Abstract

This study longitudinally examined age-related changes in the match-running performance of retained and released elite youth soccer players aged 8-18 years. The effect of playing position on age-related changes was also considered. Across three seasons 263 elite youth soccer players were assessed in 1-29 competitive matches (988 player-matches). For each player-match, total distance and distances covered at age-group-specific speed zones (low-speed, high-speed, sprinting) were calculated using 1 Hz or 5 Hz GPS. Mixed modelling predicted that match-running performance developed non-linearly, with age-related changes best described with quadratic age terms. Modelling predicted that playing position significantly modified age-related changes ($p < 0.05$) and retained players covered significantly more low-speed distance compared to released players ($p < 0.05$), by $75 \pm 71 \text{ m}\cdot\text{h}^{-1}$ (mean \pm 95% CI) (effect size \pm 95% CI: 0.35 ± 0.34). Model intercepts randomly varied, indicating differences between players in match-running performance unexplained by age, playing position or status. These findings may assist experts in developing training programmes specific to the match-play demands of players of different ages and playing positions. Although retained players covered more low-speed distance than released players, further study of the actions comprising low-speed distance during match-play is warranted to better understand factors differentiating retained and released players.

Introduction

The match-running performance of elite male senior soccer players has been extensively described (e.g. Di Salvo et al., 2007; Bradley et al., 2009; Carling, 2011). Indeed, a recent study of English male Premier League players showed that during a 90 minute match, mean \pm SD distance covered was 10714 ± 991 m, of which 2492 ± 625 m was at high-speed ($> 4 \text{ m}\cdot\text{s}^{-1}$) (Bradley et al., 2009). Moreover, these playing characteristics have been shown to distinguish between players of differing standards, for example, Mohr et al. (2003) showed that top-class professional players performed more high-speed running ($> 4.17 \text{ m}\cdot\text{s}^{-1}$) and sprinting ($> 8.33 \text{ m}\cdot\text{s}^{-1}$) during match-play than moderate-ability professional players. However, to date very few studies have considered the match-running performance of elite youth soccer players, which is surprising considering the potential such information could have in providing insight into talent identification and development processes in soccer. Indeed, understanding age-related changes in the match-running performance of elite youth soccer players would have implications for the assessment of match performance, the design of effective training programmes, and the development of relevant physiological testing procedures (Carling et al., 2008). Moreover, examining match performance characteristics that discriminate more and less successful elite youth soccer players may aid the process of identifying players with the potential to become senior professionals (Waldron & Murphy, 2013).

The findings of the limited number of studies that have considered the match-running performance of elite male youth soccer players suggest, through cross-sectional comparison of 8-10 years (Goto et al., 2013), 11-16 years (Harley et al., 2010), and 12-18 year old players (Pereira Da Silva et al., 2007; Buchheit et al., 2010; Mendez-Villanueva et al., 2013), that there is a general trend for total distance covered during

1
2
3 match-play to increase with age. These total distances ranged from 4356 ± 478 m in
4
5 U9 players (Goto et al., 2013) to 8867 ± 859 m in U18 players (Buchheit et al., 2010).
6
7 However, match durations are shorter for younger players and so it is considered
8
9 appropriate to normalise distances covered to match-time (Carling et al., 2008). When
10
11 adjusted to match-time, differences between age groups in distance covered still exist
12
13 but are less apparent, especially at older ages (Buchheit et al., 2010). Nevertheless, to
14
15 confirm age-related changes in distance covered during match-play, studying a group
16
17 of elite youth players across an age range that encapsulates an entire talent
18
19 development programme is required.
20
21

22
23 The age-related changes in distance covered at various speeds by elite youth soccer
24
25 players during match-play are less clear than changes in total distance covered.
26
27 Buchheit et al. (2010) showed that when adjusted to match time, U18 players covered
28
29 more sprinting distance ($> 5.31 \text{ m}\cdot\text{s}^{-1}$) compared to U13-U17 players. However, when
30
31 mean 10 m flying peak speed of each specific age group was used to categorise speed
32
33 zones only limited differences in high-speed distance covered per minute during
34
35 match-play were evident in elite youth players aged U9-U10 (Goto et al., 2013) and
36
37 U12-U16 (Harley et al., 2010). Conversely, Mendez-Villanueva et al. (2013) used
38
39 individualised speed zones and showed that in the first half of match-play elite youth
40
41 players aged U13 covered more distance at very high relative speeds compared to
42
43 U15-U18 players. Thus, the age-related changes in distance covered at varying speeds
44
45 during match-play of elite youth soccer players remain unclear and require further
46
47 investigation, across a wider age range.
48
49

50
51 Another major shortcoming of research assessing age-related changes in match-
52
53 running performance of elite youth players is that study designs have been cross-
54
55 sectional in nature, that is, comparisons made between different players in each age
56
57
58
59
60

1
2
3 category (Strøyer et al., 2004; Pereira Da Silva et al., 2007; Buchheit et al., 2010;
4
5 Goto et al., 2013; Mendez-Villanueva et al., 2013). Multiple observations of the same
6
7 individuals are needed to allow changes within and differences between young players
8
9 to be identified more accurately (Williams et al., 2011). The use of repeated measures
10
11 multi-level statistical techniques to assess longitudinal changes in match-running
12
13 performance characteristics would also support this type of study design (Brink et
14
15 al.,2010).

