Submitted to Proceedings of the National Academy of Sciences of the United States of America

HVCN1 is the only mammalian voltage-gated proton channel. In human B lymphocytes, HVCN1 associates with the B Cell Receptor (BCR) and is required for optimal BCR signaling and redox control. HVCN1 is expressed in malignant B cells that rely on BCR signaling, such as Chronic Lymphocytic Leukemia (CLL) cells. However, little is known about its regulation in these cells. We found that HVCN1 was expressed in B cells as two protein isoforms. The shorter isoform (HVCN1_S) was enriched in B cells from a cohort of 76 CLL patients. When overexpressed in a B-cell lymphoma line, HVCN1_S responded more profoundly to PKC-dependent phosphorylation. This more potent enhanced gating response was mediated by increased phosphorylation of the same residue responsible for enhanced gating in HVCN1_L, Thr²⁹. Furthermore, the association of HVCN1_S with the BCR was weaker, which resulted in its diminished internalization upon BCR stimulation. Finally, HVCN1_S conferred a proliferative and migratory advantage, as well as enhanced BCR-dependent signaling. Overall, our data show for the first time the existence of a shorter isoform of HVCN1 with enhanced gating that is specifically enriched in malignant B cells. The properties of HVCN1_S suggest it may contribute to the pathogenesis of BCR dependent B-cell malignancies.

proton currents | chronic lymphocytic leukemia | Hv1 | gating kinetics | phosphorylation

Introduction

The voltage-gated proton channel HVCN1 (or Hv1 or VSOP) is a small protein that conducts protons across membranes selectively (1, 2) and in a regulated manner. Previously, we described its function in B lymphocytes, where proton channels sustain B Cell Receptor (BCR) signaling *via* regulation of ROS production by the NADPH oxidase enzyme complex (3). In addition, we found HVCN1 to be directly associated with the BCR. Upon receptor stimulation, the BCR and HVCN1 were co-internalized to late endosomal/lysosomal organelles called MIICs, or MHC class II containing compartments, where antigens bound to the BCR are digested into small peptides and loaded onto MHC class II molecules for presentation to T cells (3).

HVCN1 is expressed not only by normal but also by malignant B cells, such as Chronic Lymphocytic Leukemia (CLL). CLL cells are characterized by their reliance on BCR signaling for survival and growth (4), so it is possible that they maintain or upregulate HVCN1 expression in order to sustain their growth. Other tumor types have been found to rely on HVCN1 for survival, such as breast (5) and colorectal cancer (6). In these tumor cells, proton channels prevent excessive acidification of the cytoplasm and allow increased cell migration. In malignant B cells, HVCN1

may regulate intracellular pH and at the same time sustain BCR signaling. However, its precise roles remain to be elucidated.

We show here that CLL cells and other B-cell lines specifically express higher levels of a shorter isoform of HVCN1, HVCN1_S. We identified the existence of two distinct isoforms of relatively similar size when immunoblotting B cell lysates with an HVCN1-specific antibody (3). HVCN1_S is only weakly expressed in normal B cells and in light of its apparent upregulation in tumor cells, we set out to characterize its function. We show that HVCN1_S responds more strongly to phosphorylation by PKC and identify the phosphorylation site. We provide evidence that HVCN1_S in B cells is preferentially expressed at the plasma membrane, even upon BCR stimulation and subsequent internalization, due to a weaker association with the BCR. Lastly, we show that HVCN1_S expression results in stronger BCR signaling, increased proliferation and augmented chemokine-dependent migration. Overall, our data indicate that HVCN1_S is an alternative protein isoform that mediates stronger currents upon PKC phosphorylation, is more highly expressed at the plasma membrane, and can confer a growth advantage to malignant B cells.

Significance

B lymphocytes are crucial cells in immune responses. Their activity is regulated by signaling pathways involving reactive oxygen species (ROS). Voltage-gated proton channels modulate B-cell responses by facilitating production of ROS. Here we compare the full-length proton channel, HVCN1_L, with a shorter isoform, HVCN1_S, which lacks the first 20 amino acids. Cells with HVCN1_S display greater proton channel activity upon stimulation. In addition, HVCN1_S is internalized to a lesser extent by interactions with the B Cell Receptor, resulting in greater plasma membrane expression. Compared with normal B lymphocytes, HVCN1_S is expressed at higher levels in B cells from patients with Chronic Lymphocytic Leukemia and in B-cell lines, where its greater activity may contribute to the pathogenesis of disease.

