This work forms part of the research contributing to the translational research portfolio of the Cardiovascular Biomedical Research Unit at Barts which is supported and funded by the National Institute for Health Research

Left Ventricular Non-Compaction (LVNC) is an intriguing, but poorly understood condition that can lead to heart failure, malignant arrhythmias and thromboembolic events. It can be associated with neuromuscular disorders and can co-exist with other cardiac malformations (1).

Diagnostic imaging criteria were first described for native echocardiography by Chin (2), Jenni (3) and Stollberger (1) and followed by CMR criteria proposed by Petersen (4) and Jacquier (5). It is important to emphasise here that currently there is no diagnostic tool, neither genetic nor imaging, that can, in all patients, reveal the underlying truth of whether or not somebody is affected by LVNC. The absence of such a 'gold-standard' is the main reason why all cardiac imaging studies have limitations when attempting to determine their diagnostic accuracies with a basis of a *likely* diagnosis of LVNC and not a *definitive* diagnosis. To avoid a circular argument in diagnostic accuracy studies for LVNC the imaging findings alone should not be considered sufficient for a diagnosis of LVNC, but should be supported with evidence of malignant arrhythmias, neuromuscular disorders or a family history of LVNC or thromboembolic events. Another observation holds true for most LVNC diagnostic accuracy studies: In a derivation dataset, cut-off values for continuous variables, such as the non-compaction to compaction ratio, are typically determined using receiver-operating characteristics curves and trade off sensitivity and specificity according to the purpose of the test; rarely is the diagnostic accuracy of a cut-off value validated in a validation dataset.

Sensitivity and specificity are independent of the prevalence of disease. A useful diagnostic test provides information that changes the likelihood of having disease (post-test probability) from the likelihood of having disease without the test information (pre-test probability). The positive and negative predictive values quantify this information of the test as a function of sensitivity, specificity and pre-test probability (this may be the prevalence of disease). **Figure 1** represents the relationships between pre- and post-test probabilities over the entire range of pre-test probabilities given the sensitivities and specificities published (4, 5). An uninformative test (50% sensitivity and 50% specificity) does not change the probabilities and equals the identity line (45 degree line) in the figure. The graph also shows that in the range of pre-test probabilities that are consistent with the currently published range of LVNC prevalence (0.014 to 0.05%) (6) both CMR criteria do not provide sufficient diagnostic information, as the post-test probability remains low. Both CMR criteria help refine the post-test probability in the low and intermediate pre-test range. Above a pre-test probability of 10%, the post-test probability is above 90% for the Petersen criteria showing the value of CMR as a rule-in test in such a population. Similarly, the negative CMR test result in the same population reduced the post-test probabilities to very low likelihoods and thus underlines its potential use as a rule-out test.

Currently no prediction rule is available based on the above clinical information to determine the pre-test probability for LVNC. Patients with a family history of LVNC, known LVNC complications, associated muscular disorders or regional wall motion abnormalities would have higher than

background prevalence pre-test probabilities of having LVNC. To illustrate the use of CMR in diagnosing or excluding LVNC in intermediate probabilities consider the following CMR screening in a family with an autosomal dominant inheritance pattern. The nephew of an index patient has a pre-test probability of 25% compared to the child of the index patient who has 50%. Here, positive CMR scans using Petersen criteria lead to a post-test probability of having LVNC of 96.6% and 98.9%, respectively. Negative CMR scans lead to a post-test probability of having LVNC of 4.5% and 12.4%. (4)

The clinical value of CMR in the diagnosis of LVNC is currently unclear due to a lack of prospective population-based studies including cardiac imaging and LVNC cohorts. The natural history of LVNC with normal ejection fraction compared to normally functioning and normally trabeculated hearts remains unknown and the natural history of LVNC with impaired LV systolic function compared to matched dilated cardiomyopathy patients is unclear. This information could inform how to best manage such patients. Many open questions remain, such as should patients with heavily trabeculated hearts and normal function be treated to reduce the likelihood of adverse remodelling or thromboembolic events? Should LVNC patients with impaired systolic function be managed differently from those with dilated cardiomyopathy?

