27 **Abstract**

28 Cigarette smoke (CS), a highly complex mixture containing more than 4000
29 compounds, causes aberrant cell responses leading to tissue damage around the
30 airways and alveoli which underlies various lung diseases. Phosphodiesterases
31 (PDEs) are a family of enzymes that hydrolyze cyclic nucleotides. PDE inhibition
32 induces bronchodilation, reduces the activation and recruitment of inflammatory cells,
33 and the release of various cytokines. Currently, the selective PDE4 inhibitor
34 roflumilast is an approved add-on treatment for patients with severe chronic
35 obstructive pulmonary disease (COPD) with chronic bronchitis and a history of
36 frequent exacerbations. Additional selective PDE inhibitors are being tested in pre-
37 clinical and clinical studies. However, the effect of chronic CS exposure on the
38 expression of PDEs is unknown.

39 Using mRNA isolated from nasal and bronchial brushes and lung tissues of never-
40 smokers and current smokers, we compared the gene expression of 25 PDE coding
41 genes. Additionally, the expression and distribution of PDE3A and PDE4D in human
42 lung tissues was examined. This study reveals that chronic CS exposure modulates
43 the expression of various PDE members. Thus, CS exposure may change the levels
44 of intracellular cyclic nucleotides and thereby impact the efficiency of PDE-targeted
45 therapies.

46

47 **Abbreviations**

48 CS, cigarette smoke; PDE, phosphodiesterase; cAMP, cyclic adenosine
49 monophosphate; cGMP, cyclic guanosine monophosphate; COPD, chronic
50 obstructive pulmonary disease.

51

52 Introduction

53 Cigarette smoke (CS), which is a complex mixture of more than 4000 chemicals, is
54 known to cause several respiratory ailments due to damage around the airways and
55 alveoli (19). It has been demonstrated that CS exerts a variety of toxic effects on
56 cellular functions in the lung, including but not limited to increased risk of protein and
57 lipid oxidation, abnormal ceramide metabolism, endoplasmic reticulum stress, and
58 cell death (4, 8, 26). Cyclic nucleotides are ubiquitous intracellular second
59 messengers that, by acting in discrete subcellular microdomains, regulate a plethora
60 of physiological and pathological processes in the lung including bronchodilation and
61 cytokine release (1, 3, 7). Phosphodiesterases (PDEs), which are a family of
62 enzymes that hydrolyze cyclic nucleotides, play important roles in inflammatory cell
63 accumulation, cytokine and chemoattractant release, bronchoconstriction, vascular
64 hypertrophy and remodeling (17, 27) These PDEs regulate their intracellular signals
65 in a compartmentalized manner (17, 27). The superfamily of PDEs is composed of 11
66 families with distinct substrate specificities, molecular structures and subcellular
67 localization. Depending on the substrate preference for either cyclic adenosine
68 monophosphate (cAMP) and/or cyclic guanosine monophosphate (cGMP), PDEs are
69 divided into 3 groups: cAMP-specific PDEs (PDE4, PDE7, and PDE8), cGMP-specific
70 PDEs (PDE5, PDE6, and PDE9) and dual-specific PDEs (PDE1, PDE2, PDE3,
71 PDE10 and PDE11) (17, 27). Each PDE family has at least one, often multiple coding
72 genes, resulting in more than 21 genes (18).

73 Earlier studies indicated that altered gene/ protein PDE isoform levels were
74 correlated with respiratory disease pathophysiology (ie. PDE3 and PDE4) (11, 24,
75 27). PDE inhibition has benefits in structural lung cells, including preventing CS-
76 induced epithelial dysfunction (14, 15, 22), inducing airway smooth muscle relaxation
77 (5, 28), and preventing emphysema (12, 16). Current therapies focus primarily on
78 PDE3 and PDE4 inhibitors (27). For example, the selective PDE4 inhibitor roflumilast
79 is approved as add-on treatment for severe chronic obstructive pulmonary disease
80 (COPD) patients with chronic bronchitis and a history of frequent exacerbations.
81 Additional selective PDE inhibitors are being tested in pre-clinical and clinical studies
82 (18, 27). However, the impact of chronic CS exposure on the expression of PDEs is
83 ill defined. The aim of our study was to investigate the effect of chronic CS exposure

84 on PDE gene expression and protein distribution in nasal epithelium, bronchial
85 epithelium and lung tissue in current and never smokers.