Fig. 1. HVCN1_S is an alternative isoform of the voltage-gated proton channel HVCN1 enriched in malignant B cells. A) Left and center panels, immunoblots showing expression of two isoforms of HVCN1, HVCN1_L (‘L’) and HVCN1_S (‘S’), in B-cell lines, primary B cells and CLL samples. R=R11, U=U2932 and H=HBL1 are Diffuse Large B Cell Lymphoma cell lines, E=EJM=multiple myeloma cell line, Ra=RAJI=Burkitt lymphoma cell line. Right panel, densitometry analysis of protein expression of HVCN1_S in B cells from healthy donors (*n* = 7) and CLL patients (*n* = 76). Protein expression levels as determined by western blot, relative to loading control (β-actin or α-tubulin) and normalized to a positive control used across different blots (cell line HBL1). Statistical analysis carried out with Mann-Whitney U test. B) Left and center panels, *in vitro* transcription-translation assays with recombinant HVCN1_L and mutated ttgHVCN1_L. Right panel, expression of ttgHVCN1_L transduced in LK35.2 cells. C) PCR on HBL1 mRNA to identify the three mRNA sequences reported for human HVCN1 (see Fig. S1). Left panel, duplex PCR with primers designed for mRNA variant 2, which amplifies a band of 432 bps, and primers recognizing all variants (228 bps). Right panel, PCR performed with different annealing temperatures with primers designed to recognize HVCN1 mRNA variants 1 and 3. The expected bands for isoforms 1 and 3 are 433 and 393 bps, indicated by arrows. D) Immunoblots of a CLL sample and LK35.2 cells overexpressing HVCN1_L and HVCN1_S with an anti-HVCN1 that recognizes residues 26-46 (left panel) and residues 1-20 (HVCN1_L-specific, right panel).

Results

Identification of an HVCN1 isoform enriched in malignant B cells. We investigated HVCN1 expression in a panel of B-cell lines and noticed the presence of two bands of similar molecular weight. Some cell lines appeared to express more of the shorter isoform, while the Burkitt cell line Raji expressed it exclusively (Fig. 1A, left panel). Peripheral blood B cells expressed this short isoform (here called HVCN1_S) at much lower levels compared to CLL cells (Fig. 1A, center and right panel).

When we started this study, the NCBI DNA and RNA database reported only one viable splicing variant for human HVCN1 (See SI Appendix Fig. S1, variant 1). Given the presence of an ATG 60 base pairs (bps) downstream of the first ATG, we set out to investigate if a shorter isoform could be the result of translation from this alternative start site. To this end, we expressed recombinant HVCN1 Long (HVCN1_L) in an *in vitro* translation assay (Fig. 1B, left panel). We then mutated the first ATG to TTG, which results in significantly reduced translation from this codon (Fig. 1B, center panel). A shorter protein was expressed from the mutated plasmid (Fig. 1B, center panel), also when expressed in whole cells (Fig. 1C, right panel), indicating that the second ATG functioned as a start codon.

More recently, three splicing variants for human HVCN1 have been reported (Fig. S1). Variant 1 and 2 differ in the use of alternative 5'-UTRs but code for the same full-length HVCN1 protein, whereas variant 3 utilizes the same 5'-UTR as variant 1 but it does not possess the first coding exon. Therefore, variant 3 lacks the first ATG and consequently translation can start only from the second ATG 60 bps downstream. To test the existence of the three mRNA variants, we designed specific PCR primers and tested them with mRNA from the cell line HBL1. We used the same reverse primer and specific forward primers for variants 1/3 and 2, annealing on their respective 5'-UTRs. To distinguish variants 1 and 3, we relied on differences in the band size of the amplified PCR product (433 for variant 1 and 393 for variant 3). As Fig. 1C left panel shows, the PCR with primers for variant 2 and all variants produced bands of the expected sizes. For variants 1 and 3, we ran a gradient PCR (Fig. 1C, right panel), which showed the expected bands of 433 and 393 bps (Fig. 1C, arrows). Overall, our results indicate the existence of three distinct mRNA variants and therefore suggest that HVCN1_S is the result of alternative mRNA splicing, which produces a protein identical to the long isoform but lacking the first 20 amino acids.

In order to confirm the nature of this shorter isoform, we raised an antibody towards the first 20 amino acids of HVCN1, which should recognize the long isoform only. Our original anti-HVCN1 antibody, which recognizes a region in the N-terminus closer to the first transmembrane domain (amino acids 26–46), detected both isoforms in CLL cells (Fig. 1D left panel). Also, recombinant HVCN1_L and HVCN1_S were both detected. In contrast, an immunoblot with the anti-HVCN1_L-specific antibody only detected the long isoform, both recombinant and endogenously expressed (Fig. 1D, right panel). These results confirmed that the shorter isoform of HVCN1 is a protein with a shorter N-terminus domain, lacking the first 20 amino acids.

Both isoforms are voltage-gated proton channels. Biophysical properties of HVCN1_L and HVCN1_S were compared in transduced LK-35.2 cells using the whole-cell voltage-clamp configuration over a wide range of pH. The H⁺ currents generated by the two isoforms appeared generally similar. Fig. S2A (SI Appendix) confirms that both isoforms were proton selective, because the reversal potential for current (*V*_{rev}) was close to the Nernst potential for H⁺ (*E*_H). This result is expected because the selectivity filter is in the middle of the S1 transmembrane helix (1), far from the N-terminus where the two isoforms differ.