16
17
18 Match-running performance of elite youth players is known to be influenced by
19
20 playing position. In elite youth players aged 12-18 years, centre backs cover the least,
21
22 and centre midfielders the most, total distance (Buchheit et al., 2010). Despite
23
24 differences in speed zone definitions between studies, it appears that centre backs also
25
26 cover the least, and wide midfielders and centre forwards the most, high-speed
27
28 distance (Pereira Da Silva et al., 2007; Aslan et al., 2010; Buchheit et al., 2010;
29
30 Mendez-Villanueva et al., 2013.). These differences suggest a mature tactical
31
32 understanding of position-specific tasks (Buchheit et al., 2010). Whether these
33
34 findings extend to younger elite youth players remains unclear.
35
36
37

38
39 There have been some attempts to differentiate between elite and sub-elite youth
40
41 soccer players on the basis of match-running performance (Strøyer et al., 2004,
42
43 Waldron & Murphy, 2013). However, to date, only Goto et al. (2013) have examined
44
45 the match-running performance of a group of highly selected, homogenous players,
46
47 involved in elite talent development programmes, from a talent identification
48
49 perspective. The authors examined 36 elite youth soccer players aged U9 and U10 and
50
51 showed no differences between retained and released players in total distance covered
52
53 per hour, but retained players completed more low-speed running distance compared
54
55 to released players. The promising work of Goto et al. (2013) needs to be extended to
56
57
58
59
60

1
2
3 provide insight into any differences between released and retained elite youth players
4
5 across a wider age range.
6

7
8 The aim of the present study was to employ a longitudinal design to examine age-
9
10 related changes in match-running performance of retained and released elite male
11
12 youth soccer players aged 8-18 years. A secondary aim was to examine how playing
13
14 position affects the age-related changes in match-running performance of elite male
15
16 youth soccer players age 8-18 years.
17

18 19 **Material and methods**

20 21 *Participants*

22
23
24
25 A total of 263 elite male youth soccer players aged 8-18 years, belonging to three
26
27 professional academies participated in the study. The U9-U14 age groups averaged
28
29 three 90 minute training sessions a week, the U15 and U16 age groups averaged four
30
31 90 minute training sessions a week and, the U17-U19 age groups averaged six 90
32
33 minute training sessions a week. Players participated in a competitive match once a
34
35 week. The mean \pm SD age, height, and body mass of players within each age group
36
37 are displayed in Table 1.
38
39

40
41
42 Ethical approval for the study was obtained from the Ethical Advisory Committees at
43
44 Nottingham Trent University and Loughborough University. Prior to taking part in the
45
46 study, players and parents or guardians were provided with a written and verbal
47
48 summary outlining the purpose, procedures involved, possible risks and benefits, and
49
50 the voluntary and confidential nature of the research. Written assent was obtained
51
52 from players and written consent was obtained from parents or guardians. Prior to
53
54 undertaking sprint tests, players went through a health screening process to identify
55
56 any reasons that may prevent any players from taking part in the study.

5
6 *Design*
7

8 Across three soccer seasons from 2010/11 to 2012/13 (mean \pm SD duration range per
9 player: 0.72 ± 0.85 years), the match-running performance of 263 elite youth soccer
10 players was assessed in 1-29 competitive inter-academy matches (mean \pm SD number
11 of matches per player: 3.77 ± 4.46 matches), resulting in a total of 988 player-matches.
12 To evaluate match-running performance, total distance covered, and distance covered
13 in low-speed ($<45\%$ age group mean peak flying speed), high-speed ($\geq 45\%$ age group
14 mean peak flying speed), and sprinting ($\geq 75\%$ age group mean peak flying speed)
15 zones were calculated for each player-match, using a GPS system. Distances were
16 adjusted for match time to allow comparisons between ages. This repeated measures
17 design allowed age-related changes in each match-running performance characteristic
18 to be assessed. Playing position for each player-match was recorded to allow the
19 effect of playing position on the age-related changes in match-running performance of
20 elite youth players to be considered. At the end of the study the playing status of
21 players was categorised as released or retained depending on whether they were
22 signed to their academy on 1st Feb 2014, resulting in 97 players being categorised as
23 released and 166 players being categorised as retained. Differences between released
24 and retained elite youth players in the age-related changes in match-running
25 performance characteristics were then examined.

Experimental Procedures

Match configuration.

The matches analysed were part of the regular series of inter-academy matches between Premier League academies during a season. The configuration of matches varied depending on age group. Indeed, U9 and U10 matches were small-sided games, that ranged from 5-a-side to 7-a-side and U11 matches ranged from 7-a-side to 11-aside. These matches were formed of four periods, with total match duration between 60-80 minutes. For the U12 age group and older, matches were 11-a-side. The U12 and U13 matches were formed of three or four periods, with total match duration between 75-80 minutes. For the U14 age group and older, matches were formed of two periods, with total match duration between 80-90 minutes. Matches were played on pitches with dimensions in accordance with recommendations made by the Football Association (n.d.) for a given age group / match configuration. For example, U10 7 v 7 matches took place on pitches with dimensions of ~ 35 m x ~ 55 m.

The playing position of each player was recorded for every match. Goal keepers were excluded from the analysis. Players were categorised as a centre back (CB), full back (FB) centre midfielder (CM), wide midfielder (WM) or centre forward (CF). Players who changed position mid-match were categorised as multi positional (Multi). For small-sided games teams did not employ centre backs or wide midfielders.

Match analysis.

Each player's match-running performance was assessed using a 1 Hz or 5 Hz GPS system (GPSport, Australia). Both systems have been validated for use by team players (Macleod et al., 2009; Waldron et al., 2011). Possible differences between the

1
2
3 two GPS systems in measuring distances were controlled for statistically by including
4 the GPS sampling rate as a covariate during data analysis (Cummins et al., 2013).
5
6 During match-play, each player wore a harness containing a GPS unit positioned
7 between the shoulder blades. Post-match, each GPS unit was downloaded to a laptop
8 computer and analysed using commercially available software (Team AMS, v 2.1).
9
10 Total distance and distance covered within age specific speed zones were calculated
11 (see below). All distances were adjusted to 60 minutes of match-play to allow for
12 differences in match duration due to substitutions and match configurations. Players
13 were only included for analysis if they had played at least half of a given match. For
14 all data, mean \pm SD satellite coverage was 8.8 ± 1.1 .

