3 **25 ABSTRACT**  
4

5  
6 **26** Nowadays, there is a growing interest to add value to food industry by-products and incorporate  
7  
8 **27** them as new ingredients for novel food products. However, there is very little knowledge about  
9  
10 **28** consumers' reactions towards novel food products made with upcycled ingredients. This  
11  
12  
13 **29** manuscript provides the first critical scientific investigation of UK consumers' preferences for  
14  
15 **30** novel food products made with upcycled ingredients **using four attributes: price (£0.40/300 g pack**  
16  
17 **31** **or £1.50/300 g pack), flour ("with wheat flour" or "with upcycled sunflower"), protein ("source of**  
18  
19 **32** **protein" or no information) and Carbon Trust label ("with Carbon Trust label" or no label). Using a**  
20  
21  
22 **33** hypothetical ranking experiment involving biscuits, results showed that consumers prefer biscuits  
23  
24  
25 **34** made with conventional (i.e., wheat) flour and tend to reject biscuits made with upcycled sunflower  
26  
27 **35** flour. Results suggest there is heterogeneity in consumers' valuation, with three groups identified:  
28  
29  
30 **36** the first group with price sensitive consumers and the strongest preferences for low price biscuits,  
31  
32 **37** the second group with traditionalist consumers and strongest rejection for upcycled sunflower-  
33  
34 **38** flour, the third group with environmentalist consumers and the strongest preference for biscuits  
35  
36  
37 **39** with the Carbon Trust label. Most consumers had not heard of upcycled ingredients before, but  
38  
39  
40 **40** they would consider buying foods with upcycled ingredients. These findings provide insights into  
41  
42 **41** the psychology of consumers' preferences, which can be used to most effectively communicate the  
43  
44 **42** benefits of upcycled ingredients to the public. This will also have important implications for future  
45  
46  
47 **43** labelling strategies for policy makers providing valuable insights to upcycled food products'  
48  
49  
50 **44** manufacturers.

2  
3 **50 1. INTRODUCTION**  
4

5  
6 51 Every year about 30% of the total food produced in the world for human consumption is lost or  
7  
8 52 wasted both at food supply chain (i.e., food loss) and consumption levels (i.e., food waste),  
9  
10 53 corresponding to approximately 1.3 billion tonnes (FAO, 2011). In Europe, industrial food loss  
11  
12  
13 54 quantities range between 19% and 39% of the total food loss in food supply chains (Stenmarck et  
14  
15 55 al., 2016). In the UK, according to a recent report by the Waste & Resources Action Programme  
16  
17  
18 56 (WRAP (2017)), in 2015 the manufacturing sector was the main producer of food loss in the supply  
19  
20 57 chain, with 1.85 million tonnes of waste produced (which increased by 9% compared to the  
21  
22  
23 58 previous 2016 WRAP report). Out of this total amount, almost 1 million tonnes were estimated to  
24  
25 59 be edible parts. Thus, although there is high recognition of the importance of food loss within food  
26  
27  
28 60 supply chains, a large part of research in industrialized countries has focused more on food waste  
29  
30 61 research on the consumer end (Parfitt, Barthel, & Macnaughton, 2010), while the contribution of  
31  
32  
33 62 the food processing stages on food loss have been overlooked. Fruit and vegetable loss represents  
34  
35 63 the wasting of food commodities, but also includes wasting of important resources such as land,  
36  
37  
38 64 water, fertilisers, chemicals, energy, and labour (Augustin, Sanguansri, Fox, Cobiac, & Cole,  
39  
40 65 2020). The food loss produced by the manufacturers from processing raw materials into food are  
41  
42  
43 66 usually referred to as food by-products (Galanakis, 2012). These by-products include both loss  
44  
45 67 from animal processing (i.e., meat, seafood, and dairy) and fruit and vegetable-derived processing  
46  
47 68 (i.e., peels, stems, seeds, bran, residues after extraction of oil or juices, etc.) (Helkar, Sahoo, &  
48  
49  
50 69 Patil, 2016). Since the fruit and vegetable processing industry is one of the greatest producers of  
51  
52 70 by-products (FAO, 2015; Parfitt et al., 2010), during the last few years, particular attention has  
53  
54  
55 71 been given to the valorization of this by-product category (Galanakis, 2012; Gómez & Martinez,  
56  
57 72 2018; Trigo, Alexandre, Saraiva, & Pintado, 2019). Valorizing fruit and vegetable by-products  
58  
59 73 would make our bio-economy more circular and would help to lower the high environmental  
60  
61  
62 74 impact of by-product disposal (Kroyer, 1995). Considering the vast amount of by-products

75 available, even a small increase in their value could have significant economic advantage to food  
76 manufacturers, provided that food supply chains adapt and work towards integration (Garcia-  
77 Garcia, Stone, & Rahimifard, 2019).

78  
79 Scientists are continuously exploring new ways to add value to food by-products. Examples  
80 include extracting and purifying valuable health-promoting compounds from by-products using  
81 new technologies (Barba, Zhu, Koubaa, Sant'Ana, & Orlie, 2016; Galanakis, 2013), exploring the  
82 effects of feeding such by-products to animals (Mirzaei-Aghsaghali & Maheri-Sis, 2008; Molina-  
83 Alcaide & Yáñez-Ruiz, 2008) or using by-products for energy production (Hagman, Eklund, &  
84 Svensson, 2019; Martin & Parsapour, 2012). Within valorization, it is believed that the most  
85 valuable approach with by-products would be to upcycle them rather than recycling them, which  
86 means using them as food, rather than feed or energy (Roth, Jekle, & Becker, 2019). A similar  
87 concept is explained in the Food Recovery Hierarchy of the US Environmental Protection Agency  
88 (Bhatt et al., 2018), where energy recovery, composting or incinerating are considered less  
89 preferred options to reduce food waste compared to the most preferred options of “source reduction  
90 and reuse” and “feed hungry people”.

