#### Abstract

Short synthetic routes to a range of BEDT-TTF derivatives functionalised with two, four or eight hydroxyl groups are reported, of interest because of their potential for introducing hydrogen bonding between donor and anion into their radical cation salts. The cycloaddition of 1,3-dithiole-2,4,5-trithione with alkenes to construct 5,6-dihydro-1,3-dithiolo[4,5-b]1,4-dithiin-2-thiones is a key step, with homo- or hetero-coupling procedures and O-deprotection completing the syntheses. The first synthesis of a single diastereomer of tetrakis(hydroxymethyl)BEDT-TTF, the cis, trans product, was achieved by careful choice of O-protecting groups to facilitate separation of homo- and hetero-coupled products. Cyclisation of the trithione with enantiopure $1 R, 2 R, 5 R, 6 R$-bis(O,O-isopropylidene)hex-3-ene-1,2,5,6-tetrol (from $D$ mannitol) gave two separable diastereomeric thiones, which can be transformed to enantiomeric BEDT-TTF derivatives with four or eight hydroxyl groups.

Following on from the extensive studies on tetrathiafulvalene (TTF), ${ }^{1}$ bis(ethylenedithio)tetrathiafulvalene, more commonly known as BEDT-TTF or ET 1, has played a prominent role in the recent development of molecular conductors, superconductors and bifunctional materials, and a wide range of its radical cation salts have been prepared and their properties investigated. ${ }^{2}$ Particular highlights are the salts $(\mathrm{ET})_{2}\left(\mathrm{Cu}(\mathrm{NCS})_{2}\right)$ and $(\mathrm{ET})_{2}\left(\mathrm{~N}(\mathrm{CN})_{2}\right) \mathrm{X}(\mathrm{X}=\mathrm{Cl}$ or Br$)$ which become superconducting at low temperatures, ${ }^{3}$ the paramagnetic superconducting radical salt $(\mathrm{ET})_{4}\left[\mathrm{Fe}(\text { oxalate })_{3}\right] \cdot \mathrm{H}_{2} \mathrm{O} \cdot \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CN},{ }^{4}$ a layered salt with a mixed chromium(III) / manganese (II) oxalate network which has independent electrical and ferromagnetic properties, ${ }^{5}$ and salts with $\mathrm{MHg}(\mathrm{SCN})_{4}{ }^{-}(\mathrm{M}=\mathrm{K}$ or Tl$)$ which form a chiral surface metal in a magnetic field. ${ }^{6}$ The superconducting salts are of great interest to theoretical physicists since the salts are clean systems whose electrical behaviour can be modelled, and provide test beds for exploring new aspects of superconductivity. A range of substituted ET derivatives is now becoming available. ${ }^{7}$ The installation of a substituent on one of the ethylene bridges forms a stereogenic centre, and a number of racemic monosubstituted ET donors have been prepared, for example with sidechains terminating in amino ${ }^{8}$ or amido ${ }^{9}$ groups, e.g. 2-3, or a long hydrocarbon chain, ${ }^{10}$ e.g. 4. The enantiopure ester $5^{11}$ has also been reported. Disubstituted and tetrasubstituted derivatives e.g. the enantiopure dimethyl-ET ${ }^{12} \mathbf{6}$ and its meso isomer, ${ }^{12}$ enantiopure tetramethyl-ET ${ }^{13} 8$ and racemic dichloro-ET ${ }^{14} 7$ as well as materials with additional ring systems such as $\mathbf{9}^{15}$ have been prepared. However, care is necessary to avoid preparing mixtures of stereoisomers when each "end" of the ET molecule is substituted. ${ }^{7}$ A number of interesting properties are emerging. Thus, a 2:1 superconducting perchlorate salt of enantiopure dimethyl-ET $6\left(T_{c}=3.0 \mathrm{~K}, 5.0 \mathrm{kbar}\right)$ was reported by Hilti, Zambounis et al., while a $2: 1$ hexafluorophosphate superconducting salt was obtained from the meso-isomer of this donor $\left(\mathrm{T}_{\mathrm{c}}=4.3 \mathrm{~K}\right.$, 4.0 kbar) by Mori et al. ${ }^{12}$ Troitksy has used the hexadecyl-ET 4 to prepare conducting thin films. ${ }^{16}$ New ET derivatives containing metal binding sites such as $\mathbf{1 0}$ with potential for preparing bifunctional materials with magnetic metal ions, ${ }^{17-18}$ and an enantiopure donor 11 derived from (-)- $\beta$-pinene have recently been prepared. ${ }^{11}$ Cross coupling reactions have been utilised to prepare substituted derivatives of the ethylenedithio-TTF system 12. ${ }^{19}$ Furthermore, substituted derivatives of selenium containing donors, such as BETS $^{20}$ 13, may soon become available following developments in synthetic approaches ${ }^{21}$ which will be of interest since some BETS
radical cation salts have electrical properties which can be modified by an external magnetic field. ${ }^{20}$