A unique property of all known voltage-gated proton channels crucial to their function is ΔpH-dependent gating (2, 7). The position of the proton conductance-voltage (*g*_H-*V*) relationship depends strongly on both pH_o and pH_i, with the consequence that the channel opens only when there is an outward electrochemical gradient, and the open channel will extrude H⁺ from the cell. HVCN1_L and HVCN1_S exhibited similar ΔpH-dependent gating, both activating at potentials about 10 mV positive to *V*_{rev} at symmetrical pH (SI Appendix Fig. S2B).

To compare gating kinetics we used the perforated-patch voltage-clamp method, a more physiological configuration that preserves cytoplasmic contents. Comparison of the gating kinetics of HVCN1_L and HVCN1_S in unstimulated LK-35.2 cells (SI Appendix Table S1) reveals that HVCN1_S channels opened more slowly, with a time constant of current turn-on, τ_{act}, more than double that of HVCN1_L. Closing kinetics (τ_{tail}) and the position of the *g*_H-*V* relationship did not differ significantly.

HVCN1_S responds more strongly to PKC-dependent phosphorylation. Proton currents in phagocytes and other cells are greatly augmented by phosphorylation of the channel by protein kinase C, PKC (8). The enhanced gating response is stimulated effectively by the PKC activator, PMA, and is best studied using the perforated-patch configuration that preserves intracellular signaling pathways (9). Fig. 2 illustrates families of proton cur-

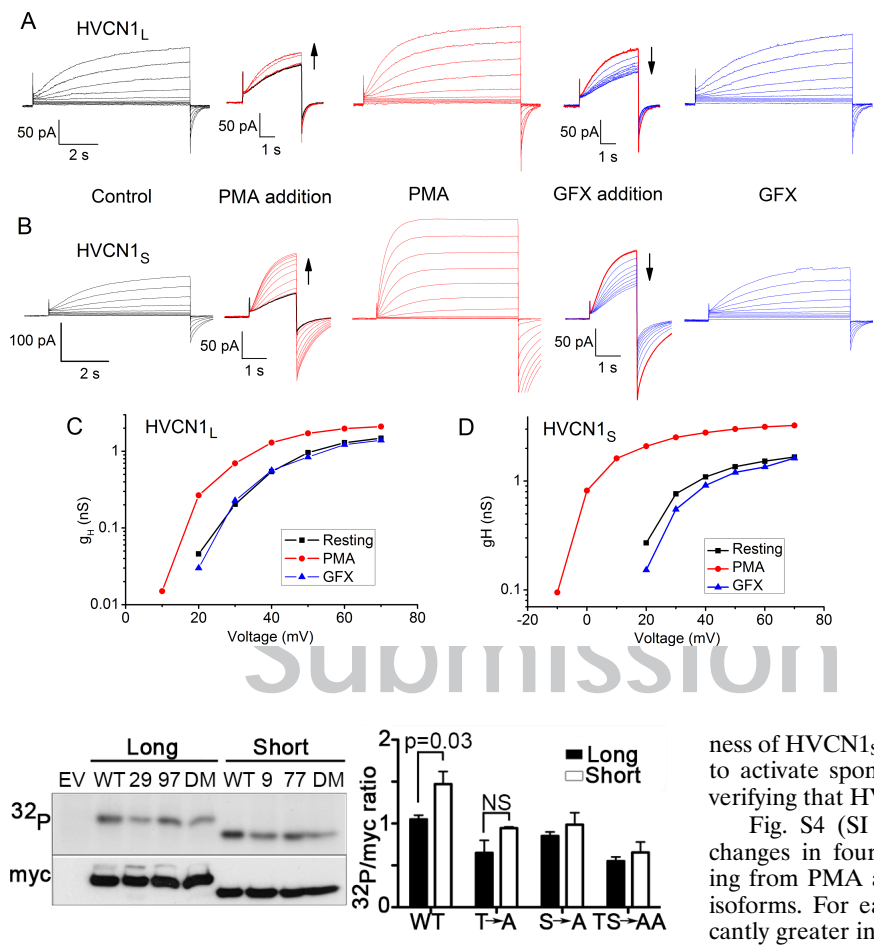

Fig. 3. HVCN1_S is phosphorylated more by PKC- δ than HVCN1_L. PKC- δ *in vitro* kinase assay showing phosphorylation of HVCN1_L and HVCN1_S wild type (WT), single mutants T29A (29) or T9A for HVCN1_S (9), S97A (97) or S77A for HVCN1_S (77), and double mutants T29A/S97A and T9A/S77A for HVCN1_S (DM). The assay was carried out with recombinant HVCN1_L and HVCN1_S expressed in HEK293T cells and immunoprecipitated with an anti-myc antibody. Cells transfected with an empty vector (EV) were used as negative control. The myc immunoblot indicates loading. Bars represent the densitometry analysis of the ³²P-HVCN1 versus myc-HVCN1 of three independent experiments (mean \pm SEM). NS, not significant.

rents in cells expressing HVCN1_L and HVCN1_S, before and after PMA stimulation. In response to PMA, the currents turn on more rapidly and at more negative voltages, turn off more slowly, and the current amplitude is increased. Although HVCN1_L responds distinctly, the response of HVCN1_S was consistently more profound. Because there is a tendency early in each experiment for proton currents to become larger and activate at more negative voltages as the amphotericin in the pipette solution improves electrical access to the cell membrane, and as p*H*_i is clamped to 7.0 by the applied NH₄⁺ gradient (9, 10), the PMA response may be exaggerated if measurements are made before complete equilibration. A crucial quantitative control is to reverse the effects of PMA using the PKC inhibitor, GF 109203X (GFX). The reversal of enhanced gating by GFX in both representative cells in Fig. 2 was complete, validating the responses.

