mdx* mice was followed by retro-orbital bleeds performed at various time points (0 min, 30 min, 1 hour, 2 hour, 4 hour, 8 hour and 24 hour). An ELISA designed to detect the laminin- α 1 chain demonstrated that laminin-111 had a half-life of ~90 minutes within the serum of *dy^W -/-* mice. The protein was cleared from the bloodstream much more quickly than that of the WT littermate controls. This phenomenon suggests that the laminin-a2 deficient muscle is much more leaky and therefore requires laminin-111 to help stabilize the sarcolemma and provide protection against the sheer stresses of mechanotransduction. Labeled EHS mLAM-111 was detected 18 hours post-intramuscular injection.

Hematoxylin and Eosin staining

Tibialis Anterior muscle was cryosectioned and 10 μ m sections were placed on surgipath microscope slides. Tissue sections were fixed with ice-cold 95 % ethanol for 2 minutes followed by 70 % ethanol for 2 minutes and then re-hydrated in running water for 5 minutes. Gill's hematoxylin (Fisher Scientific, Fair Lawn, NJ) was then used to stain the sections and rinsed in water for 5 minutes. Scott's solution (0.024 M NaHCO₃, 0.17 M MgSO₄) was then applied for 3

minutes and rinsed in water for 5 minutes. Tissue cryosections were then immersed in eosin solution (Sigma-Aldrich, St. Louis, MO) for 2 minutes. Sections were then dehydrated in ice cold 70 % and 95 % ethanol for 30 seconds each, followed by 100 % ethanol for 2 minutes. Xylene was then used to clear the sections for 5 minutes prior to mounting with DepeX mounting medium (Electron Microscopy Services, Washington, PA). Centrally located Nuclei were counted from images composing representative montages for each mouse. Images were assessed at 200 X magnification by bright field microscopy. The number of centrally located nuclei per muscle fiber was determined by counting each image which contributed to myofibers being counted per treatment group. At least 4 animals from each treatment group were analyzed.

Statistical Analysis

All averaged data are reported as the mean \pm s.d. P-values of < 0.05 were considered to be statistically significant.

RESULTS

Laminin-111 half-life calculation for $\alpha 2^{-/-}$ mice

The ELISA results for the half-life of laminin-111 (Figure 38) revealed that once intraperitoneally injected laminin remains in the serum of WT mice for 120 minutes whereas $\alpha 2^{-/-}$ serum retains the laminin for 90 minutes. The protein was cleared from the bloodstream much more quickly than that of the WT littermate controls. This phenomenon suggests that the laminin- $\alpha 2$ deficient

muscle is much more leaky and therefore requires laminin-111 to help stabilize the sarcolemma and provide protection against the sheer stresses of mechanotransduction. One has to ponder over where the laminin is going. Pharmacodynamic studies will need to be employed to help answer these questions.

Laminin-111 Half-life calculation for *mdx* mice

The laminin-111 half-life worked out to be 140 minutes for WT mice and only 50 minutes for *mdx* mice before it was cleared out of the serum (Figure 39). The n numbers were good at n=3 each treatment group.

EHS mouse Laminin-111 detection in a WT CD1 mouse 18 hrs post-intramuscular injection

The IVIS system was utilized after EHS mLam-111 had been labelled with Dylight-488. The labelled laminin was then intramuscularly injected into the tibialis anterior muscle of a WT CD1 mouse (Figure 40). Laminin was detected up to 18 hours post-injection showing that laminin-111 had a long half-life when injected directly into target muscle.

rhLAM-111 DNA for CHO cells

DNA for rhLAM-111 was purified in preparation for transfection into the CHO system was cleaned (Figure 42). It had to be RNased. α was on one plasmid and β & γ chains on the second plasmid. The plasmids had to be linearized before transfection into the CHO cells. However, the DNA yield has

been low due to the large size of each plasmid. Therefore, more reagents will be needed in order to grow and purify more DNA that is necessary for large scale rhLAM-111 production.

rhLam-111 protein production verification and quality control

Silver staining is an extremely sensitive method with which showed the purity of rhLam-111 protein produced from the CHO system (Figure 43). Immunoblotting revealed that all three chains of laminin-111 (α , β , & γ) were able to be produced after transfection and were demonstrated via separate immunoblots. The control used was manufactured human laminin-111. Fairbanks coomassie staining was used as a second verification to look at the total number of proteins in the cell supernatant of the rhLam-111 CHO media compared to naïve media. Controls used included supernatant from the dialysis of rhLam-111 and CHO naïve dialyzed media.

Clustering and cell adhesion assays

rhLaminin-111 in a 100 nM concentration was able to form neuromuscular junctions (NMJs) in clustering assays of differentiated C2C12 cells (Figure 44) and rhLam-111 proved to be more adherent to *mdx* myoblasts compared to WT C2C12 myoblasts in cell adhesion assays¹⁸⁷.

Immunofluorescent detection of laminin-111

After systemic treatment both mouse laminin-111 and human recombinant laminin forms were able to be detected in *dy^w/-* Tibialis anterior muscle (Figure

45). This showed that the rhLAM-111 was able to be delivered systemically to the target muscle of interest.

Functional assessment of $dy^W/-$ mice treated with laminin

There was no real significant difference in the functional activity of mice treated with EHS mLam-111 compared to mice treated with rhLam-111 (Figure 46). This could mean that this study needs more n numbers to comment further. More pure rhLam-111 needs to be produced.

Integrin immunoblotting after laminin-111 treatment

rhLam-111 was not effective in producing the same effects as EHS mLaminin-111 on $\alpha 7A$ or $\alpha 7B$ integrin in $dy^W/-$ mice treated with the recombinant protein (Figure 47).

Histological analysis of laminin treated $dy^W/-$ mice

There was no difference regards muscle pathology between EHS mLam-111 treated and rhLam-111 treated animals (Figure 48). However there was a trend towards WT for rhLam-111 treatment regards increased minimal feret's diameter measurements. Laminin-111 treatment, especially rhLam-111 was able to increase myofiber size.

Immunological response to laminin-111 treatment

With the rhLAM-111, we tested whether there was any immunogenicity whenever it was injected systemically into the $dy^W/-$ mouse every week from 2

weeks old up to 5 weeks old (Figure 49). It had already been contemplated that other contaminating proteins in the rhLAM-111 coupled with the fact that human protein injected into a mouse could elicit an immune response especially during a 3 week experiment. An ELISA was performed on the harvested serum from these mice alongside WT, PBS and EHS mLAM-111 treated littermate controls. Preliminary results showed that there was an immune response elicited towards the injected hrLAM-111 upon the detection of elevated IgG antibodies in the serum of these mice.

hLam-111 transgenic mouse production

Gawlik *et al.* 2004 demonstrated feasibility of transgenic expression in $dy^{W/-}$ mice by generation of Laminin- $\alpha 1$ $dy^{W/-}$ mice. Recently, the Burkin lab has been able to generate transgenic founder mouse lines positive for human Laminin- $\alpha 1$, $\beta 1$ and $\gamma 1$ chains (Figure 50). This transgenic overexpression of Laminin-111 will be included within the study in order to investigate the most exaggerated effect due to the presence of Laminin-111.