Here we describe the synthesis of a range of ET donors carrying between one and eight hydroxyl groups. Introduction of hydroxyl groups on to a donor molecule brings not only the possibility of hydrogen bonding in the radical cation salts to anchor the anions in unique sites and orientations, but also provides a point for attachment of further functionality. In the TTF series mono-, di- and tetra(hydroxymethyl) derivatives have been reported, ${ }^{22-24}$ hydrogen bonding to anions in their radical cation salts has been observed, ${ }^{24}$ and they have been utilised in the construction of more complex systems. ${ }^{25} \mathrm{We}$ and others have reported synthetic routes to racemic hydroxymethyl-ET 14, ${ }^{18,26,27}$ the cheapest and most efficient using the acetyl protecting group, and we have also synthesized the enantiopure form. ${ }^{28} \mathrm{~A}$ number of semiconducting microcrystalline $2: 1$ radical cation salts of racemic $\mathbf{1 4}$ have been prepared. ${ }^{26}$ Routes to the ET donor with cis oriented hydroxymethyl groups $\mathbf{1 5},{ }^{27}$ a stereoisomeric mixture of the tetrakis(hydroxymethyl)ET $\mathbf{1 6}^{\mathbf{2 9}}$ and donors with expanded outer rings substituted with hydroxyl or hydroxymethyl groups $17-18^{30-31}$ have been reported. Two radical cations salts of di(hydroxymethyl)-substituted materials have been described: $(\mathbf{1 5})_{2} \mathrm{Cl}$ and $(\mathbf{1 7})_{2} \mathrm{I}_{3}$. In the former ${ }^{27}$ the chloride is hydrogen bonded by hydroxyl groups from three donors, and lies between stacks of
donors, while in the latter ${ }^{32}$ the donors hydrogen bond with each other while the triiodides lie in isolated pockets. Here we describe, with experimental details, syntheses of racemic hydroxyethyl-ET 19 and trans-di(hydroxymethyl)-ET 20, the first synthesis of a single diastereoisomer of the tetrol tetrakis(hydroxymethyl)ET, the cis,trans isomer 21, and the syntheses of the enantiopure tetrol 22 and octol 23, with the aim of making these new interesting donors accessible to the materials chemistry community.

## Discussion.

## Preparation of hydroxyethyl-ET 19.

The general approach in these syntheses is illustrated by the synthesis of hydroxyethyl-ET, HEET, 19. The synthetic routes rely on the cyclisation of the trithione 24 with the appropriate alkene, a reaction first used by Neilands. ${ }^{33}$ Refluxing but-3-en-1-ol with trithione 24 in toluene gave the thione 25 in $83 \%$ yield, followed by protection of the hydroxyl group as an acetate to give 26, which was necessary for a successful subsequent cross coupling reaction. Thione sulfur/oxygen exchange gave oxo compound 27, which was cross coupled with the unsubstituted thione 28 to give the protected donor 29 in 54 \% yield. Hydrolysis gave HEET 19 in five steps with an overall yield of $14 \%$ (Scheme 1). Both hydroxymethyl-ET $14^{18}$ and HEET 19 have
been functionalised either by ester formation or by tosylation and substitution. For example, HEET forms ester 32 with thiophene-3-carbonyl chloride and ester 34 with the thiophene containing carboxylic acid 33 in the presence of DCC/DMAP, and its tosylate 30 is substituted with thiophene-3-methylthiolate to give sulphide 31.

Scheme 1

## Preparation of trans-vic-bis(hydroxymethyl)-ET 20.

The ET derivative with two vicinal trans oriented hydroxymethyl groups was prepared in a similar way. Cyclisation of trithione $\mathbf{2 4}$ with the trans-but-2-en-1,4-diol, which was prepared from but-yn-1,4-diol by reduction with lithium aluminium
hydride, ${ }^{34}$ gave diol 35 in $41 \%$ yield. Protection of hydroxyl groups as acetates to give 36, was followed by the standard three steps of (a) sulfur/oxygen exchange to give oxo compound 37, (b) cross coupling with unsubstituted thione 28 to give the protected donor 38 in $55 \%$ yield, and (c) deprotection to give the trans diol 20 in an overall yield of $17 \%$ (Scheme 2). The different disposition of the hydroxymethyl groups, compared to the cis isomer 15, is expected to affect the structures of its radical cation salts with anions which can act as hydrogen bond acceptors.