Fig. S3 (SI Appendix) shows normalized *g*_H-*V* relationships after the PMA response and after GFX treatment in all cells studied expressing HVCN1_L or HVCN1_S. This comparison is more informative than control *vs.* PMA for reasons just discussed and because some cells were spontaneously active, as judged by GFX reversal being greater than their initial response to PMA. A possible spurious explanation for the greater PMA responsive-

Fig. 2. HVCN1_S responds more strongly to PMA stimulation than HVCN1_L. Perforated-patch voltage clamp was used to evaluate the electrophysiological properties of the two HVCN1 isoforms. Families of currents in 10 mV increments up to 70 mV from *V*_{hold} = -40 mV are shown in representative LK35.2 cells expressing HVCN1_L (A) or HVCN1_S (B) before stimulation, after application of the PKC activator PMA, and after inhibition of PKC by GF 109203X (GFX). Between the families are superimposed currents obtained during test pulses to 60 mV (for HVCN1_L) or 40 mV (for HVCN1_S) applied at 30-s intervals before and after addition of PMA or GFX to the bath solution. C) & D) Proton conductance-voltage relationships, *g*_H-*V*. The current amplitude was determined by extrapolating a single exponential fitted to the rising current, and *g*_H was calculated from the current using *V*_{rev} measured in each solution. Measurements were made in symmetrical pH 7.0 solutions containing 50 mM NH₄⁺ to clamp p*H*_i (9).

ness of HVCN1_S is that HVCN1_L might have a greater tendency to activate spontaneously. Fig. S3 does not support this view, verifying that HVCN1_S is indeed more responsive.

Fig. S4 (SI Appendix) summarizes the magnitude of the changes in four kinetic parameters of HVCN1 gating resulting from PMA and GFX treatment of cells expressing the two isoforms. For each parameter, the PMA response was significantly greater in HVCN1_S than HVCN1_L. Also for each parameter, GFX reversed the PMA response completely. In summary, HVCN1_S channels exhibit a more profound response to phosphorylation than do HVCN1_L channels.

Because B cells from CLL patients have higher than normal levels of HVCN1_S, their responsiveness might be enhanced. B cells from CLL patients and normal controls were studied by perforated-patch voltage clamp (*n* = 4 and 3, respectively), confirming that both CLL and normal B cells had proton currents that responded to PMA and GFX. Interestingly, CLL cells, which have a variable mixture of HVCN1_S and HVCN1_L (SI Appendix Table S3) exhibited enhanced gating responses comparable with those of LK35.2 cells expressing HVCN1_S exclusively (SI Appendix Fig. S5), indicating that HVCN1_S prevails in the response.

Identification of HVCN1_S phosphorylation site. Two predicted high-probability PKC- δ phosphorylation sites exist in the N-terminus of HVCN1_L (11), Thr²⁹ and Ser⁹⁷. We reported previously that both sites were phosphorylated after PMA exposure, but only Thr²⁹ contributed detectably to the enhanced gating response of HVCN1_L channels (11). Because the lack of the first 20 amino acids of the N-terminus might result in different protein folding or architecture, it was important to examine the contribution of both corresponding sites in HVCN1_S, namely Thr⁹ and Ser⁷⁷. We generated mutants that lacked one (T9A and S77A) or both (T9A/S77A) putative phosphorylation sites.

Cells with the T9A mutation (*n* = 9) and the double mutant T9A/S77A (*n* = 5) did not respond detectably to either PMA or GFX (SI Appendix Fig. S6), implicating Thr⁹ as crucial to the responses. In contrast, cells expressing the S77A mutant did respond to PMA and to GFX. Mean changes in parameter values are given in SI Appendix Table S2. Therefore, the key residue in the PMA response is Thr⁹ (HVCN1_S), the equivalent of Thr²⁹ in HVCN1_L channels (11). Any participation of Ser⁷⁷ (HVCN1_S) or

