$\mathrm{M}=\mathrm{Pd}, \mathrm{Pt} ; \mathrm{R}=i-\mathrm{Pr}, n-\mathrm{Bu}$
[CNC]M-I

$\{[\mathrm{C}, \mathrm{N}] \operatorname{Pd}(\mu-\mathrm{OH})\}_{2}$

The synthesis and structure of chelating amido-NHC and amido-bis(NHC) complexes of Pd and Pt are described, including the first [CNC]Pt complexes and the first Pd arylamido-NHC complex.

#### Abstract

With a view to applications in bifunctional catalysis, a modular cross-coupling strategy has been used to prepare amine bis(imidazolium) salts ( $3 a$ and $\mathbf{3 b}$ ) and an amine mono(imidazolium) salt (6) as precursors to chelating amido-NHC ligands. Treating the proligands 3 with 3 equivalents of the bulky base KHMDS and $\mathrm{Pd}(\mathrm{OAc})_{2}$ or $\mathrm{PtCl}_{2}(\mathrm{COD})$ gave the four amido bis( $N$-heterocyclic carbene) pincer complexes [CNC-R]M-I [M = Pd (7) or Pt (8); R $=i-\operatorname{Pr}(\mathbf{a})$ or $n-\mathrm{Bu}(\mathbf{b})]$, including the first examples of platinum complexes of a CNC ligand. The reaction of 7a with AgOTf in pyridine gave the cationic complex \{[CNC-i-Pr]Pd-py\}OTf (9a). Heating a mixture of amine mono(imidazolium) salt 6 with $\mathrm{PdCl}_{2}$ or $\mathrm{K}_{2} \mathrm{PtCl}_{4}, \mathrm{~K}_{2} \mathrm{CO}_{3}$ and KI in pyridine at $100{ }^{\circ} \mathrm{C}$ gave the complexes $[\mathrm{C}, \mathrm{NH}] \mathrm{MI}_{2} \mathrm{py}[\mathrm{M}=\mathrm{Pd}(10)$ or $\mathrm{Pt}(11)]$, in which the amine arm of the NHC ligand is not deprotonated and does not coordinate to the metal. For a solution of 10 in 1,4-dioxane, deprotonation of the amine occurred in a biphasic reaction with aqueous KOH at $40^{\circ} \mathrm{C}$, giving the dimeric amido complex $\{[\mathrm{C}, \mathrm{N}] \mathrm{Pd}(\mu-\mathrm{OH})\}_{2}$ (12). The more

inert Pt analogue 11 was unreactive under the same conditions. Solid-state structures of the complexes $\mathbf{7 a}, \mathbf{7 b}, 9 a, 10,11$ and 12 have been determined by single crystal X-ray diffraction.

## Introduction

Bifunctional catalysis, in which an electrophilic metal and a nucleophilic ligand act in concert to activate a substrate, enables reactions to take place that are not possible using classical catalytic transformations that occur only at the metal centre. ${ }^{1-3}$ Wide-ranging applications have been found for bifunctional catalysis, many in asymmetric synthesis, including hydrogenation under $\mathrm{H}_{2},{ }^{4}$ transfer hydrogenation, ${ }^{5,6}$ isomerisation of allylic alcohols, ${ }^{7}$ alkene hydroamination, ${ }^{8}$ hydrosilylation, ${ }^{9}$ Michael addition, ${ }^{10} \mathrm{C}-\mathrm{H}$ activation ${ }^{11-15}$ and lactide polymerisation. ${ }^{16}$ The most studied of these reactions is the asymmetric transfer hydrogenation between alcohols and carbonyl compounds, catalysed by half-sandwich complexes of Ru, Ir or Rh with a chiral diamine ligand such as N -tosyl-1,2-diphenylethylenediamine. The key steps in the catalytic cycle occur after deprotonation of the primary amine group to give a metal amido complex: subsequent transfer hydrogenation from $i-\mathrm{PrOH}$ to the $\mathrm{M}-\mathrm{N}$ bond gives a metal amine-hydride complex that transfers an acidic and a basic hydrogen to the carbonyl substrate. ${ }^{17}$ Crucially, the chelating amine ligand makes the catalyst more resistant to undesirable M-N bond cleavage. ${ }^{18}$ Other chelating groups such as aryl, ${ }^{19}$ phosphine ${ }^{20-22}$ and thiol/thioether ${ }^{23}$ have also been used to tether the reactive nitrogen to the metal in transfer hydrogenation. However, the application of N -heterocyclic carbene (NHC) donor groups to tether a nucleophilic amido ligand to an electrophilic metal in bifunctional catalysis has yet to be fully exploited, ${ }^{24,25}$ and even simple coordination chemistry of multidentate amido-NHC ligands is under-explored. Of note, tridentate bis(amido)-NHC [NCN] pincer complexes of zirconium and hafnium have been reported, ${ }^{26,27}$ and amido-bis(NHC) [CNC] and amido-NHC [C,N] complexes of some early and late transition metals are also known. ${ }^{28-35}$ Most closely related to this work, Douthwaite has described the palladium [CNC] complex A and, during the course of our research, Luo has reported the Pd complexes (B). ${ }^{36,37}$

Fig. 1
As part of a research programme exploring new applications in bifunctional catalysis, we have been investigating late transition metal complexes containing amido-NHC ligands. Herein, we report tridentate amido-bis(NHC) [CNC] ligand complexes of palladium and for the first time platinum. We also report the first bidentate arylamido-NHC [C,N] ligand complex of palladium.

## Results and Discussion

The synthesis of the amine bis(imidazolium) pro-ligands proceeded with a palladium catalysed amination of 2-bromoiodobenzene to give bis(2-bromophenyl)amine (1) using a procedure adapted from the literature (Scheme 1). ${ }^{38}$ A copper catalysed Ullman-type reaction ${ }^{39}$ of imidazole with 1 gave the coupled product 2 in $90 \%$ yield. Subsequent alkylation of $\mathbf{2}$ with $i$ propyliodide or $n$-butyliodide gave the imidazolium iodide salts $\mathbf{3 a}$ and $\mathbf{3} \mathbf{b}$ in 89 and $93 \%$ yields respectively. As expected, the alkylation reaction proceeded faster for the primary alkyl halide than the secondary alkyl halide. Hence, the pro-ligands $\mathbf{3 a}$ and $\mathbf{3 b}$ were prepared in three steps in 74-78\% yield from commercially available materials.

## Scheme 1.

The same methodology was also applied to prepare an analogous pro-ligand containing only one imidazolium moiety: starting instead from $N$-(2-bromophenyl)-2,6-diisopropylaniline (4), ${ }^{40}$ the Ullman-type cross coupling with imidazole gave intermediate 5 and subsequent alkylation with $i$-propyl iodide gave the imidazolium pro-ligand 6 (Scheme 2 ).

Scheme 2.