86

87 **Methods**

88 *Bronchial and nasal brushings collection, RNA extraction and microarray processing*

89 The Study to Obtain Normal Values of Inflammatory Variables From Healthy Subjects
90 (NORM; [NCT00848406](#)) included healthy smokers and never smokers as previously
91 described (10). The study was approved by the University Medical Center Groningen
92 ethics committee and all subjects provided their written informed consent. The
93 characteristics of healthy smokers and never smokers are summarized in **Table 1A**.
94 Nasal and bronchial epithelium was collected at the same time, using a Cyto-Pak
95 CytoSoft nasal brush (Medical Packaging Corporation, Camarillo, Calif) or a
96 Cellebriety bronchial brush (Boston Scientific, Marlborough, Mass). Microarrays were
97 used for genome wide gene expression profiling. Methods for RNA extraction,
98 labeling and microarray processing have been described previously (10). PDEs were
99 also measured in lung tissue samples by microarray, which has been previously
100 described (2). In the current study we focused on a subset of samples collected as
101 part of the Groningen cohort. All the microarray data was analyzed using the
102 Bioconductor-limma package in R software version 3.5.1.

103 To identify PDEs differentially expressed in matched nasal and bronchial brushes
104 between current (n=41) and never smokers (n=36), we ran a linear model using
105 limma (R statistical software) correcting for age and gender; while for the lung tissue
106 samples we compared current smokers (n=165) and never smokers (n=39), using a
107 linear model correcting for age and gender. Clinical characteristics of subject groups
108 are tabulated in **Table 1B**.

109 *Immunoblotting*

110 Human lung tissue was obtained from eleven non-COPD control individuals without
111 airway obstruction with different smoking statuses (5 never smokers and 6 current
112 smokers) (**Table 1C**) according to the Research Code of the University Medical
113 Center Groningen (<http://www.rug.nl/umcg/onderzoek/researchcode/index>) and
114 national ethical and professional guidelines ("Code of conduct; Dutch federation of

115 biomedical scientific societies"; <http://www.federa.org>). RIPA buffer (65 mM Tris, 155
116 mM NaCl, 1% Igepal CA-630, 0.25% sodium deoxycholate, 1 mM EDTA, pH 7.4 and
117 a mixture of protease inhibitors: 1 mM Na₃VO₄, 1 mM NaF, 10 µg/mL leupeptin, 10
118 µg/mL pepstatin A, 10 µg/mL aprotinin) was used to lyse tissue. Equal amounts of
119 total protein were loaded for 10% SDS–polyacrylamide gel electrophoresis. After
120 transferring to a nitrocellulose membrane, primary antibodies anti-PDE3A (kindly
121 provided by Chen Yan, rabbit polyclonal antibody, 1:1000) (23), anti-PDE4D (kindly
122 provided by Prof. Marco Conti, ICOS 4D, rabbit monoclonal antibody, 1:2000) (20,
123 21) and anti-GAPDH (HyTest, 1:10,000) were incubated at 4°C overnight, followed
124 by secondary antibody (anti-mouse, IgG, 1:5,000 or anti-rabbit, IgG, 1:5,000, Sigma)
125 incubation at room temperature for one hour. The antibodies specificity was indicated
126 previously (28). Protein bands were developed on film using Western detection ECL-
127 plus kit (PerkinElmer, Waltman, MA). ImageJ software was used for densitometric
128 analyses (28).

129 *Immunohistochemistry*

130 Human lung tissue (**Table 1C**) sections were stained with primary antibodies anti-
131 PDE3A (Santa Cruz, goat polyclonal antibody, 1:100), anti-PDE4D (kindly provided
132 by Prof. George Baillie, sheep polyclonal antibody, 1:4500) (13) overnight at 4°C.
133 The following day, tissue sections were incubated with HRP-conjugated anti-sheep
134 and anti-goat antibodies for 2 hours (1:100, DAKO).

135 For color development, NovaRed (Vector Laboratories) was applied on slides and
136 hematoxylin was used as a counterstain. Images were captured using a slide
137 scanner (Nanozoomer 2.0 HT, Hamamatsu Photonics) with 20× magnification.
138 Semi-quantification of the staining intensity in the epithelium and smooth muscle
139 around airways from never smokers (n=87 airways from 12 donors) and current
140 smokers (n=24 airways from 8 donors) was performed by 4 blinded observers on a
141 scale from [0] to [3].

142 *Statistical analyses*

143 Lung homogenate data were analyzed using GraphPad Prism 6 (GraphPad, La Jolla,
144 USA) and presented as mean ± SEM. The statistical significance of the data was
145 examined using two-tailed unpaired Students t test for normally distributed data or by

146 by either Mann-Whitney comparison or Kolmogorov-Smirnov comparison. For all data
147 a $p < 0.05$ was considered statistically significant.