DISCUSSION

These were disappointing results for rhLam-111 *in vivo* trials but it is important to remember that this recombinant protein is still in the early stages of trial production and it is difficult to produce due to its large size (~900 kDa). Various avenues of human laminin-111 production were explored to date. The

main method of production of human recombinant laminin (hrLAM-111) involved transient transfection with laminin- α 1 into a stable CHO_S cell line that produced the $-\beta$ and $-\gamma$ chains of laminin. This transfection proved successful in that immunoblotting performed on the media harvested showed that all three chains of LAM-111 were present. Talon technology could be used in order to knockout hamster α -4 and α -5 produced by the CHO_S cells. However, the purification protocol may have precipitated out most of the laminin-111 with which we are interested. The exact concentration of hrLAM-111 will need to be determined. A new strategy has been devised in order to generate a huge batch of hrLAM-111 with the CHO_S system and the resulting media will be harvested and sent for FPLC purification.

ACKNOWLEDGEMENTS

I would like to thank Dr. Mark Hubbard, Dr. Breeana Hubbard and Dr. Ryan Wuebbles for their technical assistance in the design of the CHO_S system and ELISA experiments. I would also like to thank Apurva Sarathy for the immunofluorescent clustering assay.

Figure 38. Laminin-111 half-life calculation for $dy^{W-/-}$ mice

Half-life of EHS mouse laminin-111 (intraperitoneally injected), was calculated using an ELISA designed to detect laminin- α 1 in mouse serum collected over a period of time. This figure was kindly provided by Dr. Ryan Wuebbles.

Figure 39. Laminin-111 Half-life calculation for *mdx* mice

Half-life determination performed using Graphpad Prism non-linear regression (curve fit) with exponential one-phase decay from the peak Laminin-111 concentration. A more complete insight into the action of laminin-111 will be achieved by investigating the pharmacokinetics and pharmacodynamics of laminin-111 administered to *mdx* mice. Pharmacokinetics involved collecting

serum (30 min, 1 hour, 2 hour, 4 hour, 8 hour, 24 hour, 48 hour, 72 hour) via retro-orbital bleeds from 5 WT and 5 *mdx* mice injected intraperitoneally (I.P) with 0.01 mg/g mLAM-111. Baseline serum will be collected at 0 hour prior to the initial injection. ELISA assays were carried out on the serum in order to help determine the movement of laminin-111 once it was *in vivo* and how fast laminin-111 can clear out of the lymphatic system. This information will ultimately help decide this protein's mechanism of action alongside the collection of pharmacodynamics data which will involve the collection of tissue at various time points after injection in order to discover how quickly laminin-111 can be delivered to the muscle. This figure was kindly provided by Dr. Ryan Wuebbles.

Transcriptome Data

ABSTRACT

Merosin deficient congenital muscular dystrophy type 1A (MDC1A) is caused by loss of laminin-211 and laminin-221 within the basal lamina of skeletal and cardiac muscle. This absence of laminin-211/221 reduces the capacity for myofiber adhesion, loss of sarcolemmal integrity and subsequently the ability of the skeletal muscle syncytium to generate force in a coordinated and efficient manner. Patients experience progressive muscle wasting which confines them to a wheelchair at an early age and respiratory failure that leads to their untimely death. Currently, there is no effective treatment or cure for this devastating disease. This study set out to determine the transcriptional changes that occur within the diaphragm muscle during MDC1A disease progression using RNA-Seq technology. Our results show major transcriptional changes with age in pathways associated with immune response, cell growth and survival and muscle repair. Galectin-3 is known to help stabilize myofibers and these transcripts were found to be upregulated (six-fold) in diseased muscle compared to wild-type muscle. Together, this study will help to identify novel therapeutic targets that may be useful in the treatment of MDC1A.

INTRODUCTION

Merosin deficient congenital muscular dystrophy (MDC1A) is caused by the loss of Laminin-211 and Laminin-221 heterotrimers which are most abundant in skeletal and cardiac muscle basal lamina; mutations in the *LAMA2* gene cause the loss of these Laminin isoforms. This reduction of Laminin reduces the capacity for myofiber adhesion, loss of sarcolemmal integrity and subsequently affects the ability of the skeletal muscle syncytium to generate force in a coordinated and efficient manner. Patients, from birth, experience progressive muscle wasting which confines them to a wheelchair at an early age and respiratory failure that leads to their untimely death. Currently, there is still no effective treatment or cure for this devastating disease.

Merosin deficient congenital muscular dystrophy (MDC1A) affects approximately 0.89/100,000 individuals worldwide (1:100,000 - 1:500,000) and is deemed to be the most common form of congenital muscular dystrophy. Loss of merosin (Laminin- α 2 protein) is caused by mutations occurring in the *LAMA2* gene which is located on chromosome 6q22-23^{90,91}. This loss of Laminin- α 2 protein in MDC1A results in the absence of Laminin-211 and Laminin-221 heterotrimers which are abundant in skeletal and cardiac muscle basal lamina. Patients, also experience demyelinating neuropathy, muscle atrophy, limited eye movement and also respiratory failure that leads to their untimely death which can be as early as the first decade of life (Jones *et al.*, 2001; Muntoni *et al.*,

2004; Philpot *et al.*, 1999). There is an increased likelihood of seizures occurring after six months of age due to changes in white matter of the brain (Jones *et al.*, 2001; Muntoni *et al.*, 2004; Philpot *et al.*, 1999). Currently, there is still no effective treatment or cure for this cruel disease (Mendell, *et al.*, 2006; Muntoni *et al.*, 2004).

MATERIALS AND METHODS

Generation of Laminin- α 2 $-/-$ mice

All experiments involving mice were performed under an approved protocol from the University of Nevada, Reno Institutional Animal Care and Use Committee. The *dyW* $^{+/-}$ mice were a gift from Eva Engvall via Paul Martin (The Ohio State University, Columbus, OH, USA). Male and female heterozygous mice were bred together. In order to genotype mice, genomic DNA was isolated from tail snips or ear notches using a Wizard SV DNA purification system (Promega, Madison, WI) following manufacturers instructions. To detect the mutation in the laminin- α 2 gene, the following primers were used: DYWF (5'-ACTGCCCTTTCTCACCCACCCTT-3'), LAMA2exonR1 (5'-GTTGATGCGCTTGGGAC-3') and Lac/ZR2 (5'-GTCGACGACGACAGTATCGGCCTCAG-3'). PCR conditions were as follows: 95°C for 5 minutes then 33 cycles of 94°C for 20 seconds, 62°C for 30 seconds and 72°C for 45 seconds. After these cycles, then 72°C for 10 minutes. A wild-type band was 250 bp whereas the laminin- α 2 targeted allele produced a 480 bp band.