24
25

26 Distance covered by players during match-play was classified into different categories
27 on the basis of age group sprint performance to provide more detailed information
28 regarding speed of movement. Speed zones were normalised to age using the mean
29 peak 10-20 m flying sprint speed of each age group (procedural details below). Player
30 activity was classified into three speed zones: low-speed, high-speed and sprinting.
31
32 The low-speed zone represented any distance covered at less than 45 % of the age
33 group mean peak 10-20 m flying speed and included standing, walking, jogging, and
34 slow-running activity. The high-speed zone represented any distance covered at 45 %
35 or more of the age group mean peak 10-20 m flying speed and included cruising, fast-
36 running, and sprinting activity. The sprinting zone represented any distance covered at
37 75 % or more of the age group mean peak 10-20 m flying speed and included
38 sprinting activity (Table 2).

1
2
3 The 10-20 m flying sprint speed of 107 players from the study population, in addition
4 to 161 other elite youth soccer players, was repeatedly assessed across five soccer
5 seasons (2007 to 2011) resulting in 1,119 player-sprints for elite youth soccer players
6 aged 8-18 years. Participants completed a 20 m sprint test with a split at 10 m, on an
7 indoor new-generation synthetic surface. Times were measured to the nearest 0.01 s
8 using infrared photoelectric cells (Brower timing system, Utah, USA). Sprint tests
9 were preceded by a familiarisation and standardised warm-up procedure. Three 20 m
10 sprints were performed; each effort was separated by a 2-5 minute recovery period.
11 The sprint with the shortest time between 10 and 20 m was used to calculate peak 10-
12 20 m flying sprint speed for each player. The mean peak 10-20 m flying speed for
13 each age group was calculated.

28 *Data Analysis*

29
30 Due to the hierarchical structure of the data, mixed modelling was used to predict the
31 development with age of each match-running performance characteristic (MLwiN v
32 2.22, Bristol, U.K.). For each variable, a two-level hierarchical structure was defined
33 with repeated measures (level 1) nested within players (level 2). Unlike traditional
34 longitudinal data analysis techniques, such as the repeated measures ANOVA, mixed
35 modelling does not require the same number of measurement occasions per individual.
36 Moreover, the temporal spacing of measurements may vary between players (Rasbash
37 et al., 2009). Hence, this statistical technique is well suited to the current data
38 structure. A mixed model is able to describe the underlying trends of a particular
39 component in the population (fixed part), and also models the unexplained variation
40 around the mean trend for that component (random part) (Twisk, 2003).

58
59
60

1
2
3 Each match-running performance characteristic was modelled in turn. Relevant
4 parameters were systematically added to a null model and were accepted or rejected
5 on the basis of changes in model fit as indicated by differences in -2 loglikelihood
6 between models, and the effect of predictor variables on the outcome variable as
7 indicated by z-scores. Firstly, to investigate the variance between players, the
8 intercept was allowed to vary randomly between players. Then the effect of age
9 (centred at 13 years) on the variable was modelled. Quadratic age terms were then
10 modelled. Subsequently, the effect of playing position and being retained or released
11 was modelled. Finally, the effect of the sampling frequency of the GPS unit used was
12 controlled for. Following each analysis, the assumption that variation in intercepts
13 were normally distributed with an average of zero, was checked (Twisk, 2003).
14 Statistical significance was accepted at the 95% confidence level ($p < 0.05$). Where
15 appropriate, pairwise comparisons between playing positions were conducted to
16 identify where differences occurred. Mean \pm SD were used to describe the average
17 and variability of data. To calculate the range in which predicted values were likely to
18 fall, 95% confidence intervals (CI) were reported. Effect sizes (ES) and associated
19 confidence intervals were calculated using the method of Tymms (2004) to assess any
20 meaningful effects, and these were interpreted as small (0.20-0.49), medium (0.50-
21 0.79) or large (> 0.80) effects (Cohen, 1988).

57
58
59
60

1
2
3 The random part of the mixed models predicted that the fit of all models was
4 improved by allowing the intercepts to vary randomly ($p < 0.05$), as indicated by the
5 between-player standard deviations displayed in Table 3. From the fixed part of the
6 mixed models, Figures 1 & 2 display the predicted age-related changes in match-
7 running performance for each playing position. The mean \pm SD match-running
8 performance for each age group is also displayed for each playing position on Figures
9 1 & 2 (see Supplementary table for mean \pm SD match-running performance by age
10 group and position). Modelling indicated that age-related changes were non-linear;
11 each match-running performance characteristic best described with a quadratic age
12 term ($p < 0.05$). Models predicted that total distance, low-speed distance, high-speed
13 distance, and sprinting distance all increased with age, but at a constant negative rate,
14 resulting in an eventual plateau and subsequent decrease in total distance, high-speed
15 distance, and sprinting distance with age at 17.7 years, 16.1 years, and 17.3 years,
16 respectively. Conversely, low-speed distance continued to increase throughout the age
17 range without plateau (Figures 1 & 2).

41
42 Modelling predicted that playing position affected the age-related changes of all
43 match-running performance characteristics ($p < 0.05$) (Table 3). Pairwise comparisons
44 revealed significant differences between most playing positions in match-running
45 performance ($p < 0.05$). However, for total distance there were no significant
46 differences between: CB vs. FB, CM vs. WM, and CM vs. Multi ($p > 0.05$), with CB
47 completing the least and WM the most, total distance. For low-speed distance there
48 were no significant differences between: CB vs. FB, CB vs. WM, CB vs. CF, CB vs.