148

149 **Results**

150 In the nasal epithelium of current smokers, PDE4A, PDE7A, and PDE8A were
151 significantly decreased compared to never smokers ($p < 0.05$), whereas PDE10A were
152 significantly increased ($p < 0.05$) (**Fig. 1, Table 2**). In bronchial epithelium from current
153 smokers PDE1A, PDE3A, PDE4D, PDE5A, PDE7A, PDE7B, PDE8A, PDE8B, and
154 PDE11A were significantly downregulated ($p < 0.05$) (**Fig. 1**), while PDE4C, PDE6A,
155 PDE6B, and PDE9A were upregulated ($p < 0.05$) in the current smokers compared to
156 never smokers (**Fig. 1**). In total lung tissue, only 4 PDE genes were changed, with a
157 decrease ($p < 0.05$) of PDE1A and PDE11A and an increase ($p < 0.05$) of PDE4D and
158 PDE6A in current smokers versus never smokers (**Fig. 1**).

159 Since PDE3 and PDE4 are pharmaco-therapeutic targets for obstructive lung disease
160 (6), we further studied these PDEs at the protein level. To investigate the influence of
161 CS on the protein expression, we used total lung homogenates of never and current
162 smokers. Protein expression of PDE3A and PDE4D did not differ across the groups
163 in total lung homogenates (**Fig. 2A**).

164 To dissect the cell type distribution of PDE3A and PDE4D, immunostainings for these
165 PDE isoforms were performed. As shown in **Fig. 2B**, PDE3A and PDE4D were
166 expressed in airway epithelium and airway smooth muscle in both never smokers
167 and current smokers. PDE3A was also strongly expressed in vascular smooth
168 muscle. In current smokers, PDE3A and PDE4D increased in airway epithelium
169 compared to never smokers (**Fig. 2B**), but no difference was observed in airway
170 smooth muscle.

171

172 **Discussion**

173 This study is the first to report differences of PDE family member mRNA levels in
174 response to CS exposure in patients. Using nasal and bronchial epithelium as well as
175 total lung tissue, our study shows that the gene expression of multiple PDEs in
176 current smokers is changed compared to that of never smokers. Importantly, the

177 gene expression changes of a number of PDE members was reflected in two study
178 groups, including PDE1A (decreased in bronchial epithelium and lung tissue), PDE6A
179 (increased in bronchial epithelium and lung tissue), PDE7A (decreased in nasal
180 epithelium and bronchial epithelium) and PDE11A (decreased in bronchial epithelium
181 and lung tissue). Studies in the lung with focus on PDE1A, PDE6A, PDE7A and
182 PDE11A are largely lacking. Our data suggest that these PDE isoforms are of central
183 importance in the changes induced by CS exposure. Strikingly, PDE4D had a
184 contrasting pattern of change (decreased in bronchial epithelium and increased in
185 lung tissue), possibly pointing to an alternative regulatory role for this PDE in the
186 different compartments of the respiratory tract or alternatively cell type specific
187 expression and the shift in these cell types may cause the shift in expression levels
188 during smoke exposure.

189 Alterations in expression of PDEs are linked to pulmonary disorders. Acute CS
190 extract exposure increased the gene expression of PDE3B and PDE4D and the
191 protein expression of PDE3A and PDE4D in human airway smooth muscle cells (28).
192 In whole lung tissue of mice, acute CS exposure induced a higher PDE4 activity,
193 accompanied by an increase in both gene and protein expression of PDE4B and
194 PDE4D (28). These studies reflect the increase we saw in PDE4D in lung tissue but
195 not the nasal or bronchial epithelium, possibly suggesting the PDE4 lung tissue
196 signal is driven by mesenchymal cells rather than the epithelial cells. In concert, in
197 asthmatic airway smooth muscle cells, isoproterenol-induced cAMP production was
198 decreased due to enhanced PDE4D protein expression, in comparison to non-
199 asthmatic airway smooth muscle cells (24). Acute CS exposure did not alter the gene
200 and protein expression of PDE3A in human bronchial epithelial cells (28). In our
201 study, a decrease of PDE3A mRNA was observed in the bronchial epithelium of
202 current smokers compared to never smokers, which highlights the chronic influence
203 of CS exposure on the gene expression of PDE3A. In contrast, an increased PDE3A
204 protein expression was found in airway epithelium in current smokers, pointing to a
205 possible differential effect of CS on gene and protein regulation of PDE3A. Gene
206 expression of PDE4D was decreased in the bronchial epithelium, but was increased
207 in lung tissue. In agreement, protein expression of PDE4D was increased in airway
208 epithelium in current smokers. As protein expression of PDE3A and PDE4D were not
209 different in total lung homogenates, changes in CS-induced PDE expression are

210 restricted to distinct lung compartments. In addition to altered regulation of PDE3A
211 and PDE4D, we now show that chronic CS exposure could also modulate the gene
212 expression of other PDE members, for which the functions are largely unknown and
213 urgently require more investigations.