Experimental procedures were performed once mice were 10 days old and 2 weeks of age with weekly weighing until the end of study which was at 2 weeks and 5 weeks of age where all mice were subject to *in vivo* experiments. To reduce experimental bias, investigators assessing and quantifying experimental outcomes were blinded to the treatment and control groups.

Husbandry

$dy^{W/-}$ mice were housed with their wild-type littermates alongside the provision of mashed kibble and access to water. Husbandry and protocols were carried out via IACUC approval. Knockout mice that lost $\geq 20\%$ body weight (g) were euthanized. Pups were genotyped at 10 days old and at the end of each study, the female WT and $dy^{W/-}$ mice were euthanized by CO₂ inhalation in accordance with a protocol approved by the University of Nevada, Reno Animal Care and Use Committee. The diaphragm muscles from these mice were dissected, flash-frozen in liquid nitrogen and stored at -80°C as previously reported by ¹³⁴.

Laminin-111 protein treatments

$dy^{W/-}$ mice were systemically injected with 0.01 mg/g/week of laminin-111 protein (Invitrogen). Laminin-111 was stored at -80°C and thawed slowly at 4°C overnight before use. $dy^{W/-}$ mice were systemically injected (weekly) from 10 days old until 5 weeks old.

Experimental Design

Female Wild-type (n=5) and dy^W $-/-$ (n=5) mice were sacrificed at 2 weeks old untreated. Another treatment group within this study incorporated female dy^W $-/-$ (n=4) systemically treated from 10 days old to 5 weeks old with 0.01 mg/g/week laminin-111. Alongside this treatment group dy^W $-/-$ control mice (n=4) were systemically injected with a volume of sterile Phosphate buffered saline (PBS) that equated to such in the laminin-111 treatment group. At 5 weeks of age, PBS and laminin-111 treated dy^W $-/-$ mice were sacrificed following a protocol approved by the Animal Care and Use Committee at the University of Nevada, Reno. Temporal analysis of WT, PBS and Laminin-111 treatment groups at 5 weeks of age was planned with the hope of identifying what changes occur within the transcriptome of these animals.

Muscle transcripts

The muscle transcript ontology groups of interest included: Integrin signaling, Inflammation, Fibrosis, Apoptosis (ILK, AKT), Extracellular Matrix signaling, Cell surface receptors and signaling (integrins and dystrophin and utrophin glycoproteins) and Cell Survival pathways (AKT).

RNA-Sequencing

Diaphragm tissue was homogenized and suspended in TRIzol reagent (GibcoBRL, Life Technologies). Total RNA was isolated following the manufacturer's instructions (GibcoBRL, Life Technologies). The pooled samples were DNased and cleaned before being sent to the UC Davis genome center for

RNA-Sequencing. The RNA samples were measured after cleaning and were then pooled in order to reduce cost. Aliquots of individual mouse RNA samples were stored at -80°C and then used for qRT-PCR in order to confirm the results received from the RNA-Seq data generated. TRIzol was added to individual samples, RNA was extracted, DNased, RNA samples were pooled, cleaned and eluted using RNeasy Mini Spin Columns (Qiagen) according to the manufacturer's instructions (double sample pool for cleaning), RNA was measured for content using the nanodrop.

Data Analysis

Microsoft Excel and Ingenuity Pathway Analysis (IPA) software were employed in order to visualize the signaling pathways affected within the treatment groups. Protein expression levels were analyzed and processed using GraphPad Prism software. Fold-changes in protein were calculated using changes in intensity within ImageJ software.

Statistical Analysis of RNA-Seq data

Each sample was subjected to alignment and counting of mapped reads. For this, TopHat was used for alignment to the genome, then reads were counted per locus (all isoforms counted together for one gene) using htseq-counts. In order to adjust for large differences in the number of mapped reads in each sample (with the sample with the most reads having more than 6 times as many

reads as the sample with the fewest reads), prior to analysis, counts were down-sampled using binomial sampling as described by¹⁴³. Genes with less than 1 count per million reads in all 8 samples were filtered from the counts table, leaving 15,026 genes in the analysis. Differential expression analysis was conducted using the Bioconductor package edgeR, version 3.4.2¹⁴⁴⁻¹⁴⁷. Analysis was conducted using a multifactorial GLM with factors for time, group (WT, PBS treated $dy^{W/-}$ and LAM-111 treated $dy^{W/-}$), and their interaction. This multifactorial method was chosen during analysis as it is considered to be more powerful than running each discrete comparison. Due to the lack of replication, tagwise dispersion parameters were estimated from a multifactorial GLM with factors for time and group but no interaction effect. *P*-values were adjusted for multiple testing using the false-discovery rate (FDR) method of Benjamini and Hochberg (1995)¹⁴⁸. Log2-fold changes and FDR-adjusted *p*-values less than 0.1 for all 15,026 genes included in the analysis.

RESULTS

Transcriptome data analysis encompassed changes in 5 week old diaphragm tissue harvested from PBS treated $dy^{W/-}$ versus LN-111 Treated- $dy^{W/-}$ mice. Relatively few significant changes (~275 total genes), most genes have apparently little to do with muscle or ECM, many genes associated with bone growth and maintenance, muscle and ECM associated genes which were found to be significantly

altered were tenascin N, elane (elastase), aggrecan, MMP8, MMP9, MMP13, proteinase-3. Several genes associated with neuronal signaling. Our results at this age may represent individual disease state changes and not changes specifically associated with Laminin-111 treatment. 5 week old diaphragm from Wild-type versus Untreated dy^W $-/-$ changes: Over 1,000 genes were significantly altered, current analysis is continuing on the known functions for all genes on the list, one interesting gene upregulated in the dy^W $-/-$ diaphragm is osteoactivin (GPNMB).

Heat map for 2 week old dy^W $-/-$ mouse signaling networks misregulated by loss of laminin- α 2

Signaling networks upregulated include immune cell trafficking, cellular movement and inflammatory response. Signaling networks down-regulated include cell death and cellular maintenance. It is important to remember that this is before disease onset (Figure 51). A main overview of pathways affected include: Inflammatory Response, Cellular movement, Immune cell trafficking, Apoptosis, Fibrosis, Scar tissue formation and ROS.

Heat map for 5 week old dy^W $-/-$ mouse signaling networks that were misregulated upon laminin-111 treatment

Networks upregulated include vitamin and mineral metabolism alongside lipid metabolism. Networks down-regulated include inflammatory response and

immune cell trafficking (Figure 52). A main overview of pathways affected include Inflammatory response, Cellular movement, Immune cell trafficking, Necrosis, and Repair pathways upregulated with laminin treatment.