17 their playing position were evaluated, the range of effect sizes (with associated 95%
18
19 CI) were: Total distance: CB vs. WM, 1.6 ± 0.6 ; CB vs. FB, 0.3 ± 0.4 ; Low-speed
20
21 distance: FB vs. CM, 1.0 ± 0.4 ; FB vs. CF, 0.1 ± 0.4 ; Low-speed distance: CB vs.
22
23 WM, 2.0 ± 0.6 ; CB vs. FB, 0.6 ± 0.4 ; Sprinting distance: CB vs. WM, 1.9 ± 0.7 ; CB
24
25 vs. CM, 0.1 ± 0.5 .

26
27
28
29
30 Models predicted that retained players completed significantly more low-speed
31
32 running compared to released players, ($p<0.05$) by $75 \pm 36 \text{ m}\cdot\text{h}^{-1}$ (95% CI: ± 71 , ES \pm
33
34 95% CI: 0.35 ± 0.34). There were no other significant or meaningful differences
35
36 between released and retained players in match-running performance ($p>0.05$), with
37
38 effect sizes ($\pm 95\%$ CI) of 0.14 ± 0.32 , 0.10 ± 0.32 , and 0.08 ± 0.37 for total, high-
39
40 speed, and sprinting distances respectively.

41
42
43
44 It is possible to calculate the performance of players of differing ages, playing
45
46 positions and playing statuses using the coefficients from Table 3. For example, the
47
48 prediction equation for total distance for a 12.2 year-old, wide midfielder, measured
49
50 with 5 Hz GPS system who is retained is: **Wide midfielder** intercept + (β_1 *age centred
51
52 at 13 y) + (β_2 *age centred at 13 y²) + (β_3 *5 Hz sampling rate) + (β_4 *retained), which
53
54
55
56
57
58
59
60

1
2
3 is: $6510 \text{ m}\cdot\text{h}^{-1} + (270 \text{ m}\cdot\text{h}^{-1}\cdot-0.8 \text{ y}) + (-29 \text{ m}\cdot\text{h}^{-1}\cdot0.64 \text{ y}) + (-296 \text{ m}\cdot\text{h}^{-1}) + (50 \text{ m}\cdot\text{h}^{-1}) =$
4
5
6 $6030 \text{ m}\cdot\text{h}^{-1}$.
7

8 9 **Discussion**

10
11 The aim of the present study was to employ a longitudinal design to examine age-
12 related changes in the match-running performance of retained and released elite male
13 youth soccer players aged 8-18 years. The mixed models suggested that match-
14 running performance characteristics changed with age in a non-linear manner and
15 there was significant variation between players (*between-player SD*). Modelling also
16 suggested that match-running performance characteristics were influenced by playing
17 position and that retained players covered more low-speed distance compared to
18 released players.

21
22
23
24
25
26
27
28
29

30 *Age-Related Changes*

31
32 Predictive modelling suggested that total distance increased with age at a constant
33 negative rate, which resulted in a plateau and subsequent decrease at 17.7 years
34 (Figure 1). Total distance increasing with age and then differences disappearing at
35 older ages is a pattern similar to that seen in previous research (Buchheit et al., 2010;
36 Harley et al., 2010). For example, Buchheit et al. (2010) showed that in U13-U18 elite
37 youth players, when adjusted for match time, U13 players covered significantly less
38 distance than U16-U18 players, but there were no differences in distance covered
39 between any of the older age groups. A combination of growth, training, and tactical
40 factors may account for the pattern of change in distance covered with age.
41
42
43
44
45
46
47
48
49
50
51
52

53
54 The increase in distance covered during match-play with age may be due to the
55 improving physiological capacity of players associated with growth and training.
56
57
58
59
60

1
2
3 Indeed, Armstrong and Welshman (1994) indicated that $\dot{V}O_2$ peak ($l \cdot \text{min}^{-1}$) in boys
4
5 increases linearly from the age of 8 to 16 years of age. Moreover, performance on an
6
7 intermittent exercise test has been shown to increase with age in elite youth soccer
8
9 players aged 14-18 years (Roescher et al., 2010), and this improving physiological
10
11 capacity may allow older players to cover more distance during match-play. The
12
13 preceding argument is strengthened by studies showing that intermittent exercise test
14
15 performance is related to total distance covered during match-play in elite youth
16
17 players (Castagna et al., 2009). However, for this argument to be valid, it would be
18
19 expected that the age-related changes in intermittent exercise test performance would
20
21 mirror the age-related changes in match-running performance, which does not appear
22
23 to be the case. Indeed, the intermittent exercise test performance of elite youth soccer
24
25 players increases in a linear manner with age (Roescher et al., 2010), whereas the
26
27 current study shows that total distance covered during match-play increases at
28
29 a constantly negative rate with eventual plateau at age 17.7 years. Why does match-
30
31 running performance start to decrease at older ages despite intermittent exercise test
32
33 performance continuing to increase? It is possible that at older ages the technical and
34
35 tactical aspects of match-play are also changing, meaning that there is not requirement
36
37 or opportunity for players to perform to their maximal capacity. However, it is also
38
39 possible that the discrepancy in development between intermittent exercise test
40
41 performance and match-running performance is due to differences between countries
42
43 in playing style. Indeed the aforementioned studies involved players from across
44
45 Europe and it has been shown that different countries display differences in physical
46
47 and technical performance during match-play, hence possibly modifying the
48
49 relationship between fitness test performance and match-running performance (Dellal
50
51 et al., 2011).
52
53
54
55
56
57
58
59
60