A common method for the coordination of $N$-heterocyclic carbene ligands to transition metals is to prepare the silver(I) NHC complex from the reaction of an imidazolium salt and $\mathrm{Ag}_{2} \mathrm{O}$; subsequent transmetallation then gives the required metal-NHC complex. ${ }^{41,42}$ Douthwaite et al. have shown that this is a viable route to the complex $\mathbf{A} .{ }^{36}$ However, treating our more rigid proligands $\mathbf{3 a}$ or $\mathbf{3 b}$ with $\mathrm{Ag}_{2} \mathrm{O}$ in DCM at room temperature gave an intractable mixture of products. Performing the reaction in refluxing THF also gave an unidentifiable mixture, as did including $\mathrm{Pd}(\mathrm{OAc})_{2}$ or $\mathrm{PdCl}_{2}(\mathrm{COD})$ in the reaction mixture. Conversely, Luo et al. have reported that treatment of an amine bis(imidazolium) salt with $\mathrm{Ag}_{2} \mathrm{O}$ followed by $\mathrm{PdCl}_{2}(\mathrm{MeCN})_{2}$ gave the corresponding [CNC]PdCl complexes B, although a silver complex of their ligands could not be isolated. ${ }^{37}$ Presumably, a silver(I) NHC complex was generated in situ., and subsequent transmetallation to Pd was successful. For our ligands, however, this strategy also proved to be unsuccessful.

Luo reported that the preparation of [CNC] pincer complexes of palladium B by deprotonation of the amine bis(imidazolium) ligand with an organometallic or amide base were unsuccessful. ${ }^{37}$ In contrast, we found that treating a DME solution of $\mathbf{3 a}$ or $\mathbf{3 b}$ with 3 equivalents of potassium hexamethyldisilazide (KHMDS) at $0^{\circ} \mathrm{C}$ in the presence of $\mathrm{Pd}(\mathrm{OAc})_{2}$ gave, after work-up and purification by column chromatography, the complexes [CNC-i-Pr]Pd-I (7a) and [CNC-n-Bu]Pd-I (7b) in 33 and 42\% yields respectively, Scheme 3. These moderate
yields do not appear to arise from the purification procedure: the ${ }^{1} \mathrm{H}$ NMR spectrum recorded for the crude product showed several other species that could not be identified and repeating the column chromatography gave complete recovery of analytically pure material. Using $\mathrm{PdCl}_{2}(\mathrm{COD})$ in the reaction instead of $\mathrm{Pd}(\mathrm{OAc})_{2}$ or using THF as the solvent gave lower yields, and performing the reaction in the absence of a palladium salt gave an intractable mixture of products. Coordination of the anionic tridentate bis( $N$-heterocylic carbene) ligand to palladium was confirmed by ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectroscopy: the ${ }^{1} \mathrm{H}$ NMR spectra for $7 \mathbf{a}$ and $\mathbf{7 b}$ lack a signal that could be assigned to the NCHN proton of an imidazolium cation (these were present as singlet resonances at $\delta_{H} 9.56$ and 9.72 ppm respectively in the spectra recorded for 3a and $\mathbf{3 b}$ ) and the ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra for $\mathbf{7 a}$ and $\mathbf{7 b}$ contained signals at $\delta 165.3$ and 167.0 ppm respectively for the carbene bound to palladium. An unexpected feature of the ${ }^{1} \mathrm{H}$ NMR spectrum recorded for 7 a was the downfield shift observed for the $i-\operatorname{Pr} \mathrm{CH}$ resonance, which appeared as an apparent septet at 6.35 ppm . The ligand completing the fourth coordination site at Pd was confirmed as iodide by FAB MS and microanalysis.

## Scheme 3.

Crystals of $\mathbf{7 a}$ and $\mathbf{7 b}$ suitable for single crystal X-ray diffraction were obtained by the slow evaporation of a $\mathrm{C}_{6} \mathrm{D}_{6}$ solution of each; ORTEP figures for the solid state structures are shown in Figures 2 and 3 and selected bond lengths are shown in Table 1.

## Table 1.

Fig. 2.
Fig. 3.
The complexes 7a and 7b both display the expected square planar geometry around Pd and iodide is confirmed as the ligand filling the fourth coordination site. The [CNC] ligand is strongly distorted from planarity: the angle between the square plane around Pd and the trigonal plane around the amide nitrogen is $53.3^{\circ}$ in $\mathbf{7 a}$ and $57.4^{\circ}$ in $\mathbf{7 b}$. Hence, the ligand adopts a helical conformation and two atropisomers arise. Complex 7a crystallizes in the noncentrosymmetric chiral space group C222(1), and only one enantiomer is present in the unit cell. Complex 7b, however, crystallizes in the non-centrosymmetric achiral space group Aba2, and hence both enantiomers are observed in the unit cell. Atropisomerism has been observed for pyridyl and aryl bridged NHC pincers and rapid interconversion of the atropisomers is common. ${ }^{29,43,44}$ In addition, the [CNC]PdCl complex $\mathbf{A}$ and the related amine complex $\{[\mathrm{CN}(\mathrm{H}) \mathrm{C}] \mathrm{PdCl}\} \mathrm{Cl}$ also show interconversion of atropisomers at ambient temperature. ${ }^{36,45}$

Conversely, variable temperature ${ }^{1} \mathrm{H}$ NMR spectra recorded for $7 \mathbf{a}$ in $\mathrm{C}_{6} \mathrm{D}_{6}$ up to 344 K showed no coalescence of the diastereotopic methyl groups or indeed any line broadening consistent with fluxionality. Hence, these [CNC] palladium complexes appear to possess greater stereochemical rigidity that could enable new strategies for the synthesis of nonracemic chiral complexes from achiral ligands. ${ }^{46}$

The Pd-N bond lengths in the two complexes 7a and 7b are typical for a $\mathrm{Pd}(\mathrm{II})$-amide bond and the Pd-C bond lengths are also typical for two trans NHC ligands bound to square planar palladium. ${ }^{47}$ These bond lengths do not differ significantly from those reported for the complexes B by Luo. ${ }^{37}$ There is a large angle ( $7 \mathbf{a}: 81.3^{\circ} ; \mathbf{7 b}: 78.3^{\circ}$ ) between the planes of the two NHC ligands. In turn, the plane of each NHC ring lies at an angle of $\mathrm{ca} .40^{\circ}$ to the square plane around $\operatorname{Pd}\left(7 \mathbf{a}: 41.1^{\circ} ; \mathbf{7 b}: 38.7,41.2^{\circ}\right)$. Although two trans NHC ligands will often lie in the same plane as each other, a large angle between these two planes - either as forced by the conformation of a pincer ligand or as the result of steric interactions between bulky NHCs and the cis ligands - is not uncommon; the torsion angle between the two trans NHC rings has no correlation with the $\mathrm{Pd}-\mathrm{C}$ bond length, as would be expected for a purely $\sigma$-bonding interaction between palladium and the carbene. ${ }^{47}$

In 7a there is a very short $\mathrm{H}--\mathrm{I}$ l contact ( $2.859 \AA$ ) between the methyne hydrogen of the $i$ propyl substituent and the iodide ligand. This H -bonding interaction also appears to be present in solution, as there is a large downfield shift ( $\delta_{H} 6.35 \mathrm{ppm}$ ) for the signal arising from this proton in the ${ }^{1} \mathrm{H}$ NMR spectrum for 7a. Similar short H---I distances are observed for $\mathbf{7 b}$ ( 2.789 and $2.917 \AA$ ).