2 week old dy^W $-/-$ Integrin involvement in extracellular matrix interactions, cellular movement and survival signaling pathways

Integrin is consistently involved in the alteration of signaling pathways (Figure 53) and there is also involvement in initiating ERK/MAPK downstream signaling pathways (Figure 54) in 2 week old Dy^W $-/-$.

Comprehensive summary of ≥ 4 -fold changes in 2 week old dy^W $-/-$ mice

138 transcripts misregulated ≥ 4 -fold between WT and dy^W $-/-$ at 2 weeks old.

Comprehensive summary of ≥ 4 -fold changes in 5 week old dy^W $-/-$ mice

468 transcripts misregulated ≥ 4 -fold between dy^W $-/-$ PBS treated and Dy^W $-/-$ Laminin treated at 5 weeks old.

DISCUSSION

The aim of this study was to identify transcriptional changes within diaphragm muscle for the MDC1A mouse model compared to wild type controls. Muscle contraction causes acute damage to the integrity of the sarcolemma within healthy skeletal muscle resulting in myofiber rupture that releases many susceptible candidates for immune targeting. This process may be aberrantly

activated in the progressive disease state of Laminin- α 2 deficient skeletal muscle resulting in chronic injury with the prolonged release of many intracellular molecules including proinflammatory cytokines, growth factors and cytosolic calcium which is directly involved in the activation and recruitment of T-lymphocytes facilitating a positive feedback mechanism for further myofiber contraction, rupture, apoptosis and fibrotic scar tissue formation. It is unclear from past and current studies what exact role or what key immune players have in the pathophysiology of MDC1A. Treatment with Laminin-111 (found embryonically) reduces muscle pathology and improves viability in the *dy^W/-* MDC1A mouse model. Laminin-111 helps to strengthen and reinforce the sarcolemma in the *dy^W/-* mouse during prolonged progressive muscle injury induced by contraction offering a protective niche against the occurrence of this degenerative scenario by reducing inflammation, fibrosis and apoptosis via improved matrix-mechanotransduction.

At 2 weeks of age the variability between animals is low and the RNA-Seq data appears solid. At 5 weeks of age there is significant variability between mice and the RNA-Seq data requires more interpretation. The changes observed in some of the transcripts were the result of only one mouse in the 5 week study. RT-PCR data analysis confirms this result. Osteoactivin is involved in differentiation of skeletal and muscle tissue and may serve as a novel biomarker for disease progression. RT-PCR confirmed that it is increased in mice and also now in an MDC1A patient muscle that we have in our tissue archive.

Osteoactivin (OA) is a (*Dchi1*) dendritic-cell associated heparin sulphate proteoglycan- dependent integrin ligand^{155,156}. In humans, OA is known as the *GNMB* gene. The osteoactivin gene encodes a protein of 572 amino acids and is localized to the membrane as a Type-1 transmembrane glycoprotein^{151,156}. OA is expressed in osteoblasts actively involved in bone matrix production and mineralization. OA is also necessary for osteoblast differentiation *in vitro*¹⁵⁰. Syndecan-4 is a receptor on T-cells for OA which therefore initiates an inhibitory function on T cell activation¹⁵⁷. OA is upregulated in muscle denervation and unloading stress. The regulatory mechanisms of OA in muscle and bone have not yet been determined, however the role of OA in transdifferentiation of myoblasts into osteoblasts has been eluded to in a published study by¹⁴⁹. Interestingly, osteoblast differentiation is characteristically identified by expression of markers which include Osteoactivin (*GpnmB*) and Osteocalcin (*Bglap*)¹⁵⁸. Transdifferentiation is the manner in which a somatic cell retains plasticity and can be transformed into another somatic cell. This process can also be described as lineage reprogramming. It was first demonstrated whenever mouse embryonic fibroblasts became myoblasts by forced expression of MyoD¹⁵⁹.

Laminin-111 is the predominant Laminin isoform found in the basal lamina of developing embryonic skeletal muscle¹¹⁵. However in adult skeletal and cardiac muscle Laminin-111 is replaced by Laminin-211 and Laminin-221 isoforms which help to anchor myofibers to the basement membrane and form neuromuscular junctions^{116,188}. Laminin- α 2 protein is an essential component of the basal lamina that surrounds muscle fibers and is composed of α , β , and γ

heterotrimers¹⁶¹. MDC1A is caused by the loss of Laminin- α 2 protein. Regeneration of Laminin- α 2 deficient muscle is also dependent on the presence of Laminin^{124,162}. Molecules that reinforce muscle-basal lamina interactions and restore normal survival signaling pathways are likely candidates for drug-based therapeutics for MDC1A.

Laminin-111 can be systemically delivered to all major muscles affected in MDC1A patients helping to enhance muscle integrity and addresses the primary defect of cellular adhesion in MDC1A. Laminin-111 is unlikely to elicit an immune response since it is naturally expressed during embryonic development and in the adult kidney basement membrane¹⁴². Treatment with Laminin-111 has been shown recently to reduce muscle pathology and improve viability in the (*dy^W-/-*) MDC1A mouse model¹³¹. In one such study, Evan's Blue Dye uptake was used to examine the integrity of the sarcolemma and Laminin-111 treatment had beneficial effects in Laminin- α 2 deficient muscle by causing a 7.3-fold reduction in sarcolemmal rupture. The α 7 β 1 integrin is the major Laminin-binding integrin in cardiac and skeletal muscle¹⁶³. MDC1A patients and *dy^W-/-* mice have reduced levels of α 7 integrin contributing to severe muscle pathology¹⁸⁸. Laminin-111 has been shown to increase α 7 integrin expression in mouse and human muscle cells¹⁶⁴.

Laminin-111 treatment in mice appears to block Osteoactivin expression and therefore would potentially restore MAPK signaling in muscle and prevent further fibrosis. The immunofluorescence data confirms in patients the mouse RNA-Seq data and RT-PCR studies.

Slc34a2	-6.77686	1.30E-18	Solute Carrier Family 23 (Ascorbic Acid Transporter), Member 1 Sodium/ascorbate cotransporter. Mediates lectrogenic uptake of vitamin C, with a stoichiometry of 2 Na(+) for each ascorbate
Rhbg	-6.50039	0.023785	Rh Family, B Glycoprotein (Gene/Pseudogene) Functions as a specific ammonium transporter
Mlc1	-6.50039	0.023785	Megalencephalic Leukoencephalopathy With Subcortical Cysts 1 Regulates the response of astrocytes to hypo-osmosis by promoting calcium influx
Pnliprp1	-6.36448	0.036951	Pancreatic Lipase-Related Protein 1 May function as inhibitor of dietary triglyceride digestion. Lacks detectable lipase activity towards triglycerides, diglycerides, phosphatidylcholine, galactolipids or cholesterol esters (in vitro) (By similarity)
Slc25a21	-6.36448	0.036951	Solute Carrier Family 23 (Ascorbic Acid Transporter), Member 1 Sodium/ascorbate cotransporter. Mediates