1
2
3 Summation of the low-speed distance curve and high-speed distance curve is
4 approximately equal to the total distance curve (see Figure 1). Therefore, examination
5 of these curves can identify specific patterns of age-related change in distance covered
6 at various speeds. In general terms, as per total distance, there was a trend for an
7 increase in distance covered at varying speeds with age. Also, players completed more
8 low-speed distance relative to high-speed distance. For example, at age 12 years,
9 players were predicted to cover a total distance of 5627-6257 m, of which 24-30 %
10 (1359-1913 m) was at high-speed. Similarly at age 16 years players were predicted to
11 cover a total distance of 6475-7105 m, of which 25-31 % (1651-2205 m) was at high-
12 speeds. Whilst cautioning comparisons between studies applying different speed
13 zones thresholds, Harley et al. (2010) showed 30% of total distance was covered at
14 high-speed in elite youth players aged U12-U16.
15
16
17
18
19
20
21
22
23
24
25
26
27
28
29

30 There were different patterns of age-related changes in distance covered at different
31 speeds. Indeed, whereas low-speed distance continued to increase throughout the age
32 range there was a decrease in high-speed distance from age 16.1 years and sprinting
33 distance from age 17.3 years. Age-related changes in distance covered at given speed
34 zones are age group specific. Therefore at older ages, players are less likely to
35 produce distance at speeds close to their highest capabilities compared to slightly
36 younger players, suggesting that it is high-speed running and sprinting that are
37 especially constrained by the increased tactical demands of match-play at older ages.
38
39 The pattern of age-related change in high-speed running between players U13-U18
40 observed in the current study is similar to previous cross-sectional data. Mendez-
41 Villanueva et al. (2013) used individualised speed thresholds and showed that in the
42 first half of match-play elite youth players aged U13 covered more very high-speed
43 distance compared to U15-U18 players and there were no differences between older
44
45
46

51
52
53
54
55
56
57
58
59
60

1
2
3 age groups. However, the current study is the first to provide insight into age-related
4
5 changes in distances covered at varying speeds during match-play across a wide age
6
7 range of elite youth players.
8
9

10 *Playing Position*

11
12 According to the predictive models, playing position influenced total distance and
13
14 distance covered at varying speed zones. There were significant differences between
15
16 most playing positions in match-running performance and whilst effect sizes were
17
18 generally *small*, clear activity profiles according to positional role emerged and these
19
20 were similar to those seen in elite youth players (Buchheit et al., 2010) and
21
22 professional senior players (Di Salvo et al., 2007). Indeed, midfielders covered the
23
24 most total distance probably due to their linking role between attack and defence
25
26 within the team (Di Salvo et al., 2007). Whilst wide midfielders covered the most
27
28 high-speed distance and sprinting distance, centre midfielders covered the most low-
29
30 speed distance. The reason for this may be that due to their central position on the
31
32 pitch, centre midfielders have less space in which to attain high speeds on a regular
33
34 basis. Conversely, wide midfielders are often required to produce high-speed runs in
35
36 order to create goal scoring opportunities. Similarly, centre forwards covered the
37
38 second most distance sprinting suggesting that very high-speed running is required for
39
40 tasks such as capitalising on goal scoring opportunities (Faude et al., 2012). Centre
41
42 backs covered the least total distance, high-speed distance, and sprinting distance,
43
44 potentially because their major aim is to prevent goals being conceded and so they
45
46 restrict their movements to certain strategic areas on the pitch (Buchheit et al., 2013).
47
48 Full back's main duties are defensive, hence these players covered similar total
49
50 distances to centre backs. However, their wider position means they are less
51
52 constrained in their movements and can be involved in attacking build-up play and
53
54
55
56
57
58
59
60

1
2
3 this was reflected by them completing more high-speed and sprinting distance
4
5 compared to centre backs. The current study is the first to assess the positional match-
6
7 play demands of elite youth players across an age range that includes both children
8
9 and adolescents approaching adulthood. That there was an effect of playing position
10
11 on all match-running performance characteristics suggests that from as young as
12
13 eight-years-old, elite youth players are able to adjust their match-running performance
14
15 based upon the tactical requirements of their playing position.
16
17

18 19 *Playing Status*

20
21
22 There was no significant or meaningful difference between released and retained
23
24 players in total distance covered, which is contrary to previous work showing that
25
26 U14 elite players cover more distance compared to sub-elite players (Waldron &
27
28 Murphy, 2013). However, in support of the current results, Goto et al. (2013) showed
29
30 that in elite youth players aged U9-U10, there was no difference between released and
31
32 retained players in distance covered. Taken together, this suggests that in a more
33
34 homogenous groups of players, total distance covered may not be sensitive enough to
35
36 differentiate between playing standards. Moreover, there were no differences between
37
38 released and retained players in high-speed distance and sprinting distance in the
39
40 current study.
41
42
43
44

45
46 Previous research has suggested that high-speed running is an important aspect of
47
48 performance as it may aid key activities such as successful attempts at scoring, losing
49
50 a marker, reaching a ball before an opponent, gaining more time on-the-ball etc
51
52 (Carling et al., 2008; Faude et al., 2012). Waldron and Murphy (2013) showed some
53
54 support for this proposition when they revealed U14 elite players covered more high-
55
56 speed distance (3.64-5.28 m.s⁻¹) compared to sub-elite players. However, they found
57
58
59
60

1
2
3 no difference between groups in very high-speed movement ($>5.28 \text{ m}\cdot\text{s}^{-1}$). Therefore
4
5 it appears that whilst high-speed distance may be moderately effective in
6
7 discriminating between elite and sub-elite players, when players have already been
8
9 identified as elite and subjected to systematic talent development programmes, these
10
11 factors are not sensitive enough to discriminate between players. The previous
12
13 suggestion is supported by the current study and Goto et al. (2013) who showed no
14
15 difference in moderate or high-speed running distance between released and retained
16
17 elite youth players aged U9-U10. That playing status had a limited effect on total,
18
19 high-speed, and sprinting distances suggests that other factors, such as anthropometric,
20
21 physiological, psychological, technical, and tactical characteristics may need to be
22
23 included in future studies of soccer talent. Indeed, Huijgen et al. (2012) recently
24
25 showed that in 16-18 year-old elite youth soccer players, retained players were
26
27 discriminated from released players on the basis of a combination of superior sprint
28
29 speed, dribbling skill, and tactical skill (positioning and deciding). However, it is also
30
31 possible the 1 Hz and 5 Hz GPS sampling rate used in the present study may be too
32
33 low to capture some of the high-speed movements performed by elite youth soccer
34
35 players, making it a possible limitation of the study.
36
37
38
39
40