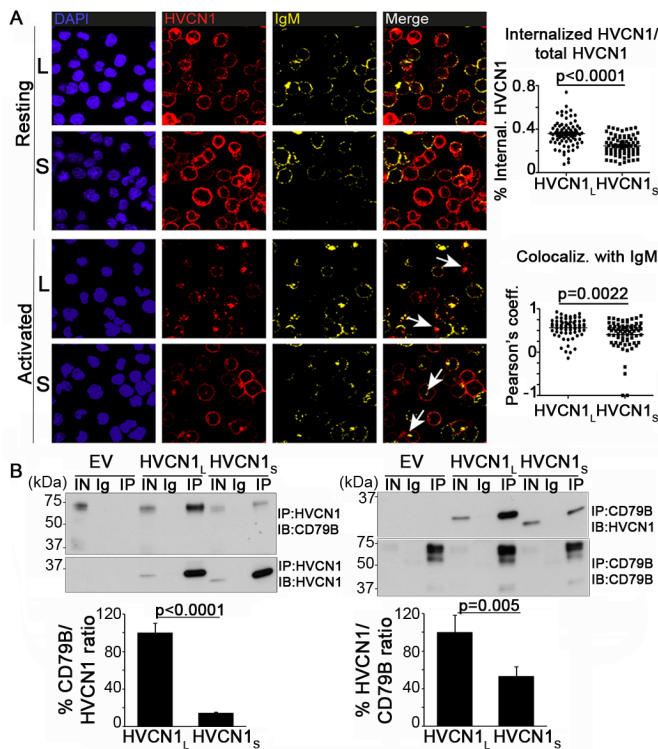

Fig. 4. HVCN1_s is associated and internalized with the BCR to a lesser extent compared to HVCN1_L. A) Left panel, confocal images of A20 D1.3 cells overexpressing HVCN1_L or HVCN1_s, at steady state ('resting' panels) or 30 min after activation with an anti-IgM crosslinking F(ab')₂ fragment ('activated' panels). Merge panels represent IgM and HVCN1 staining. White arrows indicate co-internalized HVCN1 and IgM. Right panels, quantification of percentage of internalized HVCN1 (upper graph) and co-localization coefficient for HVCN1 and IgM (lower graph). Each symbol represents a single cell [*n* = 78 (upper); *n* = 67 (lower)], and horizontal lines indicate the mean. Pearson's co-localization coefficient (0 = no co-localization, 1 = total co-localization). B) Co-immunoprecipitation of overexpressed HVCN1_L or HVCN1_s and endogenous CD79B (immunoglobulin-associated-β or Ig-β). Proteins were co-immunoprecipitated from A20 D1.3 cells and analyzed by immunoblot in non-reducing conditions. EV, cells transfected with empty vector; IN, input cell lysate (2% of the cell lysate used for immunoprecipitation); Ig, negative control beads conjugated to mouse or rat IgG; IP, immunoprecipitation; IB, immunoblot. Graphs represent densitometry analysis of both co-IP experiments (mean ± SEM, three independent experiments).

Ser⁹⁷ (HVCN1_L) in the enhanced gating response was below our ability to detect it.

Intriguingly, T9A cells studied before stimulation exhibited 9-fold faster activation and a 24-mV more negative *V*_{threshold} than did unstimulated HVCN1_s cells (SI Appendix Table S1), resembling enhanced gating mode behavior. We re-analyzed data from analogous mutations studied previously in the full-length channel (11) and found that T29A also exhibited "enhanced gating" in unstimulated cells (Table S1). Unstimulated "phosphomimetic" T29D cells exhibited weaker enhanced gating than T29A. Evidently, this Thr position is a potent determinant of gating kinetics. Together, these results suggest that phosphorylation of Thr²⁹ in HVCN1_L or Thr⁹ in HVCN1_s produces enhanced gating by a mechanism not simply involving the negative charge provided by the phosphate group. However, we cannot rule out the possibility that these mutations alter gating through a mechanism unrelated to that elicited by phosphorylation.

Since HVCN1_s responded more strongly to PKC phosphorylation and the effect was mediated by phosphorylation of Thr⁹ exclusively, we speculated that it could reflect increased phosphorylation of this residue. Indeed, our *in vitro* kinase assay

Fig. 5. HVCN1_s expression modulates BCR signaling, cell proliferation and migration. A) BCR stimulation with 20μg/ml F(ab')₂ anti-IgM in A20 D1.3 cells overexpressing empty vector (EV), HVCN1_L and HVCN1_s. Immunoblot showing phosphorylated Erk (p-Erk) and total Erk. Bars indicate the ratio of the densitometry analysis of p-Erk versus total Erk from three independent experiments (mean + SEM). B) Proliferation of A20 D1.3 cells assessed by EdU incorporation after 3 h incubation. Results are shown as percentage of EdU⁺ cells versus total number of GFP⁺ cells of two independent experiments (mean + SEM). C) Transwell chamber migration assay towards the chemokine CXCL12. Migrated cells were counted after 4 h. Results are shown as fold increase of the percentage of migrated cells in the presence of CXCL12 versus media alone. Data represent the average of two experiments (mean + SEM).

showed that overall phosphorylation of wild-type HVCN1_s was significantly higher than for wild-type HVCN1_L (Fig. 3, WT lanes in left panel). In order to assess phosphorylation of the critical PKC site mediating the enhanced-gating response, we carried out the same experiment with T29A (T9A for HVCN1_s), S97A (S77A for HVCN1_s), and T29A/S97A (T9A/S77A for HVCN1_s) mutants. As shown in Fig. 3, phosphorylation of the T9A mutant was reduced as much as for the T29A one, confirming that this Thr is phosphorylated by PKC in both isoforms. The analysis of the other PKC site mutant, S97A (S77A for HVCN1_s) and double mutants indicated a further reduction in overall phosphorylation, as we reported previously for HVCN1_L (11), suggesting that the Ser is also phosphorylated by PKC. However, as before, the patch-clamp experiments (SI Appendix Fig. S6 and Table S1) indicated that phosphorylation of Thr⁹ alone is responsible for the enhancement of HVCN1_s proton currents.