We found that the coordination chemistry could be extended from palladium to platinum. Hence, reacting the imidazolium salts $\mathbf{3 a}$ or $\mathbf{3 b}$ with $\mathrm{PtCl}_{2}(\mathrm{COD})$ and 3 equivalents of KHMDS gave the analogous platinum pincer complexes [CNC-i-Pr]Pt-I (8a) or [CNC-n-Bu]Pt-I (8b), although the yields were poor, Scheme 3. As for $\mathbf{7 a}$ and $\mathbf{7 b}$, iodide rather than chloride occupies the fourth coordination site, as confirmed for both complexes by mass spectrometry and microanalysis. Coordination of the tridentate pincer ligand to platinum gave similar NMR spectra to the Pd complexes: in particular, the ${ }^{13} \mathrm{C}$ NMR spectrum recorded contained characteristic singlets at $162.5 \mathrm{ppm}(\mathbf{8 a})$ and $164.0 \mathrm{ppm}(\mathbf{8 b})$ corresponding to the carbene. Moreover, for 8 a the apparent septet corresponding to the $i-\mathrm{Pr} \mathrm{CH}$ was shifted downfield to 6.38 ppm , indicating that a H -bonding interaction with the iodide ligand is also present in the Pt complex. Therefore, although we have thus far been unable to grow crystals of $\mathbf{8 a}$ or $\mathbf{8 b}$ suitable for X-ray crystallography, the data we have obtained indicates that the complexes
have a very similar structure to those of their palladium analogues. Although several pincer carbene complexes of Pd have been reported, platinum pincer carbene complexes are surprisingly rare, ${ }^{48,49}$ and these are the first reported platinum [CNC] complexes.

We were interested to see if the halide ligand could be replaced with a neutral donor in a cationic complex. When 7a was dissolved in $\mathrm{d}_{5}$-pyridine the ${ }^{1} \mathrm{H}$ NMR spectrum indicated the presence of two different complexes. One of these complexes exhibited an apparent septet attributable to the $i-\operatorname{Pr}$ group at 6.40 ppm (which we assign, by the downfield shift, as $\mathbf{7 a}$ ) whereas the other exhibited an apparent septet at 3.68 ppm . The addition of 1.5 equivalents of silver triflate to this solution gave quantitative conversion to the latter complex (Scheme 3), which we subsequently identified as the triflate salt $\{[\mathrm{CNC}-i-\operatorname{Pr}] \operatorname{Pd}-\mathrm{py}\} \mathrm{OTf}$ (9a) by single crystal X-ray diffraction. The solid-state structure of 9 a is shown in Figure 4 and selected bond lengths are shown in Table 1. Unfortunately the crystal was weakly diffracting and hence the data is weak; the crystal also contained disordered dichloromethane. Despite this, it is possible to discuss the prominent structural features of 9 a . The geometry around Pd is square planar, with the tridentate pincer and a molecule of pyridine bound to the metal. The triflate anion is not coordinated to Pd , and also shows significant disorder in the crystal, requiring the splitting of one of the F atoms in one of the triflate ions. It is apparent that there is still a significant twist in the [CNC] ligand: in the two independent molecules of 9a present in the unit cell the angle between the square plane around the metal and the trigonal planar amide nitrogen is 49.9 and $49.4^{\circ}$ and the torsion angle between the planes of the two trans NHC ligands is 72.8 and $70.5^{\circ}$. There are no significant differences between the metal amide and metal carbene bond lengths in the iodide complex 7a or the cation 9a. Our attempts to isolate an analytically pure sample of 9a on a larger scale were unsuccessful as it was not possible to completely separate 9a from pyridine.

Fig. 4.
The strategy described above for the coordination of the [CNC] ligands to Pd and Pt was also attempted with the amine mono(imidazolium) pro-ligand 6, but NHC complexes could not be isolated under these conditions. Alternatively, treating 6 with $\mathrm{K}_{2} \mathrm{CO}_{3}, \mathrm{PdCl}_{2}$ and potassium iodide in refluxing pyridine gave [C,NH]Pdl 2 py (10) as a yellow-orange solid in $89 \%$ yield after column chromatography (Scheme 4). Performing the reaction with $\mathrm{K}_{2} \mathrm{PtCl}_{4}$ instead of $\mathrm{PdCl}_{2}$ gave the platinum analogue [C,NH]Ptl 2 py (11) as yellow crystals in $47 \%$ yield. Scheme 4.

The solid-state structures of both 10 and 11 were determined by single crystal X-ray diffraction (Figures 5 and 6; selected bond lengths are given in Table 2). The structure of 10 is very
similar to the structures of trans-(NHC)Pdl ${ }_{2}$ py complexes that have been reported previously. ${ }^{50-53}$ The NHC-amine ligand in both complexes is only bound to the metal through the carbene; the amine nitrogen is not coordinated. The inner coordination sphere is completed by two trans iodide ligands and a pyridine ligand. In 10, the bond lengths and angles around the square planar Pd are extremely similar for the two independent molecules found in the unit cell, despite the two molecules having very different angles between the mean plane of the NHC and pyridine ring (14.9 and $40.2^{\circ}$ ). The $\mathrm{Pd}-\mathrm{C}$ bond lengths (1.957(7) and $1.981(7) \AA$ ) are shorter than for the pincer complexes, demonstrating the weaker trans influence of the pyridine ligand in 10 compared with the NHC in $\mathbf{7 a}, \mathbf{7 b}$ and $\mathbf{9 a}$. The unit cell for 11 also contains two unique molecules, which like 10 differ greatly with respect to the angle between the mean plane of the NHC ring and the pyridine ring (19.8 and $38.7^{\circ}$ ). However, both of the unique molecules show very similar bond lengths around $\mathrm{Pt}(e . g . \mathrm{d}(\mathrm{Pt}-\mathrm{C})$ are 1.965(13) and $1.968(11) ~ \AA$ ).

The signals arising from the carbene are difficult to assign in the ${ }^{13} \mathrm{C}$ NMR spectra for 10 and 11. For 10, the signal at 147.3 ppm is most likely the carbene resonance, as the nearby signals for $4^{\circ}$ carbons at 146.6 and 148.0 ppm are broad like the signals we can unambiguously assign as arising from the 2,6-diisopropylphenyl group. Likewise for 11, the carbene resonance appears to be the sharp signal at 143.6 ppm , rather than one of the broad $4^{\circ} \mathrm{C}$ signals at 147.2 and 148.2 ppm (unfortunately ${ }^{195} \mathrm{Pt}$ satellites, which would have aided the identification of the carbene resonance, could not be observed). These signals fall into the range previously reported for carbenes in trans-( NHC ) $\mathrm{MX}_{2} \mathrm{py}\left(\mathrm{M}=\mathrm{Pd}\right.$ or Pt ) complexes. ${ }^{51,52,54}$

Fig. 5.

Fig. 6.