91  
92 Fruit and vegetable by-products can be processed to become functional and nutritious ingredients  
93 that can re-enter the food chain as part of new foods (Trigo et al., 2019). Despite the technological  
94 challenges related to the processing, functionality and sensory quality of such ingredients, some  
95 upcycled ingredient manufacturers have already launched (or are about to launch) their products  
96 into the market. Examples are brewers’ spent grains in cereal bars (such as Remashed in the UK  
97 and Regrained in the US), coffee grounds in baked goods (Coffee Cherry Company in the US and  
98 Kaffe Bueno in Denmark), oil cakes such as rapeseed or sunflower in high-protein flours  
99 (Planetarians in the US and NapiFeryn BioTech in Poland) (Fastcompany, 2019; Food Business

1  
2  
3 100 News, 2019; Food Navigator USA, 2018).  
4

5  
6 101  
7  
8 102 In order to successfully market food products with upcycled ingredients it is essential to investigate  
9  
10 103 consumers' preferences and willingness to pay (WTP) towards these novel food products. So far,  
11  
12  
13 104 very little is known about how consumers might perceive foods made with upcycled ingredients.  
14  
15 105 Some of the few available investigations include the research from Bhatt et al. (2018) in the US on  
16  
17  
18 106 "value-added surplus products (VASP)", Aschemann-Witzel and Peschel (2019) in Denmark on  
19  
20 107 potato protein in a mock-up soy-based cocoa drink, and in Italy with two studies by Coderoni and  
21  
22  
23 108 Perito (2020) and Perito, Di Fonzo, Sansone, and Russo (2019) on consumer acceptability of foods  
24  
25 109 with by-products deriving from olive oil production. The concept of foods made with upcycled  
26  
27  
28 110 ingredients is new and in the available literature the names used to refer to these products vary  
29  
30 111 greatly among studies. We will discuss them here in more detail.  
31

32  
33 112 Bhatt et al. (2018) referred to foods created from surplus ingredients as "value-added surplus  
34  
35 113 products (VASP)". The authors tried to identify the best term to describe VASP products by asking  
36  
37 114 consumers to rank the appropriateness of nine product labels (i.e., upcycled, reprocessed,  
38  
39  
40 115 reclaimed, upscaled, rescued, up-processed, rescaled, resorted) and found that the word "upcycled"  
41  
42 116 was the most preferred. Then, they investigated whether VASP products were perceived by  
43  
44  
45 117 consumers as having benefits for the individual or for the society, concluding that the VASP foods  
46  
47 118 scored higher as a benefit for society than as an individual. The authors concluded that appropriate  
48  
49  
50 119 product descriptions, labels and benefits could all positively influence consumers' decision-making  
51  
52 120 on this new food category.  
53

54  
55 121 Aschemann-Witzel and Peschel (2019) explored how Danish consumers of cocoa drinks react to  
56  
57 122 the use of potato protein, a by-product of potato starch production, in a mock-up soy-based cocoa  
58  
59 123 drink. The authors refer to upcycled ingredients as "waste-to-value" products. They found that  
60  
61  
62 124 consumers did not perceive the new potato protein-based cocoa drink more favourably than the  
63

1  
2  
3 125 conventional version, nor did they consider it better in quality. The authors concluded that brand,  
4  
5  
6 126 design, and information on why a “waste-to-value” ingredient is used could improve attitudes  
7  
8 127 towards the product.  
9  
10  
11 128 In Italy, Perito et al. (2019) focused on what they called “foods from olive by-products” and  
12  
13 129 assessed consumers’ willingness to accept (WTA) them. They found that consumers perceived the  
14  
15 130 use of olive by-products as a new technology to prepare well-known foods. Consumers were  
16  
17  
18 131 concerned about the technology used in the production process, rather than the product itself. The  
19  
20 132 study concluded that information on the characteristics of olive by-products could offset consumer  
21  
22  
23 133 technophobia and the authors recommended suitable marketing campaigns centred on the by-  
24  
25 134 product benefit to increase consumer WTA the products.  
26  
27  
28 135 Coderoni and Perito (2020) carried out a web based questionnaire in Italy using the same concept  
29  
30 136 of olive by-product as Perito et al. (2019), testing purchase intentions for what they refer to as  
31  
32  
33 137 “waste-to-value” foods and analysing other drivers such as aversion to new foods or foods  
34  
35 138 processed in new ways. The authors concluded that to deliver new “waste-to-value” products in the  
36  
37  
38 139 market, their health and environmental benefits should be indicated on the label. However, based  
39  
40 140 on findings from Vega-Zamora, Torres-Ruiz, and Parras-Rosa (2019) and Agovino, Cerciello, and  
41  
42 141 Gatto (2018), they suggest that attention must be paid to the messages conveyed as failure to notice  
43  
44  
45 142 or interpret labels could hinder the final market uptake.  
46  
47 143  
48  
49  
50 144 Consumers’ acceptability provides important information for producers and marketers when  
51  
52 145 developing new food products, however simply asking consumers for their acceptability without  
53  
54  
55 146 considering price may not provide the needed practical information (Asioli et al., 2017). Thus the  
56  
57 147 inclusion of price as an attribute to estimate consumers’ WTP in monetary terms is relevant for  
58  
59  
60 148 several reasons (Jaeger, 2006). Firstly, a large number of studies indicate that price is one of the  
61  
62 149 most relevant factors that affect consumer choices (Asioli, Næs, Granli, & Lengard Almli, 2014;  
63  
64  
65

1  
2  
3 150 Lusk & Briggeman, 2009; Steenhuis, Waterlander, & de Mul, 2011). Secondly, for new food  
4  
5  
6 151 products that are not yet in the market and for which there are no market data available (i.e.,  
7  
8 152 scanner data), an estimation of consumers' WTP could help industry to suggest retail prices when  
9  
10 153 launching new products (Lusk & Shogren, 2007; Shogren, 2011). Thirdly, an estimation of new  
11  
12  
13 154 food products' prices is useful for industry to compare with production costs, conduct a  
14  
15 155 costs/benefits analysis and evaluate the economical/business sustainability of the new products  
16  
17  
18 156 (Lusk & Shogren, 2007). However, to the best of our knowledge, no study has directly investigated  
19  
20 157 consumers' preferences and WTP in monetary terms and individual differences for food products  
21  
22  
23 158 containing upcycled ingredients. Due to the new nature of upcycled ingredients, it would be  
24  
25 159 valuable to gather insights on how to best introduce this new upcycled food category to the market  
26  
27  
28 160 and how to communicate the nutritional and environmental advantages of foods made with by-  
29  
30 161 products to consumers through appropriate labelling strategies. **This study aimed at understanding**  
31  
32  
33 162 **the most preferred attribute composition for upcycled foods using the attributes price (low or high),**  
34  
35 163 **type of flour (conventional or upcycled), protein content ("source of protein" or no information)**  
36  
37 164 **and Carbon Trust label ("with Carbon Trust label" or no label).**  
38  
39