HVCN1_s has a weaker association with the BCR than does HVCN1_L. We found previously that HVCN1 was associated with the BCR in both normal and malignant B cells (3). The association causes HVCN1 to be internalized together with the BCR after its stimulation, an event that downregulates HVCN1 expression at the cell surface (3). Since the intracellular domains are likely to be the regions mediating the association with the BCR, we investigated if HVCN1_s behaved differently from HVCN1_L. We overexpressed both isoforms in the B lymphoma cell line A20 D1.3 and assessed their expression at steady state and after BCR stimulation with a F(ab')₂ anti-IgM. Cells expressed similar levels of HVCN1, IgM, and the BCR co-receptor CD79B (SI Appendix Fig. S7A-C). We did not notice significant differences in the pattern of expression of the two isoforms at steady state. Importantly, however, upon BCR stimulation, the extent of HVCN1 internalization for the two isoforms appeared different (Fig. 4A). Quantification of the immunofluorescence staining showed a significantly larger percentage of internalized HVCN1 in cells expressing HVCN1_L compared to HVCN1_s (36% vs. 25%, Fig. 4A, upper graph). Furthermore, the extent of co-localization with IgM was also reduced from 0.562 to 0.407 (Fig. 4A, lower graph). Diminished HVCN1_s internalization was not due to reduced IgM internalization, which was actually increased, compared to cells overexpressing HVCN1_L (SI Appendix Fig. S7D). These data

545 indicate that HVCN1_S association with the BCR is different and
546 this results in increased localization of proton channels at the
547 plasma membrane.

548 In order to determine the reason for the different associa-
549 tion of HVCN1 isoforms with the BCR, we carried out a co-
550 immunoprecipitation (co-IP) with an anti-CD79B and the recip-
551 rocal experiment with an anti-myc (for the myc-tagged HVCN1
552 isoforms). As shown in Fig. 4B, interaction of HVCN1_S with
553 CD79B was indeed significantly weaker with both co-IP assays.
554 The differences between the two antibodies are likely due to
555 differences in the efficiency of pull down (with the anti-myc being
556 more efficient than the anti-CD79B). Overall, these data show
557 that the first 20 amino acids present in HVCN1_L are critical for
558 the association with the BCR and their absence in HVCN1_S re-
559 sults in greater expression of this isoform at the plasma membrane
560 after BCR stimulation.

561 **HVCN1_S expression is enriched in CLL cells.** Given the
562 increased expression HVCN1_S in B-cell lines and in CLL samples
563 (Fig. 1A), combined with its ability to mediate stronger proton
564 currents (Fig. 2), we investigated whether its expression could
565 have an impact on CLL disease progression. To this end we
566 analyzed the expression of HVCN1_S in a cohort of 76 samples of
567 peripheral blood CLL cells with annotated clinical data. Details
568 of the patients' characteristics are reported in SI Appendix Table
569 S3. The samples investigated showed variable expression of both
570 isoforms, with an average ratio of HVCN1_S to HVCN1_L of $0.52 \pm$
571 0.034 (mean \pm SE). As shown in Fig. 1A, HVCN1_S was markedly
572 higher in CLL than in primary B cells from healthy donors, in
573 which HVCN1_S is barely detectable. Given the wide range of
574 HVCN1_S expression in CLL cells, we split samples in two groups,
575 one with a ratio of HVCN1_S/HVCN1_L below the median value
576 of 0.477 (*i.e.*, with lower expression of HVCN1_S), and one with
577 higher HVCN1_S expression (above the median). A Kaplan-Meier
578 curve for overall survival showed patients with higher expression
579 of HVCN1_S had reduced overall survival, although differences
580 did not reach statistical significance (SI Appendix Fig. S8). We
581 further analyzed the data specifically for the two main subgroups
582 of CLL patients, those presenting a mutated variable region in
583 the BCR heavy chain (*IGHV*) and those with an unmutated
584 *IGHV*. Given the small number of samples for which we knew the
585 mutation status (SI Appendix Fig. S8 and Table S3), it was not
586 surprising that differences did not reach statistical significance,
587 nonetheless higher expression of HVCN1_S tended to correlate
588 with a poorer outcome in both groups.