## Table 2.

Pre-catalysts of the type trans-(NHC)Pdl ${ }_{2}$ py (PEPPSI catalysts: Pyridine-Enhanced Precatalyst Preparation, Stabilization and Initiation) deliver excellent activity in cross-coupling reactions; ${ }^{55-57}$ complexes with NHC ligands that are functionalised with carbonyl (amide ${ }^{50-52}$ and ketone ${ }^{52}$ ), alcohol and ether groups ${ }^{51,53}$ have also been reported previously, but, to the best of our knowledge, $\mathbf{1 0}$ is the first amine functionalised complex of this type. Furthermore, the nucleophilic substitution reactions of alkyl or benzyl halides used to prepare the functionalised NHC ligands in these previously reported complexes contrasts with the cross-coupling strategy used to synthesise the pro-ligand 6, which enables efficient access to aryl substituted NHC
ligands with the functional group (amine) also bound to the aromatic ring. Platinum analogues of these Pd catalysts have been reported, ${ }^{54}$ but these are much less common.

We first attempted to deprotonate the amine group in 10 to yield an amido-NHC complex using KHMDS as the base. Surprisingly, the novel dimeric amido complex $\{[\mathrm{C}, \mathrm{N}] \mathrm{Pd}(\mu-\mathrm{OH})\}_{2}$ (12) was the only compound that could be isolated from this reaction. Presumably the hydroxide ligand was produced from adventitious moisture, but the reaction showed poor reproducibility, even when an excess of water was added to a rigorously dry reaction mixture. Alternatively, 12 could be isolated in good yield by stirring a solution of 10 in 1,4-dioxane with aq. KOH , Scheme 4. The IR spectrum recorded for 12 contains a weak resonance at $3601 \mathrm{~cm}^{-1}$ that is consistent with the bridging hydroxide ligand.

The solid-state structure of 12 was determined by single crystal X-ray diffraction (Fig. 7; selected bond lengths are given in Table 2). Two crystallographically equivalent monomer units make up the dimer in 12 , with a non-bonding $\operatorname{Pd}(1) \cdots P d\left(1^{\prime}\right)$ distance of $3.2348(6) \AA$. The $\mathrm{Pd}_{2} \mathrm{O}_{2}$ ring is almost planar, with a $\mathrm{Pd}-\mathrm{O}-\mathrm{Pd}-\mathrm{O}$ torsion angle of $4.7^{\circ}$, but the two $\mathrm{Pd}-\mathrm{O}$ bond lengths are different, with the bond trans to the NHC (2.086(2) Å) ca. $0.03 \AA$ longer than the bond trans to the amido ligand (2.052(2) $\AA$ ) due to the stronger trans influence of the carbene. A search of the Cambridge Structural Database for complexes of the type $\left[L^{1} L^{2} \mathrm{Pd}(\mu-\mathrm{OH})\right]_{2}$ revealed that the $\mathrm{Pd}-\mathrm{O}$ bond length tends to correlate with the Lewis basicity of the trans ligand. ${ }^{47}$ Hence, the shortest Pd-O distances (2.005(2) to $\left.2.016(3) A ̊\right)$ have been observed with a pyridine or imine donor trans to $\mu-\mathrm{OH} ;{ }^{58-61}$ the database contained no examples of NHC or amido ligands in complexes of this type, but the $\mathrm{Pd}-\mathrm{O}$ bond lengths in 12 are similar to those reported for complexes with a phosphine trans to the $\mu-\mathrm{OH}$ ligand, ${ }^{62-64}$ and the longest Pd-O distance ( $2.126 \AA$ ) is for $\mu-\mathrm{OH}$ trans to a phenyl ligand. ${ }^{65}$

Fig. 7.

## Table 2.

Both the metal-amide (1.998(3) Å) and metal-carbene (1.945(3) $\AA$ ) distances are the shortest for all the complexes that we report herein. Unusually for a metal hydroxide, there is an absence of H -bonding in the solid state, which may be a consequence of the bulky N -aryl and $N$-alkyl substituents that surround the hydroxide ligand. The bridging hydroxide ligand can be clearly identified in the ${ }^{1} \mathrm{H}$ NMR spectrum for 12 at $\delta_{H}-3.97 \mathrm{ppm}$, slightly upfield of the typical range of ca. -0.25 to -3.5 ppm for cationic and neutral $\mathrm{Pd}(\mu-\mathrm{OH})_{2}$ moieties. ${ }^{62,66-69}$ In the
previously reported $\beta$-diiminato complex $\left\{\left[\mathrm{Ph}_{2} \text { nacnac }\right] \operatorname{Pd}(\mu-\mathrm{OH})\right\}_{2}$ the OH signal was observed even further upfield at -5.24 ppm , most likely as a consequence of the shielding effect of the two nearby phenyl groups of the $\mathrm{Ph}_{2}$ nacnac ligands. ${ }^{69}$ Likewise, the 2,6-diisopropylphenyl group in 12 also appears to shield the bridging hydroxide, which sits ca. $2.54 \AA$ above the aromatic ring in the solid state. In the ${ }^{13} \mathrm{C}$ NMR spectrum for 12 , the carbene signal could not be clearly identified as there are four signals for $4^{\circ} \mathrm{C}$ atoms between $\delta$ 144-148 ppm.

Palladium complexes of a bidentate amido-NHC ligand have been reported for an amido donor that is derived from deprotonation of an N -acyl group. ${ }^{50}$ However, to the best of our knowledge, compound $\mathbf{1 2}$ is the first reported Pd complex of either an arylamido or alkylamido functionalised NHC ligand.

We attempted to prepare the platinum analogue of $\mathbf{1 2}$ by also treating a solution of $\mathbf{1 1}$ in 1,4dioxane with aqueous KOH at $40^{\circ} \mathrm{C}$, but 11 was unreactive under these conditions. This observation is consistent with a mechanism where hydroxide reacts at the metal first and follows the common trend that ligand substitution reactions are slower for Pt than $\mathrm{Pd} .^{70-72}$ Increasing the temperature of the reaction to $60^{\circ} \mathrm{C}$ gave complete conversion of 11 to a mixture of products, but we were unable to isolate a pure compound from this reaction.

## Conclusions

We have prepared precursors to bidentate amido-NHC [C,N] and tridentate amido-bis(NHC) [CNC] ligands in high yield using an efficient sequence of two cross-coupling reactions and an alkylation. Different strategies were required to coordinate these ligands to Pd and Pt. For the [CNC] ligands, reaction of the amine bis(imidazolium) salts 3 with KHMDS and either $\mathrm{Pd}(\mathrm{OAc})_{2}$ or $\mathrm{PtCl}_{2}(\mathrm{COD})$ enabled the isolation of the palladium complexes $[\mathrm{CNC}-i-\mathrm{Pr}] \mathrm{Pd}-\mathrm{I}(7 \mathrm{a})$ and [CNC- $n$-Bu]Pd-I (7b) and the first [CNC] platinum complexes [CNC-i-Pr]Pt-I (8a) and [CNC-n-Bu]Pt-I (8b); treating 7a with AgOTf in pyridine also gave the cationic complex [CNC-i$\operatorname{Pr}] \operatorname{Pd}(p y)\} O T f 9 a$ with pyridine bound in the fourth site. For the $[\mathrm{C}, \mathrm{N}]$ ligand, reaction of the amine mono(imidazolium) salt 6 with $\mathrm{PdCl}_{2}$ or $\mathrm{K}_{2} \mathrm{PtCl}_{4}, \mathrm{~K}_{2} \mathrm{CO}_{3}$ and KI in pyridine at $100^{\circ} \mathrm{C}$ gave the complexes $[\mathrm{C}, \mathrm{NH}] \mathrm{MI}_{2} \mathrm{py}[\mathrm{M}=\mathrm{Pd}(\mathbf{1 0})$ or $\mathrm{Pt}(11)]$, in which the amine arm of the NHC ligand is not deprotonated and does not coordinate to the metal. The amine group in $\mathbf{1 0}$ was deprotonated in a biphasic reaction with aqueous KOH at $40^{\circ} \mathrm{C}$, giving the dimeric amido complex $\{[\mathrm{C}, \mathrm{N}] \operatorname{Pd}(\mu-\mathrm{OH})\}_{2}$ (12), the first reported arylamido-NHC complex of palladium. Under the same conditions, the more inert Pt analogue 11 was unreactive. We are currently investigating the reactivity of these ligands and complexes with a view to applications in