40 165  
41  
42 166 A ranking experiment was used to investigate UK consumers' preferences for hypothetical biscuits  
43  
44  
45 167 made with defatted sunflower cake flour. The upcycled sunflower flour was chosen as an  
46  
47 168 ingredient for this study because the company Planetarians<sup>2</sup> successfully manufactured it from  
48  
49  
50 169 sunflower cake, the residue left after sunflower oil extraction. Through a steam flashing and  
51  
52 170 extrusion process, the sunflower cake is transformed into a high protein food grade ingredient  
53  
54  
55 171 (Manchuliantsau & Tkacheva, 2019). This protein-rich ingredient could be potentially used by the  
56  
57 172 food industry in a variety of applications, such as bakery, pasta and meat products. This ingredient  
58  
59

---

60  
61 <sup>2</sup> See details: <https://www.planetarians.com/>  
62  
63  
64  
65

1  
2  
3 173 was also recently used in baked goods with promising results (Grasso, Liu, & Methven, 2020;  
4  
5  
6 174 Grasso, Omoarukhe, Wen, Papoutsis, & Methven, 2019). Biscuits were chosen as a base food for  
7  
8 175 this study due to their popularity and appeal amongst consumers, in addition to being ready to eat,  
9  
10  
11 176 affordable, having a long shelf life and a wide range of tastes (Turksoy & Özkaya, 2011).  
12

## 13 177 14 15 16 178 **2. MATERIALS AND METHODS**

### 17 18 179 **2.1 Experimental design**

19  
20  
21 180 In the online ranking experiment four attributes were used to describe the different types of  
22  
23 181 biscuits: “price”, “flour”, “protein” and “Carbon Trust label” (Table 1). In terms of the attribute  
24  
25 182 “price”, two price levels were specified to approximately reflect the upper and lower market prices  
26  
27  
28 183 of a typical 300 g pack of biscuits in UK shops (£0.40/300 g pack and £1.50/300 g pack). Price was  
29  
30  
31 184 chosen as an attribute because, as indicated in the introduction, it is one of the most relevant factors  
32  
33 185 that affect consumer choices (Lusk & Briggeman, 2009). For the attribute “flour”, two levels were  
34  
35 186 specified: the most conventional type of flour used to make biscuits (i.e. “with wheat flour”) or the  
36  
37  
38 187 innovative flour (i.e. “with upcycled sunflower”). This attribute was used to test consumers’ WTP  
39  
40 188 for new foods with upcycled ingredients. The attribute “protein” was included with two levels:  
41  
42  
43 189 “source of protein” or no information about this was reported. “Source of protein” refers to the  
44  
45 190 nutrition claim as per European Food Safety Authority wording (EFSA, 2012), indicating that at  
46  
47  
48 191 least 12% of the energy value of the food is provided by protein. Protein content in food products  
49  
50 192 overall has a positive consumer perception, especially if the protein is of plant-origin (Banovic et  
51  
52  
53 193 al., 2018). Finally, we included information about the environmental impact of biscuit production  
54  
55 194 because it has been shown that sustainability information may affect consumers’ WTP (Reimers &  
56  
57 195 Hoffmann, 2019). We used the “Carbon Trust label” referring to the environmental impact of food  
58  
59  
60 196 production, transportation and use of the food products in terms of CO<sub>2</sub> emissions. Thus, two levels  
61  
62  
63  
64  
65

197 of Carbon Trust label were used: “with Carbon Trust label” or no label was reported.

198  
199 **Table 1 – Attributes and levels used in the study.**

ATTRIBUTES	LEVELS
Price	0 - £0.40/300g
	1 - £1.50/300g
Flour	0 - with wheat flour
	1 - with upcycled sunflower
Protein	0 - no information reported
	1 - source of protein
Carbon Trust label	0 - no label
	1 - with Carbon Trust label

200  
201 The selected attributes and their levels were used to generate a balanced incomplete design that  
202 resulted in the creation of sixteen product alternatives. These were then divided into two blocks of  
203 eight product alternatives each using Minitab v. 19.1.1 (Minitab Inc., Coventry, UK) to prevent  
204 respondents’ fatigue. A series of mock-up product images of biscuits packs varying in four design  
205 attributes were created (see Fig. 1 for an example).

**Fig.1 – Example of mock-up product image created for the study.**

The randomisation was conducted within each block of eight choice sets. The ranking experiment was introduced with an explanation and description of the attributes and levels. Participants were presented with biscuit packs and asked to rank them from the most preferred to the least preferred option. Before starting the ranking tasks, respondents were asked to read a cheap talk script as an attempt to mitigate possible hypothetical bias that typically affects WTP estimates in stated preference studies (Cummings & Taylor, 1999).

To ease the cognitive burden of the participants, this ranking was conducted similarly to Øvrum, Alfnes, Almli, and Rickertsen (2012) as a series of choices over seven screens. On the first screen all eight biscuit packs were shown and the participants were asked to mark their four most preferred biscuits. The six next screens proceeded as follows. On screen (2) the four selected biscuit packs from screen (1) were shown and the participants were asked to select the most preferred biscuit among these (i.e., their top-ranked biscuit pack). On screen (3) the three remaining biscuit packs from screen (2) were shown and the participants were asked to select the most preferred biscuit among these. On screen (4) the two remaining biscuits from screen (3) were shown and the participants were asked to select the most preferred option among these. Screens

1  
2  
3 225 (5)–(7) proceeded in the same way as screens (2)–(4) but now for the four least preferred biscuit  
4  
5  
6 226 packs.  
7  
8 227  
9  
10  
11 228 Upon completion of the ranking task the respondents were asked to fill out a questionnaire on  
12  
13 229 attitudes, knowledge of upcycled food ingredients and socio-demographics characteristics. In terms  
14  
15 230 of attitudes, consumers’ aversion towards new food products was investigated using the Food  
16  
17  
18 231 Neophobia Scale (FNS) (Pliner & Hobden, 1992) with a scale anchored from 1 (strongly disagree)  
19  
20 232 to 7 (strongly agree). In terms of knowledge towards upcycled food ingredients, we asked if  
21  
22  
23 233 consumers had heard of the term “upcycled” in relation to a food ingredient before the study. If  
24  
25 234 consumers had heard of the term, they were asked to self-report their level of knowledge on  
26  
27  
28 235 upcycled ingredients using a scale anchored from 1 (very low knowledge) to 7 (very high  
29  
30 236 knowledge). All consumers were then asked if they would consider buying foods with upcycled  
31  
32  
33 237 ingredients. Depending on their answer, consumers were asked why they would or would not  
34  
35 238 consider buying foods with upcycled ingredients. To answer these questions consumers were given  
36  
37  
38 239 a choice of five different reasons as well as a free text entry. At the end of the survey socio-  
39  
40 240 demographic information was gathered. A pre-test involving fifty consumers was performed to test  
41  
42 241 the survey. Informed consent was obtained by all study participants and the study was approved by  
43  
44  
45 242 a University Ethical committee.