			lectrogenic uptake of vitamin C, with a stoichiometry of 2 Na(+) for each ascorbate
Il8	-6.22697	1.36E-10	Interleukin-8 important mediator of the innate immune response
Lamp3	-6.01392	1.69E-09	Lysosome associated membrane protein
Ager	-4.38287	0.012432	Advanced Glycosylation End Product-Specific Receptor The advanced glycosylation end product (AGE) receptor encoded by this gene is a member of the immunoglobulin superfamily of cell surface receptors. It is a multi-ligand receptor, and besides AGE, interacts with other molecules implicated in homeostasis, development, and inflammation, and certain diseases, such as diabetes and Alzheimer's disease.
Irx1	-4.2336	0.010733	Iroquois Homeobox 1 role in many developmental processes
Car5a	-3.82149	0.065864	Carbonic anhydrase 5a, mitochondrial
Nkx2-1	-3.61684	0.089384	NK2 Homeobox 11 Transcription factor that binds and activates the promoter of thyroid specific genes such as thyroglobulin, thyroperoxidase, and thyrotropin receptor. Crucial in the maintenance of the thyroid differentiation phenotype. May play a role in lung development and surfactant homeostasis
Gm4956	-3.02513	0.035316	Predicted gene
Lama2	-3.0068	8.05E-11	Laminin- α 2
Wfdc2	-2.45846	0.041273	WAP Four-Disulfide Core Domain 2 Broad range protease inhibitor

Plek	2.010477	0.036951	Pleckstrin Major protein kinase C substrate of platelets
Cyp4f18	2.010628	0.05633	Mucosa-specific cytochrome P450 enzyme active in the metabolism of sex steroids and xenobiotic substrates
Ms4a6b	2.015674	0.005589	Membrane-spanning 4-domains, subfamily A, member 6B immune?
Plac8	2.042618	0.000878	Placenta-Specific 8 brown fat cell differentiation, defense response to bacterium, nucleus chromatin binding, protein binding
Cd52	2.048367	0.01817	CD52 Molecule May play a role in carrying and orienting carbohydrate, as well as having a more specific role
Dio2	2.070554	0.002823	Deiodinase, Iodothyronine, Type II1 Responsible for the deiodination of T4 (3,5,3',5'-tetraiodothyronine) into T3 (3,5,3'-triiodothyronine). Essential for providing the brain with appropriate levels of T3 during the critical period of development
Stx11	2.079843	0.04176	Syntaxin 11 SNARE that acts to regulate protein transport between late endosomes and the trans-Golgi network
Lat2	2.111883	0.008663	Linker For Activation Of T Cells Family, Member 2 Involved in FCER1 (high affinity immunoglobulin epsilon receptor)-mediated signaling in mast cells. May also be involved in BCR (B-cell antigen receptor)-mediated signaling in B-cells and FCGR1 (high affinity immunoglobulin gamma Fc receptor I)-mediated signaling in myeloid cells. Couples activation of these receptors

			and their associated kinases with distal intracellular events through the recruitment of GRB2
Emr1	2.116129	0.024873	Egf-Like Module Containing, Mucin-Like, Hormone Receptor-Like 1 Could be involved in cell-cell interactions
Cybb	2.136779	0.027832	Cytochrome B-245, Beta Polypeptide Critical component of the membrane-bound oxidase of phagocytes that generates superoxide. It is the terminal component of a respiratory chain that transfers single electrons from cytoplasmic NADPH across the plasma membrane to molecular oxygen on the exterior
Slamf7	2.140173	0.088282	Isoform 1 mediates NK cell activation
Clec4a2	2.142002	0.002082	C-type lectin domain family 4, member $\alpha 2$ immune system process, innate immune response integral component of membrane, membrane carbohydrate binding
Runx1	2.14289	0.00018	Runt-Related Transcription Factor 1 The protein encoded by this gene represents the alpha subunit of CBF and is thought to be involved in the development of normal hematopoiesis. Chromosomal translocations involving this gene are well-documented and have been associated with several types of leukemia.
Gpr34	2.146967	0.003833	G Protein-Coupled Receptor 34 G protein-coupled receptors (GPCRs), such as GPR34, are integral

			membrane proteins containing 7 putative transmembrane domains (TMs). These proteins mediate signals to the interior of the cell via activation of heterotrimeric G proteins that in turn activate various effector proteins, ultimately resulting in a physiologic response.
Itgam	2.178598	0.039179	Macrophage antigen-1
Atp8b4	2.189358	0.049184	ATPase, Class I, Type 8B, Member 4 This gene encodes a member of the cation transport ATPase (P-type) family and type IV subfamily. The encoded protein is involved in phospholipid transport in the cell membrane
Ly9	2.200132	0.062293	Lymphocyte Antigen 9 May participate in adhesion reactions between T lymphocytes and accessory cells by homophilic interaction
Msr1	2.223096	0.054442	Macrophage Scavenger Receptor 1 Membrane glycoproteins implicated in the pathologic deposition of cholesterol in arterial walls during atherogenesis. Two types of receptor subunits exist. These receptors mediate the endocytosis of a diverse group of macromolecules, including modified low density lipoproteins (LDL). Isoform III does not internalize acetylated LDL
Lst1	2.229202	0.019488	Leukocyte Specific Transcript 1 Possible role in modulating immune responses. Induces morphological changes including production of filopodia and microspikes

			when overexpressed in a variety of cell types and may be involved in dendritic cell maturation. Isoform 1 and isoform 2 have an inhibitory effect on lymphocyte proliferation
Cxcl10	2.232386	0.023785	Chemokine (C-X-C Motif) Ligand 10 Chemotactic for monocytes and T-lymphocytes. Binds to CXCR3
Evi2b	2.233146	0.055725	Ecotropic Viral Integration Site 2B
Card14	2.257698	0.057749	Caspase Recruitment Domain Family, Member 14 Plays a role in signaling mediated by TRAF2, TRAF3 and TRAF6 and protects cells against apoptosis. Activates NF-kappa-B via BCL10 and IKK. Stimulates the phosphorylation of BCL10
Egr1	2.280286	0.009349	Early Growth Response 1 Transcriptional regulator. Recognizes and binds to the DNA sequence 5'-CGCCCCCGC-3'(EGR-site). Activates the transcription of target genes whose products are required for mitogenesis and differentiation
Arl11	2.281866	0.023785	ADP-Ribosylation Factor-Like 11 May play a role in apoptosis. May act as a tumor suppressor
Thbs4	2.292313	6.20E-06	Thrombospondin 4 Acts as an extracellular mitogen and stimulates early erythroid progenitors proliferation in presence of EPO. Adhesive glycoprotein that mediates cell-to-cell and cell-to-matrix interactions. Can bind to fibrinogen, fibronectin, laminin and type V collagen