## Experimental

All manipulations were performed under dry, oxygen free nitrogen using standard Schlenk techniques unless otherwise stated. THF and toluene were dried by passing through a column of activated alumina and then degassed; DME was pre-dried over sodium and distilled from Na-benzophenone; anhydrous DMF was purchased from Sigma-Aldrich and used as supplied; KHMDS was purchased as a solution in toluene and titrated against 4-phenylbenzylidene benzylamine. ${ }^{73} \mathrm{Bis}\left(2\right.$-bromophenyl)amine (1), ${ }^{38} \mathrm{~N}$-(2-bromophenyl)-2,6-diisopropylaniline (4) ${ }^{40}$ and $\mathrm{PtCl}_{2}(\mathrm{COD})^{74}$ were prepared as reported in the literature. All other reagents were obtained from Sigma-Aldrich, Johnson Matthey or Alfa Aesar and used as supplied. NMR spectra were recorded on a Bruker DPX300, DRX400 or AV500 spectrometer; chemical shifts have been referenced to the residual protonated solvent peak and $J$ values are given in Hz. IR spectra were run in a diamond ATR cell using a Perkin Elmer Spectrum 1 instrument. ESI mass spectra were recorded on a micromass Quattra LC spectrometer in $\mathrm{MeCN} / \mathrm{MeOH}$ with a cone voltage of +50 or -25 V unless stated; FAB mass spectra were obtained on a Kratos concept spectrometer using NBA as the matrix. Elemental analyses were performed at London Metropolitan University.

## Bis(2-(1H-imidazol-1-yl)phenyl)amine (2)

Compound 1 ( $2.97 \mathrm{~g}, 9.10 \mathrm{mmol}$ ), imidazole ( $1.24 \mathrm{~g}, 18.2 \mathrm{mmol}), \mathrm{Cs}_{2} \mathrm{CO}_{3}(11.86 \mathrm{~g}, 36.40$ $\mathrm{mmol}), \mathrm{Cul}(0.346 \mathrm{~g}, 1.82 \mathrm{mmol})$ and 8 -hydroxyquinoline $(0.264 \mathrm{~g}, 1.82 \mathrm{mmol})$ were suspended in DMF ( 5 mL ) in a pre-dried sealable tube. The tube was sealed and heated at $125^{\circ} \mathrm{C}$ for 15 h . The reaction mixture was then allowed to cool to room temperature and diluted with DCM ( 50 mL ). The mixture was filtered through a pad of Celite and washed with a solution of $5 \% \mathrm{LiCl}_{(\mathrm{aq.})}(5 \times 100 \mathrm{~mL})$ and brine $(2 \times 50 \mathrm{~mL})$. The solution was then dried $\left(\mathrm{MgSO}_{4}\right)$ and the volatiles removed in vacuo to give a green solid ( $2.47 \mathrm{~g}, 90 \%$ ) m.p. $80-82{ }^{\circ} \mathrm{C}$. $\delta_{\mathrm{H}}\left(500 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}\right) 5.12(1 \mathrm{H}, \mathrm{s}, \mathrm{NH}), 7.11(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.8, \mathrm{ArCH}), 7.24-7.32(4 \mathrm{H}, \mathrm{m}, \mathrm{Ar} \mathrm{CH})$, $7.36(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.8, \mathrm{Ar} \mathrm{CH}), 7.75$ (br, imidazole CH$) ; \delta_{\mathrm{C}}\left(67.9 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 119.3,122.6,127.6$, 129.7, 137.7. $\mathrm{u}_{\max } / \mathrm{cm}^{-1}$ (solid) $3116 \mathrm{w}, 3096 \mathrm{w}, 2914 \mathrm{w}, 1593 \mathrm{~m}, 1510 \mathrm{~s}, 1500 \mathrm{~s}, 1482 \mathrm{~s}, 1459$ m, $1312 \mathrm{~s}, 1278 \mathrm{~m}, 1236 \mathrm{w}, 1108 \mathrm{~m}, 1088 \mathrm{w}, 1059 \mathrm{~s}, 963 \mathrm{~m}, 907 \mathrm{~m}, 821 \mathrm{~m}, 772 \mathrm{~s} . \mathrm{m} / \mathrm{z}$ (ESI) $302\left(100 \%, \mathrm{M}+\mathrm{H}^{+}\right), 324\left(21 \% \mathrm{M}+\mathrm{Na}^{+}\right)$; HRMS $\mathrm{C}_{18} \mathrm{H}_{16} \mathrm{~N}_{5}$ calcd. 302.1400, found 302.1414. Compound 2 could not be isolated in analytically pure form, but this did not hinder subsequent steps. Some signals are broad or not apparent in the NMR spectra; we speculate that this is
due to inter- and intramolecular H -bonding.