46  
47 243

## 48 49 50 244 **2.2 Data**

51  
52 245 The data used in this study are drawn from an online survey composed of a ranking experiment  
53  
54  
55 246 followed by a questionnaire conducted during summer 2019 involving 106 consumers in the UK  
56  
57 247 using the online platform Qualtrics LLC (Provo, US). Consumers were randomly recruited by  
58  
59  
60 248 Qualtrics using sampling quotas in terms of age and gender. Consumers were informed about the

1  
2  
3 249 opportunity to participate in a survey on consumers' evaluation of biscuits. Only consumers who  
4  
5  
6 250 were at least 18 years old, who bought and ate biscuits and did not follow gluten-free diets were  
7  
8 251 included in the study.  
9  
10  
11 252  
12  
13 253 The socio demographic characteristics of the sample are presented in Table 2. Given the quota  
14  
15 254 sampling, the final sample was composed of 50% females and 50% males, which is very similar to  
16  
17  
18 255 the most recent UK population census data, composed of 50.64% females and 49.36% males  
19  
20 256 (Office for National Statistics, 2019). In terms of age, 30.19% of participants were 18-32 years old,  
21  
22  
23 257 19.81% were 33-46 years old, 32.80% were 47-61 years old and 17.92% were 62-75 years old.  
24  
25 258 These age ranges are similar to the UK census population, respectively 27.30%, 25.09%, 27.99%  
26  
27  
28 259 and 16.63% (Office for National Statistics, 2019). One or two people composed more than 50% of  
29  
30 260 households and 2/3 of the respondents did not have children under 18 years old. Almost 50% of the  
31  
32  
33 261 sample had annual income before tax less than £30,000 while more than 50% of the respondents  
34  
35 262 were public or private sector employees. In terms of education, almost 85% of the consumers had  
36  
37 263 at least an undergraduate university degree.  
38  
39

40 264

Employment	
<i>Student</i>	7 (6.60%)
<i>Independent worker</i>	5 (4.72%)
<i>Private-sector worker</i>	34 (32.08%)
<i>Public-sector worker</i>	23 (21.70%)
<i>Retired</i>	17 (16.04%)
<i>Unemployed</i>	8 (7.55%)
<i>Not seeking work</i>	11 (10.38%)
<i>Other work</i>	1 (0.94%)
Education	
<i>Secondary school (e.g. GCSE)</i>	29 (27.36%)
<i>Sixth form College qualification (e.g. A level, BTEC)</i>	40 (37.74%)
<i>Undergraduate University Degree (e.g. BA, BSc)</i>	21 (19.81%)
<i>Postgraduate University Degree (e.g. Masters, PGCE)</i>	9 (8.49%)
<i>Postgraduate University Degree (PhD)</i>	5 (4.72%)
<i>Other</i>	2 (1.89%)

## 2.3 Econometric analysis

Ranking data are analysed within the utility framework by so-called discrete choice models (DCMs) (Hensher, Rose, & Greene, 2005; Louviere, Hensher, & Swait, 2000; Train, 2009). DCMs are based on modelling “Utility”, which is the net benefit a consumer obtains from selecting a specific product in a choice situation, as a function of the design attributes. The utility of a product

1  
2  
3 272  $j$  for individual  $n$  in a choice occasion  $t$  (choice set) is written:  
4

$$5 \quad 6 \quad 7 \quad 8 \quad 9 \quad U_{njt} = \beta'_n \mathbf{x}_{jt} + \varepsilon_{njt} \quad (1)$$

10  
11 275  
12  
13 276 where  $\beta_n$  is a vector of individual-specific parameters accounting for preference heterogeneity,  $\mathbf{x}_{jt}$  is  
14  
15 277 a vector of design attributes, and  $\varepsilon_{njt}$  is a random error term. Under the assumption that the random  
16  
17  
18 278 errors follow a so-called extreme value distribution (Train, 2009) and are independent and  
19  
20 279 identically distributed (i.i.d) the choice probability for product  $j$  and choice set  $t$  given the  
21  
22  
23 280 parameter  $\beta_n$  has a simple form:

$$24 \quad 25 \quad 26 \quad 27 \quad 28 \quad 29 \quad P_{njt} = \frac{\exp(\beta'_n \mathbf{x}_{jt})}{\sum_{i=1}^{J_t} \exp(\beta'_n \mathbf{x}_{it})} \quad (2)$$

30 283  
31  
32  
33 284 where  $J_t$  is the number of products in choice set  $t$ .  
34

35 285  
36  
37 286 Among the different DCMs we focused on two of the most applied choice models: the Mixed Logit  
38  
39  
40 287 (ML) model to investigate the pooled sample and the Latent Class Logit (LCL) model to  
41  
42 288 investigate consumers' heterogeneity (Greene & Hensher, 2003; Train, 2009). ML models are  
43  
44  
45 289 widely applied due to their flexibility and because they allow models that may better match real-  
46  
47 290 world situations (Train, 2009). This flexibility comes from the fact that one may freely include  
48  
49  
50 291 random parameters of any distribution and also correlations between random factors. Thus, in the  
51  
52 292 main specification of the model the design attributes for "flour" (i.e., FLOUR), "protein" (i.e.,  
53  
54 293 PROTEIN), "Carbon Trust label" (i.e., CARBON) and "price" (i.e., PRICE) were included. The  
55  
56  
57 294 utility ML model for biscuits  $j$  for individual  $i$  in choice occasion  $t$  is written:

$$58 \quad 59 \quad 60 \quad 61 \quad 62 \quad 63 \quad 64 \quad 65 \quad U_{ijt} = \beta_{1i} \text{FLOUR}_{ijt} + \beta_{2i} \text{PROTEIN}_{ijt} + \beta_{3i} \text{CARBON}_{ijt} + \beta_{4i} \text{PRICE}_{ijt} + \varepsilon_{ijt} \quad (3)$$