589 **HVCN1_S expression results in stronger BCR-dependent sig-
590 naling, proliferation and chemokine-dependent migration.** In
591 order to establish if HVCN1_S could confer a growth advantage
592 to malignant B cells, we first assessed BCR-dependent signaling
593 in A20 D1.3 cells transduced with empty vector (EV), HVCN1_L
594 and HVCN1_S. As shown in Fig. 5A, the presence of HVCN1_S
595 resulted in more prolonged activation of the extracellular signal-
596 regulated kinase (Erk), which is responsible for the upregulation
597 of several anti-apoptotic proteins in CLL cells (12). Furthermore,
598 to determine if the two proton channel isoforms regulated cell
599 proliferation, we measured the extent of EdU incorporation, a
600 nucleoside analogue included into nascent DNA. Interestingly,
601 only HVCN1_S provided a significant advantage compared to EV
602 cells (Fig. 5B).

603 Another important property of CLL cells is the ability to
604 respond to the chemokine CXCL12, which affects their migra-
605 tion, homing and survival (13). Since HVCN1 was shown to
606 regulate migration of breast cancer (5) and colorectal cells (6), we
607 set out to characterize if HVCN1 isoforms affected chemokine-
608 dependent migration in a B-cell setting. As Fig. 5C shows, both
609 HVCN1_L and HVCN1_S expression resulted in increased migra-
610 tion to CXCL12, however, only HVCN1_S resulted in a significant
611 advantage. Taken together, these data indicate that HVCN1_S pro-

612 motes malignant B-cell survival through enhanced proliferation
613 and migration.

614 Discussion

615 Only one proton channel gene has been identified in any species.
616 However, the human gene can generate two different isoforms,
617 HVCN1_L and HVCN1_S (3). In this paper, we confirmed the
618 existence of alternative splicing variants as reported in the NCBI
619 nucleotide database, presenting evidence that translation of
620 HVCN1_S starts at an alternative ATG. The resulting protein is
621 20 amino acids shorter at the N-terminus, as confirmed here by
622 immunoblotting with an antibody raised against the first 20 amino
623 acids of full-length HVCN1 (HVCN1_L). Compared to peripheral
624 B cells from healthy donors, B-cell lines and CLL cells showed
625 increased expression of total HVCN1 due to an upregulation of
626 HVCN1_S. Higher levels of HVCN1_S tended to correlate with
627 decreased overall survival in a cohort of 76 blood samples from
628 CLL patients. Given the wide range of expression of HVCN1_S in
629 CLL and the limited number of samples analyzed, it would be
630 necessary to screen a much larger panel of samples in order to
631 determine if this trend is significant. This would be particularly
632 interesting for the mutated CLL subgroup, since these patients
633 have a more favorable prognosis overall, however, some still
634 present more aggressive disease and markers to identify this
635 subpopulation are lacking.

636 Comparison of their electrophysiological properties revealed
637 that HVCN1_S channels open about twice slower than HVCN1_L.
638 A more profound difference was seen in response to stimula-
639 tion by PMA. Agonists that activate PKC strongly amplify the
640 proton conductance in many human and mammalian cells (8,
641 9, 14-18), a phenomenon called "enhanced gating." Although
642 both isoforms responded to PMA, the HVCN1_S response was
643 significantly greater. This differential responsiveness enables cells
644 to modulate proton channel activity by preferential expression
645 of HVCN1_S or HVCN1_L isoforms. That the PMA response of
646 CLL cells resembled that of LK35.2 cells expressing exclusively
647 HVCN1_S reveals that in a mixture of isoforms, HVCN1_S will
648 dominate due to its lower $V_{\text{threshold}}$.

649 The distinct gating of the two isoforms HVCN1_S and
650 HVCN1_L that differ only in the first 20 amino acids of the N-
651 terminus emphasizes the importance of this intracellular domain
652 in modulating gating kinetics. Proton channels are thought to
653 open as a result of outward movement of the S4 transmem-
654 brane helix (19-21). Being an extension of the S4 helix, the C
655 terminus affects gating directly (22). Nevertheless, gating kinetics
656 is modulated drastically (a) in the enhanced gating mode by
657 phosphorylation of Thr²⁹ (11), (b) by the point mutation T9A in
658 HVCN1_S or T29A in HVCN1_L (SI Appendix Table S1), and (c)
659 in the naturally occurring mutation M91T (23), all of which are
660 localized to the N-terminus.

661 Because T9A and T9A/S77A mutants failed to respond to
662 PMA or GFX, enhanced gating of HVCN1_S is evidently mediated
663 entirely by phosphorylation of Thr⁹. This residue is equivalent to
664 Thr²⁹, the key phosphorylation site producing enhanced gating in
665 HVCN1_L (11). Here we show that phosphorylation of Thr⁹ and
666 overall phosphorylation is greater in HVCN1_S than in HVCN1_L,
667 suggesting that the loss of the first 20 amino acids facilitates phos-
668 phorylation of this residue. Additionally, the mechanism by which
669 phosphothreonine orchestrates enhanced gating may be modified
670 in HVCN1_S. Whether the two isoforms are phosphorylated at
671 steady state in tumor B cells will depend upon expression and
672 activation of PKC in these cells. Because PKC was expressed and
673 activated in the great majority of CLL samples investigated (SI
674 Appendix Table S3), we believe constitutive phosphorylation of
675 proton channels in CLL cells to be highly likely.