## Bis(2-(3-iso-propyl-1H-imidazolium)phenyl)amine diiodide (3a)

In a sealable tube under an atmosphere of air, $i$-propyl iodide ( $0.36 \mathrm{~mL}, 3.7 \mathrm{mmol}$ ) was added to a green suspension of $2(0.500 \mathrm{~g}, 1.66 \mathrm{mmol})$ in MeCN ( 10 mL ). The tube was sealed and heated at $90^{\circ} \mathrm{C}$ for 24 h , giving a red solution. The mixture was allowed to cool to RT and filtered. The volatiles were removed in vacuo to give an orange solid ( $0.951 \mathrm{~g}, 89 \%$ ) m.p. 81$84{ }^{\circ} \mathrm{C} . \delta_{\mathrm{H}}\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 1.70\left(12 \mathrm{H}, \mathrm{d}, J=6.7, \mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right), 4.97(2 \mathrm{H}$, sept, $J=6.7$, $\left.\mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right), 7.14\left(2 \mathrm{H}, \mathrm{dt},{ }^{3} \mathrm{~J}=7.8,{ }^{4} \mathrm{~J}=1.2, \mathrm{CH}\right), 7.30\left(2 \mathrm{H}, \mathrm{dd},{ }^{3} \mathrm{~J}=7.9,{ }^{4} \mathrm{~J}=1.2, \mathrm{CH}\right), 7.36(2 \mathrm{H}$, dd, $\left.{ }^{3} J=7.8,{ }^{4} J=1.5, \mathrm{CH}\right), 7.46\left(2 \mathrm{H}, \mathrm{dt},{ }^{3} \mathrm{~J}=7.9,{ }^{4} \mathrm{~J}=1.5, \mathrm{CH}\right), 7.53(2 \mathrm{H}, \mathrm{t}, J=1.7, \mathrm{NCHCHN})$, $7.75(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=1.7, \mathrm{NCHCHN}), 9.56(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=1.7, \mathrm{NCHN}) ; \delta_{\mathrm{C}}\left(67.9 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 22.9$ $\left(\mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right), 52.8\left(\mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right), 121.5,122.9,123.8,124.2,126.1,127.7,132.0,135.6,137.7$ (aromatic C). $\mathrm{u}_{\max } / \mathrm{cm}^{-1}$ (solid) $3066 \mathrm{w}, 2978 \mathrm{w}, 1597 \mathrm{~m}, 1546 \mathrm{~m}, 1497 \mathrm{~s}, 1458 \mathrm{~m}, 1375 \mathrm{w}$, 1305 m, 1264 w, 1192 s, 1161 w, 958 w, 875 w, 827 w, 758 vs, 681 w, 650 s. m/z (ESI) 514 (18\%, [M-I] ${ }^{+}$), 386 ( $\left.100 \%[\mathrm{M}-\mathrm{I}-\mathrm{HI}]^{+}\right), 344$ ( $36 \%,\left[\mathrm{M}-\mathrm{I}-\mathrm{HI}-{ }^{-} \mathrm{Pr}\right]^{+}$); HRMS $\mathrm{C}_{24} \mathrm{H}_{29} \mathrm{I}_{2} \mathrm{~N}_{5}$ calcd. 514.1462, found 514.1465. Hydroxy palladium $\mathbf{N}$-(2-(3-iso-propylimidazolin-2-yliden-1-yl)phenyl)-2,6diisopropylphenylamide dimer, $\{[\mathrm{C}, \mathrm{N}] \operatorname{Pd}(\mu-\mathrm{OH})\}_{2}(12)$

A solution of complex $10(0.100 \mathrm{~g}, 0.125 \mathrm{mmol})$ in 1,4-dioxane ( 18 mL ) was stirred vigorously with a solution of $\mathrm{KOH}(0.350 \mathrm{~g}, 6.250 \mathrm{mmol})$ in $\mathrm{H}_{2} \mathrm{O}(3 \mathrm{~mL})$ at $40^{\circ} \mathrm{C}$ for 24 h . After cooling to RT, the volatiles were removed in vacuo. The crude solid was re-dissolved in DCM ( 15 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$ and filtered through Celite. Removing the solvent under reduced pressure gave 12 ( $0.076 \mathrm{~g}, 63 \%$ ) as an orange/red powder m.p. $190^{\circ} \mathrm{C}$ (dec.). Crystals suitable for structure determination by X-ray diffraction were obtained by slow evaporation of an $\mathrm{Et}_{2} \mathrm{O} /$ pentane solution of 12. $\delta_{H}\left(300 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}\right)-3.97(2 \mathrm{H}, \mathrm{s}, \mathrm{OH}), 0.96\left(12 \mathrm{H}, \mathrm{d}, \mathrm{J}=6.9, \mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right), 1.11$ ( $\left.12 \mathrm{H}, \mathrm{d}, J=6.7, \mathrm{NCH}\left(\mathrm{CH}_{3}\right)_{2}\right), 1.46\left(12 \mathrm{H}, \mathrm{d}, J=6.9, \mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right), 3.49(4 \mathrm{H}$, sept, $J=6.9$, $\left.\mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right), 5.17\left(2 \mathrm{H}\right.$, sept, $\left.J=6.7, \mathrm{NCH}\left(\mathrm{CH}_{3}\right)_{2}\right), 5.80(2 \mathrm{H}, \mathrm{d}, J=8.1, \mathrm{CH}), 6.23(2 \mathrm{H}, \mathrm{t}, J=7.7$, $\mathrm{CH}), 6.63(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=8.1, \mathrm{CH}), 7.02(2 \mathrm{H}, \mathrm{d}, \mathrm{J}=2.2, \mathrm{NCHCHN}), 7.08\left(6 \mathrm{H}, \mathrm{br} \mathrm{s}, 2,6-^{-} \mathrm{Pr}_{2} \mathrm{C}_{6} H_{3}\right)$, $7.22(2 \mathrm{H}, \mathrm{d}, J=7.7, \mathrm{CH}), 7.50(2 \mathrm{H}, \mathrm{d}, J=2.2, \mathrm{NCHCHN}) ; \delta_{\mathrm{c}}\left(75 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right) 23.8\left(\mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right)$, $24.7\left(\mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right), 25.5\left(\mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right), 28.1\left(\mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right), 50.1\left(\mathrm{NCH}\left(\mathrm{CH}_{3}\right)_{2}\right), 110.8,117.4$, 117.7, 117.8, 118.9 (ArCH), 122.9 (ArC), 124.7, 125.2, 126.7 (ArCH), 144.7, 145.7, 147.4, 147.5 $\left(4^{\circ} \mathrm{C}\right) . \mathrm{u}_{\mathrm{max}} / \mathrm{cm}^{-1}$ (solid) $3601 \mathrm{w}(\mathrm{OH}), 2961 \mathrm{~m}, 2863 \mathrm{w}, 1598 \mathrm{~m}, 1493 \mathrm{~s}, 1455 \mathrm{~m}, 1426 \mathrm{~m}, 1410$ m, 1356 s, 1337 s, 1284 m, 1221 m, 1161 w, 1124 w, 1081 w, 1055 m, 952 w, 850 s, 825 m, $801 \mathrm{~m}, 767 \mathrm{~m}, 735 \mathrm{~s}, 723 \mathrm{~s}, 713 \mathrm{~s}, 693 \mathrm{~m}, 672 \mathrm{~s} . \mathrm{m} / \mathrm{z}(\mathrm{ESI}, 25 \mathrm{~V}) 466$ (100\% [(C,N)Pd] $\left.{ }^{+}\right), 500$ ( $\left.100 \%\left[(\mathrm{C}, \mathrm{N}) \mathrm{Pd}(\mathrm{OH})_{2}\right]^{-}\right)$. Anal. Calcd. for $\mathrm{C}_{48} \mathrm{H}_{62} \mathrm{~N}_{6} \mathrm{O}_{2} \mathrm{Pd}_{2}$ : C, 59.56; H, 6.46; N, 8.68. Found C, 59.47; H, 6.30; N, 8.73 \%.

## X-ray Crystallographic Studies

All single crystal diffraction data were collected using graphite-monochromated Mo Ka Xradiation ( $\lambda=0.71073 \AA$ ) on a Bruker APEX 2000 CCD diffractometer at 150 K . The data were corrected for Lorentz and polarisation effects and empirical absorption corrections applied. Structures were solved by Patterson methods and structures refined by least-squares full-matrix refinement against $F^{2}$ employing SHELXTL version 6.10. ${ }^{75}$ Hydrogen atoms were included in calculated positions $(\mathrm{d}(\mathrm{C}-\mathrm{H})=0.95$ to $0.99 \AA$ ) riding on the bonded atom with isotropic displacement parameters set to $1.5 \mathrm{U}_{\text {eq }}(\mathrm{C})$ for methyl H atoms and $1.2 \mathrm{U}_{\text {eq }}(\mathrm{C})$ for all other C atoms. All non-H atoms were refined with anisotropic displacement parameters.