1  
2  
3 297  
4  
5  
6 298 The ML model used here assumes random parameters with normal distributions for all design  
7  
8 299 attributes. These random coefficients are further assumed to be independent. This model provides  
9  
10  
11 300 estimates of the mean and the standard deviation of the random conjoint parameters. The ML  
12  
13 301 model was estimated using the module *mixlogit*, to obtain the regression coefficients, and the  
14  
15 302 module *wtp* to obtain the corresponding WTP in monetary terms (i.e., £) (Hole, 2007) run in  
16  
17  
18 303 STATA 15.1 software (StataCorp LP, College Station, US). We run different ML models using  
19  
20 304 different number of draws both with correlated and not correlated variables. Based on LL, AIC and  
21  
22  
23 305 BIC parameters the best model was two thousand Halton draws with no correlated variables used in  
24  
25 306 the simulations. More details on estimation of ML models are found in Train (2009) and Hole  
26  
27  
28 307 (2007).

29  
30 308  
31  
32  
33 309 Next, in order to investigate if consumers' socio-demographics characteristics and consumers'  
34  
35 310 aversion towards new food products have an effect on consumers' preferences for biscuits, starting  
36  
37 311 from the base model (3) a ML including interactions with socio-demographics (i.e., age, gender  
38  
39  
40 312 and education) and FNS (Cronbach alpha: 0.901) was performed. A similar approach was used by  
41  
42 313 Asioli, Næs, Øvrum, and Almlil (2016).

43  
44  
45 314 Thus, in the model we interacted design attributes for "flour" (i.e., FLOUR), "protein" (i.e.,  
46  
47 315 PROTEIN), "Carbon Trust label" (i.e., CARBON) and "price" (i.e., PRICE) with the socio-  
48  
49  
50 316 demographics characteristics such as age (i.e., AGE), gender (i.e., GENDER) and education (i.e.,  
51  
52 317 EDUCATION). In addition, we interacted for "flour" the consumers' aversion towards new food  
53  
54 318 products (i.e., FNS). The utility ML model for biscuits  $j$  for individual  $i$  in choice occasion  $t$  is  
55  
56  
57 319 written:

58  
59 320  
60  
61  
62 321 
$$U_{ijt} = \beta_{1i} FLOUR_{ijt} + \beta_{2i} PROTEIN_{ijt} + \beta_{3i} CARBON_{ijt} + \beta_{4i} PRICE_{ijt} + \beta_{5i} (FLOUR*AGE)_{ijt} + \beta_{6i}$$

$$\begin{aligned}
& (\text{PROTEIN*AGE})_{ijt} + \beta_{7i} (\text{CARBON*AGE})_{ijt} + \beta_{8i} (\text{PRICE*AGE})_{ijt} + \beta_{9i} \\
& (\text{FLOUR*GENDER})_{ijt} + \beta_{10i} (\text{PROTEIN*GENDER})_{ijt} + \beta_{11i} (\text{CARBON* GENDER})_{ijt} + \beta_{12i} \\
& (\text{PRICE* GENDER})_{ijt} + \beta_{13i} (\text{FLOUR*EDUCATION})_{ijt} + \beta_{14i} (\text{PROTEIN* EDUCATION})_{ijt} \\
& + \beta_{15i} (\text{CARBON* EDUCATION})_{ijt} + \beta_{16i} (\text{PRICE* EDUCATION})_{ijt} + \beta_{17i} (\text{FLOUR*FNS})_{ijt} \\
& + \varepsilon_{ijt} \quad (4)
\end{aligned}$$

Next, to investigate consumers' heterogeneity, the LCL model was used. The LCL model assumes constant model parameters within each group and captures consumer heterogeneity assuming a mixing distribution for the groups (Greene & Hensher, 2003; Hess, Ben-Akiva, Gopinath, & Walker, 2011). The LCL model assumes that the consumer group can be split in subgroups with a constant  $\beta$  vector in each group (Greene & Hensher, 2003). The choice probability that an individual of class  $s$  chooses alternative  $j$  from a particular set constituted of  $J_t$  alternatives, is expressed as:

$$P_{j/s} = \frac{\exp(\beta'_s \mathbf{x}_{jt})}{\sum_{i=1}^{J_t} \exp(\beta'_s \mathbf{x}_{it})} \quad (5)$$

where  $s = 1, \dots, S$  represents the number of classes and  $\beta'_s$  is the fixed (constant) parameter vector associated with class  $s$ . In order to establish the likelihood, these choice probabilities have to be multiplied over the choice sets and finally combined over all individuals. To estimate the LCL model it is possible to use the Expectation – Maximization (EM) algorithm which allows for a good numerical stability and good performance in terms of run time (Bhat, 1997; Pacifico & Yoo, 2013; Train, 2008). One of the main issues in the LCL model is the choice of  $S$ , which is the number of latent classes. Given the fact that  $S$  is not a parameter, it is not possible to test it directly (Shen, 2009). Louviere et al. (2000) suggested a number of methods to guide the model selection.

1  
2  
3 346 Specifically, they suggested that the model that minimizes AIC, BIC and CAIC should be preferred  
4  
5  
6 347 (see for more details, Louviere et al. (2000). In this study, the Latent Class Logit (LCL) model used  
7  
8 348 will include main effects in order to calculate the class parameters  $\beta_s$ . The main results from the  
9  
10  
11 349 method are the subgroups, the regression parameter within each group and indications of how well  
12  
13 350 each consumer fits into the different subgroups. The method is invariant to the relative scale of the  
14  
15  
16 351 input variables. The LCL model was estimated using the modules *lclgit2*, *lclgitml2*, *lclgitwtp*  
17  
18 352 and *lclgitpr2* (Yoo, 2019) run in STATA 15.1 software (StataCorp LP, College Station, US).  
19