214 The PDE4 inhibitor roflumilast is approved for the treatment of patients with severe
215 COPD (25), however unwanted side effects including nausea and vomiting still limit
216 its oral administration (9). Dual inhibition of PDE3 and PDE4 acted as an add-on tool
217 further enhancing their therapeutic benefits (9, 27). Here we show that PDE4 was the
218 only PDE subfamily for which gene expression changes were observed in all 3
219 groups (nasal epithelium, bronchial epithelium and lung tissue), the gene expression
220 of PDE4A, PDE4C and PDE4D (not PDE4B) were significantly changed. In contrast,
221 only the gene expression of PDE3A was significantly decreased in the bronchial
222 epithelium. We report here on a change in protein expression of both PDE3A and
223 PDE4D in the airway epithelium of current smokers. Therefore, targeting PDE3A and
224 PDE4D specifically might potentially increase the therapeutic benefit for patients with
225 fewer side effects, however, clearly more preclinical experiments are needed.

226 This is the first study to show that chronic CS exposure leads to alterations in PDE
227 expression in different cell types in the lung. Further investigation will expand our
228 understanding of the contribution of a defined subset of PDEs to mechanisms driving
229 lung diseases and elucidate the possibility of using PDEs subfamilies as potential
230 pharmaceutical targets for treating COPD depending on patients' smoking status.

326 Figure legend

327 Figure 1. Comparison of gene expression of PDE isoforms in current smokers versus
 328 never smokers. (A) The difference of PDE isoforms was compared in nasal
 329 epithelium (red points), bronchial epithelium (blue points) and lung tissues (black
 330 points). All the points above black solid line are considered as significant change.
 331 The left side of the black dotted line indicate genes decreased in current smokers
 332 compared to never-smokers, whereas the right side indicate genes increased in
 333 current smokers compared to never-smokers.

334 Figure 2. (A) Protein expression of PDE3A and PDE4D in lung homogenates of never
 335 smokers (n=5) and current smokers (n=6). (B) Representative images of PDE3A and
 336 PDE4D staining. Arrows indicate airway epithelium and smooth muscle. Semi-
 337 quantitative staining intensity around airways of never smokers (n=87, airways from
 338 12 donors) and current smokers (n=24, airways of 8 donors). PDE, brown staining
 339 (NovaRed); hematoxylin counterstain.

340

341 Table 1A. **Clinical characteristics NORM study**

	All (N=77)	Never-smokers (N=36)	Current smokers (N=41)
Age, yr	36.06 (16.23)	34.89 (17.10)	37.10 (15.55)
BMI kg/m ²	23.73 (3.50)	23.52 (3.76)	23.91 (3.29)
Gender, Male/Female	41/36	16/20	25/16
Pack years****	8.68 (13.4)	0	16.30 (14.63)
FEV ₁ % predicted	108.14 (10.49)	109.75 (10.24)	106.73 (10.62)
Reversibility % from baseline	3.82 (3.05)	3.82 (3.50)	3.82 (2.64)
FEV ₁ /FVC	83.06 (6.37)	84.54 (6.57)	81.75 (5.97)
RV % predicted	93.74 (17.46)	94.78 (21.62)	92.83 (12.99)
TLC % predicted	104.04 (9.42)	105.44 (9.19)	102.80 (9.56)
RV/TLC % predicted	85.62 (12.38)	85.25 (15.59)	85.95 (8.84)

342 *BMI, body mass index; FEV₁, forced expiratory volume in one second; FEV₁/FVC, forced*
 343 *expiratory volume in one second/ forced vital capacity; RV, residual volume; TLC, total lung*
 344 *capacity; RV/TLC, residual volume/ total lung capacity.*

345 *The mean and standard deviation are shown for continuous variables. Unpaired T-test*
 346 *showed no significant difference between the two groups except **** Significant at p <*
 347 *0.0001.*