Crystal data for $\mathbf{7 a} \cdot\left(\mathbf{2 C}_{6} \mathrm{H}_{6}\right) . \mathrm{C}_{36} \mathrm{H}_{38} \mathrm{IN}_{5} \mathrm{Pd}, M_{w}=774.01 \mathrm{gmol}^{-1}, T=150(2) \mathrm{K}$, orthorhombic space group C222(1), $a=10.8012(19) \AA, b=19.746(4), c=15.230(3) A, \alpha=\beta=\gamma=90^{\circ}, V=$ $3248.2(10) \AA^{3}, Z=4, \rho_{\text {calcd }}=1.583 \mathrm{Mgm}^{-3}, \mu=1.555 \mathrm{~mm}^{-1}, F(000)=1552$, crystal size 0.33 x $0.26 \times 0.21 \mathrm{~mm}^{3}, 13040$ reflections collected, 3336 unique $[R(\mathrm{int})=0.0341]$ which were used in all calculations. Empirical absorption correction made, $T_{\min }$ and $T_{\max } 0.831$ and 0.646 respectively. $\mathrm{GOF}=1.064$, final R indices $[I>2 \sigma I] R_{1}=0.0260, w R_{2}=0.0661, \mathrm{R}$ indices (all
data) $R_{1}=0.0277, w R_{2}=0.0667$. Largest diff. peak and hole 0.692 and -0.554 e $\AA^{-3}$.
Disordered $\mathrm{C}_{6} \mathrm{H}_{6}$ was omitted using the SQUEEZE option of PLATON. ${ }^{76}$ The solvent accessible voids are $1128.7 \AA^{3}$ with an estimated $375 \mathrm{e} /$ cell to be added. Eight solvent $\mathrm{C}_{6} \mathrm{H}_{6}$ molecules/unit cell accounting for 336e were included in the formula, FWt, (000) and density calculations.

Crystal data for 7b $\cdot\left(\mathrm{C}_{6} \mathrm{H}_{6}\right) \cdot \mathrm{C}_{32} \mathrm{H}_{36} \mathrm{IN}_{5} \mathrm{Pd}, M_{w}=723.96 \mathrm{gmol}^{-1}, T=150(2) \mathrm{K}$, orthorhombic space group Aba2, $a=29.370(5) \AA, b=20.178(3) \AA, c=10.3042(17) \AA, a=\beta=y=90^{\circ}, V=$ $6106.4(18) \AA^{3}, Z=8, \rho_{\text {calcd }}=1.575 \mathrm{Mgm}^{-3}, \mu=1.648 \mathrm{~mm}^{-1}, F(000)=2896$, crystal size $=0.15$ $\times 0.14 \times 0.10 \mathrm{~mm}^{3}, 23246$ reflections collected, 5940 unique $[R($ int $)=0.0843]$ which were used in all calculations. Empirical absorption correction made, $T_{\text {min }}$ and $T_{\text {max }} 0.802$ and 0.628 respectively. GOF $=0.934$, final R indices $[\mid>2 \sigma I] R_{1}=0.0457, w R_{2}=0.0751, \mathrm{R}$ indices (all data) $R_{1}=0.0594, w R_{2}=0.0790$. Largest diff. peak and hole 0.894 and -1.009 e $\AA^{-3}$.

Crystal data for 9a•(0.75CH2 $\left.\mathrm{Cl}_{2}\right) \cdot \mathrm{C}_{30.75} \mathrm{H}_{32.50} \mathrm{Cl}_{1.50} \mathrm{~F}_{3} \mathrm{~N}_{6} \mathrm{O}_{3} \mathrm{PdS}, M_{w}=782.76 \mathrm{gmol}^{-1}, T=150(2)$ K, triclinic space group $\mathrm{P}-1, a=10.372(4) \AA, b=11.933(5) \AA, c=26.284(11) \AA, \alpha=$ $101.593(10)^{\circ}, \beta=94.150(9)^{\circ}, \gamma=95.257(10)^{\circ}, V=3159(2) \AA^{3}, Z=4, \rho_{\text {calcd }}=1.646 \mathrm{Mgm}^{-3}, \mu=$ $0.842 \mathrm{~mm}^{-1}, F(000)=1590$, crystal size $0.22 \times 0.13 \times 0.02 \mathrm{~mm}^{3}, 25010$ reflections collected, 12296 unique $\left[R\right.$ (int) $=0.2109$ (completeness to theta $=26.00^{\circ} 98.9 \%$ ). Empirical absorption correction made, $T_{\min }$ and $T_{\max }=0.802$ and 0.338 respectively. GOF $=0.795$, final R indices $[\mid>2 \sigma I] R_{1}=0.0910, w R_{2}=0.1639, \mathrm{R}$ indices (all data) $R_{1}=0.1872, w R_{2}=0.1958$. Largest diff. peak and hole 1.347 and -2.118 e $\AA^{-3}$.

Disordered $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ was omitted using the SQUEEZE option of PLATON. ${ }^{76}$ The solvent accessible voids are $207.5 \AA^{3}$ with an estimated 124 e/cell to be added. Three solvent $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ molecules/unit cell accounting for 126 e were included in the formula, FWt , (000) and density calculations. The $\mathrm{CF}_{3}$ group of one of the triflate anions was disordered and one of the F atoms has been split; attempts to split other atoms failed.

Crystal data for $\mathbf{1 0} \cdot\left(\mathbf{0 . 5} \mathrm{CH}_{2} \mathrm{Cl}_{2}\right)\left(\mathbf{0 . 2 5} \mathrm{C}_{6} \mathrm{H}_{14}\right) \cdot \mathrm{C}_{31} \mathrm{H}_{40.50} \mathrm{ClI}_{2} \mathrm{~N}_{4} \mathrm{Pd}, M_{w}=864.82 \mathrm{gmol}^{-1}, T=$ 150(2) K, triclinic space group $\mathrm{P}-1, a=13.616(9) \AA, b=15.293(10) ~ \AA, c=18.724(13) ~ A, \alpha=$ $73.804(12)^{\circ}, \beta=73.014(12)^{\circ}, \gamma=64.088(12)^{\circ}, V=3302(4) A^{3}, Z=4, \rho_{\text {calcd }}=1.740 \mathrm{Mgm}^{-3}, \mu=$ $2.539 \mathrm{~mm}^{-1}, F(000)=1694$, crystal size $0.20 \times 0.20 \times 0.13 \mathrm{~mm}^{3}, 25832$ reflections collected, 12785 unique $[R($ int $)=0.0875]$ (completeness to theta $=26.00^{\circ} 98.6 \%$ ). Empirical absorption correction made, $T_{\min }$ and $T_{\max }=0.831$ and 0.455 respectively. GOF $=0.952$, final R indices $[\mid>2 \sigma I] R_{1}=0.0589, w R_{2}=0.1341, \mathrm{R}$ indices (all data) $R_{1}=0.0825, w R_{2}=0.1428$. Largest diff.
peak and hole 2.244 and -0.858 e $\AA^{-3}$.
Disordered $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and $\mathrm{C}_{6} \mathrm{H}_{14}$ were omitted using the SQUEEZE option of PLATON. ${ }^{76}$ The solvent accessible voids are $325.1 \AA^{3}$ with an estimated 144 e /cell to be added. Two solvent $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ molecules and one $\mathrm{C}_{6} \mathrm{H}_{14}$ molecule/unit cell accounting for 134 e were included in the formula, FWt, (000) and density calculations.