In this issue of iJACC, Stacy et al. (7) present, for a number of diagnostic CMR criteria which are similar but slightly modified compared to those in previously published studies, associations with prevalent (existing) heart failure and with incident (future) combined clinical events (death, heart failure readmission, embolic events or ventricular arrhythmias). The motivation for

this retrospective study with chart reviews to determine outcomes is to investigate whether end-systolic measures of LVNC are feasible and can improve clinical recognition of LVNC. 122 patients (2.5% of the 4,762 patients screened) are included as reports mention trabeculations or LVNC. The authors find that measures of end-systolic non-compaction to compaction ratios (ES-NCCR) are the strongest predictors of not only prevalent heart failure (adjusted odds ratio 29.4 (CI: 6.6-125), but also incident combined clinical events (adjusted odds ratio 8.6 (CI 2.5-33), albeit with very wide confidence interval reflecting uncertainty. This study is welcomed as it provides some much-needed insight into the not entirely benign natural history of some patients with a LVNC diagnosis based on the CMR findings. However, no firm conclusions can be drawn, as to whether ES-NCCR is superior to end-diastolic measures for diagnosis of LVNC leading to related events. Given the above explanations regarding the relationship of pre-and post-test probabilities of LVNC and the arguments presented in **Figure 1**, it is likely that a large proportion of the so-called LVNC population does not have the disease. In particular patients with normal ejection fraction may have no disease. It is possible that ES-NCCR may identify LVNC patients with more pronounced impairment of regional or global dysfunction due to the reduced contraction of the trabeculations. Whether this approach is superior to using a diastolic measure with attention to regional and global function is unclear. Even though the authors adjusted the odds ratios for co-variables including heart failure, it is possible that the adjusted odds ratios for end-systolic parameters were higher compared to the end-diastolic ones due to the lack of contraction of trabeculations when ejection fraction is impaired. Whether end-

systolic parameters are more useful in diagnosing LVNC or predicting clinical events in normal ejection fraction remains unclear.

The study by Stacey and colleagues is limited by its retrospective nature and relatively small sample size, leaving it unable to provide sufficient information on the natural history of patients with normal ejection fraction and impaired ejection fraction separately (and to compare the latter group to dilated cardiomyopathy patients).

Prospective studies are needed to document the natural progression of LVNC and to determine clinical and imaging predictors of adverse outcomes, which could be the basis for a simple diagnostic prediction rule. This is a task for a coordinated effort between the international imaging and heart muscle disease communities to come together to plan, raise funds and organise such a study.

Figures

Figure 1: Relationship between pre- and post-test probability for published sensitivities and specificities to diagnose left ventricular non-compaction. Petersen criteria: sensitivity 86%, specificity 99%; Jacquier criteria: sensitivity 93.7%, specificity 93.7%. An uninformative test has a sensitivity and specificity of 50%. In very low pre-test probabilities consistent with the reported LVNC prevalence of 0.014 to 0.5% neither CMR criteria are very informative. In low and intermediate pre-test probabilities both CMR criteria are informative, one slightly better at ruling out disease one better at ruling in disease.

Journal publishers and authors share a common interest in the protection of copyright: authors principally because they want their creative works to be protected from plagiarism and other unlawful uses, publishers because they need to protect their work and investment in the production, marketing and distribution of the published version of the image. In order to do so effectively, publishers request a formal written transfer of copyright from the author(s) for each image published. Publishers and authors are also concerned that the integrity of the official record of publication of an image (once refereed and published) be maintained, and in order to protect that reference value and validation process, we ask that authors recognize that distribution (including through the Internet/WWW or other on-line means) of the authoritative version of the image as published is best administered by the Publisher.

To avoid any delay in the publication of your image, please read the terms of this agreement, complete all required information, and electronically submit your form as quickly as possible.