20  
21 353

### 23 354 **3. RESULTS**

#### 26 355 **3.1 Questionnaire results on upcycled ingredient knowledge**

27  
28 356 The majority of consumers (85%) had not heard of the term “upcycled” in relation to a food  
29  
30  
31 357 ingredient before this study. The remaining 15% of consumers who had heard of upcycled  
32  
33 358 ingredients before the study, had on average a midpoint self-reported knowledge of 3.7 in the 1-7  
34  
35 359 scale from very low to very high knowledge. The majority of consumers (85%) would consider  
36  
37  
38 360 buying foods with upcycled ingredients. Consumers were asked why they would (or would not)  
39  
40 361 consider buying foods with upcycled ingredients. For consumers that would consider buying foods  
41  
42  
43 362 with upcycled ingredients, the three most chosen reasons were “because they would be good for the  
44  
45 363 environment” (49%), “because I would contribute to food waste reduction” (47%), “because I  
46  
47  
48 364 would like to know what they taste like out of curiosity” (46%). The least popular answers for  
49  
50 365 consumers that would consider buying foods with upcycled ingredients were “because they would  
51  
52  
53 366 be cheaper than conventional foods” (21%) and “because they would be healthier than  
54  
55 367 conventional foods” (25%). On the other hand, consumers who would not consider buying foods  
56  
57 368 with upcycled ingredients, selected as the main reason for their choice “I have a feeling they would  
58  
59  
60 369 not taste nice” (8%), followed by “I am not interested in their health benefits” and “they are waste

370 products and I would not like to have them in new foods” (5%). Finally, “they would be more  
371 expensive than conventional foods” and “I am not interested in their environmental benefits” were  
372 the least selected reasons (3%).

### 3.2 Estimation results from Mixed Logit (ML) Model

375 The ML model was estimated in three steps. Firstly, we estimated the regression coefficients of ML  
376 model using the command *mixlogit* (Hole, 2007) run in STATA 15.1 software (StataCorp LP,  
377 College Station, US). The results from the estimation of the regression coefficients of the ML  
378 model using equation (3) are shown in Table 3. Specifically, in Table 3 the regression coefficients  
379 of “price” “flour”, “protein” and “Carbon” are reported, as well as the corresponding standard  
380 errors and significances for the design attributes. On average, consumers preferred biscuits of a low  
381 price, produced with conventional wheat flour and with the labelling information “source of  
382 protein” and Carbon Trust. Looking specifically at the coefficients for the design attributes, price  
383 had the highest magnitude suggesting that this attribute was the one that mostly affected  
384 consumers’ preferences. The second most important attribute that influenced consumers’  
385 preferences was the Carbon Trust label as, on average, consumers preferred biscuits with the  
386 Carbon Trust label information. The third most important attribute that affected consumers’  
387 preferences was the information on protein content, with consumers on average preferring biscuits  
388 with the information “source of protein”. Finally, the least important attribute that influenced  
389 consumers’ preferences was the type of flour, with the data showing that on average consumers  
390 preferred biscuits with conventional wheat flour.

391 It is interesting to note all the design attributes have significant SDs indicating that there were large  
392 individual differences in preferences for the design variables with particular reference to “price”,  
393 “flour” and “Carbon”.

**Table 3 – Estimated parameters for Mixed Logit (ML) model with design attributes’ main effects.**

ATTRIBUTE	Mixed Logit (ML) Model			SD		
	Coefficient	SE	P-value	Coefficient	SE	P-value
Price	-3.25	0.40	0.00	2.89	0.41	0.00
Flour	-0.72	0.23	0.00	1.93	0.25	0.00
Protein	0.90	0.17	0.00	1.21	0.19	0.00
Carbon	1.66	0.24	0.00	1.81	0.27	0.00
MODEL PARAMETERS						
LL				-878.36		
AIC				1772.72		
BIC				1822.47		

Secondly, based on the ML model presented above and on Table 3, we calculated the consumers’ WTP for the attributes “flour”, “protein” and “Carbon” (Table 4) using the command *wtp* (Hole, 2007) run in STATA 15.1 software (StataCorp LP, College Station, US). Table 4 displays the same information reported in Table 3, but expressed in monetary terms, using the marginal WTP. This is the ratio of the coefficient of an attribute (“flour”, “protein” or “Carbon”) divided by the coefficient for price (-1). In line with the results from Table 3, consumers were willing to pay a lower price for biscuits made with upcycled flour (i.e., -£0.22/pack), and a higher price for biscuits with both the “source of protein” nutrition claim (i.e., +£0.28/pack) and the Carbon Trust label (i.e., +£0.51/pack).

**Table 4 – Estimated Willingness to Pay in Preference Space.**

ATTRIBUTE	WTP (£/300gr)
Flour	-0.22

Protein	0.28
Carbon	0.51

Lastly, we investigated the effect of socio-demographics (i.e., age, gender and education) and consumers’ aversion towards new food products (FNS) on consumers’ preferences for biscuits. The results from the estimation of the regression coefficients of the ML model using equation (4) are shown in Table 5. Specifically, in Table 5 the regression coefficients of “flour”, “protein”, “Carbon” and “price”, as well as the interactions’ terms of the design attributes with “age”, “gender”, “education” and “FNS” are reported. Table 5 also shows the corresponding standard errors and significances for the design attributes. Looking at the interactions among design variables and socio-demographic characteristics, we found that only the interaction between “protein” and “education” was significant at 5% p-value, but negatively correlated meaning that more educated people preferred biscuits with lower protein content. It is interesting to note that the link between “flour” and “FNS” was not significant, indicating no link between aversion to new food products and the use of upcycled ingredients.

**Table 5 – Estimated parameters for Mixed Logit (ML) model with design attributes’ main effects and interactions with the age, gender, education and the interaction of “flour” with consumers’ aversion towards new food products (FNS).**

**3.3 Estimation results from Latent Class Logit (LCL) with design attributes' main effects.**

The final stage of the study was to estimate the LCL model in two steps. Firstly, we estimated the regression coefficients for each design attributes of LCL model for the different consumers' segments using the command *lclogit2* (Yoo, 2019) run in STATA 15.1 software (StataCorp LP, College Station, US). Based on the BIC parameter (see for details Yoo (2019)), the optimal number of groups for the LCL model was found to be three. The BIC value was 1875.93 with two groups<sup>3</sup>.