## Preparation of cis,trans-tetrakis(hydroxymethyl)-ET 21.

Tetrakis(hydroxymethyl)substituted ETs are very attractive donors because of the hydrogen bonding potential at both "ends" of the molecule. However, there are five possible stereoisomers depending on whether the two groups at each end of the molecule lie cis or trans, 41-45 ( $\mathrm{R}=\mathrm{CH}_{2} \mathrm{OH}$ ) (Scheme 3), and two of these stereoisomers ( $\mathbf{4 1}$ and $\mathbf{4 5 )}$ ) are racemic mixtures. It is important to develop syntheses of individual stereoisomers, since electrocrystallisation of a stereoisomeric mixture is a strategy frought with problems; identification of the product relies on X-ray crystallography to determine which stereoisomer or stereoisomers are present, ${ }^{35}$ assuming that all crystals have the same composition of course. An outline of the stereochemical consequences of various coupling strategies is given in Scheme 3. Homo-coupling of a racemic trans-disubstituted oxo compound 39 will give a
racemic mixture of the tetrasubstituted ET 41 from self coupling of each enantiomer of 39 , as well as a meso compound 42 arising from coupling of the two opposite enantiomers. Homo-coupling of a cis disubstituted oxo compound 40 will give diastereomeric products 43 and 44 . In both cases, separation of the products is likely to be extremely difficult. Homo-coupling of one enantiomer of the trans oxo compound 39 would yield one enantiomer of the all-trans isomer 41, but attempts to prepare the appropriate single enantiomer of the trans oxo compound $42(\mathrm{R}=$ $\mathrm{CH}_{2} \mathrm{OH}$ ) have so far been unsuccessful. The fifth stereoisomer 45 is the product of cross coupling of the cis and trans disubstituted oxo compounds 39 and $\mathbf{4 0}$, but is accompanied by all other homo-coupled products.

Scheme 3

However, we have now developed a strategy for isolation of this last stereoisomer cis,trans-tetrakis(hydroxymethyl)ET 21. The overall synthetic plan is shown in Scheme 4. The key step is the protection of the hydroxyl groups of the cis and trans compounds for coupling with groups of quite different polarities. Thus, hydroxyl groups of the cis-di(hydroxymethyl) thione 46 were protected with two BTDMS groups to give thione $47^{27}$ which was converted to its oxo compound 48. The hydroxyl groups of the trans-di(hydroxymethyl) thione 35 were protected as acetates to give thione 36. Cross coupling of cis- and trans compounds 48 and 36 in triethyl phosphite gave three sets of materials: the desired cross coupled material 53 ( 2 x TBDMS, 2 x acetyl O-protecting groups) and the two pairs of homo-coupled materials: $\mathbf{4 9}$ and 50 ( $4 \times$ TBDMS O-protecting groups) and 51 and 52 ( $4 \times$ acetyl O-
protecting groups). The three groups of materials were separated by chromatography. The cross coupled product, with two protecting groups of each type, runs between the two sets of homo-coupled products which each carry four protecting groups of the same type. Finally, the tetrol 21 was prepared by hydrolysis of the protecting groups of 53 with aqueous $20 \% \mathrm{HCl}$ in THF. We believe this principle of using two protecting groups of quite different polarities will find application in the synthesis of further polysubstituted donors.

## Preparation of enantiopure tetrol and octol donors 22 and 23.

We have already reported the total diastereoselectivity of the reactions of the trithione 24 with enantiopure alkenes (-)- $\alpha$-pinene, (-)- $\beta$-pinene and ( + )-2-carene. ${ }^{11}$ Encouraged by this, we extended the study to the structurally less complex enantiopure alkene 54 (Scheme 5) which has two stereocentres adjacent to the double bond and four protected hydroxyl groups and which is readily prepared from $D$ mannitol. ${ }^{36}$ Trithione 24 reacted with this alkene to give major (31\%) and minor (5\%)

1:1 addition products which were assigned structures 55 and 56 respectively, based on the X-ray crystal structure of the minor isomer 56 (Fig. 1). Thus, the major product is formed by addition of trithione $\mathbf{2 4}$ to the Si face of enantiopure alkene 54 as shown in Fig 2, while the minor adduct is formed by addition to the Re face. Molecular mechanics studies indicated there was no strong conformational preference for rotation about the bonds between the alkene and each cyclic ketal, with a small energy minimum for the conformation shown in Fig 2.

Fig. 1. Molecular structure of minor diastereomer 56.

Fig. 2. Preferred conformation of alkene 54 with the $S i$ face upwards.