Slc2a6	2.326007	0.086347	Solute Carrier Family 23 (Ascorbic Acid Transporter), Member 1 Sodium/ascorbate cotransporter. Mediates electrogenic uptake of vitamin C, with a stoichiometry of 2 Na(+) for each ascorbate
Ifi44l	2.329776	0.022705	Interferon-Induced Protein 44-Like Exhibits a low antiviral activity against hepatitis C virus
Ccr2	2.330837	0.001005	Chemokine (C-C Motif) Receptor 2 migration of immune cells. Other functions include angiogenic activity, apoptosis, T-cell differentiation and phagocyte activation. Inadvertent activation of chemokine receptors leads to autoimmunity by inappropriately targeting self-antigens for destruction by cytotoxic T-cells and macrophages.
Lilrb3	2.333939	0.002031	Leukocyte Immunoglobulin-Like Receptor, Subfamily B (With TM And ITIM Domains), Member 3 May act as receptor for class I MHC antigens. Becomes activated upon colligation of LILRB3 and immune receptors, such as FCGR2B and the B-cell receptor. Down-regulates antigen-induced B-cell activation by recruiting phosphatases to its immunoreceptor tyrosine-based inhibitor motifs (ITIM) (By similarity)
Pmaip1	2.339957	0.021507	Phorbol-12-Myristate-13-Acetate-Induced Protein 1 Promotes activation of caspases and apoptosis.

			Promotes mitochondrial membrane changes and efflux of apoptogenic proteins from the mitochondria. Contributes to p53/TP53-dependent apoptosis after radiation exposure. Promotes proteasomal degradation of MCL1.
Wfdc17	2.352242	0.031692	WAP four-disulfide core domain 17 ?
S100a4	2.354645	0.0002	S100 Calcium Binding Protein A4 S100 proteins are localized in the cytoplasm and/or nucleus of a wide range of cells, and involved in the regulation of a number of cellular processes such as cell cycle progression and differentiation.
Clec7a	2.35468	0.012432	C-Type Lectin Domain Family 7, Member A1 innate immune response The encoded glycoprotein is a small type II membrane receptor with an extracellular C-type lectin-like domain fold and a cytoplasmic domain with an immunoreceptor tyrosine-based activation motif.
Gm6377	2.378228	0.0912	Predicted gene
Socs3	2.394801	0.013639	Suppressor Of Cytokine Signaling 3 SSI family members are cytokine-inducible negative regulators of cytokine signaling. The expression of this gene is induced by various cytokines, including IL6, IL10, and interferon (IFN)-gamma.
Ly86	2.396271	0.002823	Lymphocyte Antigen 86 May cooperate with CD180 and TLR4 to mediate the innate immune response to bacterial lipopolysaccharide (LPS) and

			cytokine production. Important for efficient CD180 cell surface expression (By similarity)
Adam8	2.425141	0.00152	ADAM Metallopeptidase With Thrombospondin Type 1 Motif, 15
Ankrd1	2.47285	0.007531	Ankyrin Repeat Domain 1 (Cardiac Muscle) May play an important role in endothelial cell activation. May act as a nuclear transcription factor that negatively regulates the expression of cardiac genes. Induction seems to be correlated with apoptotic cell death in hepatoma cells
Clec4a3	2.481941	0.003883	C-type lectin domain family 4, member a3 C-type lectins are an important group of proteins found in the immune system of animals.
Milr1	2.485463	0.026871	Mast Cell Immunoglobulin-Like Receptor 1 Immunoglobulin-like receptor which plays an inhibitory role in degranulation of mast cells. Negatively regulates IgE-mediated mast cell activation and suppresses the type I immediate hypersensitivity reaction (By similarity)
Lilrb4	2.490647	0.00152	Leukocyte Immunoglobulin-Like Receptor, Subfamily B (With TM And ITIM Domains), Member 4 Inhibits receptor-mediated phosphorylation of cellular proteins and mobilization of intracellular calcium ions
Ccr5	2.534424	0.020598	Chemokine (C-C Motif) Receptor 5 (Gene/Pseudogene) Receptor for a number of inflammatory CC-chemokines including

			MIP-1-alpha, MIP-1-beta and RANTES and subsequently transduces a signal by increasing the intracellular calcium ion level.
Evi2a	2.563247	0.002919	Ecotropic Viral Integration Site 2A May complex with itself or/and other proteins within the membrane, to function as part of a cell-surface receptor
Mx1	2.570041	0.069429	Myxovirus (Influenza Virus) Resistance 1, Interferon-Inducible Protein P78 (Mouse) Enhances ER stress-mediated cell death after influenza virus infection. May regulate the calcium channel activity of TRPCs
Sox11	2.584335	4.99E-05	SRY (Sex Determining Region Y)-Box 17
Tlr1	2.584702	0.030108	Toll-Like Receptor 1 Participates in the innate immune response to microbial agents. Specifically recognizes diacylated and triacylated lipopeptides. Cooperates with TLR2 to mediate the innate immune response to bacterial lipoproteins or lipopeptides. Acts via MYD88 and TRAF6, leading to NF-kappa-B activation, cytokine secretion and the inflammatory response (By similarity)
Cd72	2.59714	0.018697	Cluster of differentiation Plays a role in B-cell proliferation and differentiation
Nlrc5	2.616321	0.078665	NLR Family, CARD Domain Containing 5 Probable regulator of the NF-kappa-B and type I interferon signaling pathways. May also regulate the type II interferon signaling pathway. Plays a role in

			homeostatic control of innate immunity and in antiviral defense mechanisms
Cd200r1	2.647261	0.012242	CD200 Receptor 1 Both the receptor and substrate are cell surface glycoproteins containing two immunoglobulin-like domains.
C3ar1	2.653413	0.000146	Complement Component 3a Receptor 1 Receptor for the chemotactic and inflammatory peptide anaphylatoxin C3a. This receptor stimulates chemotaxis, granule enzyme release and superoxide anion production
Ms4a6d	2.665341	4.59E-06	Membrane-Spanning 4-Domains, Subfamily A, Member 3 (Hematopoietic Cell-Specific) Hematopoietic modulator for the G1-S cell cycle transition.
Gpr141	2.669057	0.008658	G Protein-Coupled Receptor 34 G protein-coupled receptors (GPCRs), such as GPR34, are integral membrane proteins containing 7 putative transmembrane domains (TMs). These proteins mediate signals to the interior of the cell via activation of heterotrimeric G proteins that in turn activate various effector proteins, ultimately resulting in a physiologic response.
Igfn1	2.679489	0.093525	Immunoglobulin-Like And Fibronectin Type III Domain Containing 1
Clec12a	2.688102	0.000152	C-Type Lectin Domain Family 12, Member A Cell surface receptor that modulates signaling cascades and mediates tyrosine phosphorylation of target MAP