41 In the current study, retained players did cover significantly and meaningfully more
42
43 low-speed distance compared to released players, which seems rather counterintuitive
44
45 as it is difficult to see why low-speed activity would influence success. Nevertheless,
46
47 whilst previous findings are equivocal there is some support for this result. Indeed,
48
49 Waldron and Murphy (2013) showed elite U14 players covered more low-speed
50
51 distance ($<1.67 \text{ m}\cdot\text{s}^{-1}$) compared to sub-elite players, but this difference did not extend
52
53 to moderate-speed distance ($1.67\text{-}3.63 \text{ m}\cdot\text{s}^{-1}$). Goto et al. (2013) showed increased
54
55
56
57
58
59
60

1
2
3 low-speed running distance in retained versus released players, but this difference did
4
5 not extend to walking and jogging.
6
7

8 One possible explanation for low-speed distance differentiating between released and
9
10 retained players in the current study is that players performing high amounts of low-
11
12 speed activity are completing tactically astute movements. This supports the evidence
13
14 of Huijgen et al. (2012) who showed that in 16-18 year-old elite soccer players,
15
16 retained players had superior deciding and positioning tactical skills compared to
17
18 released players. Indeed, retained players constantly adjusting their position at low
19
20 speeds in relation to the ball, their teammates, and the opposition may result in less
21
22 need to produce high-intensity bursts to be in an appropriate playing position
23
24 (Waldron & Murphy, 2013). There is limited support for this theory at this stage but
25
26 future research should consider tactical aspects of match-running performance
27
28 characteristics.
29
30
31
32

33 Another reason retained players produced more low-speed distance than released
34
35 players may relate to the classifications of movement employed in the current study.
36
37 Low-speed running was defined on the basis of age-group-specific sprint speed, but
38
39 high intensity actions can occur at low speeds (Stølen et al., 2005). For example,
40
41 quick accelerations and decelerations, directional changes, jumping actions, and
42
43 sustaining forceful contractions to maintain balance and control of the ball against
44
45 defensive pressure, are all high intensity activities that may have been classified as
46
47 low-speed running in the current study. It is possible that retained players engage in
48
49 these key activities more frequently and therefore accrue more low-speed distance
50
51 compared to released players. Future research is required to investigate this
52
53
54
55
56 phenomenon.
57
58
59
60

Random Variation Between Players

Modelling revealed that there was random variation between players in total distance, low-speed distance, high-speed distance, and sprinting distance that was not explained by age, playing position or playing status. Differences between players in maturity status, physiological training status, match circumstance, and technical and tactical abilities may be responsible for this unexplained variation. For example, previous research into elite youth match-play has shown differences in match-running performance between conventional centre forwards and centre forwards playing slightly behind a strike partner (Buchheit et al., 2010), whereas this distinction was not considered in the current study. Regardless, it is clear that there is variation between successful players in match-running performance characteristics, highlighting the complex nature of match-play in elite youth soccer.

Perspectives

Results from the current study show that match-running performance characteristics change non-linearly with age and playing position influences development. These findings may allow talent development experts to plan training programmes specific to the demands of match-play at different ages and for different playing positions. This result supports the work of Buchheit et al. (2010) who also showed match-running performance changed with age and was highly dependent on playing position in elite youth soccer players aged 12-18 years. However, another key finding in the current study was that there was considerable variation between players in the development of match-running performance characteristics, suggesting a need for flexibility when developing training programmes. Indeed factors such as growth, physiological training status, and technical and tactical abilities probably influence

1
2
3 match-running performance characteristics and so need to be considered in any talent
4 development programme. Although retained players covered more low-speed distance
5 compared to released players it is not recommended that this be a focus of talent
6 identification procedures. Further study of the actions comprising low-speed running
7 distance in elite youth soccer match-play is warranted in order to better understand
8 factors that differentiate retained and released players.

LIST OF FIGURES:

Figure 1. Total [T], low-speed [L], and high-speed [H] distance covered ($\text{m}\cdot\text{h}^{-1}$) during match-play in elite youth soccer players aged 8-18 years. Curves are based on predicted growth curves from mixed models of longitudinal data. Points are based on the 'raw' age group data (mean \pm SD). Data are presented by playing position during match-play.

Figure 2. Sprinting distance covered ($\text{m}\cdot\text{h}^{-1}$) during match-play in elite youth soccer players aged 8-18 years. Curves are based on predicted growth curves from mixed models of longitudinal data. Points are based on the 'raw' age group data (mean \pm SD). Data are presented by playing position during match-play.