The X-ray structure of the minor product 56 shows that the dithiin ring takes up a twisted boat conformation with both ring $s p^{3}$ carbon atoms strongly displaced to the same side of the plane defined by the other atoms of the fused ring system but with C 5 displaced by more than C4 (C4: by $1.277(4)$, C5 by $1.486(5) \AA$ ). The torsions about the dithiin $s p^{2} \mathrm{C}$-S bonds are $-48.8(5)$ and $52.0(5)^{\circ}$, and the twist in
the boat structure is indicated by the largest torsion in this ring about the C5-S5 bond: $-66.3(4)^{\circ}$, much larger than that of $28.4(5)^{\circ}$ for the C4-S4 bond. The trans arrangement of the dioxolane rings means that one lies over the organosulfur ring system and the other lies away from it. Each dioxolane ring adopt an envelope conformation with the flap at the carbon atom between the oxygen atoms. The best planes of these rings lies at 40.3(2) and 50.7(2) ${ }^{\circ}$ to the best plane through the planar portion of the organosulfur system. There are distinct differences in the chemical shifts of the carbon atoms in the dithiin ring for the major and minor diastereoisomers 55 and 56. The major isomer exhibits chemical shifts for the $s p^{3} \mathrm{C}$ atoms at $\delta_{C}: 44.3$ and for the $s p^{2} \mathrm{C}$ atoms at $\delta_{C}: 118.9$ similar to those of other trans disubstituted derivatives e.g. the dimethyl derivative 60 ( $\delta_{C}: 43.5$ and 120.4) whose solid state conformation lies between a half chair and an envelope. ${ }^{37}$ In contrast, for the minor diastereomer the shifts of the corresponding carbon atoms are larger: $\delta_{C}$ : 51.7 and 128.3. The trans diester 61, which like the minor isomer also show a boat conformation in the solid state, has corresponding shifts at $\delta_{C}: 50.2$ and $\delta_{C}: 129.9$ for 61. ${ }^{38}$ These larger shifts may relate in part to the poorer conjugation of the dithiin S atoms with the dithiole ring when the former has the boat conformation.

61

The major product 55 was converted to its oxo compound 57 with mercuric acetate and coupled to the unsubstituted thione $\mathbf{2 8}$ using triethyl phosphite to give the protected donor 58 in $35 \%$ yield after chromatography. Finally, deprotection with 2 M HCl in THF yielded the enantiopure tetrol 22 in $94 \%$ yield. Furthermore, self coupling of the oxo compound 57 in triethyl phosphite furnished the donor bearing four ketal groups 59 in $60 \%$ yield, which could be deprotected in a similar way to give the enantiopure octol 23.

The oxidation potentials of the new hydroxyl substituted donors, measured in dichloromethane, indicate that the overall pattern of two reversible oxidations is
retained (Table 1), though the octol 23 was completely insoluble in this solvent, and measurements in THF did not indicate a reversible system. We are now investigating the electrocrystallisation of these materials. Of particular interest will be to see how the interaction of the hydroxyl groups with the anions control the solid state structures of the radical cation salts.

## Conclusion.

We have reported syntheses of a series of ET-derivatives carrying one, two, four and eight hydroxyl groups, two of them in enantiopure form. Molecules 22-23 are particularly attractive donors, since, apart from the potential for having chiral hydrogen bonding networks in their radical cation salts, these donors are starting materials for preparing dendrimeric materials. These single enantiomers will also provide important substrates for investigating the influence of chirality on electrical and magnetic properties. The second enantiomers will be available from the other enantiomer of alkene 54, and the racemate is available by mixing equal amounts of the two enantiomers, a rare case where it is more work to prepare the racemate than the enantiomer. Rikken has reported magnetochiral anisotropy in the conductivity of carbon nanotubes, ${ }^{39}$ and our donors will provide a test bed for investigating the effect of chirality on the electrical properties of organosulfur donors. Furthermore, the
diastereoselectivity of the cycloaddition of thione 24 with alkene 54 is a very encouraging result suggesting that cycloadditions of trithione 24 with further enantiopure alkenes will be a key step in designing and preparing further enantiopure donors.

## Experimental.

General. NMR spectra were measured on a JEOL JNM-EX270 spectrometer at 270 MHz for ${ }^{1} \mathrm{H}$ and at 67.8 MHz for ${ }^{13} \mathrm{C}$ using $\mathrm{CDCl}_{3}$ as solvent and tetramethylsilane (TMS) as standard unless otherwise stated, and measured in p.p.m. downfield from TMS with coupling constants reported in Hz . IR spectra were recorded on PerkinElmer Spectrum RX 1 FT-IR spectrometer, and are reported in $\mathrm{cm}^{-1}$. Optical rotation data were measured on a PerkinElmer 241 polarimeter. Mass spectra were recorded at the EPSRC Mass Spectrometry Centre. Chemical analysis data were obtained from Mr. T. Spencer, University of Nottingham. An X-ray diffraction dataset was measured by the EPSRC National Crystallography Service at Southampton University. Flash chromatography was performed on 40-63 silica gel (Merck).