676 Furthermore, we present evidence that HVCN1_S has a
677 weaker association with the BCR, which results in greater ex-
678

pression at the plasma membrane and reduced internalization upon BCR stimulation. Evidently, the first 20 amino acids of HVCN1 are important for association with the BCR. It will be interesting to investigate which residues in HVCN1 are involved in this interaction and whether there is a direct association with the BCR complex (either the immunoglobulin or the co-receptors CD79A and CD79B) or if additional scaffolding proteins are involved. Malignant B cells such as CLL cells are stimulated through their BCR in the tumor microenvironment and each round of stimulation normally results in BCR internalization (4). That tumor B cells upregulate an isoform of HVCN1 that remains at the plasma membrane more after BCR stimulation suggests these cells might find plasma membrane expression of HVCN1_S beneficial to their growth. This is corroborated by the advantage in BCR-dependent Erk activation, proliferation, and chemokine-dependent migration conferred by HVCN1_S. Higher levels of HVCN1 expression correlate with metastatic tendency and poor prognosis in breast cancer (5) and colorectal cancer (6); although the isoform involved has not been reported.

Overall, our data show the existence of a shorter isoform of HVCN1 with enhanced gating responses that is specifically enriched in malignant B cells. The enhanced gating of HVCN1_S produces larger proton currents in CLL cells that may contribute to the pathology, as suggested by stronger BCR signaling, increased cell proliferation and chemokine response provided by HVCN1_S expression

Materials and Methods

Cell lines and plasmids. The mouse B lymphoma cell lines LK35.2 HyHEL10 (IgG2a, κ-chain; H-2^{kd}) and A20 D1.3 (IgG2a, κ-chain; H-2^d) overexpressing recombinant IgM receptors were a gift from F. Batista. The cells were transduced with MigRI retroviral vectors coding for myc-tagged HVCN1_L or HVCN1_S. T29A (T9A for HVCN1_S), S97A (S77A for HVCN1_S), and T29A/S97A (T9A/S77A for HVCN1_S) mutants were generated using QuikChange site-directed mutagenesis kit (Stratagene). The retroviral particles were produced in Phoenix α packaging cell line as described elsewhere (11).

Phosphorylation assay. HEK293T cells were transfected by Ca²⁺ phosphate with myc-tagged HVCN1_L, HVCN1_S, and mutant plasmids. 48 h after transfection, cells were lysed in 20 mM Hepes, 1% Triton X-100, 137 mM NaCl, 2.5 mM β-glycerophosphate, 1 mM Na₃VO₄, 2 mM EDTA, and proteases inhibitors (Sigma Aldrich). 1 mg of proteins was immunoprecipitated with anti-myc tag antibody (9B11, Cell Signaling Technology) conjugated to protein-G Sepharose beads for 1 h. After washing with lysis buffer, beads were incubated in 40 μl kinase assay buffer (20 mM Hepes, 1 mM EGTA, 0.4 mM EDTA, 5 mM MgCl₂, 0.1 mM CaCl₂, 0.05 mM dithiothreitol, 0.1 mg/ml phosphatidyserine, 0.01 mg/ml diacylglycerol, 2.5 mM β-glycerophosphate, 1 μM PMA, 100 nM PKC-δ (Millipore), 100 μM cold ATP and 10 μCi of [γ-³²P]ATP (Perkin Elmer) for 20 min at 30°C. The reaction was stopped by resuspending beads in 2x Laemmli sample buffer. Samples were then separated by SDS-PAGE, transferred to a nitrocellulose membrane and exposed to X-ray films. Membranes were immunoblotted with anti-myc antibody to determine loading.

Electrophysiology. Whole-cell or perforated-patch variants of the patch-clamp technique were carried out as described in detail previously (24). Perforated-patch studies included ~225 μM amphotericin B in the pipette to permeabilize the patch membrane, and 50 mM NH₄⁺ to clamp pH_i to pH_o. For whole-cell studies, the main pipette solution (also used externally) contained (in mM) 130 TMACH₃SO₃, 2 MgCl₂, 2 EGTA, 80 Mes, titrated to pH 5.5 with ~20 TMAOH. Bath solutions at pH 7.0 had (in mM) 90 TMACH₃SO₃, 3 CaCl₂, 1 EGTA, 100 BES, and 36-40 TMAOH. When pH was varied, buffers with pK_a near the desired pH were used: Homopipes for pH 4.6, MES for pH 5.5-6.0, BisTris for pH 6.5, HEPES for pH 7.5, and Tricine for pH 8.0. Experiments were done at 21°C or at room temperature (20-25°C). No leak correction has been applied to current records.

Patch-clamp Studies of CLL and healthy B cells. Cells were shipped frozen on dry ice. After thawing, they were suspended in RPMI with serum, centrifuged at 1100 rpm for 5 min and resuspended in a small volume (1-2 ml) of RPMI with serum.

Statistics. Statistical analysis was carried out by Student's unpaired t-test. Further materials and methods are provided in Supporting Information Appendix.