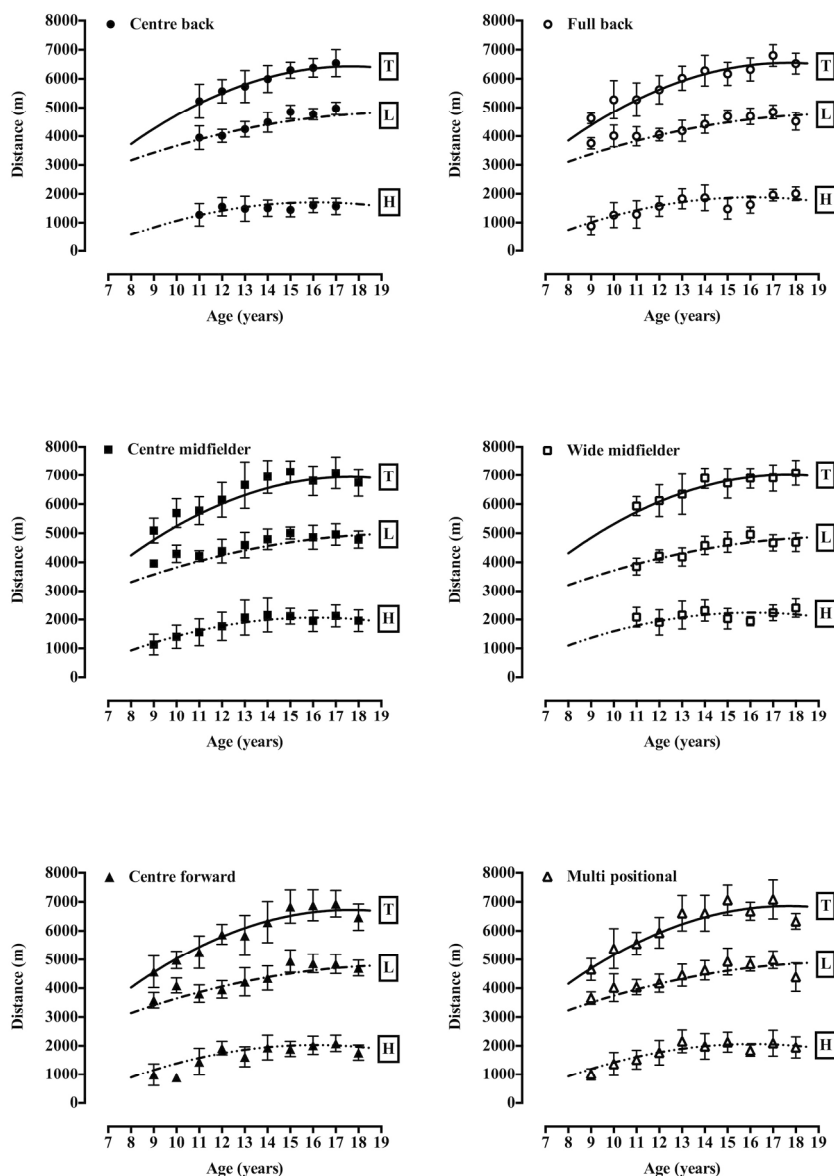

Figure 1. Total [T], low-speed [L], and high-speed [H] distance covered (m.h-1) during match-play in elite youth soccer players age 8-18 years. Curves are based on predicted growth curves from mixed models of longitudinal data. Points are the based on the 'raw' age group data (mean \pm SD). Data are presented by playing position during match-play.

165x233mm (300 x 300 DPI)

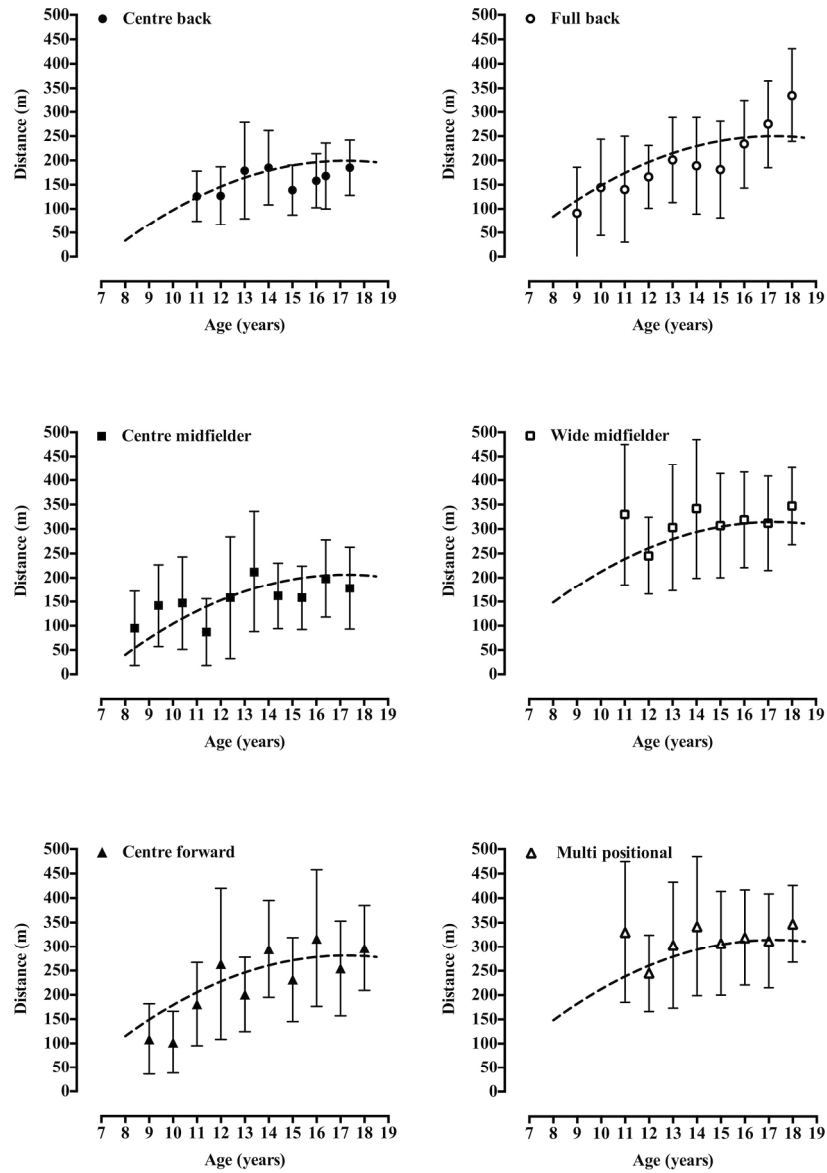

Figure 2. Sprinting distance covered (m.h-1) during match-play in elite youth soccer players age 8-18 years. Curves are based on predicted growth curves from mixed models of longitudinal data. Points are based on the 'raw' age group data (mean ± SD). Data are presented by playing position during match-play. 166x238mm (300 x 300 DPI)