This value reduced for three groups (1861.63) and raising it to four groups resulted in numerical

<sup>3</sup> The 2-cluster solution was composed by group 1 (N=41 consumers) and group 2 (N=65 consumers) as following, (i.e., attribute and regression coefficient):

- Group 1: Price (-12.79), Flour (-0.38); Protein (0.57) Carbon (1.13);
- Group 2: Price (-0.67), Flour (-0.37); Protein (0.48) Carbon (0.73).

convergence problems. Therefore, a three-group solution was considered. The results of the LCL model with the three-group solution are reported in Table 6 showing two large and one small groups. Specifically, in Table 6 the regression coefficients of “flour”, “protein”, “Carbon” and “price” are reported as well as the corresponding standard errors and significances for the design attributes. In group 1 (52 consumers) consumers had the strongest rejection for the upcycled sunflower flour (i.e., “traditionalist consumers”) while in group 2 (41 consumers) consumers had strong preferences for low price biscuits (i.e., “price-sensitive consumers”). The p-value for price in group 2 is due to the substantial amount of statistical noise at the point of estimate. Finally, in group 3 (13 consumers) consumers had strong preferences for biscuits with the Carbon Trust label (i.e., “environmentalist consumers”). The main difference among the three groups was therefore the difference in preference for price and the Carbon Trust label.

**Table 6 – Estimated Regression Coefficient from Latent Class Logit (LCL) Model.**

ATTRIBUTE	GROUP 1			GROUP 2			GROUP 3		
	“Traditionalists”			“Price sensitive”			“Environmentalist”		
	(N=52)			(N=41)			(N=13)		
	Coefficient	SE	P-value	Coefficient	SE	P-value	Coefficient	SE	P-value
Price	-0.60	0.13	0.00	-7.17	5.63	0.20	-1.42	0.40	0.00
Flour	-0.46	0.14	0.00	-0.37	0.17	0.03	-0.13	0.40	0.77
Protein	0.50	0.13	0.00	0.57	0.15	0.00	0.81	0.36	0.03
Carbon	0.38	0.14	0.01	1.14	0.17	0.00	5.30	1.84	0.00

Secondly, based on the LCL model presented above and in Table 6, for each consumers’ group we estimated the consumers’ WTP for “flour”, “protein” and “Carbon”. We used the command *lclogitwtp* (Yoo, 2019) in STATA 15.1 software (StataCorp LP, College Station, US) which calculates the ratio of the coefficient of an attribute (“flour, “protein” or “Carbon”) divided by the

1  
2  
3 452 coefficient for price (-1). Results are shown in Table 7. Consumers' WTP for a 300 g pack of  
4  
5  
6 453 biscuits for "flour", "protein", "Carbon" and "price" for each group are reported as well as the  
7  
8 454 corresponding standard errors and significances for the design attributes. Table 7 is therefore  
9  
10  
11 455 similar to Table 6, but it expresses information in monetary terms using the marginal WTP.  
12  
13 456 "Traditionalist" consumers were willing to pay a much lower price for biscuits made with upcycled  
14  
15 457 flour (i.e., -£0.77/pack) and a higher price for biscuits that were a "source of protein" (i.e.,  
16  
17  
18 458 +£0.82/pack) and that carried the Carbon Trust label (i.e., +£0.62/pack). "Price-sensitive"  
19  
20 459 consumers did not show any significant WTP for a particular attribute level, as price was the  
21  
22  
23 460 dominating attribute (see Table 3). This means that consumers in this group are interested only in  
24  
25 461 low price products. "Environmentalist" consumers were willing to pay a much higher price for  
26  
27  
28 462 biscuits that were a "source of protein" (i.e., +£0.57/pack) and that carried the Carbon Trust label  
29  
30 463 (i.e., +£3.71/pack).  
31  
32  
33 464

55 467 **4. DISCUSSION & CONCLUSIONS**  
56

57 468 This study aimed to explore consumers' preferences, WTP and heterogeneity for biscuits made  
58  
59  
60 469 with upcycled ingredients and test the use of the "source of protein" claim and Carbon Trust label  
61  
62  
63  
64  
65

1  
2  
3 470 on the pack. We will discuss here how the results from this study advance theory, add to other  
4  
5  
6 471 studies on upcycled ingredients and provide useful managerial insights into the new area of foods  
7  
8 472 made with upcycled ingredients.  
9

10  
11 473  
12  
13 474 Results from the questionnaire revealed very poor consumers' knowledge of upcycled ingredients  
14  
15 475 with only 15% of consumers claiming to have heard of foods with upcycled ingredients before  
16  
17  
18 476 taking part in the study. These results suggest that, although foods with upcycled ingredients can be  
19  
20 477 manufactured (Grasso et al., 2020; Grasso et al., 2019; Spinelli, Padalino, Costa, Del Nobile, &  
21  
22  
23 478 Conte, 2019), the concept of upcycled ingredients and related benefits might be too novel for  
24  
25 479 consumers and therefore suitable information campaigns should be designed to address this in the  
26  
27  
28 480 UK. More positive results on consumer knowledge of upcycled ingredients were obtained in Italy  
29  
30 481 by Coderoni and Perito (2020). In their study, 61% of respondents declared to have heard about  
31  
32  
33 482 waste to value foods (and they also knew what the term meant), 20% had heard about those  
34  
35 483 products (but did not know what they meant) and finally 19% did not know about the existence of  
36  
37 484 waste to value foods. These different results might be linked to country-specific differences or to  
38  
39  
40 485 the different methods used to gather the data.  
41

42 486 Despite the low knowledge, the majority of consumers (85%) would consider buying foods with  
43  
44  
45 487 upcycled ingredients. This is an important outcome, since the concept of upcycled ingredient  
46  
47 488 overall was not rejected. Coderoni and Perito (2020) also reported positive findings in Italy, with  
48  
49  
50 489 56% of respondents in their study claiming that they would buy a food product made with  
51  
52 490 wastes/by-products. The percentage rose to 69% if the food made with wastes/by-products also  
53  
54 491 reduced the environmental impact of production.  
55

56  
57 492 Looking at the reasons why consumers would consider buying foods with upcycled ingredients, it  
58  
59 493 seems that environmental and food waste prevention were the most important factors, followed by  
60  
61  
62 494 curiosity, while the nutritional benefit did not seem to be considered as important for consumers.  
63

1  
2  
3 495 The relationship between food consumption, food waste and the environment has received a lot of  
4  
5  
6 496 attention by the UK media and retailers in recent times (BBC, 2019; SkyNews, 2019) and  
7  
8 497 consumers might have been favourably influenced by this communication. Future marketing  
9  
10 498 strategies and labelling information should consider these factors to maximise the reach of foods  
11  
12  
13 499 with upcycled ingredients. Coderoni and Perito (2020) found that Italian respondents in their study  
14  
15 500 were also more likely to buy waste-to-value foods if they thought that this could provide health  
16  
17  
18 501 benefits and a lower environmental impact.