General Terms of Publication

- 1. As an author you (or your employer or institution) may do the following:**

- make copies (print or electronic) of the image for your own personal use, including for your own classroom teaching use;
- make copies and distribute such copies (including through e-mail) of the image to research colleagues, for the personal use by such colleagues (but not commercially or systematically, e.g. via an e-mail list or list server);
- post a pre-print version of the image on Internet websites including electronic pre-print servers, and to retain indefinitely such version on such servers or sites;
- post a revised personal version of the final text of the image (to reflect changes made in the peer review and editing process) on your personal or institutional website or server, with a link to the journal homepage (on elsevier.com);
- present the image at a meeting or conference and to distribute copies of the image to the delegates attending such meeting;
- for your employer, if the image is a 'work for hire', made within the scope of your employment, your employer may use all or part of the information in the image for other intra-company use (e.g. training);
- retain patent and trademark rights and rights to any process or procedure described in the image;
- include the image in full or in part in a thesis or dissertation (provided that this is not to be published commercially);
- use the image or any part thereof in a printed compilation of your works, such as collected writings or lecture notes (subsequent to publication of the image in the journal); and
- prepare other derivative works, to extend the image into book-length form, or to otherwise re-use portions or excerpts in other works, with full acknowledgement of its original publication in the journal.

All copies, print or electronic, or other use of the paper or image must include the appropriate bibliographic citation for the image's publication in the journal.

• **Requests from third parties**

Requests for all uses not included above, including the authorization of third parties to reproduce or otherwise use all or part of the image (including figures and tables), should be referred to the Elsevier Global Rights Department by going to our website at <http://www.elsevier.com/locate/permissions> and selecting 'Permissions'.

• **Author warranties**

- The image you have submitted to the journal for review is original, has been written by the stated authors and has not been published elsewhere.
- The image is not currently being considered for publication by any other journal and will not be submitted for such review while under review by the journal.
- The image contains no libellous or other unlawful statements and does not contain any materials that violate any personal or proprietary rights of any other person or entity.
- You have obtained written permission from copyright owners for any excerpts from copyrighted works that are included and have credited the sources in your image.
- If the image was prepared jointly with other authors, you have informed the co-author(s) of the terms of this copyright transfer and that you are signing on their behalf as their agent, and represent that you are authorized to do so.

• **US Government employees**

- If all co-authors are US Government employees there is no copyright to transfer. Please sign the form, to confirm the author warranties.
- If there is a number of co-authors, of which at least one is a US Government employee (and this work was prepared in such capacity) and at least one is not a government employee, the non-government author should sign this form, indicating transfer of those rights which such author has (also on behalf of any other non-government co-authors).

• **Crown Copyright**

- UK Government employee authors may elect to transfer copyright.
- UK Government employees wishing to claim Crown Copyright should mark the appropriate box overleaf, sign the form to affirm the author warranties and attach the completed authorization form as per HMSO guidelines at <http://www.hmso.gov.uk/copyright/guidance/articles/htm>.
- The work of Canadian or Australian Government employees is automatically subject to Crown Copyright. Please mark the appropriate box and sign the form to affirm the author warranties.
- If there is a number of co-authors, of which at least one is claiming Crown Copyright and at least one is not an employee of the UK, Canadian or Australian Government, the non-government author should sign this form, indicating transfer of those rights which such author has (also on behalf of any other non-government co-authors).

• **Elsevier's AiP (Articles in Press) service**

Elsevier may choose to publish an abstract or portions of the paper before we publish it in the journal. Please contact our Production department immediately if you do not want us to make any such prior publication for any reason, including disclosure of a patentable invention. ***If you have checked a box indicating that you are NOT signing on behalf of all co-authors on the manuscript, the Editorial Office will be in contact to collect the remaining signatures. If you checked the box indicating that you are signing on behalf of all co-authors, please complete this form and submit. Nothing further will be needed.**

- I am not signing on behalf of all co-authors of the manuscript.
 I am one author signing on behalf of all co-authors of the manuscript.