Crystal data for 11. $\mathrm{C}_{29} \mathrm{H}_{36} \mathrm{I}_{2} \mathrm{~N}_{4} \mathrm{Pt}, M_{w}=889.51$ gmol-1, $T=150(2) \mathrm{K}$, triclinic space group P $1, a=13.412(3) \AA, b=15.242(3) \AA, c=18.357(4) A, \alpha=95.858(4)^{\circ}, \beta=104.069(4)^{\circ}, \gamma=$ $114.812(4)^{\circ}, V=3214.0(12) \AA^{3}, Z=4, \rho_{\text {calcd }}=1.838 \mathrm{Mgm}^{-3}, \mu=6.309 \mathrm{~mm}^{-1}, F(000)=1688$, crystal size $0.23 \times 0.08 \times 0.04 \mathrm{~mm}^{3}, 25327$ reflections collected, independent reflections 12490 $[R($ int $)=0.0920]$ (completeness to theta $=26.00^{\circ} 98.80 \%$ ). Empirical absorption correction made, $T_{\min }$ and $T_{\max }=0.831$ and 0.518 respectively. GOF $=0.897$, final $R$ indices $[l>2 \sigma I] R_{1}=$ $0.0602, w R_{2}=0.1004, \mathrm{R}$ indices (all data) $R_{1}=0.1104, w R_{2}=0.1130$. Largest diff. peak and hole 3.255 and -1.506 e. $\AA^{-3}$.

Crystal data for $12 \cdot\left(\mathrm{C}_{5} \mathrm{H}_{12}\right) . \mathrm{C}_{53} \mathrm{H}_{74} \mathrm{~N}_{6} \mathrm{O}_{2} \mathrm{Pd}_{2}, M_{w}=1039.98$ gmol $^{-1}, T=150(2) \mathrm{K}$, tetragonal space group I4(1)/a, $a=19.443(2) A, b=19.443(2) \AA, c=25.426(4) A, \alpha=90^{\circ}, \beta=90^{\circ}, \gamma=$ $90^{\circ}, V=9612(2) \AA^{3}, Z=8, \rho_{\text {calcd }}=1.437 \mathrm{Mgm}^{-3}, \mu=0.796 \mathrm{~mm}-1, F(000)=4336$, crystal size $0.31 \times 0.24 \times 0.15 \mathrm{~mm}^{3}, 37121$ reflections collected, independent reflections $4713[R(\mathrm{int})=$ 0.0767 ] (completeness to theta $=26.00^{\circ} 100.00 \%$ ). Empirical absorption correction made, $T_{\text {min }}$ and $T_{\max }=0.802$ and 0.634 respectively. GOF $=1.029$, final R indices $[\mid>2 \sigma I] R_{1}=0.0378$, $w R_{2}=0.0914, R$ indices (all data) $R_{1}=0.0497, w R_{2}=0.0960$. Largest diff. peak and hole 0.690 and -0.388 e. $\AA^{-3}$.

Disordered pentane $\left(\mathrm{C}_{5} \mathrm{H}_{12}\right)$ was omitted using the SQUEEZE option of PLATON. ${ }^{76}$ The solvent accessible voids are $1135.0 \AA^{3}$ with an estimated $332 \mathrm{e} /$ cell to be added. Eight solvent $\mathrm{C}_{5} \mathrm{H}_{12}$ molecules/unit cell accounting for 336 e were included in the formula, FWt , (000) and density calculations.

## Acknowledgements

We thank the Leverhulme Trust (WBC), The Nuffield Foundation (IRG) and the University of Leicester for financial support and Johnson Matthey for a loan of palladium salts.

## Supplementary information

X-ray crystallographic data (CIF) for compounds 7a, 7b, 9a, 10, 11 and $12 ;{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR
spectra for all compounds.

## Ilustrations

Fig. 1. Pd [CNC] complexes similar to those reported herein.

Fig. 2. ORTEP view of 7 a (ellipsoids drawn at $50 \%$ probability). Hydrogen atoms except $H(10)$ have been omitted for clarity.

Fig. 3. ORTEP view of 7b (ellipsoids drawn at 50\% probability). Hydrogen atoms have been omitted for clarity.

Fig. 4. ORTEP view of one of the independent cations of 9 a (ellipsoids drawn at 50\% probability). Hydrogen atoms have been omitted for clarity.

Fig. 5. ORTEP view of one of the independent molecules of $\mathbf{1 0}$ (ellipsoids drawn at 50\% probability). Hydrogen atoms except $\mathrm{H}(1)$ have been omitted for clarity.

Fig. 6. ORTEP view of one of the independent molecules of 11 (ellipsoids drawn at 50\% probability). Hydrogen atoms except $\mathrm{H}(1)$ have been omitted for clarity.

Fig. 7. ORTEP view of 12 (ellipsoids drawn at 50\% probability). Hydrogen atoms except $\mathrm{H}(1)$ have been omitted for clarity.

Scheme 1. Synthesis of the amine bis(imidazolium) pro-ligands $\mathbf{3 a}$ and $\mathbf{3 b}$. $^{a}$

(ii)

${ }^{2}$ Reaction conditions: (i) 2 eq. imidazole, $\mathrm{Cs}_{2} \mathrm{CO}_{3}$,
CuI ( $10 \mathrm{~mol} \%$ ), 8 -hydroxyquinoline ( $10 \mathrm{~mol} \%$ ),
DMF, $125^{\circ} \mathrm{C}, 24 \mathrm{~h}$;
(ii) 2.2 eq. RI, MeCN, $90^{\circ} \mathrm{C}, 24-48 \mathrm{~h}$

Scheme 2. Synthesis of the amine imidazolium pro-ligand 6. ${ }^{\text {a }}$

${ }^{\text {a }}$ Reaction conditions: (i) 1 eq. imidazole, $\mathrm{Cs}_{2} \mathrm{CO}_{3}$,
$\mathrm{Cul}(10 \mathrm{~mol} \%)$, 8 -hydroxyquinoline ( $10 \mathrm{~mol} \%$ ),
DMF, $125^{\circ} \mathrm{C}, 72 \mathrm{~h}$;
(ii) 1.1 eq. $i$-Prl, $\mathrm{MeCN}, 90^{\circ} \mathrm{C}, 48 \mathrm{~h}$

Scheme 3. Synthesis of palladium and platinum [CNC] complexes.

Scheme 4. Synthesis of amine-NHC complexes 10 and 11 and the amido-NHC complex 12.
$6 \xrightarrow[\mathrm{~K}_{2} \mathrm{CO}_{3}, \mathrm{KI}, \mathrm{py}]{\mathrm{PdCl}_{2} \text { or } \mathrm{K}_{2} \mathrm{PtCl}_{4}}$

Table 1. Selected bond lengths $(\AA)$ for $\mathbf{7 a}, \mathbf{7 b}$ and $\mathbf{9 a}$.

|  | 7a | 7b | 9a <br> molecule <br> 1 | molecule <br> 2 |
| :--- | :---: | :--- | :--- | :--- |