			kinases
Lgals3	2.699016	4.20E-05	Lectin, Galactoside-Binding, Soluble, 3 Involved in acute inflammatory responses including neutrophil activation and adhesion, chemoattraction of monocytes macrophages, opsonization of apoptotic neutrophils, and activation of mast cells
Clec4n	2.720614	0.000662	C-type lectin domain family 4, member n defense response to fungus, immune system process, ...integral component of membrane, membrane carbohydrate binding, protein binding
Ccr1	2.738489	0.016852	Chemokine (C-C Motif) Receptor 1 Receptor for a C-C type chemokine. Binds to MIP-1-alpha, MIP-1-delta, RANTES, and MCP-3 and, less efficiently, to MIP-1-beta or MCP-1 and subsequently transduces a signal by increasing the intracellular calcium ions level. Responsible for affecting stem cell proliferation
Gm7325	2.749498	0.000134	predicted gene
Saa1	2.788181	0.052635	Serum Amyloid A1 Major acute phase reactant. Apolipoprotein of the HDL complex
Fcgr4	2.793587	0.012277	Fc receptor, IgG, low affinity IV cellular response to lipopolysaccharide, NK T cell proliferation cell surface, external side of plasma membrane
Mcoln2	2.854397	0.007715	Mucolipin 2 cation channel proteins
Oas1a	2.890803	0.011099	2'-5'-Oligoadenylate Synthetase 1, 40/46kDa critical role in cellular innate

			antiviral response. In addition, it may also play a role in other cellular processes such as apoptosis, cell growth, differentiation and gene regulation.
Rrad	2.893496	6.90E-11	Ras-Related Associated With Diabetes1 May play an important role in cardiac antiarrhythmia via the strong suppression of voltage-gated L-type Ca(2+) currents. Regulates voltage-dependent L-type calcium channel subunit alpha-1C trafficking to the cell membrane (By similarity). Inhibits cardiac hypertrophy through the calmodulin-dependent kinase II (CaMKII) pathway. Inhibits phosphorylation and activation of CAMK2D
Havcr2	2.899389	0.000878	Hepatitis A Virus Cellular Receptor 2 Regulates macrophage activation. Inhibits T-helper type 1 lymphocyte (Th1)-mediated auto- and alloimmune responses and promotes immunological tolerance. May be also involved in T-cell homing. Receptor for LGALS9
Tnc	2.946252	1.59E-09	Tenascin C Extracellular matrix protein implicated in guidance of migrating neurons as well as axons during development, synaptic plasticity as well as neuronal regeneration. Promotes neurite outgrowth from cortical neurons grown on a monolayer of astrocytes. Ligand for integrins alpha-8/beta-1, alpha-9/beta-1, alpha-V/beta-3 and alpha-

			V/beta-6
Myh3	2.948189	2.06E-05	Myosin, Heavy Chain 6, Cardiac Muscle, Alpha Muscle contraction
Cx3cr1	3.009414	3.78E-06	Chemokine (c-x-c motif) ligand 13 chemotactic for b lymphocytes
Tac1	3.015431	0.083316	Tachykinin, Precursor 1 Tachykinins are active peptides which excite neurons, evoke behavioral responses, are potent vasodilators and secretagogues, and contract (directly or indirectly) many smooth muscles
Ctss	3.048477	0.00151	Cathepsin S Thiol protease. Key protease responsible for the removal of the invariant chain from MHC class II molecules. The bond-specificity of this proteinase is in part similar to the specificities of cathepsin L and cathepsin N
Mpeg1	3.084788	0.001367	Macrophage Expressed 1 Cell cycle.
Chrng	3.107202	1.37E-05	Cholinergic Receptor, Nicotinic, Gamma (Muscle) After binding acetylcholine, the AChR responds by an extensive change in conformation that affects all subunits and leads to opening of an ion-conducting channel across the plasma membrane
Bcl2a1b	3.15306	0.00136	B cell leukemia/lymphoma 2 related protein A1b extrinsic apoptotic signaling pathway in absence of ligand, intrinsic apoptotic signaling pathway in response to DNA damage, mitochondrial outer membrane
Slfn1	3.166401	0.042972	Schlafen 1 cell cycle arrest,

			negative regulation of cell proliferation, ... Component cytoplasm, nucleus Function protein binding
Rgs1	3.167701	0.003181	Regulator Of G-Protein Signaling 1 Inhibits signal transduction by increasing the GTPase activity of G protein alpha subunits thereby driving them into their inactive GDP-bound form. This protein may be involved in the regulation of B-cell activation and proliferation
Tlr13	3.197299	0.002081	Toll-Like Receptor 3 Toll-like receptors (TLRs) are single transmembrane cell-surface receptors, which have a key role in the innate immune system.
Slfn4	3.274274	0.002823	Schlafen 4 ????? Macrophage activation
Clec4e	3.303059	0.040944	C-Type Lectin Domain Family 4, Member E Induces secretion of inflammatory cytokines through a pathway that depends on SYK, CARD9 and NF-kappa-B
Clec4d	3.320008	0.018258	C-Type Lectin Domain Family 4, Member D Functions as an endocytic receptor. May be involved in antigen uptake at the site of infection, either for clearance of the antigen, or for processing and further presentation to T cells
AF251705	3.338226	4.59E-06	Cd300C antigen
Gp49a	3.354174	0.000132	Glycoprotein 49 A integral component of membrane, membrane
Lair1	3.393095	4.20E-05	Leukocyte-Associated Immunoglobulin-Like Receptor 1 Leukocyte-Associated Immunoglobulin-Like Receptor 1

MyI7	3.427885	0.05736	Myosin, Light Chain 7, Regulatory mediates plus-ended movement along microfilaments. It is involved in muscle contraction through cyclic interactions with actin-rich thin filaments, creating a contractile force. It is regulated by phosphorylation via myosin light chain kinase (MLCK) and by intracellular Ca ²⁺ concentrations.
Gpnmb	3.513174	1.71E-06	Glycoprotein (Transmembrane) Nmb GPNMB may be involved in growth delay and reduction of metastatic potential.
Tnnt2	3.528144	5.39E-06	Troponin T Type 2 (Cardiac) Troponin T is the tropomyosin-binding subunit of troponin, the thin filament regulatory complex which confers calcium-sensitivity to striated muscle actomyosin ATPase activity
B3gnt5	3.568479	0.00959	UDP-GlcNAc:BetaGal Beta-1,3-N-Acetylglucosaminyltransferase 5 Probably plays a central role in regulating neolactoseries glycolipid synthesis during embryonic development
Trem2	3.62577	5.62E-09	Triggering Receptor Expressed On Myeloid Cells 2 May have a role in chronic inflammations and may stimulate production of constitutive rather than inflammatory chemokines and cytokines.
Cd300Ib	3.713677	0.000585	CD300 Molecule-Like Family Member B Acts as an activating immune receptor through its interaction with