Table 1. Basic characteristics of elite youth football players according to age

Age Group	Age (y)	Height (cm)	Mass (kg)
U9	9.2 ± 0.3	137.6 ± 5.4	31.4 ± 5.0
U10	10.2 ± 0.3	142.8 ± 5.6	35.5 ± 6.7
U11	11.1 ± 0.3	146.9 ± 4.9	38.1 ± 4.8
U12	12.2 ± 0.3	154.0 ± 7.2	42.8 ± 6.6
U13	13.1 ± 0.3	161.9 ± 9.4	49.8 ± 9.3
U14	14.1 ± 0.3	170.7 ± 6.8	59.1 ± 8.5
U15	15.0 ± 0.4	175.7 ± 6.2	65.8 ± 7.1
U16	16.0 ± 0.4	178.0 ± 6.4	70.1 ± 6.5
U17	17.0 ± 0.3	178.2 ± 6.8	73.6 ± 5.8
U18	18.0 ± 0.3	179.8 ± 5.3	73.3 ± 5.7
Total	14.5 ± 2.6	162.1 ± 16.0	53.0 ± 16.1

Note. Data are displayed as mean ± SD.

Table 2. Age group specific speed zone thresholds ($\text{m}\cdot\text{s}^{-1}$) as a percentage of mean peak 10-20 m flying speed

Age Group	Low-speed Zone (<45%)	High-speed Zone (\geq 45%)	Sprinting Zone (\geq 75%)	Mean \pm SD Peak 10-20 m Flying Speed
U9	<2.74	\geq 2.74	\geq 4.56	6.08 \pm 0.32
U10	<2.84	\geq 2.84	\geq 4.73	6.31 \pm 0.34
U11	<2.91	\geq 2.91	\geq 4.85	6.47 \pm 0.35
U12	<3.05	\geq 3.05	\geq 5.08	6.78 \pm 0.38
U13	<3.19	\geq 3.19	\geq 5.31	7.08 \pm 0.45
U14	<3.34	\geq 3.34	\geq 5.6	7.42 \pm 0.41
U15	<3.49	\geq 3.49	\geq 5.81	7.75 \pm 0.33
U16	<3.51	\geq 3.51	\geq 5.85	7.81 \pm 0.36

U18	<3.59	\geq 3.59	\geq 5.98	7.97 \pm 0.36

Notes. The speed values displayed for a given age group were calculated as a percentage of the mean peak 10-20 m flying speed for that age group. This was <45%, \geq 45%, and \geq 75% of the age group mean peak 10-20 m flying speed for low-speed, high-speed, and sprinting zones respectively.

Table 3. Mixed models for the longitudinal development of match-running performance characteristics.

Parameter	Total Distance (m·h ⁻¹)	Low-Speed Distance (m·h ⁻¹)	High-Speed Distance (m·h ⁻¹)	Sprinting Distance (m·h ⁻¹)
	Estimate ± CI	Estimate ± CI	Estimate ± CI	Estimate ± CI
Centre back	5930 ± 140 ^{cdef}	4417 ± 86 ^c	1510 ± 100 ^{bcdef}	160 ± 25 ^{bdef}
Full back	6040 ± 120 ^{cdef}	4364 ± 73 ^{cdf}	1680 ± 86 ^{acdef}	211 ± 22 ^{acdef}
Centre midfield	6440 ± 120 ^{abe}	4570 ± 76 ^{abdef}	1866 ± 90 ^{abd}	167 ± 24 ^{bdef}
Wide midfield	6510 ± 130 ^{abef}	4466 ± 80 ^{bc}	2039 ± 94 ^{abcef}	275 ± 25 ^{abcef}
Centre forward	6220 ± 130 ^{abcdf}	4391 ± 80 ^{cf}	1828 ± 94 ^{abd}	242 ± 24 ^{abcd}
Multi positional	6350 ± 110 ^{abde}	4488 ± 71 ^{bce}	1865 ± 82 ^{abd}	240 ± 22 ^{abcd}
Age	270 ± 24	162 ± 16	108 ± 18	17 ± 4
Age ²	-29 ± 6	-11 ± 4	-17 ± 4	-2 ± 1
GPS rate	-296 ± 67*	-392 ± 43*	96 ± 49*	13 ± 14
Status	50 ± 110	75 ± 71*	-27 ± 84	-5 ± 21
<i>Random Effects</i>				
Between-player SD	350 ± 250	220 ± 160	270 ± 190	60 ± 45
Within-player SD	380 ± 170	240 ± 110	280 ± 120	80 ± 36

Notes. Independent intercept estimates (at age 13 y) for each playing position are displayed. Main effect of age, age² and playing position for all models (p<0.05). Between position differences (p<0.05): ^a significant difference vs CB, ^b vs FB, ^c vs CM, ^d vs WM, ^e vs CF, ^f vs Multi. For Status, the effect of being retained is displayed (*p<0.05). For GPS rate, the effect of a 5 Hz sampling rate is displayed (*p<0.05). Between-player SD: the stable between-player differences within playing positions. Within-player SD: the typical variation in a player's value from match to match. ± 95% confidence intervals (CI) are displayed for parameter estimates.

Supplementary Table. Match-running performance characteristics by age group and position