19  
20 502 Results from the FNS indicate that upcycled ingredients were not significantly linked to food  
21  
22  
23 503 neophobia. This is a positive outcome, since several studies have shown that the FNS correctly  
24  
25 504 forecasts responses to new foods (Siegrist, Hartmann, & Keller, 2013; Sogari, Menozzi, & Mora,  
26  
27  
28 505 2019; Verbeke, 2015). Previous studies on FNS and foods made with upcycled ingredients reached  
29  
30 506 different conclusions. Coderoni and Perito (2020) reported that FNS negatively correlated with  
31  
32  
33 507 purchase intentions, while the willingness to try foods made with olive oil by-products had a  
34  
35 508 significant negative correlation with technophobia but not with neophobia in Perito et al. (2019).

36  
37 509  
38  
39  
40 510 Price was the attribute that mostly affected consumers' WTP followed by the Carbon Trust label,  
41  
42 511 protein and finally information on the type of flour. These results are in accordance with other  
43  
44  
45 512 studies where positive consumers' preferences towards the carbon footprint label (Echeverría,  
46  
47 513 Hugo Moreira, Sepúlveda, & Wittwer, 2014) and nutrition claim on proteins (Van Wezemael,  
48  
49  
50 514 Caputo, Nayga Jr, Chryssochoidis, & Verbeke, 2014) were found. Since "price", "protein" and  
51  
52 515 "Carbon" were all more important to consumers than the ingredients used (i.e. "flour"), consumer  
53  
54  
55 516 acceptance of foods with upcycled ingredients could be shaped by promoting these foods with a  
56  
57 517 lower price, with the Carbon Trust label and with appropriate nutrition protein claims.

58  
59 518 On average, consumers preferred biscuits made with conventional (i.e., wheat) flour and tended to  
60  
61  
62 519 reject biscuits made with upcycled sunflower flour. However, we found significant consumers'

520 heterogeneity with three different groups of consumers identified. The “environmentalist” group  
521 had the lowest rejection towards upcycled sunflower flour in biscuits and the strongest preference  
522 for the protein claim and the Carbon Trust label. This group might therefore be the most suitable to  
523 target the marketing and promotional strategies for the launch of the new biscuits made with  
524 upcycled ingredients, as it has been reported that a strong environmental consciousness can lead  
525 towards more sustainable lifestyle choices (Truelove & Parks, 2012).

527 This manuscript has two main limitations. Firstly, the sample size is small which could limit the  
528 representativeness of our findings. Secondly, being this a hypothetical study, it might suffer from  
529 hypothetical bias which could have affected the estimation of consumers’ WTP. Although this  
530 study was anonymous and a cheap talk was used to limit hypothetical bias effect, it is also possible  
531 that social desirability bias might have influenced consumers’ responses. Preferences for the  
532 Carbon Trust label might have been due to this label being more known to consumers compared to  
533 the concept of upcycled ingredients.

534  
535 Appropriate consumer-friendly definitions and labelling for upcycled ingredients need to be  
536 developed and suitably communicated before these new products are launched on the market.  
537 Indeed, in the food context, there have been many examples that reflect how the name of a dish, a  
538 food product or a label affect consumers’ perceptions (Irmak, Vallen, & Robinson, 2011; Kunst &  
539 Hohle, 2016). Further work also needs to be conducted to find the most suitable way to  
540 communicate the nutritional and environmental advantages of upcycled ingredients to consumers.  
541 It is possible that increasing consumer familiarity with the concept and benefits of upcycled  
542 ingredients will improve the acceptability of new foods made with such by-products and this  
543 hypothesis should be tested in future studies. In general, exposure has been reported to be an  
544 important driver of acceptance and should be an element to secure new product acceptance

1  
2  
3 545 alongside with taste (Lease, MacDonald, & Cox, 2014). Other studies on consumers' preferences  
4  
5  
6 546 towards food by-products also concluded that appropriate definitions, information on benefits and  
7  
8 547 marketing strategies are key to success (Aschemann-Witzel & Peschel, 2019; Bhatt et al., 2018;  
9  
10 548 Coderoni & Perito, 2020; Perito et al., 2019).

12  
13 549  
14  
15 550 In addition to communicating information on upcycled ingredients to consumers, there are further  
16  
17  
18 551 areas to explore. While currently there are no specific regulations concerning foods made with by-  
19  
20 552 products, many regulatory challenges are likely to affect the sale of upcycled ingredients in Europe.  
21  
22  
23 553 Some upcycled ingredients might in fact be considered novel foods, because they were not  
24  
25 554 produced or used in the EU before 1997, and might need to be authorized by the European Food  
26  
27  
28 555 Safety Authority (EFSA) before entering the EU market (EFSA, 2016). It would be important for  
29  
30 556 the regulatory authorities to consider the environmental and nutritional benefits of upcycled  
31  
32  
33 557 ingredients in order to allow for procedures that would simplify their entrance into the market and  
34  
35 558 make a positive impact on our societies. This would in turn encourage food ingredient  
36  
37  
38 559 manufacturers to invest in the development of upcycled ingredients and offer more cost-effective  
39  
40 560 options to food manufacturers for the development of healthier and more sustainable foods.

41  
42 561  
43  
44  
45 562 Future research should include the replication of this study using larger samples of UK consumers  
46  
47 563 and in other countries, the use of different food products and testing the effect of different message  
48  
49  
50 564 framing information (i.e., private and public benefits of using upcycled ingredients) about upcycled  
51  
52 565 ingredients to consumers. In addition, future studies should include sensory tests of these new  
53  
54  
55 566 products as it is well known in the literature that sensory attributes are key drivers of consumers'  
56  
57 567 preferences (Asioli et al., 2017; Grunert, 2005; Lima, de Alcantara, Ares, & Deliza, 2019). Sensory  
58  
59 568 testing of foods with upcycled ingredients could therefore provide further realistic valuable  
60  
61  
62 569 consumer insights into this topic. It is also recommended to carry out real experiments using real

1  
2  
3 570 products in the field, in supermarkets, using real choice experiments (RCE) or experimental  
4  
5  
6 571 auctions which will provide further external validity of these results (Alfnes & Rickertsen, 2011;  
7  
8 572 Lusk & Shogren, 2007).  
9

10  
11 573 Finally, a multidisciplinary effort bringing together regulators, new product developers, food  
12  
13 574 manufacturers and marketers will be needed to ensure that foods with upcycled ingredients can  
14  
15 575 enter the food market and find a stable position on the supermarket's shelf.