			ITAM-bearing adapter TYROBP, and also independently by recruitment of GRB2
Timp1	3.741032	2.32E-11	Tissue inhibitor metalloproteinases
Dcx	3.765629	0.046214	Doublecortin Microtubule-associated protein required for initial steps of neuronal dispersion and cortex lamination during cerebral cortex development
4930433N12Rik	3.765629	0.056142	RIKEN cDNA 4930433N12 gene unclassified gene
AI747448	3.795366	0.002081	Expressed sequence AI747448 calcium-activated chloride channel
Myl4	3.800622	1.24E-12	Myosin, Light Chain 4, Alkali; Atrial, Embryonic Regulatory light chain of myosin. Does not bind calcium
Ms4a7	3.80414	1.77E-11	Membrane-Spanning 4-Domains, Subfamily A, Member 7 May be involved in signal transduction as a component of a multimeric receptor complex
Ccl8	3.867142	0.003541	Chemokine (C-C Motif) Ligand 8 Chemotactic factor that attracts monocytes, lymphocytes, basophils and eosinophils. May play a role in neoplasia and inflammatory host responses. This protein can bind heparin. The processed form MCP-2(6-76) does not show monocyte chemotactic activity, but inhibits the chemotactic effect most predominantly of CCL7, and also of CCL2 and CCL5 and CCL8
Il1rn	3.946387	0.056142	Interleukin 1 Receptor Antagonist This protein inhibits the activities of

			interleukin 1, alpha (IL1A) and interleukin 1, beta (IL1B), and modulates a variety of interleukin 1 related immune and inflammatory responses
Ccl7	3.96701	0.000472	Chemokine (C-C Motif) Ligand 7 Chemotactic factor that attracts monocytes and eosinophils, but not neutrophils. Augments monocyte anti-tumor activity. Also induces the release of gelatinase B. This protein can bind heparin. Binds to CCR1, CCR2 and CCR3
Ccl2	3.998562	0.001005	Chemokine (C-C Motif) Ligand 2 Chemotactic factor that attracts monocytes and basophils but not neutrophils or eosinophils. Augments monocyte anti-tumor activity. Has been implicated in the pathogenesis of diseases characterized by monocytic infiltrates, like psoriasis, rheumatoid arthritis or atherosclerosis. May be involved in the recruitment of monocytes into the arterial wall during the disease process of atherosclerosis
Dio3	4.085234	0.016763	Deiodinase, Iodothyronine, Type III May play a role in preventing premature exposure of developing fetal tissues to adult levels of thyroid hormones. Can regulate circulating fetal thyroid hormone concentrations throughout gestation. Essential role for regulation of thyroid hormone inactivation during embryological development
Ms4a4c	4.164097	2.26E-05	Membrane-Spanning 4-

			Domains, Subfamily A, Member 3 (Hematopoietic Cell-Specific) Hematopoietic modulator for the G1-S cell cycle transition.
Fgr	4.197254	0.002033	Feline Gardner-Rasheed Sarcoma Viral Oncogene Homolog Non-receptor tyrosine-protein kinase that transmits signals from cell surface receptors devoid of kinase activity and contributes to the regulation of immune responses, including neutrophil, monocyte, macrophage and mast cell functions, cytoskeleton remodeling in response to extracellular stimuli, phagocytosis, cell adhesion and migration.
Ccr7	4.285654	0.007423	Chemokine (C-C Motif) Receptor 7 Receptor for the MIP-3-beta chemokine. Probable mediator of EBV effects on B-lymphocytes or of normal lymphocyte functions
Fcgr1	4.308408	6.39E-06	Fc Fragment Of IgG, High Affinity Ia, Receptor (CD64) Functions in both innate and adaptive immune responses
Spp1	4.54767	4.59E-06	Secreted Phosphoprotein 1 Binds tightly to hydroxyapatite. Appears to form an integral part of the mineralized matrix. Probably important to cell-matrix interaction Function: Acts as a cytokine involved in enhancing production of interferon-gamma and interleukin-12 and reducing production of interleukin-10 and is essential in the pathway that leads to type I

			immunity (By similarity)
Gm14635	6.136662	0.078665	Predicted gene
Slurp1	6.286614	0.055416	Secreted LY6/PLAUR Domain Containing 1 Has an antitumor activity. Was found to be a marker of late differentiation of the skin. Implicated in maintaining the physiological and structural integrity of the keratinocyte layers of the skin
Ccl3	6.422436	0.034844	Chemokine (C-C Motif) Ligand 3 Monokine with inflammatory and chemokinetic properties. Binds to CCR1, CCR4 and CCR5. One of the major HIV-suppressive factors produced by CD8+ T-cells.
Gal	6.546565	0.023785	Galanin/GMAP Prepropeptide Contracts smooth muscle of the gastrointestinal and genitourinary tract, regulates growth hormone release, modulates insulin release, and may be involved in the control of adrenal secretion
Alpi	6.546565	0.023785	Alkaline Phosphatase, Intestinal The intestinal alkaline phosphatase gene encodes a digestive brush-border enzyme. This enzyme is upregulated during small intestinal epithelial cell differentiation.
LOC100038947	6.766751	0.011099	Signal-regulatory protein beta 1-like macrophages immune?
Dnahc1	6.766751	0.019805	Dynein, Axonemal, Heavy Chain 1 Force generating protein of respiratory cilia. Produces force towards the minus ends of microtubules. Dynein has ATPase activity; the force-producing power stroke is thought to occur on release of ADP. Involved in

			sperm motility; implicated in sperm flagellar assembly (By similarity)
R3hdml	7.277344	0.001005	R3H Domain Containing-Like Putative serine protease inhibitor (By similarity)

Table 5: Comprehensive summary of ≥ 4 -fold transcript changes in 2 week old dy^W $-/-$ mice

Upregulated genes in 2 week old dy^W $-/-$ versus WT mice are represented by red. Downregulated genes in 2 week old dy^W $-/-$ versus WT mice are represented by green. There were 138 transcripts affected ≥ 4 -fold (up- or down- regulated) in total.

Gene	logFC_KOB_over_KOA	FDR	Function

Hgd	3.213909162	0.047933	Dimethylglycine Dehydrogenase This gene encodes an enzyme involved in the catabolism of choline, catalyzing the oxidative demethylation of dimethylglycine to form sarcosine. The enzyme is found as a monomer in the mitochondrial matrix, and uses flavin adenine dinucleotide and folate as cofactors. Mutation in this gene causes dimethylglycine dehydrogenase deficiency, characterized by a fishlike body odor, chronic muscle fatigue, and elevated levels of the muscle form of creatine kinase in serum.

5 weeks old

Table 6: Comprehensive summary of ≥ 4 -fold transcript changes in 5 week old dy^W $-/-$ mice

Upregulated genes in 5 week old LAM-111 treated versus untreated dy^W $-/-$ mice are represented by red. Downregulated genes in 5 week old LAM-111 treated versus untreated dy^W $-/-$ mice are represented by green. There were 468 transcripts affected ≥ 4 -fold (up- or down- regulated) in total.
